A Flexible Repository Service The OpenDLib Solution

Donatella Castelli and Pasquale Pagano

{castelli, pagano}@iei.pi.cnr.it Area della Ricerca CNR di Pisa 56126 Pisa, Italy ISTI-CNR

stores and disseminate digital documents. The service is accessible through of information space to be handled. It is thus application-independent and an http-based protocol, and is generic with respect to the type and contents developed as part of a digital library service system called OpenDLib, that can be implemented as a basic component in many kinds of digital libraries. This paper describes the features that render it broadly applicable. Abstract. The Repository Service that we propose is a software module,

Introduction

etc.) are currently heavily engaged in projects for digitalization. The Communities support future extensions or redeployment [5]. Such systems cannot be considered only very specific requirements and their architecture has not been designed to specific user communities [1-4]. Thus, their underlying programming logic covers to handle, search and manipulate digital documents. The technology, however, is Many application sectors (libraries, humanities, museums, local administrations, to handle and disseminate new digital content; similarly the solution does not lie a solution to the demand from the application communities for easy-to-use systems not yet sufficiently developed to respond fully to these requests. Existing digital that are involved in this process are increasingly demanding suitable technologies in building other ad-hoc systems. The construction of a DL is very complex; very library (DL) systems have usually been built as quick solutions to meet the needs of that other technical solutions need to be found. Our research efforts over the last few communities can afford the economic cost of such a development. It is clear

> enough to respond to the requirements of a wide variety of user communities. on designing and developing a general system of digital library services, flexible three years have focussed on this problem. During this period we have worked about the nature of the documents handled. A key service of this system is the services that implement the digital library functionality making few assumptions or harvesting the content to be managed. OpenDLib consists of a federation of digital library by instantiating the system appropriately and then either loading types of documents, metadata formats, and organizations of the information space This system, called OpenDLib [6], can be used to create an application-specific Repository Service. This is a flexible service able to store and disseminate different

cation contexts: the model of the information space, and a configurable behavious hat varies according to the values given to a set of customization parameters. Two main features renders the Repository Service adaptable to different appli-

able to represent structured, multilingual and multimedia documents. The DoMDL its parts. These formats are not embedded in the system but must be indicated at collections of videos structured as sequences, shots and frames. Multiple metadata be configured to handle documents structured as books or journals, or to manage the DL configuration time and can be modified dynamically throughout the DI records in different formats can be associated with the same document and with can be customized according to the DL content to be handled. For example, it car to a document model, called the Document Model for Digital Library (DoMDL) multiple hierarchies of collections. The documents in the collections must conform The model of the information space organizes the digital library content into

Examples of manifestations are: the MPEG file which main-ECDL '99 conference, the AVI file of the same video, the poscript file of the paper Manifestation. A Manifestation models the physical formats under which a docu-

J199

The entity View is specialized in two sub-entities: Metadata and Content. The former view perceives a version through the conceptualizations given by its metadata representations. These can be a flat list of pairs (fields, values), as with the Dublin Core metadata records [8], or more complex conceptual structures, such as IFLA-FRBR descriptions [9]. Typically this is the view indexed to support fielded querying and browsing, but it can have other uses. For example, it may be the view disseminated free of charge in an environment in which documents are covered by access rights, or the view disseminated on a mobile device.

The Content is the view of the document content. It has two sub-entities: *Body, and Reference*. Each of them has a different representational semantics characterized by different constraints and relationships (see Figure 2).

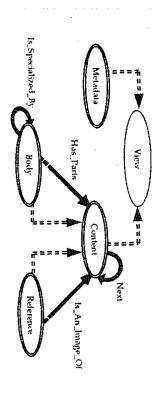

Fig. 2. The View Entity, its Specialised Entities and its Relationships

The Body entity represents a view of the document content that can be either perceived as a whole or as the aggregation of other views. For example, the ECDL'02 proceedings can have a textual view that is built as the aggregation of the textual views of its components article. Similarly, the "black and white (B&W) view" of the "Herald Tribune" newspaper can be modeled as the aggregation of a certain number of "B&W page views". Each of these pages, in turn, can be represented as the aggregation of particular "B&W" views of articles and pictures, each authored by a different person, and possibly, published elsewhere. The relation Has.Parts maintains the link between a Body view and its components views. If the parts are ordered, i.e. they document is a sequence of parts, then two consecutive parts are linked by the Next relation.

A body view can be specialized, i.e. there may be other views that represent more detailed perceptions of the same content. For example, the view "slides of the Andreas Rauber presentation" might be specialized by: "B&W view of the slides", and by "Colored view of the slides". A view is related to all its specializations though the relation *Is_Specialised_By*.

A Reference entity represents a view that, being equal to an already registered one, does not need to be explicitly stored. It has been introduced in the model to avoid duplication of information and it has no conceptual counterpart. This view can be used, for example, when a new version of a composite document is submitted. All the views that have not been changed with respect to the previous version can be specified as reference and linked to the original through the relation Is_An_Image_Of. There is thus no need to load and store them again. As a consequence of its definition, this type of view has no manifestation and no assigned explicit property, except the link to the existing view. This link is sufficient to derive all the information that is required to retrieve and disseminate the complete description of the view modeled as reference.

Note that Body and Reference do not partition the Content view. For example, the views Summary and Keyframe are content views that do not belong to any of these subclasses.

The relations Has_Versions, Has_Views, and Has_Manifestations link the different aspects of a document. Note that these relations are multiple, i.e. there can be several objects in the range associated with the same object in the domain. This means that there can be multiple versions of the same documents, multiple views of the same version and multiple manifestations of the same view.

Versions and views may be described by one or more metadata records in different formats. This records are accessible through the relations *Version_Metadata* and *View_Metadata*.

Each of the entities described above has a set of attributes which model properties of the corresponding aspect of the document. For space reasons we cannot list them here. The complete list can be found in [10]. We only want to mention that each entity has an attribute that specifies the rights on the modeled document aspect. This makes it possible, for example, to model possibly different rights on different editions, or different rights on different parts of the same view, and so on.

By combining the rich document model with the possibility of having multiple metadata descriptions for each aspect, the DoMDL document model provides a very powerful representational mechanism that can satisfy the needs of many different information spaces. This is one of the key aspects that enables the Repository to serve different application contexts. In the next section we will describe the other specific feature of the Repository Service that make it widely applicable.

The Repository Service

The Repository Service stores and disseminates DoMDL documents and metadata descriptions in different formats. It is implemented as a software module whose

matters, as a simple OAI-compliant archive. server, even if the other services, like the Query Mediator or the Registry, are documents published by other institutions. their documents. This does not mean that there must be one Repository Service quence of the request, formulated by many institutions, to maintain control over located elsewhere. The choice of distributing the Repository Service is a consepublishing institution can host an instance of the Repository Service on its local for each organization, actually an institution may decide to host on its own server In the OpenDLib architecture, the Repository is a distributed service, i.e. each
