Here, we used Regional Homogeneity (ReHo) to quantify synchronous neural activity at ‘rest’ (fMRI) in neonates with (R+) and without (R-) an established risk factor for ASD (such as a sibling with a diagnosis). We hypothesized that there would be a group difference in synchronous activity and how it changes with age in the social brain.

Methods:

High temporal resolution fMRI during natural sleep was acquired in a Philips 3T Scanner from 24 R+ and 19 R- neonates within the first 4 weeks of life [R+ median age 42.85 weeks post-menstrual age (PMA); R- median age 42.71 weeks PMA]. Data pre-processing was implemented in FSL (www.fmrib.ox.ac.uk/fsl), with non-linear spatial normalization into an age-appropriate template space (http://brain-development.org/brain-atlases/multi-structural-neonatal-brain-atlas/). The pre-selected social regions-of-interest were based on the social brain atlas (https://neurovault.org/collections/2462/) and comprised the superior temporal gyrus, the fusiform gyrus, the posterior and the anterior cingulate and the insula, defined using the same neonatal atlas that was used as a template. Voxel-wise regional homogeneity (ReHo) values were extracted using AFNI 3dReHo for 27 nearest neighbors per voxel. Unpaired t-tests with permutation testing were used to compare the interaction between age and regional homogeneity maps in the regions of interest between groups with false discovery rate (FDR) correction for multiple comparisons.

Results:

We found a main effect of group; R+ neonates had significantly higher ReHo in all regions except the fusiform and the right insula. In addition, ReHo increased with age in the R- group, but decreased with age in the R+ group in every region-of-interest apart from the fusiform. This was most prominent in the bilateral posterior cingulate and left insula cortices where the ReHo-age interaction was significant (see figure 1).

Conclusions:

Our data indicates that atypical maturation of networks which support social behaviour happens from birth in infants at risk of ASD.

10:55 **139.002** Neural Sensitivity to Social Stimuli at 8 Months Predicts Social Behaviour at Two Years and ASD-Outcome at Three Years.

*G. Bussu[1], **A. Gui**[2], C. Tye[3], E. J. Jones[4], T. Gliga[2], M. Elsabbagh[5], T. Charman[6], M. H. Johnson[7], K. Johnsen[8], J. K. Buitelaar[9] and &. The BASIS Team[2], (1)Donders Institute for Brain, Cognition and Behaviour, Radboudumc, Nijmegen, Netherlands, (2)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (3)Department of Child & Adolescent Psychiatry, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (5)McGill University, Montreal, PQ, Canada, (6)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (8)Mentis Cura, Reykjavík, Iceland, (9)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands*

Background: Autism Spectrum Disorder (ASD) is typically diagnosed at age two or three, and is characterised by difficulties in social communication and interaction. Atypical neural responses to social stimuli have been associated with difficulties in socialisation in toddlerhood (Webb et al. 2011; Dawson et al., 2012). Early evidence suggests that such brain-related changes emerge earlier than clinical manifestations, raising the possibility of early identification (Elsabbagh et al., 2012; Jones et al., 2016). In order to have clinical potential, such effects must be replicated and extended to individual-level prediction.

Objectives: We first tested whether differences in neural correlates of attention engagement to social stimuli at 8 months are associated with atypical social behaviour at two years and autism outcome at three years (study 1). Additionally, we investigated whether a specific subset of brain responses to the same stimuli can predict individual ASD outcome (study 2).

Methods: EEG activity was recorded from 67 low-risk (LR) infants and 145 high-risk (HR) siblings while looking at faces with direct and averted gaze and visual noise (Figure 1). Clinical outcome of HR infants was established at 36 months (typical development [HR-TD; n=77]; atypical development [HR-Aty; n=37]; ASD [HR-ASD; n=31]). The Vineland Adaptive Behavior Score (VABS) questionnaire was used to assess social behaviour at 24 months.

Analysis 1 examined whether groups showed differences in mean amplitude of the Nc (attention-related) component when looking at face versus noise. In study 2, a Support Vector Machine (SVM) classifier discriminated HR-ASD from other siblings using ERP features selected by a genetic algorithm.

Results: Analysis 1: LR and HR groups showed significantly different Nc responses to the face-noise contrast (p=.04), with HR showing a significantly less negative early Nc component when looking at faces vs noise (p<.000). HR-ASD infants showed a larger difference in mean amplitude of the early Nc over the right frontal region with respect to the other groups (t(340)=-2.09, p=0.037). The amplitude difference in the face-noise contrast in infancy significantly predicted VABS socialization scores at two years (beta=-0.55, p=.007, Figure 2). Analysis 2: classification of HR-ASD at 8 months was possible with 80.4% Area Under the Curve (AUC; 95% confidence interval, CI [72.4, 87.6]). The most relevant features included differences in P4 (latency) and P1 for the gaze shift contrast; and P1 (amplitude), N290 (latency), and P4 for the face-noise contrast. Finally, responses to faces and the face-noise contrast showed high predictive power for ASD (80.7% AUC; 95% CI [72.5, 88.0]).

Conclusions: Differences in neural responses to faces vs. noise at 8 months can predict socialisation skills at 2 years, and individual ASD outcome at 3 years. Early disruptions to social attention engagement can be critical to later development of ASD traits such as social interaction difficulties, and have important clinical implications for early risk assessment and targeted intervention.

11:20 **139.003** Early Functional EEG Connectivity in Infants at Risk for Autism Associates with Later Circumscribed Interests; A Replication Study

***R. Haartsen**[1], E. J. Jones[2], E. V. Orekhova[3], T. Charman[4], M. H. Johnson[5] and &. the BASIS Team[6], (1)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom of Great Britain and Northern Ireland, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)MEG-Center, Moscow University of Psychology and Education, Moscow, Russian Federation, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (6)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom*

Background:

Previous studies have suggested functional EEG connectivity as potential biomarker of Autism Spectrum Disorders (ASD). However, findings are mixed and replication is essential for application in the clinical field and understanding of underlying mechanisms. Our previous study found functional EEG hyper-connectivity in 14-month-old infants who developed ASD at a later age compared to those who did not met ASD criteria. The amount of hyper-connectivity in selected fronto-central connections was related to later severity of restricted and repetitive behaviours (RRBs) in infants who later developed ASD, whereas no associations were found with later communication difficulties.

Objectives:

The current study had three objectives: 1) replicate the findings of hyper-connectivity in infants who later develop ASD, 2) replicate the association between early hyper-connectivity and later RRBs, and 3) further investigate the latter association by looking at subtypes of RRBs.

Methods:

Functional EEG connectivity was measured with the debiased weighted phase lag index for the alpha range (7-8 Hz) from EEG recordings while 14-month-old infants watched videos. Clinical outcome and symptom severity at 36 months of age were assessed via parental interview with the Autism Diagnostic Interview – Revised (ADI-R). The final sample included infants with low familial risk ($N_{LR} = 20$), and with high familial risk who showed typical development ($N_{HR\text{-}TD} = 47$), atypical development ($N_{HR\text{-}Atyp} = 21$), or met ASD criteria ($N_{HR\text{-}ASD} = 13$) at 36 months. Global (average) connectivity values in the HR-ASD group were compared to the LR, HR-TD and HR-Atyp group separately. Spearman's correlations were used to investigate associations between connectivity and the Repetitive Behaviour and Social and Communication scales of the ADI-R.

For correlational analyses for the subtypes of restricted and repetitive behaviours, datasets for infants with high familial risk from the previous and current study were combined. We focused on three subtypes of RRBs: repetitive motor behaviours ($N_{HR} = 103$), insistence on sameness ($N_{HR} = 102$), and circumscribed interests ($N_{HR} = 90$) measured with the ADI-R.

Results:

Global EEG connectivity in the HR-ASD group showed no significant differences compared to the LR, HR-TD, or HR-Atyp group. In the HR-ASD group, functional connectivity across selected fronto-central connections was associated with RRBs (Figure 1). No significant associations were observed with social and communication difficulties in the HR-ASD or HR group.

Further analyses in the combined datasets showed that functional EEG connectivity in the HR group was significantly associated with circumscribed interests, whereas correlations with repetitive motor behaviours and insistence on sameness did not reach significance.

Conclusions:

First, we did not replicate the finding of hyper-connectivity in the HR-ASD group compared to the other groups. The heterogeneity in ASD might underlie our failure to replicate categorical outcome findings.

Second, we did replicate the previously observed association between functional EEG connectivity and dimensional traits in HR-ASD infants. This is the first replication of an infant neural predictor of later variation in dimensional traits.

Lastly, the associations with functional connectivity were strongest for circumscribed interests. It is possible that atypical connectivity in the cortico-basal ganglia-thalamo-cortical loop underlies this observation.

11:45 **139.004** Stability of Autonomic Arousal and the Relationship with Cognitive and Social Skills

T. Bazelmans[1]*, E. J. Jones*[2]*, T. Charman*[3] *and S. J. Webb*[4]*, (1)King's College London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: There is an increasing interest in physiological biomarkers (such as heart rate (HR) and high-frequency heart rate variability (HRV)) in Autism Spectrum Disorder (ASD). However, we have little information about the reliability of autonomic arousal in children with ASD. Moreover, studies have reported contrasting results when it comes to group differences, with support for lower parasympathetic activity in ASD or no group differences compared to typically developing (TD) children. Also, the relationship between autonomic arousal and developmental abilities is unclear. Within TD children, lower HRV and higher HR during periods of rest has been associated with poorer developmental outcome. In ASD similar results are found in middle-childhood, but not yet earlier in development.

Objectives: This study has three aims: 1. To compare toddlers with ASD and TD on HR and HRV; 2. To look at measurement stability using intra-individual variability and test-retest reliability, 3. To examine the relationship between autonomic arousal and cognitive and social abilities.

Methods: Heart rate was collected during two visits ($M = 19.2$ days apart) for 71 children with ASD and 67 children with TD (2 to 4-years-old). Social and cognitive abilities were measured using the Preschool Language Scale, the Communication and Socialization subscales of the Vineland Adaptive Behavior Scales, and the preschool Behaviour Rating Inventory of Executive Functioning. The children watched four 90-second "rest" videos (wildlife animals) as part of a screen-based battery. Data was analysed in 30-second epochs. First, average HR and HRV between groups was compared using t-tests. Second, stability of the physiological measures was evaluated (a) by calculating intra-individual variation and (b) with interclass correlations. Third, we ran separate regression analyses with HR and HRV as the independent variables and Language, Communication, Socialization and EF as the dependent variables, controlling for age and Visual Reception score of the Mullen Scales of Early learning.

Results: Groups did not differ in HR ($t(136)=-1.33$, $p=.187$, $d=-.23$) or HRV ($t(136)=0.87$, $p=.386$, $d=.15$). Intra-individual variability of HR was higher in the ASD group than the TD group. For HRV, this was only the case for the second visit. Test-retest reliability of HR and HRV was average to good in both groups (ICC range: .59-.73). There was an interaction effect of HR & group and HRV & group for Language, Communication and EF, but not Socialization. The effect on Communication remained after controlling for age and visual reception. Post-hoc analyses showed that only in the ASD group there was a positive correlation between HRV and Communication (partial $r = 0.30$, $p=.013$).

Conclusions: First, in this large sample, measures of autonomic control do not discriminate between 2 to 4-year-old children with ASD and TD during rest. Secondly, test-retest reliability was comparable in both groups; however, the ASD group showed higher intra-individual variability within a session. HRV was positively correlated with communication abilities in the ASD group, but not the TD group. Overall, these findings suggest there is an association between autonomic arousal and communication skills in ASD; variability within a person is important to consider in future research.

Panel Session
Medical and Psychiatric Comorbidity
140 - The Co-Occurrence of Autism and Gender Dysphoria or Gender Incongruence
10:30 AM - 12:30 PM - Willem Burger Hal

Panel Chair: John Strang, *Center for Autism Spectrum Disorders, Children's National Health System, Washington, DC*

Discussant: Annelou L.C. de Vries, *VU University Medical Center, 1007 MB Amsterdam, Netherlands*

The over-representation of ASD among individuals clinically referred for Gender Dysphoria (GD) has been observed across multiple sites internationally; up to 25% of youth gender referrals present with significant autism symptoms. There is also emerging evidence for an over-representation of gender identity differences among ASD-referred youth. The ASD/GD co-occurrence is conceptually and clinically complex, and a range of theories have been proposed to explain it. However, studies to date have addressed the prevalence of the co-occurrence without considering the personal voices and experiences of gender dysphoric autistic individuals. Panelists address key questions for this population: 1. What do autistic transgender youth and their families want and need from care providers?; 2. How are autism and gender dysphoria traits related in the general population? 3. What are the developmental gender histories, experiences, and hopes of autistic transgender youth?; and 4. What are the mental health concerns of autistic youth who report gender dysphoria? These questions are addressed through qualitative and community-based participatory methods, directly capturing the voices of autistic gender dysphoric youth; evaluation of subclinical trait-based relationships in the general population; and assessments of GD traits among ASD-referred youth.

10:30 **140.001** Autistic Gender Dysphoric Youth: Community-Based Participatory Research Development of a Clinical Program

__J. F. Strang__[1], M. Knauss[2], L. Kenworthy[1], D. Gohari[1], M. D. Powers[1] and L. Anthony[3], (1)Children's National Health System, Washington, DC, (2)Alliance of Community Health Plans, Washington, DC, (3)University of Colorado, Denver, Aurora, CO

Background: The co-occurrence of ASD and Gender Dysphoria (GD) in adolescents is clinically complex, as autistic youth often have differences in self and social-awareness, future thinking/planning, and self-advocacy skills, skills critical for both gender identity discernment and, when appropriate, social and physical gender transition. Yet, there are no clinical programs/approaches developed for autistic gender dysphoric (ASD+GD) youth.
Objectives: This study assesses the clinical needs/priorities of ASD+GD youth and their parents, and through Community-based Participatory Research (CBPR) methodology, develops and assesses the acceptability/usefulness of a novel clinical group program for this co-occurrence.

Methods: Youth age 12-19 with concurrent DSM-V diagnoses of ASD and GD (Tanner stage II–V), and their parents (total individuals, N=57), participated in an ongoing clinical group program aimed at supporting autism-related and gender-related needs, coping, and positive outcomes for ASD+GD youth. Youth and parents provided individual written feedback to specific probes following each clinical session addressing what they desired/needed from the clinical service, perceived successful/unsuccessful components of the program, and individual clinical/support needs. Youth and parents also completed in-depth interviews at three-month intervals. Successive clinical group sessions applied participant recommendations from previous youth/parent feedback according to CBPR methodology. Independent Framework Analyses (FA) were conducted with youth and parent data, and compared for thematic convergence/divergence. A key-stakeholder group including autistic, transgender, transgender autistic, and transgender de-transitioned self-advocates, as well as clinical gender and autism specialists reviewed the FA thematic needs/priorities, and the clinical priorities were translated into specific clinical methods/techniques. Youth/parents rated each resulting clinical approach for its usefulness on a continuous 10cm slider scale.

Results: Clinical priorities (themes) shared by both youth and parents include the importance of a group program specifically for gender spectrum autistic youth and their parents (as opposed to separate autism or transgender groups), structured opportunities for gender-role exploration in the group context, and teaching of specific skills for gender presentation (e.g., makeup/styling skills and mannerisms). A youth priority not appearing in the parent thematic framework was the recommendation to create opportunities for youth to meet a range of community visitors at different points on the gender spectrum to serve as concrete role models for diverse gender paths/options. Parent-specific thematic priorities for their children included supports for safety awareness and safety skills and supports to explore whether youth experiences of gender might be impacted/driven by autism-related characteristics (e.g., less flexible thinking). Eighteen clinical techniques were derived from the thematic priorities of youth and their parents. Parent ratings of the usefulness of the clinical approaches were high (Mean for all approaches=87.27; SD=6.96, with a range 0-100, 50 as a midpoint, and higher scores reflecting greater perceived utility), as were youth ratings (M=70.00; SD=15.74).

Conclusions: CBPR methodology captures the clinical priorities of ASD+GD youth and their parents. Novel clinical components emerged including recommendations for introducing ASD+GD youth to a range of adult gender spectrum individuals (e.g., transgender individuals, cisgender formerly transgender individuals, gender expansive individuals who use no medical gender supports, etc.) to assist in gender discernment, and practical instruction in skills for gender expression/style.

10:55 **140.002** Gender Nonconformity and the Autism Spectrum in and Beyond the Clinical Context: An Examination of Children with and without Mental Health Diagnoses

__A. I. van der Miesen__, Child- and Adolescent Psychiatry, VU University Medical Center, Amsterdam, Netherlands

Background: In recent years, there has been a strong clinical and research interest in the overlap between gender nonconformity (GNC) and autism spectrum disorder (ASD). GNC and ASD seems to frequently co-occur in clinical populations. It is unknown, however, whether these previous findings regarding the GNC-ASD link reflect a general clinical phenomenon (i.e., individuals with a clinical diagnosis in general are more prone to have a second clinical diagnosis) or suggest a unique overlap between (symptoms of) ASD and GNC.
Objectives: To investigate GNC in children with a mental health condition, including children who have been diagnosed with ASD, and to investigate potential associations between GNC and symptoms of ASD in children who never have been diagnosed with a mental health condition.

Methods: Parents of children (6-12 years of age) were recruited to participate in a parent-report online questionnaire from June–December 2016. Our participants consisted of a total sample of parents of 2445 children (1198 girls, 1247 boys). Children (*Mean age* = 8.82, *SD* = 1.99) were categorized as either typically developing (i.e., from the nonclinical subgroup; *n* = 2004; 1022 girls, 982 boys) or as part of a clinical subgroup of the population meaning that they had a mental health condition, including for example ASD (*n* = 441; 165 girls, 276 boys).The Gender Identity Questionnaire for Children (GIQC) was used to measure GNC and the Children's Social Behavior Questionnaire (CSBQ) was used to investigate symptom levels of ASD including six different subdomains of ASD.

Results: Our findings showed that GNC was associated with children who have been diagnosed with ASD and sensory processing disorder. Among children who have never been diagnosed with a mental health condition, increased GNC was associated with increased symptoms of ASD. In addition, GNC was associated with the subdomain of ASD of stereotyped behaviors (i.e., stereotyped movements and alternate responses to sensory input) and difficulties orienting socially.

Conclusions: Increased GNC was found to be not only associated with children with an ASD diagnosis, but also with increased symptoms of ASD in a nonclinical population. These findings suggest that GNC may not be unique to ASD in clinical populations only. The relationship between symptoms of ASD and GNC might thus exists beyond the clinical domain, indicating that this association might reflect a more general phenomenon. In addition, in nonclinical populations, the specific symptoms of ASD of stereotyped behavior and orientation problems were found to be uniquely associated with GNC. Elevated levels of GNC in children may thus not be related to all facets of ASD equally.

11:20 **140.003** Gender Histories, Life Experiences, and Future Plans and Hopes of Gender Dysphoric Autistic Youth: A Framework Analysis

M. D. Powers[1], *M. Knauss*[2], *D. Gohari*[1], *L. Anthony*[3], *L. Kenworthy*[1] *and J. F. Strang*[1], *(1)Children's National Health System, Washington, DC, (2)Alliance of Community Health Plans, Washington, DC, (3)University of Colorado, Denver, Aurora, CO*

Background: Despite evidence that autism spectrum disorder (ASD) and gender dysphoria (GD) commonly co-occur, no studies to date have captured the life experiences and perspectives of autistic gender dysphoric youth through their own voices.
Objectives: Identify primary themes in the lived experiences and ambitions of gender dysphoric autistic youth. Reduce researcher bias through participatory methods including the involvement of key stakeholders in the qualitative data analytics.

Methods: We conducted 22 semi-structured clinical interviews of adolescents and young adults (age 12-20 years) who met DSM-V criteria for ASD and current (N=20) or historical/desisted (N=2) GD. 64% of participants were assumed male at birth, and 36% were assumed female at birth, paralleling population-based sex ratios in ASD. Data was analyzed using framework analysis, which systematically analyzes qualitative data in a 5-step process (Ritchie et al., 2003; Bargiela et al., 2016): familiarization with the data, identification of the thematic framework, indexing of statements and related units into the thematic framework, graphic representation of the data and distribution of the participants' responses, and final analysis. The analytic team included key stakeholders (autistic, transgender, and autistic-transgender self-advocates).

Results: The framework analytic process categorized 92% of participant responses, revealing eight categories of thematic statements: feelings about gender and body, gender in social situations, gender discernment, needs, future plans and ambitions, meeting other gender-spectrum people, the existence of bias, and the experience of being both neurodiverse and gender diverse. Twenty-three subthemes were identified under the criterion of >25% participant endorsements. Theoretical saturation for themes and subthemes occurred at 6 participants (van Rijnsoever, 2017). Almost all participants noted that expressing interests and behaviors of the other gender was not enough for them, and that they needed to live as their affirmed gender (i.e., transgender). Further, most indicated that their gender experiences were not related to anxiety about puberty, noting that they wished to go through the puberty of their affirmed gender. About half of the participants described their gender expression as somewhat non-traditional/non-gender binary. Nearly three-quarters described their gender identity as coming into focus over time through development; a similar number of participants believed that their affirmed gender would remain constant in the future. One-quarter of participants discussed the possibility that their gender identity might change in the future (i.e., gender dysphoria desistence). A majority of youth reported that their worries about societal disapproval of transgender and gender diverse people inhibited their gender expression and exploration of gender identity.

Conclusions: Numerous similar life experiences, perspectives, and ambitions emerged among gender dysphoric autistic youth. In directly capturing the perspectives of these individuals, this study gives voice to a previously unheard population. Results are relevant to gender and autism clinicians and researchers, given that up to one quarter of adolescents referred for gender dysphoria have significant co-occurring autism characteristics.

11:45 **140.004** Mental Health Among Gender-Dysphoric Individuals with ASD

M. A. Stokes *and R. George, Deakin University, Burwood, Australia*

Background:
There is increased mental-health adversity among individuals with Autism Spectrum Disorder (ASD). At the same time, gender-dysphoric individuals experience poorer mental health when compared to non-gender dysphoric individuals. Recent research suggests that autistic individuals report increased gender-dysphoric traits (GDT).

Objectives:
The current study aimed to investigate whether as membership of minority grouping becomes increasingly narrowed (i.e.: an individual is a member of an increasing number of minority groups), mental health will worsen as a function of increasingly restrictive minority group membership. We hypothesized that individuals with ASD and individuals with GDT would have higher rates of Depression, Anxiety and Stress, and lower levels of Personal Well-being when compared to their respective control groups, and that as Minority status increases, Mental Health would worsen.

Methods:
The present study compared the rates of Depression, Anxiety, and Stress using the DASS-21 and Personal Well-being using the personal well-being index (PWI) between 261 typically-developing individuals and 309 autistic individuals.

Results:
Results demonstrated that while ASD Diagnosis did not additively worsen Mental Health, when GDT was added to ASD Diagnosis, the effect was to worsen Mental Health, ($p<0.01$). This suggests a hierarchy of threats to Mental Health through Minority-group membership, where the effect of GDT is more extreme than a diagnosis of ASD.

Conclusions:

These results reveal complexity in the manner in which GDT and ASD interact with each other. Further, these results demonstrate that recognition and support for those with ASD around issues of gender is paramount, lest their mental health be further damaged by a lack of recognition of this vulnerable cohort.

Panel Session
Early Development (< 48 months)

141 - How Does It Feel? Emotional Lives of Toddlers with ASD

10:30 AM - 12:30 PM - Jurriaanse Zaal

Panel Chair: Katarzyna Chawarska, *Child Study Center, Yale University School of Medicine, New Haven, CT*

Discussant: Carla Mazefsky, *Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

There is a prevailing notion that the emotional life of children with ASD is dominated by negative emotions. Such a negative affectivity bias may have a profound effect on attention, learning, and social interactions. Yet, research has focused primarily how children with ASD discriminate and understand the emotions of others or strategies they use to regulate their own emotions, rather than on how they react emotionally to the world around them. Thus, little is known about the intensity, valence, and congruency of emotions in response to real-world events in children with ASD, particularly during the early stages of the disorder. Understanding emotional expressivity and their links with attention and physiology will improve our grasp of the inner lives of toddlers with ASD and inform clinical practice and theory by identifying affective factors shaping their developmental trajectories. The multidisciplinary panel of junior and senior researchers will present never-published data from an ongoing large, prospective study of attentional, physiological, and emotional processes underlying early affective development in ASD. The results reveal complex and surprising emotional profiles of toddlers with ASD and show feasibility and reliability of the behavioral, attentional, and physiological measures for studying the emotional lives of toddlers with social disabilities.

10:30 **141.001** Attenuated Fear and Accentuated Frustration Responses to Real-World Challenges Aimed at Eliciting Negative Emotions

S. Macari[1], *F. E. Kane-Grade*[2], *E. Hilton*[1], *A. Milgramm*[3], *P. Heymann*[1], *L. DiNicola*[4], *D. Macris*[1], *K. K. Powell*[1], *S. Fontenelle*[1], *M. Lyons*[1], *A. Giguere Carney*[1], *K. Bailey*[1], *F. Shic*[5] *and K. Chawarska*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (3)Center for Autism and Related Disabilities, Albany, NY, (4)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (5)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Expression of emotion is a fundamental capacity present from birth and helps to ensure basic infant-environment interactions (Izard, 1978). Although both anger and fear are negative emotions, anger is expressed in response to goal blockage and results in approach behaviors such as protesting and struggling, while fear occurs in response to threat or uncertainty and is associated with withdrawal behaviors such as turning away and freezing. Positive affect is a relatively neglected dimension. Like anger, it is characterized by approach tendencies and manifests in laughter and increased activity level. Young children with ASD have been described to exhibit a restricted range of emotional expressions (DSM-V, 2013), or less positive and more negative affect than their peers (Garon et al., 2009; Jahromi et al., 2012; Macari et al., 2017; Snow et al., 1987; Yirmiya et al., 1989). However, little is known about emotional reactivity in toddlers with ASD in response to a range of standardized challenges.
Objectives: To examine emotional reactivity in toddlers with ASD compared to their non-ASD peers in response to in-vivo behavioral probes, eliciting three emotions: joy and the conceptually distinct emotions of fear and anger.

Methods: Selected episodes from the Laboratory Temperament Assessment Battery (Lab-TAB; Goldsmith & Rothbart, 1999) were administered to 99 toddlers (M=21mo, range: 13-30mo): 43 with ASD and age-matched peers with developmental delays (DD; n=16) or with typical development (TD; n=40). Nine episodes were designed to elicit Fear, Joy, and Anger. Intensity of emotional response was coded offline by blinded coders and standardized composites were computed across facial, vocal, and musculoskeletal channels.

Results: Between-group ANOVAs revealed no significant effect of diagnosis for intensity of joy, ($F(2,99)=.14$, $p=.87$) but significant group differences for intensity of fear ($F(2, 95)=6.44$, $p<.01$) and anger ($F(2,98)=3.54$, $p<.05$). Toddlers with ASD exhibited less intense fear than TD ($p=.002$; $d=.75$) and DD ($p=.011$, $d=.80$) controls and expressed significantly more intense anger than their DD peers ($p=.016$, $d=.73$), and marginally more intense anger than TD ($p=.064$, $d=.40$) controls. Within the ASD group, the ADOS-Toddler Social Affect score was significantly negatively correlated with the intensity of joy ($r=-.33$, $p<.05$) but not with the negatively-valenced emotions.

Conclusions: Results indicate that, compared to non-ASD peers, toddlers with ASD exhibited similar levels of positive affect in response to pleasurable stimuli. This finding is consistent with work showing that processes underlying the neural response to obtaining rewards (i.e., liking, or the hedonic aspect of the reward system) may be intact in ASD (Damiano et al., 2014). However, our results indicate that toddlers with ASD exhibited less intense fear responses to novel and potentially frightening stimuli and more intense angry affect in the context of goal blockage during the Lab-TAB's naturalistic and standardized emotion-elicitation probes. Consistent with studies of typically-developing infants (Planalp et al., 2017), our results suggest utility in isolating components of negative affectivity. The basic attentional and physiological processes underlying attenuated reactivity during frightening situations and accentuated reactivity during frustrating situations require further examination.

10:55 **141.002** Do Toddlers with ASD Express Emotions That Are Incongruent with Valence of Real-World Events?

F. E. Kane-Grade[1], *S. Macari*[2], *K. Villarreal*[2], *A. Zakin*[2], *H. Neiderman*[2], *M. Wilkinson*[2], *E. Hilton*[2], *A. Milgramm*[3], *P. Heymann*[2], *L. DiNicola*[4], *D. Macris*[2], *K. K. Powell*[2], *S. Fontenelle*[2], *M. Lyons*[2] *and K. Chawarska*[2], *(1)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Center for Autism and Related Disabilities, Albany, NY, (4)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Affective expressions are critical for communication and social interaction (Ekman, 1982). Although early conceptualizations suggested diminished affective expressions in children with ASD (*DSM-III-R*, 1987), subsequent research revealed that children with autism are not less expressive (Capps et al., 1993); rather, they may display emotions that are incongruent with the environmental context (McGee, Feldman, & Chernin, 1991; Reddy, Williams, & Vaughn, 2002). Still, little is known regarding whether congruency of emotional expression depends on the valence of environmental events and whether incongruent responses are present regardless of the emotion expression channel (e.g., facial or vocal).
Objectives: 1) To examine intensity of incongruent facial and vocal expressions during positively- (Joy) and negatively- (Frustration and Fear) valenced probes of the Laboratory Temperament Assessment Battery (Lab-TAB; Goldsmith & Rothbart, 1996) among toddlers with ASD, developmental delays (DD), and typical development (TD); 2) To examine the relationship between the intensity of incongruent emotional expressions and severity of ASD symptoms.

Methods: Participants included 99 toddlers (ASD, *n*=43; DD, *n*=16; TD, *n*=40) (M_{age}=21 months). Nine in-vivo probes were presented to elicit three emotions: Frustration, Joy, and Fear. Sessions were coded offline by blinded coders for peak intensity of emotional expression from two channels: vocal and facial.

Results: Intensity of facial expressions and vocalizations of joy during fear- and anger-eliciting probes were contrasted between the three groups of children via linear mixed effects models. Vocal distress and facial expressions of fear and anger during joy eliciting probes were analyzed between the diagnostic groups using univariate ANOVAs. No group differences in facial expression of joy during negatively-valenced probes (*F*(2, 143)=2.17, *p*=.14) or group by task interaction were found. Similarly, no group differences in facial expression of anger (*F*(1,98)=.93, *p*=.40) or fear (*F*(1,98)=.99, *p*=.38) during Joy probes were found. However, when examining vocalizations, differences between groups emerged. A main effect of diagnosis (*F*(1, 130)=6.57, *p*=.002) showed that toddlers with ASD expressed more intense positive vocalizations than TD (*p*=.001, *d*=.48) and DD (*p*=.01, *d*=.49) toddlers during negatively-valenced probes and produced more intense distress vocalizations than TD (*p*=.03, *d*=.49) and DD (*p*=.05, *d*=.67) toddlers during Joy probes. In the ASD group, intensity of incongruent distress vocalizations during Joy probes was associated with ADOS Social Affect scores (*r*=.37, *p*=.02).

Conclusions: While the intensity of incongruous facial expressions of toddlers with ASD during positively and negatively-valenced probes did not differ from those observed in age-matched DD and TD peers, their vocalizations appeared more atypical. Specifically, their probe-incongruous distressed or positive vocalizations were more intense than those observed in controls. The results suggest ambiguity in vocal expressions in toddlers with ASD, which may result in affective miscommunication between the children and their caretakers and peers and hamper their efforts to convey their needs and interact socially. Examining the mechanisms underlying incongruous emotional expressivity in toddlers with ASD constitutes a novel and highly clinically and theoretically fruitful area of inquiry in autism research.

11:20 **141.003** Decreased Fear Response in Toddlers with ASD Is Linked with Attenuated Changes in Physiological Arousal

***L. Boccanfuso**[1], F. Shic[2], S. Macari[3], L. DiNicola[4], A. Milgramm[5], E. Hilton[3], F. E. Kane-Grade[6], P. Heymann[3], M. S. Goodwin[7], A. Vernetti[3] and K. Chawarska[3], (1)Vän Robotics, LLC, Irmo, SC, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (5)Center for Autism and Related Disabilities, Albany, NY, (6)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (7)Northeastern University, Boston, MA*

Background: Compared to typically developing toddlers (TD) and controls with developmental delay (DD), toddlers with autism spectrum disorder (ASD) express less intense negative emotional behaviors in response to real-world fear-eliciting challenges (Macari et al., 2017;Abstract #1)). It is not clear if this phenomenon is due to differences in behavioral display of emotions or in arousal levels in response to these events. Physiological arousal is thought to be altered in ASD; however, research findings have been inconsistent, likely due to differences in induction techniques, intensity and valence of emotional triggers, and measurement methods.
Objectives: To examine concurrently for the first time, physiological arousal (changes in skin conductance level, ΔSCL) and intensity and valence of behavioral affective responses to structured real-world challenges in toddlers with ASD. (2) To test whether ASD toddlers show greater ΔSCL in response to Anger- and Fear- but not Joy-eliciting probes as seen in typical development (Kreibig et al., 2010). (3) To test whether the magnitude of ΔSCL is associated with intensity of emotions exhibited during Fear and Anger but not during Joy probes.

Methods: Participants included 26 toddlers with ASD (age: M=23mo, SD=3) and 24 age-matched TD controls (age: M=22mo, SD=4). ΔSCL was measured in response to multi-trial conditions eliciting Fear, Anger, or Joy, using an Affectiva Q-Sensor placed on the child's ankle. ΔSCL was calculated between the start and end of each trial, standardized and averaged within each condition. Intensity of emotional behavioral responses was coded offline.

Results: At baseline, the ASD and TD groups showed comparable SCL scores (p>.40). A linear mixed model analysis of ΔSCL indicated no effect of diagnosis (p=.74), a significant effect of condition, (p<.001), and a diagnosis by condition interaction (p=.012)(**Figure1**). ΔSCL in the ASD group was comparable to the TD group in the Anger (p=.58) and Joy (p=.17) conditions, but was lower in the Fear condition (p=.016). In the two groups combined, ΔSCL was positively correlated with intensity of Anger (r(36)=.30, p=.07) and Fear (r(35)=.45, p=.008), but not with Joy (p=.75). Regression analysis of ΔSCL in the Fear condition revealed a significant contribution from parent-reported ECBQ Fear score (p<.002) and observed intensity of anger and fear (both p<.002, Adjusted R^2=.42), but not from autism severity, NVDQ, or VDQ.

Conclusions: Physiological arousal increased in response to negatively- but not to positively-valenced challenges in both groups. The magnitude of changes in physiological response to Anger and Joy probes was comparable between ASD and TD toddlers. However, ASD toddlers showed an attenuated physiological response to Fear, mirroring the differences observed at the behavioral level (Macari et al., 2017). Changes in physiological arousal level were predicted uniquely by both parent-rated fearful temperament and intensity of behavioral fear responses, but not by severity of autism or levels of functioning. These findings show the usability of measuring physiological arousal when examining emotional response in toddlers with ASD and inform both clinical and theoretical approaches regarding response to threat in ASD.

11:45 **141.004** Attentional Capture By Angry Faces and Angry Voices Is Associated with Intensity of Fear Induced By Real-World Challenges in Toddlers with ASD

***K. Chawarska**[1], F. Shic[2], Q. Wang[1], A. Vernetti[1], D. Macris[1] and S. Macari[1], (1)Child Study Center, Yale University School of Medicine, New Haven, CT,* *(2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Behavioral and neurophysiological evidence suggests that biologically-relevant stimuli such as facial expressions (Vuilleumier & Schwart, 2001) and emotionally-valenced sounds (Ethofer et al., 2006) are prioritized in the attentional system as reflected by their enhanced capacity to capture attention. Rapid detection of emotional signals is thought to be affected in ASD, though evidence remains scant and conflicting, particularly in the early developmental stages. Here we examine, for the first time, attention capture by threatening stimuli presented through visual (static faces) and auditory channels (nonsense phrases) in toddlers with ASD and typically-developing (TD) controls. We also examine, for the first time, direct links between attention capture by threat and intensity of fear response during real-world challenges.
Objectives: To examine if attentional capture by threatening stimuli in visual and auditory domains are associated with intensity of fear response during real-world challenges as well as with severity of autism symptoms and verbal and nonverbal developmental quotient in toddlers with ASD and TD controls.

Methods: Toddlers with ASD (n=29) and age-matched TD (n=29) toddlers (Mean age=23 mo, SD=4) participated in an eye-tracking study investigating attentional capture by threatening stimuli. The toddlers completed a preferential looking paradigm in which their latency to orient to static angry faces (Face condition) and angry voices (Voice condition) were measured. Toddlers also completed a series of real-world behavioral fear-inducing probes adapted from the Laboratory Temperament Assessment Battery (LabTAB, Goldsmith et al., 1999). Ratings of peak intensity fear responses were coded offline by a blind rater. Subsequently, we evaluated correlations between latency to orient to threat and intensity of fearful emotions during the challenges.

Results: The groups did not differ in the latency to orient to angry faces (p=.467) or angry nonsense phrases (p=.566). In the combined groups, the latency to orient to the threatening targets was not associated with severity of autism symptoms, or with verbal or nonverbal DQ in either condition (all p-values>.4). However, there were significant correlations between the intensity of fearful behavioral responses during the Lab-TAB probes and latency to orient to angry voices (r(54)=-.32, p=.020) and faces (r(26)=.45, p=.023).

Conclusions: This is the first study to report on associations between attention capture by threatening information conveyed through visual and auditory channels and intensity of negative affect in response to real-world fear-inducing challenges. Latency to orient to threat was not associated with severity of autism symptoms or levels of verbal or nonverbal functioning. However, children who responded with more intense fear tended to orient faster to angry voices and slower to angry faces. The mechanisms underlying this disparity are not known, but they may be related to differences in temporal structure of the stimuli or to differences in neural networks involved in processing emotional signals in visual and auditory modalities. Data collection for this project is ongoing and we plan to examine these questions in greater detail. These findings provide novel insights into threat processing and the complex associations between affective attention and emotional expression in very young children with and without ASD.

Panel Session
International and Cross-Cultural Perspectives

142 - Reducing Racial and Ethnic Disparities in Early Detection and Treatment of Children with ASD

10:30 AM - 12:30 PM - Arcadis Zaal

Panel Chair: Sandy Magaña, *Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX*

Discussant: David Mandell, *Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

This panel is focused on efforts to reduce racial and ethnic disparities in autism diagnosis and treatment. Substantial racial and ethnic disparities have been documented among children with ASD with respect to early detection, diagnosis, and receipt of evidenced-based (EB) interventions. For example, Black and Latino children have been found to be underdiagnosed with ASD, diagnosed later, and when diagnosed, less likely to receive EB treatments. In this panel, we use the framework of health disparities research outlined by Kilbourne and colleagues (2006), which describes three phases: 1) detecting disparities, 2) understanding disparities and 3) reducing disparities. Research that has documented disparities in diagnosis and treatment fits into the detecting disparities phase. There is some research on the understanding disparities phase related to barriers to receiving diagnosis and treatment. While more research is needed in each of these phases, interventions to reduce disparities in autism are beginning to emerge. These interventions can occur on the individual/family level, the provider level, or the policy level. In this panel, we describe research that represents all three levels.

10:30 **142.001** Autism Screening in Primary Care: Who Benefits and How?

C. Nadler^{1,2}, *C. Low Kapalu*^{1,2}, *V. Staggs*^{1,2}, *K. Williams*^{1,2}, *Y. Tupa*^{1} *and S. Nyp*^{1,2}, *(1)Children's Mercy Kansas City, Kansas City, MO, (2)University of Missouri Kansas City School of Medicine, Kansas City, MO*

Background: While the American Academy of Pediatrics recommends standardized screening for autism in primary care, the 2016 United States Preventive Services Task Force (USPSTF) statement found the evidence for this practice to be inadequate. While tools like the Modified Checklist for Autism in Toddlers (M-CHAT) are recognized as robust and early intervention is recognized as effective, the downstream impact of universal screening has not been well investigated, particularly for individuals facing known health disparities (i.e., reduced access to autism diagnostic and treatment services).
Objectives: To investigate the effects of correct identification of autism risk via standardized screening in primary care using a matched sample of children whose positive autism screens were overlooked by their providers as a naturalistic control group.

Methods: We extracted health records for 5771 children receiving care at an urban academic medical center who attended at least one 18 or 24/30 month well visit (Time 1; T1), as well as at least one second well visit between 4-6 years of age (Time 2; T2). For T1 visits, provider interpretation of the M-CHAT was compared to results from manual rescoring, yielding groups of children whose positive screens were either correctly identified or overlooked. To adjust for differences between the groups due to non-random assignment, we used 1:1 propensity score matching to select a sample in which the two groups were balanced on demographics, number of M-CHAT items failed (i.e., symptom severity), and other T1 variables. To investigate the effects of correct identification, we compared the groups on T2 diagnostic outcomes and services access using logistic regression.

Results: Of the 534 children with positive M-CHATs at T1, only 54 were correctly identified by their providers; of these, 47 had appropriate matches among the group whose positive screens were overlooked. Combined (n = 94), children in the matched samples reflect the significant racial/ethnic diversity of the clinic population (43.6% Black, 28.7% Latino, 17.0% White, 10.6% Other). Controlling for number of M-CHAT items failed at T1, correctly identified children were more likely to be diagnosed with autism (aOR = 29.42, p = .020) or another psychiatric condition (aOR = 2.90, p = .037) at T2. Notably, correctly identified and overlooked children with positive screens had similarly low rates of access to intervention at T2 (43% and 38%, respectively; aOR = 1.18, p = .719), with no differences related to demographics.

Conclusions: These results provide mixed support for universal primary care autism screening. While correct identification of a positive screen by 30 months of age was significantly associated with being diagnosed with autism by age 6, correct identification was not associated with improved access to intervention. There was little evidence that correct identification led to differential diagnostic outcomes or access to intervention based on race/ethnicity, sex, or socioeconomic status, so universal screening may mitigate health disparities in diagnosis and treatment access observed in previous research. However, the functional benefits of screening may be limited if the low rates of access to services observed here are representative for diverse populations.

10:55 **142.002** Improving Autism and Developmental Screening for Practices Serving Latinos: The REAL-START Project

K. Zuckerman[1], *A. E. Chavez*[1,2], *L. Wilson*[3], *C. Reuland*[4], *M. King*[5], *J. Scholz*[6], *K. Ramsey*[7], *K. Unger*[8] *and E. Fombonne*[9], *(1)Division of General Pediatrics, Oregon Health & Science University, Portland, OR, (2)Psychology, UMass Boston, Boston, MA, (3)Divison of General Pediatrics, Oregon Health & Science University, Portland, OR, (4)Pediatrics, Oregon Pediatric Improvement Partnership at Oregon Health & Science University, Portland, OR, (5)Early Life Health, Health Share of Oregon, Portland, OR, (6)Oregon Pediatric Society, Portland, OR, (7)Oregon Health and Science University - Portland State University School of Public Health, Portland, OR, (8)Pediatrics, Oregon Health & Science University, Portland, OR, (9)Psychiatry, Pediatrics & Behavioral Neurosciences, Oregon Health & Science University, Portland, OR*

Background:

U.S. Latino children are diagnosed with Autism Spectrum Disorder [ASD] less often, at older ages, and at the point of greater severity. Improving ASD identification in the primary care setting may increase access to diagnosis and treatment and reduce disparities.

Objectives:

We conducted a 12-month intervention in 6 Oregon primary care practices serving Latino communities. The goal of the intervention was to raise rates of adherence to American Academy of Pediatrics [AAP] ASD and developmental screening guidelines at 18- and 24-month well child visits, and to increase Early Intervention [EI] referrals for children with high risk of ASD or other developmental conditions.

Methods:

Forty-two medical providers from 6 practices attended a 1 ½ - hour initial in-person training on the ASQ-3 (Ages and Stages -3; general developmental screener) and MCHAT-R/F (Modified Checklist for Autism in Toddlers – R/F; autism screener), and on proper referral practices for children with screen failure. Three 1-hour follow-up trainings at 3, 6, and 9 months addressed topics specific to Latinos, such as communication about screening to families with low health literacy, the relationship between bilingualism and language delays, and access to autism services through Medicaid. Practice leaders met with a facilitator 4 times to review practice- and provider-level data on screening and referral rates, and conducted quality improvement activities to improve these rates. A medical record review captured screening and referral rates for all 18- and 24-month well visits at baseline and at 3, 6, 9, and 12 months after the initial intervention. A query of the Oregon Early Intervention database assessed EI eligibility rates. Estimates of screening rates accounted for clustering at the clinic and provider level and are adjusted for child age.

Results:

In total, 2357 18- and 24-month well child visits were captured during the intervention; 39% of visits were for Latino children. Practices improved age-adjusted rates of ASD screening with MCHAT-R/F at well visits, from 58% of well visits screened at baseline to 89% at the end of the intervention (p<0.001). Practices also improved rates of general developmental screening with ASQ-3, from 59% to 95% (p<0.001). Rates of complete adherence to AAP guidelines (i.e., conducting both screens) increased from 35% to 87% (p<0.001). The greatest improvements in screening rates occurred in the first 6 months of the intervention. Screening and referral rates were comparable for Latinos and non-Latinos throughout the intervention. While the proportion of children referred to EI due to screen failure stayed relatively constant, the absolute number of referrals increased. Additionally, the absolute number of children who qualified for EI services increased slightly (3.0 to 4.5 per study period; p = 0.28), but the proportion of children referred to EI who were found to be eligible decreased slightly.

Conclusions:

This longitudinal intervention was effective in sustainably increasing screening for ASD and other developmental disabilities in primary care settings with many Latino patients. Increased screening rates were associated with increased Early Intervention referral rates, and a trend toward increased EI eligibility.

11:20 **142.003** Adapting an Ebi for Children with ASD for Community Implementation with Latino Families: Therapist and Parent Recommendations for Adaptations

C. Chlebowski[1], *B. Wright*[2], *S. Magaña*[3], *E. Hurwich-Reiss*[4] *and L. Brookman-Frazee*[5], *(1)National Institute of Mental Health, Bethesda, MD, (2)University of California, Los Angeles, Los Angeles, CA, (3)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (4)University of California, San Diego, La Jolla, CA, (5)Psychiatry, University of California, San Diego, San Diego, CA*

Background: Disparities exist in identification, diagnosis, and treatment for Latino children with ASD. There is increased focus on the use of evidence based interventions (EBI) in mental health treatment and the need for culturally responsive EBIs has been identified (APA, 2006). Identifying culturally appropriate ways to adapt EBIs using input from stakeholders is critical.

Objectives: This qualitative study used focus groups and interviews to gather parent and therapist perceptions of implementation of a structured EBI for children with ASD (*An Individualized Mental Health Intervention for ASD* (AIM HI)) when utilized with Latino families with the goal of identifying potential training and EBI adaptations.

Methods: Data collection occurred from focus groups with therapists (n=17) and semi-structured interviews with Latino parents (n=29) who participated in the AIM HI community effectiveness trial. Of the therapists, 35% self-identified as Hispanic/Latino and 47% reported speaking Spanish. All parents self-identified as Hispanic/Latino; 86% spoke Spanish and 66% preferred Spanish. Focus groups and interviews were transcribed and coded to identify relevant themes.

Results: The following themes were identified using rapid assessment analysis process (RAP) of focus groups and consensus coding of interviews. Three salient themes emerged regarding potential adaptations.

Theme 1 Adapting training: The most frequent themes for training adaptations were related to helping therapists deliver AIM HI with Latino, or non-English speaking families. A clear need was identified for increased training in using a culturally-informed approach to intervention delivery and individualizing AIM HI for diverse families. The need for training when working with an interpreter was another identified theme.

Theme 2 Adapting AIM HI: Salient themes regarding adapting AIM HI focused on making the intervention more accessible to parents by simplifying behavioral terminology and adding a parent workbook. Increasing the accessibility of AIM HI to Spanish speaking families was a salient theme with therapists identifying the need for additional translated AIM HI materials to provide information and context to non-English speaking families. Adaptations to increase the utility of AIM HI included adding a parent module with psychoeducation about ASD (in both English and Spanish).

Theme 3 Adapting AIM HI delivery: Themes regarding adapting intervention delivery differed by stakeholder group. Therapists advocated using technology (text messages, phone based app) to communicate with parents during treatment; however, no parents endorsed wanting to be sent treatment information weekly via electronic method. The majority of parents (61%) reported that they preferred information from their therapist to be delivered in *both* verbal and printed format (e.g., resources and handouts); 64% reported that they preferred their therapist to provide treatment forms and materials to them incrementally week by week as opposed to receiving a complete workbook at the beginning of treatment (an option preferred by 32% of parents).

Conclusions: These findings highlight the need to adapt EBI training and intervention delivery for Latino families, with a focus on understanding the needs of stakeholder groups. Based on these findings, future study in our research program will involve developing and piloting testing a toolkit specifically addressing the recommendations generated from this qualitative data.

11:45 **142.004** Randomized Control Trial: Impact of the Parents Taking Action Program on Latino Children with ASD and Their Parents

K. Lopez[1]*, S. Magaña*[2] *and M. Morales*[3]*, (1)Arizona State University, Phoenix, AZ, (2)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (3)Disability and Human Development, University of Illinois at Chicago, Chicago, IL*

Background:

ASD prevalence among Latino children has increased dramatically over the past decade and research has documented substantial disparities in treatments and services among Latino children with ASD compared to White children. To reduce disparities for Latino children with ASD, Parents Taking Action (PTA), a culturally informed psychoeducation program, was developed. PTA is based on an ecological validity model, which addresses specific dimensions of culture in the development of interventions. PTA is a 14-week program delivered by promotoras de salud (community health workers). Promotoras are bilingual Latina mothers of children with ASD and have been identified as active members in their community. PTA content informs parents about ASD and their child's rights, and teaches parents evidenced-based (EB) strategies grounded in applied behavior analysis to use with their children.

Objectives:

To test the efficacy of PTA with respect to parent outcomes (utilizing EB strategies), and child outcomes (reduction of symptoms, increase in service use).

Methods:

Participants included 89 Latina mothers and 93 children in Illinois and California. Children were all diagnosed with ASD. Following a baseline assessment, dyads were randomly assigned to a treatment now or treatment later group. Those in treatment now (mothers mean age 37.9, SD=5.3; children mean age 5.5, SD=1.8) immediately received PTA along with two follow-up assessments (after completing the program and 4 months later). The treatment later group (mothers mean age 36.2, SD=6.6; children mean age 5.2, SD=1.8) was offered the PTA program after completing two follow-up assessments (4 and 8 months post-baseline). Assessments included the Childhood Autism Rating Scale, Social and Communication Questionnaire (SCQ), Family Outcome Survey (FOS), service use questions, and measures specific to the study regarding efficacy in using EB strategies and frequency of using the EB strategies. The data included in the present study are from the baseline and time 2 assessments.

Results:

The linear mixed effects model for the child outcome showed that the treatment group had reduced SCQ scores at time 2 (lower score = less impairment). For parent outcomes, the linear mixed effects model showed a significant interaction between time and treatment group on efficacy in using the EB strategies and frequency in the use of strategies, showing an increase in these outcomes for the treatment group. We did not find a treatment effect for the FOS. Service use increased for the treatment group in California but not in Illinois.

Conclusions:

The results show that PTA is a culturally informed program for Latino families that enhances parents' abilities to apply evidenced based strategies with their children, which can lead to enhanced social communication skills among children. Future analysis should examine the impact of all outcomes over time, and could examine the efficacy of the program for other underserved communities.

Poster Session
143 - Technology Demonstration
10:00 AM - 1:30 PM - Hall Grote Zaal

77 **143.077** Connecting through Kinect: A Participatory Approach to Designing a Collaborative Emotion Recognition Game with and for Autistic Individuals

K. Gillespie-Lynch[1]*, M. Kholodovsky*[2]*, D. S. Smith*[3]*, R. Arab*[2]*, P. Asanov*[2] *and D. Sturm*[2]*, (1)Department of Psychology, College of Staten Island; CUNY*

Graduate Center, Brooklyn, NY, (2)College of Staten Island, Staten Island, NY, (3)CSI, Brooklyn, NY

Background: Autistic people face challenges communicating with others in-person which are often reduced online (Gillespie-Lynch et al., 2014). However, evidence that computer-mediated interventions are effective in helping autistic people develop *generalizable* social-communicative skills remains limited (Whyte et al., 2015). Participatory research wherein autistic people are involved as collaborators in game design/evaluation can help address the disconnect between the *potential* of computerized autism interventions and limited benefits documented thus far. Parsons and Cobb suggested that effective technologies to support autistic people are developed by aligning Theory, Technologies and Thoughts (autistic perspectives).

Objectives: We aim to document the process of including autistic youth in designing/evaluating a game to help autistic people understand complex emotions and collaborate and to determine if the game is effective at scaffolding collaboration and emotion recognition.

Methods: Our game is designed to support generalizable skills by providing an immersive environment wherein participants can simultaneously engage digitally and in-person while learning how to interpret emotions. Standing near one another, participants complete collaborative emotion matching puzzles using Kinect technology. Animated tutorials teach gameplay. All instructions are nonverbal so that the game is accessible for people with diverse communicative abilities. In the core game, two players use gestures to move puzzle pieces. Each puzzle depicts the outline of a figure in an emotional context. After players construct the body; they must agree on the correct emotion for the face by selecting from three emotions. This collaborative component was adapted from a picture-matching task that was effective at promoting collaboration among minimally verbal autistic children (Holt & Yuill, 2014).

Results: We invite autistic college students in our mentorship program to provide feedback on design and become more involved if interested. Two autistic college students and their mentors provided initial feedback. Later, five autistic students and their mentors were videotaped playing the game and completed structured interviews. Students provided detailed suggestions about how to improve the look, feel and content of the game including: providing demos, making rewards meaningful, improving image quality, and giving the game a relatable storyline. Qualitative coding of game play revealed that players typically looked at the screen rather than each other while playing although they exhibited positive affect and communicated verbally.Therefore, we created a story focused on a protagonist facing a challenge many autistic youth face, bullying, about how friendship (with a friendly dragon) can help one overcome bullying (Figure 1). We added a pause feature to to encourage direct interaction during the collaborative phase and a tutorial demonstrating collaboration. Qualitative coding of five mentees playing the revised game revealed that the pause feature fostered more in-person interaction. After completing usability evaluations, we will examine benefits of repeated engagement with the game for minimally verbal autistic individuals and their siblings.

Conclusions: Our autistic collaborators have provided useful suggestions that have led to extensive improvements in game design. They reminded us to incorporate key design principles (a storyline and an interpretable reward system) that are believed to promote generalization but are often lacking in games designed for autistic people.

78 **143.078** Design of a Multi-Sensory Stimulation and Data Capture System for Investigating Multi-Sensory Trajectories in Infancy

*D. Bian[1], Z. Zheng[2], A. Swanson[3], A. S. Weitlauf[4], **Z. Warren**[5] and N. Sarkar[2], (1)Electrical Engineering & Computer Science, Vanderbilt University, Nashville, TN, (2)Vanderbilt University, Nashville, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, NASHVILLE, TN, (4)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (5)Vanderbilt University Medical Center, Nashville, TN*

Background: Differences in behavioral responses to basic sensory stimuli are hallmark features of ASD that may impact the deficits in social responsivity which characterize the disorder over time. While the neural basis of complex social and communicative behaviors develops throughout childhood, brain responses to more basic, sensory stimuli are in place much earlier, making sensory processing differences a potential target for earliest detection. Characterization of these sensory differences and prospective study of their developmental impact has been limited by a scarcity of methods by which to assess them in infants. Current single-sensory-modality studies contrast with the rich multisensory environment of human infants, with tools and paradigms for charting this more meaningful and complex processing sorely lacking.

Objectives: To investigate the feasibility and tolerability of a multi-sensory paradigm including the sense of touch.

Methods: We developed a precisely controlled system for multi-sensory (auditory, visual, and tactile) stimuli delivery endowed with the capacity to monitor eye gaze, peripheral physiological, and electroencephalogram (EEG) data. We designed a mechatronic device to simulate affective touch, which can be synchronized with other sensory deliveries. All the data can be captured with user-defined event markers for later data segmentation. A feasibility study with 10 participants aged between 3- to 20-months-old was conducted. All participants watched a series of videos where a female actress was seen and heard reciting a prepared English or Spanish monologue. To determine how much time participants spent gazing at core areas of the face, we defined three principal regions of interest (ROIs) around the eyes, the nose and mouth, respectively, on the face of the talker. The videos were played twice in random order. We manipulated the affective touch simulation device to stroke the participants' forearms for one of the identical stimulus displays.

Results: Seven out of the 10 participants went through all of the experimental procedures. Eye gaze data, peripheral physiological data (PPG and GSR), and EEG data were all properly recorded with event markers. Three participants pulled their arms out of the tactile device in the middle of the experiment, which might be because the current design of the tactile device has difficulty in fixing small arm in place. The data were collected regardless of the absence of the tactile stimulus. Results indicated that participants looked at the stimulus screen 27% of the time, with gaze toward demarcated ROI for 57% of this time. No specific differences in the tactile stimulus conditions were noted across groups (with and without affective touch).

Conclusions: This work describes a novel multi-sensory stimulus delivery system that can record multi-dimensional data in real time. This feasibility study demonstrated that the system is tolerated by infants aged 3- to 20-months-old. Eye gaze data, peripheral physiological data, and EEG data were successfully recorded. Such a system could potentially be used to help study multisensory differences and process differences over time for both high- (e.g., infant siblings of children with ASD) and low-risk infants.

79 **143.079** Design and Evaluation of an Artificial Intelligent Agent to Measure Communication Skills of Children with ASD

*L. Zhang[1], A. Swanson[2], A. S. Weitlauf[3], **Z. Warren**[4] and N. Sarkar[1], (1)Vanderbilt University, Nashville, TN, (2)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, NASHVILLE, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt University Medical Center, Nashville, TN*

Background:

Researchers are increasingly exploring virtual reality environments as potential intervention platforms for children with Autism Spectrum Disorder (ASD). A Collaborative Virtual Environment (CVE) is a virtual reality environment that could facilitate real-time interactions with peers across distance. However, interactions within CVEs change based on specific partner input and as such, fundamentally limit consistent, controlled, and replicable interactions within the CVEs. In addition, manual coding of interactions is necessary to understand patterns of communication for meaningful measurement, creating a resource burden that fundamentally limits realistic paradigm scale-up. An Artificial Intelligence (AI) agent may address these problems by interacting with children as a consistent partner and automatically measuring their verbal communication patterns. Therefore, a virtual intelligent system (VIS) that combines CVE and AI technologies may facilitate complex, dynamic real-world interactions with social partners, as well as automatically measure these interactions to enable scale-up of CVEs to improve social communication skills.

Objectives:

We present a novel VIS that could not just promote peer-based interaction in real time, but also yield quantitative metrics of social communication that can be used within system to facilitate salient aspects of social collaborative learning. The objective of this work is to evaluate whether the VIS could be used as a consistent partner to measure social communication skills of children with ASD in peer-based interactions.

Methods:

Our VIS was composed of a CVE and an AI agent. The CVE was developed with Unity3D game engine (http://unity3d.com/). A series of 9 puzzle games were designed in a shared virtual environment. The interaction in the CVE was governed by implicit rules that required cooperation and communication in order to achieve success. An AI agent was designed to i) monitor the peer-based interactions in the CVE, and ii) to be a consistent partner that could talk and play these games with each child. The AI agent was composed of five modules, i.e., a speech recognition module, a natural language understanding module, a dialogue manager module, a natural language generation module, and a text-to-speech module. In the natural language understanding module, the AI agent could generate communication related features for meaningful measurements using natural language processing and machine learning technologies.

Results:

The Unity-based CVE system was developed with 9 different collaborative tasks. The AI agent was developed with the capability to achieve real-time conversation and interactions. We conducted an initial pilot study with 20 age-matched and gender-matched pairs. All participants enjoyed communicating and playing games with both human-partners and AI-partners. The AI agent was able to capture some communication features, such as number of words, frequency of questions, and frequency of response, which could be used to measure the communication skills of children with ASD.

Conclusions:

The initial pilot study indicated the potential value of VIS in automatically measuring social communication skills of children with ASD in peer-based interactions. This automatic measurement capability will enable a future adaptive system that will modify tasks based on the communication skills of each individual to enhance social communication with peers.

80 **143.080** Autism Data Goes Big: A Publicly-Accessible Multi-Modal Database of Child Interactions for Behavioural and Machine Learning Research

Vlasenko*[7,12], *M. Zanfir*[8], *V. Evers*[5] *and C. De-Enigma*[13], *(1)Department of Computing, Imperial College London, London, United Kingdom, (2)Centre for Research in Autism and Education, University College London, London, United Kingdom, (3)Serbian Society of Autism, Belgrade, Serbia, (4)Chair for Embedded Intelligence for Health Care and Wellbeing, University of Augsburg, Augsburg, Germany, (5)Human-Media Interaction, University of Twente, Enschede, Netherlands, (6)Informatics, University of Augsburg, Augsburg, Germany, (7)Complex Intelligent Systems, University of Passau, Passau, Germany, (8)"Simion Stoilow" Institute of Mathematics of the Romanian Academy (IMAR), Bucharest, Romania, (9)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (10)Institute of mathematics Simion Stoilow of the Romanian Academy (IMAR), Bucharest, Romania, (11)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (12)Idiap Research Institute, Martigny, Switzerland, (13)DE-ENIGMA project consortium, Enschede, Netherlands*

Background: Advances in artificial intelligence (AI), machine learning and "big data" have been almost exclusively developed based on neurotypical adult data, meaning that these tools may substantially misinterpret or fail to recognise the facial, vocal, and physical behaviours of autistic children. Existing (non-medical, non-genetic) autism datasets have been "small data": insufficient to train autism-specific algorithms, and infrequently shared between researchers. Thus, the autism and technology subfield has been largely excluded from harnessing the cutting-edge techniques present elsewhere in academic research and industry, limiting our ability to deliver personalised, intelligent technologies for education, intervention, and daily life. More—and shareable—data is needed to advance research in this area. Previous projects with adults' data have demonstrated that publicly accessible databases are logistically feasible, can operate on ethical terms acceptable to participants, and can accelerate research in related areas (e.g. https://semaine-db.eu/).

Objectives: To develop the first free, large-scale, publicly available multi-modal database of autistic children's interactions that is suitable for both behavioural and AI research. It will use data collected in DE-ENIGMA project studies on autistic children's emotion learning with a humanoid robot (http://de-enigma.eu/).

Methods: 62 British and 66 Serbian children aged between 5 and 12 years (19 female), participated in DE-ENIGMA studies on emotion recognition teaching. Each child was randomly assigned to robot-assisted or adult-assisted activities. These were based on steps 1-4 of the emotion training programme, "Teaching Children with Autism to Mind Read" (Howlin, Baron-Cohen, & Hadwin, 1999). Each child participated in 4-5 sessions, all recorded by multiple audio, video, and depth recording devices (see Table 1 and Figure 1). The parents of 121 of these children have granted consent for database inclusion.

Results: The DE-ENIGMA project has created a multi-modal database accessible via a web portal (http://db.de-enigma.eu), to which academic researchers worldwide may apply for access under a licensing agreement that prohibits commercial or governmental use. It includes ~13 TB of multi-modal data, representing 152 hours of interaction. The database is filterable based on data type (audio, video, depth, annotations) and session characteristics (child age group, study condition, country). Furthermore, 49 children's data have been annotated by experts for emotional valence, arousal, audio features in English or Serbian, and body gestures.

Conclusions: This database will be the largest existing dataset of its kind (i.e. autistic interaction, rather than genetic or medical data). The audio and video in particular represent a rich resource for behavioural research questions about autism, such as child-robot or child-adult interactions, emotion recognition, social and communicative behaviours, and cross-cultural comparison. It also provides the required scale of data needed for furthering machine learning, computer vision, audio processing and other technical techniques that include autistic behaviours. The annotated data are in effect ready-labelled training data for future autism-focused machine learning research. Finally, the DE-ENIGMA database should accelerate both new behavioural and technological work on autism by providing free starting data to researchers, a potentially enormous saving of time and resources that may also reduce the many obstacles to participation in this area.

143.081 Autism Characteristics, Adaptive Skills, and Performance in an Emotion-Recognition Teaching Programme with a Humanoid Robot

A. M. Alcorn[1], *D. Girard*[2], *E. Ainger*[1], *T. Tavassoli*[3], *S. Babović Dimitrijevic*[4], *S. Petrović*[4], *S. Skendžić*[4], *V. Petrović*[4], *E. Pellicano*[5] *and C. De-Enigma*[6], *(1)Centre for Research in Autism and Education, University College London, London, United Kingdom, (2)Psychology, University of Quebec in Montreal, Montréal, QC, Canada, (3)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (4)Serbian Society of Autism, Belgrade, Serbia, (5)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (6)DE-ENIGMA project consortium, Enschede, Netherlands*

Background: Several existing projects have shown promise in using robot-assisted interventions for teaching social and academic skills to autistic children, including emotion recognition. Most such work, however, has included older, so-called 'high functioning' autistic children and has therefore neglected to address the feasibility of robot-assisted emotion interventions for young autistic children, those with intellectual disability, or limited spoken language. Given claims that robot-assisted interventions could present lower, less complex social demands than human-led interventions, it is *particularly* important to investigate their feasibility for children whose social, daily life, or language skills may present barriers to participation in "traditional" interventions.

Objectives: This project tested the feasibility of an emotion-recognition training programme in developing the potential of robot-assisted interventions for a large sample of autistic children in Serbia and in the UK.

Methods: 128 autistic children aged 5-12 years were assessed in a 6-step emotion-training programme based on "Teaching Children with Autism to Mind Read" (Howlin, Baron-Cohen, & Hadwin, 1999). In the robot-assisted condition (n=64, 10 females), a Robokind R25 humanoid robot ("Zeno"; see Figure 1) helped to deliver the programme controlled covertly by the adult, whilst 64 children (9 females) participated in the therapist-assisted comparison condition. Parents completed the Vineland Adaptive Behaviour Scales – 2nd edition (Sparrow et al., 2005), and researchers completed the CARS2-ST (Schopler et al., 2010) based on direct observation and parent information.

Results: Children in the robot- and therapist-assisted conditions were closely matched on autism severity and adaptive behaviours (Table 1). Emotion recognition performance, operationalised as the proportion of correct answers in steps 1-2 of Howlin et al.'s emotion-training programme, was inversely correlated with CARS-2 scores in both the robot-assisted (r = -.40, p < .001) and therapist-assisted conditions (r = -.47, p < .001). Higher Vineland composite scores (i.e. better adaptive behaviours) were significantly positively correlated with task performance for children in the therapist-assisted (*r* = .38, *p* < .01), but *not* the robot-assisted condition (*r* = .16, *p* = .27). Using the Vineland communication subscale as a proxy for language skills, better language was positively associated with performance in both conditions, but more strongly for the children in the therapist-assisted (*r* = .50, *p* < .001) than in the robot-assisted condition (*r* = .28, *p* < .05).

Conclusions: This study examined the relationship between everyday adaptive behaviours and emotion recognition performance within robot-assisted and therapist-assisted activities, as part of establishing the feasibility of using such interventions with a younger and less able participants than those studied thus far. Results suggest that while it *is* generally feasible for this group to participate, individual performance moderately correlated with lower CARS-2 scores and higher adaptive behaviour and language scores, *but less so in the robot-assisted condition*. This pattern may support claims that robots impose lower social demands, or are less complex to work with than a person. This study was the first phase of data collection for a large-scale project, with further studies iteratively developing a new robot-assisted emotion teaching intervention.

82

143.082 Are Some Emotions Harder Than Others? a Study of Autistic Children Recognising Human and Robot Facial Emotion Expressions in the UK and Serbia

D. Girard[1], *A. M. Alcorn*[2], *E. Ainger*[2], *T. Tavassoli*[3], *S. Babović Dimitrijevic*[4], *S. Skendžić*[4], *S. Petrović*[4], *V. Petrović*[4], *E. Pellicano*[5] *and C. De-Enigma*[6], *(1)Psychology, University of Quebec in Montreal, Montréal, QC, Canada, (2)Centre for Research in Autism and Education, University College London, London, United Kingdom, (3)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (4)Serbian Society of Autism, Belgrade, Serbia, (5)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (6)DE-ENIGMA project consortium, Enschede, Netherlands*

Background: Although difficulties in accurately recognising human facial expressions are well established in autism, recent findings indicate that autistic individuals are just as good at recognizing robot faces as neurotypical individuals. Several studies further highlight the potential of using robot-based technology as assistive tools in interventions for autistic children, which tend to have intact or superior abilities to comprehend and manipulate closed, rule-based, predictable systems. It is unclear, however, whether some emotions are more difficult to recognise than others in robot- versus therapist-assisted interactions.

Objectives: This study sought to compare autistic children's ability to recognise static and dynamic facial emotion expressions (angry, afraid, happy, sad) between robot- and therapist-assisted interactions. These comparisons were made in two distinct cultural contexts (Serbia and the UK).

Methods: 128 autistic children (UK: n=62; Serbia: n=66) aged 5-12 years were assessed in a 6-step facial emotion recognition training programme for 4 basic emotions (fear, anger, happiness, sadness) based on Howlin, Baron-Cohen, and Hadwin's (1999) approach. Steps 1-2 consisted of correctly matching across static emotional images. Steps 3-5 consisted of correctly matching or identifying dynamic real emotional displays. Performance on the task was operationalised as the percentage of correct answers for each emotion separately in both steps 1-2 and steps 3-5. Children were randomly assigned either to a robot-assisted condition (n=64, 10 female), where a Robokind R25 humanoid robot ('Zeno') helped to deliver the programme (controlled covertly by an adult), or a therapist-assisted comparison condition (n=64, 9 female). Researchers assessed autism symptomatology using the CARS2-ST (Schopler et al., 2010) based on direct observation and parent information.

Results: All subgroups were closely matched on age (p=.67) and had, on average, mild-to moderate autism severity symptoms. We used Mann-Whitney U test to compare the performance of our groups as the performance distribution for each emotion was highly skewed. For static facial expressions (steps 1-2), there were no significant differences in children's recognition performance between robot- and therapist-assisted conditions – with the exception of fearful expressions, which were more easily recognised by Serbian children in the robot-assisted condition (U=373, p=.010). For dynamic facial expressions (steps 3-5), Serbian children in the robot-assisted condition were significantly more accurate in recognising fearful (U=398, p=.043) and sad faces (U=403, p=.043) compared to the therapist-assisted condition. There were no significant differences, however, between UK children's recognition accuracy in robot- and therapist-assisted conditions (all ps>.05).

Conclusions: These results indicate that children's performance for static and dynamic facial expressions was similar for robot- and therapist-assisted interactions. For Serbian children, implementation of the emotion-training programme within the robot-assisted interaction seemed to benefit their recognition accuracy for static and dynamic fearful faces, as well as dynamic sad faces. These results suggest that the extent to which a robot-assisted training programme can facilitate emotion recognition in autistic children may vary as a function of cultural context. Also, the use of the robot technology seems to help correctly identify only *some* specific type of facial expressions. These findings will inform the next phase of this large-scale project.

83 **143.083** Design of a Robot-Based Emotion-Mirroring Game to Engage Autistic Children with Emotional Expressions

B. R. Schadenberg[1]*, P. Chevalier*[1]*, J. J. Li*[1]*, E. Ainger*[2]*, A. M. Alcorn*[2]*, S. Babović Dimitrijevic*[3]*, V. Charisi*[1]*, S. Petrović*[3]*, D. Reidsma*[1]*, E. Pellicano*[4]*, D. K. Heylen*[1] *and V. Evers*[1]*, (1)Human-Media Interaction, University of Twente, Enschede, Netherlands, (2)Centre for Research in Autism and Education, University College London, London, United Kingdom, (3)Serbian Society of Autism, Belgrade, Serbia, (4)Macquarie University, Sydney, Australia*

Background: Autistic children often have difficulty recognising emotional facial expressions of others relative to typically developing children. One possible way for children to learn to recognise facial expressions may be to observe their face being imitated by another party. Game-like interactions that include imitation and mirroring can help young autistic children to attend to and "play" with emotional facial expressions, as a building block in recognising those expressions and grasping emotional concepts. A social robot could be particularly useful in this regard by providing a less complex, more predictable - and potentially less threatening - way of interaction than a human.

Objectives: In a novel emotion-mirroring game, autistic children can play with a social robot who mirrors their facial expression in real-time. This study sought to determine whether autistic children understand and enjoy playing this game with the robot.

Methods: Data collection is ongoing. One autistic child (aged 8, male) from a regular elementary school in the Netherlands participated in this pilot study. The child played the emotion-mirroring game for 4 minutes, followed by another game for an additional 4 minutes. The emotion-mirroring game is set up as a triadic interaction between child, an adult, and the robot, which is the Robokind R25 humanoid robot, called "Zeno". Computer vision is used to track the child's facial features through a webcam, which are translated to the robot's facial features. This game aims to gradually familiarise the child with Zeno, prepare the child to (1) pay attention to Zeno's facial features specifically, (2) to generate facial expressions in response to Zeno, and (3) to understand the cause-and-effect nature of mirroring. To that end, the game starts with the adult and child making faces using an ordinary mirror, while Zeno is out of sight. Once the child understands the concept of a mirror, the adult introduces the robot to the child. Zeno mirrors the child face and the adult scaffolds cause-and-effect understanding. The game ended with the child being asked to imitate Zeno's happy and sad facial expression.

Results: The child completed the game with ease. After playing with the mirror and being told that "now Zeno is the mirror", the child spontaneously started making facial expressions without being explicitly asked to do so. In the last step, Zeno asked the child to imitate its facial expressions. The child imitated the happy expression by opening the mouth and raising the eyebrows, but missed the smile. The sad expression was perfectly imitated by the child. Overall, the child appeared very interested in the robot, called it the "best visitor ever", and was reluctant to leave at the end. Additionally, there was one spontaneous initiation towards the robot and two to the adult.

Conclusions: The game design appeared to have been successful in explaining the emotion-mirroring game to the autistic child and creating an enjoyable interaction. The next step is to assess the effectiveness of this and other similar games in teaching emotion recognition to autistic children in controlled experiments.

84 **143.084** Feasibility, Enjoyment, and Effectiveness of a Robot Social Skills Intervention for Children with ASD

J. B. Lebersfeld*, C. J. Brasher, C. D. Clesi, C. E. Stevens, F. J. Biasini and M. I. Hopkins, University of Alabama at Birmingham, Birmingham, AL*

Background: Children with Autism Spectrum Disorder (ASD) demonstrate difficulty with social skills, including understanding emotional facial expressions. Children with ASD are intrinsically motivated by technology. To capitalize on this, a robotic monkey (SAM: Socially Animated Machine) was developed to lead a social skills intervention. Research found that this intervention was feasible and enjoyable for children with ASD and average cognitive ability, and participants improved in complex emotion recognition following intervention.

Objectives: Given the aforementioned success, the current study aimed to investigate the effectiveness for children with ASD across all levels of cognitive ability. This study examined whether the robot intervention improves 1) emotion matching, 2) facial recognition, 3) social skills, and 4) is enjoyable for this population.

Methods: Fifteen children with ASD ages 5-14 with well below average to average cognitive skills participated in the study. ASD diagnosis was confirmed using the Autism Diagnostic Observation Schedule, Second Edition. Participants were assigned to the intervention group (n=8) or control group (n=7). Both groups completed eight weekly sessions with the robot. The intervention group played emotion games with SAM, and the control group played non-emotion games. Emotion matching accuracy, facial recognition (Benton Facial Recognition Test), and social skills (Social Responsiveness Scale (SRS-2), parent and teacher) were compared across groups pre- and post-intervention. After completion, parents and children rated the child's enjoyment on a 0-10 scale.

Results: Univariate ANCOVAs were adjusted for pre-intervention scores. One outlier was excluded from emotion matching accuracy analysis. Accuracy for both groups improved from pre- to post-intervention (Intervention: *M*=81.0% to *M*=95.2%, Control: *M*=72.6% to *M*=83.9%). Overall post-intervention accuracy did not differ between groups. Emotions were separated into simple emotions (happy, sad) and complex emotions (anger, fear, surprise, disgust). Although groups did not differ on simple emotions, the analysis of complex emotions trended toward significance (*F*(1,11)=4.516, *p*=.057; Intervention: *M*=92.2%, Control: *M*=79.2%). For individual emotions, the intervention group significantly improved in matching facial expressions displaying fear (*F*(1,11)=6.637, *p*<.05; Intervention: *M*=96.4%, Control: *M*=75.0%) and disgust (*F*(1,11)=9.239, *p*<.05; Intervention: *M*=97.5%, Control: *M*=66.8%) but not anger or surprise. Analyses indicated no significant group differences in facial recognition or social skills. Both groups enjoyed talking with SAM (*M*=9.43, *SD*=1.51) and wanted to interact with the robot again (*M*=8.93, *SD*=2.13). Parents indicated that their children enjoyed the sessions (*M*=8.86, *SD*=1.56), were motivated to attend (*M*=8.36, *SD*=1.99), and would like to have additional interactions (*M*=8.64, *SD*=1.55).

Conclusions: The SAM robot intervention is feasible, enjoyable, and motivating for children with ASD across a range of cognitive skills. Considering that children with ASD acquire skills more effectively while engaged and motivated in the learning process, this study shows further evidence for the use of robots with this population. The SAM robot intervention improved emotion recognition for some complex emotions, but not all, and improvements did not generalize to other measures. It is possible that the outcome measures chosen did not adequately capture acquired skills. Aspects of the SAM robot intervention will be explored further to maximize effects and generalizability, including the content, dose, frequency, and duration of sessions.

85 **143.085** Cloud Computing Enabled Social Robot Platform for Children with Autism Spectrum Disorders

Z. Tan[1], *B. Xing*[2], *W. Song*[2], *W. Cao*[1], *H. Zhu*[2,3], *L. Yi*[4] *and J. Chen*[5], *(1)South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (2)Centre for Optical and Electromagnetic Research, South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (3)Child Developmental & Behavioral Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (4)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (5)School of Electrical Engineering and Computer Science, KTH Royal Institute of Technology, Stockholm, Sweden*

Background:

Children with autism spectrum disorder (ASD) have a core problem in terms of social communication deficits. Recent advances in social robots, which are capable of interacting with humans by following social behaviours and rules attached to its role, open a way to promote engagement and communicative exchange in children with ASD. Many researches have demonstrated that social robots can offer children with ASD a safe environment, and facilitate diagnosis and assessment. However, it is of key importance that the social robot provides accurate response to children with ASD, which might be difficult to be realized with limited computation power offered by the robot itself.

Objectives:

We are aiming at developing cloud computing enabled social robot platform that engages in developing social communication skills of children with ASD. The platform facilitates fast and reliable connections between the social robots and remote data centres that provide sufficient computation capability in supporting timely and precisely interactions with children.

Methods:

Figure 1 presents the schematic diagram of our developed cloud computing enabled social robot platform. Two inset pictures are the examples to illustrate how the social robots are interacted with the participating child. The cloud enabled platform is composed of a web client, social robots, external equipment for data collection, and data centres. All collected data (that could be from the social robots and/or external equipment) is then sent to data centres, which can be either third-party cloud or operated locally, through WiFi or cable connections. The web client used for management can view the information sent to the data centres and communicate remotely with the robot.

Results:

We have tested automatic voice response that is carried out by our platform. All the measurements were done in Chinese. The test question is “what is your name?”. The question itself lasts 1.39s. 7 different answers, all of which address questions precisely, were received for 7 measurements. The length of the answering audio varies from 1.78s to 6.31s. The total waiting time, which is defined as the time duration from the end of question to the beginning of answering, varies from 3.20s to 5.77s. More than 90% of the waiting time is spent for the social robot uploading the audio file to the data centres. It is because of very limited data rate provided by the network interface embedded in the social robot. To further reduce the latency, the uploading data rate should be improved. On the other hand, compared to our developed cloud enabled platform, the stand-alone social robot performs less stable and is not always able to provide proper answers, which implies it might not be an appropriate solution to interact with children with ASD.

Conclusions:

We developed cloud computing enabled social robot platform, which provides fast and reliable interactions, and assists in diagnosing and assessment, for developing social communication skills of children with ASD. The developed platform is able to provide automatic and precise response to the participants, which is hardly realized by the stand-alone social robots.

86 **143.086** Converting Existing Vocabulary Tests into Robotic Programs

S. Walsh Matthews[1] *and A. R. Marquis*[2], *(1)Languages, Literatures, and Cultures, Ryerson University, toronto, ON, Canada, (2)Psychology, Ryerson University, Toronto, ON, Canada*

Background: Recent studies (e.g., Walsh Matthews et al. 2016; Kim et al. 2015; Ismail et al., 2012) show increased social communicative behaviour by children with Autism Spectrum Disorder (ASD) following human robot interaction (HRI). To further these test effects, we designed a study that would substitute human-conducted vocabulary testing with HRI by re-creating Tager-Flusberg’s (1985) experiment to examine the nature of substantive lexical semantic representations in children with ASD. The HRI programming allowed for the examination of basic level and superordinate semantic categories might aid in cognitive representational tasks and that longer, more intensive interactive robotic programming would promote the production of more accurate responding by minimising the observers’ impact during in-session observations.

Objectives: To program novel robotic behaviours on the small humanoid NAO to mimic the Peabody Vocabulary Test (PVT) via randomized Robotic

Vocabulary Tests (RVT.) The test is to be administered with children previously diagnosed with ASD. Participants would have an opportunity to interact with NAO to see which of the dances/songs would promote greater interactivity between participant and robot. From our first observations, rewards were generated at different intervals and of different lengths to further evaluate the role of interaction and its relevant effect on responses.

Methods: The study is grounded in Tager-Flusberg's (1985) experiment 1 to assess autistic children's understanding of words "for basic and superordinate level categories" (1169). Replacing the PVT with a programmed RVT version, stimuli (images representing two overall categories: superordinate including tools and food and basic including boat and birds) were transferred into accessible image cards recognised by the robot. Within each category there are three possible stimulus types: match (central members of a category), false lure (related nonmembers), and unrelated objects (unrelated nonmembers). The robotic script runs four randomized RVTs which include two short versions with 5-second robotic dances and songs and two longer versions that have multiple and randomized robotic diversion programming. Select ASD participants (aged 4-9), interacted with NAO once per week for three consecutive weeks.

Results: The length of HRI did not have a significant impact on the participant's *overall* accuracy performance at both time points (p = 0.87 and p = 0.54, respectively). However, when analyzing the performance based on category level, where we would expect to find differences, we see differential performance. Based on our preliminary analyses, (see Figure 1), participants perform better on basic level cards when the interaction is long compared to short, and a slight increase in performance for superordinate level cards when the interaction is long compared to short.

Conclusions: Findings from Tager-Flusberg's original experiment found children likely had inflexible categorical semantic organization. Inconsistent with this, we see that children show improvements in their semantic organization when the robot's behaviours are more interactive. Further analyses will be needed to confirm this trend, however, early findings supports our hypotheses driven by Idealised Cognitive Models (Lakoff, 1987), such that HRI would increase the potential for new conceptual categories, or at least invite opportunities to engage with them.

87 **143.087** Fostering Real-World Interaction in Autistic Pupils with Digital Technology: Design Recommendations from Practitioners in Special Education

M. H. Laurie[1], *A. Manches*[2] *and S. Fletcher-Watson*[3], *(1)Patrick Wild Centre, University of Edinburgh, Edinburgh, United Kingdom, (2)Moray House School of Education, University of Edinburgh, Edinburgh, United Kingdom, (3)University of Edinburgh, Edinburgh, United Kingdom*

Background:

Technology is widely used by autistic children, and is increasingly used to develop skills in language, communication, curriculum learning and the social domain. However, alongside the demonstrated benefits of educational technology for autistic children, there is ongoing concern from parents and practitioners that technology is socially isolating, and prohibits real-world interaction. It is essential to understand this point of view in order to create, implement, and evaluate technologies for use by autistic children.

Objectives:

To draw on practitioner experiences to determine how technology might influence real-world interaction in autistic children, i.e. what types of interaction have the potential to be impeded / fostered by technology, and what technologies inhibit / promote interaction.

Methods:

186 education practitioners (including teachers, educational assistants, therapists and psychologists) completed a survey about technology use in autism education. We collected information about demographics, pupil profiles, technology use (hardware, software, purpose) and attitudes to technology. Subsequently, two focus groups with class teachers at different schools were conducted (*n* = 11), in which the impact of digital technologies on social interaction was discussed.

Results:

For most practitioners, socially interactive uses of technology were not overtly considered or prioritised, and instead, technology was most frequently used to support learning and communication. In the survey, practitioners were almost evenly split between strongly agreeing and strongly disagreeing that technology contributed to social isolation, producing extremely mixed results, and practitioners provided anecdotal experiences of both scenarios in open-ended questions. In the focus groups, most practitioners felt that technology could discourage social interaction amongst their pupils, particularly screen-based medias such as mobile tablets. However, the same practitioners also reported many scenarios and examples of where technology encouraged and fostered interaction amongst their pupils. These interactions ranged from simple to complex, and included tolerating others, sharing space, verbal communication, turn-taking, and forming relationships through shared interests, with interactions directed towards both staff and peers. From the focus groups, factors related to the individual child, the technological hardware, the software, and the environment emerged as influential to technology's impact on social behaviour. Features related to digital technologies that had most influence on social interaction, according to practitioners, included physical affordances, customization and flexibility, context of technology use, and collaborative opportunity.

Conclusions:

Technology has the potential to foster real-world interaction in children with autism, according to education practitioners. Social interaction via technology is an unexpected benefit, rather than an intended outcome, despite the importance of developing social skills in autistic children. The data will be interpreted and presented as a set recommendations for practitioners and tech developers, to derive design criteria that can maximise opportunities for social interaction in autistic children using technology.

88 **143.088** Digital Social Stories

E. Smith[1], *H. Johnson*[1], *A. Constantin*[2] *and M. Brosnan*[3], *(1)University of Bath, Bath, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom of Great Britain and Northern Ireland, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background:

Social stories are a widely used intervention for people with a diagnosis of Autism Spectrum Disorder (ASD). Practitioners perceive them to be highly effective but meta analyses of the research literature reveals mixed findings. Crucial influences upon the effectiveness of social stories is argued to be in the consistency of their development and delivery as well as the behaviours targeted for intervention. The majority of existing research literature has focussed on evaluating effectiveness relating to either increasing or decreasing a specific behaviour. However, in practice the most common use of social stories by parents and practitioners is for supporting children with novel events and transitions.

Objectives:

The Digital social stories iPad app has been developed through participatory design and was evaluated for its impact upon supporting children with ASD in preparation for a novel event.

Methods:

Participants were 10 autistic children (8 male; 2 female), aged 7-11. All children were due to attend a 4-day school summer camp and their teacher had identified a specific area/event that was anticipated to cause a high level of concern/anxiety and problematic behaviours (e.g. being away from their family, eating different food). A unique social story was written for each child within the digital social stories app and presented on the iPad. The researcher read the social story with the child every day during the week before the camp. The child's teacher rated their level of anxiety, understanding and closeness to their individual target goal (identified in the social story) on an 11 point scale (0-10) before and after the social story intervention. A rating of problem severity during camp was also obtained.

Results:

Results revealed a significant increase in the child's perceived level of understanding ($t = 2.34$, $p = 0.044$), a move towards achieving the child's individual goal ($t = 4.15$, $p = 0.002$), and a decrease in perceived anxiety levels ($t = 4.49$, $p = 0.002$) when comparing the pre- and post- intervention teacher ratings. Problem severity during camp was also significantly correlated with getting closer to the goal (difference between pre- and post measure) $r = 0.66$, $p = 0.038$. Changes in anxiety ($r = .57$, $p = 0.089$) and understanding ($r = 0.50$, $p = 0.14$) were not significantly correlated with problem severity but did indicate a trend in the right direction.

Conclusions:

Empirical support was found for using Digital social stories to help children prepare for a novel, potentially challenging event by decreasing anxiety, increasing understanding and facilitating a move towards the child's individual target goal. Much research on social stories to date has been single case study design and this study represents a relatively large sample size, as well as focussing upon supporting upcoming events that may be challenging, rather than a specific challenging behaviour (which is typically the focus within the research literature).

The Digital social stories iPad app will be present, and participants can interact with the system to develop Social Stories. Funding for the project was provided by The Leverhulme Trust.

89

143.089 Evidence-Based and Scalable Parent Training for ASD

D. Grodberg[1]*, R. A. Oien*[2] *and K. Larsen*[3]*, (1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)The Arctic University of Norway, Tromso, NORWAY, (3)Oslo university hospital, Oslo, Norway*

Background: To address the need for increased access to care and lower-cost treatments for children with ASD, researchers have investigated the effectiveness of solely parent-delivered treatment with positive results (Hardan et al., 2014; Minjarez et al., 2011; Coolican et al., 2010). Moreover, a recent RCT indicates that teaching parents ABA principles via video coaching is effective, and treatment acceptability is equivalent between the telemedicine and clinic-based groups (Lindgren et al. 2016). MindNest Health is a digital health tool that trains parents to implement ABA skills and strategies as well as positive behavioral approaches. A self-guided curriculum comprising animated parent-child simulations trains parents in ABA strategies and skills. A behavioral coach helps parents identify target goals for their child and supports parents as they navigate the program from training to implementation. Coaches refer to a higher level of care when clinically indicated. Pilots of the MindNest Health digital tool are beginning in the US, Norway, and China.

Objectives: This project aims to use the Behavior Intervention Rating Scale (BIRS) to record users' acceptance of this technology solution in the context of user testing performed by a user testing company. Users will mark a likert scale indicating whether they Strongly disagree (1), Disagree (2), Slightly Disagree (3), Slightly agree (4), or Agree (5) with questions that measure perceived acceptability and effectiveness of the intervention.

Methods: The BIRS was filled out by 6 parents after participating in user testing.

Results: Responses on the BIRS filled out by users in the context of user testing by an independent user testing company predominantly reflected high scores.

Conclusions: MindNest Health's digital platform holds promise to improve access to evidence-based and scalable interventions for children with ASD. A live demo will be presented during the poster session.

90

143.090 Remote Mentoring Model for Autism Assessments in the India

S. Nagesh*, Latika Roy Foundation, Dehradun, India*

Background: Reductions in under five mortality rates has shifted global program and policy focus to lives that thrive and live with or without disability in most parts of the world. In the Indian Himalayas, identification and assessment of developmental disabilities in young children poses a huge challenge, and intervention therefore remains a far dream. With no developmental pediatricians in Uttarakhand, the Himalayan state of India, the program uses expertise from a qualified early development expert based in a high income country to train, support and supervise a team of local professionals in the field of Autism, for assessment and intervention.

Objectives: The model provides expert supervision and support in the local language and maximizes use of limited resources of time, money and personnel. The model depends on a strong mentorship capacity, committed time by professionals to assess, record, share and seek guidance, and deep relationship building which in turn strengthens the support between the family and the team

Methods: The program began with on site training on the use of new tools for autism diagnosis (ADOS and ADIR). The module initiated with training to build the knowledge base and was followed by multiple hands-on sessions on the use of assessment tools with families whose children were suspected to have autism. Multiple sessions with close supportive supervision were followed by the local professional teams conducted the assessments independently. The assessments reports were emailed to the consultant and video recordings were uploaded on the Internet using strict privacy settings. The local team received immediate feedback and timely support with diagnoses and intervention plans for the child and the family. Technical assistance also involved access to web resources, and training for parent groups. The consultant and the local team meet face to face twice a year to develop further insights, review complex cases, facilitate parent meetings, and training in advanced modules.

Results: In six months, the team assessed, diagnosed and provided intervention support to fifty children with autism. The model did not need funding and provided on-site training support using new assessment tools and distance support to validate assessments and diagnoses thereafter to a team of local professionals for children with autism. Children and families receive the benefit of best practice interventions and specialist inputs that would otherwise not be available for them. While we understand the pivotal role technology plays in this program, we cannot undermine the value of on-site visits and face-to-face meetings.

Conclusions: Though the technology is not complex, for local professionals to learn and use the video camera, email, whatsapp and youtube are innovations in their own right. This model can be adapted and applied to settings where there is a need for training and support. The distance-mentoring model can supplement the more traditional model of site based service delivery and support. The foundation is aiming to scale the model for children with cerebral palsy and Down syndrome.

91 **143.091** Let Us Converse Virtually! Conversation Skills Training through Virtual Reality

Y. Politis[1]*, L. Goodman*[1]*, M. Leahy*[2] *and C. Sung*[3]*, (1)University College Dublin, Dublin, Ireland, (2)Michigan State University, East Lansing, MI, (3)Department of Counseling, Educational Psychology and Special Education, Michigan State University, East Lansing, MI*

Background: People with ASD typically have difficulties with communication and socialization skills, and they may exhibit repetitive behaviours or have restricted interests (Fombonne, 2005; Levy & Perry, 2011; Rivet & Matson, 2011; Suzuki 2011). Such difficulties have been shown to be linked to the development of problem behaviours, and thus people with ASD do struggle to keep or find employment, become part of the community, and they overall report low quality of life ratings (National Research Council 2001). Assistive technology's role for people with ASD is to primarily improve their quality of life and help them in their transition from education and training to independent living. The Virtual Reality (VR) technology first appeared in the 1960s, but was neither a commercial success nor was it very engaging. VR has re-emerged in recent years as a more affordable, user friendly platform, that has reached a point where it can imitate the real world (Freina & Ott, 2015). Moreover, VR can assist in making conversations easy, structured and inclusive (Newbutt, 2013).

Objectives: To examine the effectiveness of a training intervention on conversation skills for people with ASD, through a Virtual World (VW) environment (using a laptop which is a non-immersive delivery method).

Methods: The paper will initially describe the VW development phases, where a Participatory Design approach was adopted. This will be followed by a description of the intervention process. The participants initially interact with the researcher physically (Phase 1) and then virtually (Phase 2) to determine whether virtual reality on itself has a positive impact. Phase 3 involves instruction (PowerPoint presentations, videos, and quizzes) in the virtual environment followed by the same interaction to determine whether instruction in virtual reality is beneficial. Phase 4 will be a repeat of Phase 1 to determine whether the participants bring any skill acquisition from the virtual to the real world. The intervention is a Multiple Baseline Design (MBD) with 3 participants and consists of at most 17 sessions over a 7 to 9-week period.

Results: The user feedback on the VW development has revealed ways we can change the VW to make it more appealing, acceptable, and user-friendly to the participants. The users offered several suggestions regarding: the content of instructional material (e.g., conclude each PowerPoint presentation with a quiz), organization of content (e.g., better organise video playlist) and visual presentation of content (e.g., enlarge video screens and increase text font). The paper will also present the analysis of the ongoing MBD, based on an adapted assessment tool from the Conversation Skills Rating Scale. A comparison of the results between phase 1 and 4 will determine the effectiveness of the training, if the baseline is stable.

Conclusions: The user feedback received to date suggests that VR has a significant role to play in training for people with ASD and that immersive VR (head mounted displays) could possibly be even more effective. Overall the feedback was constructive and will result in a better product for a follow-up study in 2018.

92 **143.092** Social Visual Attention Training Using Virtual Humans and Eye-Tracking

O. Grynszpan[1]*, J. Nadel*[2] *and J. C. Martin*[3]*, (1)LIMSI CNRS UPR3251, Université Paris-Sud, Orsay, France, (2)French National Centre of Scientific Research (CRNS), Paris, France, (3)LIMSI, Orsay University, Orsay, France*

Background: Visual attention is essential to grasp the transient emotional information expressed by faces during human social interactions. During the last two decades, a sizeable amount of literature on eye-tracking has reported diminished visual attention to faces in individuals with Autism Spectrum Disorder (ASD) when they attend to social scenes. Addressing such deficits with educational approaches raises complex issues as there are no systematic rules as to when faces should be looked at during a social interaction.

Objectives: Our goal is to test a novel method for training visual attention to relevant emotional signals expressed by faces based on the use of virtual humans and eye-tracking technology.

Methods: Twenty one adolescents with ASD (3 girls and 18 boys) participated in the study. They were randomized to an experimental group and a control group that were matched for verbal and non-verbal abilities. Participants in the control group were allotted to a computerized educational program in geometry. The experimental group were trained with a system that enabled users to control a graphic interface with their eyes via an eye-tracker. Participants were placed in front of a screen that displayed a virtual human that addressed them. The graphic display was entirely blurred except for a rectangular viewing window that followed the gaze of the participant. One of the utterances of the virtual character could be interpreted in two distinct ways according to the context. The context was provided by the character's facial expressions that enabled disambiguating this key sentence and therefore understanding the whole message. Participants then had to answer close-choice questions that assessed their understanding of the virtual human's message. To answer correctly, participants had to look at the relevant emotional features of the face at the right time while they were attending to what the virtual human was saying.

Results: Social and communicative abilities were assessed before training, after training and after a two months follow-up period. The evaluation was based on a battery of social tests that were not used for training. There was a significant improvement on the test which was the most proximal to the training task. It involved understanding a written dialog between characters whose faces could be displayed on demand.

Participants in the experimental group scored higher then control participants on this test after training [*F*(2,38) = 4.76 *p* = 0.035].

Conclusions: The efficacy of the novel social training method that we designed was supported by the results of this pilot randomized controlled study. The presentation will involve a live demo of the system, that is, the audience will be able to use the software, see the virtual humans and control the viewing window with their eyes via the eye-tracker.

Acknowledgments: This work was supported by a grant from the Orange Foundation (project #71/2012)

93 **143.093** Discovr - Virtual Reality Social Cognition Training for Adults with Autism

B. van Pelt[1,2] *and K. Greaves-Lord*[1]*, (1)Erasmus MC, Rotterdam, Netherlands, (2)Yulius, Dordrecht, Netherlands*

Background:

Deficits in social cognition are amongst the most challenging aspects of autism spectrum disorder (ASD), making it a core symptom, impairing individuals throughout their lives. Building relationships or finding a job does not come naturally, when the intention and comprehension of basic rules and subtle cues of social interaction are poorly understood. This, leading to social exclusion and deteriorating quality of life. Social skills training is usually initiated for handling problems in the emotional- & social perception and poor metalizing skills (Theory of mind). Interventions based on Cognitive Behavioural Therapy (CBT), have proven their efficacy. However, it is crucial for the effectiveness of the training to achieve transfer of knowledge and skills, to situations in everyday life and novel environments. In conventional training, pictures, text, comics, movies or role-playing is used. Although these can be a good method for didactic purposes (providing knowledge/insights), it is important for practicing social skills that this can happen in a setting that has the same dynamic, complex and interactive nature of true social situations. Advancements in technology make it possible to offer a more tailored social cognition training, incorporating the environment of the patient into their therapy. Virtual Reality(VR) is such an advancement. VR provides a safe, dynamic and interactive treatment setting, that could transcend the social cognition training as is available today. Research shows that Virtual Reality is a promising tool in strengthening social cognition in people with ASD (Kandalaft et al. 2013, Parsons et al., 2002 & 2006). VR offers an 'ecologically valid', immersive environment to experiment with (new) social behavior in a secure, controlled setting that provides direct feedback and learning experiences. Scenarios from the person's life can be trained with gradual intensity, making VR a sufficiently realistic way to transfer skills to the person's own environment.

Objectives:

In a pilot-study we explore a CBT based Virtual Reality intervention, to enhance social cognition of adults diagnosed with autism. Primary outcomes of this study are: (1)Feasibility, Tolerance and Acceptance of the intervention and (2) Improvement in Social Cognition.

Methods:

The intervention protocol is dived into modules (16 sessions over a 8 week period, 1 hour sessions), training the patient in Emotion recognition, Social perception/Theory of Mind and interactive social interaction. An Avatar mediated system enables the therapist to communicate directly with the patient in the Virtual world. Through voice alteration and avatar selection, the therapist can mimic social situations from the patient's life. A pre-post assessment design (with 8 week follow-up) enables us to assess the usability, tolerance and effectiveness of the intervention.

Results:

Starting April 2018, the treatment will be embedded into multiple mental health organisations in the Netherlands. A small usability study (n=2) will be presented to show qualitative data from our patient panel. We will present the VR apparatus along with a poster on the protocol and pilot study. Visitors are welcome to experience the VR-world.

Conclusions:

Based on previous research, VR intervention could be a valuable addition to the therapeutic instruments for improving social cognition/skills in ASD.

94 **143.094** The Use of Cultural Animation to Teach Students with Autism in Mixed-Classroom

N. Sari*, Erasmus Rotterdam University, Rotterdam, Netherlands*

Background: N/A

Objectives: This pilot project aimed to explore the feasibility of using animations to facilitate the learning of spoken English for students with autism in an inclusion school in Indonesia. The aim of the animation was to increase students' with autism attention during class activities.

Methods: Sample: The animation was used for 8 students with autism attending an inclusion school in Jember, Indonesia. Students with autism were spread across five classes: one in the second grade, 2 in the third grade, 3 in the fifth grade, and 2 in the sixth grade. Students with autism were between eight and twelve years of age, and diagnosed with ASD through comprehensive diagnostic evaluation.

The animation: The duration of the animation was five minutes and the theme was based on cultural diversities in Indonesia. The animation was developed by the researcher and presented seven characters, each representing one of the ethnicities from Indonesia. The targeted language expression was how to ask and give opinion in English. So, the use of "what do you think" and "I think..." were the main learning topic for the students with autism.

Use of the animation in the classroom: The teacher played the animation in the beginning of the class and paused at several parts. The goal of pausing was to highlight the language expression. After the students with autism watched the animation, the teacher applied roleplay models of non-autistic students and then asked the students with autism to speak the targeted English expression in front of the class. The teacher used concise, friendly and comprehensible instructions, and avoided verbal overload (Addabbo, 2004).

Students with autism and teachers were interviewed about their experience of the animations in the classroom. In addition, the use was documented by videos and photos.

Results: Students with autism were confident to use the animations and did the roleplay in front of the class. Moreover, students with autism paid attention enthusiastically during the class. The teachers mentioned that the animation was effectively inviting the students' with autism attention. In addition, students with autism were more enthusiastic about the next English class.

Conclusions: Preliminary findings indicated that animations could be used in inclusive classrooms to support teachers' knowledge and teaching skill in teaching language skills to students with autism.

95

143.095 “Doctor Tea” Helps Children with ASD Going to the Hospital without Fear

L. Boada[1] *and M. Parellada*[2], *(1)Hospital Universitario Gregorio Marañón. Child and Adolescent Psychiatry. IISGM. CIBERSAM, Madrid, Spain, (2)Fundación Investigación Biomedica Gregorio Marañon, Madrid, Spain*

Background:
People with autism spectrum disorder (ASD) have greater medical needs than the rest of the population (Gurney, McPheethers and Davis, 2006), and they also have particular characteristics that make it very difficult for them to access the medical services (need for anticipation, lack of flexibility, problems identifying and describing symptoms, hypersensitivity to certain stimuli, stress over waiting times, etc.). A specific program for medical specialty care of ASD subjects was started in 2009 at the Hospital Gregorio Marañón (Parellada, 2013). Subsequently, a web-based tool was developed to help decrease the anxiety and stress associated with medical visits and procedures in attendees to the clinical program.

Objectives: To evaluate the effectiveness of this web program for reducing patient stress and anxiety, improving the family's quality care perception, and reducing medical visit time.

Methods:

1. **"Doctor TEA" software is built on a Web platform** and is composed of a set of structured contents (in film format of a real hospital, in 2D, in 3D, with cartoons and pictograms) showing the physical spaces, medical professionals, techniques, and instruments used for a selected medical examination–magnetic resonance, electroencephalogram, orthopantomography, blood test and stomatology or ophthalmology visits-. (Please, see http://www.doctortea.org/entra/pruebas/**).** The website also includes interactive games showing different aspects of a medical visit.
2. **Evaluation:** Pilot study. Participants: 40 patients with autism spectrum disorder recruited through the ASD Comprehensive Medical Care Program at Gregorio Marañón University Hospital in Madrid (Parellada, 2013).
3. Procedure: 20 patients will use the "Doctor TEA" software for 2 weeks and 6 sessions of 15 minutes. The other 20 will not receive any intervention. Participants in these two groups will be matched for clinical diagnosis, mental retardation, age, and type of medical visit/test they will require. Following the experimental period, they will have their actual medical visit/test. Next, an evaluation will be performed in both groups using three specific questionnaires completed by families, patients (when possible), and a health professional. The main dependent variables will be: patient comfort perceived by the doctor/nurse, patient self-rated anxiety, next-of-kin rated anxiety).

Results: At the present time the software is complete and we are collecting data for its effectiveness evaluation.

Conclusions: Daily clinical practice suggests that anticipation and specific desensitization for medical procedures training, patient anxiety towards medical procedures is considerably reduced. The reasoning behind this program, which are freely available to the public, is to try to demonstrate that TICs can help people with autism to anticipate and understand medical visits and tests that any hospital or health centre may perform.

Interactive demonstration will be presented in the technical session.

Financial support: Orange Foundation has already developed several software tools which are publicly available to facilitate the integration of persons with ASD (www.fundacionorange.es).

96

143.096 Project Leapp(Learning to Eat App): Developing an Ipad-Based Video Modelling Intervention to Increase Food Variety in Children with Autism Spectrum Disorder.

C. Lee[1], *R. Perlin*[1], *C. Raffaele*[1], *J. Wiegelmann*[2], *M. Pena*[3], *A. Zarem*[1], *C. Ferreira*[1], *A. Hodge*[1], *A. Dupuis*[4], *E. Biddiss*[1] *and S. Smile*[1], *(1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Geneva Centre for Autism, Toronto, ON, Canada, (3)Holland Bloorview Bloorview Kids Rehabilitation Hospital, Bloorview Research Institute, Canada, Toronto, ON, Canada, (4)Biostatistics, University of Toronto, Dalla Lana School of Public Health, Toronto, ON, Canada*

Background: Feeding difficulties (FD) are identified in up to 89% of children with ASD[1]. FD can lead to challenges such as disruptive mealtime behaviors, strained parent-child interactions and adverse health effects for the child[2-3]. A multidisciplinary team approach is recommended to address FD in ASD. However, barriers include access and availability of feeding specialist team, cost, and time. Early intervention programs geared at preventing and/or addressing FD in ASD in preschoolers is lacking. Video modeling intervention (VMI) is a novel and promising approach where a child is expected to imitate the behaviours of interest after viewing a recording of it[4-6]. VMI has been successful in teaching play and communication skills to children with ASD, but to our knowledge has not been attempted as a strategy targeting feeding behaviours in ASD. We intend to create a novel VMI with an animated model to deliver an early intervention program to address FD in ASD.

Objectives: To develop and pilot an animated VMI, Learning to Eat Application (LEApp) that provides auditory and visual feedback along with positive reinforcement to increase food variety in children with ASD. We hypothesize that an animated VMI can be designed for use by preschoolers with ASD and their parents to be implemented in a naturalistic environment.

Methods: Our methodology combines the principles of participatory design[7] and interaction design [8] . Three focus groups (i) an inter-disciplinary panel (comprising of speech and language pathologist, occupational therapist, family leader, game programmer, illustrator, behavioural therapist and developmental paediatricians), ii) parents of children with ASD, and ii) community clinicians) were recruited to address the design and content of LEApp (n=13). A descriptive thematic analysis was applied to the focus group data [9]. Focus groups occurred in an iterative manner to inform the development of the LEApp prototype.

Results: A final LEApp prototype was created through analysis of focus group data. Themes that emerged reflected common areas of content and design: (1) feeding expectations; (2) feeding strategies; (3) application specific recommendations. Overarching themes relating to (1) challenges and (2) parent education aided the formulation of the information content of the application.

Conclusions: Project LEApp represents the first step in the creation and exploration of a novel tool that has the potential to impact an essential skill early in the lives of children with ASD. By involving children, their parents and multidisciplinary specialists throughout the process, LEApp has the potential not only to impact feeding outcomes, but can also be shared and utilized universally by families in any setting, thus filling a need in existing feeding intervention. LEApp also provides an educational platform for families to learn about strategies to address FD within their home setting and at their own pace.

Tech demo description: We would like to demonstrate LEApp's functionality by displaying the parent-child interface of the application. The application features an animated character, Nibbles, who takes the parent and child through three different video modeling sequences that highlight five stages of feeding (i.e., touch, smell, lick, taste, eat).

97 **143.097** Multi-Spring: Facilitating Social Interaction through a Customizable, Multimodal Learning Platform

K. T. Johnson[1]*, C. S. Ferguson*[2] *and R. W. Picard*[2]*, (1)MIT Media Lab, Cambridge, MA, (2)MIT, Cambridge, MA*

Background:

Practitioners have long explored using motivating, personalized reinforcement to achieve developmental goals for children with Autism Spectrum Disorder (ASD) (Koegel & Mentis, 1985; Vismara & Lyons, 2007). SPRING – Smart Platform for Research, Intervention, and Neurodevelopmental Growth – is a customizable, interactive research-and-play platform, built to systematically probe the effects of these reinforcement modalities on learning and physiological regulation (Johnson & Picard, 2017). SPRING has shown promise in facilitating increased engagement and skill development for children with autism and other neuro-differences, but it has lacked multi-user functionality and built-in means to prompt social skills, such as joint attention, turn taking, and cooperative play -- until now. Adding this functionality allows practitioners to customize the reinforcement and developmental challenge of each individual SPRING unit while simultaneously encouraging social engagement by linking the units over a virtual network.

Objectives:

Here, we present a Multi-SPRING system designed to
(1) Stimulate early social experiences, such as joint attention, turn taking, and cooperative play;
(2) Facilitate simultaneous play between individuals with different skill levels, such as typical and autistic peers or siblings, while providing personalized reinforcement tuned to each individual's motivating interests;
(3) Reduce anxiety associated with unaided social interactions and extend engagement in a multi-person activity;
(4) Passively capture time-synchronized, quantitative measures of users' affective states via wearable physiological sensors and data of users' play progressions via SPRING.

Methods:

Each SPRING unit has a removable, modular center that can be adapted to the needs of an individual child by inserting different physical modules. An integrated smartphone and embedded LEDs allow user-selected customization of motivating reinforcement, such as favorite video clips, images, music, or colorful light displays. The smartphone also enables scaffolded difficulty levels within a single module so each child can be met with the "just right" challenge. Embedded digital sensors capture and store time-stamped data of a child's interaction with SPRING. Paired with wearable physiological sensors, these data allow multimodal analysis of a child's affective state and learning progression.

The new Multi-SPRING system links multiple SPRING units in real-time through a virtual private room, much like a chat room. This method enables social multi-player interactions, such as turn taking and cooperative play, while continuously capturing activity data logs from every child for future study.

Results:

Early results with Multi-SPRING suggest that the system can elicit both cooperative and competitive play and can increase time spent in a multi-person play environment. Our INSAR demonstration will showcase data and analysis from several Multi-SPRING trials, including videos with synchronized physiological and performance data. It will also include opportunities to interact with the system and provide feedback for further development.

Conclusions:

We have created a new customizable, multi-user research-and-play platform designed to facilitate social skill development for children with ASD. Through the highly motivating, individualized play environment, children can progress at their own pace while practicing social skills. Early results suggest that SPRING's novel multi-player environment elicits social interaction in a way that can engage learners with very different interests.

98 **143.098** A Multimedia Screening System to Predict Later ASD Symptoms in Diverse Community Settings: A Machine-Learning Design for Infants and Toddlers

F. Shic[1]*, K. Chawarska*[2]*, E. S. Kim*[3]*, C. A. Wall*[4]*, M. Wilkinson*[2]*, E. Barney*[1]*, J. C. Snider*[5]*, Q. Wang*[2]*, Q. A. Yang*[5]*, M. Kim*[5]*, B. Li*[6]*, M. Mademtzi*[2]*, C. Foster*[7]*, D. Macris*[2]*, F. E. Kane-Grade*[8]*, A. Milgramm*[9]*, P. Heymann*[2]*, E. Hilton*[2]*, A. Zakin*[2]*, H. Neiderman*[2]*, K. Villarreal*[2]*, K. K. Powell*[2]*, S. Fontenelle*[2]*, M. Lyons*[2]*, A. Giguere Carney*[2]*, K. Bailey*[2]*, Y. A. Ahn*[10]*, M. C. Aubertine*[11] *and S. Macari*[2]*, (1)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (4)Department of Psychology, University of South Carolina, Columbia, SC, (5)Seattle Children's Research Institute, Seattle, WA, (6)Computer Science and Engineering, University of Washington, Seattle, WA, (7)Binghamton University, Binghamton, NY, (8)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (9)Center for Autism and Related Disabilities, Albany, NY, (10)University of Miami, Miami, FL, (11)Seattle Children's Hospital and Research Institute, Seattle, WA*

Background:

There is a need to create more efficient, accessible autism screening systems so as to reach more diverse populations, decrease parent burden, and provide a roadmap for incorporating advances in digital and machine learning technologies to facilitate state-of-the art prediction of developmental outcomes. The Yale Adaptive Multimedia Screeners (YAMS-One and YAMS-Toddler) were designed to meet these needs.

Objectives:

To describe the development of the YAMS-One system, designed to predict autism symptoms at 18 months from questions asked to parents when their child is 12-months-old, and the YAMS-Toddler, designed to predict concurrent levels of autism symptoms via questions asked when children are 18- to 24-months of age. Results described are based on machine-learning results acquired from n=386 infants and toddlers.

Methods:

Phenotypic data from participants seen at a research clinic fed machine learning algorithms. Participants were [YAMS-One] high-risk infant siblings of children with ASD seen at 12- and 18-months of age (n=76), and [YAMS-Toddler] toddlers seen between 15- and 27-months of age (n=310: ASD, n=102). Machine learning algorithms were tuned to predict ADOS Module 1 scores from questionnaire and assessment items at either 12-months [YAMS-One] or their ADOS-concurrent visit [YAMS-Toddler]. From over 400 items in both versions, spanning autism-specific, developmental, and temperament/regulatory-focused instruments, manual data cleaning and participant culling was followed by: (1) variable imputation (kNN, n=5, median); (2) variable selection (elastic net); (3) machine learning fitting. 100 repeats of 10-fold cross validation were used to estimate prediction accuracies.

Results:

[YAMS-Toddler] Naïve approaches using linear regression and no variable selection were inadequate for predicting ADOS totals (r=.02). Support vector regression was a benchmark for machine learning (r=.641), but required all items. Tree-based CART provided adaptive item parsimony, but suffered from generalization problems (r=.440). Random-forests, like SVM, showed good performance (r=.603) but also required all items. A hybrid sparse-forest variant of CART was developed to create sets of 5 trees that together showed robustness comparable to random forest (r=.548). Results were similar for [YAMS-One], r=.511.

Discussion:

Items unsuited for video-based translation were rejected and training restarted. Final items were examined for redundancy and collapsed into composites via forum review by clinicians and developmental scientists. Items were translated into scripts enacted by mothers and their children (reflecting diverse demographics) for developing professionally-filmed content. Video clips were incorporated into a tablet-based system alongside digital consent, demographic surveys, and implementations of text-based [YAMS-One] CSBS-ITC (Wetherby & Prizant, 2002) or [YAMS-Toddler] M-CHAT-R/F (Robins et al., 2014) for validation. Clinical review screens were developed so health providers could act on validated CSBS/M-CHAT results. Handshaking with backend servers facilitated data monitoring. YAMS was recently piloted in diverse pediatric and research clinics, and showed promising results (e.g. YAMS-Toddler & ADOS scores: *r*(46)>.60, *p*<.001).

Conclusions:

This study reflects the development of a multimedia screener reflecting the multidisciplinary expertise of clinical, developmental, and computer science. The resultant screening system was based on machine learning results adapted for parsimony in delivery and reflected necessary tradeoffs based on clinical and practical needs. Results of the deployment of the YAMS-systems are ongoing.

99 **143.099** Tracking Toddlers' Head Movement with Facial Landmarks during the Viewing of a Social Scene

Q. Wang[1], *A. Milgramm*[2], *S. Macari*[1] *and K. Chawarska*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Autism and Related Disabilities, Albany, NY*

Background: Infants at high risk for developing autism spectrum disorder (ASD) exhibit atypical head movements as early as 1-2 months after birth (Denisova & Zhao, 2017). However, it is challenging to track or quantify head movement with subjective observation. With improvement of computer vision technologies, automated tracking of head movement in toddlers can be a helpful quantification tool for this behavior.
Objectives: (1)To apply 3D head movement tracking with facial landmarks in behavioral videos; (2)To compare spontaneous head movement in toddlers with and without ASD engaged in a free-viewing eye-tracking task involving social scenes; and (3)To examine the extent to which head movement is correlated with social affect (ADOS-SA) and restricted and repetitive behaviors (ADOS-RRB). We hypothesized that ASD toddlers would exhibit increased head movement, and that this would be related to RRB symptoms.

Methods: Openface implementation (Amos et al., 2014) with dlib was applied for face detection and facial landmark extraction from video frames with classic Histogram of Oriented Gradients (HOG) feature combined with a linear classifier (Kazemi & Sullivan, 2014). The positional and rotational position and their changes through time were identified by head pose estimation in dlib (Kazemi & Sullivan, 2014). Participants included 26 toddlers (ASD, n=13, M_{age}=41.70±3.03; typically developing (TD), n=13; M_{age}=37.87±2.69) who completed a 3-minute head- and eye-tracking task consisting of an actress engaged in dyadic bids for engagement. Linear mixed model (LMM) analyses were used to examine fixed effects of actress' speech (present/not present), actress' gaze direction (mutual/averted), clinical diagnosis (ASD/TD), and their interactions on the maximum amplitude of toddlers' head positions (pxyz) and rotation angles (rx,ry,rz; see Figure 1).

Results: LMM analyses of pxyz revealed a main effect of speech (*F*(1,799)=9.08, *p*=0.003); less head movement was observed when speech was present. There was no main effect of gaze direction, clinical diagnosis, or their interactions, and no correlation with ADOS-SA or RRB (*p*'s>.1). Analyses of rx, ry, and rz also revealed a main effect of speech (*p*'s<.05) with less rotation at speech presence, but no effect of gaze direction (*p*'s>.1). While ry analysis revealed a main effect of diagnosis (*F*(1,24)=5.01, *p*=0.035; ASD>TD), rx revealed no effect (*F*(1,24)=2.44, *p*=0.13; ASD=TD) and rz revealed a marginal effect (*F*(1,24)=3.70, *p*=0.066; ASD>TD). In toddlers with ASD, rx correlated with ADOS-SA (*r*(13)=0.73, *p*=0.005); rz marginally correlated with SA (*r*(13)=0.54, *p*=0.055); ry did not correlate with SA (*p*>.1). None of the rotational angles correlated significantly with ADOS-RRB (*r*'s=.113-.266; *p*'s>.1).

Conclusions: Both groups displayed less head movement in the presence of speech, suggesting that speech may elicit greater attentional engagement with the stimuli and associated suppression of extraneous motor activity. Gaze direction, however, had no effect on toddlers' head positions or rotation angles. ASD toddlers displayed more rotational head movement then TD controls in both y and z directions. Further, rotational head movement was related to social affect, but unrelated to repetitive behavior. This finding suggests that during a dyadic condition, head rotations may be a result of diminished interest in or uncomfortableness with social situations rather than unsuppressed motor behavior.

100 **143.100** Integrating Deep Learning with Behavior Imaging to Accelerate Industry's 'Learning' of Autism Core Deficits

R. Oberleitner[1], *J. Schwartz*[2], *C. J. Smith*[3], *M. Morrier*[4], *U. Reischl*[5], *J. Fodor*[6], *B. Martin*[6] *and C. E. Rice*[7], *(1)Behavior Imaging Solutions, Boise, ID,* *(2)Behavior Imaging, Boise, ID, (3)Southwest Autism Research & Resource Center, Phoenix, AZ, (4)Psychiatry and Behavioral Sciences, Emory University School of Medicine, Decatur, GA, (5)Boise State University, Boise, ID, (6)University of Idaho, Moscow, ID, (7)Emory Autism Center, Decatur, GA*

Background: During the past several decades, the worldwide prevalence of children diagnosed with autism spectrum disorder (ASD) has increased dramatically. Since ASD does not have clear biomarkers and is a behaviorally defined disorder, a key element in the diagnostic process is direct observation of behavior and expert diagnosticians. This approach can lead to significant variability in results . However, new approaches using Artificial Intelligence (AI) are being developed that have the potential to improve the diagnostic accuracy of this process.
Objectives: 1. How Deep Learning Method Can Be Deployed to 'Learn' from 1 to 1000 Clinicians' Assessments of Patient Video Data 2. How Clinicians Evaluating Children via Archived Video can document Atypical Behaviors related to Autism

Methods: A Deep Learning (DL) computational method called a ‘DL Classifier’ is being introduced to help clinicians analyze video information collected by a telehealth assessment called NODATM (Naturalistic Observation Diagnostic Assessment). NODA results in a diagnostic category (ASD v. non ASD) based on clinician-annotated videos performed by expert diagnosticians. Clinicians identify both atypical and typical behaviors in children at specific moments on video samples parents collect and share from their home. Given a large enough dataset, the DL Classifier delineates the behavioral information into recognized patterns that can be automatically ‘flagged’ on video data as typical or atypical - for review by an expert diagnostician. The more clinicians train the DL Classifier, the better it gets in recognizing atypical and typical behaviors. A DL Classifier was developed to compute patterns in 244 videos captured and previously shared by families as part of the NODA diagnostic assessment process; these videos cumulatively had 6,243 atypical / typical tags previously applied at select time points by clinicians. The Classifier was applied in several iterative computational methods to analyze 1. still images within NODA video, then 2. short video segments associated with associated tags applied by clinicians.

Results: All ‘Deep Learning’ tags suggested by the Classifier were compared to tags used to generate the classifier. Classifier resulted in 80% accuracy based on analysis of still images, and 86% accuracy based on analysis of video segments.

Conclusions: A more commercial-grade 'DL Classifier' is being integrated into the existing Behavior Imaging / NODA platform, and we’re predicting accuracy will improve with more Classifier development, and more training of the NODA 'data set' by clinicians. When further validated, the proposed NODA DL classifier represents a significant advancement in the diagnosis and care of children with ASD, especially by building an industry-wide consensus on autism symptoms, and specifically -- through a reduction of time that will be required to obtain an accurate diagnosis.

101 **143.101** Scalable Gaze Analysis for ASD Is in Your Pocket

Z. Chang[1], *J. Hashemi*[1], *K. L. Carpenter*[2], *G. Dawson*[3] *and G. Sapiro*[1], *(1)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (2)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (3)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background:
Eye tracking technology is widely used in Autism research as studies show that infants and toddlers with Autism Spectrum Disorder (ASD) have a tendency to focus on non-social features (i.e., toys, objects). Conventional autism research studies are carried out in controlled clinical settings with expensive commercial eye/gaze trackers that require explicit user calibration. This setup is not scalable, introduces environmental bias, and is challenging for participants. New computer vision techniques can estimate the eye gaze of a person using a single photo taken from a cellphone camera without any explicit calibration, opening up new screening methods that are feasible beyond the clinical settings.

Objectives:

To incorporate eye tracking into mobile devices for large-scale, remote data collection and screening and monitoring of ASD children in a naturalistic environment.

Methods:

We developed an iPhone and desktop application that displays a stimulus consisting of dots appearing sequentially on the screen. The user is asked to tap each dot as it appears, during which an image of the user’s face is recorded using the front facing camera of the iPhone (or desktop camera). The user’s face and eye regions are automatically detected using computer vision algorithms and used as input to train a neural network for gaze estimation. The output of the network is the corresponding region in which the dot falls within.

Results:

We tested our eye tracking algorithm on 9 naïve subjects (7 male, 2 female) of varying ethnicity and age. When holding the iPhone in landscape, on average we achieved 93% accuracy discriminating whether the user was looking at the left or right half of the screen without explicit calibration. We also achieve over 80% accuracy discriminating between 3 regions in landscape and 2 regions in portrait.

Conclusions:

We incorporated eye tracking technology into a mobile (or desktop) application for remote, large scale data collection of ASD children. We demonstrate that we are able to achieve sufficiently high accuracy in estimating the user’s focus of attention on the phone screen without the need for explicit calibration. The proposed region based gaze analysis approach is sufficient for ASD and other behavioral analysis techniques, with properly defined stimuli, e.g., social half vs, non-social half. Application of calibration-free eye tracking on mobile devices could lead to scalable new behavioral imaging methods for detecting subtle neurologic processes relating to attention, and may be useful for early Autism screening and monitoring.

102 **143.102** A New Ipad Game for Ecological Motor Assessment of Children: Bespoke Wearable and Smart Tablet Engineering for Autism-Friendly Assessment.

A. Mitchell[1], *A. Maggio*[2], *L. Millar*[3], *D. Campolo*[4], *P. Rowe*[5] *and J. Delafield-Butt*[6], *(1)Humanities & Social Sciences and Biomedical Engineering, University of Strathclyde, Glasgow, United Kingdom of Great Britain and Northern Ireland, (2)Humanities & Social Sciences and Biomedical Engineering, University of Strathclyde, Glasgow, United Kingdom, (3)Faculty of Engineering, University of Strathclyde, Glasgow, United Kingdom, (4)Robotics Research Centre, School of Mechanical & Aerospace Engineering, Nanyang Technological University, Singapore, Singapore,* *(5)Department of Biomedical Engineering, University of Strathclyde, Glasgow, United Kingdom, (6)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom*

Background:

Increasing evidence suggests motor control disruption in individuals with autism spectrum disorder (ASD) may be a cardinal symptom. Thus, recording sub-second kinematics may lead to the identification and objective quantification of motor characteristics specific to autism, potentially allowing a novel instrument to aid early screening and diagnosis. Kinematic analysis has traditionally involved expensive and laborious optical motion tracking systems. With the recent advent of wearable inertial movement units sensors (IMUs), new possibilities are afforded for accessible serious game platforms for the measurement of goal-directed hand movements to a target, with many repetitions for high-grade statistical analysis.

Objectives:

This study: To engineer a serious game paradigm for fun, fast, and ecologically valid computational kinematic assessment of possible autism-specific goal-directed arm motor patterns in children.

Methods:

Equipment. An integrated platform of (i) a bespoke engineered wearable IMU with tri-axial accelerometer and gyroscope, (ii) smart tablet device (iPad mini), and (iii) a bespoke engineered forceplate (fPad).

Wearable sensor was engineered with an Arduino component protected within a 3D-printed acrylic container strapped to the child's wrist (60g). The fPad contained 4 strain gauges on metal legs bolted to the underside of an acrylic plate allowing measurement of applied forces during gameplay. The iPad was situated upon the fPad and pre-loaded with a browser-based game. The iPad and fPad were encased within a handcrafted balsa wood case with sanded edged, painted matt-black for maximum screen contrast.

Data were sampled at 80Hz, sent to an on-site server over Wi-Fi and synchronised.

The game, Bubble-Pop, encouraged regular arcing motions to hit targets in corners of the screen. Targets were bubbles 2.7 cm in diameter, with centres distanced at 11.2cm horizontally or 7.2cm vertically from each other. Level 1 has 4 bubbles, one in each corner, requiring 40 pops with choice of popping order. Level 2 has 2 bubbles, in the top corners, requiring 30 pops with 1 target at a time. Levels are played 3 times to generate 210 windows of movement over 7 minutes.

Results:

Motor kinematic profiles generated from the wearable, iPad, and fPad include: hand acceleration and jerk, duration, impact force to target acceleration, target accuracy and precision, target contact duration, touch gesture variables, and variability of these features. Motor profiles are compared within and between groups for improved characterisation of children's motor pattern.

Conclusions:

Sub-second motor kinematic data is achievable using a wearable, iPad, and fPad serious game solution. Children enjoy the game and repeat goal-directed movements many times per trial (>210 movements in ca. 7 mins) providing high-quality data for robust statistical analyses of motor kinematics. In sum, we have designed a new, fun bespoke technological tool to facilitate motor assessment of children with or without ASD. It may ultimately lead to improved diagnosis of ASD in early childhood with cheaper, simpler, faster and more accessible assessment of movements in children than currently available. In future work we will employ this technology to identify motor patterns unique to ASD in a large cohort (n>100) of children 2-5 years old.

103 **143.103** Towards an Automated Analysis of Social-Communication Behaviors in Autism Spectrum Disorder

Z. Tősér[1], *Z. Arnold*[2], *M. Csakvari*[3], *A. Lorincz*[3], *E. V. Ocampo*[2], *M. Pollack*[2], *A. Wainer*[2] *and L. Soorya*[2], *(1)Argus Cognitive, Inc., Lebanon, NH, (2)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (3)Department of Software Technology & Methdology, Eotvos Lorand University, Budapest, Hungary*

Background: Clinical assessment of autism spectrum disorder (ASD) involves sophisticated and psychometrically sound assessment of characteristic behaviors such as emotional expressions, reciprocity, and atypical mannerisms. Available gold standard assessments require highly trained evaluators and an expert clinical eye – constraining crucial early detection and intervention needs in communities. Additionally, available tools have limited utility in research settings seeking objective assessments of subtle behaviors for mechanistic and treatment research. Objectives: This collaborative project integrates artificial intelligence (AI) methods and clinical expertise to advance methods for detecting and monitoring social-communication behaviors associated with for ASD and related neuropsychiatric conditions.

Methods: Forty-seven individuals were enrolled in the pilot feasibility study to refine protocols and procedures for quantitative assessment of social-communication behaviors with approximately half (n=23) completing initial analysis and quality control checks. Participants included typically developing children (n=13), individuals with rare genetic disorders associated with ASD (n=7), and children with idiopathic ASD (n=28). System components included sensors such as off-the-shelf cameras and microphones, secure data analytic protocols to transfer data from clinics to "core lab", and analytic software to turn sensor data into clinically relevant behavior codes. Data below are reported from images collected during administration of the Autism Diagnostic Observation Schedule-2 (ADOS-2, Lord, Rutter, DiLavore, Risi, Gotham, & Bishop, 2012). Evaluators wore Tobii Glass 2 in clinical assessment rooms equipped with 2-D and 3-D cameras. No additional modifications were made to the clinical environment or ADOS-2 protocol. Data was also collected during multi-modal clinical research protocols utilizing semi-structured behavioral assessments such as the Unstructured Imitation Assessment (UIA, McDuffie, et al, 2007), clinical assessments such as the Clinical Global Impressions Scale (CGI), and caregiver reports such as the Social Responsiveness Scale-2(SRS-2, Constantino, 2012).

Results: Analytic software measured several behavioral features of ASD including gaze contact, gaze distribution, responsive gaze, facial expressions of emotion, vocalizations, speech content, speech quality, and integration of vocalization and body language. Data from subset of verbally fluent, children with ASD (n=8) were compared to clinical scores from the ADOS2 Module 3 for initial clinical validation. Spearman's rho was used to provide an estimate of the strength of the relationship between biometric data and qualitative clinical scores. These preliminary analyses suggest moderate to strong correlations between ADOS-2 summary codes (e.g. amount of reciprocal social communication) with patient behaviors (e.g. average duration patient looks at clinician), clinician behaviors (e.g. clinician initiates eye contact) as well as interactions (e.g. average duration of eye contact between patient and clinician). Analysis and system training is underway for the full scope of social-communication behaviors described above, as well as validation with clinical assessments and caregiver reports of social-communication behaviors.

Conclusions: An understanding of hallmark social-communication features of ASD has been crucial to advancing clinical care and research. Automated, objective assessments are exciting and promising developments but require standardization and clinical validation. Research applications may see more near-term benefits from use of digital biomarkers to elucidate relationships between observable behaviors and molecular & neurobiological variables; as well as measure target engagement & outcomes from clinical trials.

104 **143.104** Automated Detection of Stereotypical Motor Movements in Children with Autism Spectrum Disorder Using Geometric Feature Fusion

*C. Tralie[1], **M. S. Goodwin**[2] and G. Sapiro[3], (1)Duke University, Durham, NC, (2)Northeastern University, Boston, MA, (3)Department of Electrical and Computer Engineering, Duke University, Durham, NC*

Background:

One of the two main diagnostic criteria for autism spectrum disorder (ASD) in the DSM-5 is restricted, repetitive patterns of behavior, interests, and/or activities, and one of the ways these behaviors manifest in ASD is stereotypical motor movements (SMM). Traditional measures of SMM primarily include rating scales, direct behavioral observation, and video-based methods, all of which can be subjective, inaccurate, time-intensive, and difficult to compare across different individuals with ASD. More reliably, accurately, and efficiently detecting and monitoring SMM over time could provide important insights for understanding and intervening upon a core symptom of ASD.

Objectives:

Leverage a novel set of features based on sliding windows and topological data analysis to computationally detect the onset and type of SMM using accelerometer data from children with ASD. Also demonstrate that novel features we developed enable a more parsimonious representation of periodic SMM when combined with previous methods that, collectively, boost automated classification performance reported in the published literature.

Methods:

We used publicly available data from [Goodwin etal. 2014] to study automated classification of SMM in a subset of 6 subjects, with each session spanning approximately 20 minutes. Each subject had a 3-axis accelerometer on his/her left wrist, right wrist, and torso to measure stereotypical hand flapping and body-rocking. Each accelerometer time series was accompanied by annotated ground truth labels provided by human coders indicating time-stamped onset and offset for the following three operationally defined SMM: flap, rock, and flap+rock. We segmented all of the accelerometer data into 2-second windows that overlapped by 130 milliseconds. For each window, we extracted both recurrence quantification analysis (RQA) features (as in [Großekathöfer et al. 2017], 9 dimensions per accelerometer, 27 dimensions total) and applied novel topology-based "persistence" features that measure "roundness" of a sliding window reconstruction of the joint embedding of the 3-axis accelerometers using persistent homology (novel feature, 1 number per accelerometer, 3 dimensions total). After subsampling the windows corresponding to periods when no SMM was observed to balance the data, we analyzed the ability of our features to classify SMM into the three target classes by running simple cross-validation experiments.

Results:

After combining all labeled sessions, we tested using 10-fold cross validation with a decision tree using only RQA features, only persistence features, and both combined. For the task of identifying the class of a SMM in a 2-second window or the absence therein, RQA features produced 85.9% classification accuracy, and persistence features (which use an order of magnitude fewer dimensions) yielded a similar classification accuracy of 84.8%. Moreover, when these methods were combined, they together yielded automated classification performance of 90.6% accuracy, demonstrating that in addition to their parsimony, the newly developed feature enables increasingly more accurate automated detection of SMM.

Conclusions:

Based on recent theory on periodicity analysis using geometry, this study demonstrates the feasibility and validity of achieving excellent performance for automatically detecting and classifying SMM computationally in a low dimensional space with only 3 degrees of freedom.

105 **143.105** The Canadian National Autism Neuroinformatics Platform Phase I: Development and Validation of a Universal Library of Instruments

***L. A-Abbas**[1], R. Bruno[2], C. Rogers[3], T. Savion-Lemieux[2], A. Yusuf[4], F. Duhamel[5], J. Frei[2], S. Bentata[5], P. Kostopoulos[3], S. Das[3], A. C. Evans[6], M. Elsabbagh[7] and I. Peltekova[8], (1)Research Institute - McGill University Health Centre, Montreal, QC, Canada, (2)Research Institute-McGill University Health Centre, Montreal, QC, Canada, (3)McGill Centre for Integrative Neuroscience, Montreal Neurological Institute, McGill University, Montreal, QC, Canada, (4)Psychiatry, McGill University, Montreal, QC, Canada, (5)McGill University Health Center, Montreal, QC, Canada, (6)Montreal Neurological Institute, McGill University, Montreal, QC, Canada, (7)McGill University, Montreal, PQ, Canada, (8)McGill University, Montreal, QC, CANADA*

Background:New approaches in neurodevelopmental research increasingly seek to integrate enormous amounts of data through sophisticated informatics so as to determine the relationship between genotypes and phenotypes,both structural and functional,as they change over time during development. Such approaches dwarf the resources of most laboratories, who are increasingly moving toward "cloud computing" solutions.Canada has several large scale projects and cohort studies that currently utilize independent and uncoordinated neuroinformatics solutions. A newly established National Autism Neuroinformatics Platform addresses this informatics problem by connecting existing infrastructure of large scale Canadian studies in autism and deploying high impact solutions already successful in other areas of research,e.g.,CBRAIN and LORIS.Key platform building blocks currently under development include a Testothèque (instrument library),family registry,project-specific data capture platforms,and a Federated/curated gene-brain-behavior data repository.

Objectives: In Phase 1 of this platform development, we focused on integration, documentation, and increasing accessibility of commonly used behavioral and clinical research measures.Hundreds of assessment tools are used in autism studies,overlapping with those used in clinical services.Despite the apparent simplicity and low cost of electronic data capture, few instruments are customized and accessible for large registries and multi-sites clinical studies.This led to the development of a new Testothèque:A library of electronic data capture instruments to support large scale projects at various stages.

Methods:A number of steps were taken to ensure the validity and accessibility of the Testothèque:(1)We integrated all behavioral and clinical research measures currently in use across multiple large scale national autism studies into a common database;(2)we established guidelines for the development and validation of electronic data capture instruments using an iterative process involving technical, clinical, and data experts;(3)we applied the guidelines in the development and validation of bilingual English and French data capture instruments customized for various platforms including RedCap and LORIS;(4)we are currently building a user-friendly interface to increase the accessibility and utility of the Testothèque to the research community.

Results:We completed databasing of over 50 behavioral and clinical research measures into the Testothèque.Informed by users of multidisciplinary backgrounds,fields were designed and populated to facilitate search,selection,and comparison of various measures,e.g.,constructs measured,age range,versions,copyrights.We also designed data capture instruments corresponding to each measure.Bilingual versions were developed, and automated scoring was implemented where possible.Using a new Development and Validation Checklist,each instrument was iteratively validated by two experts (content and technical) and 2-3 reviewers (target users).Validation criteria include:completeness/accuracy of library fields,instrument content and data validity(including captured and scored data),target user experience (e.g.parent,research assistant),and compatibility/inter-operability with existing large-scale project databases.

Conclusions:Our first phase has highlighted key challenges for future integration of behavioral data with other data modalities, including neuroimaging and genetics.Conventional platforms used in autism research do not allow for such integration.Further, implementation of a truly open platform, e.g.,creating an open Testothèque, is currently limited by copyrights and pre-existing agreements restricting data access.However, implementation of the National Autism Neuroinformatics Platform has already led to substantial gains in time efficiency, reduction/elimination of data entry errors,improved progress tracking/reporting,ease of data export, and increased overall transparency in complex study protocols.Some challenges were also identified and will be addressed in subsequent phases.

106 **143.106** Using Baby Facereader to Investigate Facial Expressiveness in at-Risk Populations

***A. Maroulis**, VicarVision, Amsterdam, Netherlands*

Background: Autism spectrum disorders (ASDs) are characterized in varying degrees by difficulties in social interaction, verbal & nonverbal communication (NVC) and repetitive behaviors. Looking at the face as a medium of NVC, researchers have often limited their research scope in studying smiles or laughter at high-risk (HR) populations. While smiling is a facial action with strong relevance to ASD, a detailed investigation into intensity, variability and lability of facial expressions is highly relevant but often avoided due to the cumbersome nature of detailed behavior coding such as the Baby Facial Action Coding System. Automatic facial expression coding solutions in the field of computer vision are a promising approach to overcoming this difficulty. To date, however, such solutions measure facial expression in adults and do not generalize well to infant populations. This demonstration presents Baby FaceReader, a novel solution that automatically measures infant facial expressions. Furthermore, the demonstration shows how Baby FaceReader can be used to investigate facial expressiveness in HR populations.
Objectives: To demonstrate that Baby FaceReader is a valid tool to measure facial expression behavior in terms of action units (AUs) in infants. To use Baby FaceReader to evaluate intensity, variability and lability of facial expression behavior in HR populations.

Methods: To evaluate Baby FaceReader's validity we collected all images from the Baby FACS manual that have been comprehensively coded for Action Units. After removing duplicates, the dataset consisted of 74 images. We ran Baby FaceReader on the dataset to extract AU classifications and computed F1 scores for each AU. F1 scores are a standard evaluation metric of predictions in pattern recognition and are computed using the formula in figure 1.

To evaluate intensity, variability and lability of facial expression behavior in HR we ran Baby FaceReader on a dataset of videos of two-year infants (20 HR, 5 control) during the social stimuli presentation of an eye-tracking paradigm. To compute (a) intensity, we took the average intensity of all expressed AUs during the social stimuli presentation; (b) variability, we counted the number of different facial configurations produced during the social stimuli; (c) lability, the number of times the infant's facial configuration changed during the social stimuli.

Results: Based on previous results, we expect to reach an average F1 score of at least 0.7 across all AUs in our evaluation of Baby FaceReader. We have not yet evaluated intensity, variability and lability in our video dataset.

Conclusions: Automatic coding is a promising advance in studying infant facial expression as it allows more time and depth for analysis. Baby FaceReader is one such complete solution that could be used in the study of ASD during development.

107 **143.107** Screening Tool for Autism Risk Using Technology – START: Developing a Tablet-Based Platform to Detect Autism Risk in Low-Resource Settings

***B. Chakrabarti**[1], I. Dubey[1], M. Belmonte[2], T. Gliga[3], G. Estrin[3], R. Bishain[4], J. Dasgupta[5], D. Mukherjee[5], S. Bhavnani[5], M. H. Johnson[6], S. Chandran[4], V. Patel[7], S. Gulati[8] and G. Divan[9], (1)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)Com DEALL Trust, Bangalore, India, (3)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (4)Computer Science and Engineering, Indian Institute of Technology, Bombay, India, (5)Centre for Chronic Conditions and Injuries, Public Health Foundation of India, Gurgaon, India, (6)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (7)Department of Global Health and Population, Harvard Medical School, Boston, MA, (8)Child Neurology Division Department of Pediatrics, All India Institute of Medical Sciences, Delhi, India, (9)Sangath, Bardez, Goa, India*

Background: Early diagnosis is key to early intervention and thereby to best outcomes in Autism Spectrum Conditions (ASC). In low-resource settings such as India, lack of access to early detection poses a significant barrier. Latest WHO data on India show that the ratio of specialists (psychiatrists) to patients can be as low as 0.30 per 100,000 people. In rural areas, furthermore, psychiatric expertise is non-existent. To fill the gap between the need for early identification and limited availability of expertise, it is important to develop alternative methods and tools that can be used by a low-skilled workforce, are inexpensive, and are portable so that they can be taken to the field without requiring any additional infrastructure.
Objectives: The "Screening Tool for Autism Risk using Technology" (START) project is developing an open-source, scalable autism screening tool in the form of an app that can be run on a tablet computer with minimal training.

Methods: This project is an interdisciplinary collaboration between neuroscientists, mental health professionals, public health researchers, computer vision scientists, app designers and app developers. Eight institutes/organisations (University of Reading, Birkbeck University of London, Nottingham Trent University, Indian Institute of Technology, All India Institute of Medical Sciences, Public Health Foundation of India, Sangath, and Therapy Box Ltd) from three countries (India, UK, and USA) participate in this consortium, funded by the UK Medical Research Council Global Challenge Research Fund. The project is divided into three work streams. The first stream is responsible for putting together a battery of behavioural tasks suitable for children between ages 2-5 years, to capture social, cognitive, and sensory-motor aspects of development relevant for autism. The second work stream is responsible for building a scalable pipeline to carry out data quality checks, data transfer to a central server, and maintenance of the research database. The third work stream will undertake field testing of the tool in India, collecting data from children with and without autism for validation.

Results: The app includes parent-report questionnaires and behavioural tasks to measure social preference, motor function, and sensory interest. A key innovation is tablet-camera based eye tracking, allowing capture of very low-resolution gaze direction data for coarse measures such as preferential looking and attentional disengagement, without the need for an external eye-tracker. Motor function tests are built in light of the emerging data from similar tablet-based tasks on the iOS platform (Anzulewicz, Sobota, & Delafield-Butt, 2016; Belmonte et al., 2016). The app also includes a task measure of social motivation previously associated with a group difference in children with autism (Ruta et al., 2017). Finally, the app includes a free-play section that provides an opportunity to video-record parent-child play interaction for subsequent analysis.

Conclusions: The working prototype establishes feasibility of a portable platform that can capture multiple task and interview measures, including eye-tracking and assays of motor function. The platform integrates mobile health technology for task-sharing application in low-resource settings by non-specialist community health workers, and offers the potential for scaling up as part of regular community health assessments.

108 **143.108** An Embodied Computational Model to Explore Environmental-Neural Interactions in Disorders of E/I Balance.

P. J. Hellyer[1], *F. E. Turkheimer*[2], *E. J. Jones*[3] *and R. Leech*[4], *(1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, UK, London, England, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, UK, London, United Kingdom, (3)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (4)Imperial College London, London, United Kingdom*

Background: Computational simulations of spontaneous neural dynamics have revealed the importance of local homeostatic excitation/inhibition (E/I) balance mechanisms for the maintenance of flexible neural dynamics in the healthy brain. Further, imbalances in E/I regulation have recently emerged as a leading candidate causal path to autism and common comorbidities like epilepsy. E/I balance is particularly vital during early development, where massive changes to both the structure and function of the brain occur over a relatively short time-period. Maintaining regulation during this period is challenging, and changes in homeostatic set point through alteration of E/I balance may enable waves of new learning. However, current experimental approaches lack a mechanistic understanding of how E/I balance may affect behaviour and brain development. Thus dynamic modelling approaches must be used.

Objectives: Here, we demonstrate a tool for exploring the effect of E/I based homeostatic mechanisms on specific modes of behaviour using an 'embodied' computational model; and consider putative applications of this for the emergence of autism-related traits during development.

Methods: Our approach begins by defining a virtual 'agent' that can move within a 2-dimensional plane, bounded by surrounding walls (Figure 1). ‘Neural’ Dynamics in the model are provided using a range of structurally based computational models, tuned to the specific hypothesis (e.g. [1] (Figure 1A/B). Movement of the agent in the virtual environment is determined by activity within two pre-defined “motor” nodes in the model. Direct manipulation of a group of experimenter-defined task-positive nodes simultaneously enables both “visual” and “somatosensory” inputs to the model - providing an 'open loop' interaction between the dynamics of the 'brain' of the agent and its subsequent manipulation of the environment (Figure 2).

Results: Using this framework we demonstrate the potential of a range of simple manipulations of this model to enable exploration of local and large-scale E/I homeostatic mechanisms during learning and development - particularly those described in [2]. Such an approach raises the possibility of rapidly testing and manipulating hypotheses drawn from rich computational accounts of neural stability dependent on E/I balance. Our demonstration highlights the use of this tool to illustrate that local homeostatic balancing of E/I at the local level enables the emergence of exploratory behavioural dynamics (Figure 3). Moreover, we show that such mechanisms, manipulated during critical points of development lead to long-term alteration in the rich computational dynamics in the brain.

Conclusions: We demonstrate here a role for homeostatic plasticity in local E/I circuits in the emergence of stable exploratory behaviour (trajectories through the environment). Our initial work highlights the possible use of such a tool to explore GABAergic and Glutamatergic models of Autism - providing an in-silico model from which to explore novel treatment approaches. Our longer-term goal is to test predictions from this model within developmental datasets, such as prospective longitudinal cohorts of infants at risk for autism.

109 **143.109** Is Acttrust a New Device to Measure Sleep Problems in Autism?

P. Ballester-Navarro[1], *E. Martínez-Saíto*[2], *E. Fernández Jover*[3], *A. Palazón*[4] *and A. Peiró*[5], *(1)Hospital General Universitario de Aucante, Alicante, Spain, (2)Department of Clinical Pharmacology, Organic Chemistry and Pediatrics, in the University Miguel Hernández, Madrid, Spain, (3)Bioengineer Institute, Elche, Spain, (4)Paediatrics Service, Alicante, Spain, (5)Clinical Pharmacology, Alicante, Spain*

Background: Sleep problems in adults on the autism spectrum are poorly studied in adulthood, where insomnia is the most prevalent. Establishing quantitative criteria with an adequate equipment to analyse, is important for translational research.

Objectives: The aim of the study is to compare ActTrust, Condor instruments device with Ambulatory Circadian Monitoring (ACM) a method already validated.

Methods**:** Adults diagnosed with autism by DSM-5, wore two devices (ActTrust and ACM, 1 week) to study sleep parameters (Sleep onset latency (SOL), Time in bed (TIB), total sleep time (TST), num. of awakenings, wakes after sleep onset (WASO) and sleep efficiency (SE)). Insomnia was defined by any of those conditions SOL>30min, TST<7-9h, WASO>30m, SE<85%. Fisher exact test was used to compare the results. Also, receiver operator characteristic (ROC) curves were generated for all sleep variables to examine sensitivity and specicity of the sleep measures.

Results: Fifty-two adults on the spectrum (age 31 (11) years old, 77% males) completed the study. No significant differences were found for insomnia cases, when compared by Fischer exact test (p =.091). ROC curves for the ACM were greater than for ActTrust (except for TIB and TST), which could mean a better control-case discrimination .

Conclusions: Insomnia prevalence was well estimated by any of the two devices. ROC curves in ACM estimate better insomnia except for TIB and TST. Further studies should be performed to complete ActTrust validation to define SP in autism.

110 **143.110** Multi-Modal Data Platform for Autism Research

ABSTRACT WITHDRAWN

Background:

The growing quantity and diversity of data collections in autism research has created a demand for neuroinformatics platforms harmonizing multi-modal cohorts across large-scale distributed collaborations. Providing researchers with integrated analysis tools to leverage these combined data assets in a robust, sustainable and transparent manner is pivotal to the future of neurodevelopmental research. Data sharing initiatives such as the NIMH Data Archive (NDA) and research networks critically rely on secure online platforms to manage distributed datasets spanning diverse modalities of brain, behavior and genotypic data.

The 'MNI Ecosystem' (Das 2016, fig.1) consisting of LORIS (Das 2012), CBRAIN (Sherif 2014) and BrainBrowser (Sherif 2015) provides an open-source neuroinformatics environment designed to address these challenges, hosting large-scale projects such as the NIH MRI study of Pediatric Development (NIHPD), the IBIS autism network, and developing initiatives such as the Canadian National Autism Neuroinformatics Platform.

Objectives:

LORIS, CBRAIN and BrainBrowser are open-source software packages developed at the Montreal Neurological Institute (MNI), designed to integrate data capture, analysis and visualization within a unified context. This 'MNI Ecosystem' combines demographic, neuroimaging, clinical/behavioral, biobanking and summary genetic data via web-accessible databasing and a user-friendly online suite of data management tools. Transparency, flexibility and interoperability with other data systems are core principles of this neuroinformatic ecosystem.

Methods:

LORIS is a web-based data capture and management system designed for seamless interoperability with other clinical/behavioral, imaging and genomic data platforms. Modality-specific tools native to LORIS include secure online surveys, data uploaders, mobile-friendly data input and quality control workflows. Customizable instruments are programmed with complex scoring and multi-language support. BrainBrowser, a web-based visualization tool embedded within LORIS, provides an interactive 3D viewer for neuroimaging scans. Data capture systems for MRI, EEG and modalities such as eye-tracking can load data directly into LORIS, and summary genomic and biobanking data are integrated via extensible modules.

Integrated querying tools enable users to design, curate and save custom datasets, exporting them to processing suites and platforms such as CBRAIN, a high-performance computing portal. Once a dataset is exported to CBRAIN, software pipelines analyze and return post-processed results to be stored in the LORIS database.

Results:

In autism and neurodevelopmental research, LORIS serves as the core infrastructure for large-scale longitudinal projects such as the IBIS autism research network and the NIHPD database. These initiatives have contributed significantly to the interoperability and core data standard development of the NIMH Data Archive (NDA).

In the context of autism and related disorders, the Canadian National Autism Neuroinformatics Platform is deploying a combined gene-brain-behavior data platform in LORIS and CBRAIN. This initiative plans to leverage existing data collections with new multi-modal cohorts, to amplify the translational impact of these data assets across the Canadian research community.

Conclusions:

Combined in a single platform, LORIS, CBRAIN and BrainBrowser provide a robust neuroinformatics infrastructure for acquisition, validation and analysis of data collected from many domains. Customizable for large-scale multi-modal ASD cohorts, the MNI ecosystem platform enables powerful and transparent leveraging of resources and tools for cross-disciplinary computational approaches in autism and neurodevelopmental research.

111 **143.111** Automated Artifact Detection for EEG Data Using a Convolutional Neural Network

***T. McAllister**, A. Naples and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Electroencephalography (EEG) is a valuable tool for studying Autism Spectrum Disorder (ASD). It provides a rich, temporally precise measure of brain activity that is inexpensive and appropriate for individuals of all ages and levels of cognitive ability. However, EEG is easily contaminated by artefactual signal generated by movement and muscle activity. It is necessary to identify and exclude artefactual data, and there is little consensus on methodology for its automated detection. Consequently, EEG, particularly in developmental and clinical populations, is still checked for artifact by hand, a time intensive and error-prone process. In other domains, such as high-level image recognition, convolutional neural networks (CNN) have been effective in automating complicated classification tasks and show promise for automatically classifying EEG artifact.

Objectives: We (1) develop a CNN to classify contaminated EEG collected from infants at normal and high risk for ASD; (2) assess its performance against human experts; and (3) assess its performance in classification between normal and high-risk infants to explore potential differences in artifact across groups.

Methods: Data collected in 118 EEG sessions of infants at normal (NR) or high-risk (HR) of developing ASD were split into event-related epochs and manually coded by a human expert as artefactual or normal. Epochs were converted into two dimensional arrays of amplitude by time across EEG channels, yielding 5834 artefactual and 5388 clean examples. These were split into a training set (N=8800) and validation set (N=2422) for a six-layer CNN built with the python library Tensorflow. Data were processed in two CNNs: the first downsampled (DS) data into 256 discrete values, the second rescaled (RS) data to range from (-100,100) μV.

Results: The CNNs were tested using the validation set of novel epochs. Clean epochs incorrectly labeled artefactual were considered false positive epochs (FPE) while overlooked artifacts were considered false negative epochs (FNE). Both the DS-CNN and RS-CNN classified EEG with approximately 80% accuracy. The DS-CNN had 14% FPE and 6% FNE. The RS-CNN had 4.6% FPE 16% FNE. However, performance was differential in the CNN network. When the DS-CNN was tested with only HR epochs, it was correct 80.6% of the time, and had 17% FPE. With only NR epochs, the DS-CNN was correct 76% of the time, and had 15% FPE. When the RS-CNN was tested with only HR epochs, it was correct 78.5% of the time, and had 4% FPE. When the RS-CNN was tested with only NR epochs, it was correct 80.5% of the time, and had 6% FPE.

Conclusions: Our results show that CNNs can accurately classify EEG artifact at rates approaching human expert performance in a fraction of the time and warrant further development. With different pre-processing or more specifically tailored networks, CNNs could be a valuable method of EEG artifact detection. Ongoing analyses of classification performance between groups will allow us to detect differential patterns of artifact by risk status allowing for advances in automated classification while generating insights into patterns of activity that differentiate groups based on risk status.

112 **143.112** Kinect Motion Capture of Toddlers with Autism during ADOS Assessments

I. Budman[1]*, I. Menashe*[2]*, G. Meiri*[3] *and I. Dinstein*[4,5,6]*, (1)Department of Biomedical Engineering, Ben Gurion University, Beer Sheva, Israel, (2)Public Health Department, Ben-Gurion University, Beer Sheva, Israel, (3)Soroka Medical Center, Beer Sheba, Israel, (4)Negev Autism Center, Ben Gurion University of the Negev, Beer Sheba, Israel, (5)Department of Cognitive and Brain Sciences, Ben Gurion University of the Negev, Beer Sheba, Israel, (6)Department of Psychology, Ben Gurion University of the Negev, Beer Sheba, Israel*

Background:
Motion tracking is a very promising technology for quantifying repetitive movements and motor problems in autism. In addition, motion tracking of multiple interacting individuals (e.g., clinician and child) could yield informative measures regarding social capabilities and preferences. Such measures may aid not only in the initial clinical evaluation of toddlers with autism, but also as longitudinal measures that might change with age and in response to interventions. Most motion capture systems require placement of markers/sensors on the body of participants, which preclude their use with toddlers who have severe symptoms and sensory hyper-sensitivities. The Microsoft Kinect system, however, enables marker-free motion tracking that would be possible with all children. This system is being implemented as part of the data collection for the regional autism database initiative at the Negev Autism Center in Israel (www.negevautism.org).

Objectives:
To develop an automated motion tracking tool that will quantify repetitive movements, motor problems, and measures of social interaction during a 45 minute ADOS assessment involving a clinician and toddler. In addition, to identify motion tracking measures that are correlated with autism severity and can aid with the clinical diagnosis of autism and longitudinal follow-ups.

Methods:
We have developed an automated marker-less motion-capture system consisting of 4 Kinect sensors arranged in a rectangular arrangement, in the corners of the ADOS assessment room. Recordings of the clinician and the toddler are performed at 30fps for a length of at least 45 minutes. The sensors are calibrated and synched using ipiSoft, which also fits the depth-data from the sensors to a human skeletal model. Initial analyses were carried out with skeletal data of the torso and head only, separately for the clinician and the child. This enabled assessment of distance between clinician and child as well as the deviation angle between the direction that the clinician was facing and that of the child.

Results:
To date, we have successfully analyzed data from 8 children, which have revealed excellent quality and reliability throughout the 45 minute recordings. We extracted the distance and deviation angle for each frame in the recording and examined the relationship between the mean of each measure and symptom severity as estimated by the ADOS. Analysis of additional recordings that are currently carried out at a rate of 6 new children per week will enable us to perform statistical tests regarding these relationships.

Conclusions:
Marker-less motion tracking using the Kinect system are likely to yield important informative measures regarding the severity of autism in individual children. Further development of this tool will also enable quantification of repetitive behaviors and motor problems in the same children.

113 **143.113** Early Detection of Autism Using a Mobile Application: Asdetect

J. Barbaro[1]*, N. Sadka*[1]*, W. Nadachowski*[2]*, M. Burnside*[3]*, L. Burnside*[4]*, C. Dissanayake*[1]*, M. Leahy*[4] *and M. Denham*[4]*, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Autism Cooperative Research Centre, Melbourne, Victoria, Australia, (3)Salesforce.com, Melbourne, Victoria, Australia, (4)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Victoria, Australia*

Background: Early detection of autism is critical as it provides access to early intervention, improving children's developmental outcomes and quality of life, and decreasing family stress. Over the past 10 years, two large-scale community-based studies for the early detection of autism have been conducted within the Victorian Maternal and Child Health (MCH) system in Australia, using Social Attention and Communication Surveillance; SACS; Barbaro & Dissanayake, 2010; 2013). Monitoring over 30,000 children, the SACS is the most accurate and sensitive early detection method for autism currently available, with 81% positive predictive value (PPV), and estimated sensitivity and specificity of 83.8% and 99.8%. To make this research accessible to the world's population, including Lower Middle Income Countries (LMICs), an app based on the SACS was developed called ASDetect.

ASDetect (asdetect.org) is a free mobile application for the early detection of autism (11-30 months) that incorporates a modified version of the SACS. Short videos demonstrate key social-communication behaviours followed by a question, with automatic calculation of a child's 'likelihood' for autism (high/low).

Objectives: To determine the psychometric properties of ASDetect in sensitively and accurately identifying children with autism, and to evaluate its acceptability amongst parent users and professionals.

Methods: Parents of children aged between 11-30 months are invited to participate via their MCH nurse, or via social media/word of mouth. Parents register their child's details on a webpage, download ASDetect, and complete an assessment. All children at 'high likelihood' for autism, and a small percentage of children at 'low likelihood' for autism, are invited for a free diagnostic assessment by the ASDetect team. Children are assessed at intake and every 6 months until 24-months, with the ADOS-Toddler, Mullen Scales of Early Learning, and ADI-R administered.

Results: To date, 175 parents have registered, with 127 completing an assessment. 26 children (20.5%) were identified at 'high likelihood' for autism, with 12 of the 13 children assessed thus far meeting criteria for autism; the remaining child had a developmental/language delay. Updated results to May 2018 will be presented at the conference.

Conclusions: These preliminary data show very promising results for ASDetect's positive predictive value (PPV; accuracy) in identifying children with autism. However, more data are needed to determine its overall psychometric properties, and acceptability by parents and professionals, which will continue to be collected until 2019, with all children followed up to 30-months-of-age.

114 **143.114** Automatic Computer Vision Analysis of Emotional and Behavioral Responses of Children with Autism

J. Hashemi[1]*, K. L. Carpenter*[2]*, K. Campbell*[3]*, S. Espinosa*[1]*, Q. Qiu*[4]*, S. Marsan*[5]*, E. Adler*[4]*, H. L. Egger*[6]*, G. Dawson*[7] *and G. Sapiro*[1]*, (1)Department of Electrical and Computer Engineering, Duke University, Durham, NC, (2)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (3)Duke Center for Autism and Brain Development, Durham, NC, (4)Duke University, Durham, NC, (5)Psychology and Neuroscience, Duke University, Durham, NC, (6)Department of Child and Adolescent Psychiaty, New York University Langone Health, New York, NY, (7)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background: The gold standard for Autism Spectrum Disorder (ASD) screening involves parental report of child behaviors followed by observational assessment by a trained clinician. With emerging methods in computer vision and machine learning and wide spread access of mobile devices, new low-cost, scalable, and objective screening methods of child behavior are feasible. These include designing and displaying specific video stimuli on the screen while simultaneously coding behaviors while he/she is watching.

Objectives: To develop and deploy multiple video stimuli, designed to elicit behaviors relevant to ASD screening, on a mobile device and validate them with computer vision methods that automatically code affective and attentive child responses.

Methods: Multiple short video stimuli (<1 minute) designed to elicit specific social and emotional responses were displayed on an iPad, while at the same time the front facing camera recorded the child's face at 1080p resolution and 30 frames per second. Computer vision algorithms to assess head position, head turns, and affect were developed. In addition, human raters trained on Facial Action Coding System for Infants and Young Children coded multiple videos for ground truth affect and head turn labeling. A subset of the responses coded by the human raters and computer vision methods were analyzed for agreement. All responses coded by the computer vision methods were analyzed to determine whether stimuli differentially elicit child behavior.

Results: 104 toddlers (22 with and 82 without ASD) ages 16-31 months participated in the study with informed consent and IRB oversight. All of the participants' facial and head behaviors were coded with the automatic computer vision methods while a subset of them (15 ASD and 18 non-ASD) were also coded by human raters. Out of the 97 videos that were coded by human raters for affect, the automatic methods agreed with the raters on 82% of the frames. Out of the 87 head turns that were coded by human raters, the automatic method correctly identified 81% of the head turns. Compared with toddlers without ASD, toddlers with ASD displayed reduced positive emotions throughout many of the stimuli. From the automatic coding, toddlers with ASD also displayed longer latency between the time when their name was called and when they social referenced by turning their heads.

Conclusions: We developed and deployed multiple video stimuli on a mobile device to elicit ASD-specific behavioral responses. From the video data and our computer vision methods, we were able to automatically code affective and attentive responses. We validated our automatic methods with trained human raters, and demonstrate the effectiveness of our video stimuli to differentially elicit child behaviors. Applications such as the one presented could lead to new or refined behavioral risk marker assessments.

Technology demonstration: We will have a demo where the audience can watch a video stimuli on a mobile device while the front facing camera records their face. After the video, we will present facial statistics (affect, head movement) that were automatically computed with our methods.

Poster Session
144 - Early Development (< 48 months)
11:30 AM - 1:30 PM - Hall Grote Zaal

1 **144.001** A Comparison of High-Risk Siblings with Multiplex and Simplex Familial Risk Status: A Baby Siblings Research Consortium Study

N. M. McDonald[1]*, L. Carver*[2]*, T. Charman*[3]*, K. Chawarska*[4]*, S. Curtin*[5]*, I. Hertz-Picciotto*[6]*, E. J. Jones*[7]*, A. Klin*[8]*, R. Landa*[9]*, D. S. Messinger*[10]*, S. Ozonoff*[11]*, W. L. Stone*[12]*, H. Tager-Flusberg*[13]*, S. J. Webb*[14]*, G. S. Young*[11]*, L. Zwaigenbaum*[15] *and S. Jeste*[16]*, (1)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (2)University of California San Diego, La Jolla, CA, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Child Study Center, Yale University School of Medicine, New Haven, CT, (5)University of Calgary, Calgary, AB, Canada, (6)University of California at Davis, Davis, CA, (7)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (8)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (9)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (10)University of Miami, Coral Gables, FL, (11)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (12)Psychology, University of Washington, Seattle, WA, (13)Psychological and Brain Sciences, Boston University, Boston, MA, (14)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (15)University of Alberta, Edmonton, AB, Canada, (16)University of California, Los Angeles, Los Angeles, CA*

Background: Converging evidence suggests that there are multiple genetic pathways to autism spectrum disorder (ASD). One high-risk group that has been studied widely includes infants with older siblings with ASD, with risk modulated by the number of affected individuals in a family (multiple affected: multiplex, one affected: simplex). Investigation of multiplex siblings offers a unique opportunity to determine the quality of differences in early development associated with heightened genetic load for ASD in children with and without ASD outcomes. This study contrasts developmental profiles associated with different levels of familial risk in a large, multi-site sample of children from the Baby Siblings

Research Consortium (BSRC) database.
Objectives: To compare children with multiplex and simplex familial risk for ASD on: (1) rates of ASD, atypical, and typical outcomes at 36 months; (2) developmental abilities, adaptive skills, and ASD symptoms within no ASD and ASD outcome groups.

Methods: Participants included 885 (simplex: 806, multiplex: 79) children with familial risk who were enrolled in longitudinal studies across 10 BSRC sites. Simplex children had one older sibling with ASD and multiplex children had two or more older siblings with ASD. *Developmental abilities* were measured with the Mullen Scales of Early Learning (MSEL), *adaptive skills* with the Vineland Adaptive Behavior Scales-2nd Edition (VABS-II), and *ASD symptoms* with the Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview-Revised (ADI-R). Children were placed into one of three groups at 36 months: Typical (MSEL ^{3}85, ADOS <3), Atypical (MSEL <85, ADOS severity ^{3}3), ASD (Clinical Best Estimate & ADOS ^{3}4).

Results: See Table 1 for detailed results and statistical analyses. (1) Multiplex children were less likely than simplex children to be classified as Typical and more likely to be classified as ASD or Atypical. (2a) In the no ASD group, multiplex-no ASD children had lower MSEL scores than simplex-no ASD children; the Receptive Language subscale most strongly differentiated the groups. ADOS, ADI-R, and VABS-II scores did not differ. (2b) In the ASD group, there were no differences in ADOS scores, but multiplex-ASD children had higher ADI-R Communication scores than simplex-ASD children. Multiplex-ASD children tended to have lower MSEL and VABS-II scores than simplex children, particularly on the VABS-II motor scale, although these did not reach significance.

Conclusions: Results are consistent with previous reports of a twofold increase in ASD risk for multiplex siblings. In contrast with a study of school-age children with ASD (Cuccaro et al., 2003), we found evidence that multiplex children with and without ASD were somewhat more affected than simplex children. Within the no ASD group, these deficits were primarily characterized by lower developmental abilities. Findings may reflect an increased incidence of inherited risk variants in multiplex children that, while increasing the likelihood of atypical outcomes, may also be less specific to ASD. Further analyses will include longitudinal modeling of developmental trajectories in the first years of life to identify the earliest markers of atypical development in multiplex siblings. Results support the need for direct examination of genetic contributions to neurodevelopmental phenotypes of infant siblings.

2 **144.002** A Longitudinal Analysis of Early Social Anxiety Risk Factors in Siblings of Children with Autism Spectrum Disorder

A. L. Hogan[1]*, N. Poupore*[1] *and J. E. Roberts*[2]*, (1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Psychology, University of South Carolina, Columbia, SC*

Background: Siblings (ASIBs) of children with autism spectrum disorder (ASD) are at elevated risk for a variety of suboptimal developmental outcomes, including anxiety disorders. Childhood anxiety can have detrimental long-term effects that carry into adulthood and impact quality of life. However, early intervention for anxiety has been shown to ameliorate these long-term impacts. In neurotypical (NT) infants and toddlers, several early risk markers for social anxiety have been identified. These include high and stable expression of behavioral inhibition, a temperament profile characterized by excessive fear in response to novelty, and reduced physiological reactivity, as indexed by blunted respiratory sinus arrhythmia (RSA) responses. Identifying early risk markers of social anxiety in ASIBs can provide important insight into the emergence and trajectories of prodromal anxiety features in this high-risk population.
Objectives: To examine the developmental trajectory of early social anxiety risk markers in non-ASD ASIBs and low-risk controls (LRCs) in the first two years of life.

Methods: Participants included 32 later-born siblings of children with ASD who were not diagnosed themselves with ASD at >=24 months (non-ASD ASIBs) utilizing standard clinical best estimate procedures including the ADOS-2. Low-risk controls (n=42) with no personal or family history of ASD or related disorders were included. Participants were assessed at several timepoints from 7 to 28 months of age, for a total of 214 observations (ASIB: n = 90; LRC: n = 124) Behavioral inhibition was measured via the Fear subscales from the IBQ-R (< 18 months) and ECBQ (>=18 months) (Gartstein & Rothbart, 2003; Putnam, Gartstein, & Rothbart, 2006). Physiological reactivity was measured through heart activity recorded during a baseline period and the Stranger Approach paradigm (Goldsmith & Rothbart, 1996), which is designed to elicit behavioral inhibition in response to a novel adult. Reactivity was defined as Baseline RSA – Stranger RSA.

Results: Multi-level growth models were employed, with age, group, and age by group interaction entered as predictors. For parent-rated behavioral inhibition, significant main effects of age (b = -0.03, p < .01) and group (b = 0.39, p < .05) were revealed, with a non-significant interaction effect (b = -0.03, p = .11) (Figure 1). For physiological reactivity, the age by group interaction was significant, (b = -0.07, p < .05) (Figure 2), indicating that physiological regulation in ASIBs becomes more blunted with age.

Conclusions: Results suggest that non-ASD ASIBs exhibit elevated behavioral inhibition throughout the first two years of life, though by the age of 2, they are approaching normative levels. Conversely, physiological reactivity in response to a novel stranger becomes more atypical as non-ASD ASIBs age. These patterns of behavioral inhibition and blunted physiological reactivity are early risk markers for social anxiety in neurotypical infants. Thus, it appears that even ASIBs without ASD themselves are showing atypical social responsivity and may be at elevated risk for later social anxiety symptoms and diagnoses.

3 **144.003** An Ultrasound Study of Fetal Biometrics in Relation to Maternal Autistic Traits.

E. Aydin[1]*, R. Holt*[1]*, D. Chaplin*[2]*, R. Hawkes*[2]*, T. Austin*[2] *and S. Baron-Cohen*[3]*, (1)University of Cambridge, Cambridge, United Kingdom, (2)Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: The prenatal period is a critical time for brain development. During this period of early development, the unborn child has the potential to be negatively influenced by factors such as maternal infections and teratogens. Such epigenetic factors in the intrauterine environment have been linked to the development of many neurodevelopmental outcomes, including Autism Spectrum Conditions (ASC). Research has shown that autistic traits are partly heritable. Therefore, we predict mothers' scores on the Autism Spectrum Quotient (AQ) will influence fetal growth development. To date, only a handful of studies have observed prenatal development in relation to ASC. All studies have observed this potential marker of abnormal development retrospectively, either from measures taken at the time of birth or using growth measures from medical ultrasounds at 12 and 20 weeks.

Objectives: This study observed longitudinal fetal growth measures taken at 12-, 20- and between 26-30 weeks of pregnancy to observe the potential influence of material autistic traits on fetal development.

Methods: The sample comprises of 130 singleton pregnancies with no immediate family with an ASC diagnosis. Prenatal ultrasounds were procured from medical records at 12- and 20-weeks, and an additional ultrasound between 26-30 weeks pregnancy. 2D and 3D scans were performed using a GE 8 Expert Ultrasound system. Mothers were asked to complete an AQ at the time of their 3rd scan. Fetal head circumference (HC), abdominal circumference (AC), femur length (FL) and ventricular atrium (VA) measures were taken at each time point and standardised according to UK fetal biometry reference charts. Using partial correlations, the standardised growth measures and the discrepancies between them were compared across maternal AQ scores. This was carried out separately for each gestation and growth parameter.

Results: There was no significant correlation between fetal growth (HC, AC, FL or ventricular atrium) and mothers' AQ score even when controlling for gender and gestational age.

Conclusions: These preliminary findings suggest that there is no association between fetal physical development and mothers' AQ scores. This supports previous retrospective findings suggesting there are no differences in fetal biometry in children diagnosed with ASC. However, all pregnancies included in the study were low risk for ASC due to a lack of a diagnosis in the immediate family. The absence of any significant relationship here could reflect the narrow range of AQ scores, of the effects of parental traits on child development could be subtler, and are more likely to be evident in child behaviour later in development. Previous research has implicated a relationship between HC and brain size, suggesting the inference of fetal brain growth from HC. However, this is yet to be tested. This study will further explore brain development in relationship to HC during fetal growth and will follow these infants' development until they are 18-months old to observe subsequent physical and behavioural development.

144.004 Assessment Modality (Parent Questionnaire vs. Clinical Interview) Impacts Adaptive Functioning Scores in Preschoolers at Heightened Genetic Risk of ASD

*M. Cola[1], A. Faggen[1], J. Parish-Morris[1], S. Paterson[1], R. T. Schultz[1], **J. Pandey**[1] and .. The IBIS Network[2], (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)University of North Carolina, Chapel Hill, NC*

Background: The DSM-5 emphasizes the significance of adaptive function in the diagnosis of neurodevelopmental disorders, but these skills can be difficult to characterize in young children using standardized assessments. To date, there has been a paucity of research comparing adaptive functioning measures to each other, specifically within the preschool age group. Strong correlations have been reported across some adaptive functioning assessments when used with typically developing populations, but research in ASD populations has found significant discrepancies between assessments (Lopata et al., 2013). Prior literature suggests that at least a sub-group of younger siblings of children with ASD who do not develop ASD themselves are at heightened risk for a variety of developmental difficulties by age 3 (Messinger et al., 2013; Ozonoff et al., 2014). Accurately measuring adaptive functioning in this group is crucial, as these scores are used to design intervention plans that support school readiness. In order to determine the scope and targets of support, it is essential to find standardized assessments that accurately assess the adaptive skills of preschoolers at all levels of functioning.

Objectives: Determine which modality of assessment (parent report or clinician interview) better characterizes adaptive functioning by comparing scores on two commonly used assessments (the Adaptive Behaviors Assessment System, Second Edition (ABAS-II) Parent Form, and the Vineland Adaptive Behavior Scales-II (VABS-II) Survey Interview Form) with each other and with a measure of general developmental functioning (the Mullen Scales of Early Learning; MSEL).

Methods: Twenty-six 3-year-olds returned for a diagnostic visit as part of their participation in the longitudinal Infant Brain Imaging Study (IBIS). Participants fell into one of two groups: (1) at high-familial risk for ASD by virtue of having an older sibling with ASD, but not currently diagnosed with ASD themselves (HR-neg, N=20) and (2) at low-familial risk for ASD with no ASD diagnosis themselves (LR; N=6). All parents were mailed the ABAS-II to complete at home, while the MSEL and VABS-II were administered during the diagnostic visit.

Results: Across all domains of developmental function, children in both groups performed in the average range (Table 1) and did not differ significantly from one another (Welch's *ps*<.10). Within-group correlations were performed to assess relationships between VABS-II, ABAS-II, and MSEL scores. In the HR-neg group, VABS-II scores correlated with scores on the MSEL, while ABAS-II did not. In contrast, neither VABS-II nor ABAS-II scores correlated with MSEL scores in the LR group (which we will add to by the conference date).

Conclusions: Preliminary analyses indicate that the modality of assessment (parent questionnaire vs. clinical interview) impacts children's adaptive functioning scores, particularly when children are at heightened genetic risk for ASD. Our findings suggest that since parents of HR-neg children might not have a typical model to compare against when independently completing a questionnaire about adaptive functioning, that a clinical interview could provide critical support to more accurately capture children's strengths and weaknesses. Therefore, researchers should be cautious in assuming that different measures of adaptive behaviors are comparable in this age range and in HR samples.

5

144.005 Atypical Response to Caregiver Touch in Infants at Risk for Autism Spectrum Disorder

***G. Kadlaskar**[1], B. Keehn[1], A. Seidl[1], H. Tager-Flusberg[2] and C. A. Nelson[3], (1)Speech, Language, and Hearing Sciences, Purdue University, West Lafayette, IN, (2)Psychological and Brain Sciences, Boston University, Boston, MA, (3)Boston Children's Hospital, Boston, MA*

Background: A significant majority of individuals with autism spectrum disorder (ASD) experience hypo-and/or hyper-sensitivity in one or more sensory modalities, which have been linked with deficits in social communication and adaptive behavior. Touch is an important communicative signal, which forms the basis of early caregiver-child interactions and facilitates social communication and language processing in early development. Typically developing infants can use tactile cues to find linguistic units in continuous speech. For example, a touch on a foot while hearing the word "foot" may help infants form word-to-world mappings. Thus, touch may be an essential element aiding in early speech processing, since, when integrated with speech it could be informative as to the linguistic structure. Early aberrant responses to tactile stimulation in ASD, therefore, could impact the language development.

Objectives: To examine orienting frequency and latency to caregiver-initiated touch in 12-month-old infants at high risk for autism (HRA) that did (HRA+) and did not (HRA-) meet later diagnostic criteria for ASD compared to low-risk comparison (LRC-) infants, and the association between touch responsivity and language outcomes at 24 and 36 months.

Methods: To date, we have examined 30 (HRA+=10; HRA-=10; LRC=10), ten-minute videos of caregiver-infant interactions that were recorded during naturalistic play sessions. Trained coders, blind to group membership, evaluated the frequency, type, and location of caregiver-initiated touches to infants during play interactions (e.g., tap on the leg with or without a toy) along with infants' looking behaviors before, during and after each touch. Infants' looking behaviors were coded as 'touch related' (e.g., infant shifts attention to caregiver, touch-related toy, or touch location), 'non-touch related' (e.g. infant shifts attention to non-touch related object or location) and 'no shift' (e.g., no attentional shift).

Results: Preliminary analyses showed no significant differences in the frequency of caregiver touches delivered to infants in all three groups. Analysis of variance indicated marginally significant differences in the percentage of no-shift responses to caregiver touches between groups. Follow-up independent samples t-tests showed that the HRA+ infants had a greater percentage of no-shift responses to caregiver touches (67.1%) compared to HRA- infants (48.4%, *p*=.044) but not LRC- infants (56.9%, *p*=.191). In addition, for all infants, latency of touch-related attentional shifts was negatively correlated with verbal developmental quotient (DQ) scores, as measured by the Mullen Scales of Early Learning, at 36 months but not at 24 months (see Figure 1).

Conclusions: Our preliminary findings suggest that infants that go on to receive a diagnosis of ASD may more frequently fail to shift their attention in response to caregiver touch. These findings are in agreement with prior reports of 'sticky attention' in HRA infants in response to visual cues, and suggest that infants later diagnosed with ASD may show impaired disengagement of attention in response to tactile stimulation. Furthermore, faster orienting to touch was associated with better verbal DQ scores at 36 months, suggesting that touch may be instrumental in early infant language learning.

6 **144.006** Baby Movements in the Womb: Searching for Early Markers of Autism Spectrum Disorders

A. Caruso[1], *F. Fulceri*[1], *L. Iaconianni*[2], *A. Guzzetta*[3,4] *and M. L. Scattoni*[1], *(1)Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy, (2)Diagnostic Ultrasound Center Eco B.I., Rome, Italy, (3)IRCCS Stella Maris Foundation, Calambrone (Pisa), Italy, (4)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*

Background: To date, the early surveillance leading to an early intervention represents the only successful strategy to improve clinical outcomes in Autism Spectrum Disorder (ASD). The Italian network for early detection of ASD (NIDA) applies a clinical/biological standardized protocol for developmental surveillance in High Risk (HR, i.e. siblings of children with a diagnosis of ASD, preterm and small for gestational age newborns) and Low Risk infants (LR, i.e. siblings of typically developing children) with the aim of identifying early risk indexes of ASD. The NIDA network has recently characterized the early phases of motor development in HR infants detecting abnormalities in general movements in the first two weeks of age. Since fetal movements are considered to reflect the developing nervous system, it has been hypothesized that their examination could be a promising tool to identify early sign of ASD

Objectives: To develop novel multidisciplinary observational methods to identify fetal movements with a prognostic value for ASD.

Methods: The NIDA's standardized protocol for developmental surveillance in HR and LR infants has been implemented with fetal movements screening. Data collected are going to be used to generate normative data and subsequently compare them to data collected on fetuses at risk of developing ASD. Multivariate statistical methods are fundamental to analyze fetal/newborn/infant data to detect early markers of ASD. This undergoing prospective study has been approved by Istituto Superiore di Sanità (ISS) ethic committee and complies with the guiding policies and principles for experimental procedures endorsed by the National Institutes of Health.

Results: The fetal screening standard operative procedures (SOPs) have been defined in collaboration with a child psychiatrist expert on infant movement assessment and with a gynecologist certified by the Fetal Medicine Foundation. First and second trimester ultrasound (US) examinations last ten minutes including five minutes of two-dimensional US followed by five minutes of four-dimensional US. The US probe view approaches the entire fetus or alternatively focuses on the upper torso of the body. One hour of cardio-tocographic recording occurs in the third trimester. Fetal movements are classified into different activities including general movements. The fetal biometric data are also detected across trimesters.

Conclusions: The NIDA project is actually monitoring the neurodevelopment of 70 HR and 75 LR infants. It has been expected that fetal US screening may be helpful in detecting predictive and/or prognostic markers of ASD.

7 **144.007** Can the Social Responsiveness Scale Index Maternal Responsiveness during Play?

A. M. Kellerman[1], ***A. J. Schwichtenberg***[1], *R. Abu-Zhaya*[1], *M. Miller*[2], *G. S. Young*[3] *and S. Ozonoff*[3], *(1)Purdue University, West Lafayette, IN, (2)University of California, Davis, MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA*

Background: The *Social Responsiveness Scale* (SRS) is a commonly used questionnaire to measure elements of the broader autism phenotype (BAP), or what is sometimes referred to as quantitative autistic traits (QAT). Previous studies document the presence of sub-clinical autism traits in families raising children with autism spectrum disorder (ASD) but the functional and treatment-related implications of these traits are poorly understood and understudied. Family members with elevated QAT may require more support when implementing parent-mediated interventions. To identify parents who may need more support, the use of the SRS has been recommended. However, it is unclear if SRS scores are associated with maternal behaviors within a social context.

Objectives: To assess the associations between maternal SRS-2 scores and maternal responsiveness in context (for this study within a play session).

Methods: Dyads were recruited from families with at least one older child with ASD (high-risk group, *n* = 90) or families with no history of ASD (low-risk group, *n* = 62). Play interactions included mothers and a younger infant sibling. Children with ASD where not included to minimize the impact of their social difficulties on maternal ratings of responsiveness. Dyadic interactions were micro-coded for gaze, positive affect, and vocalizations when infants were 6, 9, and 12 months of age. Using these micro-codes, theory-driven composites were created to index observed maternal responsiveness (i.e., initiations, responses, responsiveness timing). Maternal social responsiveness ratings were reported by a spouse/partner on the SRS.

Results: The majority of maternal SRS T scores fell within the normal range of reciprocal social behavior (Figure 1). Maternal SRS T scores were also comparable across risk high- and low-risk groups, *F*(1, 151) = .70, *p* = .40 (high-risk group, range: 43-70, *M* = 49.09, *SD* = 4.85; low-risk group, range:

44-61, *M* = 49.57, *SD* = 3.66). To assess whether SRS scores were associated with observed maternal responsiveness, general linear models were specified, with terms for infant sex and family income. Observed maternal social initiations, responses, and responsiveness timing were not associated with SRS T scores at 6, 9, or 12 month visits (*p* range .07 - .97).

Conclusions: SRS scores were not associated with maternal behaviors within a social context. This study had the power to detect moderate-to-large effect sizes. Although, the lack of association may reflect several factors. First, the SRS was designed to capture more than just social difficulties and includes other elements of the BAP (e.g., rigidity). Second, marked social difficulties may only be apparent with higher scores (severe range) of the SRS, which were not represented in this sample. In sum, the present study does not support the use of the SRS to identify parents who may need additional support during parent-mediated interventions but further research is warranted with parents' scores falling within the severe range.

8 **144.008** Characterisation of Associations between Social and Non-Social Attention and Later ASD Symptoms in Infants with Tuberous Sclerosis Complex: An Eye-Tracking Study

C. Tye[1]*, E. J. Jones*[2]*, L. Mason*[2]*, M. H. Johnson*[3] *and P. Bolton*[1]*, (1)Department of Child & Adolescent Psychiatry, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom*

Background: Tuberous sclerosis complex (TSC) is a single-gene disorder associated with variable developmental outcomes, with up to 60% receiving a diagnosis of autism spectrum disorder (ASD). The specific mechanisms through which individuals will go on to develop ASD are yet to be clearly defined. An increasing proportion of TSC cases are identified prenatally, providing a unique opportunity to study risk pathways through infancy. Social and non-social attention have been implicated in infants at familial risk for ASD. The degree of homology of association between these attentional parameters and risk for ASD, and the role of early-onset epilepsy, in TSC is unknown.

Objectives: To characterise differences in social and non-social attention in infants with TSC and typically developing infants and explore associations with epilepsy and emerging ASD symptoms.

Methods: The Early Development in Tuberous Sclerosis (EDiTS) Study is an ongoing prospective longitudinal study of infants with TSC (total n=25) and age-matched typically developing infants (total n=25) enrolled from birth to 24 months of age. Infants undergo developmental assessments (e.g. Mullen Scales of Early Learning) at each visit. We use portable eye-tracking technology in the home environment to measure social and non-social attention using a range of tasks. In this study, we focused on two paradigms that have been used in several previous infant studies: a face 'pop-out' task, to measure proportion of time looking at faces, and a gap/overlap task, to measure the disengagement effect (response time in baseline versus overlap).

Results: Data is currently available for 10 infants with TSC and 15 typical infants at 5, 8, 10 and 14 months old, with analysis ongoing. Infants with TSC show a slower gain in skills, particularly in the non-verbal domain from 5 to 10 months of age (p=.007) associated with younger age at seizure onset (rho=.61, p=.04). At 5 months, infants with TSC display increased peak looking time to faces compared to typical infants (2.42 versus 4.17, p=.03), associated with younger age at seizure onset (rho=-.47, p=.08), but not with ASD symptom scores at 14 months (Q-CHAT). Conversely, infants with TSC show longer disengagement times on the gap/overlap task from 10 months of age compared to typical infants (254ms versus 177ms, p<.05), which was associated with increased ASD symptoms at 14 months (rho=.60, p=.05).

Conclusions: These preliminary findings indicate atypical social visual attention from 5 months combined with reduced flexibility in control of non-social visual attention from 10 months in infants with TSC, suggesting early developmental changes that partially mimic ASD risk markers in familial cases. The variable timing in the onset of social versus non-social attentional differences suggest the interaction of multiple brain systems over the first year of life that give rise to variable pathways. In TSC, variation may reflect the differential effect of epilepsy on low- and high-order cognitive domains. Identification of sensitive and objective biomarkers of risk for ASD in TSC will aid in directing more specific interventions and in testing the efficacy of novel early intervention targets.

9 **144.009** Characteristics of Toddlers with Autism Who Are Placed in Special Education Versus Regular Education in Israel

M. Ilan[1,2]*, M. Faroy*[2,3]*, N. Fingher*[4]*, A. Bar-Sinai*[5]*, A. Michaelovski*[2]*, H. Fluser*[2]*, H. Binoun-Chaki*[2]*, A. Horev*[2]*, R. Segev-Cojocaru*[2]*, O. Dotan*[2]*, I. Menashe*[6]*, I. Dinstein*[5,7] *and G. Meiri*[2]*, (1)Department of Psychology, Ben-Gurion University of the Negev, Beer Sheva, Israel, (2)Soroka Medical Center, Beer Sheba, Israel, (3)Tel-Aviv Jaffa Academic collage, Tel Aviv, Israel, (4)Brain and Cognitive science, Ben-Gurion University of the Negev, Beer Sheba, Israel, (5)Department of Psychology, Ben Gurion University of the Negev, Beer Sheba, Israel, (6)Public Health Department, Ben-Gurion University, Beer Sheva, Israel, (7)Negev Autism Center, Ben Gurion University of the Negev, Beer Sheba, Israel*

Background:

In Israel and most western countries, toddlers who receive an autism diagnosis are eligible for placement in either special education settings or regular education settings with an educational assistant. Remarkably little research has compared the efficacy of these educational options, which differ dramatically in their structure, content, and cost. A first important step in determining the efficacy of each option is to examine the initial characteristics of toddlers who are placed in each setting. While several studies with school age children have reported that children with lower communication skills and cognitive abilities are more often placed in special education, it is not clear if the same is true for toddlers and preschoolers. In Israel and most other western countries, the initial educational setting is selected by the parents and clinicians offer very little evidence-based advice regarding the optimal choice. To study this issue we utilized data from toddlers who were recruited to the regional autism database at the Negev Autism Center (www.negevautism.org).

Objectives:

To compare the characteristics of children with autism across educational settings using autism symptom severity measures, cognitive scores, and socio-demographic parameters.

Methods:

105 children with autism ages 1.6 – 4.8 years old (mean: 2.7) were recruited at Soroka University Medical Center (SUMC) in Beer Sheba, Israel. Socio-demographic data was collected from the parents and all toddlers participated in ADOS assessments. Most of the toddlers also completed cognitive assessments. Comparisons were performed between toddlers in regular public daycare with assistance (n=10, average age 2.58) versus

toddlers in special education daycare (n=28, average age 2.01) and between toddlers in regular kindergartens with assistance (n=23, average age 2.95) versus toddlers in special education kindergartens (n=45, average age 3.07).

Results:

Toddlers in special education kindergartens exhibited significantly higher ADOS scores in comparison to toddlers in regular education kindergartens (p = 0.03, t-test). A similar trend was also evident between special and regular day care groups (p = 0.07, t-test). There were no significant differences in cognitive scores (p > 0.19, t test). Paternal education did not differ across groups, but maternal education was significantly higher for toddlers with autism who were placed in regular kindergartens (p < 0.02). There were no significant differences across groups in parental age or socio-economic status of estimated by place of residence.

Conclusions:

Toddlers with autism who have more severe autism symptoms tend to be placed in special education rather than regular education settings in Israel. This difference, however, was relatively small (Cohen's d = 0.6) and no significant difference was apparent in cognitive score and most socio-economic parameters. These data suggest that placement choice is close to random and not guided by structured evidence-based clinical advice. Determining the efficacy of each educational setting for toddlers with different characteristics, using longitudinal studies is, therefore, critical for providing better clinical care.

10 **144.010** Children with Autism Spectrum Disorder (ASD) with or without a History of Developmental Regression: Differences in Developmental Levels, Adaptive Functioning, and Behavior and Emotional Problems

N. Reyes[1]*, G. N. Soke*[2]*, L. Wiggins*[2]*, B. Barger*[3]*, E. Moody*[4]*, J. Reaven*[1]*, C. Robinson Rosenberg*[5]*, A. M. Reynolds*[6]*, L. Schieve*[2] *and S. Hepburn*[7]*, (1)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Centers for Disease Control and Prevention, Atlanta, GA, (3)Georgia State University, Atlanta, GA, (4)University of Colorado, Denver, Aurora, CO, (5)University of Colorado / JFK Partners, Aurora, CO, (6)University of Colorado Denver School of Medicine, Aurora, CO, (7)Colorado State University, Fort Collins, CO*

Background: Previous research has documented the occurrence of developmental regression (i.e., the loss of previously-acquired language or social skills) in some children with Autism Spectrum Disorder (ASD). However, there is limited research on the developmental outcomes of children with ASD and a history of regression.

Objectives: We assessed the proportions of language and social regression in preschool children with ASD and examined differences in developmental levels, adaptive functioning, and behavior and emotional problems in children with ASD with or without regression.

Methods: We used data from the Study to Explore Early Development, a US multi-site community-based case-control study. In this analysis, we included 671 children born between 2003 and 2006 who met the SEED case definition for ASD based on the Autism Diagnostic Observation Schedule and the Autism Diagnostic Interview-Revised (ADI-R). Based on caregivers' ADI-R responses, children were assigned to one of four groups: (1) *no regression*, (2) *language regression only*, (3) *social regression only,* and (4) *language+social regression.* We used the Mullen Scales of Early Learning (MSEL) to evaluate developmental levels (i.e., language, motor, and visual reception abilities); Vineland Adaptive Behavior Scales-II (VABS-II) to assess adaptive functioning, and Child Behavior Checklist-Preschool (CBCL-P) to examine behavior and emotional problems. Descriptive statistics and ANOVA tests were computed to examine differences in these areas according to regression status.

Results: 8.94% (n=60) and 8.64% (n=58) of mothers reported child language regression and social regression, respectively and 8.35% (n=56) reported regression in both domains.

Differences in Developmental Levels: We found significant differences between the four regression groups in MSEL age equivalents (all p-values <0.05). Specifically, children in the *no regression* group had higher age equivalence than children in the *language only* group in visual reception, fine motor, receptive language, and expressive language domains. Also, the *no regression* group had higher age equivalence than the *social only* group in the fine motor domain, and higher age equivalence than the *language+social regression* group in the receptive and expressive language domains. Similarly, the *no regression* group had higher early learning composite standard scores than the *language only regression* group.

Differences in Adaptive Functioning: Significant differences were also found between groups in the VABS-II communication domain only, with children in the *no regression* group having higher VABS-II communication standard scores than children in the *language only* and *language+social regression* groups (*p*=.012).

Differences in Behavior and Emotional Problems: We found significant differences between groups in CBCL-P internalizing behavior t-scores (*p*=.002), but not CBCL-P externalizing behavior t-scores. Children in the *no regression* group had lower t-scores in the internalizing problems domain than children in the *language only* and *social only* groups.

Conclusions: These findings confirm the occurrence of regression in some children with ASD, and suggest that children with loss of skills might have lower developmental levels and adaptive functioning as well as increased behavior and emotional problems. Therefore, children with a history of regression are likely to need more support and interventions to target their specific needs.

12 **144.012** Concurrent Associations between FYI Attentional Constructs and ADOS Scores in 12-Month High-Risk Siblings

H. Neiderman[1]*, S. Macari*[1]*, A. Zakin*[1]*, F. E. Kane-Grade*[2]*, K. Villarreal*[1]*, M. Wilkinson*[1]*, D. Macris*[1]*, S. Fontenelle*[1]*, K. K. Powell*[1]*, M. Lyons*[1] *and K. Chawarska*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA*

Background: Deficits in social attention as well as the presence of atypical sensory attention constitute some of the core symptoms of ASD observed at an early age (Chawarska et al., 2014; Baranek et al., 2013). Current work has focused on identifying behavioral markers of ASD as early as 12 months (Reznick et al., 2006). Recently, researchers used the First Year Inventory (FYI), designed to identify risk for ASD at 12 months, to create new composite scores based on attentional constructs: responding to social attention (RSA), initiating social attention (ISA) and nonsocial sensory attention (NSA; Stephens et al., 2017). Their preliminary analyses revealed that the new algorithm scores predicted some variance in social responsiveness scores at 3 years. However, little research has examined these constructs in relation to concurrent ADOS scores in high-risk siblings.

Objectives: To examine if infants at high and low familial risk for ASD differ in mean scores on attentional constructs and to investigate concurrent associations between attentional construct scores and severity of autism symptoms indexed by the ADOS-Toddler.

Methods: Participants included infants at high-risk (HR) for ASD (N=122; M_{age}= 12.3 months) and at low-risk (LR) for ASD (N=70; M_{age}=12.3 months). At the 12-month visit, parents completed the FYI and clinicians administered the ADOS-Toddler. Differences in mean scores between HR and LR groups on the attentional constructs were tested. Stepwise regression analyses tested the predictive value of the attentional constructs on concurrent ADOS-Toddler Total scores, Social Affect (SA) scores and Restricted, Repetitive Behavior (RRB) scores.

Results: Independent t tests revealed that HR infants showed more deficits in ISA (M=1.90, SD=.60) than LR infants (M=1.64, SD=.55), t(190)=2.97, p<.01) and more deficits in RSA (M=1.57, SD=.35) than LR infants (M=1.44, SD==.33); *t*(190)=2.53, *p*<.05. HR infants also presented with more atypical NSA scores (M=1.62, SD=.34) compared to LR (M=1.78, SD=.43); *t*(190)=-2.86, *p*<.01. All three attentional constructs correlated significantly with concurrent ADOS-T Total scores, *r*=.38(*p*<.001), *r*=.31(*p*<.001), and *r*=.23(*p*=.001) for ISA, RSA and NSA, respectively. There were significant correlations between ADOS SA scores and ISA (*r*=.38, *p*<.001), RSA (*r*=.31, *p*<.001) and NSA (*r*=.20, *p*<.01). Stepwise regression analyses showed that only ISA contributed uniquely to ADOS SA scores (*F*(1,189)=31.763, *p*<.001), accounting for 14.4% of the variance. While there were significant correlations between ADOS RRB scores and NSA (*r*=.225, *p*=.001) as well as ISA (*r*=.18, *p*<.01), only NSA was significantly associated with ADOS RRB scores (*F*(1,189)=13.135, *p*<.01) accounting for 5.1% of the variance.

Conclusions: The attentional constructs derived from the FYI differentiate between HR and LR infants, with HR infants' scores indicative of fewer social initiations and responses and more atypical sensory attention. Levels of responding to social attention was not related to severity of autism symptoms. However, parent-reported indices of initiating social attention as well as nonsocial sensory attention were directly related to ADOS algorithm scores. The initiating social attention construct may be pivotal in detecting early deficits in social attention and the NSA construct shows promise in capturing early RRB behaviors.

13

144.013 Consistency between Parent-Report and Direct Measure of Toddler Temperament

K. Villarreal[1]*, S. Macari*[1]*, H. Neiderman*[1]*, F. E. Kane-Grade*[2]*, M. Wilkinson*[1]*, A. Zakin*[1]*, D. Macris*[1]*, L. DiNicola*[3]*, P. Heymann*[1]*, A. Milgramm*[4]*, E. Hilton*[1] *and K. Chawarska*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Center for Autism and Related Disabilities, Albany, NY*

Background: According to parent report, toddlers with Autism Spectrum Disorder (ASD) show increased negative emotionality and diminished positively-valenced temperamental features (Clifford et al. 2012; Macari et al. 2017) compared to toddlers with typical development (TD). Complementary to parent report are direct measures of temperament such as the Laboratory Temperament Assessment Battery (Lab-TAB; Goldsmith & Rothbart, 1999), designed to induce emotions through challenges that imitate everyday situations. However, only modest associations have been found between parent report and observational measures in preschoolers (Gagne et al., 2011) and infants (Planalp et al., 2017). Despite the importance of temperament for understanding heterogeneity of syndrome expression in ASD (Macari et al, 2017), little is known about the agreement between laboratory-observed emotional reactions and parent report in toddlers with ASD.

Objectives: To investigate the relationships between intensity of positively- and negatively-valenced emotions elicited during the Lab-TAB and parent reported temperament on related scales of the Early Childhood Behavior Questionnaire (ECBQ; Putnam, Gartstein, & Rothbart, 2006).

Methods: Participants included 74 toddlers, 39 with ASD (M_{age}=21.9 months) and 35 with TD (M_{age}=20.8 months). All toddlers completed the LabTAB consisting of nine behavioral tasks designed to elicit three emotions: frustration, joy and fear. Behavioral ratings of peak fear, anger and joy reactions were coded offline by blind raters using indices of facial, bodily, and vocal emotion expression. ECBQ was used to quantify parental perception of child temperament. Correlation analysis was used to evaluate the relationship between Lab-TAB Frustration and ECBQ Anger; between Lab-TAB Joy and ECBQ Positive Anticipation; and between Lab-TAB Fear and ECBQ Fear separately in the ASD and TD groups. Fisher r-to-z transformations were used to test the significance of the difference between correlations.

Results: The ASD group showed a moderately strong positive correlation for all domains (anger *r*=.415, fear *r*=.414, joy r=.334, all p-values= < .05); the TD group showed moderate to high correlations for fear and joy (*r*=.697 and *r* =.368 respectively, p-values= <.05) but not for anger (*r*= .212 *p*=.221). In terms of differences between diagnostic groups in the magnitude of ECBQ/Lab-TAB correlations, no significant difference was observed for anger or joy (*p*>.05), but for fear, the correlation was marginally higher in the TD group than in the ASD group (*p* =.076).

Conclusions: Both the ASD and TD groups showed moderate associations between parent-reported and observed intensity of joy, however, regarding anger, only the ASD group displayed a significant relationship. Concerning fearful emotion, both groups exhibited significant intercorrelations, but parent ratings in the TD group were more consistent with real-world behaviors as compared to those of the ASD group. This finding suggests that parents of toddlers with ASD may have difficulty gauging the intensity of their toddler's apprehension, which could be related to ambiguity in emotional expression often exhibited in those with ASD (Kane-Grande et al., 2017; Abstract #2 of the panel). A mismatch between what the parent observes and what the child feels may hamper social exchanges within the dyad. Thus, the findings may have important clinical implications in social communication interventions.

14

144.014 Construction and Validation of the Esbcq: The Early Social Communicative Behavior Questionnaire

M. Buruma *and E. M. Blijd-Hoogewys, INTER-PSY, Groningen, Netherlands*

Background:

There has been an increasing interest in the diagnosis of Autism Spectrum Disorders (ASD) in infants (children younger than 3 years). These children have limited social communication skills, such as poor joint attention and symbolic play.

In ASD diagnostics, parent questionnaires are often used. In 2009, we developed the Early Social Communicative Behavior Questionnaire (ESCBQ; Blijd-Hoogewys & Buruma, 2009). The ESBCQ items are formulated, based on 1) literature research concerning both typical and atypical development of early social communicative behavior in infants, 2) existing instruments concerning this topic, and 3) clinical expertise with young children with ASD. The following subjects are questioned: eye contact, social interest, reaction to name, emotions, attachment, sharing pleasure, taking turns, looking, following gaze, following a point, pointing, showing, giving, playing, interaction games, imitation, gestures, and language.

Objectives:

The objective of this study was to develop a questionnaire that can be easily used to measure early social communicative behavior in infants in a reliable and valid way.

Methods:

The ESBCQ is a parent questionnaire, consisting of 108 items, questioning early social communication skills that typically developing children should master at the age of 24 months. The ESBCQ-2 is a shortened version of 58 items.

*Research group 1 - Standardization group ESBCQ-1

In order to explore the psychometric properties of the ESCBQ, 1230 parents of typically developing children aged 0-6 years filled in the questionnaire. Also, 108 parents of children with ASD filled in the ESBCQ.

*Research group 2 - Standardization group ESBCQ-2

Data collection is ongoing. Currently, 402 parents have filled in the questionnaire (222 boys, 180 girls). Also, 204 parents of children with ASD (INTER-PSY & Virenze) and 86 parents of children (Driestroom) with an intellectual disability filled in the ESBCQ-2.

Results:

*Research 1:

It takes 20-25 minutes to fill in the ESBCQ. The total score shows a steady increase with age, with a plateau at 30 months, for both boys and girls. The questionnaire has good psychometric properties: the internal consistency, based on inter-item reliability, is good (Cronbach's alpha = .97). Also the test-retest reliability (second measurement after 1 week) is good (N = 43, Wilcoxon Signed Rank test, M1 = 93.19 vs. M2 = 95.63, r = .91, p = .001).

A Principal Component Analysis conveyed three clusters (56% explained variance) (see Figure 1): 1) language, gestures, pretending and symbolic play; 2) pointing and giving; 3) gaze shifting and following attention (gaze and points).

*Research 2:

The ESBCQ was shortened and ameliorated, to make it more user friendly. This resulted in the ESBCQ-2 (Buruma & Blijd-Hoogewys, 2014). This is based on additional item analyzes (Differential Item Analyses) and clinical expertise. The ESBCQ-2 contains 58 items. The completion time is 10-15 minutes. Preliminary results are promising.

Conclusions:

The ESCBQ(-2) is a new questionnaire with good psychometric properties. The three clusters found coincide with what is expected from literature. More research is underway, focusing on the use of the ESCBQ as a 'diagnostic' tool.

15 **144.015** Deployment of a Multimedia Screening Tool for ASD in a Diverse Community Setting: Feasibility and Usability

M. Wilkinson[1], *S. Macari*[1], *K. Chawarska*[1], *E. Barney*[2], *J. C. Snider*[3], *E. S. Kim*[4], *Q. Wang*[1], *Q. A. Yang*[3], *C. A. Wall*[5], *M. Kim*[3], *B. Li*[3,6], *M. Mademtzi*[1], *C. Foster*[1], *D. Macris*[1], *F. E. Kane-Grade*[7], *A. Milgramm*[8], *P. Heymann*[1], *E. Hilton*[1], *A. Zakin*[1], *H. Neiderman*[1], *K. Villarreal*[1], *Y. A. Ahn*[3], *M. C. Aubertine*[9] *and F. Shic*[2], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Seattle Children's Research Institute, Seattle, WA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Department of Psychology, University of South Carolina, Columbia, SC, (6)Computer Science and Engineering, University of Washington, Seattle, WA, (7)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (8)Center for Autism and Related Disabilities, Albany, NY, (9)Seattle Children's Hospital and Research Institute, Seattle, WA*

Background: With an increase in autism prevalence (Christensen et al., 2012), there is an urgent need to identify children at risk for developing ASD. The American Academy of Pediatrics suggests developmental screening at 9-, 18-, and 30-month well-child visits (Council on Children with Disabilities, 2006). Screening leads to an earlier ASD diagnosis (Miller et al., 2011), yet children are not screened equally across racial groups, with African-American and Latino children being screened later than Caucasians (Herlihy et al., 2011). Thus, it is essential to create screening tools to help identify those at risk, especially among diverse populations. To fill this need, we have created a tablet-based multimedia screener system, the Yale Adaptive Multimedia Screener (YAMS). The application allows for time-efficient screening through an easy-to-understand platform that automates scoring of risk.

Objectives: To examine the feasibility, acceptability, and usability of a tablet-based multimedia screener in a diverse population of children ages 10-33 months in primary pediatric care centers serving under-resourced populations.

Methods: Feasibility of YAMS use at multiple community pediatrics sites was indexed by our success rate in ability to identify and approach the families of infants and toddlers (10-33 months old) attending their routine well-child visits at three community pediatric locations. Acceptability of the screener was evaluated by recruitment rate. Usability was determined using five questions based on the After-Scenario Questionnaire (Lewis, 1991).

Results: 409 infants and toddlers were identified as potential participants based on their age. 132 (32.3%) families missed their well-child appointment. Of the 277 patients who attended their scheduled appointment, 56 (20.2%) were not approached to participate because of schedule conflicts or lack of sufficient English skills. Of the 221 families invited to participate, 187 enrolled in the study (84.6%). 78 (41.7%) children were African-American, 45 (24.1%) were mixed race, 23 (12.3%) were Caucasian, and 6 (3.2%) were Asian. 82 (43.9%) children were Hispanic/Latino. The average parent/guardian age was 30.42, ranging from 17.2 to 67.7 years. 51 (27.3%) were single parents. Education level for 113 (50.8%) parents was a high school degree or less. Five usability questions related to helpfulness of videos, satisfaction with the amount of time it took to complete, and ability to understand questions, rated on a Likert scale of 1-7, resulted in average parent feedback of 6.52, suggesting YAMS is a highly usable application.

Conclusions: This feasibility study suggests challenges and successes in the ability to reach a diverse inner-city population using an electronic multimedia screening tool. Through initial stages of deployment, results suggest some difficulty reaching participants based on their appointments, but among participants there was a high level of satisfaction in terms of the overall usability, the time it took to complete the application, as well as the helpfulness of the videos as a platform for illustrating screening questions. In addition to high levels of satisfaction with the app, our high participation rate will allow continuation of the development process by expanding the testing of YAMS in additional community settings as well as utilizing front-desk staff to more efficiently recruit participants.

16 **144.016** Development of Neural Responses to Hearing Own Name in Infants at Low and High Risk for ASD

***M. Arslan**, P. Warreyn, N. Dewaele, J. R. Wiersema, E. Demurie and H. Roeyers, Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background:

People attend to their own name even in noisy environments and use this as a signal to follow social conversations. Typically developing infants start to orient towards the sound of their own name already at 4-5 months of age, which was also observed by altered neural responses via event-related potentials (ERPs). A reduced attention to this ostensive cue was however detected in infants who are at high risk for autism spectrum disorder (ASD) and is considered to be an early sign of ASD. Enhanced attention to the own name may be important for language acquisition by functioning as a tool for speech segmentation, particularly in the beginning of the second year of life when language acquisition progresses very fast. Therefore, a reduction in this attention may result in weakened early social information processing, interfering with the development of social skills.

Objectives:

With this study, we aimed to identify the neural patterns of two infant groups at low-risk (LR) and high-risk for developing ASD (HR), longitudinally at the ages of 10 and 14 months, while they were hearing their own name versus a stranger's name.

Methods:

Data from 68 10-month-old infants and 72 14-month-old infants were collected. After excluding data from 32 infants due to excessive movement and artifacts, data from 25 LR and 28 HR at the age of 10 months and 25 LR and 30 HR at the age of 14 months were analyzed. ERPs were measured during an own name/stranger name task with both balanced auditory and visual stimuli (Parise et al, 2010).

Results:

The ERP components were investigated in three different time-windows. At the age of 10M the LR infants' neural responses to hearing their own name already differed from hearing a stranger's name in the early component (100-300ms post-stimuli), indicating an early involuntary attention to the own name. The HR group failed to show the same response. At the age of 14M, groups showed a different lateralization to hearing their own name versus a stranger name in the same early time-window. The groups particularly differed in their response to hearing their own name in the left frontal area. Likewise, in the later time-windows indicating attentional engagement, the atypical patterns in the ERPs of the HR group became apparent by the age of 14M.

Conclusions:

The preliminary results suggest that LR infants discriminated and paid more attention to their own name compared to a stranger name already by the age of 10 months; while HR infants did not show the same effects, implying that they may not pay special attention to their own name. In addition, differences between HR and LR infants were identified more clearly by the age of 14 months. These results imply that HR infants become differentiated from LR infants by their brain development around the age of 1 year with respect to paying attention to their own names. Associations of the ERPs to hearing one's own name with later social-communicative functioning will be presented at the conference.

17

144.017 Diminished Empathic and Social Responses in Infancy As Early Markers of ASD Diagnosis

***Y. Paz**[1], R. Roth-Hanania[2,3], L. V. Gabis[3], T. Orlitsky[1], C. Zahn-Waxler[4] and M. Davidov[1], (1)The Hebrew University of Jerusalem, Jerusalem, Israel, (2)Tel Aviv-Yaffo Academic College, Tel Aviv, Israel, (3)Pediatrics, Sheba Medical Centre, Tel-Hashomer, Ramat Gan, Israel, (4)Center for Healthy Minds, University of Wisconsin, Madison, Madison, WI*

Background: Empathy is an important socio-emotional capacity, which promotes adaptive social functioning. Children diagnosed with Autistic spectrum disorder (ASD) suffer from an impaired empathic ability and show lower emotional response to distressed others than typically-developing children (Sigman, Kasari, Kwon & Yirmiya, 1992). Those impaired abilities can be seen early in development, with prior work showing their presence from early in the second year of life (Hutman et al., 2010).

However, no study to date has examined empathic responding during the first year of life as a predictor of subsequent ASD diagnosis. This is likely because up until recently it has been assumed that empathic concern only emerges during the second year of life (Hoffman, 2001). But recent research shows that, contrary to this theoretical assumption, typically-developing infants can also express empathy for distressed others early in the first year of life (Roth-Hanania, Davidov, & Zahn-Waxler, 2011; Davidov et al., 2013). Reduced empathic responses during the first year should thus be studied as early markers of evolving ASD.

Objectives: The current study sought to investigate empathic abilities as early markers (prodromal signs) of ASD in a prospective longitudinal study of high risk infants. We predicted that empathic concern and social interest at 6-months would be negatively correlated with subsequent ASD diagnosis.

Methods: The sample consists of infants, siblings of children with ASD, assessed at age 6, 12 and 18-months. Here we present the results of the first 12 infants, who have completed the assessment so far, as an initial pilot sample of a larger cohort.

At 6-months, Infants' responses to two distress simulations (enacted by mother and experimenter) were assessed and blindly coded for empathic concern (on a 0-3 validated scale). Infants' social interest was also measured using an eye-tracking task examining preference for images of people vs. objects.

At 12-months, a clinical, neurological and developmental examination was performed including morphometric measurements and assessment of milestones.

At 18-months, diagnostic assessment of ASD was conducted (screeners- SACS, M-chat, Q-chat; ADOS-2). Two of the infants have been diagnosed with ASD, eight as typically-developing, and two with developmentally-delayed communicative abilities.

Results: Consistent with hypothesis, empathic concern at 6-months (for both simulations combined) was significantly negatively correlated with subsequent ASD diagnosis, $r=-.77$, $p=.003$. Moreover, at-risk infants later diagnosed had significantly lower empathic concern mean score compared to a large normative sample of typically-developing 6-month-olds that we have collected (N=155; respective means: 0.44 vs. 1.03, $t=-2.33$, $p=.05$). In contrast, the at-risk infants subsequently found to be typically-developing did not differ from the normative sample (1.12 vs. 1.03, $t=.55$, *ns*). Finally, in the people vs. objects task, there was a significant negative correlation between the tendency to prefer people (proportion of trials in which the infant first fixated on the person image) and subsequent ASD diagnosis, r=-.65, p=.044.

Conclusions: Empathic abilities and social interest in early infancy may be promising prodromal markers of subsequent ASD diagnosis in high risk infants. Additional research is needed to establish these early markers, which may promote early diagnosis and intervention.

18 **144.018** Distinct ERP Profiles for Auditory Processing in Infants at-Risk for Autism and Language Impairment

***V. Riva**[1], C. Cantiani[2], G. Mornati[1], M. Gallo[1], L. Villa[1], E. Mani[1], I. Saviozzi[1], C. Marino[3] and M. Molteni[4], (1)Child Psychopathology Unit, Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Lecco, Italy, Italy, (2)Child Psychopathology Unit, IRCCS Eugenio Medea, Bosisio Parini, Italy, (3)Centre for Addiction and Mental Health (CAMH), University of Toronto, Toronto, ON, Canada, (4)Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Italy*

Background:

Early identification of autism spectrum disorder (ASD) is crucial for the formulation of intervention programs to be applied at very young ages. There is a strong interest in identifying reliable brain-based predictors, which may constitute useful tools for early detection of at-risk cases. Deficits in language skills may be a hallmark feature of ASD and language delay observed in ASD shows striking similarities to that observed in children with language impairment (LI). Deficits in auditory processing are seen in both LI and ASD, however, auditory processing in the two at-risk populations has never been compared directly using Event-Related Potentials (ERPs) techniques.

Objectives:

The study aims to characterize infants at-risk for ASD at the electrophysiological level and to compare them with infants at-risk for LI and with typically developing infants, to find specific markers with predictive and prognostic value.

Methods:

At 12 months of age, auditory processing in infants at-risk for ASD (HR-ASD; n = 20), for LI (HR-LI, n = 19) and controls (TD, n = 22) was characterized via EEG/ERP using a passive double-deviant oddball paradigm. Pairs of complex tones were presented at a rapid rate (70ms inter-stimulus interval). For standard tone-pairs (STD), the same tone characterized by a fundamental frequency of 100Hz and a duration of 70ms was repeated twice. Stimuli with the second tone differing in either frequency (300Hz, DEVF) or duration (200ms, DEVD) served as deviants and were presented in a pseudo-random order. Furthermore, all infants were then evaluated at 20 months of age, to prospectively investigate developmental trajectories from early auditory processing to autism-related traits (M-CHAT questionnaire) and language skills (Language Development Survey, LDS).

Results:

The results are intriguing and unique as this is the first study that provides abnormalities in ERP auditory processing profiles in ASD compared to LI high-risk infants and controls.

In both ASD and LI at-risk groups, the latency of the mismatch response is delayed compared to controls ($F_{(1,58)} = 3.58$, $p = 0.008$). On the other hand, only the group at-risk for autism shows enhanced P3 mean amplitude compared to infants at-risk for LI and controls ($F_{(2,58)} = 3.65$, $p = 0.032$). Correlational analyses revealed that infants with enhanced P3 amplitude at 12 months were characterized by higher scores in the ASD screening test at 20 months (U = 99.00; $p = 0.021$), whereas infants with faster mismatch response at 12 months produced more words at 20 months ($r_{(54)} = -0.291$, $p = 0.036$).

Conclusions:

The results reveal that at 12 months of age the two at-risk groups can be compared and differentiated based on their electrophysiological abnormalities in auditory processing, showing distinct predictive value on later socio-communicative and linguistic skills. These results may support the use of objective measurement of auditory processing to delineate specific pathophysiological mechanisms in ASD, as compared to LI. These results can help identifying infants at-risk for ASD and possibly provide specific markers that help to distinguish ASD from more specific linguistic delays.

19 **144.019** Do Infants at Risk for ASD Attend More to the Mouth When Watching Dynamic Videos?

***K. H. Finch**[1], H. Tager-Flusberg[2] and C. A. Nelson[3], (1)Boston University, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA, (3)Boston Children's Hospital, Boston, MA*

Background:

Typically developing 4- to 12-month-olds attend more to the mouth when watching videos of a woman speaking directly to them which is thought to aid in understanding speech (Lewkowicz & Hansen-Tift, 2011). This process might be impaired in infants who develop ASD as they show different gaze patterns to speaking faces (Shic et al., 2014). Moreover, differences in gaze patterns to speaking faces have been found in 9-month-olds who are at familial risk for ASD but do not develop ASD (Guiraud et al., 2012). However, it is unclear if this difference extends to all infants at risk for ASD.

Objectives:

Our current study investigated differences in gaze patterns in infants at risk for developing ASD. We included infants at familial risk and infants who fail a 12-month screener as well as an age-matched group of infants at low-risk.

Methods:

Participants

67 English-speaking 12- to 14-month-olds were divided into two groups: 1) low-risk typically developing controls (LR; N=47) or 2) high-risk for ASD (HR N=20) defined as either having an older sibling with ASD (HRA; N=10) or failing the Communication and Symbolic Behavior Scales Checklist (Wetherby & Prizand, 2002) at 12 months (HRS; N=10).

Procedure

Infants watched dynamic videos of a woman speaking directly to them on a Tobii T60 eye-tracker. The current study utilized a McGurk paradigm by presenting four video types up to 30 times each: 1)congruent-ba (Visual /ba/, Audio /ba/ or VbaAba), 2)congruent-ga (VgaAga), 3)incongruent-impossible (VbaAga), and 4)incongruent-McGurk (VgaAba).

Analysis

There were two areas of interest (AOIs): eyes and mouth. We calculated proportions by dividing the total amount of time looking at each AOI by the total amount of time looking at any portion of the face. We performed ANOVAs with condition (VbaAba, VgaAga, VbaAga, VgaAba) and AOI (eyes, mouth) as within-subjects factors and group (LR, HR) as a between-subjects factor.

Results:

There was a main effect of condition (F(3,195)=25.40, *p*<.001) with infants looking more towards the face in the congruent-ga and incongruent-McGurk conditions. There was a main effect of region (F(1,65)=6.46, *p*=.013) with infants looking more towards the mouth than the eyes. There was a condition by region interaction (F(3,195)=17.38, *p*<.001) that was driven by infants looking more towards the mouth in the congruent-ga and incongruent-McGurk conditions. There were no significant group differences. Moreover, preliminary analysis comparing LR, HRA, and HRS groups yielded similar results, including no group differences (see Figure 1).

Conclusions:

We found that LR and HR infants showed similar gaze patterns when watching videos of a woman speaking directly to them. All infants looked more towards the mouth, especially when the visual articulatory cues were less clear (/ga/ versus /ba/). While this work focuses on group level analysis, the data do show individual variability with some infants looking more towards the eyes while others attend more to the mouth. With larger sample sizes, future work should continue to investigate individual variability as well as group differences including distinguishing between infants who later develop ASD from those who are simply at risk for ASD.

20 **144.020** Understanding the Link between Language Abilities, Broader Autism Phenotype, and Atypical ERPs to Words in Toddlers with and without ASD

K. H. Finch[1]*, H. Tager-Flusberg*[2] *and C. A. Nelson*[3]*, (1)Boston University, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA, (3)Boston Children's Hospital, Boston, MA*

Background:

Atypical neural responses to speech have been found in toddlers with ASD and in their unaffected siblings (Kuhl et al., 2013; Seery et al., 2013). However, given that language difficulties are often seen in these populations, it is difficult to interpret whether these neural differences are a result of the ASD diagnosis or impairments in their language abilities.

Objectives:

Our study investigated event-related potentials (ERPs) to words in 36-month-olds with and without ASD, including those at familial risk with and without the broader autism phenotype (BAP). We also controlled for language abilities in our analyses.

Methods:

Participants

74 monolingual, English-speaking 36-month-olds were divided into four groups: low-risk control (LRC; N=31), high-risk for ASD (HRA; older sibling with ASD) without ASD or BAP (HRA-Typ, N=16), HRA without ASD with BAP (HRA-Atyp, N=13) and HRA with ASD (ASD; N=14).

Procedure

EEG was recorded while toddlers passively listened to a stream of words. Forty nouns were presented up to three times across two categories: 1) words acquired 'early' (understood by 18-month-olds according to the MCDI normative data) and 2) words acquired 'late' (not included on the MCDI; Dale & Fenson, 1996).

Analysis

Analysis focused on the mean amplitude of the N200 (200-350ms post-stimulus onset) and N350 (350-500ms post-stimulus onset) as their distribution varies depending on word familiarity (Mills et al., 2005). Two regions of interest from each hemisphere were constructed: frontal and temporo-parietal. We performed ANOVAs with condition (early, late), time bin (200-350ms, 350-500ms), and hemisphere (left, right) as within-subjects factors and group (LRC-Typ, HRA-Typ, HRA-Atyp, ASD) as a between-subjects factor. Average amplitude of the frontal and temporo-parietal sites were the dependent variables. We controlled for language abilities using the verbal developmental quotient from the Mullen Scales of Early Learning (Table 1).

Results:

Within the frontal sites, there were no significant main or interaction effects.

Within the temporo-parietal sites, we found a significant hemisphere by group interaction (F(3,69)=3.52, *p*=0.020). This interaction was driven by group differences in the left hemisphere (*p*=0.041), but closer inspection within the left hemisphere revealed no differences between the groups (all *p*>0.070). We found a significant condition by time by group interaction (F(3, 69)=2.96, *p*=0.038). This was driven by the HRA-Atyp children showing a more negative response in the N200 for the late words compared to the LRC-Typ (*p*=0.046) and ASD children (*p*=0.004). There were no other significant main or interaction effects.

Conclusions:

When controlling for language abilities, the HRA-Atyp group showed a different timed response to late words compared to the ASD and LRC groups in the temporo-parietal sites. This difference may reflect a weaker lexical representation of words in the HRA-Atyp toddlers compared to the LRC toddlers. The difference between the HRA-Atyp and ASD groups is surprising, but perhaps this is due to the variability often seen in the language abilities of children with ASD, including in our own sample. Our results suggest that both language abilities and ASD symptoms are important to consider when interpreting neural differences in lexical processing

21 **144.021** Early Motor Signs As Biomarkers of Neurodevelopmental Disorders: Applying Recent Findings in Autism to Attention Deficit Hyperactivity Disorder

A. Athanasiadou[1]*, J. K. Buitelaar*[2]*, O. Chorna*[3]*, F. Fulceri*[4]*, M. L. Scattoni*[4] *and A. Guzzetta*[5]*, (1)Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (2)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University*

Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (3)IRCCS Stella Maris, Pisa, Italy, (4)Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy, (5)IRCCS Stella Maris Foundation, Calambrone (Pisa), Italy

Background:

Increasing evidence suggests that specific motor behaviors observed during the first months of life may be a marker of autism spectrum disorders (ASD). Analogously, ADHD, which shows clinical and genetic overlap with ASD, is increasingly recognized as a neurodevelopmental disorder associated with atypical brain connectivity, likely resulting in abnormalities of neural function that are expressed through the quality of early movement patterns. However, the correlation between early motor signs and later diagnosis of ADHD is not yet understood, as research on the subject is scarce and the findings controversial. Some authors suggest that the activity level in infancy is an early sign of ADHD, while others argue that the quality of movements in infancy does not predict the outcome.

Objectives:

In order to shed light on early motor signs in ADHD we systematically reviewed the publications investigating motor behavior during the first year of life in infants that later develop ADHD symptoms or are diagnosed with the disorder.

Methods:

A literature search was performed on PubMed and PsycInfo databases. Our search included the following keywords: i) “ADHD” OR “Attention deficit hyperactivity disorder” OR “Attention deficit-hyperactivity disorder”; ii) AND “infant” OR “infancy” OR “neonatal” OR “newborn” OR “baby”; AND “movement” OR “motor” OR “sensory-motor” OR “sensori-motor” OR “motion”. In total, 170 articles were identified via database searching; 30 studies were selected for review of abstract or complete article.

Results:

Nine published reports were selected. The quality ratings of the included studies ranged between 11 and 14/14. Overall, the reports were of good quality. The review revealed conflicting evidence of the utility of infant motor activity as an indicator of ADHD. Some suggest that specific motor activity qualities in infancy may be utilized as early indicators of ADHD risk, while others state that infant motor activity does not predict the disorder.

Conclusions:

Early motor signs, if present, appear to be non-specific, and therefore not readily useful in clinical screening. Spontaneous motility seems to be a promising aspect of early ADHD detection, although further studies with large cohorts implementing quantitative and qualitative scoring systems are recommended to determine its clinical role in populations at risk for ADHD.

22 **144.022** Early Origins of Autism Comorbidity: Neuropsychiatric Traits Correlated in Childhood Are Independent in Infancy

***Z. Hawks**[1] and N. Marrus[2], (1)Department of Psychological & Brain Sciences, Washington University, St. Louis, MO, (2)Washington University School of Medicine, St. Louis, MO*

Background: Previous research has suggested that behavioral comorbidity is the rule rather than the exception in autism. This link between autistic and psychopathologic traits is reinforced by clinical studies indicating that autistic symptom severity is correlated with the severity of non-autistic behavioral impairments and, within families, some of the genetic influences on the causation of ASD have been shown to overlap with genetic influences on other psychiatric conditions of childhood. Critically, research into early developmental factors that contribute to the emergence of autism can guide therapies, as the condition is known to be strongly responsive to early intervention.

Objectives: Our primary aim was to evaluate shared genetic and environmental influences on quantitative autistic traits (QATs) and other early trait-based manifestations of general psychopathology to clarify the developmental origins of their overlap beginning in infancy. To this end, we prospectively examined previously uncharacterized relationships among early precursors of social communication, a core feature of QATs, and psychopathologic traits.

Methods: Social communicative traits (assessed using the *Social Communication and Interaction* scale from the Video-Referenced Ratings of Reciprocal Social Behavior and the *Competence* scale from the Brief Infant-Toddler Social and Emotional Assessment; vrRSB *SCI* and BITSEA *Competence*, respectively) and early liability for general psychopathology (assessed using the *Behavior Problems* composite from the BITSEA) were assessed at 18 months of age in 314 twins ascertained from the general population. 222 twins were re-evaluated at 36 months of age, at which point QATs were assessed using the Social Responsiveness Scale (SRS) and internalizing and externalizing behaviors were assessed using the Achenbach Scales of Empirically Based Assessment. Patterns of trait overlap at 18 months were evaluated using correlational analyses, exploratory factor analyses, and hierarchical linear modeling (HLM). HLM was also used to evaluate the predictive utility of 18-month on 36-month traits.

Results: Standardized ratings of variation in social communication (i.e., *SCI, Competence*) at 18 months were highly heritable and strongly predicted *QATs* at 36 months. These early indices of autistic liability were independent from contemporaneous ratings of *Behavior Problems* (Figure 1), which were predominantly environmentally-influenced. Autistic liability did not significantly, incrementally predict CBCL *Internalizing* or *Externalizing* scores at 36 months (Figure 2).

Conclusions: We observed that variation in social communication was independent from variation in other domains of general psychopathology and exhibited a distinct genetic structure. This suggests that the commonly-observed comorbidity of specific psychiatric syndromes with autism may arise from subsequent interactions between autistic liability and independent susceptibilities to other psychopathologic traits. Indeed, given that studies in older children have identified shared genetic variance for autistic impairment and symptoms of general psychopathology, these results are consistent with a model of causal overlap in which inherited liability for *non-specific* psychopathologic symptoms can amplify the severity of autistic syndromes over the course of development. This suggests opportunities for preventive amelioration of their interactions in infancy, perhaps via interventions to target developmentally-independent, behaviorally-modifiable traits that may conspire to exacerbate autistic severity over the course of development.

23 **144.023** Early Risk Markers of Social Anxiety in Infants with Fragile X Syndrome

***C. J. Black**[1], A. L. Hogan[1], J. E. Roberts[2] and N. Poupore[1], (1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Psychology, University of South Carolina, Columbia, SC*

Background: Fragile X syndrome (FXS) is a neurodevelopmental disorder that typically presents with intellectual disability and an increased prevalence of maladaptive behaviors (Cornish et al., 2013). FXS is the most common genetic cause of autism spectrum disorder (ASD) accounting for 2-6% of ASD cases (Cohen et al., 2005). Both FXS and ASD have high comorbidities with anxiety disorders which often are not diagnosed until later in development (Cordeiro et al., 2010; Kessler et al., 2005). Given that early features of social anxiety are present before formal diagnoses, prospective studies of infants with FXS provides a unique opportunity to study the earliest predictors of anxiety. In typically developing (TD) infants, elevated fear and atypical physiological regulation (e.g., respiratory sinus arrhythmia, RSA) have been identified as early markers of the later emergence of social anxiety. (Booker et al., 2013). No studies have examined behavioral fear or physiological regulation as risk markers of social anxiety in infants with FXS.

Objectives: The current study uses a bio-behavioral approach to investigate differences in social fear responses in 12-month-old infants. We hypothesized that physiological regulation during social interactions is disrupted in FXS, causing them to exhibit a dampened physiological response to a novel social situation. Additionally, we believed that FXS infants would have higher parent reported fear in comparison to TD.

Methods: Participants included 18 infants with FXS (Male: n =12, chronological age: M =13.01 months, SD=1.02) and 30 TD infants (Male: n = 23, chronological age M=12.41 months, SD=0.61). The fear subscale from the Infant Behavior Questionnaire-Revised (IBQ-R) reflects scores associated with both social and non-social fear. Physiological response to a novel social scenario was measured via heart activity monitor during a baseline period and during the Stranger Task of the LABTAB (Goldsmith & Rothbert, 1996). This task is designed to elicit a social fear response in young children. RSA reactivity was computed as the change in RSA from baseline to stranger task.

Results: The difference between groups on the IBQ-R was not significant, $t(33) = 0.37$, $p > 0.05$. Moreover, there was no difference between groups in RSA reactivity $F(1,36) = .14$, $p > 0.05$. Paired sample t-tests were conducted between baseline and stranger RSA for each group. The TD group showed a significant decrease from baseline ($M = 4.61$, $SD = 1.03$) to stranger task (M = 3.84, $SD = .0.76$), $t(22) = -3.80$, $p < .001$. The FXS group did not show a difference between baseline ($M = 4.49$, $SD = 1.41$) and stranger task ($M = 3.79.50$, $SD = 1.43$), $t(15) = 2.08$, $p > .05$.

Conclusions: These results provide intriguing insights into the early physiological risk markers of social fear. Despite the lack of elevated fear in the FXS group, the blunted RSA response to social fear shows a potential early biomarker of social anxiety. Having a physiological biomarker reflecting prodromal symptomology could be instrumental to early identification and treatment of social anxiety in FXS and other high risk populations like ASD. Future studies, should investigate infant's behavioral responses in tandem with RSA regulation.

24 **144.024** Effects of a Parent Mediated Intervention on Positive Social Behavior of Toddlers with Autism: A Randomized Controlled Trial

***K. Baggett**[1], B. Barger[2], H. Schertz[3] and S. Odom[4], (1)Mark Chaffin Center for Healthy Development, School of Public Health, Georgia State University, Atlanta, GA, (2)Georgia State University, Atlanta, GA, (3)Indiana University, Bloomington, IN, (4)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: The purpose of this presentation is to report the results of a randomized controlled trial in which we examined the effects of a parent mediated intervention on the social behavior of toddlers with autism spectrum disorder (ASD). The Joint Attention Mediated Learning (JAML) program is a parent-mediated, relationship-based, developmentally oriented intervention focused primarily on supporting joint attention learning. While prior research has demonstrated large effects of the JAML intervention on the important targeted outcome of child joint attention, no published studies have examined potential effects of the JAML program on child social behavior, in general, or on parent positive support behaviors as potential mediators of child change.

Objectives: Research objectives include (a) examination of JAML effects on toddler positive social behavior directed toward their parents and (b) exploratory examination of the effects of JAML on parent positive support behavior and its relationship to child positive social behavior.

Methods: Twenty-three toddlers with Autism Spectrum Disorder, age 15 to 30 months, and their parents in Colorado, Kansas, Missouri, and Indiana were randomized to the JAML intervention group or a control group. Eligibility screening with the Autism Diagnostic Observation Schedule (ADOS-2) was conducted to establish ASD for inclusion. Parent-child free-play interactions at home were video recorded at pre- and post-assessment. Trained observers, naïve to group assignment and time point, completed the Indicator of Parent-Child Interaction (IPCI-2) based on direct observation of parent-child interaction videos. Mean interobserver agreement for child and parent behaviors was .86 and .85 (R= .74-.98 and .76-.96), respectively.

Results: While there were no significant differences in observed child behaviors or parent positive support behaviors between the intervention and control group at pre-assessment, toddlers in the intervention group, in contrast to the control group, demonstrated significant pre-post gains in positive social behavior toward their parents ($t(10) = -4.05$, $p < .01$) and follow through behavior ($t(10) = -2.50$, $p < .05$) with large to medium effects (d=1.29, d=.72, respectively). Exploratory analysis revealed a medium effect (d=.58) on parent following child's lead from pre- to post-assessment for parents in the JAML intervention group as compared to parents in the control group. Parent following child's lead was positively correlated with child positive social behavior (r=.38) and child follow through (r=.60), p<.05.

Conclusions: These pilot and exploratory results build on prior published work and provide preliminary evidence of JAML effects beyond the primary targeted child outcome of joint attention. Specifically, effects extended more generally to parent-child interaction, including positive toddler social and engagement behavior toward their parents. The finding of medium effects of the JAML intervention on parent positive support behavior, in particular, following child's lead, which was significantly correlated with child positive engagement behavior, points to the need for conducting sufficiently powered controlled trials to determine JAML effects on parent positive support behaviors and their potentially mediating effects on child positive social behavior.

25 **144.025** Electroencephalographic Markers of Atypical Development in Infants with Tuberous Sclerosis Complex

***K. J. Varcin**[1], A. H. Dickinson[2], C. A. Nelson[3] and S. Jeste[2], (1)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (2)University of California, Los Angeles, Los Angeles, CA, (3)Boston Children's Hospital, Boston, MA*

Background: Tuberous sclerosis complex (TSC) is one of the most commonly-occurring single-gene disorders associated with ASD. Recent work from our group has demonstrated that at the behavioral level, infants with TSC/ASD can be distinguished from infants with TSC/noASD by 12 months, and that by 3 years, infants with TSC/ASD show striking phenotypic homology in the profile of social communication impairment to that

of toddlers with non-syndromic ASD. In animal models, mutations in the TSC1/2 gene (through downstream effects on the mTOR pathway) have been linked to alterations in synaptic development and neuronal connectivity, which likely exert effects from very early in development. There is currently limited understanding regarding developmental trajectories of brain function in human infants with TSC, and especially those that go on to develop ASD.
Objectives: We aimed to identify potential neural markers associated with the development of ASD in TSC. Specifically, we examined whether developmental trajectories of electroencephalographic (EEG) power (as a marker of neural synchrony) and coherence (as a measure of connectivity) distinguish infants with TSC/ASD from infants with TSC/noASD from very early in development.

Methods: These data were collected as part of a multisite, prospective study of infants with TSC (n=40) and typically developing (TD) infants (n=32) across the first three years of life. Baseline EEG was recorded from infants at 9, 12, 18, 24 and 36 months using a high-density system (EGI Inc.). ASD diagnosis at 24 and 36 months was determined using the Autism Diagnostic Observation Schedule and clinical best estimate. We assessed developmental functioning using the Mullen Scales of Early Learning and we collected clinical information regarding epilepsy and medication status across development.

Results: Mixed-effects models revealed differences in developmental trajectories of both EEG alpha power and alpha phase coherence between (i) TSC and TD infants, and (ii) TSC/ASD and TSC/noASD. TSC infants had reduced whole-brain alpha power across early development (from 9-36mo) compared to TD infants (p<.001). From 12 months, alpha power trajectories differentiated TSC/ASD infants from TSC/noASD, with TSC/ASD infants showing the lowest levels of whole-brain alpha power (p<.01). We also identified significant differences in alpha phase coherence across early development between TSC/ASD and TSC/noASD infants from 12 months (t(24)=2.07, p<.05). These differences were identified despite overall comparable rates of seizures and medication exposure between the TSC/ASD and TSC/noASD groups.

Conclusions: We identified differences in brain function between infants with TSC/ASD and TSC/noASD from 12 months of age, well before the age at which an ASD diagnosis may be established in this population. Our findings suggest that EEG may show promise in identifying patterns of brain function that may precede or underlie the development of ASD in TSC. In particular, group differences in alpha trajectories are suggestive of alterations in white matter development in TSC/ASD. These findings highlight the need for further prospective studies mapping early brain function in TSC from within the first year of life, to identify whether differences in developmental trajectories may precede even the earliest emerging behavioral signs of ASD.

26 **144.026** Emerging Divergence between Cognition and Adaptive Socialization Skills in Infants Who Develop ASD

C. A. Saulnier[1], *J. Bradshaw*[2] *and C. Klaiman*[1], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Department of Psychology, University of South Carolina, Columbia, SC*

Background:

Individuals with ASD exhibit delays in adaptive skills in comparison to age and IQ, and this gap appears wider in older versus younger individuals of average intelligence (Klin et al., 2007; Kanne et al., 2010). Since the majority of individuals with ASD do not have cognitive impairment (CDC, 2016) but still fail to achieve levels of independence in adulthood (Howlin et al., 2004; 2013), it is imperative to determine when this divergence emerges.

Objectives:

This study investigates the discrepancies between adaptive socialization and cognitive skills from 12 to 36 months in infants who develop ASD.

Methods:

Participants included 171 infants (60.2% male; 90.1% White; 2.9% Black; 7% Other) participating in a longitudinal study on ASD from birth through age 3 with the following outcome diagnoses: ASD=21; Broader Autism Phenotype (BAP)=19; High Risk Unaffected (HR-UA)=29; and Low Risk Typical Development (LR-TD)=102. Infants were assessed at 12, 24, and 36 months (12 and 24m for LR) with the *Mullen Scales of Early Learning* and the *Vineland Adaptive Behavior Scales, Second Edition, Survey Form*. Mullen Visual Reception scores were used as a proxy for nonverbal cognition (See Table 1). Mixed effects linear growth regression models were conducted to compare linear trends between cognitive and socialization skills from 12-36 months across diagnostic groups. Linear trend estimates derived from these models were compared across groups using slopes with the associated 95% confidence intervals.

Results:

Regression slopes for adaptive socialization scores declined significantly from 12-36 months for the HR-ASD ($t(118)=-3.27$, $p=0.001$) and HR-BAP ($t(107)=-3.70$, $p<0.001$) infants (Figure 1). In contrast, socialization skills did not decline for HR-UA or LR-TD infants. Socialization scores for HR-ASD infants were significantly lower than LR-TD infants starting at 12-months, and lower than both LR-TD and HR-UA infants at starting at 24-months. In contrast, cognition for all groups remained stable from 12 to 24/36 months. Regarding the gap between adaptive socialization and cognitive skills, a significant interaction emerged for HR-ASD ($t(99.3) = 2.95$, $p=0.004$), HR-BAP ($t(89.4)=3.68$, $p<0.001$), and LR-TD ($t(301)=2.21$, $p=0.028$) infants, but slope trajectories for each domain for the LR-TD group did not differ significantly from zero (socialization $p=0.109$; cognitive $p=0.145$).

Conclusions:

Adaptive socialization skills decline between 12 and 36 months for infants with both ASD or shadow symptoms of the disorder in comparison to both unaffected HR and LR infants, with differences evident as early as 12 months between infants who develop ASD and their unaffected peers. Though our sample has unusually high nonverbal cognition (which accounts for the significant gaps between cognition and adaptive skills in the LR-TD group), the gap between adaptive socialization skills and cognition widens over time for infants with ASD symptomatology, whereas it remains stable for infants unaffected by ASD. Given the pronounced deficits in adaptive behavior that are observed in older individuals with ASD, these findings underscore the need to assess for adaptive behavior early and repeatedly for infants with and at risk for the disorder.

27 **144.027** Emotional Face Processing and Spatial Frequency in 10-Month-Old Infants at Risk for Autism.

R. Di Lorenzo[1], *N. Munsters*[1], *C. van den Boomen*[1], *C. Junge*[2], *E. Ward*[3] *and C. Kemner*[1], *(1)Utrecht University, Utrecht, Netherlands, (2)Department of Developmental and Experimental Psychology, Utrecht University, Utrecht, Netherlands, (3)Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands*

Background: People diagnosed with Autism Spectrum Disorder (ASD) frequently experience problems in rapidly processing emotions. Furthermore, they often focus more on local details than on coarse global information. According to previous research, these two visual abnormalities are related, at least in early childhood: toddlers with ASD can discriminate emotions only when a face contains just local (but not global) information, whereas control children show the opposite pattern (Vlamings et al., 2010). It remains unclear when the developmental trajectory of visual processing becomes atypical in ASD.
Objectives: The present research tests whether already at 10 months of age infants at risk of developing ASD (i.e., siblings of a child with ASD) differ from a control group of infants at low risk for ASD (i.e., siblings of a child without ASD). Specifically, we investigated group differences in electrophysiological activations evoked by fearful and neutral faces filtered to contain only local or global information (See Figure 1).

Methods: Forty participants (22 high-risk and 18 low-risk 10-month-olds) were included in the preliminary data-analyses (we are planning to test more infants). We recorded their EEG, while participants passively watched emotional expressions (fearful or neutral expression) of faces containing only detailed (higher spatial frequencies, HSF) or global information (lower spatial frequencies, LSF).

Results: Our analyses focused on typical infant ERP components associated with face processing: N290 and P400. Mean peak amplitudes for each component were entered in a 2 (fear; neutral) by 2 (detailed; global) ANOVA, with group-membership as a between-subjects variable. Preliminary results show that the groups differ significantly on the amplitudes for both ERP components ($p < .05$), with the high-risk group having smaller amplitudes compared to the low-risk group. No other significant effects were found (all $p > .10$).

Conclusions: Our preliminary results show no differences between high and low-risk 10-month-olds in emotion discrimination or in the processing of detailed vs. global information, which suggests that this visual processing starts to deviate later on in development. However, we found that overall the high-risk group has a reduced cortical response to facial stimuli compared to low-risk infants. This could indicate that atypical face perception is an endophenotype of ASD. Possibly, in infants later diagnosed with ASD this impairment develops into atypical emotion discrimination that was reported in toddlers.

28 **144.028** Emotional Response Coherence in Toddlers with ASD

A. Zakin[1], *S. Macari*[1], *F. E. Kane-Grade*[2], *K. Villarreal*[1], *H. Neiderman*[1], *M. Wilkinson*[1], *E. Hilton*[1], *A. Milgramm*[3], *P. Heymann*[1], *L. DiNicola*[4], *D. Macris*[1], *K. K. Powell*[1], *S. Fontenelle*[1], *M. Lyons*[1] *and K. Chawarska*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (3)Center for Autism and Related Disabilities, Albany, NY, (4)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: The theory of emotions as tripartite complexes postulates that emotions are conveyed by facial expressions, vocalizations, and body postures (Izard, 1977). Expressive incoherence is the mismatch in the expression of emotions across channels. There is very limited data regarding coherence across expressive channels in ASD. A recent study suggests that in response to in-vivo probes eliciting frustration, school-age children with ASD show a mismatch between their facial and bodily expressions, especially during negatively-valenced events (Costa et al., 2017). This limited coherence across emotion expression channels could lead to problems in the parent-child dyad, as caretakers may have difficulty accurately reading the emotional state of children with ASD. Little is known about the existence of emotional expressive incoherence at the earliest stages when ASD can be reliably diagnosed.
Objectives: To examine if toddlers with ASD exhibit expressive incoherence compared with age-matched peers with developmental delays (DD) and typical development (TD) in response to in-vivo probes aimed at eliciting anger, fear, and joy.

Methods: 83 toddlers (ASD, n=43; TD n=40) ages 13-30 months (M=21) completed nine episodes of the Laboratory-Based Temperament Assessment Battery (Lab-TAB; Goldsmith & Rothbart, 1999). Episodes were designed to elicit Anger, Fear, and Joy. The assessments were videotaped and coded offline by blinded coders for intensity of emotional responses during Fear, Joy, and Anger probes separately in the facial, vocal, and musculoskeletal channels. Within each emotion, Pearson's r correlations were used to compare the strength of associations across pairs of channels (facial-bodily, vocal-bodily, and facial-vocal) and Fisher r-to-z transformations were used to test the significance of the difference between correlations.

Results: In general, the correlations between the channels within ASD and TD groups were statistically significant with the magnitude of the effect ranging from r=.313 to r=.863 in the ASD group and from r=.339 to r=.692 in the TD group (Figure 1). Comparison of the magnitude to coherence (Pearson's r) between the two groups identified only two differences, both in the Joy condition. Specifically, there were significant differences between the ASD and TD groups in two pairs: facial-vocal expression coherence (p=.02), and bodily-vocal expression coherence (p=.01). In both cases, the ASD toddlers evidenced higher emotional coherence than the TD toddlers.

Conclusions: Our results indicate that TD toddlers and toddlers with ASD largely evidence similar emotional coherence across the three channels of emotional expression during tasks designed to elicit anger, fear, and joy. Contrary to our hypotheses, the bodily-vocal channels and the facial-vocal channels appear more coherent among children with ASD than TD children in the Joy condition. Our data do not provide support for emotional response incoherence in ASD.

29 **144.029** Face Looking, Eye Contact, and Joint Attention during Naturalistic Toy Play: A Dual Head-Mounted Eye Tracking Study in Young Children with ASD.

D. P. Kennedy[1], *G. Lisandrelli*[1], *R. Shaffer*[2], *E. Pedapati*[3], *C. A. Erickson*[3] *and C. Yu*[1], *(1)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (2)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (3)Division of Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Although numerous studies have identified abnormalities in social attention and social coordination in children with ASD, evidence of such abnormalities comes almost exclusively from laboratory experiments involving discrete trials and/or highly simplified screen-based stimuli. Very little is known about whether and how young children with ASD allocate and coordinate visual social attention in everyday life, which is characterized by moving heads and eyes, changing views of faces, and multiple competing visual targets.
Objectives: Using dual head-mounted eye tracking during naturalistic parent-child toy play, we assessed whether young children with ASD ages 24 to 48 months exhibit abnormalities in three social behaviors that have previously distinguished children with ASD from typically developing children in traditional laboratory-based studies: (1) face looking, (2) mutual eye contact (i.e., moments in which both the parent and child look at

each others' faces), and (3) joint, or shared, attention on objects.

Methods: Twenty-three parent-child dyads (N = 7 ASD; N = 16 TD) provided usable eye tracking data (out of 39 dyads tested: 20 ASD, 19 TD). Parents and children were fitted with head-mounted eye trackers, and were free to play with 24 different toys for five minutes. Parents were instructed simply to play with their children as they typically would at home. Offline data processing was carried out using a manual coding procedure, in which the targets of gaze for both the parent and child were coded separately. Joint attention was objectively identified as moments where both the parent and child looked at the same object at the same time. See Figure 1.

Results: Both ASD and TD children spent remarkably little time looking at faces [ASD: 1.2% (±1.3%); TD: 1.4% (±1.8%); t(18)=-.34, p=0.74, d=0.15], amounting to approximately six seconds of face looking over the course of a five-minute interaction. Interestingly, parents of children with ASD tended to look more at their children's faces [23%(±4%)] than did parents of TD children [12% (±8%)] [t(18)=-3.1, p=0.006, d=1.7]. Mutual eye contact was an extremely rare event, [TD: 0.6% (±0.8%); ASD: 0.7% (±1.4%)], and rates did not differ between groups (t(18)=-0.14, p=0.89, d=0.06). Joint attention was quite common in both groups [TD: 48% (±17%); ASD: 45% (±15%)], but also did not differ between groups [t(18)=0.32, p=0.76, d=0.16]. Proportions of parent-led versus child-led joint attention bouts were not different between the groups [t(18)=-0.25, p=0.81, d=0.11)].

Conclusions: Our results suggest that findings from screen-based and highly constrained studies may not always translate to more naturalistic behavior. We found that children with and without ASD rarely looked at faces, in contrast to what would be predicted from screen-based eye-tracking studies. Furthermore, an important behavior reflecting coordinated social engagement — namely, joint attention — was present and occurred at typical levels among the ASD dyads, suggesting multiple routes beyond face looking to achieve coordination (Yu & Smith, 2013). Future studies will examine additional aspects of naturalistic parent-child dyadic interaction in ASD, including vocalizations, object exploration, and sustained attention.

30 **144.030** First Year Inventory Attention Constructs in Infants at Risk for Autism Spectrum Disorders

D. Macris, *S. Macari, K. K. Powell, S. Fontenelle, M. Lyons, A. Giguere Carney, K. Bailey and K. Chawarska, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Atypical patterns of attention are thought to be early predictors of autism spectrum disorders (ASD; Chawarska et al., 2016; Keehn et al., 2013). Parent report of attentional patterns could provide crucial information in early identification of ASD. One screener, the First Year Inventory (FYI; Baranek et al., 2003) shows promise in identifying 12-month-olds at risk for later ASD diagnosis (Reznick et al., 2007; Rowberry et al., 2014). The FYI may also be valuable in evaluating early attentional behaviors. Stephens et al. (2017) developed three new scores for the FYI: Responding to Social Attention (RSA), Initiating Social Attention (ISA), and Nonsocial Sensory Attention (NSA). These attention constructs predicted general social responsiveness at 3 years, but it is unclear how well the constructs predict diagnostic status or other aspects of development.

Objectives: To investigate how the attention constructs of the FYI relate to developmental outcomes at 24 months in infants at high and low risk for ASD.

Methods: Parents of 102 infants with older siblings diagnosed with ASD (HR; 70 male) and 63 infants with no family history of ASD (LR; 32 male) completed the FYI around their child's first birthday. At 24 months, children completed the Mullen Scales of Early Learning (MSEL), ADOS-T, and Vineland-II. Based on outcome diagnoses at 24/36 months of age, participants were categorized as: ASD (n=18), LR typically-developing (LR-TYP; n=50), HR typically-developing (HR-TYP; n=37), and children with other developmental delays (ATYP; n=60).

Results: One-way ANOVAs revealed significant effects of diagnostic group in RSA, $F(3,161)=5.92$, $p<.01$, and ISA, $F(3,161)=5.79$, $p<.01$, but not in NSA scores. Post-hoc Tukey HSD tests revealed that for RSA, LR-TYP children scored lower than children with ASD or ATYP, both $p<.05$ (Figure 1). For ISA, LR-TYP children scored lower than ASD, ATYP, and HR-TYP children, all $p<.05$. Multiple regressions showed that attention constructs from the FYI at 12 months predicted the following at 24 months: MSEL Verbal Developmental Quotient (VDQ), $F(3,161)=6.46$, $p<.01$, $R^2=.11$; MSEL Nonverbal Developmental Quotient (NVDQ), $F(3,161)=2.77$, $p=.04$, $R^2=.05$; Vineland Communication SS, $F(3,151)=6.60$, $p<.01$, $R^2=.12$; Vineland Daily Living SS, $F(3,151)=3.67$, $p=.01$, $R^2=.07$; and Vineland Social SS, $F(3,151)=6.09$, $p<.01$, $R^2=.11$. RSA was a significant predictor in the Vineland-II Communication model; ISA was a significant predictor in the MSEL VDQ and Vineland-II Daily Living and Social models; and NSA was a significant predictor in the MSEL VDQ model, $p<.05$ and a marginally significant predictor in the MSEL NVDQ model, $p=.06$. The attention constructs did not predict ADOS-T total scores or Vineland-II Motor SS, $p>.28$.

Conclusions: Children later diagnosed with ASD and other developmental delays scored more atypically on two of the three FYI attentional constructs (RSA and ISA) than LR typically-developing children. Furthermore, the constructs differentially predicted the cognitive ability and adaptive behavior of the children one year later. This suggests that parent-reported information via the new attentional constructs of the FYI show promise not only in identifying children who are at risk for developing ASD, but also predicting later vulnerabilities in verbal and nonverbal development and adaptive behavior.

31 **144.031** Gaze Behavior of 9- and 13-Month-Old Infants during Live Face-to-Face Interactions: Joint Attention Observed with an Eye-Tracking System.

M. Asano[1], *N. Naoi*[2], *Y. Hakuno*[1], *J. Yamamoto*[1] *and Y. Minagawa*[1], *(1)Keio University, Tokyo, Japan, (2)International Christian University, Mitaka, Japan*

Background:
Initiating joint attention (IJA) using gaze shift is suggested to appear around 9–12 months (Bakeman & Adamson, 1984). Typically developing (TD) infants older than 12- month- old control their gaze shift without adult support. During development, children show various combinations of joint attention behaviors such as gaze shifting, pointing, and verbalizing (Oyabu, 2004; Seibert, Hogan, & Mundy, 1987; Tomasello, 1995)

Autism spectrum disorder (ASD) is characterized by deficits in social interaction and communication. Since joint attention seems to precede the onset of theory of mind, the ability to share attention with others plays an important role in the development of social cognition in infancy. However, little is known about infants' gaze behavior in the naturalistic context of joint attention.

Objectives:

We examined gaze behavior of 9- and 13-months-old typically developing infants and infants at-risk for ASD during live face-to-face interactions for IJA using an eye-tracking system.

Methods:

Data of 20 infants was analyzed in this preliminary study. They participated the sessions at their age of 9- and 10-months-old and 12-and 13-months-old. During the recording an infant sat on the parent's lap facing to a live female experimenter. The experimenter presented the infant a wind-up toy for 20 s to elicit shared attention between the experimenter's face and toy. The infant's gaze behavior was recorded during interactions using Tobii eye-tracker (Tobii x-2-60, Sampling rate: 60 Hz). We separated participants into two groups for each age: 9- and 10-months-old group consisted of 11 TD infants and 9 infants at-risk for ASD. 12- and 13-months-old group consisted of 8 TD infants and 8 infants at-risk for ASD. We conducted the t-test between each groups to analyze looking time for object (toy) and face.

Results:

Our results revealed that during IJA, the 9-and 10-months-old TD infants looked at the toy and experimenter's face longer than the infants at-risk for ASD (t (10) =1.95, p=0.07). For 12- and 13-months-olds, on the other hand, the infants at-risk for ASD looked at the toy longer than the TD infants. However, only marginal significance was observed for this difference (t (10) =1.95, p=0.07).

Conclusions:

Although this is very preliminary study with limited participants, we were able to show that we can capture the eye gaze during social interaction. This method could show the early signs of social deficits for the infants at-risk for ASD during naturalistic social interactions. We will collect more data to discuss about the group difference in the poster.

32 **144.032** Gender Differences during Toddlerhood in Autism Spectrum Disorder: A Community-Based Longitudinal Follow-up Study

L. P. Lawson[1,2], *R. Joshi*[3], *J. Barbaro*[4] *and C. Dissanayake*[4], *(1)Olga Tennison Autism Research Centre, La Trobe University OTARC, Melbourne, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)Autism Spectrum Australia, Melbourne, Australia, (4)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background:

Due to the large disparity in prevalence of Autism Spectrum Disorder (ASD) between the genders (3-4 males for every female), differences between diagnosed males and females have long been of interest. The few studies that have investigated gender difference in infants and toddlers focus on differences at one point in time within clinically referred samples or high-risk infant cohorts. It is important to consider children's developmental trajectories when examining early gender differences in ASD. Further, it is important, where possible, to examine gender differences in samples not subject to the biases inherent in high-risk and clinical cohorts.

Objectives:

The aim in the current study was to examine gender differences in early autism manifestations and cognitive development in a low risk community-ascertained sample of children with ASD from 24 to 48 months of age.

Methods:

Participants were drawn from the Social Attention and Communication Study (SACS; Barbaro & Dissanayake, 2010), where trained Maternal and Child Health nurses undertook developmental surveillance of children in a low-risk community-based setting during their routine child checks. Following identification of early markers of ASD, children were referred for a behavioural and developmental assessment. Sixty-seven participants (46 males; 21 females) who received a diagnosis of ASD at 24-months of age and attended a follow-up assessment 2-years later comprised the study sample. Research reliable clinicians administered the Mullen Scales of Early Learning and Autism Diagnostic Observation Schedule at both time points.

Results:

No significant gender differences were observed on verbal, non-verbal, or overall cognitive ability at either time point. However, there was a significant main effect of time, such that both males and females with ASD improved in their verbal ability, and hence overall cognitive ability, from toddlerhood to preschool. In regards to autism manifestations, no significant differences were found between males and females on overall autism severity or restricted, repetitive behaviours. However, there was a significant gender difference within the social affect scale, such that females with ASD had more severe social-communication impairments compared to males at both time points. In addition, both genders improved significantly across time on overall autism severity, restricted repetitive behaviours, and social affect.

Conclusions:

The only gender difference in our very young community-based sample of children with ASD was in social communication, where females had more social-communication impairments than males. This finding may reflect that toddler females with fewer or different social attention and communication impairments may not be identified during routine developmental surveillance of social attention and communication behaviours, and thus not referred for an ASD assessment prior to 24 months of age. Further, the improvements observed in both genders on verbal ability and autism manifestations from toddlerhood to preschool age supports the rationale of early identification and intervention for children with ASD.

33 **144.033** Genetic and Environmental Contributions to a 2-Factor Model of Social Communication in Toddler Twins

N. Marrus[1], *J. Grant*[2], *A. Glowinski*[2], *A. Agrawal*[2], *T. Jacob*[3], *B. Harris-Olenak*[4], *A. C. Heath*[2], *J. N. Constantino*[1] *and J. T. Elison*[5], *(1)Washington University School of Medicine, St. Louis, MO, (2)Washington University in St. Louis, St. Louis, MO, (3)Veterans Affairs Palo Alto Health Care System, Palo Alto, CA, (4)Family Research Center/VA Palo Alto HCS, Menlo Park, CA, (5)University of Minnesota, Minneapolis, MN*

Background: Elucidating the early phenotypic and genetic architecture of autistic traits is critical for resolving developmental mechanisms underlying autism spectrum disorder (ASD), a highly heritable condition. Previously, we have shown that the video-referenced rating scale of reciprocal social behavior (vrRSB) quantifies continuous variation in autistic traits among toddlers in the general population and differentiates toddlers with ASD. Here we capitalize on the vrRSB to model the phenotypic and genetic structure of social communication, a core ASD symptom domain, during toddlerhood, when autistic symptoms commonly emerge.
Objectives: 1) To characterize the factor structure for social communication in toddlers. 2) To determine genetic and environmental contributions

to early social communication. 3) To examine continuity of these influences during toddlerhood.

Methods: Parental ratings on the vrRSB were collected in two toddler-aged populations: 1) an epidemiologic, longitudinal twin sample identified through birth records in Missouri and California (n=317 twin pairs) and 2) a research participant registry at the University of Minnesota (n=1870). Social communication was indexed using the 13 video-referenced items on the vrRSB, in which caregivers rate their child in comparison to a typically developing scoring anchor presented by video. An exploratory factor analysis (EFA) was performed for ages 18 and 24 months using the larger Minnesota sample, followed by confirmatory factor analysis (CFA) at both ages in the twin sample. A quadrivariate twin model assessed the degree of genetic and environmental influences on the factor structure for social communication at ages 18 and 24 months, as well as the covariance between genetic and environmental influences on latent factors within and across time points.

Results: EFA identified two factors at both 18 and 24 months, an “affective engagement factor” and a “functional communication factor” (Table 1). A CFA demonstrated good model fit for these 2 factors at both ages (legend, Table 1). Twin modeling revealed substantial genetic contributions (A) and modest shared environmental (C) and unique environmental (E) contributions to factor scores at both ages (Table 2). Genetic influences explained 58-80% of the variance in the factors, with C explaining an additional 6-18% and E explaining 15-25% of the variance. Genetic correlations between factor scores within and across age were all significant and substantial, ranging from 0.69-0.90. Shared environmental influence on all factors was entirely overlapping, with no evidence of factor-specific C. Unique environmental correlations were more modest: within-age correlations between factors were estimated at 0.66 at 18 and 24 months and moderate correlations were observed for 24-month Factor 1 and both 18-month factors (rE=0.31-0.44). No significant cross-age, unique environmental correlations were observed for Factor 2.

Conclusions: In keeping with the high heritability of ASD, variation in early social communication appears largely attributable to heritable capacities for affective engagement and functional communication. Genetic influences on these factors showed strong continuity in toddlers, suggesting a potential mechanism for known stability of autistic traits. Measurable environmental influences on social communication highlight the opportunity to enhance early interventions for ASD through research identifying elements of early experience which ameliorate deficits in social communication.

34 **144.034** Genetic-Independence of Key Early Contributors to Autistic Trait Severity

A. Pohl *and J. N. Constantino, Washington University School of Medicine, St. Louis, MO*

Background: Previously, in separate lines of research, we have shown that social visual engagement (Constantino et al., *Nature*, 2017) and quantitative autistic traits (QAT, see Constantino and Charman, *Lancet Neurology* 2016) constitute highly-heritable autism endophenotypes. Here, we examine the relationship between these and other highly- heritable predictors of autism recurrence in infancy and early childhood.
Objectives: In a prospective longitudinal study of epidemiologically-ascertained infant twins, we examined the extent to which variation in social visual engagement at 18-24 months, familial QAT background, inattention at 36 months, and variation in motor coordination at 36 months predicted quantitative autistic trait burden at 48 months.

Methods: Visual social engagement was measured using eye tracking methods as described in Constantino et al. (2017), involving infant viewing of social scenes on video, and deriving for each subject a total proportion of visual orientation to eyes, mouths, bodies, and objects. We obtained ratings of variation in attention and motor coordination by parent report using respectively Achenbach’s Child Behavior Checklist and the Developmental Coordination Disorders Checklist (DCDQ). We derived a quantitative index of parental QAT using the biparental mean of the adult SRS-2 completed by spouse report.

Results: Remarkably, despite the established relationship of each predictive phenotype to autism, none were correlated with one another in early childhood ($p>0.05$ with false discovery correction applied), overwhelmingly indicating that they constitute non-overlapping traits. Moreover, Bayesian regression revealed that visual social engagement—despite its strong association with categorically-defined autism—did not predict variation in QAT among normal 48 month olds in this population sample. In contrast, biparental mean QATs was a distinct positive predictor of child QAT and explained 6% of the variance in child QATs in hierarchical regression. Furthermore, two neurocognitive phenotypes non-specific to autism, attention and motor coordination, explained the largest amount of the variance (18% and 10% respectively) in hierarchical regression, and both were significant predictors of QATs at 48 months. All three phenotypes appeared heritable in female twin pairs, while there was a large overlap in the 95% confidence interval for ICC in male monozygotic and dizygotic twin pairs in males on CBCL attention scores, suggesting sex-specific differences in heritability for this phenotype. Finally, we observed genetic overlap only between motor coordination and QATs, suggesting that genes affecting motor coordination may also directly affect autistic traits.

Conclusions: Social visual engagement, familial background for quantitative autistic traits, variation in attention, and variation in motor coordination represent genetically-independent contributors to autistic symptom burden. Linking genetic variants to these underlying traits rather than to a diagnosis of “autism” may be more productive in devising personalized approaches to developmental intervention, especially if autism represents an epiphenomenon of earlier-interacting susceptibilities.

35 **144.035** Heart Rate during Sleep at 1 Month of Age Correlates with ASD Risk Scores at 30 Months

H. E. Reed[1]*, N. H. Brito*[2]*, L. C. Shuffrey*[3]*, W. P. Fifer*[3]*, J. D. Nugent*[3] *and A. J. Elliot*[4]*, (1)Columbia University Medical Center, New York, NY, (2)Department of Applied Psychology, New York University, New York, NY, (3)Division of Developmental Neuroscience, Columbia University Medical Center, New York, NY, (4)Sanford School of Medicine at the Unviersity of South Dakota, Sioux Falls, SD*

Background: Autism spectrum disorder has been associated with a range of atypical autonomic responses, from pupillary light reflex to cardiac arousal. Heart rate (HR), an easily obtainable biomarker of autonomic function, is frequently found to be elevated at baseline in children with autism (Klusek et al, 2015). Although a few studies in children reported no correlation, this may be attributable to variations in measurement contexts. Only two studies thus far have examined cardiac variables during sleep, with both reporting autonomic dysregulation during non-REM sleep, and one reporting elevated HR in ASD across both non-REM and REM sleep (Pace et al, 2016; Harder et al, 2016). No studies to date have examined autonomic dysregulation during sleep prior to symptom development, despite the evidence of atypical brain development in ASD during this time.
Objectives: To the best of our knowledge, this is the first study to investigate a relationship between autonomic function during sleep in newborns and later autism risk.

Methods: Data was collected from healthy term newborns enrolled in the Prenatal Alcohol and SIDS and Stillbirth Network in the Northern Plains region of South and North Dakota. This cohort includes 352 children (47% male, 53% female). This sample reflects general population risk for ASD. Average heart rates were obtained at a 1-month postnatal follow up visit and calculated across a 10-minute period of quiet sleep (QS) and a 10-minute period of active sleep (AS), reflecting the different autonomic arousal profiles associated with non-REM and REM sleep respectively. Brief Infant-Toddler Social and Emotional Assessments (BITSEA) were obtained between 24-36 months of age (mean age of 30 months) (Briggs-Gowan and Carter, 2006). The BITSEA ASD Total subscale is a validated measure with high sensitivity, specificity, and PPV as a screener for ASD risk (Kiss and Carter, 2017).

Results: There was a moderate positive correlation between average HR during quiet sleep at 1 month of age and BITSEA ASD Total score at 30 months, r=0.311 (p=0.021). During active sleep, there was small positive correlation which approached significance with r=0.138 at p=0.051. Results were calculated controlling for sex, gestational age at birth, and age at BITSEA assessment.

Conclusions: These preliminary results demonstrate a significant correlation between average HR during quiet sleep in newborns and later autism risk. A similar correlation that approached significance was noted during active sleep. These results mirror previous findings of autonomic differences during sleep in ASD and are the first to indicate that this phenomenon may occur prior to symptom development. Replication on an expanded sample with confirmed ASD diagnoses is needed. If this correlation is upheld, it may have important implications for early brain development in autism. Recent research has demonstrated increased extra-axial cerebrospinal fluid (CSF) at 6 months in children who later develop ASD (Shen et al 2017). Autonomic regulation plays a major role in CSF circulation, with enhanced sympathetic tone leading to increased CSF volume (Sakka, 2011). Further research is important to understand what role, if any, autonomic dysfunction may play in brain development in ASD.

36 **144.036** Identifying Prognostic Biomarkers in Toddlers with Autism Spectrum Disorder

***E. Bacon**[1], A. Moore[2], D. Cha[1], C. Barnes[1], E. Courchesne[3] and K. Pierce[4], (1)Neurosciences, University of California, San Diego, La Jolla, CA, (2)University of California, San Diego, La Jolla, CA, (3)Neurosciences, Univeristy of California, San Diego, La Jolla, CA, (4)Univeristy of California, San Diego, La Jolla, CA*

Background:

Although significant advances have been made in the early identification of ASD, once a diagnosis is made, little information is available regarding the prognosis for a particular child. This uncertainty creates anxiety for parents and limits the ability to develop treatments tailored for a specific ASD outcome profile. We have recently demonstrated that eye tracking is a powerful tool for detecting a subset of ASD toddlers with 98% specificity using a preferential looking task, the GeoPref Test, which compares fixation times for social versus geometric images. Our original studies (Pierce et al., 2011; 2016) showed that toddlers with ASD that fixated on geometric images >69% of the time, ASD “Geo Responders” were more likely to have poorer social, language, and overall intellectual aptitude than ASD “Social Responders” (i.e., fixated on social images >69%). However, it is currently unknown if performance on the Geo Pref Test would be associated with ability a year later. We hypothesized visual input and learning ability would be more abnormal for ASD Geo, than ASD Social Responders resulting in poorer outcomes.

Objectives:

We aimed to evaluate the prognostic utility of the GeoPref Test in toddlers with ASD.

Methods:

The sample included 71 toddlers with ASD recruited from the general population through community referrals and developmental screening using the One-Year Well-Baby Check-Up Approach (Pierce et al., 2011). All toddlers were evaluated longitudinally every 9-12 months using the Mullen Scales of Early Learning, Vineland Adaptive Behavior Scales, and Autism Diagnostic Observation Schedule, and diagnoses were confirmed at age 3 years. All toddlers participated in the GeoPref Test at their intake evaluation (mean age = 23 months). Performance on clinical measures at intake evaluations and at outcome approximately 1 year following eye tracking (mean age = 38 months) were compared between ASD Geo Responders (n=24) and ASD Social Responders (n=47).

Results:

As expected, Geo Responders demonstrated more impairments on the Social Affect Domain of the ADOS ($t = 4.26$, $p < .001$) and Receptive Language Domain of the Mullen ($t = -2.89$, $p < .01$) at their initial eye tracking age relative to Social Responders. Differences in Social Affect ($t = 4.85$, $p < .001$) and Receptive Language ($t = -2.79$, $p < .01$) persisted across a 1 year period. However, Expressive Language ability of Geo Responders worsened across this same time period ($t = -2.13$, $p < .05$).There were no group differences on the Vineland.

Conclusions:

The GeoPref Test identifies group differences in developmental functioning at intake and ~1 year following eye tracking. Geo Responders evidenced a poorer clinical profile with lower language ability and higher ratings of autism symptoms. These differences persisted over time, with differences in language ability becoming more pronounced. Therefore, the GeoPref Test shows utility as not only a biomarker for identifying ASD, but a prognostic indicator for newly-identified toddlers. Given that experience dependent mechanisms are foundational to brain development, we hypothesize Geo Responders are high-risk for poorer outcomes through adolescence. Follow-up is being conducted to examine if this phenomenon persists into school-age.

37 **144.037** Imaging Biomarkers for Early Detection of Autism in Tuberous Sclerosis Complex

***A. Prohl**[1], K. Kapur[2], B. Scherrer[1], X. Tomas-Fernandez[1], J. Peters[1,2], M. Bebin[3], D. A. Krueger[4], H. Northrup[5], J. Wu[6], M. Sahin[7] and S. K. Warfield[1], (1)Computational Radiology Laboratory, Department of Radiology, Boston Children's Hospital, Boston, MA, (2)Department of Neurology, Boston Children's Hospital, Boston, MA, (3)University of Alabama at Birmingham, Birmingham, AL, (4)Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (5)McGovern Medical School, Univ. TX Health Sci Cntr-Houston, Houston, TX, (6)University of California Los Angeles, Los Angeles, CA, (7)Boston Children's Hospital/Harvard Medical School, Boston, MA*

Background: Tuberous Sclerosis Complex (TSC) is a monogenetic disorder with high penetrance of autism spectrum disorder (ASD). Our previous work has characterized imaging features associated with ASD in adult and pediatric TSC patients. We determined that there are underlying

microstructural integrity alterations in TSC patients with ASD that are not present in TSC patients without ASD, and that they exist throughout the brain, with varying degrees of severity, and are prevalent in the corpus callosum and arcuate fasciculus. There is an urgent unmet need for imaging biomarkers that can be used in the first year of life to identify and direct early intervention towards infants most likely to develop ASD.
Objectives: In light of our previous findings of abnormality in the corpus callosum and arcuate fasciculus, we set out to identify a biomarker of ASD in TSC through prospective and longitudinal study of microstructural development of the arcuate fasciculus, a fronto-temporal white matter (WM) fiber bundle implicated in language development, and in the corpus callosum, a large interhemispheric fiber bundle and collector of stochastically-distributed disease burden in TSC.

Methods: 40 participants with TSC underwent longitudinal 3T diffusion tensor imaging (DTI) within the first year of life and at 12, 24, and 36 months of age. Participants were assessed for early ASD symptoms at 12 months of age with the Autism Observation Scale for Infants (AOSI). Bilateral regions of interest were automatically defined along the arcuate fasciculi, located in the WM underlying Geschwind's Territory, Wernicke's Area, posterior to Broca's area and in the body of the corpus callosum at the midline [Figure 1]. Diffusion properties in each region were measured. The ability of diffusion properties in each region to predict high or low AOSI total score at 12 months of age was evaluated with ROC analysis of the longitudinal sample, and in a subsample of data, restricted to scans acquired before 12 months of age.

Results: From the longitudinal sample, prediction of high or low AOSI total score was best achieved with fractional anisotropy of WM underlying left Geschwind's territory (AUC=87.20, sensitivity=86.67, specificity=80.00) and left Wernicke's area (AUC=85.07, sensitivity=86.67, specificity=76.00), while radial diffusivity of WM underlying left Wernicke's area conferred a negative predictive value of 100% [Table 1a]. Prior to 12 months of age, WM microstructure underlying right Wernicke's area was most predictive of high or low AOSI total score (radial diffusivity, AUC=76.89 ; mean diffusivity, AUC=76.14) and left Wernicke's area (fractional anisotropy, AUC=75.76) [Table 1b]. AUC of corpus callosum diffusion properties did not exceed 75.00 in the longitudinal or 12 month sample, and therefore were not the best predictors of ASD symptoms at 12 months of age.

Conclusions: Temporoparietal white matter that supports language development within the first year of life is associated with later diagnosis of ASD in TSC. Although associated with ASD in adults, microstructure of the corpus callosum was not predictive of later diagnosis of ASD, suggesting its role as an accumulator of disease burden in TSC.

38

144.038 Increased Rates of Comorbid Psychopathology in Preschool-Aged Females with Autism Spectrum Disorder

C. W. Nordahl[1], *A. M. Iosif*[2], *G. S. Young*[3], *A. L. Hechtman*[3], *B. Heath*[1], *V. P. Reinhardt*[3], *D. G. Amaral*[1], *S. Ozonoff*[3] *and M. Solomon*[3], *(1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)Public Health Sciences, University of California Davis, Davis, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA*

Background: There is some evidence that females with autism spectrum disorder (ASD) have higher rates of comorbid psychopathology, particularly anxiety and depression, in older childhood and adolescence than males with ASD. Studies utilizing large samples of females with ASD are lacking, and little is known about sex differences in comorbid psychopathology in very young children with ASD.
Objectives: We evaluated sex differences in comorbid psychopathology in preschool-aged females and males with ASD. Age-matched typically developing (TD) controls were included to investigate whether differences related to ASD varied between males and females.

Methods: Participants include 229 children with ASD (76 females, 153 males) and 131 age-matched TD controls (54 females, 77 males), mean age of 36.2 (sd 7.2) months. ASD diagnoses were confirmed using ADOS and ADI-R. Psychopathology was evaluated using the DSM-oriented scales for affective, anxiety, attention deficit/hyperactivity (ADHD), and oppositional defiant problems from the Child Behavior Checklist. Sex by diagnosis interactions were examined with negative binomial regression models using T-scores from each scale. For scales with significant interactions, the proportion of males and females with ASD who scored in the clinical range (>69) was compared using chi-square tests. As a secondary analysis to explore generalized psychopathology within the ASD sample, t-scores for each DSM-oriented scale were categorized as clinical (>69), borderline clinical (65-69), and normal (< 65), and a data-driven latent class analysis (LCA) was utilized to identify subgroups with higher rates of psychopathology across DSM-oriented scales. The proportion of females and males in each of the derived subgroups was compared.

Results: Sex by diagnosis interactions were identified for ADHD (p = .01 corrected for multiple comparisons) and affective problems (p = .06 corrected). Pairwise comparisons revealed a greater difference between ASD and TD within females than males on both ADHD [Female ASD vs TD: estimate 5.7 (SE 1.2), Male ASD vs TD: estimate 2.7 (SE 0.4)] and affective scales [Female ASD vs TD: estimate 5.5 (SE 1.1), Male ASD vs TD: estimate 2.3 (SE 0.5)]. A higher proportion of females with ASD than males with ASD scored within the clinical range on both the ADHD and affective scales (ADHD: 20% females vs. 9% males, p = .04; affective: 37% females vs 22% of males, p = .03). Within the ASD group, LCA of clinical, borderline, and normal scores across DSM-oriented scales revealed three subgroups: elevated scores across all measures (35%), low scores on all measures (25%), and a group in the middle (40%). A higher proportion of females were in the group with elevated scores than males (43% vs. 31%, p = .03), suggesting a higher overall rate of psychopathology in females.

Conclusions: Comorbid psychopathology occurs at a higher rate in girls with ASD than in boys, even at the young ages tested in this study. This difference is not mirrored in typical development. Specifically, preschool-aged females exhibited higher rates of clinically significant ADHD and affective problems, suggesting a need for closer evaluation and earlier interventions to potentially improve outcomes for females with ASD.

39

144.039 Infant Effortful Control Acts As a Protective Factor for Traits of ASD in Mid-Childhood.

R. Bedford[1], *T. Gliga*[2], *T. Charman*[3], *M. H. Johnson*[4] *and A. Pickles*[5], *(1)King's College London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (5)Biostatistics and Health Informatics, King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom*

Background: Executive function impairments are characteristic of children with developmental disorders such as autism spectrum disorder (ASD). Recently, the reverse has been proposed; that strong executive functions may act as a protective factor across developmental disorders (Johnson, 2012). In the current study we use infant effortful control (EC), a proxy measure of early infant executive function, to test the hypothesis that EC can have a protective effect on subsequent ASD traits, in children at high familial risk for ASD.

Objectives: Our aim is to test whether infant EC acts as a protective factor in relation to later ASD traits, by testing the moderating effect of EC on the association between infant Autism Observation Scale for Infants (AOSI) scores and later ASD symptoms at 7 years.

Methods: Participants were 104 infants at high and low familial risk (54 high risk, HR; 50 low risk, LR) seen at multiple visits from birth to 7 years. Data for the current study comes from the 14 month infant visit (AOSI and EC) and the 7 year visit (Social Responsiveness Scale, SRS).

Results: First we ran a simple linear regression to test the association between 14-month AOSI score and 7-year SRS, showing that increased AOSI scores were significantly associated with greater 7-year autism symptoms. Next, we included EC (high and low based on median split) and the interaction between AOSI and EC in addition to the AOSI in a multiple linear regression. Results showed a significant association between AOSI and the SRS ($\beta = 0.63$, $p < 0.001$) and a significant EC*AOSI interaction ($\beta = -0.62$, $p = 0.001$). Separate simple linear regressions indicated that the interaction was driven by a significant positive association between AOSI and ASD traits in those with low EC ($p < 0.001$), with no association for those with high EC ($p = 0.54$).

Conclusions: Results suggest that early autism-like behaviours as measured by the AOSI are only associated with subsequent symptoms of autism in those with low effortful control. This supports the hypothesis that EC may act as a protective factor in infants at-risk, perhaps allowing them to compensate for additional neural atypicalities. Future studies should investigate the potential for early executive function interventions in at-risk infants using methods such as contingent eye-tracking.

40 **144.040** Integration of Longitudinal Cross-Domain Measures of Symptoms, Developmental Level and Adaptive Functioning to Predict Autism at 3 Years in High-Risk Infants

***G. Bussu**[1], E. J. Jones[2], T. Charman[3], M. H. Johnson[4], J. K. Buitelaar[5] and &. The BASIS Team[6], (1)Donders Institute for Brain, Cognition and Behaviour, Radboudumc, Nijmegen, Netherlands, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (5)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (6)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom*

Background: Individual prediction of later development of Autism Spectrum Disorders (ASD) at pre-diagnostic age might be crucial to enable early targeted interventions aimed at improving long-term outcome. Previous studies used scores from the Autism Diagnostic Observation Schedule (ADOS) at 18 months to classify ASD development (Chawarska et al., 2014), while predictive power for ASD of other behavioural measures commonly used for clinical evaluation has not been tested. Additionally, the relevance of data integration for improving classification of ASD outcome has been previously reported in neuroimaging studies (Libero et al., 2015).

Objectives: To characterise early development of ASD, we integrated information across multiple behavioural and developmental domains and multiple time-points. Additionally, we used a machine learning approach to improve individual classification of ASD among high-risk siblings (HR) at an early age from different combinations of measures.

Methods: We used data of the Mullen Scales of Early Learning (MSEL), Vineland Adaptive Behavior Scales (VABS) and Autism Observation Scale for Infants (AOSI) between 8 and 36 months in a cohort of 71 low-risk controls (LR) and 161 HR siblings. Clinical outcome of HR siblings at 36 months (HR-Typical, HR-Atypical, HR-ASD) was established by expert clinical researchers. First, we examined whether LR and HR clinical outcome groups showed differences in cross-sectional measures at 8 and 14 months, and in developmental trajectories of behavioural and developmental measures between 8 and 36 months. Second, different combinations of the same measures at 8 and 14 months were integrated into a Least-Square Support Vector Machine (LS-SVM) classifier to discriminate between HR-ASD and both HR-Typical and HR-Atypical.

Results: We observed clear but small size group effects for Mullen and Vineland scores at 8 and 14 months, and larger group effects at 24 and 36 months (Figure 1). Group differentiation was found from 8 months, except for MSEL visual reception, receptive and expressive language scores, and VABS motor and social scores, showing increasing differentiation of groups over time. Overall, LR and HR-Typical showed higher developmental level and functioning, and lower ASD symptoms than HR-Atypical and HR-ASD. Individual classification of ASD clinical outcome was possible with moderate accuracy using VABS daily living scores at 14 months (Area Under the Curve, AUC: 71.3%; 95% Confidence Interval, CI: [55.6, 85.1]). The integration of measures from different domains did not significantly improve classification (Figure 2).

Conclusions: This study extends previous high-risk studies on early markers for ASD by integrating information from multiple measures and multiple time-points; testing models for the individual classification of ASD clinical outcome; and focusing on prediction at a younger age. Our results provide further evidence of the high inter-individual and intra-individual heterogeneity of ASD, which makes it difficult to predict the later development of the disorder from clinical manifestations at an early age. Further investigation is needed to understand the interplay of different domains in the first years of life leading to an ASD outcome, and the combination of measures from different domains can be extended to include more biological data to examine whether it would further improve predictive power.

41 **144.041** Longitudinal Sex Differences in ASD Symptoms and Diagnostic Stability in Early Childhood

***N. Ludwig**[1], G. Perez Liz[2], D. N. Abrams[3], L. B. Adamson[4], D. A. Fein[5] and D. L. Robins[2], (1)Confex - The Conference Exchange, Cumberland, RI, (2)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (3)Georgia State University, Atlanta, GA, (4)Psychology, Georgia State University, Atlanta, GA, (5)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Research has demonstrated sex differences in the early screening of Autism Spectrum Disorder (ASD) in toddlers; however, studies examining the early clinical presentation of ASD have shown minimal sex differences at this age. Given research showing sex differences later in life, it is important to understand the potential developmental trajectory of sex differences and how this may impact early detection and diagnosis.

Objectives: The current study examined the relationship between sex and the developmental trajectory of clinical features and diagnostic stability of ASD in a sample of children initially evaluated based on screen positive status (i.e., at risk) on the Modified Checklist for Autism in Toddlers(-Revised) with Follow-Up (M-CHAT(-R/F) and re-evaluated two years later.

Methods: The sample included 424 ($N_{\text{male}}=318$) children who were initially evaluated as toddlers ($M_{age}=26.31$ months, $SD=4.46$) and re-evaluated two years later ($M_{\text{age}}=49.88$ months, $SD=7.19$). Evaluations included autism diagnostic measures (ADOS-2), cognitive testing (Mullen Scales of Early

Learning), and parent report of history and adaptive behavior (Vineland Adaptive Behavior Scales(-II)). Notably, ADOS-2 Calibrated Severity Scores (CSS) for Overall Total, Social Affect and Restricted, Repetitive, Behavior (RRB), as well as algorithm domain scores were utilized for analyses given minimal research examining the domain-specific CSS as an adequate measure of longitudinal changes in symptoms.

Results: Sex differences emerged in diagnostic stability. Although a similar percentage of males (8%) and females (12%) who were not diagnosed with ASD at the initial evaluation gained a diagnosis at the time of re-evaluation ($X^2(1,N=238)=.562$, $p=.453$), girls initially diagnosed with ASD were almost twice as likely (38%) as males (20%) to lose their ASD diagnosis at re-evaluation ($X^2(1,N=270)=3.647$, $p=.05$). Subsequent analyses on the subsample of children who lost an ASD diagnosis at re-evaluation ($N=51$) indicated a significant interaction between time of evaluation and sex ($F(1,47)=4.38$, $p=.043$, partial $\eta^2=.085$) for RRB algorithm domain scores; males demonstrated higher scores ($M_{male}=3.09$, $SD=2.01$) compared to females ($M_{female}=1.50$, $SD=1.71$) at the initial evaluation, but similar levels at re-evaluation ($M_{male}=.85$, $SD=1.18$; $M_{female}=.63$, $SD=.81$;). Toddlers with stable ASD diagnosis– ASD confirmed at both time points ($N=219$; $N_{male}=177$) – did not evidence differential ASD symptoms, developmental skills, or adaptive skills based on sex across time (ps>.05).

Conclusions: Results are consistent with previous literature demonstrating minimal sex differences in young children with ASD and extend previous findings by showing no sex differences in the developmental trajectory of the clinical features of ASD from toddlerhood to the preschool years. Nevertheless, sex differences emerged in diagnostic stability such that females were more likely to lose an initial diagnosis of ASD from age 2 to 4. While females demonstrated low rates of RRBs at both time-points, males demonstrated a significant decline in RRBs over time. This suggests that in females diagnosed with ASD in toddlerhood, fewer RRBs may be predictive of losing a diagnosis at age 4. Results call for future research examining early compensatory factors in females that may facilitate symptom reduction that lead them to lose their initial ASD diagnosis by preschool.

42 **144.042** Social Evaluation Is Reduced in Toddlers with ASD and Other Developmental Delays Compared to Toddlers with Typical Development

N. Ludwig[1], *R. Williamson*[2], *R. K. Ramsey*[3], *L. B. Adamson*[4], *S. F. Brosnan*[4], *W. Jones*[5] *and D. L. Robins*[6], *(1)Confex - The Conference Exchange, Cumberland, RI, (2)Georgia State University, Atlanta, GA, (3)Georgia State University, Atlanta, OH, (4)Psychology, Georgia State University, Atlanta, GA, (5)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (6)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Studies utilizing a nonverbal social attribution paradigm show that typically developing infants make dispositional state attributions about ambiguous stimuli as young as ten months of age and make goal state attributions and social evaluations by three months of age (Hamlin, Wynn, & Bloom, 2007, 2010). Given that social attribution has shown to be reduced in older individuals with ASD, early disruptions in social attribution may serve as a behavioral marker for early detection.

Objectives: This study examined whether a puppet-based social attribution paradigm developed for use in preverbal infants is appropriate for use in toddlers with and without delays and whether performance differentiates toddlers with ASD from those with non-ASD delays (DD) and typical development (TD).

Methods: The sample included 57 toddlers ($N_{ASD}=15$, $N_{DD}=20$, $N_{TD}=22$; $M_{age}=21.61$ mo, $SD=2.98$) who were presented with a nonverbal puppet-based social attribution paradigm in which a shape tries to climb a hill and another shape either helps or hinders its climb (Hamlin et al.). Toddlers were habituated to alternating helping and hindering social scenes until habituated (max. 12 trials). Toddlers were then presented with a Looking Time Test (LTT), a violation of expectation-based measure of dispositional attribution; longer looking time towards an unexpected social event (i.e., novel scene of climber moving towards hinderer vs. helper) was considered evidence that children made dispositional attributions during habituation. Toddlers also completed a Preference Test (PT) to measure social evaluation; choosing helper helper over hinderer was interpreted as evidence that children made goal attributions during habituation and integrated that knowledge in their social evaluation.

Results: Children habituated to the social scenes at similar rates across diagnosis ($X^2(2,N=57)=1.966$, $p=.374$); however, toddlers within the TD group looked longer per habituation exposure ($M=10.39$s, $SD=5.85$) compared to the DD group only ($M=7.89$s, $SD=3.30$; $F(2,54)=.0368$, $p=.047$, partial $\eta^2=.107$). Toddlers in the ASD ($M_{exp=}$ 5.36s, $M_{unexp=}$5.88s) and DD (M_{exp} = 7.00s, $M_{unexp=}$8.29s) groups did not demonstrate increased looking time towards the unexpected event during the LLT, and in contrast to studies in infants, neither did those in the TD group (M_{exp}=5.84s, M_{unexp}=5.82s; $F(2,52)=0.564$, $p=.572$, partial $\eta^2=.021$). The TD group demonstrated preference for the helper shape during the PT (71.4%$_{helper}$), whereas the ASD (28.6%$_{helper}$) and DD groups (40%$_{helper}$) did not ($X^2(2,N=55)=7.213$, $p=.027$).

Conclusions: This is the first study utilizing a nonverbal social attribution paradigm in toddlers with and without developmental delays. Contrary to expectations, TD toddlers did not show looking time differences on the LLT bringing into question whether looking time is an appropriate measure of dispositional attribution at this age. Despite this, toddlers in the TD group demonstrated evidence of social evaluation on the PT, whereas toddlers within the ASD and DD groups did not. While all toddlers habituated at similar rates, TD toddlers looked longer towards each habituation exposure compared to the DD group, which suggest that other factors may have impeded success in the DD group. Future research is warranted to examine whether deficient social evaluation is specific to ASD or characterizes developmental delays more broadly.

43 **144.043** Looking Patterns Predict Expressive Language in Toddlers with ASD Only If First Words Are Acquired

L. A. Edwards[1], *S. I. Habayeb*[2], *T. Tsang*[3], *C. A. Saulnier*[1], *W. Jones*[1] *and A. Klin*[1], *(1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Catholic University of America, Washington, DC, (3)University of California, Los Angeles, Los Angeles, CA*

Background: Infants show shifting patterns of social visual engagement to faces over the first two years of life. Specifically, after an early period of predominant eye-looking, typically developing (TD) infants show increases in mouth-looking, which seem to accelerate around the developmental time-point at which first words are spoken. Past work has provided evidence for associations between this shift and the development of speech and language abilities: in observational studies, attention to visual speech facilitated phonetic learning and language discrimination in TD infants (Teinonen et al., 2008; Weikum et al., 2007), and TD infants were more likely to look to the eyes of a talking face when learning word referents (Lewkowicz et al., 2012). In contrast to TD patterns of social visual engagement, infants later diagnosed with autism spectrum disorder (ASD) show more rapid acceleration in mouth-looking, as well as very early declines in eye looking that persist until 24 months. How patterns of visual

fixation in infants with ASD relates to speech and language abilities is currently not well understood.
Objectives: The present study compares eye-tracking measures of social visual engagement with spoken language abilities in the second year of life, an important period in typical language acquisition characterized by marked inflection in word learning. We predicted fluctuation in preferential patterns of visual engagement during this period, with a significant correlation between mouth-looking and expressive language in TD children.

Methods: Chronological age-matched samples of 10-25-month-old ASD (n=56) and TD (n=28) children watched videos of actresses engaged in child-directed caregiving activities. Social visual engagement data were collected using eye-tracking technology and quantified as percentage of time spent visually fixated on regions of interest. Between-group comparisons measured levels of fixation in ASD and TD children. Within-group regression analyses tested for associations between visual fixation and concurrent expressive language levels (measured by the *Mullen Scales of Early Learning*), controlling for age.

Results: During the second year of life, greater mouth- than eye-looking is observed in both TD (*p*=0.0001) and ASD (*p*=0.018) children. However, the adaptive value of these looking patterns differs between groups: increased mouth-looking was positively associated with improved expressive and receptive language scores in TD children (*p*=0.003 and *p*=0.022, respectively) but was unrelated to language abilities in ASD children (both *p*>0.600). If analyses are constrained to ASD children for whom word-learning had begun, a weaker but positive association with expressive language is observed (*p* = 0.040). In ASD children who had not yet begun word acquisition, no relationship between visual fixations and expressive language was observed.

Conclusions: In the second year of life, increased visual engagement with the mouths of others is adaptive in TD children and positively predicts expressive and receptive language levels. For children with ASD however, only those children who have begun word learning show a positive association between mouth-looking and expressive language; for the remaining children, high levels of mouth-looking are unrelated to expressive or receptive language.

44 **144.044** Low Focused Attention Is Associated with Elevated ASD-Related Behaviours at 15 Months

A. Hendry[1], *E. J. Jones*[2], *T. Charman*[3], *M. H. Johnson*[4] *and &. The BASIS Team*[5], *(1)Department of Experimental Psychology, University of Oxford, Oxford, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (5)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom*

Background: Focused Attention (FA) is a filter through which environmental input is selected for learning, through orientation toward and sustained engagement with the external world. Higher FA spans in infancy are associated with enhanced language skills and general developmental ability, more complex play behaviour and better executive function. Genetically-influenced difficulties with attentional control have been identified as a likely developmental pathway to ASD (and co-occurring ADHD) and risk for poor control of attention appears to be distributed across individuals with a first-degree relative with ASD – yet little is currently known about early development of control of attention in ASD. Using FA as an index for early development of attentional control in infants with an older sibling with ASD ('infant-siblings') may yield insights into this potential causal mechanism.
Objectives: The first aim of this longitudinal study was to evaluate whether poor development of FA appears to be a characteristic of infant-siblings generally. The second aim was to evaluate whether poor development of FA appears to be specifically associated with levels of early-emerging ASD-related behaviours.

Methods: 112 infants were observed during free play with a set of blocks, at ages 10.5 (controls = 22, infant-siblings = 85) and 15 months (controls = 18, infant-siblings = 72). Coders rated infants' continuous looking and touching behaviour, from which the peak epoch of FA – longest epoch of simultaneous looking to the blocks whilst manipulating the blocks – was identified (ICC =.924). At 15 months, early behavioural markers of ASD were measured using the Autism Observation Scale for Infants (AOSI).

Results: A repeated measures ANOVA on peak FA, with group (controls, infant-siblings) as a between groups factor showed no main effect of time (*F*(1,75) = 0.546 *p* = .462, = .007) and no main effect of group (*F*(1,75) = 0.224 *p* = .638, partial-eta sq= .003). The interaction effect between time and group was marginal (*F*(1,75) = 3.145 *p* = .081, partial-eta sq = .040) but the generalised eta square value was small (.017). Across all infants, lower Peak FA scores at 15 months were associated with higher concurrent total AOSI scores, indicative of elevated ASD-related behaviours (*r*(61) = -.222, *p* = .043). No significant association was found from Peak FA at 10.5 months to AOSI scores at 15 months (*r*(65) = -.057, *p* = .327).

Conclusions: As predicted, poor FA at 15 months is concurrently associated with elevated ASD-related behaviours. An equivalent predicted association from FA at 10.5 months to ASD-related behaviours at 15 months was not observed thus it is not clear from these data whether ASD-related behaviours are primary or secondary to difficulties with FA in infancy. Contrary to expectations, no evidence was found to suggest that having an older sibling with ASD is linked with impairment in FA in this sample of infant-siblings. Further research is required to establish whether differences in FA are apparent amongst the minority of infant-siblings later diagnosed with ASD.

45 **144.045** Measuring the Reward Value of Various Social Signals in Toddlers with and without Autism: An Interactive Eye-Tracking Study

A. Vernetti[1,2], *T. Charman*[3], *M. H. Johnson*[4], *T. Gliga*[2], *A. Senju*[2] *and &. the BASIS Team*[2], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom*

Background: Several accounts have been suggested to describe the origins of social difficulties in autism spectrum disorder (ASD), including accounts arguing for atypical social orienting (Klin et al., 2002) and diminished social motivation (Chevallier et al., 2012). However, increasing evidence shows that individuals with ASD seek and enjoy social interactions within specific contexts but may struggle with processing the irregularities inherent to social interactions (Pellicano and Burr, 2012).
Objectives: 1) To develop a task measuring the reward value of social signals within different contexts in young toddlers with and without ASD; 2)

To test whether toddlers with ASD orient and smile towards social stimuli differently from their typically developing peers depending on the content and predictable nature of social stimuli.

Methods: 118 toddlers at high or low familial risk for ASD took part in the study at 27-month-old and were later characterised at 36-month-old as low risk controls (LR, N=26, age: M=25.6mo, SD=1.1), high-risk with no ASD diagnosis (HR-no ASD, N=78, age: M=26.8mo, SD=1.5), or high-risk with a diagnosis of ASD (HR-ASD, N=14, age: M=26.3mo, SD=1.9). During a gaze-contingent task (Figure1), toddlers could select and trigger one of two different videos through their gaze behaviour. In a first condition, toddlers could activate a video of a person greeting or a musical toy. A second condition contrasted two social stimuli that, when looked at, displayed a person turning either towards or away from the participant. Finally, a third condition contrasted an invariant interaction (a person constantly saying Hello) with a variable interaction (a person either saying Hello, Good job or smiling).

Results: Indexes of reward-seeking behaviour (proportion of first looks and looking time towards stimulus of focus) and an index of hedonic response (proportion of smiles showed in response to the stimulus selected) were analysed (Table1). When the social interaction was predictable, all groups, including the HR-ASD group (no effect of Diagnosis, p>.513), looked longer and smiled more towards a person greeting them compared to a mechanical toy (Condition1, all p<.001) and also smiled more towards a communicative over a non-communicative person (Condition2, p<.001). However, all groups (all p<.018), except the HR-ASD group (p=.507), selectively oriented towards a person addressing the child in different ways over an invariant social interaction (Condition3).

Conclusions: Typical reward-seeking orienting and hedonic response towards predictable social stimuli seem to be present in toddlers with ASD. These results go against accounts suggesting impaired social orienting or diminished motivation to engage with social stimuli. However, the lesser drive towards the variable social interaction observed in toddlers with ASD may reflect either a bias towards more predictable social information or the difficulty to process unpredictable social encounters. These findings suggest that social interaction is intrinsically rewarding for toddlers with ASD, but the specific variability of naturalistic social interactions may modulate the extent to which social exchanges are pursued.

46 **144.046** Moderate to Late Preterm Birth Has a Negative Impact on Cognitive Profile in Autism

F. Bonnet-Brilhault[1]*, M. Brayette*[2]*, R. Blanc*[3]*, S. Roux*[4] *and E. Saliba*[4]*, (1)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (2)Université François-Rabelais de Tours, Tours, France, (3)Université Paris Descartes, Boulogne Billancourt, France, (4)Université François-Rabelais de Tours, UMR INSERM U930, Tours, France*

Background: Despite the growing number of cohort studies examining the risk of autism based on prematurity, few studies have looked at neurodevelopmental profiles of children with autism born prematurely. Moreover, although data on the outcome of children born very preterm before 32 Weeks of Amenorrhea (WA) is now abundant, the later outcome of children born moderately to late preterm (MLPT, 32^{+0} and 36^{+6} WA) and those born early term (ET, 37^{+0} and 38^{+6} WA) remains uncertain - this population being less systematically followed.
Objectives: to characterize the neurodevelopmental profiles of children with autism born MLPT, ET and full term FT (over 39^{+0} WA), using validated tools which assess autistic behaviors and cognitive level.

Methods: 415 children with Autism Spectrum Disorder (ASD) were followed up in the University Child Psychiatry Center of Tours (France) in 2010-2016. 28 (6.8%) were MLPT, 104 (25%) ET and 283 FT (68.2%). They were diagnosed by a multidisciplinary team according to DSM-4-TR criteria; ADI-R and ADOS complemented the diagnosis of ASD.

Neurodevelopmental profiles including cognitive level and autistic behaviors were determined, at median age of 6 years 9 months using validated tools. Cognitive assessment (verbal and nonverbal developmental quotients) was carried out with age adapted neuropsychological tests. Behavioral assessment was carried out using the Childhood Autism Rating Scale (CARS, Schopler et al, 1980), the Revised Behavior Summarized Evaluation scale (BSE-R, Barthélémy et al, 1997) and the Repetitive and Restricted Behavior scale (RRB, Bourreau et al, 2009).

Results: Within the total sample, 209 patients (50.4%) had an Autistic Disorder, 21 (5%) an Asperger Syndrome and 185 (44.6%) a pervasive developmental disorder not otherwise specified (PDD-NOS). No significant difference was observed between the three groups MLPT, ET and FT (χ^2=4.42; df 4; p=0.35). The autistic profiles assessed by the CARS, BSE-R and RRB scales, did not differ between these three groups of patients. No significant difference was also found for the presence or absence of an intellectual disability ID (χ^2=3.91; df 2; p=0.14). However, ID was significantly deeper to severe in premature patients compared to those born ET and FT (χ^2=12.1; df 4; p=0.017). This cognitive effect was related to a significant lower nonverbal developmental quotient in the MLPT patients compared to those born FT (p=0.006 at post-hoc tests).

Conclusions: Moderately to late preterm birth does not modify autistic severity but exacerbates developmental deficiency and increases nonverbal difficulties in autism. These results highlight that, even moderate to late, preterm birth has a negative impact on cognitive profile in patients with neurodevelopmental vulnerability.

47 **144.047** Modifying Social Attention with Gaze-Contingent Eye Tracking for Toddlers and Children with ASD

Q. Wang[1]*, E. Barney*[2]*, C. A. Wall*[3]*, S. Macari*[1]*, K. Chawarska*[1] *and F. Shic*[2]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Department of Psychology, University of South Carolina, Columbia, SC*

Background: Toddlers with ASD, compared to typically developing (TD) and developmentally delayed (DD) peers, show diminished responses to dyadic engagement (Chawarska et al, 2012) and limited attention to the activities of others when viewing a naturalistic play scene (Shic et al, 2011). This decreased attention likely reflects not only the culmination of atypical experience-dependent knowledge regarding scenes and people, but also suggests that future access to observational learning may be limited.
Objectives: 1) To explore the feasibility of automated gaze-modification strategies for toddlers with ASD, 2) To assess short-term malleability of visual attentional patterns. 3) To identify whether measures of attentional redirection can be used in the direction of intervention.

Methods: In (1) Normative Data Collection phone, TD controls (n=41, age = 37.4±16.6 months) free-viewed scenes (of an actress emulating interactions with the viewer) while their gaze was eye tracked. This data was used as a normative reference to create a gaze-contingent (GC) adaptive cue system which redirected gaze upon deviation from TD looking patterns. Redirection was accomplished by highlighting TD controls looking locations. In the 2) Experimental phase, toddlers with ASD were randomly assigned to either the adaptive cue condition (cue, n=16, age = 32.3±8.7 months) or a control condition (no-cue, n = 19, age = 35.4±9.3 months).

Proportion of time looking at the screen (%valid) and proportion of time spent looking at the actress's face (%face) were analyzed in a group (3) x block (3) linear mixed model, covarying for Mullen nonverbal DQ. Pearson correlations were applied between change in %face after GC training and the Mullen verbal and nonverbal DQ.

Results: There was a main effect of group for %face (F(2,47)=6.42, p=.003) and a significant group*block interaction (F(4, 163)=3.06, p=0.018). At pre-training there was no difference between groups (ps>0.1). During training, TDs had higher %face than the ASD no-cue (p=0.001), and the ASD cue group was not different from the TDs (p=.062) or ASD no-cue group (p=.11). Post training, the TD group still had more %face than the ASD no-cue (p<0.001) and ASD cue (p = .009) groups, but the ASD cue group had higher %face than ASD no-cue (p=.015). Only the ASD no-cue group had a significant decrease of %face from baseline to training (p=0.028) and post-training (p=0.001), with no trend in the TD and ASD cue groups (ps>0.1). A negative correlation between the Mullen nonverbal DQ and the difference between pre- to post-training of %face was observed for the ASD cue group (r=-.64, p=.013), but not significant for the ASD no-cue (r=0.38, p=0.18) or TD (r=0.11, p=0.65) groups.

Conclusions: Compared with the ASD no-cue group, gaze-contingent training was effective at mitigating decreases of attention towards the face of the dyadic social partner in the ASD cue group. After adaptive training the attention towards the social partner was significantly higher in the ASD cue group than the no-cue group. The negative association with the Mullen nonverbal DQ implies that this approach may have particular relevance as an attentional training tool for more impaired toddlers with ASD.

48 **144.048** Non-Specific Inherited Background Susceptibilities for Autism Spectrum Disorder

S. E. Mous, *Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands*

Background: Previous studies have demonstrated that autism spectrum disorder (ASD) is highly heritable and may arise from the highly deleterious effects of genetic variants as occur in monogenic and oligogenic ASD syndromes. Besides the direct genetic effects, indirect background ASD susceptibilities may amplify the effects of these genetic mutations. For example, it has been shown that the risk for clinical-level ASD affectation in offspring is strengthened when parents exhibit subclinical ASD traits. Many previous studies have demonstrated the aggregation of non-ASD-specific neurodevelopmental impairments in individuals with ASD, such as attention-deficit/hyperactivity disorder (ADHD) symptoms and motor impairments. Although these problems are not part of the DSM5 diagnostic criteria for ASD, these impairments often co-occur in children affected by ASD. Studies strongly suggest genetic overlap between ASD and ADHD and between ASD and motor impairment, but findings from genetic studies are mixed and remain inconclusive. Supporting genetic overlap though, studies have revealed the highly pleiotropic effect of rare mutations in monogenic syndromes, such as the *FMR1*, *TSC1*/*TSC2* and *NF1* mutations, which have all three been associated with both ASD, ADHD and motor impairments.
Objectives: In this talk, both direct genetic effects as well as non-ASD-specific inherited background susceptibilities that amplify the level of ASD impairment will be discussed.

Methods: The first part of this talk describes a retrospective study in 114 males with a clinical diagnosis of ASD and 114 of their male siblings. In all children, quantitative autistic traits (QAT) were assessed, as well as ADHD symptoms and motor coordination. We examined the extent to which these two—non-ASD-specific—neurodevelopmental traits might contribute to ASD recurrence in the siblings. The second part of this talk portrays the direct genetic effect, and describes (preliminary) data on the neurodevelopmental profile (including ASD and ADHD traits) of children with rare monogenic syndromes, such as Fragile X syndrome, Tuberous Sclerosis Complex and Neurofibromatosis type I.

Results: In siblings of ASD-affected probands over 50% of the variation in autistic impairment—whether ascertained quantitatively or categorically—was predicted by sibling ADHD and motor problems. Preliminary data in children with rare monogenic syndromes demonstrates that neurodevelopmental difficulties such as ASD and ADHD are highly prevalent and often co-occur in these patients.

Conclusions: These studies suggest that background ASD susceptibilities that are inherited but non-specific ("BASINS") play a significant role in the development of ASD, and may contribute to additive genetic liability in the same manner that ASD-specific susceptibilities (such as deleterious mutations) engender ASD risk (Figure 1).

49 **144.049** Onset Patterns in ASD: Early Development, Later Outcomes and the Association with Mitochondrial Dysfunctions.

S. Boterberg[1], *E. Vantroys*[2], *R. Siugzdaite*[3], *R. Van Coster*[4] *and H. Roeyers*[1], *(1)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Department of Pediatric Neurology and Metabolism, Ghent University Hospital, Gent, Belgium, (3)Department of Experimental Psychology, University of Ghent, Ghent, Belgium, (4)Department of Pediatric Neurology and Metabolism, Ghent University Hospital, Ghent, Belgium*

Background: Behavioral signs of ASD emerge through different patterns: early onset, regression and plateau. Regression is assumed to be characterized by a 'typical' development, followed by a loss of previously acquired skills at a mean age of 21 months in 33% of the children with ASD. Recently, a meta-analysis on mitochondrial dysfunctions (MD) in ASD demonstrated an overall prevalence of 5%. Children with ASD+MD showed more seizures, motor delay, gastro-intestinal abnormalities and an elevated lactate (a biochemical marker of MD). Furthermore, in 52% of the cases, regression was noted.
More insight into the course, prevalence and pathogenesis of onset patterns in ASD would be of significant diagnostic and clinical value.
Objectives: The first purpose is to explore the trajectories of onset patterns in ASD and long-term outcomes. Second, we want to examine the presence of MD and their association with the severity of ASD-symptoms and regression.

Methods: Participants were 100 children with ASD (*M* age=7.48y,sd=1.98,range=3-11y;70% boys). Parent report was used to measure early ASD-symptoms and classification to onset group (EDQ,ADI-R,RSQ). Non-verbal intelligence was measured through the WNV and current severity of ASD-symptoms by the ADOS-2. Screening of MD included measurement of lactate in urine and near-infrared spectroscopy (fNIRS) in the brain.

Results: The results revealed an early onset (≤12m;38%), a later onset (>12m;34%) and an early onset+regression group (10%). Other children had a typical development followed by regression (13%) or plateau (5%). Regression (*M* onset=22m) involved in 78% of the children loss of language skills. Children with regression (ASD-R) showed significantly lower non-verbal intelligence scores (*M* IQ=81.50,sd=21.47) compared to children without regression (ASD-NR;*M*IQ=93.04,sd=20.18;*t*(94)=2.321,*p*<.05). Examination of current severity of ASD-symptoms showed significantly more symptoms in ASD-R (*U*(98)=1152.5,*p*<.05).
Based on the lactate results, the children were divided into three groups: low lactate (*n*= 20;*M*=2.05mg/dL,sd=.84), medium lactate (*n*=58;

M=5.45mg/dL,sd=1.75) and high lactate (*n*=20;*M*=11.52mg/dL,sd=2.55). Examination of early and current severity of ASD-symptoms showed no significant differences between the two extreme groups. Furthermore, no significant differences in non-verbal intelligence were found between the low (*M* IQ=87.37,sd=24.60) and the high lactate group (*M* IQ=90.75,sd=23.40; *t*(37)=.441;*p*=.662). The proportion of ASD-R did not differ between the high and the low lactate group ($\chi^2(1)=3.135; p=.08$). In addition, there was no significant difference between the lactate value of ASD-R (*M*=5.27mg/dL,sd=2.93) compared to ASD-NR (*M*=6.23mg/dL,sd=3.77;*U*(98)=757.5,*p*=.281). However, preliminary fNIRS results showed a significant difference between ASD-R and ASD-NR in the curves of the oxy-hemoglobin response in the temporal lobe of the right hemisphere (*z*=3.215;*p*<.05).

Conclusions: We found support for different onset patterns previously suggested in the literature. Further, ASD-R display more severe impairments later in life as measured by non-verbal IQ and ASD-symptomatology.
Based on lactate in urine as a biochemical marker of MD, no significant differences in the severity of ASD-symptoms and onset patterns were found. Still, there is a need for further examination since normal lactate levels have been reported in case studies of ASD+MD. Furthermore, preliminary analysis of fNIRS data showed a higher oxy-hemoglobin level in the brain of ASD-R. Final fNIRS results will be presented at the conference.

50 **144.050** Parent-Infant Interaction in Infants with Neurofibromatosis Type 1

M. W. Wan[1]*, S. Garg*[1]*, A. Kolesnik*[2]*, E. J. Jones*[3]*, J. Green*[1] *and M. H. Johnson*[4]*, (1)University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (2)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom of Great Britain and Northern Ireland, (3)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (4)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom*

Background: Neurofibromatosis Type 1 (NF1) is a single gene autosomal dominant syndromic model of autism with a prevalence of 1 in 3000 with well described neurobiology in animal models . Unlike ASD, NF1 can be diagnosed in infancy using cord blood testing for mutations in affected families .. A recent case series describes the first developmental profiles of infants with NF1 and reports delayed or impaired motor and communicative skills in all cases relative to infants at high familial risk who were subsequently diagnosed with ASD (as well as high-risk infants that were typically developing and low-risk controls). Since infants who are later diagnosed with ASD show parent-infant interactions that diverge from those seen in typical development from around 9-10 months of age, infants with NF1 may show further divergence in such interactions, with implications for their social and communicative development.
Objectives: As part of the prospective Early Development in Neurofibromatosis Type 1 (EDEN) project, we examined the interactions of 12 ten to 11-month-old infants with NF1 with their parents. The aims are: (1) to describe their parent-infant interactions, (2) to compare their interactions to those of high-risk infants with later ASD (from the British Autism Study of Infant Siblings; BASIS), high-risk infants with typical development, and low-risk infants; (3) to explore the associations between the parent-infant interactions of infants with NF1 and concurrent motor, communicative, social and cognitive functioning.

Methods: The validated Manchester Assessment of Caregiver-Infant Interaction (MACI) is a global measure used to evaluate seven areas of interaction. Evaluations of 6-min videotaped unstructured play interaction were made by two independent trained coders blind to all family information. The Mullen Scales of Early Development and Vineland Adaptive Behavior Scale (Parent Form) were completed as part of a battery of assessments.

Results: The parent-infant interactional styles of these infants will be described, highlighting how high object (toy) interest and low attentiveness to parent seem to have differential impacts on parental response that affect the infant's social experience. Aspects of parent-infant interaction were correlated with their concurrent motor and communicative scores, but not their social and cognitive scores. We will report on group differences in MACI (parent-infant interaction) ratings.

Conclusions: Our findings are consistent with the interpretation that the early emergence of motor and communicative difficulties in infants with NF1 impact social interactions with their parents in specific ways that may reduce the social opportunities, which are important for their communicative and social development. Furthermore, unlike infants at familial risk of ASD, who have at least one older sibling, these infants do not necessarily have a sibling. Thus, these early findings may be taken as support for altered parent-infant interaction being the result of the emergence of early neurodevelopmental markers rather than learned interactive styles (from interacting with the older child in the case of ASD).

51 **144.051** Predicting ADOS Scores Based on Behavioral Ratings from Parents and Pre-School Teachers

E. Nilsson Jobs[1]*, S. Bolte*[2] *and T. Falck-Ytter*[3]*, (1)Karolinska Institute, Stockholm, Sweden, (2)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (3)Karolinska Institutet & Uppsala University, Uppsala, Sweden*

Background:
Information from different informants such as parents and teachers is regarded as valuable as it can contribute to early detection of autism spectrum disorder (ASD; Dereu et al., 2012) and lead to a greater understanding of how the child is functioning in different environments. However, information can differ between informants (Rescorla et al., 2014; Stratis & Lecavalier, 2015). The ASEBA Preschool Forms Child Behavior Checklist (CBCL) and Teacher Report Form (C-TRF) 1.5 - 5 years (Achenbach & Rescorla, 2000) are often used as screening instruments for behavioral symptoms and psychiatric conditions in children. Among other scales, the forms include a total problem scale and a scale that is related to autism symptoms, i.e. Pervasive Developmental Problems (PDP). It is still rather unexplored how well these scales are correlated with clinical assessment of ASD symptoms.

Objectives:

The aim of the study was to investigate how much variance of the ADOS – 2 comparison scores (CS) can be explained by scores on the CBCL and C-TRF (total problem scale and the autism-related PDP scale). We expected that scores from both parents (CBCL) and pre-school teachers (C-TRF) would predict autism symptoms, measured by the ADOS-2 CS at 3 years of age. We also explored if any of the two informants contributed more than the other to the model.
Methods:

Fifty-seven 3-year-old children from an at-risk-for-ASD sibling study (33 (18 girls) high-risk-for-ASD with no diagnosis; 10 (5 girls) high-risk-for-ASD with ASD diagnosis and 14 (7 girls) controls) participated. Multiple linear regressions with CBCL and C-TRF entered as predictors were conducted separately for the total problems scale and the autism related PDP scale, with ADOS- 2 CS as the dependent variable throughout.

Results:

For the total problems scales, the model was significant (R^2 = .189, *P* =.004), and neither CBCL nor C-TRF contributed uniquely to the prediction of ADOS-scores (*Beta*s = .309 - .189, *P*s = .186 - .237). For the PDP-scale, the model was significant (R^2 = .298, *P* = < .001) and only the preschool teachers' ratings contributed uniquely to model fit (*Beta* = .538, *P* = .010, explained variance 23 %). This pattern of results was also replicated when excluding all low-risk participants from the analyses.

Conclusions:

Combined, behavioral ratings based on the CBCL and C-TRF explained a substantial proportion of the variance in the ADOS scores. Parents´ scores on the CBCL total and PDP subscales did not give a unique contribution to the prediction of ADOS scores over and above the contribution provided by preschool teachers' ratings. In contrast, the pre-school teachers' ratings on the PDP scales (but not total scores) made a unique contribution to the prediction of ADOS-2 CS- scores. This suggests that pre-school teachers' ratings may be particularly useful in the context of early diagnosis of autism.

52 **144.052** Predictors of Language Development in Young Children with Autism Spectrum Disorder: A Longitudinal Study

C. C. Wu[1] *and C. W. Shen*[2]*, (1)Department of Psychology, Kaohsiung Medical University , Kaohsiung, Taiwan (Province of China), (2)Kaohsiung Medical University, Kaohsiung, Taiwan*

Background: Previous studies have shown that early language ability is related to long-term outcomes and adaptive function in children with autism spectrum disorder (ASD). It is an important issue to explore predictors of language development in young children with ASD. Joint attention and imitation were supported that they could enhance language development in young children with ASD. However, there were few longitudinal studies to examine that both joint attention and imitation contribute to language development in young children with ASD under 36-months-old.

Objectives: The purpose of this longitudinal study was to examine that joint attention and imitation predict language development in young children with ASD less than 36 months.

Methods: The participants were 74 young children with ASD aged 17-35 months (*M* = 24.2, *SD* = 4.4) at initial assessment who were followed up 18 months after their initial assessment. The Screening Tool for Autism in Two-Year-Olds, Taiwan version (T-STAT; Chiang et al., 2013) was modified for measuring joint attention and imitation, including initiating joint attention, responding joint attention, object imitation and manual imitation. In addition, Mullen Scales of Early Learning (MSEL; Mullen, 1995) was used for assessing language abilities, including receptive language, expressive language and overall language. Joint attention and imitation were assessed at initial assessment and language abilities were assessed at two time points.

Results: Language abilities at 24 months, all of receptive language, expressive language and overall language were concurrent correlated with joint attention and imitation. The significant concurrent predictors of receptive language and overall language were responding joint attention and manual imitation. In addition, the significant concurrent predictor of expressive language was manual imitation. Language abilities at 42 months, all of receptive language, expressive language and overall language were longitudinal correlated with responding joint attention and imitation. The significant longitudinal predictors of receptive language and overall language were responding joint attention and manual imitation. In addition, the significant longitudinal predictor of expressive language was manual imitation.

Conclusions: Results of this longitudinal study showed that responding joint attention and imitation were concurrent and longitudinal correlated with language abilities in young children with ASD. However, initiating joint attention was only concurrent correlated with language abilities in young children with ASD. The results showed that manual imitation was the stronger predictors for receptive language, expressive language and overall language at 24 months and at 42 months in young children with

53 **144.053** Prospective Investigation of Early Clinical Predictors of Autism Spectrum Disorders in Infants with Tuberous Sclerosis Complex: First Analysis from the Epistop Project

A. Benvenuto[1]*, R. Moavero*[2]*, M. Siracusano*[3]*, L. Emberti Gialloreti*[3]*, E. Aronica*[4]*, A. Jansen*[5]*, F. E. Jansen*[6]*, S. Jozwiak*[7]*, K. Kotulska-Joswiak*[7]*, D. Kwiatkowski*[8]*, L. Lagae*[9] *and P. Curatolo*[1]*, (1)University of Rome Tor Vergata, Rome, Italy, (2)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy, (3)Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy, (4)Academisch Mediche Centrum, University of Amsterdam, Amsterdam, Netherlands, (5)Vrije Universiteit Brussel, Brussels, Belgium, (6)University Medical Center Utrecht, Utrecht, Netherlands, (7)Children's Memorial Health Institute, Warsaw, Poland, (8)Brigham and Women's Hospital, Harvard Medical School, Boston, MA, (9)University of Leuven, Leuven, Belgium*

Background: Tuberous sclerosis complex (TSC) is a genetic multisystem disorder that confers a high risk of early neurodevelopmental conditions. Little is known about early onset of developmental delay and of autism spectrum disorders (ASD) in this high risk population. The EPISTOP project is a multi-center prospective European study focused on evaluating clinical and molecular biomarkers of epileptogenesis and neurodevelopmental disorders in the genetic model of TSC.

Objectives: The objective of the work package 7 of EPISTOP is to identify early neurodevelopmental outcome in TSC patients in the first months of life. The main goal of this preliminary analysis is to identify early deviation in developmental trajectories and in specific skills potentially predictive of ASD onset.

Methods: 99 EPISTOP TSC subjects were prospectively followed from age of 6 months with Bayley Scales of Infant Development (BSID) for the evaluation of cognitive, language and motor level. Autism Diagnostic Observation Schedule (ADOS) was administrated from 12 months for the identification of ASD risk. All tests were repeated every 6 months up to 24 months of age. At this moment, data collection is still ongoing. We focused our analysis on the correlation with BSID sub-quotients at 6, 12 and 18 months and ASD risk based on ADOS total score at 24 months. ADOS and BSID changes over time were evaluated with paired samples t-test. Comparisons between groups were performed, as appropriate, with two-sample t test, ANOVA models, and Pearson's correlations. An alpha level of 0.05 was used for all statistical analyses, which were performed using SPSS v.23.0 (IBM Corp., Armonk, NY, USA).

Results: Data is available for 69 children at age 6 months and 46 at 24 months. At 6 months, 20% of children showed developmental delay in cognitive and language areas, and 53% had an impairment in the motor area of the BSID. At 24 months, an increased percentage of developmental delay (30%) could be observed in all the three developmental quotients. At 6 months, no significant correlations were found between development level of the three BSID areas and ADOS total score (p 0.15). At 12 months, children with lower scores in cognitive and language quotients presented higher risk of ASD calculated on ADOS total score at 24 months (p 0.02). At 18 months, the statistical significance of this correlation increases (p 0.01) and involves all BSID subquotients.

Conclusions: Our preliminary observations show an early deviation from a normal developmental trajectory in infants with TSC in the first 6 months of life, particularly in the motor area. Impairment in cognitive and language level at 12 months could be predictive of ASD at 24 months in these high-risk children. Prospective neurodevelopmental assessment associated with a close neurological and EEG follow-up could be useful to identify early correlation between clinical and neurobiological markers of ASD, to design individualized treatment strategies and to improve both short and long term outcomes for this population.

54 **144.054** Quality of Interaction between Very Preterm Infants and Their Mothers and Its Relationship with General Development and Autism Features

J. Vermeirsch[1], *E. Demurie*[1], *E. Bruyneel*[2], *L. Verhaeghe*[2] *and H. Roeyers*[1], *(1)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Department of Experimental-Clinical and Health Psychology, Ghent University, Gent, Belgium*

Background: Previous research has indicated that preterm born children have an increased risk for impairments across different domains (e.g., cognition, language) and for neurodevelopmental disorders such as Autism Spectrum Disorder (ASD; e.g., Dudova et al., 2014). Apart from the biological vulnerability, environmental factors such as early parent-child interactions (PCI) also seem to be important to understand differences in developmental outcome associated with ASD (e.g., Wai Wan et al., 2012). It is surprising that, although these early PCI can have a profound impact on the development of preterm infants (PI), to date still little prospective research has been conducted on these interactions and their relationship with later outcome in infants at risk for ASD.

Objectives: This study aimed to compare the early PCI of PI with the PCI of their term born counterparts (TI) and to investigate if the developmental trajectories of PCI are similar in both groups. Among PI, this study also examined whether characteristics of such early interactions can predict the emergence of ASD symptomatology and general development at 36 months.

Methods: Drawing on the model of prospective studies of infant siblings, a longitudinal follow-up study was set up to identify early developmental trajectories. Global aspects of PCI were assessed at 5, 10, 18, 24 and 36 months of age during unstructured play interactions in 67 PI (<30 gestational weeks) and 38 TI and coded with the Coding Interactive Behaviour rating scales (Feldman, 1998). At 36 months, measures of developmental level (MSEL) and language (RDLS) were included and ASD features were observed with the ADOS-2.

Results: Results showed that PI were less involved in the interaction at 10 and 36 months, and their parents exhibited lower sensitive responding at 10 months. Moreover, the dyadic patterns between PI and their mothers were less reciprocal at 10, 24 and 36 months. Preliminary analyses showed that different maternal, child and dyadic factors of PCI in the first two years of life are related to developmental level at 36 months. Maternal sensitivity and intrusiveness at respectively 10 and 18 months and child involvement at 24 months were associated with language comprehension and production at 36 months. We also found significant associations between two child domains of interaction at 10 and 18 months and social affect scores on the ADOS-2 at 36 months. More detailed analyses will be provided at the meeting.

Conclusions: These results indicate that mother-preterm dyads experience more interactional difficulties than mother-full term dyads in the first years of life. This study also provides information on the association between the quality of PCI and different aspects of development in PI, an area that has been analysed in only a few studies. In the PI-group, different characteristics of the quality of PCI were significantly associated with later general development and ASD features. This finding may stress the importance of supporting different aspects of the early PCI in PI because it may lead to better general development and less severe ASD symptomatology later in life.

55 **144.055** Response to Distress in 12-Month-Old Infants with Familial Risk for ASD

L. P. Jackson[1], *N. M. McDonald*[2], *C. Ponting*[3], *S. Jeste*[3] *and M. Dapretto*[4], *(1)UCLA, Los Angeles, CA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

Background: Autism spectrum disorder (ASD) is a highly heritable neurodevelopmental disorder characterized by core deficits in social communication skills. Infants with familial risk for ASD (i.e., younger siblings of children with ASD) have a recurrence rate of 18.7%, with infants from multiplex families (i.e., multiple affected siblings) carrying an additional twofold increase in risk compared to those from simplex families (i.e., one affected sibling; Ozonoff et al., 2011). Although several studies have demonstrated deficits in empathic response to others' distress in toddlers with familial risk at 2-3 years of age (Campbell et al., 2017; Hutman et al., 2010; McDonald et al., 2012), only one study has examined empathic responding in infants with familial risk at 12 months, when empathic behavior first begins to emerge in typical development. Here, we examined the response to distress at 12 months in infants at variable risk for ASD (both multiplex and simplex infants) and compared them to low-risk (LR) infants.

Objectives: (1) Compare infant responses to others’ distress at 12 months between risk groups. (2) Examine whether infant responses to others’ distress correlate with standardized measures of social communication skills. (3) Examine whether infant responses to others’ distress predict 18-month ASD symptoms.

Methods: Participants included 23 LR, 26 simplex, and 9 multiplex infants at 12 and 18 months of age. During the simulated distress paradigm, an examiner pretended to hit her finger with a toy mallet. *Attention to distress,* defined by the proportion of time infants paid attention to the person in distress, was coded. Other measures of 12-month social behavior included: Early Social Communication Scales (i*nitiation of joint attention [IJA], initiation of behavioral requests [IBR], response to joint attention [RJA]*) and Autism Observation Scale for Infants (*AOSI total score*). At 18 months, ASD symptoms were measured with the Autism Diagnostic Observation Schedule–Toddler Module (*ADOS-T*).

Results: (1) Attention to distress did not significantly differ based on risk group (table 1), although multiplex infants had lower scores than the other two groups. (2) Attention to distress was significantly positively correlated with IBR, but not IJA, RJA or AOSI at 12 months (table 2). (3) Attention to distress was negatively correlated with the ADOS-T Social Affect score at 18 months (table 2). A linear regression model with all 12-month variables significantly predicted ADOS-T total score (R^2=0.378, F(5,39)=4.731, p=0.002); RJA (b=-0.313) and AOSI (b=0.253) explained the most unique variance in 18-month ADOS-T score.

Conclusions: Findings are consistent with previous work indicating that a lack of response to distress during infancy and toddlerhood is an important early sign of atypical social development, which is specifically related to emerging ASD symptoms and not to familial risk. Results also suggest, however, that it is important to measure a range of social behaviors when assessing risk for ASD. This study highlights the need for early interventions to enhance empathic responses and social communication skills starting as early as 12 months of age. Next steps include examining other aspects of infants' responses to distress, including empathic concern and hypothesis testing.

56 **144.056** Sex Differences in Screening Profiles of Toddlers with Autism

S. James[1], *E. Bacon*[2], *C. J. Smith*[1] *and K. Pierce*[2], *(1)Southwest Autism Research & Resource Center, Phoenix, AZ, (2)Neurosciences, University of California, San Diego, La Jolla, CA*

Background: Research suggests that gender differences in behavior and development exist among typically developing children. For example, female toddlers tend to show more advanced language development and social reciprocity, whereas males demonstrate higher levels of physical activity (Riddoch et al., 2007; Zambrana et al., 2012). Although under-researched, gender-specific behaviors of toddlers with autism are starting to emerge in the literature. For instance, research has found differences in the manifestation of autism symptoms (e.g. females exhibiting fewer stereotypies), which may contribute to male bias in prevalence estimates (Werling & Geschwind, 2013). If sex differences in phenotypic presentations of autism exist, screening and diagnostic measures may need to be re-examined and amended.

Objectives: This study aimed to examine sex differences in screening profiles of toddlers with autism. Specifically, we examined if items on the Communication and Symbolic Behavior Scales Developmental Profile Infant-Toddler Checklist (CSBS) varied between male and female toddlers with autism.

Methods: Data were collected as part of a larger study testing a model designed to detect, evaluate, and treat autism within the first 2 years of life. Analyses for this study focused on 265 toddlers (207 males and 58 females) who failed the CSBS and were found to have autism after receiving a developmental evaluation. Multinomial logistic regression was used to model the relationship between gender and individual CSBS items, controlling for age.

Results: Gender was found to make a significant contribution to predicting only two items of the CSBS (see Table 1): males were more likely than females to score higher on items that address stringing sounds together (OR = 2.39, $p < .05$) and number of words used meaningfully (OR = 2.82, $p < .05$). Approximately one-third (31.6%) of the females, compared to one-fifth (21.3%) of the males, were reported to not string any sounds together. Almost half (46.4%) of the females, compared to one-third (30.1%) of the males, were reported to not use any words meaningfully.

Conclusions: Among toddlers with autism, the only significant gender differences were observed in two facets of expressive language: a male advantage in stringing sounds together and number of words used meaningfully. Inconsistent with patterns observed among typically developing children, this suggests that females with autism identified by the CSBS had more impaired expressive language than their male counterparts. This sheds light on the possibility that the CSBS is better at detecting females with the classic presentation of autism characterized by expressive language delay, and less sensitive in detecting ASD females without expressive language impairment.

57 **144.057** Social Orienting and Joint Attention in 9 to 12 Month Old Children with ASD with and without Intelectual Disability: A Study with Family Home Movies

R. Palomo[1], *S. Ozonoff*[2], *G. S. Young*[2] *and M. Belinchon*[3], *(1)Department of Basic Psychology, Universidad Complutense de Madrid, Madrid, Spain, (2)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (3)Department of Basic Psychology, Universidad Autónoma de Madrid, Madrid, Spain*

Background: Studies analyzing family home movies of young children later diagnosed with autism spectrum disorder (ASD) indicate that social orienting behaviours (looking at faces/people and responding to name) are the earliest identifiable specific symptoms (Baranek, 1999; Osterling et al., 2002). The Social Motivation Model (Dawson et al., 2002, 2005a,b) considers the social orienting deficit observed in autism at the end of the first year as the earliest behavioural consequence of an alteration in the dopamine reward system balance. This model predicts that the imbalance in the social reward system has developmental consequences for social perception as well as for complex behaviours such as imitation, attention disengagement, intentional communication and especially, joint attention (Dawson, Toth, Abott et al., 2004).

Objectives: (1) To compare the early social and communicative development of children between 9 and 12 months old, later diagnosed with ASD, with and without intellectual disability (ID); (2) to test the predictions from the Social Motivation Model (Dawson et al., 2005a,b) that at the end of the first year of life all ASD groups will show social orienting deficits, which will contribute to joint attention impairment.

Methods: We coded family home movies from children with typical development (TD, n=16), ASD with ID (ASD-ID, n=17) and ASD with normal IQ (ASD-N, n= 12). First, we coded the general content from the videotapes (e.g., setting, contexts, type of social activity, number of people in the frame) using an adaptation of Baranek's (1999) code. Then, using Noldus, The Observer 5.0, we analysed several social orienting (social gaze and responding to name) and joint attention (gaze alternation and gestures) behaviours using a coding system based on Dawson's (Osterling et al., 2002).

Results: There were no significant differences in the general content of the tapes. There were no significant differences found in any of the social orienting behaviours coded or total time the children expressed positive or negative emotions. Children with TD used significantly more vowel vocalizations than both ASD groups. Compared with TD, the ASD-ID group showed significantly fewer initiations of joint attention (IJA). The ASD-N group tended to show the same pattern but differences from the TD group did not reach statistical significance. There were no significant differences in any behaviour between the two ASD groups. Social orienting behaviours were not significantly correlated with IJA gazes or gestures in either the total sample or within any of the groups. A discriminant analysis using a dichotomous classification (TD vs ASD) showed that the combination of IJA and orienting behaviours was the best predictor of diagnosis, correctly classifying 73.3% of the participants. Individually, IJA classified 71.1% of the participants, while orienting behaviours 62.2%.

Conclusions: We did not find social orienting difficulties between 9-12 month olds with TD and those who went on to develop ASD but we did find significant differences in IJA development. Thus, our results don't support the predictions of the Social Motivation Model, implying that IJA impairment in ASD is developmentally independent of and not preceded by social orienting deficits.

58 **144.058** Symptom Severity Trajectories from Infancy to Childhood in Siblings at Risk for Autism Spectrum Disorder: Social Affect and Restricted and Repetitive Behaviors.

M. Franchini[1]*, E. Duku*[2]*, V. Armstrong*[3]*, J. A. Brian*[4]*, S. E. Bryson*[5]*, N. Garon*[6]*, W. Roberts*[7]*, C. Roncadin*[8]*, L. Zwaigenbaum*[9] *and I. M. Smith*[10]*, (1)Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (2)McMaster University, Hamilton, ON, Canada, (3)IWK Health Centre / Dalhousie University, Halifax, NS, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Dalhousie University, Halifax, NS, Canada, (6)Mount Allison University, Sackville, NB, Canada, (7)isand, Toronto, ON, Canada, (8)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (9)University of Alberta, Edmonton, AB, Canada, (10)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA*

Background: Siblings of children with autism spectrum disorder (ASD) show an increased risk (up to 18.7%) of developing the same disorder and an additional 28% rate of sub-clinical manifestations, developmental delays or deficits in other areas of development/behavior. However, the distinctive patterns by which the early symptomatology emerges in these children remain unclear.
Objectives: Here, we aim to define distinct developmental trajectories for ASD symptom severity for the total score and social affect (SA) and restricted/repetitive behaviors (RRB) subdomains of the Autism Diagnostic Observation Schedule (ADOS). Trajectory groups were examined from 1.5 years to 5-7 years of age. Early clinical and cognitive predictors (before 1.5 years of age) will also be determined for each measure

Methods: We used Group Based Trajectory Models (GBTM) to derive early symptom severity trajectory groups for three diagnostic measures: Total, SA and RRB scores from the ADOS at 18, 24, 36-42, and 60-84 months of age. The sample was composed of 502 high-risk siblings (281 males), of whom 128 received an ASD diagnosis at 36 months. Clinical and cognitive measures were also collected before this period (at 6, 12 and 18 months), with respectively the Autism Observational Scale for Infants (AOSI) and the Mullen Scales of Early Learning (MSEL). Predictors and diagnostic membership were examined according to the derived trajectory groups of symptom severity for each of the three diagnostic measures.

Results: Analysis revealed three distinct trajectory groups for the symptom severity Total score and two for each subdomain (SA and RRB). Pairwise comparisons between trajectory groups for quadratic slope estimates revealed significant differences for all comparisons (all $p<.001$). No significant difference in the intercepts was evidenced between trajectories for the Total score (all $p>.24$), but there were differences for the two subdomains (all $p<0.01$). As expected, children with an ASD diagnosis were more likely to be in the trajectory groups with the highest scores on Total, SA and RRB measures. Finally, from 6 months of age, language-related cognitive measures at the MSEL were more predictive of SA trajectory membership, and motor skills at RRB trajectory membership. From 12 months of age, AOSI clinical scores were also highly predictive of severity score trajectory membership for all three diagnostic measures.

Conclusions: Our results confirm substantial heterogeneity in the early emergence of ASD symptomology in children at high risk for ASD. The results also suggest that ADOS SA and RRB subdomain severity scores yield distinctive trajectories with distinctive predictors. The current study has clinical implication in revealing developmental heterogeneity in the early emergence of ASD symptomology in each diagnostic criterion domain.

59 **144.059** Temperament As an Early Risk Marker for Autism Spectrum Disorders in a Cohort of the British Autism Study of Infant Siblings (BASIS)

M. K. J. Pijl[1,2]*, G. Bussu*[3]*, T. Charman*[4]*, M. H. Johnson*[5]*, E. J. Jones*[6]*, I. J. Oosterling*[2]*, N. N. J. Rommelse*[7]*, J. K. Buitelaar*[8,9] *and &. The BASIS Team*[10]*, (1)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Centre Nijmegen, Nijmegen, Netherlands, (2)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (3)Donders Institute for Brain, Cognition and Behaviour, Radboudumc, Nijmegen, Netherlands, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (6)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (7)Department of Psychiatry, Donders Institute for Brain, Cognition and Behaviour, Radboud university medical center, Nijmegen, Netherlands, (8)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (9)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (10)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom*

Background: Since temperamental traits can be linked to neurobiological systems and are already measurable at an early age, potentially before autistic symptoms emerge, temperament could be used as a potential early risk marker for autism spectrum disorders (ASD). Previous studies revealed that the known three temperamental constructs (i.e. surgency [SU], negative affect [NA], regulation/effortful control [EC]) are associated with ASD from infancy onwards. This study aims to investigate temperament as an early risk marker in a high-risk (HR) and low-risk (LR) infant sibling design.
Objectives: (1) Investigating group differences in early temperament *at* and *across* multiple time points between HR-ASD (HR siblings subsequently diagnosed with ASD), HR-Atypical (HR siblings not diagnosed with ASD, but following an atypical development), HR-Typical (HR siblings with a typical development), and LR siblings, and (2) Predicting ASD and atypical development at 36 months at an individual level based on temperament during the first two years of life.

Methods: As part of the British Autism Study of Infant Siblings (BASIS), 247 infants (170 HR, 77 LR) participated in a battery of assessments during their first three years of life. Parents completed the Infant Behavior Questionnaire-Revised (IBQ-R) at 8- and 14 month visits, and the Early Childhood Behavior Questionnaire (ECBQ) at the 24 month visit. (1) MANCOVAs were used to investigate whether a risk gradient was present in polynomial group contrasts (HR-ASD > HR- Atypical > HR-Typical > LR) at separate time points. In post-hoc analyses pair wise group contrasts were examined across time by performing two-way mixed ANCOVAs. (2) Machine learning algorithms were used to investigate how temperamental measures at 8, 14 and 24 months related to atypical development, and more specifically ASD, at an individual level. Sex and age at the first visit were included as covariates in all analyses.

Results: (1) Risk gradients were found for SU at 14 months (Contrast Estimate [CE] = 0.40, $p = 0.02$), NA at 8, 14 and 24 months (CE = -0.46, $p = 0.004$;

CE = -0.38, *p* = 0.02; CE = -0.69, *p* < 0.001, respectively), and EC at 14 and 24 months (CE = 0.69, *p* < 0.001; CE = 0.84, *p* < 0.001, respectively). Furthermore, differences were found between groups based on both early trajectories (as revealed by interaction effects between group and time) and levels (as shown by main group effects) of temperament. (2) None of the temperamental traits was able to accurately predict ASD at 36 months. For prediction of HR-ASD, the combination of all factors at 24 months provided the most promising classifier (AUC=72%, *p*=0.02). For prediction of atypical outcome (i.e., HR-ASD plus HR-Atypical), the integration of EC and NA at 24 months provided the most promising classifier, but performance was not significantly different from chance level (AUC=61%, *p*=0.056).

Conclusions: Our findings indicate that although differences on temperamental traits at a group level can be detected early in infancy, this does not necessarily translate into an acceptably accurate individual classification. Explanations for findings and recommendations for future research will be discussed.

60 **144.060** The Characteristics of F0 Contours in Speech Directed at Infants at-Risk for Autism

A. Woolard[1], *T. Benders*[2], *F. Karayanidis*[3], *V. Murphy*[4], *C. A. Mallise*[5], *O. Whalen*[1], *L. E. Campbell*[6] *and A. E. Lane*[7], *(1)University of Newcastle, Australia, Callaghan, Australia, (2)Linguistics, Macquarie University, Sydney, Australia, (3)Psychology, University of Newcastle, Australia, Callaghan, Australia, (4)Medicine and Public Health, University of Newcastle, Australia, Callaghan, Australia, (5)The University of Newcastle, Callaghan, Australia, (6)School of Psychology, University of Newcastle, Newcastle, Australia, (7)University of Newcastle, Callaghan, Australia*

Background: The mother-infant interaction mediates early development and sensory regulation, and these interactions largely comprise early sensory experiences for the infant. One way mothers interact with their baby is through infant-directed speech (IDS), which is a unique speech register used by adults when speaking to infants. In particular, IDS can facilitate socio-communicative and language development in infants. One salient aspect of IDS is the trajectory of pitch, known as F0 contours. Research shows F0 contours are associated with infant affect and attention, but less is known about how F0 contours vary across contexts. It is important to understand the role of IDS with infants who are at-risk for socio-communicative, sensory regulation or language delay. Infants later diagnosed with Autism Spectrum Disorder (ASD) display significant impairments in these areas, however there is currently no research investigating how maternal F0 contours are used with these infants. It was hypothesised that infants at-risk for ASD would be spoken to differently when compared to infants not at-risk.
Objectives: The aim of this study was to compare F0 contours used by mothers when interacting with infants at-risk for ASD, to those used by mothers interacting with infants not at-risk.

Methods: Six 12-month-old infants and their mothers participated in a 15-minute recorded interaction. Of the six infants in the study, three were clinically at-risk for ASD (high-risk), and three infants were not at-risk (low-risk). Infant risk for ASD was assessed using the parent-report First Year Inventory, which indicates two areas of risk; socio-communication and sensory regulation (Reznick, Baranek, Reavis, & Crais, 2007). 1039 maternal F0 contours were extracted from the audio recorded during the interaction, and classified into contour types (rising, bell, sinusoidal, u-shape, slowly-falling, rapidly-falling, and complex). Independent samples t-tests were performed to investigate differences in mean proportions of F0 contours used with high-risk and low-risk infants. Pearson product-moment correlations were conducted to determine any associations between ASD risk and the proportion of contours used.

Results: Mothers of high-risk infants spoke a total of 419 utterances during the interaction, compared to 620 spoken by mothers of low-risk infants. Preliminary analyses of contours used between mothers of high-risk infants compared to low-risk infants revealed a difference in frequency of slowly-falling contours, which was approaching significance (*t*=-2.714, df=4, *p*=.053). More complex contours (*r*=.824, *N*=6, *p*=.04) and less rising contours (*r*=-.811, *N*=6, *p*=.05) were associated with a high-risk for ASD. Higher sensory regulation risk was associated with less rising (*r*=-.853, *N*=6, *p*=.031), more complex (*r*=.858, *N*=6, *p*=.029), and more rapidly-falling contours (*r*=.829, *N*=6, *p*=.041).

Conclusions: Although the sample size is small, these preliminary results suggest that infant risk for ASD is related to the way mothers use F0 contours during interactions. This could provide evidence that infants at-risk for ASD, even as early as 12 months-old, are spoken to differently than infants not at-risk. Further research into how mothers use IDS with high-risk infants is recommended and will be presented at the conference, in order to inform early interventions that could improve outcomes for children diagnosed with ASD.

61 **144.061** The Short Quantitative Checklist for Autism in Toddlers (Q-CHAT-10) As an Early “Red Flag” Screen for Autism Spectrum Disorder: A High-Risk Sibling Cohort Study

S. Raza[1], *L. A. Sacrey*[2], *K. Reid*[1], *S. E. Bryson*[3], *J. A. Brian*[4], *I. M. Smith*[5], *W. Roberts*[6], *P. Szatmari*[7], *T. Vaillancourt*[8], *C. Roncadin*[9], *N. Garon*[10] *and L. Zwaigenbaum*[1], *(1)University of Alberta, Edmonton, AB, Canada, (2)Autism Research Centre, Edmonton, AB, CANADA, (3)Dalhousie University, Halifax, NS, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)isand, Toronto, ON, Canada, (7)The Hospital for Sick Children, Toronto, ON, Canada, (8)University of Ottawa, Ottawa, ON, Canada, (9)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (10)Mount Allison University, Sackville, NB, Canada*

Background: Identifying early risk markers of Autism Spectrum Disorder (ASD) is crucial in order to facilitate earlier detection of ASD and implement targeted interventions to improve functional outcomes. To support utilization in community practice, the development of brief screening tools are warranted. One such screening tool is the Quantitative Checklist for Autism in Toddlers (Q-CHAT), which was developed as an adaptation of the original Checklist of Autism in Toddlers (CHAT). A recent abbreviated version (Q-CHAT-10; Allison et al., 2012) shows promise, but further evaluation of this screen is warranted.
Objectives: The objective of this study was to examine the classification properties of the short Quantitative Checklist for Autism in Toddlers (Q-CHAT-10) as a rapid screen for ASD in a high-risk (HR) sibling population.

Methods: Participants were drawn from an ongoing longitudinal study of early development of ASD, and included 90 high-risk (HR) infants with an older sibling with ASD. For the purpose of evaluating the Q-CHAT-10, the group was further stratified into three groups: (1) HR toddlers who received an ASD diagnosis at 36 months (HR-ASD; *n*=19); (2) HR toddlers who meet the criteria for the broader autism phenotype (HR-broader autism phenotype (HR-BAP); *n*=31) and; (3) HR toddlers that do not meet the criteria for the broader autism phenotype (HR-typically developing (HR-TD); *n*=40). Criteria for BAP were: (1) does not meet criteria for an ASD diagnosis; (2) two or more Mullen subtests at ≥ 1.5 standard deviations (SD) below the mean; and/or (2) one or more Mullen subtests at ≥ 2 SD below the mean; and/or (4) ADOS ≥ 3. *Parent-Report Questionnaire:* The

Q-CHAT-10 is a 10-item questionnaire shortened from the Q-CHAT that assesses a broad range of ASD symptomology. Primary caregivers of HR toddlers completed the Q-CHAT-10 at 18 and 24 months. *Statistical Analyses:* Performance on the Q-CHAT-10 was compared between groups (HR-ASD, HR-BAP, HR-TD) at 18 and 24 months using two one-way ANOVAs. Group effects were explored using Benjamini & Hochberg (1995) corrections for multiple comparisons. To assess predictive ability, the sensitivity and specificity of 18- and 24-month Q-CHAT-10 scores were examined relative to the 36-month ASD diagnoses, at an individual level using the suggested cut-point of 3 (Allison et al., 2012).

Results: Higher total score on the Q-CHAT-10 differentiated the HR-ASD group from HR-BAP and HR-TD groups at both 18 ($q \leq 0.009$) and 24 months of age ($q \leq 0.001$), indicating greater frequency of ASD symptoms at these time points. Estimates of sensitivity and specificity of the Q-CHAT-10 were 0.58 and 0.72 at 18 months, and 0.59 and 0.84 at 24 months, respectively.

Conclusions: While the Q-CHAT-10 was able to distinguish groups of children with ASD from other HR toddlers who are typically developing or who exhibit the broader autism phenotype, individual classification by the Q-CHAT-10 for ASD versus not ASD was relatively poor in this limited sample. Thus, while the Q-CHAT-10 was able to identify group differences, individual classification was not sufficient to support screening in this HR sibling cohort.

62 **144.062** The Utility of a Social Emotional Questionnaire in Identifying Autism Symptomatology in Toddlers with Autism Spectrum Disorder

C. Beacham[1]*, H. Grosman*[2]*, M. Lambha*[3]*, T. Jacobsen*[4]*, S. Richardson*[5] *and C. Klaiman*[6]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Marcus Autism Center/Children's Healthcare of Atlanta, Atlanta, GA, (4)Emory University, Atlanta, GA, (5)Marcus Autism Center, Atlanta, GA, (6)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder that, among other things, can result in deficits in social emotional functioning (APA, 2013). The Ages and Stages Questionnaire: Social Emotional (ASQ:SE) is a social emotional screening instrument for children 1 through 72 months of age, but has rarely been used as a screener in children suspected of having ASD. Since the ASQ:SE screens for difficulties in self-regulation, compliance, communication, adaptive behaviors, autonomy, affect and interaction with people, it may be an ideal adjunct to more commonly used screening tools for ASD to ensure that we are comprehensively understanding the profiles of individual children with ASD.
Objectives: The current study seeks to examine the ability of the ASQ:SE to accurately screen for ASD symptomatology in toddlers 16-43 months who have been referred for an ASD evaluation.

Methods: Participants included 130 toddlers (103 males) who were participating in a larger research study examining the efficacy of eye-tracking technology in distinguishing children with ASD from those without. Of the 130 toddlers, 116 (93 males) received an ASD diagnosis and the others displayed no clinical concerns. Caregivers completed the ASQ:SE as well as the M-CHAT-R prior to their appointment. Each participant was also assessed with the Mullen Scales of Early Learning (Mullen) and the Autism Diagnostic Observation Schedule, 2nd Edition (ADOS-2).

Results: The ASQ:SE was strongly correlated with scores on the M-CHAT-R ($r(128) = .479$, $p < .0001$). Total scores from the ASQ:SE were significantly negatively correlated with all assessed domains of the Mullen ($p < .05$). Additionally, on the ADOS-2, Social Affect, Restricted/Repetitive Behaviors, and total scores were all significantly positively correlated ($p < .05$). See Table 2. 91.4% of children who were identified as having ASD failed the ASQ:SE, whereas 85.3% failed the M-CHAT-R. Of the 17 children who did not fail the M-CHAT-R, the ASQ:SE identified 10 of them who ended up with the ASD diagnosis. No differences were found between the children who failed the ASQ:SE and the children that did not. Characteristics, including behavioral patterns, of toddlers who passed the screening tools despite having an ASD diagnosis will be examined.

Conclusions: Social emotional screening tools can be helpful additions to identifying children with ASD. In combination with ASD specific screening tools, such as the M-CHAT-R, almost 94% of children, who had an ASD diagnosis were identified. The ASQ:SE was able to identify an additional 8% of children that the M-CHAT-R would have missed if used in isolation. The children assessed in this study were those whose parents or other professionals already had a concern about ASD, and thus, it is interesting that screening tools did not identify all children. Children who did not fail the ASQ:SE did not differ in their presentation when compared to children who failed it. This study shows results that indicate that the ASQ:SE could be a useful complement to identifying children with ASD within a diagnostic work up. Limitations including age restrictions on the M-CHAT-R will be discussed.

63 **144.063** Trails Next – Tracking the Next Generation

J. S. Richards, ***A. M. Sluiter-Oerlemans****, A. J. Oldehinkel and C. A. Hartman, Department of Psychiatry, Interdisciplinary Center Psychopathology and Emotion Regulation (ICPE), University Medical Center Groningen, Groningen, Netherlands*

Background:
Parental characteristics (e.g., personality, social-cognitive ability, psychopathology) are important predictors of parenting, and their interaction with environmental (e.g., SES, social support, and chronic difficulties) and child (e.g., temperament, behavior) factors has been acknowledged theoretically. However, little empirical research has comprehensively examined this interplay using detailed information about young adults and their social contexts as predictors of variation in parenting. Additionally, literature has suggested long-lasting interactions between individual characteristics and contextual factors like stressful life events. Evidence has been increasing for such person-environment (PxE) transactions and their associations with mental (ill-)health.

Studying the transactions of parental characteristics and environmental circumstances allows us to understand in much greater detail than before under which conditions particular parenting styles are especially (mal-)adaptive. It also allows us to determine whether and how PxE transactions and their consequences for mental (ill-)health reach into next generations. Such a detailed understanding provides a solid knowledge base for developing personalized and contextualized prevention and treatment efforts.
Objectives:
TRAILS Next aims (a) to study parent and child development as early as possible and elucidate transgenerational mechanisms of child and adolescent development and psychopathology, as well as (b) to clarify the role of social context and of life events and long-term difficulties herein.

Methods:

TRAILS Next is nested within the longitudinal cohort study Tracking Adolescents' Individual Lives Survey (TRAILS), see Figure 1. The current add-on study focuses on the children of TRAILS participants and their partners. Development of cognitive ability, personality and mental (ill-) health as well as environmental conditions have been studied in the prospective parents since TRAILS began in 2000-2004 when participants were approximately 11 years old (N=2773). In TRAILS Next, parents are followed from pregnancy onwards. At T1, pre- and postnatal parental experiences are collected up to when the baby is 3 months old (T2). At T2, a home visit is planned, including a short observation (motor activity of the baby, parent child-interaction), and an interview asking about major life events. Questionnaire data on parental psychopathology (including ASD symptoms), personality, parenting, and child temperament, social competence, and mental health (including ASD symptoms) are also collected. At T3, when the child is 30 months, questionnaire data as well as observational data (parent child interactions, play and tasks) are collected. At T4, questionnaire data will be collected from parents and teachers when the child is 54 months, see Figure 2.

Results:

TRAILS Next started in February 2015 and over 80 children and their parents have been included in the study so far. During this poster presentation, we present the most recent numbers and provide an (preliminary) overview of the study cohort characteristics.

Conclusions:

Findings from this study will help us understand the complex interplay of determinants of parenting and to what extent and which specific parenting and parent-child relationship dimensions explain associations between parent characteristics and child developmental outcomes. In addition, results will expand our understanding of how PxE interactions and their associations with parental mental (ill-)health reach into the next generation and are predictive of child developmental outcomes.

64 **144.064** Trajectories of Attention, Regulation, and Motor Organization from Birth to 6-Months for Infants at Risk for ASD

J. Bradshaw[1,2], *C. McCracken*[3], *C. Klaiman*[3], *L. Evans*[4], *C. Hendrix*[5] *and C. A. Saulnier*[6], *(1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Marcus Autism Center, Atlanta, SC, (3)Department of Pediatrics, Emory University School of Medicine, Atlanta, GA, (4)Marcus Autism Center, Atlanta, GA, (5)Emory University, Atlanta, GA, (6)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Although autism is believed to be a congenital disorder, little is known about its course in the neonatal and early infancy period. Yet from the first days of life, rich social interactions are present, facilitated by requisite neonatal neurological and behavioral organization. While neonatal neurobehavior (e.g., attention, regulation, and motor organization) sets the stage for the earliest forms of social interaction, these measures have rarely been used to understand the emergence of social-communication and ASD. The very early period between birth and 6-months spans key neurodevelopmental transitions wherein disruptions may, in part, determine the emergence of social and communication impairments.

Objectives: This study aims to 1) quantify neonatal and early infant trajectories of attention in infants at risk for ASD, 2) quantify trajectories of self-regulation and motor control that may be associated with attention, and 3) determine whether early patterns of attention are associated with later social-communication skills.

Methods: Participants included 42 high-risk infant siblings of children with ASD and 38 low-risk infants with no family history of ASD. Infants were administered the NICU Network Neurobehavioral Scale (NNNS) monthly from 1-week to 6-months, and the Communication and Symbolic Behavior Scales (CSBS) at 12-months. The NNNS is a reliable, standardized, measure that uses direct assessment to quantify neurological integrity, which forms the requisite basis for social interactive capacities. The attention item of the NNNS captures the infant's ability to orient to animate (faces) and inanimate (objects) stimuli that are presented in auditory-only, visual-only, and combined auditory-visual modalities. Generalized linear mixed effect models were used to compare trajectories of attention, self-regulation, and motor control between high-risk and low-risk infants. Because the relationship between age and attention was non-linear, splines functions were used to model the effect of age. Spearman correlations were used to assess the association between very early attention and later social-communication.

Results: High-risk and low-risk infants exhibited significantly different trajectories of attention from birth to 6-months [$F(12,179)=25.88; p<0.001$], with pronounced significant differences occurring between 1½ to 3-months (see Fig. 1). Investigation of the six items that make up the attention score revealed that differences were driven by attention to inanimate stimuli. High-risk infants also scored significantly lower on items of self-regulation and head/trunk motor control during this same period between 1½-3 months. Finally, we observed significant associations between social-communication at 12-months and attention at 2-months ($r_s=0.36$, $p<0.05$) and 3-months ($r_s=0.45$, $p<0.01$).

Conclusions: Infants at high risk for ASD exhibit divergent trajectories of attention beginning as early as the second month of life. We hypothesize that these differences reflect deficits in attention shifting, decreased sensitivity to social cues, and/or delayed emergence of socially adaptive, cortically-mediated behavior. Further, differences in attention for high-risk infants were accompanied by less efficient self-regulation strategies and motor control. These results provide evidence for a potential cascade of attentional and neurological abnormalities that culminate in social-communication deficits. Understanding how these behaviors are interconnected can help to develop viable early detection methods and bridge the gap between neonatal neurobehavior and complex social development.

65 **144.065** Trajectories of Social Attention in Infants at High Risk for ASD

J. B. Wagner[1], *A. Ahilan*[2], *H. Tager-Flusberg*[3] *and C. A. Nelson*[4], *(1)College of Staten Island, City University of New York, Staten Island, NY, (2)Staten Island Technical High School, Staten Island, NY, (3)Psychological and Brain Sciences, Boston University, Boston, MA, (4)Boston Children's Hospital, Boston, MA*

Background: Work with infants at high risk for ASD (HRA) has found that attention to faces at 6 months is linked to later language ability (e.g., Wagner et al., in press) and that trajectories of change in social attention between 2 and 6 months can identify infants who later receive an ASD diagnosis (Jones & Klin, 2013). More research is needed to understand how trajectories of change in social attention could relate to more continuous measures of developmental outcome.

Objectives: The present study aimed to explore how trajectories of social attention in HRA could relate to individual differences in cognitive and language ability.

Methods: A Tobii eye-tracker assessed attention to faces at 6 and 18 months in low-risk controls (LRC) with no family history of ASD (*n*=25) and HRA (by virtue of an older sibling with ASD; *n*=36). HRA were further divided into two groups based on clinical judgment from the infant's final lab visit at 24 months or older: high-risk ASD-negative (HRA–, *n*=25) and high-risk ASD-positive (HRA+, *n*=11). At both ages, infants saw images of their mother and a stranger side-by-side, and analyses focused on the first two presentations (10s each, sides counterbalanced). Difference scores were calculated between the 6 and 18 month visit for percent time on eyes (%Eyes) and mouths (%Mouths) as a function of total time on faces. The Mullen Scales of Early Learning (MSEL; Mullen, 1995) was used at 36 months to examine language through receptive language (RL) and expressive language (EL) scores and cognitive outcome through the Early Learning Composite score (ELC).

Results: Between 6 and 18 months, infants showed a decrease in %Eyes (*M*=–12.6%) and an increase in %Mouths (*M*=+10.8%). One-way ANOVAs revealed no group difference for changes in attention across age (*p*s>.48). For each group, correlations were run between trajectories of change in %Eyes and %Mouths between 6 and 18 months and MSEL RL, EL, and ELC scores at 36 months. In HRA–, positive associations were found between change in %Eyes and 36mo RL, EL, and ELC (*r*s>.45, *p*s<.05), and a negative association was found between change in %Mouths and 36mo EL (*r*=–.533, *p*=.016). For HRA+, negative associations were found between change in %Eyes and 36mo EL and ELC (*r*s<–.70, *p*s<.025), and a positive association was found between change in %Mouths and 36mo ELC (*r*=.768, *p*=.016; see Figures 1 and 2). No significant associations were found for LRC.

Conclusions: Although groups did not differ in trajectories of change in social attention between 6 and 18 months, individual differences in these trajectories were associated with different language and cognitive outcomes at 36 months, depending on group. For HRA–, increasing attention to eyes and decreasing attention to mouths predicted better language and cognitive skills, while HRA+ showed the opposite pattern, with increasing attention to mouths and decreasing attention to eyes predicting better outcomes. Future work will be needed to ask why changes in social attention that might be adaptive for HRA– might not be adaptive for HRA+, and vice versa.

66 **144.066** Understanding at-Risk Infants: Heterogeneity in Child and Parental Characteristics in a Sample Referred to Early Intervention Research

A. Gulsrud[1], *J. R. Williams*[2], *L. Hughart*[3], *N. Tu*[4], *A. M. Herrera*[5] *and C. Kasari*[3], *(1)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)Biostatistics, UCLA, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)UCLA Semel Institute, Los Angeles, CA, (5)Semel Institute, UCLA, Los Angeles, CA*

Background: Autism Spectrum Disorder (ASD) can be reliably diagnosed in children as young as two years of age, but behavioral signs of autism can be detected in children as young as 12 months of age. Growing awareness of the disorder and its earliest signs has led to an increased number of referrals for intervention in younger and younger populations and a need to better understand heterogeneity in child and parent factors at the outset of treatment.

Objectives: The goal of this study is to characterize a sample of young children at-risk for ASD referred for an early intervention study by 1) establishing subgroups of children defined by sibling status, 2) exploring the relationship between these established subgroups and measures of social-communication, RRBs, cognitive and language functioning and parental stress, and 3) examining how levels of autism symptomatology relate to parental stress by subgroup.

Methods: A total of 105 at-risk toddlers, 12 to 22 months old, were referred and screened for entry into a clinical trial. 80 of these at-risk toddlers qualified for entry into the trial by scoring with at least mild to moderate concern on the ADOS Toddler module. This population was broken down into three groups: toddlers with no siblings (41%), toddlers with siblings without autism (29%), and toddlers with at least one sibling with autism (30%). These subgroups will be referred to as: No Siblings, No Siblings with ASD, and Infant Siblings, respectively. There was no significant difference in rate of qualification into the study based on sibling status,, p=0.40, although fewer children who were Infant Siblings qualified compared to No Siblings with ASD and No Siblings (71% vs. 85% and 75%). The children were predominately male (81%) and White (47%) with an average age of 17.68 months and standard deviation of 3.10 months.

Results: On average, Infant Siblings presented with lower average levels of restricted and repetitive behaviors compared to No Siblings and No Siblings with ASD (2.46 vs. 2.70 and 3.65; F(2,77) = 4.42, p = 0.02). Infant Siblings also had statistically higher average expressive language age equivalence (12.23 months) compared to No Siblings (10.28 months) and No Siblings with ASD (8.48 months; F(2,72) = 4.33, p = 0.02). Conversely, parents of Infant Siblings reported statistically higher levels of stress on a parental daily hassle questionnaire (52%) compared to parents of No Sibling children (39%) and parents of No Sibling with ASD children (44%; F (2,49) = 3.37, p= 0.04). A positive correlation between ASD symptomatology and parental stress existed for the Infant Sibling group (r=0.28), but no other subgroup showed this association.

Conclusions: This study provides preliminary evidence for child and parent differences in subgroups of young children referred to an early intervention study. Prior to entering into treatment, Infant siblings displayed less RRBs and higher expressive language, yet still had parents with the highest levels of reported stress. Understanding variability in symptom profile and familial factors at the outset of treatment has the potential to assist in determining more tailored intervention approaches.

67 **144.067** Using Head-Mounted Eye Tracking to Examine Sticky Attention in Naturalistic Child-Parent Social Interaction

J. R. Yurkovic[1], *G. Lisandrelli*[2], *R. Shaffer*[3], *E. Pedapati*[4], *C. A. Erickson*[4], *D. P. Kennedy*[1] *and C. Yu*[1], *(1)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (2)Indiana University, Bloomington, IN, (3)Division of Developmental and Behavioral Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, (4)Division of Child and Adolescent Psychiatry, Cincinnati Children's Hospital Medical Center, Cincinnati, OH*

Background: Children with autism spectrum disorder (ASD) often display atypical profiles of attention in constrained laboratory tasks (Chita-Tegmark, 2016), but whether these differences manifest in more naturalistic situations remains largely unexplored. One such attentional difference concerns the ability to rapidly disengage attention from one stimulus to another. This "sticky attention" phenomenon has predominantly been studied using a highly constrained and screen-based experimental paradigm, known as the gap-overlap task. Although previous research has demonstrated an impaired ability to disengage in children with ASD and this ability has been associated with ASD severity (Elsabbagh et al., 2013), very little is known about "stickiness" in more naturalistic and real-world contexts – the contexts in which children interact with the environment and their social partners.

Objectives: To determine whether young children with ASD (24-48 months old) exhibit evidence for "sticky attention" -- as operationalized across a number of different quantitative metrics spanning various timescales (from seconds to minutes) -- by using head-mounted eye tracking to measure and quantify moment-by-moment visual attention during free-flowing parent-child toy play, as compared to age-matched typically developing (TD) children.

Methods: Child-caregiver dyads played with 24 novel toys in a toy room space while wearing head-mounted eye trackers (for this study, only child eye tracking was analyzed). Figure 1 shows the experimental set-up. Following eye-tracker set-up, each dyad was given the toys to freely play with, and encouraged to play as they would at home.

Results: Data was acquired from 9 child-caregiver dyads in the ASD group and 16 dyads in the TD group. Sticky attention was operationalized in four ways and spanning different timescales, shown in Figure 2: (a) duration of individual toy looks, (b) proportion of time spent on each object, (c), number of objects looked at throughout the session, and (d) number of returns to objects previously looked at throughout the session.

T-tests revealed that groups did not differ on average look duration or across quartiles of look durations (all *p*s > .10). There were no differences between the ASD group and the TD group on proportion of time spent on the most looked at object (p = 0.85). Groups did not differ on total number of objects looked at during the session (p = 0.30) or on total number of returns to previously looked at objects per session (p = 0.11). Examination of time courses or finer-grained investigations of these behaviors also revealed highly similar patterns of looking and interacting with toys (Figure 2).

Conclusions: Our initial results suggest that “sticky attention”, measured during naturalistic toy play and operationalized in different ways and across different timescales, is not present in 24- to 48-month old children with ASD. Although many researchers have observed abnormalities of attentional disengagement in ASD (but see Fischer et al., 2016) and have speculated on its real-world importance, it remains an open question how such behavioral differences measured using highly constrained laboratory tasks may manifest in real-world behavior. Future analyses will explore the role of the caregiver on the child’s visual looking patterns.

68 **144.068** Using Motion Capture Technology to Characterize Motor Atypicalities in Infants at Risk for Autism Spectrum Disorder

***S. Norin**[1], P. Nyström[1], G. Gredebäck[1], S. Bolte[2] and T. Falck-Ytter[3], (1)Uppsala University, Uppsala, Sweden, (2)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (3)Karolinska Institutet & Uppsala University, Uppsala, Sweden*

Background:

Atypical motor behaviors have been reported in infant siblings of children with autism spectrum disorder (ASD) (Leonard et al., 2014). However, studies reporting motor impairments in this population often rely on retrospective data or performance on unspecific standardized tests. In this study, we investigated movements in infants at risk for ASD using motion capture technology, which provides an objective measure of kinematic profiles with high spatiotemporal resolution.

Objectives:

The aim of the study was to investigate kinematic variables linked to motor planning and execution in infants at risk for ASD during an interceptive action task (catching a moving object).

Methods:

Our sample consisted of 58 ten-month-old infant siblings at high familial risk for ASD (HR group, n = 39) and low risk infants without familial history of ASD (LR group, n = 19), participating in an ongoing longitudinal study. Using a design by Ekberg et al. (2016), we assessed the ability to catch a ball, which was rolling towards the infant on a curvilinear path. Movements of the infant and the object were recorded with an eight-camera 3D motion-capture system (Qualisys) using passive reflexive markers. Statistical analysis was performed using linear mixed models.

Results:

The groups did not differ in terms of successful catches. However, using velocity profile analysis and dividing a movement into movement units (acceleration followed by deceleration), we found a group difference implicating atypical planning. The HR group initiated the reach (onset of transport unit, i.e. the movement’s largest subunit) later (M = 284.91 mm (distance to object), SE = 5.50) than the LR group (M = 296.16 mm, SE = 5.53), $F(1, 375) = 4.18$, p = .42. Regarding motor execution, peak velocity of the transport unit was significantly lower in the HR group (M = 1.77 mm/sample, SE = 0.08) than in the LR group (M = 1.94 mm/sample, SE = 0.08), $F(1, 392) = 5.19$, p = .023. Congruently, the distance traveled during the transport unit was significantly lower in the HR group (M = 177.89 mm, SE = 7.13) than in the LR group (M = 196.85 mm, SE = 7.15), $F(1, 392) = 7.06$, p = .008.

Conclusions:

Using detailed motion capture technology, this study was the first to investigate motor function in early development in infants at risk for ASD. Our findings reveal a complex pattern of both later initiation and differences in motor execution, but also intact ability to catch a moving object. The observed movement patterns highlight the importance of fine-grained measures of motor control in addition to more general measures from standardized scales.

69 **144.069** Vocal Imitation Skills Are Associated with Visual Attention to the Face Region in Children with Autism Spectrum Disorders.

***Y. Ishizuka**[1,2] and J. Yamamoto[3], (1)University of Tsukuba, Ibaraki, Japan, (2)Japan Society for the Promotion of Science, Tokyo, Japan, (3)Keio University, Tokyo, Japan*

Background:

In previous studies, imitation skills were classified into two types, motor imitation and object imitation and had been examining how each kind of imitation relates to other communication skills (e.g., Ingersoll & Meyer, 2011a; 2011b). On the other hand, few studies examined the relationship between vocal imitation and the other communication skills. Imitation can also serve two skills, to direct own attention to model stimulus and to do same gestures as model stimulus. However there were few studies to show the association between visual attention and vocal imitation precision (Vivanti, Nadig, Ozonoff, & Rogers, 2008).

Objectives:

The purpose of this study is to investigate the relationship between motor, object, and vocal imitation precision and other communication skills.

Methods:

13 children with autism (CA: 2-5years; DA; 1-3years) were included in this study. We plan to recruit more participants. The experiment was conducted in a testing room at a laboratory. All children participated in the imitation assessment task, eye-tracking assessment task, motor development task, and vocal communication task. They received a structured imitation assessment that included 14 object, 14 motor, and 11 vocal imitation tasks. Each child saw symmetric (e.g. touch own head with own hands) and asymmetric gesture (e.g. touch own head with a hand and touch own stomach with the other hand), self (e.g. touch own head with own hands) and other (touch other's head with own hands) directed gesture on object, and oral (e.g. make noise //a//) and face gestures (e.g. extend tongue). In eye-tracking assessment task, each child was seated in a chair at a table 30 inches from an 23.5 × 13.3 inch monitor and required to look at experimental stimulus. It was composed of object, motor, oral-facial video clips, which was same as imitation assessment task. In motor development task, we evaluate their gross motor and fine motor skills. In vocal communication task, we asked the parents the number of words that the child can understand and express in the social interaction.

Results:

We used Spearman's rank correlation coefficient to examine the associations between each imitation precision and the other communication scores. The result showed that vocal imitation precision was correlated with total time spent looking at face region and mouth region observing stimulus (face; r=.63, p=.03; mouth; r=.52, p=.08). The imitation precision wasn't associated with total time spent looking time at eye region observing stimulus (eye ： r=.14, p=.66). The result showed that vocal imitation precision was correlated with motor developmental scores and vocal communication scores (motor; r=96, p=.001; communication; r=88, p=.002).

Conclusions:

The result demonstrated that vocal imitation skills was correlated with multiple social communication skills. Our findings suggest that teaching vocal imitation is one of the most important for early intervention to increase visual attention to adult, motor development and vocal communication. This study is the first to specifically examine the relationship between vocal imitation precision and visual attention to face region. We plan to collect the data for typically developmental children and compare with these results.

70 **144.070** Vocal-Gesture Profiling at Age 2: Diminished Gesturing Is Associated with Greater Distress in Toddlers with ASD

S. Plate[1]*, N. Libster*[2]*, J. Brown*[1]*, A. Faggen*[1]*, R. F. Slomowitz*[3]*, J. Wood*[1]*, J. Maldarelli*[3]*, J. Pandey*[1]*, R. T. Schultz*[1]*, J. Parish-Morris*[1] *and .. The IBIS Network*[4]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)University of North Carolina, Chapel Hill, NC*

Background: Autism Spectrum Disorder is defined by early and persistent deficits in social communication, as well as restricted interests and repetitive behaviors. Previous research has shown that gesture and language are both atypical in infants who ultimately receive an ASD diagnosis (Colgan et al., 2006; Lazenby et al., 2016; Zwaigenbaum et al., 2005). In this study, we use a system of high-dimensional behavioral coding to explore 2-year-olds' relative use of vocalization and gesture during a structured clinical evaluation. Vocal-gesture profiles generated using this method could help identify homogeneous clusters of children that respond comparably to targeted treatments, or who follow similar developmental trajectories.

Objectives: Examine relative gesture and vocalization use in 2-year-olds at high- or low- risk of ASD that did or did not receive a diagnosis.

Methods: Forty-four 2-year-olds were administered the Communication and Symbolic Behavior Scales (CSBS, Wetherby & Prizant, 2003) as part of the Infant Brain Imaging Study (IBIS; Estes et al., 2015). Participants were classified as LR- (no family history of ASD; N=22, 6 female), HR-neg (high familial risk for ASD, no ASD themselves; N=11, 4 female), or HR-ASD (high familial risk for ASD, ASD themselves; N=11, 1 female). Videos of the CSBS were coded for vocalizations and communicative gestures. Vocalizations were categorized as speech (e.g., words, babbles) or non-speech (distress, delight, and atypical sounds like squealing or growling). To explore relative reliance on vocalization and gestures, we calculated the amount of time each child spent vocalizing and/or gesturing divided by their own total coded behavior duration.

Results: A linear mixed effects model with participant ID as a random effect revealed a significant interaction between group (LR-, HR-neg, and HR-ASD) and behavior type (speech, non-speech, gesture). Compared to the LR- group, the HR-ASD group produced a higher ratio of nonspeech vocalizations vs. communicative gestures (t=2.10, p=.04; Figure). Speech ratios did not differ by group. To determine what type of nonspeech vocalizations the HR-ASD group produced in lieu of gestures, an additional mixed effects model compared nonspeech categories in the HR-ASD and LR- groups. Results revealed that the HR-ASD group produced a significantly larger proportion of distress vocalizations (crying) vs. delight vocalizations (laughing) than the LR- group (t=2.56, p=.01).

Conclusions: Granular profiles of vocal and gestural behavior could help identify homogeneous subgroups of children that respond better to one treatment vs. another, or follow similar developmental pathways. The results of this preliminary study showed that reduced gesturing and increased nonspeech vocalization differentiated the HR-ASD and LR- groups, and that diminished gestural communication was associated with greater distress vocalizations despite similar relative amounts of speech. This suggests that when communicative gestures are diminished, children with ASD do not compensate by adding more communicative speech – rather, they produce more non-speech vocalizations that express distress. Our next steps include tracing the developmental trajectory of these vocal-gesture profiles by coding vocalizations and gestures in the same children at 6 and 12 months, and exploring ways that children use speech and gesture separately vs. in combination (Winder et al., 2013).

71 **144.071** What Is the Relationship between Motor and Language Development and Joint Attention in Infants at High and Low Risk for ASD?

E. Bruyneel[1]*, E. Demurie*[2]*, P. Warreyn*[2] *and H. Roeyers*[2]*, (1)Department of Experimental-Clinical and Health Psychology, Ghent University, Gent, Belgium, (2)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background: Children with ASD and their younger brothers and sisters (high-risk (HR-)siblings) have a high risk of experiencing difficulties in language development. Research shows that both motor development and joint attention are important predictors for later language

development. Since both markers may also influence each other, for example being able to sit makes it possible to show objects, it is important to look into the relationship of these three developmental domains in HR-siblings and in younger siblings of typically developing children (low-risk (LR-)siblings).
Objectives: The aim of the current study was to systematically investigate the relationship of early motor skills and joint attention on expressive and receptive language in HR- and LR-siblings during the first years of life.

Methods: HR-siblings (n = 35) and LR-siblings (n = 37) were followed during the first three years of life as part of a larger longitudinal study. Gross (GM) and fine motor (FM) skills were assessed at 10 and 14 months using the Mullen Scales of Early Learning (MSEL). Joint attention was measured using items (showing, initiating joint attention (IJA), response to joint attention (RJA)) of the Autism Diagnostic Observation Schedule (ADOS-2) at 14 months. Expressive (EL) and receptive language (RL) were measured by the MSEL at 24 months.

Results: HR-siblings had significantly lower scores on GM skills at 10 months (U = 383.00, p = .011) and on FM skills at 14 months (U = 355.00, p = .022). With regard to joint attention, HR-siblings presented a significantly lower quantity and quality of showing behaviors at 14 months. At 24 months HR-siblings had significantly lower scores on EL (U = 338.50, p = .027) but not on RL. In *HR-siblings*, EL at 24 months was correlated with GM skills at 10 months (ρ = .631, p = .00) and FM skills at 14 months (ρ = .546, p = .00). RL was correlated with GM skills at 10 (ρ = .598, p = .00) and 14 months (ρ = .436, p = .01), FM skills at 14 months (ρ = .608, p = .00) and IJA at 14 months (ρ = -.394, p = .03). On its turn, IJA at 14 months is correlated with FM skills at 10 months (ρ = -.440, p = .02). In *LR-siblings*, EL was only correlated with GM skills at 14 months (ρ = .358, p = .04), no correlations were found for RL.

Conclusions: Clear group differences were found for all three developmental domains, with HR-siblings scoring lower than LR-siblings. Correlational analyses showed more associations between these domains in HR-siblings, revealing different patterns in both groups. This indicates that early motor skills and joint attention may be more important in HR-siblings than in LR-siblings with regard to later language development. Implications will be discussed at the conference.

73 **145.073** Altered Cortical-Subcortical Functional Connectivity in Autism Spectrum Disorders

J. O. Maximo *and R. Kana, University of Alabama, Birmingham, Birmingham, AL*

Background: Studies examining functional brain networks in autism spectrum disorder (*ASD*) have risen exponentially over the last decade and have characterized it as a disorder of aberrant brain network connectivity. While a large number of these functional MRI studies have focused on cortico-cortical connectivity in ASD, limited attention has been paid to cortical-subcortical connectivity. Subcortical regions such as thalamus (*THAL*) and basal ganglia (*BG*) may play a vital role in ASD neuropathology considering their role in sensory processing and cognition.
Objectives: To assess patterns of cortical-basal ganglia and thalamocortical connectivity in individuals with ASD and to examine the relationship between connectivity and ASD phenotype, such as socio-communicative and repetitive behaviors.

Methods: Resting state fMRI data (*TD = 168; ASD = 138; 5-8 minute-long, eyes open scans*) from the Autism Brain Imaging Data Exchange (*ABIDE II*) were used and preprocessed using a standard resting state processing pipeline. Unimodal (*motor, auditory, lateral and medial visual*) and supramodal ROIs (*DMN, posterior DMN, salience, attention, and left and right executive*) were defined using MELODIC ICA. Partial correlation maps were obtained for functional connectivity between cortical ROIs with THAL and BG and mean Z' score obtained for each cortical seed for the ASD group were correlated with clinical measures (*ADOS, ADI-R, and RBS-R*).

Results: For unimodal connectivity, clusters of overconnectivity (*ASD > TD*) were found between THAL (*auditory and motor*) and BG (*auditory and lateral visual*) while clusters of underconnectivity (*ASD < TD*) were also found between THAL and BG with medial visual. Conversely, for supramodal connectivity, clusters of underconnectivity (*ASD < TD*) were found in THAL (*salience, left executive, and posterior DMN*) and BG (*salience and left executive*) while clusters of overconnectivity (*ASD > TD*) were also found in THAL (*DMN and posterior DMN*) and BG (*attention*). Positive correlations were found between medial visual-BG connectivity with ADOS-RRB scores and between auditory-BG connectivity with RBS-R stereotyped behavior. Negative correlations were found between DMN-THAL connectivity with ADI-R verbal scores and salience-THAL connectivity with ADOS-Social scores.

Conclusions: Our findings of altered cortical-BG and thalamocortical connectivity in ASD are consistent with previous studies. This study targeted specific brain networks responsible for key cognitive processes, where overconnectivity (*ASD > TD*) between unimodal and subcortical regions and underconnectivity (*ASD < TD*) between supramodal and subcortical regions were predominantly detected. These findings may suggest excess crosstalk within unimodal regions and subcortical regions that support basic sensory information based on previous activation fMRI studies of visual, auditory and somatosensory systems. On the other hand, supramodal regions may require increased communication for effective higher cognitive functioning with subcortical regions, which may be reduced in people with ASD. The findings of brain-behavior relationship suggest that connectivity profile of unimodal and supramodal networks in ASD may play a role in sensory sensitivity and social communication respectively.

115 **146.115** Abnormalities of Local Gyrification in Autism Spectrum Disorders after Age 40 Years

J. S. Kohli[1,2]*, R. A. Carper*[1]*, F. Hassan*[3]*, M. Kinnear*[4]*, A. J. Lincoln*[5] *and R. A. Mueller*[4]*, (1)Brain Development Imaging Laboratories, Department of Psychology, San Diego State University, San Diego, CA, (2)Joint Doctoral Program in Clinical Psychology, SDSU / UC San Diego, San Diego, CA, (3)Psychology, Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (4)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (5)Alliant International University, San Diego, CA*

Background: Although prenatal or early postnatal in onset, autism spectrum disorders (ASDs) are associated with behavioral problems throughout the lifespan. Neurodevelopmentally, evidence shows early cerebral overgrowth in the first years of life, reflected in cortical thickness (CT), surface area (SA), and the local gyrification index (lGI). However, abnormalities across later childhood and adolescence are less well understood, and little is known about adults with ASDs past the age of 40 years, including possible accelerated decline. A few studies extending into early to middle adulthood suggested increased rates of cortical thinning in ASDs in frontal, parietal, and temporal regions. One study reported increased frontal and parietal lGI in participants with ASDs aged 18-43 years, while another detected no differences in gray matter characteristics in individuals aged 30-75 years.
Objectives: The current investigated cortical morphology in adults with ASDs ages ≥40 years, in a comparison with age-matched typical controls (TC).

Methods: T1 weighted MRI sequences (0.8mm isotropic) were collected for 50 participants aged 40–61 years (27 ASD, 23 TC). Following quality assurance, 20 ASD and 21 TC, matched on age, were compared. lGI, CT, and SA were measured using FreeSurfer v.5.3.0. Statistical analyses employed a general linear model including age, non-verbal IQ, and total brain volume as covariates. Vertex-wise correlations between lGI and Social Responsiveness Scale (SRS) scores were calculated. All results were corrected for multiple comparisons using Monte Carlo null-z simulations.

Results: For lGI, significant main effects of group (ASD<TC) were observed bilaterally in insular and anterior cingulate (ACC) clusters, along with left postcentral and middle frontal, and right orbitofrontal and supramarginal clusters. lGI was also shown to decline with age in combined groups in bilateral precentral and right supramarginal clusters. No significant group, age, or group by age interaction effects were observed for CT or SA. lGI showed a significant correlation with SRS total scores in a right caudal ACC cluster (r=.68, p<.001) in the TC group only.

Conclusions: Reduced lGI may suggest accelerated tissue loss in ASDs, possibly consistent with some studies reporting increased cortical thinning in early adulthood. The finding of lGI differences in the absence of CT and SA effects indicates that lGI may be more sensitive to abnormalities of cortical macrostructure in ASDs. Clusters in the insula overlapped with a previous study of children and adolescents, in which lGI was increased in two independent samples of participants with ASDs in regions surrounding earlier developing sulci, and perisylvian regions in particular. This overlap may indicate that regions most affected by early over-gyrification are also more susceptible to subsequent decline in the disorder. Group differences in ACC are of interest given multiple post-mortem reports of its altered cellular density in ASDs and the importance of ACC in social and emotional function. Correlations between lGI and SRS scores in TC in the same region add additional support to the functional relevance of this morphometric measure.

116 **146.116** ADHD Symptomatology and White Matter Development in Autism Spectrum Disorder

A. K. Converse[1], *D. C. Dean*[1], *B. G. Travers*[1], *M. B. Prigge*[2], *E. Bigler*[3], *N. Lange*[4], *A. L. Alexander*[1] *and J. E. Lainhart*[1], *(1)University of Wisconsin - Madison, Madison, WI, (2)University of Utah, Salt Lake City, UT, (3)Brigham Young University, Provo, UT, (4)McLean Hospital, Cambridge, MA*

Background: The symptoms that characterize attention deficit hyperactivity disorder (ADHD) are often found in individuals with autism spectrum disorder (ASD). Abnormal brain white matter has been associated with both ASD and ADHD, however, greater knowledge of white matter abnormalities in comorbid ADHD in ASD may further illuminate the neurobiological substrates of these disorders. Such understanding may help to advance diagnosis and therapy in both of these developmental disorders. We therefore asked whether white matter development differs in ASD according to the degree of comorbid ADHD symptomatology.
Objectives: To examine the influence of comorbid ADHD and ASD symptomatology on developmental trajectories of white matter microstructure.

Methods: Diffusion tensor imaging (DTI) data from male participants (3-45 years, 220 time points) were acquired up to 4 times across 9 years using a 3 Tesla Siemens Tim Trio. ADHD symptom level was measured by the ADHD index and inattentive scores from the Conners' ADHD/DSMIV Scale. Following acquisition, imaging data were corrected for subject head motion and eddy-current distortions and quantitative parameter maps of fractional anisotropy (FA), mean diffusivity (MD), radial diffusivity (RD) and axial diffusivity (AD) were computed. Mean values of these parameters were then computed for a group of five regions of interest from a published meta-analysis of studies relating FA and symptom levels in individuals with ADHD (van Ewijk et al. 2012). Using a linear mixed effects model, DTI measures from these regions were described as a function of age and ADHD symptom level.

Results: In preliminary analyses, no relationships between ADHD symptom level and FA were observed in these regions. However, MD, RD, and AD were correlated with ADHD symptom level across these white matter locations.

Conclusions: Although published reports of reduced FA in the regions examined may partially reflect deficits in the general ADHD population, the present results suggest that it may not be responsible for ADHD symptoms in comorbid ASD. Future work will use voxelwise analysis to search for regions in which altered DTI parameters are associated with elevated ADHD symptomatology in individuals with ADHD. Further study would also be helpful to determine whether or not ADHD with comorbid ASD shares aspects of the neurobiological etiology of ADHD without comorbid ASD.

117 **146.117** Altered Measures of Diffusion at the Grey-White Matter Boundary in Autism Spectrum Disorder

A. Bletsch[1], *C. Mann*[1], *D. S. Andrews*[2], *E. Daly*[3], *M. Gudbrandsen*[3], *F. Dell`Acqua*[4], *A. N. Ruigrok*[5], *R. Romero-Garcia*[6], *S. Baron-Cohen*[5], *D. G. Murphy*[7] *and C. Ecker*[1,3], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe-University Frankfurt am Main, Frankfurt, Germany, (2)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (3)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (6)Brain Mapping Unit, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (7)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:
Autism spectrum disorder (ASD) is a highly complex neurodevelopmental condition that is accompanied by neuroanatomical differences on the macroscopic and microscopic level (Ecker, 2016). For example, a recent histological investigation suggests that the grey-white matter boundary is

less well defined in ASD, potentially due to an abnormal cell patterning at the grey-white matter (GWM) transition zone (Avino & Hutsler, 2010). Consistent with this finding, it has also been shown *in vivo* that the GWM tissue contrast at the white matter boundary is significantly reduced in ASD, and in many brain regions that have previously been linked to autistic symptoms and traits (Andrews et al., 2017). However, nobody has yet characterized the GWM boundary based on measures of diffusion in ASD.

Objectives:

Thus, we examined differences in fractional anisotropy (FA) and mean diffusivity (MD) at the GWM boundary in ASD individuals relative to controls. Based on previous reports of a reduced tissue contrast, we also expected significant reductions in measures of diffusion.

Methods:

92 adults with ASD (53 males, 39 females; diagnosed using ADI-R (Lord et al., 1994)), and 92 matched healthy controls (51 males, 41 females) aged 18-52 years were recruited and assessed at the King`s College London, London, and the University of Cambridge. For all 184 participants, high-resolution structural T1-weighted volumetric images and Diffusion Tensor Imaging (DTI) data were acquired. Cortical surface reconstructions were produced using FreeSurfer v6.0 (http://surfer.nmr.mgh.harvard.edu/). FA and MD measures were derived by mapping the diffusion data onto the white matter surface. Parameter estimates for FA and MD were estimated by regression of a general linear model (GLM) at each vertex along the GWM boundary with (1) diagnostic group, gender, and site as categorical fixed-effects, (2) a group-by-gender interaction, and (3) age and full-scale IQ as continuous covariates. Corrections for multiple comparisons were performed using ´random field theory` (RFT)-based cluster analysis using a $p<0.05$ (2-tailed) cluster-significance threshold.

Results:

We found that MD was significantly decreased in ASD at the GWM boundary underneath the dorsolateral (DLPFC) and medial orbitofrontal cortices, the cingulate cortex (CC), and in the medial somatosensory cortex (SMA). An increase in MD was observed in the right fusiform gyrus. When examining measures of FA, we observed significant decreases in ASD in the right DLPFC, the fusiform gyrus and entorhinal cortex, and in the right occipital lobe. Measures of FA were significantly increased in ASD in the right medial prefrontal cortex, and the right medial and lateral orbitofrontal cortex. In addition, we also observed significant group-by-gender interactions for both FA and MD in many regions with a significant main effect of group.

Conclusions:

Our results confirm that the white matter microstructure at the GWM boundary is atypical in ASD, potentially as a result of an abnormal cell patterning at the GWM transition zone. Thus, neuroanatomical features measured at the GWM boundary might be particularly sensitive for identifying and characterizing ASD. Given the significant group-by-gender interactions, it is however likely, that this aspect of the neuropathology of ASD is modulated by biological sex.

118 **146.118** Comparison of White Matter Microstructure between Affected and Unaffected Siblings Accounting for the Typical Distribution of Difference between Siblings

Y. Aoki[1], *B. Yamagata*[2], *T. Itahashi*[3], *H. Ohta*[3], *C. Kanai*[4], *R. Hashimoto*[5] *and N. Kato*[3], *(1)Showa University, Tokyo, Japan, (2)Keio University, Tokyo, Japan, (3)Medical Institute of Developmental Disabilities Research, Showa University, Tokyo, Japan, (4)Showa University, Setagaya-ku, Japan, (5)Tokyo Metropolitan University, Tokyo, Japan*

Background:

Prior studies with diffusion tensor imaging (DTI) have demonstrated that unaffected siblings of people with ASD show similar white matter abnormalities as their affected siblings compared with typically developing controls (TDC), suggesting genetic vulnerability of unaffected siblings. However, these studies did not account for the typical distribution of difference in white matter structure between siblings.

Objectives:

In the current study, we examined differences in DTI parameters between individuals with ASD and their unaffected siblings accounting for the distribution of differences in DTI parameters between pairs of TD siblings.

Methods:

Participants

Fifteen male individuals with ASD (mean age: 28.3 yo) and their unaffected siblings (mean age: 28.0 yo) were recruited. To examine the typical distribution of differences in DTI parameters, fifteen pairs of siblings of male TDC were enrolled (mean age: 28.4 for the older siblings and 25.1 for the younger siblings). In total, we recruited 60 people.

Data acquisition

We obtained diffusion tensor imaging data at Showa University.

Preprocessing

All data were visually inspected for visible artifacts. Eddy current and head motion were corrected. Data with large head motion were excluded from the analyses. Based on the ICBM DTI-81 atlas, 48 region-of-interests (ROIs) that locate in the center of major tracts were defined. Mean fractional anisotropy (FA), mean, axial, and radial diffusivity (MD, AD, RD) were computed from 48 ROIs.

Analyses

Paired t-tests

We examined the difference in mean DTI parameters between individuals with ASD and their unaffected siblings using paired t-test. Statistically significance threshold was set at $P<0.001$ (=0.05/48: number of ROIs).

Bootstrapping

First, in each ROI, we computed distribution of mean DTI parameters differences between 15 pairs of unaffected TD siblings using bootstrapping with 5000 iterations. Then, mean DTI parameters differences between siblings discordance for ASD were overlayed onto the distribution of difference of DTI parameters among TD siblings to obtain quantile rank. Threshold for significance were set at either quantile above 99.95 percentile or below 0.05 percentile (equivalent to $P=0.025/48$: corrected for multiple comparisons).

Results:

Paired t-tests

None of the tracts showed significant difference in any DTI values between individuals with ASD and their unaffected siblings (t<1.51, P>0.153 for FA, t<2.92, P>0.011 for MD, t<2.56, P>0.023 for AD, t<2.20, P>0.045 for RD).

Bootstrapping

The analysis revealed that difference in mean AD in the left stria terminalis and right anterior corona radiata between individuals with ASD and their unaffected siblings were statistically significant (above 99.99 percentile). Difference in mean FA between siblings discordant for ASD was also marginally significantly large on typical distribution (99.16 percentile).

Conclusions:

Our novel approach accounting for the typical distribution of difference in DTI parameters captured the potential neural correlates of ASD diagnosis. Given that the stria terminalis is sexually dimorphic and the current project enrolled only males, the narrow distribution of difference of DTI parameter between TD siblings is reasonable. Large difference of the DTI parameters in this tract between individuals with ASD and their unaffected siblings may suggest atypical response to sex hormone of this tract among individuals with ASD.

119 **146.119** Disrupted Thalamic-Occipital Connectivity in Six-Week-Old Infants at High and Low Risk for ASD and Its Relation to Behavioral Phenotypes

R. Jalal[1]*, A. Nair*[2]*, J. Liu*[3]*, T. Tsang*[3]*, L. P. Jackson*[4]*, S. Jeste*[3]*, S. Y. Bookheimer*[5] *and M. Dapretto*[5]*, (1)Semel Institute, University of California Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA, (4)UCLA, Los Angeles, CA, (5)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

Background:

Specific patterns of impacted thalamocortical connectivity have been found in children and adolescents with ASD using both diffusion tensor imaging (DTI) and functional connectivity magnetic resonance imaging (fcMRI; Nair et al., 2013; Nair et al., 2015). In our previous work with infant siblings at high risk for ASD (Nair et al., under review), we demonstrated that at-risk infants show a pattern of functional thalamic-prefrontal underconnectivity and thalamic-occipital overconnectivity few weeks post-birth. In comparison, little is known about the anatomical connectivity between thalamus and cortical regions in at-risk infants.

Objectives:

The goal of the current study is to examine early anatomical connectivity of thalamocortical tracts using DTI in infants at high-risk for developing ASD compared to low-risk infants.

Methods:

DTI data were acquired during natural sleep on a 3T Siemens scanner for 17 high-risk infant siblings (6 weeks post-birth) of children with ASD (HR) and 15 infants at low risk (LR) for ASD. Data were preprocessed using FDT (FMRIB's Diffusion Toolbox). Six cortical seeds were selected from motor, occipital, parietal, prefrontal, somatosensory, and temporal regions of the UNC Infant 0-1-2 neonate atlas (Shi, 2011). Probabilistic tracking was performed to derive white matter tracts originating from each cortical seed and terminated at the thalamus. The diffusion tensor was calculated at each voxel and maps of fractional anisotropy (FA), mean diffusivity (MD), radial diffusivity (RD), axial diffusivity (AD) were generated for tracts between each cortical seed and thalamus. These indices were then entered into a multivariate analysis of variance to compare between groups, and correlated with fcMRI connectivity z' scores as well as behavior measures of visual processing (Infant/Toddler Sensory Profile (Dunn, 2002); "Charlie Brown" eye-tracking paradigm).

Results:

DTI results showed aberrant patterns of thalamic-occipital connectivity in the HR group consistent with our prior fcMRI findings. Specifically, the HR group demonstrated significantly higher MD (p=.02), AD (p=.01), and RD (p=.03) values for thalamic-occipital tracts. Correlations between fcMRI z' prime scores and DTI indices revealed a normative pattern of lower fcMRI connectivity associated with low MD scores for the LR group (p=.02). However, such a pattern was not observed in the HR group. Higher thalamic-occipital MD (p=.02), AD (p=.05), and RD (p=.02) were significantly correlated with lower Sensory Profile visual processing scores in the HR group. Additionally, we found that lower thalamic-occipital FA (p<.001) and higher RD (p=.02) in the HR group was significantly correlated with greater preference for focusing on low-level perceptual features (e.g., motion, high luminance, high saturation, edges) versus character faces within clips of Charlie Brown at age 3 months.

Conclusions:

Our findings suggest that thalamic-occipital connectivity may be disrupted in at-risk infants by six weeks of age. These disruptions may also underlie early preference for sensory aspects of visual stimuli over social stimuli. Visual processing abnormalities have been found in prior studies of older children and adolescents with ASD (Keehn et al., 2013, Klin et al., 2015). Thus, our findings of thalamic-occipital connectivity anomalies and its relation to behavior phenotypes could be an early marker of ASD risk.

120 **146.120** Modeling Developmental Trajectories of White Matter Microstructure in the Autistic and Typical Brain

J. Villaruz[1]*, D. C. Dean*[1]*, B. G. Travers*[1]*, A. Freeman*[1]*, M. B. Prigge*[2]*, B. A. Zielinski*[2]*, P. T. Fletcher*[2]*, J. S. Anderson*[3]*, E. Bigler*[4]*, N. Lange*[5]*, A. L. Alexander*[1] *and J. E. Lainhart*[1]*, (1)University of Wisconsin - Madison, Madison, WI, (2)University of Utah, Salt Lake City, UT, (3)Radiology and Imaging Sciences, University of Utah, Salt Lake City, UT, (4)Brigham Young University, Provo, UT, (5)McLean Hospital, Cambridge, MA*

Background: While neuroimaging studies have increasingly associated ASD with altered brain structure and connectivity, relatively little is understood about the development of the autistic brain. Longitudinal data to characterize the trajectories of white matter microstructure in both autism and a reference population, such as typically developing controls (TDC), may reveal which white matter tracts are most significantly influenced by ASD and provide a timeline for when such divergence occurs. A continuous and probabilistic model could give important insights into white matter development, but which growth models are most appropriate for its trajectory is unknown. Furthermore, it is uncertain whether the model that best characterizes ASD white matter development differs from that of typical development. Thus, studies examining growth

models to determine which models provide the most accurate representation of white matter microstructure maturation are needed.
Objectives: Using diffusion tensor imaging (DTI) data from an ongoing longitudinal study of ASD, we investigated growth models of longitudinal white matter microstructure development and assessed which models best represent the developmental trajectories of 48 white matter tracts in individuals with ASD and TDC.

Methods: Male participants (N = 154; 99 ASD) between the ages of 3 and 52-years-old were scanned at the University of Utah up to 4 times across 9 years. The 48 white matter tracts defined in the JHU ICBM-DTI-81 template were aligned to a population-specific template created after image processing then median diffusion parameters were extracted for each tract. We fit the regional DTI data (i.e. FA, MD, RD, AD) to longitudinal linear and quadratic growth models and assessed which model best represented each tract's development using the Bayesian Information Criterion parsimony metric. These best-fit models were compared between groups to examine whether white matter development in ASD and TDC follow different trajectories.

Results: The Bayesian Information Criterion revealed 80 instances across the 4-diffusion metrics (FA, MD, RD, AD) where the best-fit models differed between ASD and TDC. In particular, 18, 19, 19, and 24 of the 48 white matter tracts differed in their FA, MD, RD, and AD trajectories, respectively. In all but 3 of these cases, which included MD and RD in the fornix and AD in the left medial lemniscus, a linear growth model was found to better fit the TDC data while a quadratic model best fit the ASD population.

Conclusions: Quantitative analysis of white matter maturation may provide insight into processes that are altered during neurodevelopment in ASD. These preliminary findings suggest that the growth models used to represent the trajectory of white matter microstructure development differs between individuals with and without ASD. Notably, these differences appear to be regionally dependent as the trajectory differences were not observed in all investigated tracts. Further investigation into additional models, such as logistic or Gompertz growth models, is required to ascertain which model best characterizes the developmental trajectories of white matter. Future analyses will examine these additional models to assess whether they provide a more accurate representation of development and whether these models differ between ASD and TDC trajectories.

121 **146.121** Multimodal Imaging Features Associated with Autism Spectrum Disorder

***D. S. Andrews**[1], A. Llera[2], C. B. Beckmann[3,4], M. Gudbrandsen[1], E. Daly[1], A. Marquand[2,5], C. M. Murphy[1,6], M. C. Lai[7,8,9,10], M. V. Lombardo[11,12], A. N. Ruigrok[11], S. C. Williams[5], E. Bullmore[11], J. Suckling[13], S. Baron-Cohen[8], M. Craig[1,6], D. G. Murphy[6,14] and C. Ecker[1,15], (1)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (3)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Department of Cognitive Neuroscience, Nijmegen, Netherlands, (4)Centre for Functional MRI of the Brain (FMRIB), University of Oxford, Oxford, United Kingdom, (5)Centre for Neuroimaging Sciences, King's College London, London, United Kingdom, (6)Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (7)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (8)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (9)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, (10)Centre for Addiction and Mental Health, Toronto, ON, Canada, (11)University of Cambridge, Cambridge, United Kingdom, (12)University of Cyprus, Nicosia, Cyprus, (13)University of Cambridge, Cambridge, United Kingdom of Great Britain and Northern Ireland, (14)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (15)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe-University Frankfurt am Main, Frankfurt, Germany*

Background: Several neuroanatomical measures of brain structure have been associated with Autism Spectrum Disorder (ASD) and may represent different biological pathways underlying the condition. Often, these anatomical features are investigated in isolation. However, the identification of between-group differences that are shared across imaging features could aid the identification of underlying neural mechanisms common to different anatomical features in ASD.
Objectives: We aimed to (1) identify multimodal components representing the inter-relationship between different *in vivo* MRI measures of grey matter volumes, cortical morphology, and white matter diffusion metrics; and (2) relate these components to the ASD phenotype.

Methods: 98 adults with ASD (49 males and 49 females; diagnosed using the ADI-R and ADOS) and 98 matched typically developing controls (51 males and 47 females) aged 18-42 years received structural and diffusion MRI scans at the Institute of Psychiatry, Psychology and Neuroscience, London, and the Autism Research Centre, Cambridge. For each participant; voxel based morphometry (VBM) was used to segment whole brain grey matter volumes, FreeSurfer software was used to estimate five morphometric features; i.e. cortical thickness, surface area, sulcal depth, local gyrification index, and grey to white matter signal intensity ratios; and track based spatial statistics (TBSS) skeletons of white matter fractional anisotropy (FA) and mean diffusivity (MD) measures were calculated. A multimodal fusion technique 'linked independent components analysis' (linked ICA) (Groves et al. 2011, 2012), was used to identify components representing shared inter-subject variation between the different measures. Relationships between individual multi-modal components and ASD diagnosis and Autism Spectrum Quotient (AQ) scores were assessed through correlation analysis.

Results: We identified one component that had a significant negative correlation with diagnosis of ASD (p=0.002) and AQ scores (p=0.0019). This component represented a spatially distributed pattern of grey matter volumetric increases spanning the cerebellum, temporal and parietal regions, as well as a pattern of decreased volumes in the frontal lobe in addition to increased gyrification in the cingulate gyrus and temporal lobes. A second component representing a similar diffuse pattern of grey matter volumetric differences as well as increased signal contrast, cortical thickness, and gyrification across temporal regions, was significantly negatively correlated with AQ scores ($p=5.1^{e-4}$).

Conclusions: We found significant correlations between a diagnosis of ASD and multimodal components representing spatially-distributed patterns of volumetric differences as well as decreased grey-white matter boundary integrity, cortical thickness and gyrification. Our findings enrich our understanding of the relationship between different imaging features, and may aid the identification of neurobiological pathways that contribute to the cross-modal pattern of atypical brain structure observed in ASD.

122 **146.122** Receptor Density and Distribution of 5-HT2 Receptors in the Cingulate Cortex in Autism: A Multiple Concentration Saturation Binding Study in Children and Adults

***C. Brandenburg** and G. J. Blatt, Hussman Institute for Autism, Baltimore, MD*

Background: Selective serotonin reuptake inhibitors (SSRIs) are among the most commonly prescribed medications in autism, however, several studies show evidence of harm and variable outcomes of efficacy from SSRI use. Some of the variability may be a result of differential changes in serotonin (5-HT) receptor subtypes across individuals.

Objectives: In an effort to determine differences in 5-HT$_2$ receptor expression between autism and neurotypical individuals, a multiple concentration ligand binding assay was performed in two parts of the cingulate cortex. These areas are important in socioemotional behavior, reward anticipation and in the default network, among other functions, and have been shown to be impacted in autism.

Methods: Using a large cohort of postmortem brain tissue, a saturation binding assay was conducted on 20µm sections from the anterior cingulate cortex (ACC) and posterior cingulate cortex (PCC) (n=16-19 autism, n=18-19 controls) by incubation with ^{3}H ketanserin (Perkin Elmer) at concentrations of 120, 90, 30, 12, 6, 3 and 1.5 nM before being loaded into X-ray cassettes with tritium standards and apposed to tritium-sensitive hyperfilm. Non-specific binding was determined with a competitive displacer (Ritanserin 100µM). After exposure, films were developed and digitized to quantify measurements of binding in femtomoles per milligram of tissue in both superficial and deep layers of each region. A Welch's t-test was utilized for statistical analysis.

Results: 5HT$_2$ receptor density in superficial and deep layers of the ACC and PCC did not have statistically significant binding density differences between total autism and control cases. However, the variance in the PCC layers was significantly higher in autism cases (p=0.038 deep; p=0.0031 superficial) using an F test and 30nM ^{3}H ketanserin as a representative concentration. The groups were then split into children (≤16) (n=8-9) and adults (>16) (n=9), which resulted in an increased binding density in the PCC of autism cases in children only (363.4 ±26.38 fmol/mg PCC deep; 400.0 ±10.93 fmol/mg PCC superficial) compared to controls (290.2 ±11.98 fmol/mg PCC deep; 308.8 ±10.93 fmol/mg PCC superficial) [p=0.028 PCC deep; p=0.0403 PCC superficial] while the ACC had similar mean and variance between groups. Adult autism cases had similar binding density compared to neurotypical individuals.

Conclusions: Although the overall comparisons of autism and neurotypical cases did not reveal a mean binding density difference across regions and layers, the variance of autism cases was significantly higher in the PCC and in children when compared to adults. This is particularly interesting given the literature on SSRI use in autism. A Cochrane review concluded that SSRI use has variable outcomes of efficacy, with adverse effects negligible in adults but significant in children. It is possible that the variance of 5HT$_2$ density seen in child autism cases contributes to the variable reactions to SSRI use. Comparison of 5HT$_2$ expression to other 5HT receptors in these cases will provide useful insight into how the 5HT system may be differentially impacted.

123 **146.123** Reduced Diameter, Perimeter and Cross Sectional Area of Corpus Callosum Axons Are Markers of a Deficit of Long-Range Connectivity in Autism

J. Wegiel[1]*, W. Kaczmarski*[1]*, T. Wisniewski*[2]*, K. Nowicki*[3]*, I. Kuchna*[4]*, S. Y. Y. Ma*[5] *and J. Wegiel*[1]*, (1)NYS IBR, Staten Island, NY, (2)NYU School of Medicine, New York, NY, (3)Developmental Neurobiology, NYS IBR, Staten Island, NY, (4)Developmental Neurobiology, NYS Institute for Basic Research, Staten Island, NY, (5)Neurobiology, NYS IBR, Staten Island, NY*

Background:

Autism is associated with lack of coherence, deficits in complex information processing, and intense and narrowly focused interests with a tendency to concentrate on systems that operate repetitively such as computers, games, or machines. MRI and neuropathological studies suggest that these functional anomalies are caused by defects in connectivity with short-range overconnectivity and long-range underconnectivity. Our studies of the corpus callosum in idiopathic autism revealed CC agenesis selectively affecting segments III-V in 3 of 11 examined autistic subjects, hypoplasia with a 49% deficit of axonal connections and a 37% reduction in the numerical density of axons in all agenesis-free autistic subjects (Wegiel et al 2017).

Objectives:

The aim of this postmortem study was to test the hypothesis that focal lack of CC axons and diffuse deficit of axons, reported as agenesis and hypoplasia, are associated with a third marker of long-range connectivity - reduced CC axon diameter. This pathology may directly contribute to reduced volume and capacity of information transfer between hemispheres, and lack of coherence and deficits in complex information processing in autistic subjects.

Methods: To detect markers of the deficit of long-range connectivity, 4 parameters were estimated using electron microscopy: axon diameter, perimeter, cross section area and myelin thickness in the brains of 10 subjects diagnosed with idiopathic autism and 10 brains of age and sex-matched control subjects. The brain hemispheres were fixed with formalin, dehydrated, embedded in celloidin and cut into equidistant serial 50-µm thick sections. Ultrastructural study was focused on axons in the CC genu. Equidistant serial celloidin sections were fixed with osmium tetroxide, dehydrated and embedded in Epon 812. The sections were photographed using a Hitachi 7500 electron microscope at 12,000 magnification. For each case twelve electron micrographs were used for measurements of axonal diameter, perimeter, crossectional area and myelin thickness. On average 420 axons were evaluated per case.

Results: The ultrastructural study revealed a significant (p<0.01) reduction of axon diameter by 15%, axon area by 19%, and axon perimeter by 9%. The distribution curve revealed a prevalence of small axons (less than 0.5 µm diameter), a similar percentage of middle-size axons (0.5-0.7 µm) but a reduced percentage of thick axons (>7 µm) in autistic subjects. Measurements of myelin thickness were less consistent due to the variable contribution of clusters of axons with a small diameter, very little amount axoplasm but an unusually thick myelin sheath found in some autistic subjects. Despite of these interindividual differences, the myelin thickness was reduced by 7% on average.

Conclusions: The study reveals another feature of the developmental impairment of long distance connectivity with a significant reduction in the diameter, perimeter, and cross sectional area of axons in the genu of the corpus callosum of subjects diagnosed with idiopathic autism. This pattern of pathology is considered a sign of reduced capacity and reduced volume of information transferred by long distance interhemispheric connections. The results suggest that CC sporadic agenesis, common hypoplasia and axonal developmental defects are an integral component of brain pathology contributing to the clinical autism phenotype.

124 **146.124** Sex-Informed Neuroanatomy of Autism: Evaluating the Quantitative and Qualitative Models of Sex-Moderation in Cortical Anatomy Using Data from the Pond Network

C. Hammill[1]*, M. J. Taylor*[1,2]*, J. P. Lerch*[3]*, E. Anagnostou*[4]*, S. Ameis*[5,6]*, P. Szatmari*[1,5,6] *and* ***M. C. Lai***[1,5,6,7,8]*, (1)The Hospital for Sick Children, Toronto, ON,* *Canada, (2)University of Toronto, Toronto, ON, Canada, (3)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (6)Centre for Addiction and Mental Health, Toronto, ON, Canada, (7)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (8)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan*

Background:

We proposed two testable models on sex-moderation that underlie the 'female-protective-effect' mechanisms contributing to autism etiologies, as a key first step to clarify the sex-differential liability related to the brain. The 'quantitative sex-moderating model' (QUAN-model) posits that mechanisms leading to autism are comparable but differ quantitatively across sexes, that females require more brain changes to develop autism. The 'qualitative sex-moderating model' (QUAL-model) posits that mechanisms leading to autism operate through different neurobiological/brain changes across sexes.

Objectives:

Testing the QUAN-model and QUAL-model against a null-model of no sex-moderation:

(1) The QUAN-model predicts that across the brain, autism-related changes in females involve similar regions but with larger effect sizes, and/or involve overlapping and additional regions, than those in males.

(2) The QUAL-model predicts that across the brain, autism-related brain changes differ by sex, involving different brain regions and/or with different patterns of changes.

Methods:

Sample includes 729 participants scanned at the Hospital for Sick Children, Toronto and via the Province of Ontario Neurodevelopmental Disorders (POND) network, using the same scanner: 249 autistic males (age mean=13.3 years, FIQ mean=96.9), 60 autistic females (age mean=14.2, FIQ mean=95.7), 210 neurotypical males (age mean=14.0, FIQ mean=112.7), 210 neurotypical females (age mean=14.2, FIQ mean=113.0). T1-weighted scans were processed with CIVET 2.1. Cortical thickness, area, volume and curvature were estimated across 75,284 vertices. To account for heterogeneity of covariates, data were pre-processed with nonparametric matching – neurotypical controls were matched to autism subjects with full-matching by weighted Euclidean matching for age and whole brain volume (weights 1 and 0.5 respectively), but IQ was *not used in matching* due to high co-occurrence between autism and intellectual disability (ID). For each metric, a whole-cortex-based model selection determined the best model by Akaike's Information Criterion.

Testing QUAN-model vs. null by Sign-Concordance: By setting 'sex' as male=0 and female=1, autism-effect in males is given as $\beta_{diagnosis}$ and autism-effect in females $\beta_{diagnosis}+\beta_{sex*diagnosis}$. The QUAN-model predicts that autism-effect is *stronger* in females than in males, therefore $\beta_{diagnosis}$ and $\beta_{sex*diagnosis}$ have the same sign (sign-concordance). This was tested against a randomization distribution of test-statistics from the model with sex-labels permuted.

Testing QUAL-model vs. null by Spatial-Correlation: Evidence for the QUAL-model will be if, across vertices, there is less spatial correlation between autism-effects in females vs. males than by chance. This was tested with the same permutation approach.

Results:

Model selection: Thickness, area, volume and smoothed absolute mean curvature were best modeled without sex-covariate interaction terms. Thickness and volume were best modelled by brain volume cubed and a quadratic age term; Area and thickness were best modelled by linear age, and brain volume to the 2/3 power.

QUAN-model: Increased sign-concordance was observed for smoothed absolute mean curvature (but not other metrics) at effect thresholds greater than 50% of maximum observed effect, supporting the QUAN-model; this result was insensitive to whether IQ was included as a covariate.

QUAL-model: All measures were within randomization intervals providing no evidence for the QUAL-model.

Conclusions:

These results suggest possible *quantitative* sex-moderation of cortical curvature in autism. How sex-moderation is associated with autism-ID co-occurrence requires further investigation.

125 **146.125** Structural Connectivity of the Amygdala in Young Adults with Autism Spectrum Disorder

C. R. Gibbard[1]*, D. H. Skuse*[2]*, J. D. Clayden*[1] *and C. A. Clark*[1]*, (1)Developmental Imaging and Biophysics Section, UCL Great Ormond Street Institute of Child Health, London, United Kingdom, (2)Behavioural and Brain Sciences Unit, Population Policy and Practice Programme, UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom*

Background: Autism spectrum disorders (ASD) are characterised by impairments in social cognition. The amygdala is thought to be involved in abilities that directly impact on social engagement, such as emotion recognition and 'theory of mind'. Structural magnetic resonance imaging (MRI) studies report both amygdala enlargement and reduction in ASD, whilst functional MRI studies have shown reduced amygdala activation in ASD participants in response to social cues. Little is known about the structural connectivity of the amygdala in ASD. Subdivisions of the amygdala have been identified that show specificity of structure, connectivity, and function, and recent diffusion tensor imaging studies have segmented the healthy adult amygdala into sub-regions *in vivo* using white matter connectivity-based parcellation schemes.

Objectives: The aim of this study was to investigate the microstructural properties of amygdala–cortical structural connections and their association with ASD behaviours, and whether connectivity of specific amygdala sub-regions is associated with particular ASD traits.

Methods: 25 high-functioning ASD (mean age: 24.7yr) and 26 neurotypical (mean age:23.2yr) participants underwent whole-brain T_1-weighted ($1mm^3$) and diffusion-weighted ($2.5mm^3$; 60 directions at $b=1000s/mm^2$; 3 b=0) MRI on a 1.5T Siemens Avanto scanner. Diffusion data were pre-processed using FSL. FSL FIRST and SIENAX were used to delineate amygdala and whole brain regions of interest, respectively. Cortical regions of interest were generated using FreeSurfer, and these cortical targets were grouped into frontal, parietal, occipital, and temporal lobes, and the insula using FSL utilities. All regions of interest were registered to diffusion space using FSL FLIRT and FNIRT. TractoR was used to seed probabilistic tractography from each amygdala voxel to the five cortical targets. An iterative 'winner takes all' process was used to parcellate the amygdala based on its primary cortical connection, which resulted in clusters of amygdala voxels that were maximally connected to the same cortical target. Fractional anisotropy (FA) and mean diffusivity (MD) were measured in each cluster's white matter tracts. Group comparisons were made using ANCOVA and linear regression models. Correlations with the self-reported autism quotient (AQ), a measure of ASD symptom severity, were made within the ASD group using partial Spearman correlation. Age, gender and full-scale IQ were covariates.

Results: Amygdala volume was greater in ASD compared to controls (F(1,94)=4.19; p=0.04). In the ASD group, MD was elevated in white matter tracts connecting the right amygdala to the right cortex (t=2.35; p=0.05), which correlated with the severity of emotion recognition deficits (rho=-0.53; p=0.01). Amygdala parcellation resulted in four clusters that maximally connected to the frontal, parietal, temporal, and insula lobes, respectively. In ASD subjects, reduced FA in white matter connecting the left amygdala to the temporal cortex was associated with greater attention switching impairment, as measured by the AQ (rho=-0.61; p=0.02).

Conclusions: This study demonstrates that both amygdala volume and the microstructure of connections between the amygdala and the cortex are altered in ASD. Findings indicate that the microstructure of right amygdala white matter tracts are associated with overall ASD severity, but that investigation of amygdala sub-regions can identify more specific associations.

126 **146.126** Structural MRI Does Not Support the DSM-5 Unification of the DSM-IV-TR Autism Spectrum Diagnoses

*E. Ferrari[1], A. Giuliano[1], P. Bosco[1], P. Oliva[2], M. E. Fantacci[3], F. Muratori[4], **S. Calderoni**[5] and A. Retico[6], (1)National Institute for Nuclear Physics (INFN), Pisa, Italy, (2)University of Sassari and INFN, Physics Department, Sassari, Italy, (3)University of Pisa, Physics Department, Pisa, Italy, (4)IRCCS Stella Maris Foundation, Calambrone (Pisa), Italy, (5)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, (6)Pisa Division, National Institute for Nuclear Physics, Pisa, Italy*

Background: Autism Spectrum Disorders (ASD) are a heterogeneous condition that affects individuals with various degrees of severity. Brain magnetic resonance imaging (MRI) represents a valuable non-invasive technique to study this condition. In literature, there is a great amount of studies based on supervised classification algorithms in order to distinguish subjects with ASD from controls through an analysis of their structural brain images. However, the results obtained are controversial and usually not reproduced on a sufficiently wide statistical sample. Recently, many studies focused on the importance of the stratification of the ASD population to improve classification performance.

Objectives: To evaluate the impact of stratification on supervised classification of subjects with Autism Spectrum Disorders. To this purpose both the diagnostic categories of the DSM-IV-TR and DSM-5 have been taken into account.

Methods: In this study, 420 morphological features extracted with Freesurfer 6.0 from 2156 subjects from the public databases ABIDE I and ABIDE II [http://fcon_1000.projects.nitrc.org/indi/abide/] were analyzed. In first place, an outlier analysis has been conducted to exclude the subjects for which the brain segmentation was unsuccessful. Then, six different supervised machine-learning algorithms have been used on different groups of subjects to study the effects of stratification; this has been repeated using different feature normalization methods. For each classifier the area under the receiver operating characteristic (AUC) has been computed. Finally, an analysis of the most relevant features for the decision-making process has been conducted.

Results: The great amount of train-test experiments we performed allowed us to obtain the following main results: 1) the feature normalization does not have a significant effect on the AUCs; 2) by contrast, the stratification and the type of classification algorithm used have a strong impact. Specifically, using a Logistic regression classifier, whilst the entire group of ASD subjects (according to DSM-5 classification) differed from controls with a modest AUC (about 0.60), once the subjects are sub-grouped according to the DSM-IV-TR separate subcategories of autism (AD), Asperger (AS) and Pervasive Developmental Disorder-Not Otherwise Specified (PDD-NOS), the AUC values achieved remain limited for AD vs. controls, AD vs. AS and AS vs. controls, whereas they are: 0.82 for AS vs. PDD-NOS, 0.80 for AD vs. PDD-NOS and 0.82 for PDD-NOS vs. controls.

Conclusions: We found out that the stratification of the ASD population in more homogeneous subgroups according to the DSM-IV-TR diagnoses leads to an improvement of the case vs. control classification performance. Despite the AUC values we obtained are still far away from allowing us to claim for the discovery of a neuroimaging-based biomarker for ASD, the identification of which brain regions are more responsible for the subgroup separations may provide new clues in the understanding of the neurobiology underling the ASD condition.

127 **146.127** Structural-Morphometric Examination of the Thalamus in Individuals with Autism Spectrum Disorder

***J. L. Sokoloff**[1], H. Peng[2] and S. E. Christ[1], (1)Department of Psychological Sciences, University of Missouri, Columbia, MO, (2)University of Missouri, Columbia, MO*

Background: The thalamus has been implicated as a potential location of neural disruption in autism spectrum disorder (ASD). This subcortical nuclear complex plays a critical role in sensory processing, an aspect of functioning which is affected in many individuals with ASD. Whereas previous studies reported atypical thalamic volume in this population (Hardan et al., 2006, 2008; Perich-Alsina et al., 2002; Tsatsanis et al., 2003), the pattern of results across studies remains inconsistent. Differences in methodologies (e.g., image resolution, analysis software, segmentation approach, anatomical boundary definitions) as well as sample characteristics (e.g., age, symptom severity) may have contributed to past disparate findings. Given these discrepancies and methodological constraints, the exact nature of thalamic abnormalities in ASD remains unclear.

Objectives: Potential ASD-related abnormalities in thalamic morphometry (e.g. shape and size) were examined via semi-automated MRI-based segmentation. The relationship between thalamic morphometry and autism symptomatology was also evaluated.

Methods: A sample of 57 individuals with ASD (mean age = 15.1 years) and a demographically-matched comparison group of 62 typically developing individuals without ASD (mean age = 15.6 years) participated. A 3T Siemens Trio MRI scanner with a standard 8-channel head coil was used to obtain high-resolution T1-weighted structural images of the brain. Following acquisition, the structural MRI data for each participant was rotated into AC-PC coordinates. Volumetric and vertex data were obtained via semi-automated MRI-based segmentation (FSL-FIRST) for the left and right thalamus. FSL-FIRST is a model-based vertex analysis software that provides localized estimates of subcortical shape and size. It provides parameterized volumetric data as surface meshes and then estimates the most probable shape based on a library of subcortical models constructed from manually segmented images (Dean et al., 2016; Opel et al., 2014).

Results: As anticipated, we found autism-related abnormalities in thalamic morphometry. The vertex analysis showed significant group differences in left thalamic shape. Compared to the non-ASD group, the ASD group was associated with significant surface depression in dorsal and anterior-ventral aspects of the left thalamus ($p < .05$ in aforementioned areas). Vertex results were supported by volumetric data, which showed a trend towards a group-difference in left thalamic volume [$F(1, 115) = 3.07$, $p = .08$, $\eta_p^2 = .03$]. In addition, we found that, within the ASD group, bilateral thalamic volume was significantly smaller in individuals with ASD who experienced sensory abnormalities (per parent report) as compared to those with ASD whom did not [$F(1, 31) = 4.50$, $p = .04$, $\eta_p^2 = .13$]. Lastly, we found a significant negative correlation between bilateral thalamic volume and ASD symptom severity as measured by the Social Responsiveness Scale (SRS; $r = -.37$, $p = .006$).

Conclusions: The current results are consistent with previous findings of thalamic abnormalities in autism and suggest a link between thalamic size and sensory symptoms as well as more general social communication difficulties. Also, the present vertex-based approach provides an additional metric for thalamic investigation and allows for the identification of specific thalamic regions that may be particularly relevant to ASD and its manifestation.

128 **146.128** The Neuroanatomy of Autism Spectrum Disorder in 22q11.2 Deletion Syndrome

M. Gudbrandsen[1], *E. Daly*[1], *R. H. Wichers*[1,2], *C. M. Murphy*[1,2], *V. Stoencheva*[1,2], *E. Perry*[1,2], *D. S. Andrews*[3], *D. G. Murphy*[4], *C. Ecker*[5], *L. Kushan*[6], *C. Bearden*[6] *and M. Craig*[1,2], *(1)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (4)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Goethe-University Frankfurt am Main, Frankfurt, Germany, (6)University of California, Los Angeles, CA*

Background: Individuals with syndromic forms of autism spectrum disorder (ASD) provide a unique opportunity to understand specific genetic risk mechanisms. For example, individuals with 22q11.2 Deletion Syndrome (22q11DS) have a 30-50% risk of developing ASD (Schneider et al., 2014). The neurobiological mechanisms contributing to this increased risk are unknown, but likely include genetically-determined differences in specific developmental pathways. We, and others, previously reported that individuals with ASD and 22q11DS both have significant differences in cortical volume(CV), surface area(SA) and cortical thickness(CT) (Ecker et al., 2013; Jalbrzikowski et al., 2013). In the present study, we examined the relationship between brain anatomy and ASD symptomatology in individuals with 22q11DS based on different diagnostic criteria, as it remains currently unknown to what extent the clinical ASD phenotype in the context of the 22q11.2 microdeletion resembles the clinical ASD phenotype in non-22q11DS individuals. For instance, clinical studies reliably report significant social/communication impairments in 22q11DS, while repetitive/stereotyped behaviours are less common (Wenger et al., 2016). We thus subdivided individuals based on ASD-symptoms in the social/communication and repetitive domains separately, in order to elucidate their respective neuroanatomical correlates.
Objectives: To establish whether 22q11DS individuals with ASD symptomatology are neuroanatomically distinct from those without.

Methods: We included 55 individuals with 22q11DS (27 male/28 female), age range 6-31 years (mean age=14+6 years). Of these, 10 (i.e. 18%) met strict diagnostic criteria based on the ADI-R cut-offs in all three domains (abbreviated as 22q11.**ASD**), and 30 (i.e. 55%) met the diagnostic cut-offs in the social/communication domain only (22q11.**SC**). Both ASD groups were matched on age and full-scale IQ to their respective controls. Participants underwent structural T1-weighted magnetic resonance imaging (MRI) at the Institute of Psychiatry, Psychology and Neuroscience, London and the Semel Institute for Neuroscience, UCLA. Vertex-wise measures of CV, CT and SA were derived using FreeSurfer v6.0.0 software (http://surfer.nmr.mgh.harvard.edu), and analysed by regression of a GLM including group, gender and IQ as categorical fixed effect factors. Corrections for multiple comparisons across the whole brain were performed using a random-field-based cluster-threshold($p<0.05$) (Worsley et al., 1999).

Results: There were no difference in brain anatomy when applying gold-standard diagnostic criteria for ASD in all three domains. However, when applying a more lenient cut-off in the restricted/repetitive behaviour domain, we found significantly increased CV in the left dorsolateral prefrontal & posterior cingulate cortex, in 22q11.**SC** compared to their respective controls, which was driven by a commensurate increase in SA. Furthermore, increased SA was found in the right temporo-parietal-junction, middle & superior temporal sulcus, and inferior temporal gyrus. Last, we found that individuals with 22q11.**SC** had significantly decreased CV and SA in the left entorhinal cortex. We did not observe any significant differences in CT.

Conclusions: Individuals with 22q11DS and ASD symptomatology, predominantly in the social/communication domains, are neuroanatomically distinct from those without. The spatially distributed network of volumetric differences associated with the autistic symptoms in 22q11DS has previously been linked to wider ASD symptoms and traits, and might provide useful information for patient stratification and predictions of clinical outcomes in the future.

129 **146.129** The White Matter Microstructure of Autism Spectrum Disorder (ASD) and Attention Hyperactivity Disorder (ADHD)

H. Ohta[1], *T. Itahashi*[1], *Y. Aoki*[2], *M. Nakamura*[1], *C. Kanai*[3], *A. Iwanami*[4], *N. Kato*[1], *J. Fujino*[1] *and R. Hashimoto*[5], *(1)Medical Institute of Developmental Disabilities Research, Showa University, Tokyo, Japan, (2)Showa University, Tokyo, Japan, (3)Showa University, Setagaya-ku, Japan, (4)Showa University, Setagayaku, Japan, (5)Tokyo Metropolitan University, Tokyo, Japan*

Background:
Previous researches have shown high rate of comorbidity (30-50%) between attention deficit hyperactivity disorder (ADHD) and autism spectrum disorder (ASD) . Some researches reported that impaired structural brain connectivity was related to the core features of ASD and ADHD. However, only a few studies directly compared the white matter microstructure between ASD and ADHD.

Objectives:

The aim of the present study is to reveal the commonality and difference of white matter microstructure between adults with ASD and those with ADHD using Diffusion Tenor Imaging (DTI).

Methods:

A total of 196 adults participated in this study; 68 Normal Controls (NC), 83 ASD, 45 ADHD. Two medical specialists diagnosed ASD and ADHD according to DSM-5 criteria. ADOS-2 was conducted on 71 out of 83 ASDs. Individuals who have mental retardation were excluded from this study. MRI scans were conducted to all participants. DTI data were processed using programs in the FMRIB Software Library (FSL) version 5.0. TBSS (Tract-Based Spatial Statistics) was used for voxelwise statistical analysis. The statistical threshold was defined at $p < 0.05$ (corrected for multiple comparisons). Age and gender were included as covariates.

Results: Lower FA of corpus callosum, bilateral superior and middle cerebellar peduncle, bilateral cerebral peduncle, right superior temporal cortex was found in ASD compared to HC. Lower FA of bilateral superior and middle cerebellar peduncle and right superior temporal cortex was found in ADHD compared to HC. Although the differences were disappeared after controlling for multiple comparison, lower FA of genu of corpus callosum in ASD and right cingulum in ADHD comparing directly between the two disorders.

Conclusions: The present study specified common white matter alternations between ASD and ADHD in cerebellum peduncle and white matter under superior temporal cortex. ASD specific alterations were observed in corpus callosum and cerebral peduncle.In the direct comparison of ASD and ADHD, lower FA values were found in genu of corpus callosum in ASD and in right cingulum in ADHD. To reveal more complete picture of association between ASD and ADHD, further studies are needed by adopting not only the categorical but also dimensional approach.

130 **146.130** White Matter Abnormalities Support the Female Protective Effect in Autism: A Group-Matched, Quality-Controlled, Diffusion Tensor Imaging Study

E. K. Lecarie[1]*, J. Lei*[2]*, S. C. Boland*[1]*, D. Yang*[3]*, P. E. Ventola*[4]*, D. G. Sukhodolsky*[4]*, K. Pelphrey*[5] *and R. J. Jou*[6]*, (1)Yale Child Study Center, New Haven, CT, (2)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (3)The George Washington University, Ashburn, VA, (4)Yale Child Study Center, Yale University School of Medicine, New Haven, CT, (5)The George Washington University, Washington, DC, (6)Yale University, New Haven, CT*

Background: Many earlier diffusion tensor imaging (DTI) studies reported widespread and heterogeneous white matter (WM) abnormalities in autism spectrum disorder (ASD). However, these findings were not replicated in more recent studies which stringently controlled for MRI data quality. Moreover, there is growing awareness that ASD manifests differently in girls, specifically the Female Protective Effect, which posits that girls require a greater etiologic load to manifest significant symptoms of autism. Therefore, neuroimaging studies should also account for gender differences, as girls with ASD may be more severely affected and exhibit a neurophenotype unlike that of boys with ASD.
Objectives: To evaluate gender differences in WM between individuals with ASD and neurotypical (NT) peers, while stringently controlling for data quality and matching for confounding variables known to produce artefactual findings.

Methods: A total of 130 children were divided into four groups: 25 ASD girls (age = 9.30 years ±4.25), 65 ASD boys (age = 9.79 years ±4.16), 16 NT girls (age = 11.30 ±4.14) and 24 NT boys (age = 11.16 years ±4.52). Participants underwent clinical assessment and DTI on a 3T MRI scanner. All scans were pre-processed using FSL, including eddy current correction and estimation of the diffusion tensor, which enables calculation of fractional anisotropy (FA), an accepted measure of WM integrity. A multi-step procedure was used to ensure stringent quality control, which consisted of visual inspection by two independent raters for removing compromised data (intraclass correlation coefficient >0.90). Voxel-wise group comparisons were performed using Tract-Based Spatial Statistics. Areas of significant difference were identified ($p < 0.05$, corrected) using Threshold-free Cluster Enhancement. A tractography atlas was used to characterize fiber tract abnormalities.

Results: No main effects of group or gender were observed for age or full-scale IQ. For the Social Responsiveness Scale, there was no main effect of gender, though a main effect of group was noted. No main effect of group was observed for any motion parameters (displacement, rotation, and translation). There were widespread regions in both hemispheres where FA was significantly reduced in ASD girls. All fiber types were represented, including association, commissure, and projection fibers. Notably, there were no significant differences in FA between ASD and NT boys.

Conclusions: The presence of neither localized nor widespread WM abnormalities in ASD boys was supported in the current study. Combined with comparable SRS scores between genders, the widespread WM abnormalities detected only in ASD girls suggests that comparable symptoms of autism require substantial structural aberrations. These results support the Female Protective Effect and the continued importance of gender differences in autism.

Poster Session
147 - Family Issues and Stakeholder Experiences
11:30 AM - 1:30 PM - Hall Grote Zaal

131 **146.131** A Qualitative Exploration of the Female Phenotype and Experience of Autism Spectrum Disorder

V. L. Milner[1]*, H. R. McIntosh*[2]*, E. Colvert*[1] *and F. Happé*[1]*, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)SGDP, Institute of Psychiatry, Psychology and Neuroscience (King's College London), London, United Kingdom*

Background:
Autism spectrum disorder (ASD) is a neurodevelopmental condition characterised by persistent deficits in social interaction, social communication and restricted and repetitive patterns of behaviour, from a young age. One of the most striking features of ASD is the high male to female ratio, which varies across the spectrum with most studies quoting 4-5:1. Much ASD research involves males only, perhaps leading to a biased understanding of the full spectrum of ASD and its manifestations. If current ASD diagnostic measures and processes are largely based on data from males, these may not meet the needs of females on the autism spectrum.

Objectives:

This study aimed to explore qualitatively the female ASD phenotype and experience, as a step towards developing trait and diagnostic measures that better recognise autism in women and girls.

Methods:

Participants were 18 females with a clinical diagnosis of ASD(n=16) or self-diagnosed ASD (n=2) aged between 11-55 years, and 4 mothers of women with ASD. Participants were invited to attend focus groups, face-to-face interviews or telephone interviews, which were audio recorded and transcribed. A topic guide was used within the session and included three overarching topics; diagnostic pathway, impact of ASD, and resilience and coping. A semi-structured interview style was used allowing in-depth answers to be collected. Two members of the research team conducted a thematic analysis following guidelines by Braun & Clarke, 2006.

Results:

From an abundance of relevant transcript data, seven overarching themes comprising 21 subthemes were identified. The seven major themes were: (1) “fitting in with the norm” ,which encapsulates the attempts, both successful and unsuccessful, that women make to attempt to fit in with their peers and society; (2) “gender”, which considers the differences between genders as well as the concept of fitting into a gender stereotype; (3) “negative components of ASD” explores the difficulties faced by the women that are associated with having ASD; (4) “coping strategies” identifies techniques adopted by the women to cope with their condition; (5) “the perspective of others” considers how other people, including peers and family members, understand and are impacted by ASD; (6) “potential obstacles for woman with ASD” uncovers the barriers and difficulties faced by the women; and, finally, (7) “positive aspects of ASD” highlights some of the benefits of having ASD and ways women have learnt to understand their condition.

Conclusions:

By capturing qualitative accounts of women’s experiences of autism, we hope to improve understanding of the obstacles and challenges faced by those with and without a diagnosis. It is hoped that the data can inform the focus of and measures used in future research. Furthermore, it is hoped that the study highlights the importance of including female stakeholder voices within ASD research.

132

146.132 A Virtual Resiliency Treatment for Parents of Children with Autism: A Randomized Pilot Trial

***K. Kuhlthau**[1], R. A. Millstein[2], C. M. Luberto[3], G. K. Perez[3], O. Lindly[3], L. Traeger[3], E. Chad-Friedman[3], J. Proszynski[3] and E. Park[3], (1)Massachusetts General Hospital, Newburyport, MA, (2)Masachusetts General Hospital, Boston, MA, (3)Massachusetts General Hospital, Boston, MA*

Background:

Parents of children with autism experience high levels of distress.Evidence-based resiliency treatments for parents of children with autism have not been developed or tested.

Objectives:

This pilot study examines a Stress Management And Resiliency Training-Relaxation Response Resiliency Program (SMART-3RP) program, a 9-session mind-body intervention that seeks to decrease distress and increase resiliency, stress coping, social support and mindfulness.

Methods:

We randomized 48 parents into immediate treatment vs. delayed intervention (control group). Assessments took place at baseline (T1) and three months later (T2) – post-intervention for immediate group and pre-intervention for the control group. For immediate treatment subjects, we examined feasibility and acceptability by examining attendance and responses to a feedback form. We examined pre-post change for the immediate treatment vs. control groups alone, controlling for relevant sociodemographic baseline characteristics. Outcomes include: distress (visual analog scale; primary [VAS]) resiliency (Current Experiences Scale [CES]), stress coping (Measure of Current Status part A [MOCS-A]), social support (Medical Outcome social support survey [MOS]) and mindfulness (Cognitive and Affective Mindfulness Scale – Revised [CAMS-R]).

Results:

The vast majority of participants were mothers (89%), white (78%), non-Latino (96%), married/partnered (76%), had at least a college degree (80%). In terms of feasibility, 65% of intervention participants completed ≥6 sessions. Among 72% of intervention group participants who completed the post-treatment survey, 83% reported practicing relaxation response exercises at least a few times a week. In response to the question, “How successfully do you think this treatment will reduce your stress-related symptoms” (1=not at all to 9=very), intervention participants responded on average 7.9. When comparing immediate treatment to control group participants for change in efficacy (see table 1), distress as measured by the VAS did not show a statistically significant change (p=.31). All secondary outcomes showed significant change in the expected direction. Immediate treatment participants showed improvements on the CES (M difference 6.17; p=.028), MOCS-A (M difference 7.66; p=.002), MOS (M difference 7.67; p=.036) and CAMS-R (M difference 2.55; p=032).

Conclusions:

Findings from our randomized pilot trial showed promising feasibility, acceptability, and efficacy. All between group differences were in the expected direction. The distress measure did not reach statistical significance although other measures did. Next steps include modifications to improve the intervention and a larger trial.

133

146.133 Addressing Quality of Life Priorities in Children and Adolescents with Autism Spectrum Disorder

***L. Morán**[1], L. E. Gomez[2], M. Á. Alcedo[2], V. B. Arias[3] and M. A. Verdugo[4], (1)University of Oviedo, Oviedo, Spain, (2)University of Oviedo, Asturias, Spain, (3)University of Talca, Maule, Chile, (4)University of Salamanca, Salamanca, Spain*

Background:

In the past years, important progress has been made in assessing quality of life of persons with intellectual disability. However, individuals with autism spectrum disorder and comorbid intellectual disability are one of the groups which have had less benefits from these advances, especially in the childhood and youth stages.

Objectives:

The aim of this study is to assess quality of life-related personal outcomes in children and youth with autism spectrum disorders and a comorbid diagnosis of intellectual disability in order to identify needs and strengths in this construct’s various domains. It also responds to the demand of caregivers and practitioners for instruments with appropriate psychometric properties to facilitate evidence-based practices, evaluating progress and obstacles related to their children’s quality of life.

Methods:

Caregivers reported on the ASD KidsLife scale (Gómez et al., in press), which evaluates personal outcomes related to the quality of life in people with autism spectrum disorders and intellectual disabilities aged 4 to 21 years old. The scale comprises 96 items organized by eight dimensions proposed by Schalock and Verdugo (2002): emotional wellbeing, material wellbeing, physical wellbeing, personal development, rights, self-determination, social inclusion, and interpersonal relationships. The sample was composed of caregivers of 420 children and adolescents with autism spectrum disorders and comorbid intellectual disabilities, aged 4 to 21 years old (*M*=12; *SD*=4.7) who were enrolled in social, educative, or medical services in 78 Spanish centres.

Results:

The highest quality of life scores were obtained in the domains of material wellbeing and personal development, while the lowest results were observed in the domains of social inclusion, self-determination and interpersonal relationships. At the item-level, the majority of caregivers endorse that the confidentiality of the child's individual evaluation is protected, the child is treated with respect, his/her rights are defended, his/her belongings and right to property are respected and he/she has an adequate hygiene and personal image. In contrast, caregivers also express concerns. For example, more than half of the participants report that their child does not take part in the creation of individual support plans nor participate in natural groups in the communities. Almost half of those evaluated cannot make self-endorsed choices in life areas and have insufficient information about their rights. Quality of life-profiles will be further evaluated in relation to both child and caregiver demographic characteristics.

Conclusions:

The implications of the study are discussed and specific recommendations are made to guide and plan professional practices in order to enhance the quality of life of children and adolescents with autism and co-occurring intellectual disability.

134

146.134 Adolescents with Autism Spectrum Disorder and Their Caregiver's Perspectives on the Adolescents' Sexuality and Relationships

N. C. Cheak-Zamora[1]*, M. Teti*[2] *and A. Maurer-Batjer*[2]*, (1)Health Sciences, University of Missouri, Columbia, MO, (2)University of Missouri, Columbia, MO*

Background: Previous research has shown that many adolescents with Autism Spectrum Disorder (ASD) are interested in pursuing sexual or romantic relationships and caregivers play a critical role in providing sex and relationships education. Unfortunately, we know little about the congruence of adolescent and caregiver narratives about the adolescent's sexual and romantic interests or effectiveness of the caregiver's education.

Objectives: The goal of this study was to fill the gap in existing research and better understand the needs of caregivers and adolescents in supporting the adolescent's sexual self-hood. To achieve this goal, this study explored and compared the perspectives of caregivers and adolescent dyads regarding sex and relationships via separate qualitative interviews.

Methods: Qualitative methodology was used to capture adolescent and caregiver in-depth thoughts and experiences. Eligibility criteria for adolescents included being between the ages of 16 and 25 years; having an ASD diagnosis; English speaking; and capable of engaging in study activities. Diagnosis of ASD and age were verified through clinical records. Caregivers were defined as primary care takers of the adolescent, age 16-25 years, with an ASD diagnosis.

Caregivers took part in 90-minute focus groups while adolescents participated in 30 to 60-minute semi-structured individual interviews. Interview guides for both groups centered on exploring transition experiences and independence needs. Data (40 pages for caregivers and 72 pages for adolescent transcripts) were entered into Atlas software and analyzed, by two coders separately, using methods of thematic analysis to capture and compare experiences and attitudes. Sex and relationships were central themes in both groups.

Results: Twenty-seven caregiver and adolescent dyads participated in the study. Most adolescents within our study had a diagnosis of Asperger's Syndrome (40.7%) or Autism/Autistic Disorder (33.3%) with 75% of adolescents rated their ASD symptoms as mild. Analysis of qualitative data revealed overarching themes about companionship, interest and experience, and access to relationship information across both groups. Caregivers (1) expressed more concerns (present and future) about companionship problems than adolescents; (2) seemed to underestimate adolescents' interests and experiences with sex/relationships; and (3) overestimated adolescents' comfort confiding in caregivers about sex/relationships. Adolescents (1) spent more time describing current friendships and romantic relationships; (2) exhibited less future-oriented thinking than their caregivers; and (3) describe multiple places to access sexual education and relationship advice but reported lacking real knowledge and practical advice.

Conclusions: Our study can inform interventions to better support adolescents' sexual development. Findings show that successful interventions need to include caregiver and adolescent curricula as well as knowledge checks for adolescents to insure engagement and information retention. The importance of sex and relationship research with adolescents with ASD cannot be overstated. Thus, understanding adolescent and caregiver perspectives on the adolescent's sexual and romantic relationship is critical to both caregiver and adolescent's holistic well-being and development.

135

146.135 An Examination of the Parentification and Infantilization Experiences of Typically-Developing Siblings of Individuals with Autism Spectrum Disorder

A. K. Nuttall[1]*, W. J. Chopik*[2]*, F. M. Hasan*[3] *and P. R. Dery*[3]*, (1)Michigan State University, East Lansing, MI, (2)Psychology, Michigan State University, East Lansing, MI, (3)Human Development and Family Studies, Michigan State University, East Lansing, MI*

Background:

Children's caregiving roles occur on a spectrum where moderate levels are expected to be beneficial for children in contrast to low parental expectations which are expected to underestimated children's abilities and lead to underfunctioning (*infantilization*) and high parental expectations expected to overburden children (*parentification*) (Jurkovic, 1997). Parentification is a multi-dimensional construct recognizing that parentification roles differ with regards to providing caregiving for parents and siblings (Hooper et al., 2011) and instrumental and emotional caregiving (Jurkovic, 1997). Moreover, parentification is particularly burdensome when there is poor parental maintenance of boundaries (Kerig, 2005) or children perceive roles as unfair or of few personal benefits (Jurkovic, 1997).

Research has examined parentification adjustment outcomes among typically-developing siblings (TDS) of children with Autism Spectrum Disorder (ASD) (Tomeny et al., 2016; 2017). However, this literature has not yet examined infantilization, nor compared the experiences of TDS to the experiences of siblings who do not have a sibling or family member with a disability. Such work can identify whether TDS are at increased risk for parentification and/or infantilization. Moreover, in order to elucidate TDS' experiences it is critical to examine parentification as a multi-dimensional construct consistent with parentification theory.

Objectives: We compared role experiences of TDS of individuals with ASD with those of siblings who did not have a family member with a disability. Specifically, we examined each key dimension of parentification (parent-focused, sibling-focused, emotional, instrumental roles, parental maintenance of boundaries, perceptions of unfairness and benefits associated with roles) and the converse of parentification, infantilization. We hypothesized that TDS of children with ASD would experience more role violations than siblings from families without a disability.

Methods: Online surveys about roles were collected from participants who self-identified as TDS of individuals diagnosed with ASD (Autism, ASD, Asperger's, and Pervasive Developmental Disability) (n=108) and siblings from families in which no members had disabilities. We used propensity score 1-1 matching on family constellation and demographic variables to select the final comparison sample. Sample characteristics are reported in Table 1 (age 18-25; N=216).

Results: Results from independent sample t-tests indicated that TDS experienced greater mean levels of parent-focused and sibling-focused parentification and instrumental parentification. There were no significant group differences with regards to emotional parentification or infantilization. TDS reported higher mean levels of role unfairness and lower mean levels of parental boundary maintenance and benefits associated with parentification roles (See Table 2).

Conclusions: Findings indicate the importance of parentification theory for understanding the experiences of TDS. Parents of TDS of individuals with ASD expect more, but not less, of TDS in comparison to families who do not have a member with a disability. TDS engaged in greater levels of instrumental (but not emotional) caregiving and provided support for not only siblings with ASD but also parents, with parents providing poor maintenance of familial boundaries. TDS' reports reflected perceptions of their roles as unfair and not beneficial to the TDS, suggesting a burdensome experience for TDS.

136 **146.136** Barriers and Facilitators to Success Using High-Tech Augmentative and Alternative Communication (AAC) Devices with Children with Autism Spectrum Disorder (ASD): An Interview Study Examining Stakeholder Perspectives

N. Murphy[1]*, J. McMAHON*[2] *and C. A. Murphy*[3]*, (1)School of Education, University of Limerick, Limerick, Ireland, (2)University of Limerick, Limerick, Ireland, (3)Clinical Therapies, University of Limerick, Limerick, Ireland*

Background: Children with a diagnosis of ASD and limited speech often use high-tech AAC devices or applications as their primary mode of communication. A wide range of factors is associated with successful implementation of AAC across the home, school and community environments. In particular, stakeholders such as family and a range of supporting professionals play an integral role in the successful selection, training and implementation of AAC technology for children with ASD. Among the key players in the process are parents, AAC specialists, teachers, speech and language pathologists and behaviour analysts. These stakeholders approach AAC interventions with different aims, priorities and methods. This qualitative interview study employs a social constructivist perspective to examine the experiences and key factors associated with AAC success and failures among a unique range of stakeholders involved in supporting children with ASD.

Objectives: The objective of this study was the exploration of experiences, barriers, and facilitators to success across a range of supporting stakeholders involved in supporting children with ASD to use high-tech AAC devices.

Methods: Eleven parents and practitioners with extensive experience supporting children with ASD using high-tech AAC devices and applications participated in this study. Individual semi-structured interviews were carried out in order to access rich descriptions of barriers, and, facilitators to using high-tech AAC with this population. The interviews were recorded, transcribed verbatim and analysed thematically as per Braun and Clarke (2006). Double coding of the interviews was used to ensure rigour.

Results: Analysis revealed nine prominent themes providing insight into important features of AAC devices for this population, barriers to successful communication outcomes, and stakeholder perspectives on features of effective AAC training and implementation. Participants shared many common concerns, but the data also revealed some diversity of views. Themes and sub-themes are described with illustrative and representative quotes.

Conclusions: Findings illustrate the multitude and complexity of factors and perspectives involved in successful support and implementation of AAC device use for children with ASD. The participants in this study approach AAC interventions differently, however, they share many of the same aims, goals, and experiences. Awareness of these shared insights may be useful to focus family and practitioners when planning and implementing AAC interventions. This research lead to the development of a questionnaire used in a Delphi study identifying factors associated with successful AAC device and intervention selection and implementation for children with ASD

137 **146.137** Building Better Bridges for Critical School Transitions of Underserved Children with ASD

J. Smith*, University of California, Los Angeles, Los Angeles, CA*

Background: Ethnically diverse, foreign-born, low-income, and rural children have been found to receive autism diagnoses later than their white counterparts, as well as receive different combinations of autism-specific services than white children with ASD (Magaña et al., 2013, Mandell et al., 2009; Mandell et al., 2010; Thomas et al., 2007; Valicenti-McDermott et al., 2012). This requires the development of policies and practices to address the needs of these communities. Community partnered participatory research (CPPR; Jones et al., 2009) is a transformative framework with documented effects with ethnically diverse cultural groups in community health (Chung et al., 2010; Kim et al., 2005). Benefits of using CPPR as a framework include increases in knowledge, engagement, acceptability of intervention, and community support and trust (Powers, 2017).

Objectives: *Building Better Bridges* is a five-year collaborative study that investigates the transition experiences of under-served families of children with ASD. Goals include the development of an intervention that engages parents, students, and school personnel to create a seamless hand-off between school systems or grade levels, and focuses on the development of critical transition skills. This abstract identifies barriers and needs in critical school transitions (i.e., preschool to primary, and primary to secondary).

Methods: Collaborators developed a protocol for focus groups and interviews with parents and staff to identify current transition processes, supports that facilitate transition, challenges and successes, and recommendations. Data included 38 transcripts with school providers (n=75) and parents (n=44) of children with ASD who had undergone a critical K-12 transition within the past year, and who met federal low-income qualifications. Focus groups and interviews were conducted in English or Spanish to match the parent's primary language, audio recorded, and transcribed. Coders established reliability on two consecutive transcripts (d > 0.61; Council on Exceptional Children, 2014); twenty percent of transcripts were double coded. Raters reached consensus on emergent codes and final themes through the constant comparative method. Stakeholder involvement ensured themes reflective of our target population.

Results: Parents reported great variability at the transition into kindergarten due to the change in systems from preschool to kindergarten. Some parents reported being well-prepared by the preschool, while other parents and some providers reported limited support due to the sending school's inability to definitely discuss district placements or services. Supports included service providers (e.g., SLPs, paraeducators, etc.) and other parents who had gone through transition. In secondary, school practices were more structured with school tours and summer bridge programs organized by the sending or receiving school. Recommendations included training for parents, paraeducators, and general education teachers, better home-school communication systems, and improved communication from one school team to another.

Conclusions: Although transition planning must be individualized, school practices vary greatly from district to district, and from school to school. There is a need to develop standard transition practices including how under-served parents are informed about transition, and how one educational team communicates information to the new team. *Building Better Bridges* addresses this need, and over the next two years, will be tested in a randomized control trial.

138 **146.138** Can Theatre Increase Autism Acceptance? Evaluating a Performance Piece Developed from Stakeholder Stories and Delivered By Autistic and Non-Autistic Actors

***A. Massa**[1], D. DeNigris[2] and K. Gillespie-Lynch[3], (1)College of Staten Island, Staten Island, NY, (2)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ, (3)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: Autistic college students face challenges despite often high academic potential, including stigma toward autism (Matthews et al., 2015). Participation in an online fact-based autism training was associated with increased autism knowledge and decreased stigma among college students in the United States, Lebanon and Japan (Gillespie-Lynch et al., 2015; Obeid et al., 2015). However, factual knowledge about autism may be less consistently associated with attitudes toward autism than *high-quality contact with autism* is (Gardiner & Iarocci, 2014; Nevill & White, 2011; White et al., 2016). According to "contact theory," direct positive contact between two groups may result in reduced biases (Allport, 1954).
Objectives: By developing a participatory performance-based intervention from the stories of autistic people and people close to them, *Beyond Spectrums*, which autistic people acted in, we aimed to use high-quality contact to decrease autism stigma and increase autism knowledge.

Methods: We gathered stories from the NYC autism community via survey. Respondents (*N* = 34) were informed that their responses would be dramaturged to create a script and answered a question from a list of choices (e.g., "In what ways have you observed autism to empower or disempower individuals?") using any form of writing they desired (story, free verse, etc.). Two of the nine performers in *Beyond Spectrums* were autistic. Participants (*N*= 101) attended one of three performances and completed demographics questionnaires and pre-test/post-test evaluations (before and immediately following the performance, respectively) assessing autism knowledge and stigma (Gillespie-Lynch et al., 2015). Participants varied in age (*M* = 29.47), gender (53% female), ethnicity (47.9% minorities), and lived experience with autism (8.3% were autistic and 19.0% had an autistic nuclear relative). Participants' responses to open ended questions about the performance were qualitatively coded after reliability was obtained.

Results: A mixed-model ANOVA revealed that men reported higher stigma than women (p = .02), a reduction in stigma from pre-test to post-test (p < .001), and an interaction between gender and change in stigma (p = .025). Another mixed-model ANOVA indicated an increase in autism knowledge following the performance piece (p < .001) but no associations with gender.

Among participants who completed open-ended evaluations of the performance, 94% indicated they had learned something new, 98% indicated that it was effective, 83% indicated that it had an emotional impact on them (often referring to a relationship with autism), and 96% indicated that it could change society. However, they often qualified societal impact (e.g., "this is a first step"). When asked how to improve it, 36% of respondents indicated that it was great as it was, 7% suggested that it could be more interactive, 35% provided polishing suggestions and 14% indicated that more autistic actors and/or stories should be incorporated.

Conclusions: Findings indicate that theatre can reduce autism stigma. A key strength of this research is that it was guided by autistic voices. Future theatrical interventions should meld greater resources with opportunities for diverse autistic people to shape the piece in order to impact stigma on a larger scale.

139 **146.139** Caregiver Perceptions of Insurance Coverage As Both a Barrier and Facilitator to ASD Resources

***M. E. Villalobos**[1,2], L. DeLustro[3], M. R. Klinger[4], L. G. Klinger[5] and J. Stinson[6], (1)Psychiatry, UNC Chapel Hill, Asheville, NC, (2)psychiatry, UNC-Chapel Hill, asheville, NC, (3)ETSU, Johnson City, TN, (4)UNC TEACCH Autism Program, Chapel Hill, NC, (5)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC, (6)ETSU, johnson city, TN*

Background: The impact of healthcare coverage on access to autism-specific services and health related quality of life factors (HRQOL, WHOQOL-BREF) is largely unknown. Until recently, health insurance plans typically did not cover autism-specific treatment (Bouder, 2009 and Baller, 2015). Increased instability of healthcare coverage has reached a new high with the implementation of the Affordable Healthcare Act and its possible repeal, in addition to concerns around state-specific Medicaid funding. Many families are faced with difficult decisions and/or few options for healthcare. Autism insurance mandates have been implemented in 43 states and previous analyses suggest that the first few years of the mandate often result in low rates of utilization (Mandell 2016) largely due to system and services delivery challenges (Baller, 2016).
Objectives: This study aimed to 1) examine the relationship of insurance changes on HRQOL factors, and 2) explore caregiver's perceptions of the healthcare coverage changes in a state with an autism insurance mandate effective in the past year.

Methods: A mixed-methods approach was used beginning with a quantitative survey assessing HRQOL and insurance changes. The survey was disseminated online to parents of youth who were part of research registry through UNC Chapel Hill. 365 caregivers completed the survey. In order to determine whether insurance variables significantly predicted HRQOL subscales (physical, psychological, social and environmental), a linear regression was conducted. Insurance variables hypothesized to predict HRQOL included the following: (1) changes in health insurance in the past two years, 2) perceived quality of change and 3) perceived quality of current insurance. For the qualitative component, 8 participants were interviewed. Qualitative interview questions were created to examine the relationship parents see between HRQOL and their own daily experiences; explore barriers and facilitators towards seeking out services, resources, or support; and elicit parental responses to potential mechanisms of disseminating support and various types of supportive providers. Theoretical thematic analysis was used to help describe transcript data. NVivo-11, a qualitative analysis software package, was used in the thematic analysis process for organization of codes and creation of themes. The current study focused on the theme "Resources."

Results: First, a linear regression was conducted to examine whether a change in insurance predicted HRQOL subscales. Caregivers who reported changes in insurance coverage scored lower on overall psychological well-being (β =-.187, p =.025). Further, caregivers who rated the quality of their current coverage lower also reported poorer environmental conditions (β = 269, p =.000) and physical health (β = -.146, p = .05). Second, qualitative analyses examining the resource theme further explained caregiver's concerns around insurance change (see Table 1): caregivers expressed concerns around loss of insurance coverage or loss of state Medicaid funding, the rising cost of services and challenges with traveling to providers who would accept their insurance.

Conclusions: Caregivers are voicing concerns around the instability of healthcare coverage, which is impacting their psychological and physical health as well as environmental quality of life. Further studies should examine potential supports for caregivers as they navigate healthcare coverage.

140

146.140 Mixed-Methods Approach to Understand Health-Related Quality of Life in Parents of Youth with ASD

M. E. Villalobos[1]*, L. DeLustro*[2]*, J. Stinson*[3]*, M. R. Klinger*[4] *and L. G. Klinger*[5]*, (1)Psychiatry, UNC Chapel Hill, Asheville, NC, (2)ETSU, Johnson City, TN, (3)ETSU, johnson city, TN, (4)UNC TEACCH Autism Program, Chapel Hill, NC, (5)TEACCH Autism Program; Psychiatry, University of North Carolina, Chapel Hill, NC*

Background: If we want to improve the lives of children with ASD we have to consider the health and overall well-being of parents and caregivers. Previous research has clearly shown that parents of children with ASD experience a higher level of stress (Eisenhower et al., 2005) and report increased psychopathology, including anxiety and depression, when compared to parents of normally developing children. The health of caregivers is irrevocably linked to a number of outcomes for the recipient of care including the effectiveness of child-focused interventions.
Objectives: This study sought out to identify psychological factors that predict health related quality of life (HRQOL, WHOQOL-BREF) in parents of youth with ASD as well as give voice to the daily lived experience of these individuals by using a mixed-methods approach. HRQOL captures a meaningful snapshot of the experience of a parent by integrating multiple dimensions of well-being including physical and psychological health along with the subjective experience of health reported by a parent.

Methods: A mixed-methods approach was used beginning with a quantitative survey. The survey was disseminated online to parents of youth who were part of research registry through UNC Chapel Hill. In order to identify variables that significantly predict HRQOL, a hierarchical regression was conducted. Independent variables hypothesized to predict HRQOL included the following: (1) perceived burden, (2) perceived positive aspects of caregiving, (3) coping strategies (adaptive, maladaptive, help-seeking, and avoidant), and (4) social support (belonging, tangible, and appraisal). For the qualitative component, 8 participants were interviewed. Qualitative interview questions were created to examine the relationship parents see between HRQOL and their own daily experiences; explore barriers and facilitators towards seeking out services, resources, or support; and elicit parental responses to potential mechanisms of disseminating support and various types of supportive providers. Theoretical thematic analysis was used to help describe transcript data. NVivo-11, a qualitative analysis software package, was used in the thematic analysis process for organization of codes and creation of themes.

Results: To test the effect of psychological variables on HRQOL, hierarchical regression was conducted. First, demographic variables, including household income, parent age, and child age were entered into the model, then social support, burden, and positive and maladaptive coping were entered. Perceived burden, tangible social support, and maladaptive coping were all significant, strong predictors (see Table 1). Themes identified through thematic analysis included social and community support, resources, lack of understanding about ASD demonstrated by others, experiences of the caregiver, caregiver coping strategies, and process of reaching a diagnosis of ASD (see Table 2).

Conclusions: Interventions aimed at improving parental health and well-being should focus on parents most at risk for lower HRQOL. This means reaching out to older parents, parents of young children, and families with fewer socio-economic resources. When deciding how to intervene with parents, providers should focus on assessing for coping strategies, perceived burden, and presence of tangible social support. It may be helpful to offer psycho-education about adaptive coping strategies and/or inform parents about local avenues of tangible social support.

141

146.141 Combining Anecdotal Observation with Scientific Discovery to Improve Translational Genetics Research in Autism Spectrum Disorders

ABSTRACT WITHDRAWN

Background: There are hundreds of genes implicated in risk for autism spectrum disorders (ASD); however, the clinical utility of this knowledge to help inform treatment remains limited. Understanding how currently implicated mechanisms contribute to variable expressivity of core symptoms and comorbidities in ASD is crucial to using genetics to inform more effective treatments. Generating hypotheses testing anecdotal evidence that highlights potential connections between comorbidities and ASD offers the opportunity to reveal important clinical and biological relationships. Previous studies have used this approach to successfully decipher pleiotropic genetic effects of ASD candidate genes (e.g., *MET* variation and expression of gastrointestinal symptoms in ASD). Sleep problems are common in individuals with ASD. Sleep has strong, neuronal-specific effects on the function of molecular, cellular and network mechanisms of synaptic plasticity. Synaptic pruning is also observed to be disrupted in individuals with ASD. Considering sleep is important to synaptic pruning it is possible that short sleep duration exacerbates atypical synaptic pruning, leading to more severe symptoms of ASD. Notably, genes encoding proteins essential for synaptic function are recurrently implicated in ASD.
Objectives: Our goal is to determine if dysfunction in synaptic genes underlies the expression of more severe symptoms observed in relation to short sleep duration in ASD.

Methods: We analyzed medical histories and whole-exome sequence data from 2,714 children in the Simons Simplex Collection. Linear regression was conducted to test if parent-reported sleep duration was associated with ASD-related symptom severity. Symptoms were compared between children in the lower 5th (extremely short) and upper 95th (extremely long) percentiles of the sleep duration distribution. Gene-set enrichment analysis for biological processes defined in Gene Ontology was conducted on ASD candidate genes included in the Autism Informatics Portal using the TopGO package in R. Sequence Miner was used to identify variants in genes assigned to the synaptic signaling biological process. Genetic risk scores were calculated, reflecting the number of variants (weighted by the likelihood of being detrimental as defined by eleven prediction algorithms) per individual. Linear regression was conducted to test if genetic risk was associated with ASD-related symptom severity. Influence of risk scores on the relationship of symptom severity and sleep duration was assessed with interaction tests.

Results: Shorter sleep duration was associated with increased social impairment, severity for numerous challenging behaviors and attention deficit disorder, depressive disorder, and obsessive compulsive disorder. Symptoms were more severe in children sleeping ≤420 minutes/night compared to ≥660 minutes/night. Increased burden of deleterious variants in synaptic signaling genes significantly influenced the relationship of short sleep duration with expression of depressive disorder.

Conclusions:

Results show a clear relationship between shorter sleep and more severe ASD symptoms, demonstrating the importance of identifying sleep problems in this patient population. We are currently exploring pleiotropic genetic effects influencing sleep duration and ASD symptom severity. Characterizing pleiotropic effects may help refine the mechanisms underlying expression of sleep problems in ASD. This, in turn, may inform more effective treatment options.

142 **146.142** Depressive Symptoms in Siblings of Children with in African American and Caucasian Families

ABSTRACT WITHDRAWN

Background: In school children, Kistner (2003) found that African American (AA) boys reported more depressive symptoms than Caucasian (C) boys, while AA and C girls reported comparable levels of depressive symptoms. Elevated rates of depression have been reported in the siblings of a child with an autism spectrum disorder (ASD) (Gold, 1993; Lovell & Wetherell, 2016). Little attention has been given to the role that racial diversity may play in children and adolescents with a sibling with ASD self reporting depression or in their parents reporting symptoms of depression in their well children.
Objectives: This ongoing study investigates: (1) are there differences in the self-report of depressive symptoms between a neutrotypical ASD sib and parental reporting; (2) are there racial differences in reporting symptoms of depression; and (3) are there racial differences in parental reporting symptoms of depression in ASD sibs.

Methods: Participants were recruited from the SC Department of Disabilities and Special Needs Autism Division. Criteria for inclusion were (1) C or AA families with at least one child with ASD 8 to 17 years, and (2) at least one sib not diagnosed with ASD. The Childhood Depression Inventory (self-report and parent report) were used to measure depressive symptoms (Kovacs 1991).

Results: The preliminary sample 11 C families, and 12 AA families. While not statically significant, AA sibs (33.3%) were 4x more likely than C sibs (7.7%) to report CDI scores ≥13. In fact AA sibs (17%) reported severe clinical symptoms (CDI ≥ 19) whereas C sibs did not. Female sibs reported higher clinically significant CDI scores than male sibs: C female: male ratio = 2:1; AA female: male ratio 3:1. AA mothers were four times more likely than C mothers to rate depression symptoms of ASD sibs in the clinical range. Both AA mothers and C mothers indicated their sons had more depressive symptoms than their daughters. An item analysis indicated AA sibs reported significantly fewer friendships (t(1, 21) =2.11, p=0.046) and fewer opportunities for fun than their C counterparts (t(1, 21)=2.57, p=0.018). AA mothers also reported ASD sibs had significantly fewer friends than C mothers reported (t(1, 22)=2.23, p=0.036). Finally, parents reported fewer symptoms of depression in ASD sibs than the children self-reported. The discordant rates for C families and AA families were 50% and 33% respectively.

Conclusions: Preliminary results indicate AA sibs reported more depressive symptoms than C sibs. The preliminary findings are inconsistent with previous studies of childhood depression. In this small study, both females regardless of race reported more depressive symptoms than males. Consistent with previous studies, parent and child ratings of depression were discordant. These results may change as participants are added to the study. Future research should address the social support needs of AA ASD sibs.

143 **146.143** Examining the Social Validity and Outcomes of Clinically Replicated PEERS (R) for Young Adults, Adolescents, and Preschoolers Groups

R. M. Klinkel[1]*, G. Lyons*[2] *and J. Gong*[3]*, (1)STAR Center for ASD and NDDs, UCSF, San Francisco, CA, (2)Psychiatry, UCSF, San Francisco, CA, (3)UCSF, San Francisco, CA*

Background: PEERS® is an empirically supported, parent-assisted social skills group that delivers comprehensive, skills-based curricula to adolescents and young adults. PEERS® research suggests positive and durable effects on the social skills of teens and young adults with ASD and related disabilities (Laugeson et al., 2012; 2015). PEERS® Preschool curriculum is undergoing initial evaluation.
Few studies are devoted to evaluating the social validity (SV) of research-demonstrated interventions such as PEERS®, while fewer studies consider relationships between SV and outcomes. Despite this, stakeholder approval is paramount when considering intervention diffusion and refinement. Indeed, stakeholders are more likely to select interventions they deem acceptable, while discontinuing those viewed as too demanding or inappropriate (Kazdin, 2000). Capitalizing on the burgeoning PEERS® evidence-base, replications considering outcomes must pivot to empirical questions that integrate stakeholder experiences.

Objectives: We are surveying parent and patient participants across four SV domains: *acceptability*, *feasibility*, *perceived effectiveness*, and *satisfaction*, and then analyzing SV in relation to parent- and patient-informed outcome measures.

Methods: We are clinically replicating PEERS® under the supervision of a certified PEERS® clinician and licensed psychologist at a university-based clinic. We included data from 57 stakeholders (92% of potential participants consented/included) across two Adolescent, two Young Adult, and one Preschool group (*n* = 30 parents; *n* = 27 patients) and aim to enroll 78 more by May 2018. Our inclusion criteria were identical to those described in PEERS® research. Every group had at least one female patient and 78% had ASD. Attrition was minimal (two drops after the 1st session, one after the 6th). We obtained pre-outcome measures prior to the first session, and post-outcome and SV questionnaires on the final session. The SV questionnaire used a 5-point scale: *strongly agree* = 5 to *strongly disagree* = 1. Outcome measures mirrored those used in prior PEERS® research.

Results: Overall satisfaction across the groups was 4.1, with relatively high ratings by parents in the preschool group (4.6) and low ratings by patients in the teen group (3.6). Descriptively, patient teens and young adults consistently rated SV less favorably than parents. Young adult patients perceived a more neutral effect (3.6), whereas parents of preschoolers perceived larger effects (4.5). In terms of acceptability of weekly lesson topics, ratings across respondents and groups were high. For outcomes, clear gains were indicated by several measures (see Table 2), whereas many measure showed minimal improvement. Some outcome data showed discrepancies between patient and parent responses. Attendance was high (M = 87%; range: 62.5-100%) and not associated with SV/outcomes. Exploratory correlations suggest, at $p < .05$, that (a) teens and young adults with ASD rated PEERS® significantly less feasible than those without ASD, and (b) some outcomes, such as Empathy Quotient, are strongly and positively associated with SV (r = 0.74).

Conclusions: Preliminary results suggest mostly positive SV of PEERS®, inconsistent outcome data, and associations emerging between SV and outcome, as well as SV and diagnosis. Understanding the SV of PEERS® could help stakeholders improve successful contact with intervention and better understand the variation in outcomes.

144 **146.144** Factors Affecting the Global Health Status of Children with ASD: An Analysis of Promis Pediatric Global Health Parent-Proxy Data from the Interactive Autism Network

***A. R. Marvin**, P. H. Lipkin and J. K. Law, Medical Informatics, Kennedy Krieger Institute, Baltimore, MD*

Background:

The overall well-being or "global health" of children with autism is important. Identifying specific factors associated with poor global health may lead to improved treatment and care.

Objectives:

To determine factors associated with global health as measured by the Patient-Reported Outcomes Measurement Information System (PROMIS) Pediatric Global Health measure (PGH-7) parent-proxy report.

Methods:

- Parent participants in the Interactive Autism Network (IAN)—a large, validated and verified, internet-mediated, parent-report research registry—completed the PGH-7 on their children age 5-17 with ASD.
- PGH-7 is a validated 7-item question bank that assesses a parent's overall evaluations of the physical, mental, and social health of his or her child. Responses to each question range from 1(worst)-to-5(best). Raw total scores (=sum of the scores for each question with minimum =7 and maximum=35) are converted to standardized T-scores (Mean=50; SD= 10), e.g., total raw score=24->T-Score=39.7 (~1SD below mean); total raw score=29->T-Score=49.3 (~the mean).
- Parents also completed IAN's Birth and Diagnosis Questionnaire (BDQ), which collects baseline data relating to each child's birth, ASD diagnosis, and development. A rating of "significantly below age level" on the cognitive functioning question and/or IQ score <70 was used as a proxy for intellectual disability (ID). A rating of "meaningful, fluent speech" was used to determine whether the child had normal verbal ability. In addition, the BDQ asks about the degree to which the child has experienced 15 common conditions or difficulties associated with ASD during the past 30 days. The BDQ also includes questions on parent marital status and household income. Children with a BDQ completed before age 5 were excluded.
- Demographic data is collected during IAN registration; analysis was limited to children who resided in the US.
- All children had a professional diagnosis of ASD, with a confirmatory score on the Social Communication Questionnaire (SCQ) screener ≥12 and a Social Responsiveness Scale (SRS) T-score>=60T.
- Multiple linear regression was performed on the PGH-7 raw total score and ordered logistic regression on each of the PGH-7 questions. Included variables are listed in Table 1.

Results:

- Demographics: n=1,052; 79% male; 86% white; 10% Hispanic; mean (SD) age at completion of PGH-7 12.3 (3.36) years.
- Household: 80% of parents married or in committed relationship; median income $60,000-$69,999.
- T-Score Percentages: 52.7% >1SD below mean (with 8.3%>2SD below mean); 46.2% +/-1SD of mean; .01%>1SD above mean.
- Multiple linear regression of PGH-7 raw total scores: number predictors reduced to six, with global health inversely related to (i) age and (ii) SRS raw score, the presence of (iii) irritability/aggression and (iv) depression, and difficulties with (v) feeding and (vi) bowel movements. $R^{2=}$.21, F(6, 889)=38.56, p<.001, with no multicollinearity.
- Ordered logistic regression of PGH-7 item scores: See Table 1. The greatest areas of concern are mental health, "sadness", and socialization.

Conclusions:

Addressing key factors associated with poor global health—most notably depression/mood disorders, feeding and bowel movement difficulties, socialization, and challenging behaviors (e.g., irritability/aggression and self-injury)—are most likely to improve overall well-being for children with ASD.

145 **146.145** Factors Relating to Parent's Decision of Treatment for Their Children with Autism in Vietnam

***H. Vu**, Hung Dong center, Hanoi, Viet Nam*

Background: Vietnam has not officially considered autism spectrum disorder (ASD) as a disability and there has not been an official national guide for ASD treatment. Most Vietnamese parents have to make treatment decisions for their children with ASD own their own.
Objectives: This study aims to examine the status of Vietnamese parents' choices for treatment services for their children with ASD.

Methods: A questionnaire included items about informant's demographic information, information of their child(ren) with ASD, and possible factors that may relate to parents' choices of intervention was created based on literature review and some parents and professional interviews. One hundred and eighteen parents from 5 provinces in Northern Vietnam participated in the study.

Results: Parents' choices of treatment varies with evidence-based as well as non-evidenced treatments. Family economy status was negatively correlated with non-evidenced treatments (*r=-0.402, p<0.05*); characteristics of children with autism (e.g. severity, skill level) had positive correlations with evidence-based (*r=0,264; p = 0.01*); and child's general functional level had negative correlations with evidence-based (*r=-0.261; p=0.01*). Parents' frequencies of looking for information are related to autism and the treatment methods; time accessing information sources; intervention locations; and parents' emotions significantly predicted evidence-based versus non-evidence treatment choices. Finally, the younger children are, the more parents hesitate in selecting interventions for children.

Conclusions: This is one of the first studies in Vietnam looking at parents' selecting behaviors and the correlates, which implies multiple suggestions for practice and research. Suggestions for future research directions, as well as policy and practice was provided to better support Vietnamese parents.

146

146.146 Family Meetings Increase Recruitment and Engagement of Genetically Defined Communities in Simons Variation in Individuals Project (Simons VIP)

__L. A. Cartner__, J. Tjernagel, A. Daniels, L. A. Green Snyder and W. K. Chung, Simons Foundation, New York, NY

Background:
The Simons Variation in Individuals Project (Simons VIP) was established in 2010 to study groups of individuals who share recurrent genetic variants known to increase the risk of autism spectrum disorder and other neurodevelopmental conditions. In 2014 Simons VIP launched an online registry, enabling longitudinal data collection. One way to enhance engagement is to collaborate with self-organized communities who share a genetic etiology ("family groups") to coordinate or attend family meetings, either in-person or virtually. Virtual meetings are interactive webinars that share study results, present on special interest topics, and include discussion time. Goals of family meetings include providing education on the genetic condition, returning findings from the registry, performing research, and family interaction time.

Objectives:
The aim of this study was to evaluate the impact of engagement with genetically defined communities, at both in-person and virtual family meetings, on the enrollment and participation in the Simons VIP online registry.

Methods:
The impact of engaging with family groups was evaluated in ten family meetings taking place between 2016 and early 2018. Six of these meetings occurred in person, while four were virtual meetings. Main outcomes assessed included study enrollment and measure completion. Measures included: medical history and Vineland Adaptive Behavior Scales Second Edition (phone interview), and standardized online behavioral questionnaires. The study period was four-months starting three months prior to and one month after the meeting date, which contains active preparation time with the family group and follow up after the event. An increase was calculated as the change in enrollment or measures completed compared to the number of enrollments or measures completed at the start of the study period. Changes in main outcome measures for groups with family meetings were compared to groups without family meetings during the same date-matched time frames.

Results:
Compared to genetic variant groups without family meetings, we found an increase in both enrollment and measure completion among those groups with whom Simons VIP actively engaged with over the study period. On average, there was a 44% increase in registry enrollment per group with engaged communities, compared to a 17% increase for groups without engagement. We also found a 192% average increase in measure completion with engaged communities, compared to a 16% increase for groups without engagement during the same time period. Note that the average increase in enrollment and measure completion is primarily driven by inaugural meetings for respective family groups.

Conclusions:
Based on findings from the initial ten family meetings, there is evidence of increased registry activity for genetically defined communities when Simons VIP engaged with those groups to participate in family meetings, irrespective of format (in-person or virtual). The virtual family meeting model is scalable to a broader range of genetically defined groups, and may be appropriate for groups just beginning to organize. The percentage increases in enrollment and measure completion varied across groups. Further research is necessary to demonstrate the impact of this type of engagement on cohort recruitment and retention.

147

146.147 Financial Impact, Quality of Life and Stigma of the Families of People with ASD in Uruguay in the Framework of a New Mental Health Law

V. Besio[1], __G. Garrido__[1], A. Rattazzi[2], R. A. Garcia[3], C. S. de Paula[4], C. Montiel-Nava[5], D. Valdez[6], A. Rosoli[7], S. H. Cukier[2] and M. Irrazabal[8], (1)Universidad de la República, Montevideo, Uruguay, (2)PANAACEA, Buenos Aires, Argentina, (3)Universidad de Chile, Santiago, CHILE, (4)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (5)La Universidad del Zulia, Gainesville, GA, (6)Universidad de Buenos Aires-FLACSO, Buenos Aires, Argentina, (7)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (8)Millennium Institute for Research in Depression and Personality, Santiago, Chile

Background: International studies have described the impact of having a family member with autism spectrum disorder (ASD). It depends on many variables including access to treatments, inclusion in the educational system, stigma and severity of symptoms. Few studies have been conducted in Latin America describing the impact on families.
Objectives: Evaluate perception of the caregivers of people diagnosed with ASD in Uruguay have of the economic impact, quality of life, stigma and the variables that determine it. Contribute inputs to the New National Mental Health Plan within the framework of the National Integrated

Health System and the Care System

Methods: Cross sectional study. During a period of 4 months (2015-2016) caregivers completed the Autism Speaks Caregiver Needs Survey. Adaptation and dissemination of the survey was carried out by professionals and parent's associative corporation. This study is part of an investigation based on the needs of caregivers of people with ASD that made in six Latin American countries (Argentina, Brazil, Chile, Uruguay, Panama, Dominican Republic) by the Red Espectro Autista Latinoamerica

Results: - 382 surveys were filled in Uruguay, with a response rate of 11.14 per 100,000 inhabitants. 53% of the respondents said their son's disorder had caused family financial problems. One family member stopped working in 35,5% and in 52% had to reduce their working hours to take care of the individual with ASD. Quality of life was assessed relating the satisfaction and importance of three variables (importance of having support in school, making friends and the relationship with professionals). Satisfaction is low if it is related to the importance given. 35% feel discriminated by others because they have a child with ASD. 34% described impotence generated by having a child with ASD

Conclusions: Financial impact may be consequence of the costs of the treatments and the reduction of the hours of work or even quit to take of care of the person with ASD. Aspects such as: educational inclusion, the quality of attention and the access to treatment might influence the perception of quality of life that families have. This data is relevant in the current national context. Recently a new Mental Health Law was passed from a Human Rights (perspective or point of view) in the framework of the National Health System. The collected data must be considered in the National Mental Care Health Plan, allowing a thorough analysis of people with TEA's health needs along their lives and their families. More extensive studies should be done to allow a better understanding of the social stigma perceived by parents and to approach the difficulties that limit the social inclusion of people with ASD and their families in Uruguay.

148 **146.148** How Autistic People Portray Autism on Youtube: Alternative Conceptions Trapped in a Digital Bubble

J. Pickens[1], *A. Arpaci*[2], *P. J. Brooks*[3] *and K. Gillespie-Lynch*[4], *(1)The Graduate Center, City University of New York (CUNY), New York City, NY, (2)Staten Island Technical High School, New York City, NY, (3)Psychology, College of Staten Island, Staten Island, NY, (4)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: Online communities can provide valuable supports for autistic individuals (Benford & Standen, 2009). Research on the video-sharing site YouTube suggests that the site may serve as a useful resource for parents of autistic individuals (Bokhari et al., 2014) and may serve as a forum for autistic individuals to challenge stigmatizing conceptions of autism. By posting YouTube content emphasizing neurodiversity, autistic individuals may counter mainstream media depictions of autism (Brownlow et al., 2013) and endorsements of the medical model that contribute to stigmatizing views about autism (Draaisma, 2009; Jones & Harwood, 2008; Sarrett, 2011), apparent worldwide (Gillespie-Lynch et al., 2017). However, YouTube may filter content to match users' preexisting views (e.g., a digital bubble; Pariser, 2011).
Objectives:

1. Use content analysis to discover how media creators on YouTube portray autism.
2. Investigate the merits of YouTube as a platform for the autistic community to challenge mainstream conceptions.

Methods: Four hundred YouTube videos about autism were collected using four related keywords: "Autism", "Autistic", "Aspergers", and "Aspie". The first 100 videos were collected for each query. We eliminated 32 duplicate videos, 14 that were irrelevant to autism, 58 in a foreign language, and 31 that were inaccessible. The remaining 265 videos were categorized in accordance with the content producer's relation to autism (autistic individual, family member of an autistic individual, autism organization, or TV news-media broadcast). Videos were coded for: demographics, attitude towards autism, and purported nature of autism. We aimed to collect the four newest responses from each of the 25 most highly ranked videos in each category. Due to disabled comment sections, we collected 360 comments. The identity of commenters was coded into the following four categories according to self-identification: autistic individual, family member of autistic individual, professional/specialist, and other. Two independent coders achieved reliability > 80% for all coding categories on 20% of the sample.

Results: Utilizing nonparametric statistics, we found striking differences in the content of videos produced by autistic people or family members (see Table 1). Videos produced by autistic people highlighted coping mechanisms, while critiquing available supports. In contrast, videos produced by family members highlighted challenges associated with autism and endorsed available supports. Videos produced by autistic individuals received fewer views, likes, and dislikes relative to videos produced by others (ps <0.001). Videos produced by autistic individuals also tended to have more comments from other autistic individuals (p=0.021). In contrast, videos by family members of autistic individuals received more views and dislikes (ps<0.001), yet fewer comments from autistic individuals (p=0.027).

Conclusions:

Autistic people were more likely to present an alternative conception of their diagnosis and feature a more diverse portrayal of autism, but fail to reach many viewers. Family members, in contrast, were likely to present a mainstream conception and garner more views despite accruing more dislikes. Despite YouTube's potential as a platform for autistic people to challenge misconceptions about autism (Brownlow et al., 2013), this study suggests that YouTube may create digital bubbles where autistic individuals challenge mainstream conceptions, yet struggle reaching viewers with different perspectives.

149 **146.149** How Does Temperamental Individuality Impact the Developmental Course of Symptoms and Maladjustment in Youth with Autism Spectrum Disorder? a 9-Year Longitudinal Study

L. De Clercq[1], *S. S. De Pauw*[1], *L. M. Dieleman*[2], *B. Soenens*[2] *and P. Prinzie*[3], *(1)Department of Special Needs Education, Ghent University, Ghent, Belgium, (2)Department of Developmental, Personality, and Social Psychology, Ghent University, Ghent, Belgium, (3)Erasmus University Rotterdam, Rotterdam, Netherlands*

Background:
Scholars increasingly suggest that the study of unique behavioural traits, as captured by temperament and personality models, may provide valuable keys to better grasp the wide behavioural variability demonstrated by individuals with autism spectrum disorders (ASD). Multiple cross-sectional studies have now identified salient temperament or personality differences associated with the autism spectrum condition, in

adulthood but also in childhood and adolescence. Surprisingly little research, however, has addressed the longitudinal impact of these temperamental variables on developmental outcomes. Two important research questions, particularly salient in childhood and adolescence, relate to the impact of this behavioural uniqueness (ideally comprehensively assessed using temperament as well as personality constructs) on the developmental course of autism symptoms on the one hand, and on the course of psychosocial problems on the other.

Objectives:

This study evaluates the dynamic interplay between unique child characteristics, as measured by temperament and personality, the course of autism-related symptoms, and the manifestation of psychosocial problems, in a 9-year longitudinal study of children and adolescents with autism. First, this study addresses stability and change in temperament/personality, dimensional ASD-symptoms, and internalizing/externalizing problems. Second, the study evaluates the impact of temperament and personality traits on the developmental course of symptoms and of psychosocial problems.

Methods:

Parents of 139 children with ASD reported on their perceptions of the child's temperament (Early Adolescent Temperament Questionnaire-Revised), personality (Hierarchical Personality Inventory for Children), dimensional autism symptoms (Social Responsiveness Scale) and psychosocial problems (Child Behavior Checklist) at three occasions. At Time 1 (T1), children were on average 10.2 years old (SD = 2.4). At Time 2 (T2), the mean age was 16.0 years and at Time 3 (T3), the mean age was 19.0 years.

Results:

Correlational and repeated measurement analyses indicate that all variables (temperament, personality, ASD-symptoms, and behavioural problems) demonstrate substantially high continuity across the nine-year interval. Nevertheless, some marked, yet limited, developmental changes can be noted: temperament and personality profiles tend to become slightly more adaptive and both ASD-symptoms and psychosocial problems linearly decrease across the measurement waves. Notably, we found that the impact of child temperament/personality on the course of SRS-symptoms was more modest than expected: higher scores on ASD-symptoms were moderately associated with higher temperamental Negative Affect and lower Effortful Control, and lower Benevolence in personality, both within- and across-time. By contrast, child temperament/personality had major, predictive validity for the presence as well as the developmental course of psychosocial problems. Externalizing problems were mainly predicted, both cross-sectionally and longitudinally, by perceived difficulties in temperamental Negative Affect, and in the personality traits Extraversion and Benevolence. Internalizing problems were mainly predicted by Negative Affect and lack of Emotional Stability in personality.

Conclusions:

This study documents that youth with ASD shows both substantial stability and change in the manifestation of temperament, personality, ASD-symptoms and psychosocial problems across childhood and adolescence. The relative impact of child temperament/personality on the developmental course of internalizing and externalizing problems appears to be much more pronounced than the impact of temperament/personality features on the developmental course of autism spectrum symptoms.

150 **146.150** Including Autistic Adults in Research to Develop and Evaluate Services Interventions: Lessons from a Long-Standing Academic-Community Partnership

C. Nicolaidis *and D. Raymaker, School of Social Work, Portland State University, Portland, OR*

Background: Though there is a growing appreciation for the value of participatory methods in other fields, autistic individuals are infrequently included as co-researchers in autism research.

Objectives: To use our team's experience conducting participatory, mixed-methods intervention research with and for autistic adults to inform future research.

Methods: The Academic Autism Spectrum Partnership in Research and Education (AASPIRE) has been conducting community based participatory research (CBPR) with autistic individuals and other stakeholders since 2006. During this time, we have successfully conducted ten research studies with autistic adults. We reviewed field notes and other materials from this body of work. We then confirmed and expanded our recollections via discussions with community and academic partners.

Results: AASPIRE was founded due to the Autistic community's frustration with research that did not meet their needs or priorities. Since its inception, AASPIRE has aimed to include autistic adults as equal partners though every phase of the research process. In theory, community partners are primarily responsible for keeping the research respectful, accessible, and socially relevant, while academic partners are primarily responsible for keeping the research scientifically rigorous and academically relevant.

In practice, authentically including autistic adults in research has required considerable attention to individualized accommodations, communication, power sharing, and trust-building. Though many team members have worked with AASPIRE since the beginning, some have left and others have joined over the years. We have had 6-10 autistic partners on the team at any time. We have tried to include partners with diverse lived experiences and to maintain a balance between autistic community leaders and other autistic adults. Since our founding, several autistic team members have obtained advanced degrees themselves.

Due to the dispersed nature of our team, much of our communication happens online. We have developed a structured email format to promote clarity. Group meetings are via text-based instant messenger chat, but partners may also provide input individually via email or telephone. We have developed a variety of facilitation strategies to keep meetings accessible, respectful, fun, and efficient. We have found that a formal consensus process helps ensure shared decision-making. Constant evaluation and adaptation of our collaboration processes has been essential to building a culture of trust.

Academic and community partners have worked together in every phase of the research, collaboratively choosing research topics, obtaining funding, creating materials, designing interventions, interpreting data, and disseminating results. We have found the CBPR process to be particularly helpful in creating accessible consent and data collection materials. The CBPR process has also been critical in designing effective interventions. We collaboratively created an online, interactive healthcare toolkit for autistic adults and their primary care providers, which we have found to decrease barriers to healthcare and improve patient-provider communication and patient self-efficacy. We have used our experiences to create a set of guidelines for the inclusion of autistic adults in research.

Conclusions: CBPR necessitates significant attention to collaboration processes, power-sharing, co-learning, and trust. Authentically including autistic adults as team members can greatly impact the quality of the research process and the resulting interventions.

151 ## **146.151** Join the Fann Club – Results from an Interdisciplinary Network for Professionals on ASD in Females

M. L. Bezemer[1], *A. J. Mol*[2], *A. A. Spek*[3], *P. van Wijngaarden-Cremers*[4] *and E. M. Blijd-Hoogewys*[1], *(1)INTER-PSY, Groningen, Netherlands, (2)Altrecht, Utrecht, Netherlands, (3)Autisme Expertisecentrum, Eemnes, Netherlands, (4)Dimence, Deventer, Netherlands*

Background:

The diagnosis for ASD seems based on the male phenotype. Consequently, ASD is diagnosed more frequently in males than in females (4.5:1; CDC, 2012). Women are often misdiagnosed or diagnosed much later in life (Shattuck et al., 2009). The different manifestation of ASD in females is not reflected in the current diagnostic DSM-criteria (van Wijngaarden et al., 2014; Zwaigenbaum et al., 2012). Despite the fact that the DSM-5 states that "girls without accompanying intellectual impairments or language delays may go unrecognized, perhaps because of subtler manifestation of social and communication difficulties", it lacks concrete criteria to diagnose these females with ASD. Our project group will develop and implement scientifically based knowledge to fill in this gap regarding women with ASD.

In order to do so, the FANN was initiated in March 2017. The FANN is a Dutch interdisciplinary network for professionals (psychologists, psychiatrists, researchers, etc.) who are committed to improve the diagnostic and treatment of females of all ages with autism. Also experienced experts (women with ASD) participate in this network. The members of FANN are all experts in the field of autism in girls and/or women.

Objectives:

The objectives of FANN are to encourage knowledge exchange, to promote collaboration in scientific research, and to prompt implementation of scientific knowledge in clinical practice.

Methods:

The FANN core group meets at least twice a year and consist of 48 registered members, from all parts of the Netherlands. The FANN friends group is a LinkedIn group and consists of 167 members. Statistics are constantly being tracked.

Results:

Based on an online questionnaire, the FANN core group indicates that the following subjects are important: being a knowledge network, providing a (digital) platform, unraveling woman-specific ASD diagnostic features, ameliorating the recognition of ASD in women (including case identification), improving quality of care for women with ASD (preventing misdiagnoses, promoting better and faster diagnosis, developing effective therapy), fostering destigmatization, focusing on acceptance of women with ASD in society, and promoting scientific research.

The FANN friends group - on LinkedIn - shares the following: information on ASD in females gathered from conferences (28%) and articles (22%), advised materials for females with ASD (16%, f.i. specialized ASD cooking recipes), advised therapists with an eye for ASD in females (16%, not only in the Netherlands, but also in Belgium), media attention (12%), research (3%) and miscellaneous (3%). The latter information expands every week. At the conference, the most current data will be presented.

Conclusions:

The FANN exists since March 2017, but already inspired many people. There is a great need for such a network, which also provides a unique angle on females with ASD.

152 ## **146.152** Latino Parents of Children with Autism: Understanding How Innovative Mobile Technology Can Increase Access to Care

I. Arriaga[1], *T. De los Santos*[1], *K. E. Guardado*[2], *A. Gulsrud*[1] *and D. Hayes-Bautista*[3], *(1)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)Pediatrics, Children's Hospital Los Angeles, Los Angeles, CA, (3)David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: Latino parents of children with autism spectrum disorder (ASD) face unique challenges obtaining diagnosis, treatment, and access to autism services. Current literature lacks evidence on how low socioeconomic status (SES) Latino parents navigate autism services and use mobile internet technology to seek such services (Hispanic Pew Research & Fryer 2002). Crilly et al., (2011) found that many under-resourced populations have lower access to the internet on a computer, but have a higher mobile internet usage. Latinos, in particular, use their phones to access the Internet at higher magnitudes compared to other race/ethnic groups including non-Latino Whites (NLW) (Lopez et al., 2013).

Objectives: To understand Latino parents' perceptions of barriers to a diagnosis and treatment of ASD in low SES Latino populations. Moreover, the study aims to explore how Latino parents use mobile technology to access autism-related care.

Methods: IRB approval was obtained to interview 21 self-identified English- and Spanish-speaking Latino parents of children with ASD and 3 key informants (community leaders). Criteria for study participation included residency in Los Angeles County, being of Latin American descent, of low SES, as defined by the U.S. Federal Poverty Guidelines, and a parent of a child between the ages of 2 and 10 years with a professional diagnosis of ASD. Key informants were eligible if they worked with low-income, Latino parents of children with autism. Focus groups and interviews were conducted utilizing open-ended prompts to elicit discussion. Interviews and focus groups were audio-recorded, transcribed verbatim, and independently coded for major conceptual models. Exploratory, qualitative analyses were conducted using a modified grounded theory approach. Six raters coded each transcript to ensure reliability. Data triangulation and methodology triangulation were employed to ensure validity and reliability of data interpretation.

Results: Lack of information and language barriers emerged as major barriers in accessing autism-related services in low-income Latino families. Participants reported a need for culturally sensitive delivery of information. Heavy use of cellular phones to access Facebook and Google in order to connect with other parents and find autism-related information emerged as major solutions that these parents found to be feasible. Participants also expressed disappointment over the *lack of support from institutions* to access school-based and health services for their children. Despite these challenges, parents reported *accessing the internet* to inform themselves about broad topics related to autism (e.g., understanding autism, laws protecting children with disabilities). Cell phones and tablets were the primary source of online access. Lastly, English and Spanish speaking parents differed in their methods of evaluating the validity of online information. Such as verifying the information with other parents versus confirming the author's credentials. *Learning how to trust online* sources was also a major concern for parents.

Conclusions: These findings suggested that more parents are using their phones to inform themselves about their child's diagnosis and access resources. Understanding how Latino parents navigate autism services for their children may facilitate the creation of novel tools to make information and services more accessible to this population.

153 **146.153** Lessons from Recruitment and Engagement of over 4,000 Independent Adults with Autism into SPARK, an Online Research Cohort

***L. Grosvenor**[1], S. Ganesan[2], A. Daniels[1], P. Feliciano[1] and W. K. Chung[1], (1)Simons Foundation, New York, NY, (2)Simons Foundation - SPARK, New York, NY*

Background:

The heterogeneity within autism spectrum disorders (ASD) presents considerable challenges for autism research. ASD research has historically been more focused on children than adults, but as individuals with ASD transition into adulthood, new challenges may emerge. More effective strategies for recruiting and engaging adults with ASD will help researchers improve our understanding of ASD as a lifelong disorder.

Objectives:

We sought to understand how independent adult participants with ASD use and engage with SPARK's digital platform to inform future recruitment strategies for ASD research.

Methods:

All participants were recruited to join SPARK online (https://sparkforautism.org). During registration, independent adults with ASD consent to participate, share basic demographic and diagnostic information, and have the option to invite their biological parents and one non-ASD sibling to the study. They are presented with online surveys and sent saliva collection kits if they choose to participate in genetic studies. Participants are sent gift cards for participation and are enrolled in a lottery for an iPad if saliva samples are returned in a timely manner. We analyzed each step in the registration process as well as survey and saliva sample return for all independent adults in SPARK, and separated participants by age and referral source to understand how these factors relate to participation.

Results:

A total of 4,057 independent adults (44% male) created profiles on the SPARK website, which means they began the process, but did not yet complete informed consent. Of those, 2,029 (50%) consented to share their data with SPARK, and 2,001 (49%) consented to participate in genetic analyses. For comparison, 61% of all SPARK account holders consent to both aspects of the study. Consenting to participate in research varied by age: 28% of ages 18-24, 66% of ages 25-32, 59% of ages 33-44, 41% of ages 45-64, and 44% of 65 and older. Age was similarly associated with survey completion, saliva sample return, and the average length of time for task completion. There is a significant main effect of age group on the time to saliva sample return [$F(4,1316) = 2.48$, $p < 0.05$]. While the majority of independent adults were referred to SPARK by clinical sites (54%), this is a lower percentage compared to independent adults without ASD who enrolled dependent children in SPARK (65%).

Conclusions:

As a large-scale, online, longitudinal autism research cohort, SPARK is well-situated to recruit and engage thousands of independent adults with ASD. Surprisingly, the majority of independent adults in SPARK are female, in contrast to only 20% in the child ASD cohort, but this may reflect gender differences in research participation. Young adults who join SPARK are less likely than older adults to complete the registration process. On average, the older adults are more likely to complete their research tasks, and do so more quickly than younger adults. These are important lessons for informing recruitment and engagement of this under-studied group, and SPARK will focus on developing strategies to ensure that more adults, specifically young adults, fully participate by completing registration and research tasks.

154 **146.154** Leveraging Pediatric Primary Care Systems to Address Disparities in Autism Diagnosis and Engagement in Services: Implementation of a Family Navigation Intervention

***E. Feinberg**[1], A. Bennett[2], C. Weitzman[3], M. Augustyn[4], S. broder-Fingert[5], A. Chu[1], J. Eilenberg[6], Y. Diaz-Linhart[4], I. Fernandez-Pastrana[4] and N. Blum[7], (1)Boston University School of Public Health, Boston, MA, (2)Children's Hospital of Philadelphia, Philadelphia, PA, (3)Yale University, New Haven, CT, (4)Boston Medical Center, Boston, MA, (5)Pediatrics, Boston University, Boston, MA, (6)Boston University, Boston, MA, (7)The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Although evidence that interventions for very young children can impact the core deficits of ASD continues to grow, systems changes supporting screening, evaluation, and timely access to services have not kept pace with advances in diagnosis and treatment. Feasible, systemic interventions with broad scale-up potential are necessary. Leveraging pediatric primary care systems creates opportunity to decrease racial and ethnic disparities in identifying children with autism and providing them timely, quality services by expanding reach and supporting maintenance of effective interventions. Patient Navigation is a primary care-based care management approach that focuses on overcoming logistical hurdles to care during a defined episode.

Objectives: To use the RE-AIM framework to evaluate Family Navigation's (FN) external validity and potential for broad scale-up

Methods: We developed FN, a version of Patient Navigation designed for low-income, urban families of children with suspected ASD. Pilot data provided evidence of FN's efficacy to reduce time to ASD diagnosis. We are now conducting a multi-site randomized comparative effectiveness trial (n=250) of our systemic, lay-delivered FN protocol, which begins at a child's 18 or 24-month health supervision visit. The trial takes place in three urban, integrated pediatric care networks. The basic structure of both arms is a collaborative care system. The conventional care management arm (CCM) is consistent with the type of care provided within a traditional - but high quality – medical home. The FN arm provides more intensive, individually tailored, care coordination and theory-based family support. The navigators are bicultural, bilingual, and trained in motivational interviewing and collaborative decision making. Children are followed by their navigator for 100 days after diagnosis, and for 12 months by our study team. We report findings related to intervention reach and implementation.

Results: Regarding intervention reach, we conducted telephone confirmatory screening in the family's primary language using the M-CHAT-R/F with 448 of 496 eligible children 18- 27 months who had a positive primary-care administered M-CHAT. Autism risk was not confirmed in 22%; 16% declined participation; 56% were enrolled. Enrolled children were 22 months (mean), 31% were Hispanic, 55% Black, and 82% low-income. Regarding intervention implementation, mean time to confirmatory screening was 5 days; mean time to diagnostic resolution 109 days; 69% of

children have completed diagnostic assessment, of whom 59% received an autism diagnosis. Among families randomized to receive FN, 80% completed the 3 core in-person visits (pre diagnostic assessment; post diagnostic resolution; wrap-up/termination of navigation); only 2% did not engage with the navigator. Follow-up rates over 12 months were 85%.

Conclusions: Findings regarding intervention reach and implementation support the generalizability of FN. The study successfully enrolled children representative of those receiving primary care services at participating sites. Key elements of the FN protocol were successfully implemented, improved efficiency of primary care screening, and provided clinically relevant information. Further analyses will provide real world primary care practices with a replicable model of care and determine FN's role in increasing access to and engagement in timely diagnostic and early intervention services for a vulnerable population of urban families.

155 **146.155** Maltreatment and Autism: The Most Vulnerable of the Vulnerable?

M. H. Fisher[1], *R. Urbano*[2], *A. Vehorn*[2], *R. Epstein*[3] *and Z. Warren*[4], *(1)Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI, (2)Vanderbilt University, Nashville, TN, (3)University of Chicago, Chicago, IL, (4)Vanderbilt University Medical Center, Nashville, TN*

Background: Compared to children without disabilities, children with autism spectrum disorder (ASD) may be at increased risk of experiencing child abuse or neglect. Despite this potential increased risk, few well-controlled population-based studies have examined the prevalence of child maltreatment for clearly defined subtypes of disability, such as ASD. Given growing numbers of children with ASD and the need for systems of care that can adequately serve them, it is important to understand the nature and scale of maltreatment of children with ASD.

Objectives: We examined the prevalence of maltreatment among a large, population-level sample of children meeting well-defined and established criteria for ASD to answer two research questions: 1) Are children with ASD more likely to be referred for a maltreatment assessment or investigation from the TNDCS hotline than comparison children? and, 2) Are children with ASD more likely than those without ASD to be classified as maltreatment?

Methods: Data were obtained from the Tennessee Autism and Developmental Disabilities Monitoring (TN-ADDM) Network, Tennessee Department of Children's Services (TNDCS) between 2006 and 2014, and the 2006 Tennessee Department of Health (TDH) birth vital records. Using deterministic linkage of common identifiers (e.g., name, address, birthday, gender), a single population-based dataset was created with information on ASD diagnosis, allegations of maltreatment (referrals to the hotline), processing of the allegations by TNDCS (triaged out or further action for either assessment or investigation), and the TNDCS determined maltreatments status. The final sample consisted all children from the 11 county TN-ADDM catchment area born in 2006, and included 387 children with ASD (cases) and 23,921 children without ASD (controls). These records were linked to all cases in the TNDCS database of children born in 2006 (N=4,385).

Results: At the time of submission, initial results indicate that twice as many children with ASD compared to control children (14.47% vs. 6.0%, $X^2 = 45.9$, $p < .001$) required 'further action' after their referral to the TNDCS hotline. Among those children referred for 'further action', slightly more children with ASD referred for Assessments had a decision of maltreatment (3.62% vs. 2.24%, $X^2 = 2.69$, $p = .101$). In contrast, there were no significant differences in findings of maltreatment between the ASD and Control groups for those children referred for Investigation (2.07% vs. 2.56%) or those with combined Assessments-Investigations (3.88% vs. 4.09%).

Conclusions: In summary, children with ASD, compared to children without ASD, are more likely to be referred for 'further action' from the TNDCS hotline. When examining the processing of referrals, the results are mixed. Children with ASD are slightly more likely than controls to have a disposition of maltreatment after receiving an Assessment. In contrast, children with ASD are equally as likely to have a disposition of maltreatment after receiving an Investigation or Assessment-Investigation. These findings highlight the complexity of examining child maltreatment rates and additional analyses will examine the differences in the number of referrals children receive, the age at which maltreatment occurs, and the difference in rates of substantiated maltreatment for those who received further assessments-investigations.

156 **146.156** Multi-Stage Screening Process: A Clinical Psychology Perspective

A. S. Carter[1], *A. Eisenhower*[2], *F. Martinez-Pedraza*[3], *A. Fettig*[4] *and E. Frenette*[1], *(1)University of Massachusetts Boston, Boston, MA, (2)Psychology, University of Massachusetts Boston, Boston, MA, (3)Psychology, Florida International University, Miami, FL, (4)University of Washington, Seattle, WA*

Background:

Despite knowledge that universal screening can reduce health disparities, screening for ASD is not routine in Early Intervention (EI) settings. The dissemination and implementation of ASD screening in EI may aid in reducing health disparities by (a) increasing rates and reducing ages at ASD diagnosis, and (b) increasing receipt of post-diagnostic intervention. In line with these goals, we have been disseminating a multi-stage, screening and assessment program for 14-36 month-old toddlers, implemented in partnership with EI agencies.

Objectives:

This paper evaluates screening dissemination outcomes using the Reach, Effectiveness, Adoption, Implementation, and Maintenance (RE-AIM) framework, specifically regarding the *adoption* and *reach* components of our multi-stage screening protocol.

Methods:

Participants were children receiving services from partnering EI agencies, and their parents. Children with previous ASD diagnoses, significant sensory, or medical challenges were ineligible to participate. Our team offered training and support to EIPs to implement a multi-stage ASD screening process as part of their routine clinical practice. Stage 1 screening involved parent report measures, parent concern and provider concern. Stage 2 screening involved an EI administered observational screener. Families who screened positive were offered a free diagnostic evaluation, conducted by clinical psychologists on the research team. Screening and diagnostic assessment were offered in Spanish and English. We collected screening implementation data for each stage, including screening completion rates and referrals following positive screens. Additionally, we gathered administrative data, including demographics of screening eligible participating children and previously diagnosed EI-enrolled children.

Results:

Regarding screening *adoption*, 2,984 Stage 1 screening packets were distributed to EIPs, of which 473 (16%) were returned, indicating child ineligibility for screening, and 1571 (62.6% of the 2511 eligible) were completed. Of the 1571 Stage 1 questionnaires completed, 39.6% (n=622) scored positive and 64.8% (n=403) of children eligible for Stage 2 (based on Stage 1 positive screening) went on to complete Stage 2. Of those screened at Stage 2, 80.4% (n=324) screened positive due to parent concern, EIP concern, or a positive observational screen score. In turn, 77.2% (n=250) of these children went on to complete a diagnostic evaluation. At the diagnostic evaluation, 80.4% (n=201) received a diagnosis of ASD, 8% of the screen eligible sample, representing a more than three-fold increase over earlier years.

In terms of *reach*, the demographics (i.e., low-income, linguistic minority, and racial minority statuses) for children who received an ASD diagnosis through our protocol compared to EI-enrolled children already diagnosed with ASD through other routes revealed higher rates of low-income, linguistic minority, and racial minority children among the research project-diagnosed group. Despite early diagnosis, children whose parents were non-US-born, not English proficient, less than high school-educated, or living below the poverty level received roughly half as many hours of EI as their demographically-advantaged counterparts.

Conclusions:

Utilizing the RE-AIM framework, we addressed how early screening and assessment for ASD shows evidence for reach and adoption in improving rates of ASD diagnosis at early ages and in reducing health disparities in early detection. However, greater systemic efforts are needed to address health disparities in service receipt.

157 **146.157** Narratives of Autism and Skilled Employment: Barriers, Facilitators, and Considerations in Professional Settings

D. Raymaker[1]*, M. Scharer*[2]*, F. Gardiner*[3]*, S. K. Kapp*[4]*, K. McDonald*[2] *and C. Nicolaidis*[1]*, (1)School of Social Work, Portland State University, Portland, OR, (2)Portland State University, Portland, OR, (3)Academic Autism Spectrum Partnership in Research and Education, Portland, OR, (4)University of Exeter, Exeter, United Kingdom*

Background: A disproportionate number of autistic people are unemployed or malemployed. Most autism-related employment programs focus on entry-level work; however, many autistic people have specialized training or post-secondary degrees, making unskilled labor undesirable or inappropriate. Although better employment outcomes are a high priority in both services research and for the autistic community, little is known about what facilitates successful skilled employment–including what "success" means to employees.

Objectives: Our objective was to use a Community Based Participatory Research (CBPR) approach to conduct a qualitative study of skilled autistic employees and job-seekers. First, we aimed to understand experiences of: barriers and facilitators, how autism characteristics affect work, and environmental or personal factors. Second, we aimed to identify areas of systemic leverage that could inform an effective intervention. Lastly, we aimed to understand what autistic individuals with skilled training thought "success" and "good employment outcomes" meant to them.

Methods: Our team of academics, autistic people, family members, and disability services providers used our CBPR process to create an interview guide for eliciting detailed stories about employment experiences from autistic participants. To maximize accessibility, we offered interviews over email, video conferencing, telephone, text-based internet messaging, and in-person. We recruited a national sample of adults with an ASD diagnosis who had been trained in a profession, and had successfully found, or were looking for, skilled work in the US. We used purposeful sampling to obtain variation in professions, and to balance participants who did or did not self-identify as successful. We conducted a thematic analysis using an inductive approach at a semantic level. We verified findings through multiple coders, and by member checking. We discussed results and interpretations with our CBPR team to finalize findings.

Results: We interviewed 44 autistic people with skilled training (45% female, 41% male, 14% non-binary; 70% non-Latino white). Ages ranged from 21 to 65 (mean 36, std. dev. 11.5). 33% had used alternatives to spoken communication, and 76% had used some kind of disability services. They spanned a large geographical area, and represented a wide range of professions in trades, arts, sciences, administration, and technology. Key themes included the high stakes of autism disclosure, unconventional paths to success, disconnects with service and support systems, autistic "superpowers" in the workplace, discrimination, the importance of intersectionality, and success is more than a job.

Conclusions: Employment supports and services for autistic people with professional skills may need to look different than those for entry level jobs: for example, using skills demonstrations instead of interviews, or focusing on obtaining mentors and internships. Disclosure of autism was a key force in success *or* failure—even for the same person in similar jobs; this suggests coaching for both employees and employers around strategic disclosure could be useful. In addressing autism-related barriers to employment, it is important to remember that autistic people experience the same range of identities and experiences as any segment of the population; therefore, supports and services should also be mindful of ways in which autistic individuals can be multiply discriminated against in professional settings.

158 **146.158** Parenting Stress in Families with Concerns about ASD in Toddlers Prior to a Diagnosis

T. DesChamps[1]*, L. V. Ibanez*[2]*, S. R. Edmunds*[3]*, C. C. Dick*[1]*, E. A. Karp*[1] *and W. L. Stone*[1]*, (1)Psychology, University of Washington, Seattle, WA, (2)UW READi Lab, Seattle, WA, (3)University of Washington, Seattle, WA*

Background: Parenting stress, a specific kind of stress that arises from attempts to adapt to the demands of parenthood, is associated with many domains of parent well-being (Deater-Deckard, 2004). Parents of children diagnosed with autism spectrum disorder (ASD) experience higher levels of parenting stress compared to parents of children with developmental delays and typical development (Hayes & Watson, 2013). However, parents often have concerns about ASD long before receiving a diagnostic evaluation and face many challenges associated with caring for their child in the time between initial concern and diagnosis (Zuckerman et al., 2015). Although initial reports suggest that ASD-concerned parents may experience greater parenting stress prior to diagnosis compared to parents without ASD concerns (Mulligan et al., 2012; Ibanez et al., in prep), parenting stress has not been investigated longitudinally. To better characterize the challenging experiences faced by ASD-concerned parents, work is needed to explore patterns of parentings stress across a uniquely tumultuous time in their child's early development.

Objectives: To assess longitudinal level and change in parenting stress among parents with explicit concerns about ASD during their child's early development.

Methods: Preliminary analyses were conducted on data collected from 282 parents expressing different kinds of concern about their young child's development (ASD concerns, *n* = 50; other types of developmental concerns [e.g., motor delay], *n* = 57; no concerns, *n* = 175). Parents were recruited through their child's health care provider as part of a larger study (data collection on-going). Self-reported parenting stress (Parenting stress Index-Short Form; Abidin, 1995) was collected 3 times at 3-month intervals from parents of children who were 16 to 36 months old. Time 1 measures of parenting efficacy (Maternal Efficacy Scale; Teti & Galfand, 1991), parent psychological and social well-being (WHO Quality of Life, 1997), and child social behavior (Parent Interview for Autism-Clinical Version; Stone, 2003) were tested as additional predictors of parenting stress. Preliminary analyses using Hierarchical Linear Models (HLM; Raudenbush & Bryk, 2002) examined between- and within-person variation in parenting stress over time.

Results: Preliminary results revealed that parenting stress remained stable across early development. However, parents concerned about ASD had significantly greater parenting stress compared to parents with non-ASD developmental concerns, $b = 28.34$, $SE = 4.12$, $p = .000$, and parents with no concerns, $b = 31.96$, $SE = 3.50$, $p = .000$. Additionally, higher levels of Time 1 parenting efficacy, psychological and social well-being, and child social behavior predicted lower levels of parenting stress, $ps < .01$. Finally, psychological well-being mitigated parenting stress more strongly among ASD-concerned parents compared to parents with no concerns, $b = -6.50$, $SE = 3.04$, $p =.03$.

Conclusions: Parents who are specifically concerned about ASD during their child's early development experience levels of parenting stress that are consistently higher than parents with either non-ASD developmental concerns or no developmental concerns. However, greater psychological well-being may mitigate parenting stress among ASD-concerned parents, suggesting that parent-focused interventions to improve psychological health may benefit parents who are navigating unique challenges prior to an ASD diagnostic evaluation.

159 **146.159** Perspectives of Young Adults with an Autism Spectrum Disorder on the Use of Electronic Health Records in Research: The Balance between Privacy and Genetic Discovery

A. Edwards[1], *M. Raspa*[1], *S. Andrews*[1], *L. Turner-Brown*[2], *L. Wagner*[1], *R. Moultrie*[1], *M. Frisch*[2], *A. Alvarez*[3] *and A. Wheeler*[1], *(1)RTI International, Research Triangle Park, NC, (2)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: The advent of electronic health records (EHRs) has enabled researchers to mine vast amounts of clinical data. Advances in genomic science have led to growing numbers of research studies recruiting adults with known or suspected genetic conditions. These individuals may have the most to gain from participation in research, but also face increased risks; therefore, it is important to understand their preferences for the use of their EHRs in research.

Objectives: To understand perspectives regarding research use of EHR data among young adults with three different genetic profiles: autism spectrum disorder (ASD), a suspected genetic condition; fragile X syndrome (FXS), a known genetic condition; and no known genetic condition.

Methods: A total of seven focus groups were conducted with young adults aged 18-40 with ASD (n=9 and n=6), FXS (n=5, n=4, and n=4), and no known genetic conditions (n=8 and n=8). Most individuals with ASD were male (87%). All individuals with FXS were female. Males and females were equally represented in the group with no known conditions. Individuals with ASD and FXS were screened for level of functioning to ensure their ability to participate. Focus groups were recorded, transcribed, coded and analyzed.

Results: All participants were willing to share their EHR with researchers under certain conditions. Fear of discrimination appeared to influence the perspectives of one of the groups with ASD, leading to higher levels of distrust of researchers. Participants in the other ASD group, however, expressed few reservations about sharing their EMR. Individuals with FXS were very open to sharing, particularly if the research focused on FXS. Individuals with no known disorder were the most conservative in their preferences, with females and minorities expressing the most concerns. All groups desired a high level of transparency regarding the purpose of the research, the information shared, the credentials of researchers, and data security measures. All groups also shared a profound distrust of insurance companies and concerns about the motives of for-profit entities. Reservations about pharmaceutical research were held by most, but were tempered by the potential for new medications especially among those with ASD and FXS. A primary concern of all groups was the risk of personal information being misused for non-research purposes (e.g., identity theft, discrimination). Individuals with ASD and FXS were more willing to share EHRs if they had a personal connection to the researcher and to share sensitive information, such as mental health records, if the research was related to their condition. Individuals without known conditions were generally unwilling to share sensitive information unless de-identified. All groups cited altruistic benefits from sharing EHRs, but the ASD and FXS groups focused more on benefits to others with ASD and FXS, in addition to direct benefits to themselves and/or their siblings.

Conclusions: Overall, participants with ASD and FXS believed the benefits of sharing EHRs for research outweighed risks if they received adequate, understandable information about study details. Receiving sufficient information was critical for all groups to make an informed decision about participation.

160 **146.160** Pilot Data Findings: Connections between Low-Resource Parents of Children with ASD and School Providers Pre- and Post-Transitions between Schools

E. McGhee Hassrick[1], *S. Iadarola*[2], *C. Friedman*[1], *Z. Shamsi*[3], *J. Chiappe*[4], *L. Hauptman*[5], *B. Bronstein*[6], *A. R. Fitzgerald*[7], *K. M. Carley*[8], *D. E. Linares*[9], *A. C. Stahmer*[10], *D. S. Mandell*[11], *P. Mundy*[12], *T. Smith*[2] *and C. Kasari*[5], *(1)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)University of Rochester Medical Center, Rochester, NY, (3)Drexel University, Phialdelphia, PA, (4)University of California Los Angeles, Los Angeles, CA, (5)University of California, Los Angeles, Los Angeles, CA, (6)University of Pennsylvania, Philadelphia, PA, (7)Department of Psychiatry and Behavioral Health, UC Davis Mind Institute, Sacramento, CA, (8)Carnegie Mellon University, Pittsburg, PA, (9)Maternal and Child Health Bureau, Office of Epidemiology and Research, Health Resources and Services Administration, Rockville, MD, (10)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (11)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (12)University of California at Davis, Sacramento, CA*

Background: Coordination between low resourced parents of children with ASD and the school and healthcare professionals that serve them is particularly challenging during school transitions due to gaps in supports between schools (Boyd, McDowall, & Cooper, 2002) and decreased communication between teachers and parents at receiving schools (Podvey, Hinojosa, & Koenig, 2013). Understanding who parents rely on for information about transition and how parent connections with providers change during transition will better position us to improve school transitions for low resourced children with ASD.

Objectives: Use descriptive whole social network methods to investigate communication exchanges about transition between parents, school staff and healthcare providers pre to post transition.

Methods: Participants were parents and key family, school and healthcare providers for 6 children with ASD transitioning to a new school and in families with incomes below the federal poverty line. We created a team roster of providers for each child, using a snowball recruitment process 6 weeks before transition (average enrollment of 8 key people per team) and at 3 months post transition (average enrollment of 12 key people). We interviewed key participants at each time using the **SoDI: The Social Dynamics of Intervention Measure**, where each participant identified the frequency with which they sought out people on the roster to discuss the child's transition. Using ORA (Carley et al 2004), we computed the **density** of each transition network (actual connections divided by total possible connections). To better understand how parents engaged in transition discussions, we computed parent **in-degree** (the # of other team members who sought out the parent to discuss transition) and parent **out-degree** (the # of people who the parent sought out to discuss transition) and parent **eigenvector centrality** (the degree to which parents were connected to other well connected team members). These measures allow us to systematically summarize parent engagement in transition networks and changes in engagement over time.

Results: During pre-transition, parents identified more key providers (M=58%) than during post transition (M= 23%). When comparing team composition by role type, the overall % of family members remains constant across transition, while the % of community providers decreases. Almost no staff from the receiving school are present during pre-transition (M= 1%), while a small, but significant number of sending school staff remain engaged post transition (M=17%). The average % of district providers decreases during post-transition (Table 1). **Whole social network analysis indicated that** the mean density of transition support decreased from pre to post transition (pre M=.29 / post M=.12). Mean parent in-degree and out-degree decreased post transition but mean eigenvector remained constant (Figure 1). Figure 1 Key: The green colored circles are people the parent identified as key supporters. The red circles are people who the parent did not identify.

Conclusions: On average, parents were more disconnected at post-transition. While no comparison data exist to determine optimal density of transition networks, data from this study suggest that low-resource families may require more support post-transition to maintain connections.

161 **146.161** Quality of Life in Families of Young Children with Autism Spectrum Disorder at Intake

C. Mello[1], *M. Rivard*[2] *and A. Terroux*[3], *(1)Applied Psychology, The Pennsylvania State University, Reading, PA, (2)Psychology, Universite du Quebec a Montreal, Montréal, QC, Canada, (3)Université du Québec à Montréal, Montréal, QC, Canada*

Background: Families of children with autism spectrum disorder (ASD) experience greater psychosocial difficulties than parents of typically developing children or children with other developmental disorders. In particular, the early childhood period poses unique challenges as parents come to terms with their child's recent diagnosis, make adjustments to the family's day-to-day life and activities, and begin to seek out services. Studies to date have identified socioeconomic, family-related, and child-related variables associated with family quality of life (FQOL) and other parent outcomes (e.g., parenting stress, mental health), but these have tended to focus on families of children who were older (e.g., school-aged or adolescent) and were receiving some form of intervention or external support.

Objectives: To report on, and identify predictors of, FQOL among families of young children with ASD following the child's former diagnosis, but prior to receiving early behavioral intervention.

Methods: Data were collected from 277 families (271 mothers, 222 fathers) of preschool-aged children (*M* = 45.9 months) with ASD. At the time of the study, these families had requested, but not received, free EIBI services from a public rehabilitation center in the province of Québec, Canada. Parents completed the Beach Center FQOL scale and standardized measures of the child's adaptive behavior, autism severity, and executive function. The child also completed a standardized assessment of intellectual functioning, and a caregiver rated the child's socioaffective competencies.

Results:

Overall, parents' satisfaction with their FQOL was relatively neutral (i.e., 3.66–3.70 on a scale of 1 to 5, M = 3.65). There were no salient differences between mothers' and fathers' FQOL levels. Families were most satisfied with their physical and material well-being and disability-related support, respectively, moderately satisfied with parenting and emotional well-being, and least satisfied with family interactions. Household income and mothers' employment were positively associated with FQOL. Reliance on, and perceived availability of, social support (primarily from the extended family) was also predictive of FQOL. While autism severity, executive functioning, adaptive behaviors and parents' subjective appraisal of their child's overall level of functioning were associated with FQOL, regression analyses indicated that adaptive behavior are a more robust predictor of mothers' FQOL, while autism severity was predictive of some aspects of fathers' FQOL.

Conclusions:: In contrast to previously examined populations, parents of young children with ASD who have taken steps to eventually receive free EIBI services for their child express relatively high satisfaction with their financial stability and support services. However, during the post-diagnosis period, they may benefit from low-intensity interventions that aim to improve interactions within the family and equip parents to respond to some salient features of their child's condition. To the extent social support is particularly important during this period, outreach and intervention efforts should aim to include other family members, particularly grandparents. By improving FQOL for these families, such interventions may ensure better parental compliance with, and effectiveness of, EIBI.

162 **146.162** Quality of Life in Families of Young Children with Autism Spectrum Disorder: Three-Year Follow-up

M. Rivard[1], *C. Mello*[2] *and A. Terroux*[3], *(1)Psychology, Universite du Quebec a Montreal, Montréal, QC, Canada, (2)Applied Psychology, The Pennsylvania State University, Reading, PA, (3)Université du Québec à Montréal, Montréal, QC, Canada*

Background: Families of children with autism spectrum disorder (ASD) are particularly vulnerable to challenges throughout the educational and care trajectory for their child. Additionally, previous studies show that parental programs offered during early childhood seems to have minimal impacts on parental mental health. All together, these situations suggest that family quality of life (FQOL) may be particular poor in these families during this period marked by elevated stress. In the following years, these families will have to cope with the diagnosis of their child (diagnosis period), reach out for the services (waiting period), adapt to early childhood intervention program for ASD, and adjust to their child's transition to school.

Objectives: To examine how parents of young children with ASD's experience of FQOL evolves over the course of three years following their registration to receive early intervention services: the 1) diagnosis and waiting; 2) early childhood intervention; and 3) integration into school periods.

Methods: Data were collected from 264 families of preschool-aged children (*M* = 45.9 months) with ASD. At the beginning of the study, these families had requested, but not received, free EIBI services from a public rehabilitation center in the province of Québec, Canada. These families subsequently received the center's most intensive service (20 hours per week, *N* = 55), a similar moderate-intensity intervention (4-10 horus per week, *N* = 94), or a low-intensity parent-mediated intervention and weekly coaching (1 hour per week, *N* = 115) for a one-year period. Once per year, parents completed the Beach Center FQOL scale and standardized measures of the child's adaptive behavior, autism severity, and executive function. The child also completed a standardized assessment of intellectual functioning, and a caregiver rated the child's socioaffective competencies.

Results: Overall, FQOL, and particularly families' satisfaction with family interactions, emotional well-being, and disability support, tended to increase over the year during which they received interventions. FQOL tended to increase more consistently with increase of intensity programs, but not in the high-intensity group, who only reported higher disability-related support. The 30 families who completed the third-year follow-up, corresponding to the child's enrollment in school, reported a decrease in satisfaction with disability-related support, which had returned to pre-intervention levels.

Conclusions: During the period in which they received free services from a rehabilitation center, families of young children with ASD tended to experience increased FQOL compared to the intake period. These gains tend to be maintained the year following the cessation of these services, but may not persist as the child begins school. Gains in FQOL appeared restricted to families of children with less severe clinical profiles, with the exception of disability-related support.

163 **146.163** Quality of Life of Parents of Individuals with ASD and Complacence with Services: A Study on a Large-n Representative Sample from Hungary

*M. V. Molnar[1], K. Stefanik[1], **M. Gyori**[1], A. Ábrahám[1], Z. Borsos[1], Á. Havasi[1], A. Horhi[1], E. Horváth[1], T. Oszi[1,2] and Á. Szekeres[1], (1)ELTE University, Budapest, Hungary, (2)Autism Foundation, Budapest, Hungary*

Background: Parents of individuals with ASD were shown to have a lower overall level of quality of life (QoL) and to experience themselves as less coherent agents than parents of typically developing individuals and of individuals with other forms of atypical development (Eapen & Guan, 2016). Positive relationships were found between these (and other related) parental indicators and the quality of the ASD-specific services received by the child with ASD (Lai & Oei, 2014; Siman-Tov, Kaniel, 2011, Frantzen et al., 2016). A pilot study from a Hungarian sample brought similar results (Gyori et al., 2016).

Objectives: The main objective of the study from which results are reported was to explore the relationship between quality of educational services received by individuals with ASD and the QoL of their families. Objectives of the present analysis were to compare QoL indicators in parents of individuals with ASD to those in parents of neurotypical individuals, and explore their relationships to indicators of autism-related services received.

Methods: Data were analyzed from a group of parents of individuals with ASD (n = 262, 237 female, 25 male; mean age 43 years, SD 7.8, providing data on 222 male and 35 female individuals with ASD, mean age 12 years, SD 7.3, range 3 – 47 years) and from a group of parents of neurotypical individuals (n = 126, 115 female, 11 male; mean age 43 years, SD 8.5, providing data on 64 male and 62 female offsprings; mean age 14 years, SD 8.5, range 3-48 years). There is no significant difference between parental groups in level of education and in type of residential settlement. Data were collected by an on-line questionnaire battery, composed of, among other tools, the WHO-QOL BREF; the Quality of Life in Autism Questionnaire (QoLA; Eapen et al, 2014); the Sense of Coherence Questionnaire; the Parenting Sense of Competence Scale; and items on educational and other services received. For respondents without on-line access or relevant competence, an assisted paper-and-pencil data collecting method was implemented.

Results: In line with findings from other countries, we found significantly lower level of overall QoL in the ASD parent group, both in WHO-QoL BREF total score ($F=13.657$, $p<0.001$) and in QoLA total score ($F=4.121$ $p<0.0001$), in their domain scores and in parental sense of competence and sense of coherence indicators. No significant relationships were found between parental QoL levels and the amount of autism-specific psycho-educational interventions received by the child, but in a subgroup of parents with a child with ASD between 3 and 18 years, there emerged weak but significant positive relationships between level of parental complacence with autism-specific educational services received, and QoL indicators (both WHO-QOL BREF and QoLA).

Conclusions: Results, coming from the first large-n representative study on the issue in Hungary, are overall in line with previous findings from other countries. As a novel aspect, they point to the potential importance of parental perception of quality and amount of autism-specific services received by the child.

164 **146.164** Racial Differences in Quality of Life of Parents of Children with Autism Spectrum Disorder

__T. Lavelle__[1] and C. Mule[2], (1)Center for the Evaluation of Value and Risk in Health, Tufts Medical Center, Boston, MA, (2)Center for Children with Special Needs, Tufts Medical Center, Boston, MA

Background: Previous research has documented a decreased health-related quality of life (HRQOL) for parents of children with autism spectrum disorder (ASD). However, limited research is available regarding whether these HRQOL outcomes vary by race/ethnicity.

Objectives: Our objective was to estimate the association between race/ethnicity and HRQOL among parents of children with ASD.

Methods: Parents of children between the ages of 3-17 years and diagnosed with ASD were selected from a nationally representative research panel in the United States to complete a survey. The online survey was administered in English. All survey respondents rated their own HRQOL on a 0-100 visual analog scale, where 100 represented the best imaginable health state, and 0 represented the worst imaginable health state. Parents of children with ASD were asked to report the severity of their child's social communication and behavior impairments, with descriptions of these impairments adapted from the DSM-5. We used linear regression analysis to examine the association between parent HRQOL scores and race/ethnicity (black, non-Hispanic, white, non-Hispanic, Hispanic, and other, non-Hispanic), controlling for socio-demographic characteristics, co-morbidities not related to the ASD diagnosis, as well as the presence of other children in the household.

Results: We received responses from 72% of parents of children with ASD who were invited to complete the survey. Eight respondents were eliminated from the sample due to age and diagnostic criteria, leaving a final analysis sample size of 137. Parents of children with ASD reported a mean HRQOL score of 77 (95% CI: 74-80). In adjusted analyses that controlled for child symptom severity and other socio-demographic and clinical characteristics, being Hispanic (vs. white, non-Hispanic) was associated with a 14 point decrease (95% CI: 1-26) in parent HRQOL. There were no statistically significant differences between black vs. white non-Hispanic parent HRQOL or "other" race vs. white, non-Hispanic parent HRQOL.

Conclusions: In adjusted analyses that accounted for other variables that affect parent quality of life, including child symptom severity, HRQOL is similar for black and white, non-Hispanic, parents of children with ASD, but Hispanic parents report significantly worse HRQOL compared to white, non-Hispanic parents. More research is needed to understand the reasons behind this decreased HRQOL in Hispanic parents of children with ASD.

165 **146.165** Stakeholders Set Research Priorities for Neurodevelopmental Disorders: A Canadian First Facilitated By Ontario Brain Institute, in Collaboration with the Pond Network

*E. Anagnostou[1], **J. Antflick**[2], R. Nicolson[3], A. Iaboni[1], M. Spoelstra[4], J. Jordao[5], C. Southward[2], S. Kwan[2], B. Andrade[6], S. Lynch[7], K. Cowan[8] and J. Mitchell[9], (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Ontario Brain INstitute, toronto, ON, Canada, (3)University of Western Ontario, London, ON, Canada, (4)Autism Ontario, Toronto, ON, Canada, (5)Research & Informatics, Ontario Brain Institute, Toronto, ON, Canada, (6)Center for Addiction and Mental Helath, toronto, ON, Canada, (7)Community Living Toronto, toronto, ON, Canada, (8)James Lind Alliance, St Leonards-on-Sea, United Kingdom, (9)toronto, ON, Canada*

Background: Research into treatments often overlooks the shared priorities of patients, caregivers and clinicians. Academia and industry are important in developing and testing new treatments, but their priorities may not be well aligned with those of patients and clinicians. As such, a mismatch between the research being conducted and the research evidence needed by patients and clinicians may develop.
Objectives:

The objective of this study was to to identify research priorities of a wide range of stakeholders in Autism Spectrum Disorder (ASD) and neurodevelopmental disorders (NDD).

Methods: We employed the JLA method to address this gap in ASD and related NDDs. The method brings patient, carer and clinician groups together on an equal footing to identify treatment uncertainties which are important to both groups, jointly prioritise the uncertainties, and produce a 'Top 10' list of jointly agreed uncertainties as research questions to be presented to funders.

Results:

The priority setting process gathered over 1200 questions from 300 respondents across neurodevelopmental disorders across Ontario, Canada. Over a period of one year individuals with ASD and other NDDs, carers, advocates, and health/education professionals consolidated, prioritized and ultimately distilled these questions into a top 10 list of research priorities:

1. What are the most effective treatment options/plans (e.g., timing, frequency, duration, type, intensity or dosage) for individuals with neurodevelopmental disorders for both short and long-term benefits?
2. How can system navigation be organized in a manner that enables coordinated services and supports across the lifespan for individuals with neurodevelopmental disorders and their families?
3. Which biological treatments (including medications, gene therapy, stem cell therapy, etc.) are effective for neurodevelopmental disorders and associated symptoms?
4. Which child and family-centered interventions or approaches promote optimal individual and family functioning?
5. Which interventions best help individuals with neurodevelopmental disorders develop emotional and behavioural regulation (including increasing impulse control and reducing compulsive behaviour)?
6. Which resources are needed to more effectively address the health, social and emotional needs of families or caregivers of individuals with neurodevelopmental disorders?
7. How can treatment decisions for individuals with neurodevelopmental disorders be more precise (i.e., based on the diagnosis, age, functional need of the individual)?
8. Which are the most effective pharmacological and non-pharmacological treatments for aggressive and self-injurious behaviour in individuals with neurodevelopmental disorders?
9. Which are the most effective pharmacological and non-pharmacological intervention(s) to reduce anxiety in individuals with neurodevelopmental disorders?
10. Which interventions are most effective to help individuals with neurodevelopmental disorders improve their social skills and develop and maintain social relationships?

At the end of the process, participants expressed high satisfaction with the process and the final top 10 list.

Conclusions:

We carried out a large stakeholder engagement project to elicit priorities for research in ASD and other NDDs, using standardized methodology developed by the JLA. The top 10 priorities will serve as powerful and important tool to spur patient-oriented research into neurodevelopmental disorders.

166 **146.166** Support Needs, Experiences with Services and Characteristics of Families of Children with Autism Spectrum Disorders.

***B. van Gent**[1] and J. P. Teunisse[2], (1)HAN University of Applied Sciences, Nijmegen, Netherlands, (2)Dr Leo Kannerhuis, Oosterbeek, Netherlands*

Background:
Families caring for a child with autism spectrum disorders (ASD) experience many challenges and stressors that can have great impact on family members and lead to burden on the system. The care families provide can only be maintained if families receive sufficient support. Various support forms are available and are being used by families. However not all support is perceived as helpful and unmet support needs remain.

Objectives:

Our objective was to determine family support needs and prior experiences with services. We aimed to identify support characteristics which parents perceived as helpful. Furthermore we examined the association between support needs, satisfaction with services and family and child characteristics.

Methods:

Questionnaires (n=76) were used to question families (n=76) of a child with ASD living at home (age 12-18) about support needs and experiences with services. Then 30 semi-structured interviews were conducted to collect more detailed and extensive information about these subjects. Transcriptions of the interviews were analyzed using open coding. After this initial coding, codes were combined into concepts.

Results:

A broad variety of support needs were identified. Outpatient care, respite care, guidance on increasing independence, guidance on behavior modification, information point on available services and more community awareness of ASD were mentioned by the majority of families. All families reported unmet needs.

Support characteristics which parents perceived as helpful were flexible outpatient care, tailored care, guidance in finding and accessing services, counseling in small groups, expertise on ASD and care provided by a known, trusted counselor.

Family and child characteristics influencing support needs were acceptance of ASD, parents self-assurance about approach, parents attitude towards help, aggression, social support and caregiver burden. These characteristics play different roles in families and influence both the type of support needs and the perception of the support being helpful.

Conclusions:

Although many services are available, families face unmet support needs. Our findings indicate that several factors determine if a service is helpful for a family. Being aware of those factors and the role they play in families is essential in providing tailored care and meeting family needs.

167 **146.167** Symptom Recognition, Parental Help-Seeking, and Diagnostic Variation in Autism Spectrum Disorder

D. Schelly *and A. Ohl, Clarkson University, Potsdam, NY*

Background:

Autism spectrum disorder (ASD) symptom recognition studies often suggest that diagnostic variation in children is primarily explained by how quickly parents notice anomalous behaviors (e.g., Daley, 2004), a factor that is thought to be associated with exposure to health-related information (Mazumdar et al., 2013). Our research in Costa Rica (Authors et al., 2017) challenges this theory by showing that parents of varying socioeconomic status (SES) are about equally good at detecting anomalous behaviors, and at similar ages to early studies in the U.S. (e.g., Howlin & Asgharian, 1999). In our previous report, we find that the prevailing mechanism driving diagnostic variation occurs at the referring clinic rather than in the homes or minds of parents.

Objectives:

The aim of the present study is to develop an alternative theory of the parental role in ASD diagnosis, especially in the context of varying levels of health-related information and exposure to other children with the diagnosis. We focus on Costa Rica, where spatial clusters of low severity cases of childhood ASD have been identified (Authors et al., 2015) – the very cases for which information should be especially helpful.

Methods:

Semi-structured interviews were conducted with the parents of 54 children with ASD, including many cases within the spatial clusters that appeared after a genetic study conducted an information campaign for case recruitment. The interviews focused on factors influencing parents' symptom recognition and help-seeking behaviors, including contact with individuals with developmental disorders and clinical encounters leading to diagnosis. Parents also discussed any influence they had on parents of other symptomatic children. The analysis follows early ethnomethodological studies (e.g., Garfinkel, 1967)—a subfield of sociology—of the practical problems of research subjects, and is influenced by later conversation analytic studies of social actions such as advice-giving, complaining, and providing encouragement (e.g., Schegloff, 2008).

Results:

Parents' first concerns are related to generic developmental problems that are not attributed to specific diagnoses. Parents occasionally seek out advice from family and friends and primary care physicians, but the responses treat the advice-seeking as "troubles talk" (Jefferson, 1988), where appropriate responses include those that provide sympathy or encouragement. Parents commonly receive unsolicited advice from strangers, but these encounters are seen as criticism. When parents encounter other children with ASD, the heterogeneity of symptoms leads them to conclude that their children "have something else." Parents become convinced their children are atypical when they fail to meet additional developmental milestones and spend time with other children.

Conclusions:

Theories that account for parental symptom recognition and help-seeking behaviors in ASD tend to put the onus of early detection on parents, which is unfortunate given our history of blaming mothers for ASD. Our data suggest factors that contradict these theories. The pathways to ASD diagnosis include a give and take between typical development and concerning developmental delays, between encouragement to wait-and-see and unwanted advice to seek help. Ultimately, it is clinicians rather than parents that create diagnostic variation.

168 **146.168** Systems Science Approach to Conceptualize and Analyze the Role of Screening

R. C. Sheldrick*, Boston University School of Public Health, Boston, MA*

Background:

System science offers a range of models and methodologies that have the potential to improve public health programs, yet they are rarely applied to the problem of improving the detection and diagnosis of autism spectrum disorder (ASD) among young children. From a systems perspective, screening is but one (albeit critical) element in a system of care, and its effectiveness for improving children's health is dependent on other resources for further assessment, diagnosis, and linkage to effective service. Systems methods have the potential to offer insight at both the theoretic and methodological level that can be used to help improve systems of care for young children with ASD.

Objectives:

The objective of this talk is to introduce two systems science methods and how they can be applied to research on screening for ASD to address (1) questions regarding missing data in diagnostic accuracy studies, and (2) the potential for policy resistance resulting from clinical uncertainty during dissemination of evidence-based screening policies.

Methods:

To address the problem of missing data in studies of the diagnostic accuracy of ASD-specific screening instruments, we developed a Monte Carlo simulation model of the multi-stage screening process described in the published literature. The model was then tested under a range of assumptions regarding overall prevalence and reasons for dropout. To address the potential for policy resistance in the dissemination of evidence-based screening instruments, we created and validated a system dynamics model of the clinical decision making process and applied it to published implementation trials of behavioral screening instruments for children.

Results:

Results of the Monte Carlo model suggest that despite design challenges in the published study, evidence supports the hypothesis that screening demonstrates adequate sensitivity and specificity. Specifically, a range of prevalence estimates between 1 in 131 (as assumed in the original study) and 1 in 39 (a maximum value that approximates reported prevalence in New Jersey) are all consistent with findings that stage 1 screening displays sensitivity over 70% and specificity over 90%. Results also suggest alternative strategies for improving “process” accuracy, including improving follow-through at each stage of the process.

Results of the system dynamics model highlight how clinicians can use accurate screening instruments to reduce either false positive or false negative errors or both. Specifically, the model helps to explain heterogeneous findings from published implementation trials by demonstrating how observed changes in referral rates may be attributable not only to the use of screening instruments, but also to decision thresholds and the provision of screening support services. The model also suggests strategies for improving detection, including using systematic feedback and co-located care models to shift focus to reducing false negative errors.

Conclusions:

Systems science offers methods to conceptualize and analyze the role of screening as a single element in a larger system of care. Evidence from systems models offers insights into published research on the accuracy and implementation of screening instruments, as well as possible strategies for further improving detection of ASD in community settings.

169 **146.169** The Autgo Initiative: Building a Bridge between Genetics and Outcomes Research

Z. Talebizadeh *and A. Shah, Children's Mercy Hospital, Kansas City, MO*

Background: While the field of autism genetics has rapidly expanded our understanding of the genetic factors contributing to autism, the ability to translate these discoveries into clinically meaningful information remains a significant barrier. Concerns over the need to improve translational aspects of autism research and engage community members have been noted in the literature and raised by patient advocates. In addition to the work done by patient advocacy groups, organizations such as the Patient-Centered Outcomes Research Institute (PCORI) support a change in the culture of research from being solely researcher-driven to becoming more patient-driven. One of the main reasons why this gap has been overlooked is the lack of communication between genetics and outcomes researchers.

Objectives: We used the PCORI engagement approach to address this barrier and develop a platform that would enable synergistic relationships between the two disciplines to facilitate utilization of genetic information in patient-centered studies.

Methods: Our project, Autism Genetics and Outcomes (AutGO), consists of two phases. In Phase I, we formed a community advisory board (n=33 members), and convened six sessions over a twelve month period. Sessions were structured as a combination of webinars, surveys, and in-person group discussions. Feedback was analyzed using content analysis strategies to identify themes. In Phase II, we formed an autism focus group (n=30 members), including outcomes and genetics researchers, clinicians, and parent representatives. An engagement/educational model was developed for the autism research community, including a research example that utilizes genetic information to address a patient-centered question.

Results: In phase I, we identified key barriers, facilitators, and needs, and distilled actions that may facilitate utilization of patient/parent perspectives in designing genetic research studies (Figure 1). In Phase II, we organized an educational workshop for the autism research community and developed an educational example to show the workflow, including study design and expected impacts for a patient-centered research approach. In this example, we showed how known genetic risk factors (SNPs) for a burdensome drug side-effect [antipsychotic-induced weight gain (AIWG)] could be evaluated to answer a health-related question in autism. We analyzed genotyping data for n=115 AIWG SNPs from >2000 probands from Simons Simplex Collection. BMI data was used to identify obese and non-obese subjects. Our results suggest that factors beyond drug side effects may contribute to the observed higher rate of obesity in autism. Furthermore, an association with rs7702361 (located in the RXFP3 gene) in autistic individuals with obesity was found, which appears to be independent of anti-psychotic medication use. The RXFP3 gene is implicated in eating disorders and our finding suggests that at least a subset of individuals with autism and obesity may have underlying metabolic problems. This information may help with treatment management for this population of patients.

Conclusions: The AutGO initiative has created a unique collaborative forum to facilitate the much needed dialogue between genetics and outcomes researchers, the applicability of which we are exploring on autism. This novel approach has the strong potential to contribute to improving the translational aspects of autism genetics research.

170 **146.170** The Effect of Therapeutic Interventions of Children with Autism Spectrum Disorders on Their Parents’ Mental Health

T. Rehberger[1]*, M. Macedoni Luksic*[2] *and A. Bezenšek*[3]*, (1)Institut of Autism Spectrum Disorders, Medvode, Slovenia, (2)Institute of ASD, Slovenia, Medvode, Slovenia, (3)Institute of Autism Spectrum Disorders, Medvode, Slovenia*

Background:

Parents raising children with autism spectrum disorder (ASD) often struggle to manage the demands of everyday family life. A child with ASD affects the lives of all family members and has an important influence on quality of family life. Past studies report that parents of children with ASD experience not only significantly more stress than parents of typically developing children but even more stress than parents of children with other special needs. As highly-stressed they are more vulnerable to experience mental health problems, such as anxiety and depression. World-wide there are currently a lot of different forms of support for parents of children with ASD. They range from informal supportive to specific educational groups which are meant to empower the parents.

Objectives:

In our study we aimed to determine whether the parents' mental health (stress, wellbeing, satisfaction with life, depression) can be affected simply by their child's progress followed by the inclusion in regular and comprehensive therapeutic intervention.

Methods:

Total of 36 parents and 36 children with ASD took part in the study. Their children, aged 2-12 years (M = 5.2 years; 12 girls and 24 boys) participated in developmental and/or behavioural therapeutic interventions for two months. A questionnaire battery was developed for the purpose of the study. It included COPE – short version, Parental Stress Scale (PSS), Warwick-Edinburgh Mental Wellbeing Scale (WEMWBS), Satisfaction with Life Scale (SWLS) and Centre for Epidemiologic Studies Short Depression Scale (CES-D 10). Parents filled out the questionnaires prior and after the treatment. Therapists measured children's progress (prior vs. after) using therapist's questionnaire specifically formed for this purpose.

Results:

The influence of the child's progress in therapeutic treatment on different aspects of their parents' mental health was not statistically significant. On the other hand, there is an evidence that the instrumental support, that parents received directly from therapist throughout the therapeutic sessions, had a positive impact on two aspects of their mental health - stress level and wellbeing.

Conclusions:

The parents in our study benefit the most from the instrumental support of professionals working with their children. The obtained results give us an insight of how to efficiently help parents of children with ASD to reduce their stress level and improve their well-being. Besides encouraging them to actively participate in their child's intervention, there is a great need for target educational groups in order to support them on their way to greater independence.

171

146.171 The Importance of Addressing Heterogeneity in Autism Genomics Research to Inform Precision Medicine

***V. W. Hu**, Biochemistry and Molecular Medicine, The George Washington University, Washington, DC*

Background: Autism spectrum disorder (ASD) encompasses a broad range of neurodevelopmental disorders marked by core deficits in social communication and interaction as well as by repetitive, stereotypic behaviors and restricted interests. Despite the shared core symptoms, there is extensive heterogeneity in the clinical symptoms and behavioral manifestations among individuals diagnosed with ASD. This heterogeneity poses a significant challenge to patient-centered studies seeking to determine how knowledge of genetic and biological underpinnings of ASD can be useful to informing treatment, especially when a combined group of cases are compared against a group of controls.

Objectives: The goals of our ongoing studies have been to reduce the clinical heterogeneity within the ASD population in order to investigate the biological pathways and functions impacted in different subphenotypes of ASD and to increase the power of genetics analyses to identify genetic variation capable of distinguishing cases from controls. We accomplish these goals by: 1) subgrouping individuals according to their severity profiles across a breadth of behavioral and clinical symptoms probed by the Autism Diagnostic Interview-Revised diagnostic instrument, and 2) performing large-scale gene expression profiling and genetics analyses of the resulting ASD subgroups in comparison to controls to identify subgroup-dependent biological deficits as well as genetic variants and loci that are associated with each subphenotype.

Methods: Individuals with ASD were divided into four phenotypic subgroups by multivariate cluster analyses of item-level severity scores from the individual's ADI-R diagnostic assessment. Lymphoblastoid cell lines from individuals representing several clinically distinct ASD subgroups and a group of controls were used for gene expression profiling on 2-color custom human transcriptome arrays which were analyzed using the MeV microarray software suite. Ingenuity Pathway Analyses software was used to identify over-represented biological pathways and functions among the differentially expressed genes. Quantitative trait and case-control association analyses using ADI-R scoresheets of cases and the respective genotype data were performed using Plink, and linkage analyses were conducted with Merlin, again using publicly available genetic databases.

Results: Distinct but partially overlapping patterns of differentially expressed genes were identified for several subtypes of ASD in comparison to that of controls. Each expression profile suggested subgroup-dependent differences in biological pathways and functions that could be exploited for targeted therapies or for diagnosis. Enriched functions included a set of circadian rhythm-associated genes, such as AA-NAT, the rate-limiting enzyme in melatonin biosynthesis. Combined quantitative trait and case-control association analyses in which cases were divided by subphenotypes identified Bonferroni-significant SNPs that clearly distinguished cases from controls, while linkage analyses revealed subgroup-dependent genetic loci that were capable of unmasking genetic heterogeneity at both inter- and intra-family levels, with the highest subgroup-dependent LOD scores exceeding 4.0.

Conclusions: Large-scale omics and genetic analyses of ASD are greatly enhanced by reducing the heterogeneity of the cases included within the study. Heterogeneity reduction is critical for identifying subgroup-specific deficits (e.g., melatonin deficiency) for targeted therapies, thus advancing precision medicine.

172

146.172 The Sociomateriality of Parent-Reported and Observation-Based Screening Tools for Autism Spectrum Disorders (ASD): A Sociological Investigation of Community-Based ASD Screening to Address Health Disparities

***T. Mackie**[1], L. Ramella[2], A. Cotroneo[3], A. Eisenhower[4], A. S. Carter[5], F. Martinez-Pedraza[6,7] and R. C. Sheldrick[8], (1)Institute for Health, Health Care Policy and Aging Research, School of Public Health, Rutgers Univer, New Brunswick, NJ, (2)Tufts Medical Center / Boston University, Boston, MA, (3)Department of Health Systems and Policy, Rutgers School of Public Health, New Brunswick, NJ, (4)Psychology, University of Massachusetts Boston, Boston, MA, (5)University of Massachusetts Boston, Boston, MA, (6)Florida International University, Miami, FL, (7)Psychology, Florida International University, Miami, FL, (8)Boston University School of Public Health, Boston, MA*

Background:

Challenges to ensuring the early identification of Autism Spectrum Disorders (ASD) among toddlers from racially and ethnically diverse backgrounds is well-documented. These challenges are related to population characteristics (e.g., limited access to ASD-specific knowledge, disability stigma, linguistic barriers for non-native English speakers, lack of institutional trust, and competing social needs) and the respective service delivery systems (e.g., inadequate cultural competency, provider non-compliance with professional guidance and challenges in diagnostic ascertainment). In this study, we investigate how the implementation of parent-reported and observation-based screening tools may address or amplify these challenges in the clinical encounter for families from historically underserved communities.

Applying a sociological lens, we examine the reflexive relationship between these technologies (i.e., the screening tools) and the social contexts in which they are introduced (i.e., 'socio-materiality of technology'). Our approach recognizes a situated ecology of use (or in some cases, non-use), consisting of various actors, practices, and their relationships. As Timmermans (1998) argues, the "potential and power of a technological device to shape an interaction is not pre-given but is realized in practice." We provide an in-depth and multi-method examination of screening tools when "realized in practice" and the ways within which these technologies potentially mitigate, reproduce, or propagate new challenges confronting diverse families across the ASD diagnostic process.

Objectives:

Examining implementation of parent-reported tools (BITSEA, POSI) and observation-based screening tools (STAT), this paper investigates the different ways within which parent-reported and observation-based screening tools restructure the clinical encounter and the tools themselves are simultaneously adapted.

Methods:

Our multi-method approach employs longitudinal interviews with caregivers of children with ASD (n=21), semi-structured cross-sectional interviews with Early Intervention providers (n=20), and observations of the screening tools with toddlers and families (n=12). We analyze transcripts and field notes using a modified grounded theory approach known as "Coding Consensus, Co-occurrence, and Comparison," in which analyses are derived from the data (based on *a priori* and emergent themes) and then illustrated by characteristic examples.

Results:

Our findings suggest that characteristics of the respective screening tools were influential both in reconfiguration of the clinical encounter and in how the providers and families adapt the tools. Administration of the parent-reported screening tools led providers and families to adapt the tools in a number of ways not seen in implementation of the observation-based screening tool. For parent-reported screening tools, providers adapted administration and content of the tools as strategies to address challenges regarding the caregiver's (1) ability to "see" and therefore report on the indicated behaviors of concern, (2) limited access to ASD-specific knowledge, (3) readiness for discussions of ASD, and (4) linguistic barriers. In contrast, adaptation to protocol in administration of the observation-based protocol primarily reflected family readiness but other challenges were rarely or not at all discussed or observed.

Conclusions:

Our study finds evidence of a reflexive relationship between ASD screening tools and the context in which they occur; this relationship occurred differently for parent-reported and observation based tools suggesting different types of tools may mitigate or reproduce well-documented challenges in addressing ASD disparities.

173 **146.173** Using a Patient Centered Outcomes Research Institute (PCORI) Approach to Engage Key Stakeholders on the Topic of Transitioning to Adulthood in Autism Spectrum Disorders (ASD)

***S. N. Brasher**, Nursing, Emory University, Atlanta, GA*

Background: There has been a significant increase in the incidence and prevalence of autism spectrum disorder (ASD) in recent years with current estimates of 1 in 68 children diagnosed with ASD and 3.5 million Americans living with ASD (CDC, 2017), including individuals with ASD transitioning from childhood to adulthood. Symptoms of ASD (e.g., impairments in social interaction, communication, repetitive behaviors) emerge in early childhood and span across adulthood. Considering ASD presents in early childhood, educating medical providers has largely focused on Pediatrics as opposed to Adult Internal Medicine. Thus, a growing concern on the forefront of everyone's mind is 'what next?' as these children transition to adults and parents, as well as providers, are no longer able to care for them

Objectives: The overarching aim of this Patient Centered Outcomes Research Institute (PCORI) award is to form equitable partnerships with key stakeholders to gain meaningful insight into issues encountered during transitioning to adulthood in ASD. This, in turn, will lead to the development of a comparative effectiveness research (CER) study on transition to adulthood in ASD.

Methods: Stakeholders were divided into four groups: two groups of young adults with ASD of varying degrees of severity, one group of caregivers of adults with ASD, and an Autism Advisory Board (AAB) comprised of diverse professionals and stakeholders. The AAB provided oversight on how to engage stakeholders and ways to formulate CER questions based on the stakeholder identified topics. Stakeholders engaged in monthly meetings and bi-annual united stakeholder group meetings to identify gaps in research, care, and services for individuals with ASD transitioning to adulthood.

Results: This newly funded PCORI Tier A award is the first step in PCORI's tiered Pipeline to PCORI. Expected results include gaining insight into the issues encountered during transitioning to adulthood that will enable the development of future research questions meaningful to this population. Given this health issue is not limited to any one area of the country (e.g., rural, urban, state), connections and outcomes have the potential to expand and influence nationally and internationally.

Conclusions: Historically, treatment and services in ASD have been targeted towards early childhood to promote developmental trajectories. While this is important, there is a need to shift interventions and services as the individual transitions from childhood into adulthood in order to account for their growing needs. Recent studies suggest that medical providers are not adequately trained or prepared to care for individuals with ASD transitioning to adulthood. As a result, families often report struggling to navigate this period between childhood and adulthood. Thus, the use of a PCORI approach to engage key stakeholders is an optimal method to gain insight into issues encountered by individuals with ASD and their families in order to build towards future research responsive to the needs of stakeholders.

174 **146.174** "the Doctor Said 'Google It' ...": Exploring African-American Caregiver's Help-Seeking for Their Child with Autism

***T. Benevides**[1], P. Kearney[2], E. DeGrace[3], M. So[4] and B. Kelly[4], (1)Augusta University, Martinez, GA, (2)Augusta University, Augusta, GA, (3)University of Oklahoma, Oklahoma City, OK, (4)Independent Investigator, Atlanta, GA*

Background: A large body of literature suggests that differences exist in service access for racial and ethnic minorities with autism spectrum disorder (ASD)[1] which are not accounted for by actual differences in need for services. Additional studies identify that parental beliefs, knowledge, and expectations may influence help-seeking among African-American (AA) caregivers. Understanding the reasons for differences in care from the perspective of AA caregivers is necessary prior to developing effective solutions to address differences in service access.
Objectives: The purpose of this study was to qualitatively identify AA caregiver beliefs, knowledge, and expectations that impact help-seeking, and the specific help-seeking steps caregivers used to obtain care for their children with ASD.

Methods: We used grounded theory methodology[2] with semi-structured interviews to ascertain how and why AA caregivers sought and obtained services from the time prior to diagnosis to the present. Beliefs and knowledge were probed, as were both formal and informal help-seeking. Purposive and snowball sampling was used to obtain a sample of caregivers of children with ASD. Inclusion criteria required caregivers to be self-identified AA adults with a primary caregiver role (>50% time spent caring for child) of a child with autism. A child's autism classification was identified by the investigator in either a medical or educational report provided by the caregiver. Additional sources of data included field notes and a follow up focus group to engage caregivers in member-checking discussion. Qualitative analysis occurred during the course of data collection and involved hand coding for beliefs, knowledge, and expectations reported during help-seeking actions. MaxQDA software was used to organize coding schemes.

Results: Demographic caregiver characteristics are presented (Table 1). Preliminary themes from the analysis include: "Just don't know/just didn't know..." (importance of knowledge in taking action); "[the doctor] told me to Google it" (impact of 'trusting' in providers on help seeking); the reliance on 'mother intuition' about their child which influenced help seeking; and the importance of others during the process ("they actually know what you go through"). Caregiver's knowledge acquisition was obtained primarily through lay and internet "network of others"; in contrast, caregivers reported asking for information from medical and education providers and not receiving the desired guidance.

Conclusions: Despite extensive literature discussing racial and ethnic disparities in access to services, little progress has been made to address culturally-relevant approaches to meet AA caregiver's needs for service and supports. Although findings are not widely generalizable due the qualitative nature of this study conducted in single southern U.S. state, important lessons for future research and provision of services include: helping parents connect with other parents is essential; the provision of resources regarding decision-making needs to be balanced by parent's reliance on 'intuition' about providers and services; and future work to improve help-seeking and reducing disparities should involve caregivers in all aspects of planning and implementation to identify preferred methods for receiving information. System interventions indicated include: provider training to facilitate care pathways, easily searchable and readable community level resources, & increasing parent advocacy skills.

175 **146.175** Autism Diagnosis Stories: What Latino Parents and Caregivers Know and Believe

L. I. Florindez[1] *and D. C. Florindez*[2]*, (1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)University of Southern California, Los Angeles, CA*

Background:
Of the 1 in 68 children diagnosed with autism spectrum disorders (ASD) in the United States (CDC, 2014), the prevalence varies significantly across racial and ethnic groups. Documented disparities exist regarding autism diagnosis for Latino children. When compared to White children, previous research has shown that Latino children are diagnosed at a later age (Mandell, Listerud, Levy, & Pinto-Martin, 2002), are less likely to be diagnosed even when meeting autism criteria (Mandell et al., 2009), and more likely to be misdiagnosed (Mandell, Ittenbach, Levy, & Pinto-Martin, 2007). Given these issues surrounding accurately diagnosing Latino children with ASD, it is necessary to explore what Latino parents, caregivers, and community members understand about ASD diagnosis.

Objectives:

The purpose of this study is to investigate what 18 Latino families know and believe about diagnosing autism, and the psychosocial, familial, medical, and cultural factors that inform their health beliefs.

Methods:

Narrative interviews with 18 Latino families (8 families with a typically developing child aged 6-12 and 10 families with a child with ASD aged 6-12) were conducted to identify the factors that impact their in-home oral care routines, including how the presence of ASD may alter their habits. Family units consisted of at minimum, the primary caregiver, and included other family members who provided care for the enrolled child. Each family was interviewed twice in their native language (Spanish or English) for approximately 1-2.5 hours each session. As a secondary line of questioning, families were probed to discuss their perceptions of ASD. Interviews were transcribed verbatim and thematically analyzed by 3 coders.

Results:

Five themes pertaining to where parents obtained their knowledge and details about their beliefs about ASD diagnosis were identified. The first, *Misconceptions,* explained the various fallacies perpetuated about ASD, including that their child is "broken" or cursed. The second theme, *Parents as students and teachers,* described how parents had to learn about their child's diagnosis to then be able to educate others and act as their child's sole advocate. Next, *Role of Family* was related to the influence of family members on sharing information and opinions, including the reluctance in some extended families to acknowledge that a child has ASD. Following, *Outside influence* clarified the information provided by non-family members, including health care providers, community members, or social network connections. The last theme, *Cultural Stigma,* focused on information that originated from the family's cultural background, including religious and folk tales, situating the ASD diagnosis within Latino culture.

Conclusions:

Researching how Latino parents, caregivers, and community members perceive Autism diagnosis will help illuminate how health information is communicated within this at-risk population, and inform the development of future targeted education and intervention programs.

176 **146.176** Raising a Child with Autism in India: Journey of Parents' over Decades

D. Taneja[1]*, N. Singhal*[1]*, T. Behl*[1]*,* ***R. Pradhan***[1]*, M. Barua*[1]*, T. Daley*[2] *and T. S. Weisner*[3]*, (1)Action For Autism, New Delhi, India, (2)Westat, Durham, NC, (3)UCLA, Los Angeles, CA*

Background: The lifelong nature of autism brings in a plethora of new experiences for the parents, making parenting a child with autism a challenging experience. How do parents usually experience while parenting a child with autism in India? What insights do they gain over the years? What would be their advice to parents of children who are now receiving a diagnosis? While they have been a parent for almost two decades or more, what do they think is happening for families receiving a diagnosis now? What government policies are required? This first study on adults with autism in India answers many such questions from the perspectives of parents of adults with autism.
Objectives: The present paper seeks to gain insight into parent's perspective on raising a child with autism.

Methods: 52 families (54 adults) living in New Delhi and NCR were interviewed in their homes. The home visits lasted for 2.5 – 5 hours. Using a range of instruments including semi structured interviews, standardized questionnaires, and home observations, parents responded to a variety of topics related to their experience of raising a child with autism and their needs.

Results: Parents spoke about the different actions that parents can take themselves; the different parenting approaches that may be used as well the key systemic changes required in low and middle income countries with limited resources such as India.

Conclusions: This is one of the first studies that informs practice and policies in India by highlighting parent's perspectives of key needs of the families of autistic individuals. The study has significant implications in generation of additional and improvement of existing services and provides valuable information to parents, particularly those of children newly diagnosed with ASD.

This study highlights the need and directions for new and improved services to cater to the needs of individuals with autism.

177 **146.177** The Role of Family Rituals and Routines: A Resilience Perspective of Mealtimes and ASD

S. L. Curtiss*, Michigan State University, East Lansing, MI*

Background: The shared meal is an iconic family ritual that provides significant benefits to families and its' members. Mealtimes serve as a context for development, rich with experiences and interactions, that can promote child well-being. For example, direct and clear communication, flexible adherence to carrying out a meal, and the repetition of roles are characteristics of mealtimes that have been linked to positive child outcomes (Fiese, Foley, & Spagnola, 2006). More frequent shared family meals are related to literacy development (Snow & Beals, 2006), healthy eating habits (Larson, et al., 2007), positive values, social competencies, and supportiveness (Fulkerson, et al., 2006). Unfortunately, general research on family mealtimes precludes children with autism so much is still unknown about the impact of the shared family meal for children with autism and their families. The research that has examined the connection between autism and mealtimes has focused on challenges and deficits, not on mealtimes as naturally occurring family processes and sources of resilience.
Objectives: For autistic families, who are more often viewed in terms of their deficits, research is needed to resituate family meals as a place where some foster resilience, without ignoring the real challenges and struggles faced in everyday family life. The goal of this study was to explore the role of mealtime rituals and routines in family life.

Methods: This is a grounded theory (Strauss & Corbin, 2008) study of 16 family mealtimes. The families varied in terms of ethnicity, socioeconomic status, community, and family structure. For each family, a mealtime was video recorded and one parent (all mothers) was interviewed about their family's meals. The observations and interviews were interpretatively coded.

Results: Mealtimes reflect and reinforce family functioning (Figure 1). The affective components of the meal were critical for mealtimes to be a place where sharing and problem solving could happen. Affective climate and bond were achieved through a dialectic of acceptance and control. Parents used controlling behavior during the meal to support their children with being successful with the tasks related to the meal. Parents also showed acceptance in terms of how they created expectations and communicated those expectations. Navigating the dialectic of control and acceptance, being at peace with the tension, and having some degree of balance were necessary to achieve the affective and symbolic elements of the meal. Family functioning was also reflected in communication, expectations, and the quality of interactions. There were times, however, when families simply did not have access to the resources necessary to support their children and, in those cases, adaptive family functioning was difficult to achieve.

Conclusions: This research provides a grounded understanding of how families use mealtimes to promote connection and facilitate problem solving. It can be used to suggest ways in which families can be supported. Warmth, acceptance, balance, and appropriate expectations were critical for family meals to foster resilience.

178 **146.178** Transitioning Pediatric Patients with Autism Spectrum Disorders to Adult Care

M. L. Massolo[1]*, M. N. Davignon*[2]*, Y. Qian*[1]*, A. E. Richards*[3] *and L. A. Croen*[1]*, (1)Division of Research, Kaiser Permanente, Oakland, CA, (2)Pediatric Specialties, Kaiser Roseville Medical Center, Roseville, CA, (3)Kaiser Permanente Division of Research, Oakland, CA*

Background: Children with Autism Spectrum Disorders (ASD) have a variety of medical and psychiatric co-morbidities, and increased use of health care services. As they become adults, their medical needs continue. The transition from pediatric to adult medicine can be challenging for patients with ASD, caregivers and health care providers. We conducted a study to determine barriers and facilitators of a smooth transition from pediatric to adult care for patients with ASD, and to inform the development of tools to support a smooth transition.
Objectives: To identify factors that influence the transition from pediatric to adult healthcare.

Methods: We conducted interviews (N=32) with patients, parents and clinical providers of transition age youth and young adults with ASD receiving health services at Kaiser Permanente (KP). We used a non-probabilistic purposive sampling approach to capture the range of ages (pre and post transition to adult care), sex and race/ethnic groups among patients. The provider group included KP adult and family providers and pediatricians. Three interviewers trained in qualitative methods developed guides and conducted all interviews. Areas explored in the interviews with patients and parents included communication with providers, accommodations (if any), experiences during appointments in pediatric and in adult care including registration, waiting room and interactions with medical assistants. In addition, we explored preparation, tools and resources for the transition. Questions to providers about their experiences transitioning patients with ASD completed the picture. Interviews, completed by telephone, ranged from 30 minutes to 1 hour.

Results: Many patients and parents expressed confusion and difficulty navigating a complex healthcare system. Obstacles to a smooth transition included gaps in care coordination and late or no preparation of the patient for the transition, lack of knowledge about ASD among adult care providers. Immigrant families encountered additional obstacles including language, cultural, and literacy barriers, and lack of culturally competent support. Many KP providers echoed the patients' and parents' frustration with the lack of patient preparation for transition, lack of resources and tools, and difficulties managing young adult patients with ASD. Possible solutions suggested by patients, parents, and KP clinicians included improved education and training for adult providers, active case management, improved care coordination, and tools to help patients move towards independence in terms of their healthcare.

Conclusions: The interviews provided insights about the experiences of a diverse group of ASD patients receiving healthcare at Kaiser Permanente. Many barriers were experienced by patients, their families and providers. Overcoming them is necessary in order to ensure a smooth transition and optimal care for this growing population of young adults.

179 **146.179** Trajectories of Maternal Depressive Symptoms Following ASD Diagnosis

A. Zaidman-Zait[1]*, P. Mirenda*[2]*, P. Szatmari*[3]*, I. M. Smith*[4]*, J. Volden*[5]*, L. Zwaigenbaum*[5]*, T. Bennett*[6]*, T. Vaillancourt*[7]*, C. Waddell*[8]*, S. Georgiades*[9]*, E. Duku*[9] *and M. Elsabbagh*[10]*, (1)Tel-Aviv University, Tel-Aviv, Israel, (2)University of British Columbia, Vancouver, BC, Canada, (3)Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (5)University of Alberta, Edmonton, AB, Canada, (6)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (7)University of Ottawa, Ottawa, ON, Canada, (8)Simon Fraser University, Vancouver, BC, Canada, (9)McMaster University, Hamilton, ON, Canada, (10)McGill University, Montreal, PQ, Canada*

Background: Given the numerous challenges and demands involved in raising a child with ASD, mothers of these children are at an increased risk for elevated levels of depressive symptoms (Estes et al., 2009; Montes & Halterman, 2007). Such symptoms are concerning, as they are detrimental to mothers' long-term health (Vos et al., 2012) and are a robust correlate of children's maladjustment (Goodman et al., 2011). In addition, children with ASD may be particularly vulnerable to maternal depression because they require more sensitive and supportive parenting, which might be compromised in mothers with depression. Thus, understanding maternal depressive symptoms and their predictors following ASD diagnosis is highly important. Several studies have highlighted heterogeneity in the way individuals respond to stressful experiences, such that some people experience ongoing, high levels of distress; some experience distress that gradually declines; and others experience little or no distress (e.g., Bonanno et al., 2012). Yet, there is lack of knowledge about longitudinal trajectories of depressive symptoms among mothers of children with ASD.
Objectives: The purpose of this study was two-fold: 1) to investigate longitudinal depressive symptom trajectories among mothers following children's ASD diagnosis, using Latent Growth Mixture Modelling (LGMM); and 2) to examine correlates of depressive symptom trajectories, including children's autism symptom severity, behavior problems, and mothers' coping resources.

Methods: Data were drawn from the Canadian Pathways in ASD study and included 247 children with ASD and their mothers. Mothers' depressive symptoms were assessed at four time points between ASD diagnosis (T1; children's mean age was 39.02 months, SD=8.7) and when the children were between 7 and 8 years old (T4).

Measures: Maternal depressive symptoms were assessed with the Symptom Checklist-90-R (Derogatis, 1994). To assess coping resources, we used the Ways of Coping Scales (Folkman & Lazarus, 1988) and the Social Support Survey (NLSCY, 2008-2009). Children's behavior problems were measured with the Child Behavior Checklist (Achenbach & Rescorla, 2001). In addition, to assess autism symptom severity, we used the Social Responsiveness Scale (SRS; Constantino & Gruber, 2005) and the severity metric of the Autism Diagnosis Observation Schedules (ADOS; Lord et al., 2000).

Analysis: LGMM was employed to examine trajectories of depressive symptoms using LatentGold software. Predictors of membership of the identified trajectories (classes) were examined using a multinomial logit model.

Results: LGMM identified four discrete latent trajectory classes of depressive symptoms, including: No impact (no depressive symptoms across time; 33%), Minimal impact (low depressive symptoms across time; 36%), Moderate - Improved (medium depressive symptoms that decreased slightly across time, 25%), and High - Worsen (high symptoms that increased over time; 6%). Overall, trajectories were mostly stable across time (see Figure 1). Children's externalizing behavior, mothers' social support, and mothers' utilization of coping strategies predicted membership in depressive symptom trajectories. Autism symptom severity and internalizing behavior problems were not significant predictors.

Conclusions: Trajectories of depression symptoms are heterogeneous and are relatively stable in mothers of children with ASD. Findings emphasize the importance of screening for mothers' well-being, making coping resources available, and early treatment addressing children's behavior problems.

180 **146.180** A Biofeedback-Based Embodied Awareness Intervention for Adults with ASD: Feasibility of a Community-Based Treatment

R. S. Brezis[1]*, A. Levin*[2]*, Y. Oded*[3]*, O. Zahavi*[4]*, G. Gampel*[5] *and N. Levit-Binnun*[2]*, (1)Kanfei Nesharim St. P.O.Box 167, Interdisciplinary Center, Herzliya, Israel, (2)Interdisciplinary Center, Herzliya, Israel, (3)Center for CBT-BF, Tel Aviv, Israel, (4)Beit-Ekstein Organization, Kerem Maharal, Israel, (5)Private Psychotherapy Practice, Tel Aviv, Israel*

Background: As the number of adults living with ASD continues to grow, a lack of resources and lack of available interventions exacerbate their low quality of life, including low levels of education and employment, and high levels of co-morbid anxiety and depression. Here we build upon existing research showing the effectiveness of mindfulness-based interventions on individuals with ASD, to provide a low-cost biofeedback-enhanced training which can be implemented by non-professional staff, and may help autistic individuals grasp abstract contemplative techniques. We hypothesize that the intervention will decrease participants' anxiety and autism symptoms, and increase their self-awareness, self-determination, and empathy.
Objectives: (a) To determine whether a biofeedback-based embodied awareness intervention is feasible in a community setting and whether adults with ASD can improve in levels of physiological regulation; **(b)** to determine whether the intervention decreases participants' anxiety and autism symptoms, and increases their self-awareness, self-determination, and empathy; and **(c)** to determine whether improvements in

physiological regulation are related to psychological measures.

Methods: Fourteen adults with ASD, residing in assisted living, were provided with 16 weekly half-hour biofeedback-based embodied awareness sessions with non-professional trainers, in which they learned to reduce their arousal levels through combined biofeedback and embodied awareness techniques, and apply those to everyday life. Quantitative and qualitative data was collected pre- and post-intervention. Physiological measures included changes in Heart Rate (HR), and HRV coherence (i.e., Low Frequencies (0.04 to 0.15 Hz)/All Frequencies). Psychological measures examined self-awareness (Toronto Alexithymia Scale; TAS), self-determination (ARC), anxiety (Glasgow Anxiety Scale; GAS), autism symptoms (Social Responsiveness Scale; SRS), and empathy (Reading the Mind in the Eyes Test; RMET).

Results: Participants were capable of successfully improving their physiological arousal levels on the biofeedback setup and we found initial indications for gains in all hypothesized domains on the quantitative measures.

Participants' HR decreased through the time of the intervention by an average of 8.38bpm ($t(12)=2.86$, $p=.014$). At the same time, their HRV coherence increased, on average, during each session ($M=6.92$, $SD=8.3$), both measures indicating greater relaxation.

Participants showed a trend towards a reduction in ASD symptoms (SRS Self- and Caregiver report), a decrease in anxiety (GAS), an increase in self-determination (ARC), an increase in adaptive behaviors to challenging situations, and an increase in empathy (RMET); though these differences did not meet statistical significance. They did not show a decrease in alexithymia (TAS).

We further found a correlation between a decrease in anxiety symptoms (GAS pre-post) and the rate of increase in HRV coherence ($rho=-.694$, $p=.008$), suggesting that as participants gained control of their HRV, anxiety levels decreased.

Qualitative reports by participants and counselors revealed that participants applied the techniques in many real-life situations, and these had far-ranging effects on their emotional regulation, work and social motivation, and self determination.

Conclusions: The study provides proof-of-concept for a low-cost, community-based intervention which can ameliorate the lives of adults with ASD. Future studies should continue to examine the impacts of biofeedback-based embodied awareness interventions at various levels of intensity, and across different sub-populations of the autism spectrum.

181 **146.181** A Community-Based Randomized-Controlled Trial of High- and Low-Tech AAC Approaches

S. P. Gilroy[1], *J. McCleery*[2] *and G. Leader*[3], *(1)National University of Ireland, Galway, Galway, Ireland, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)National University of Ireland, Galway, Ireland*

Background: Methods for teaching individuals with autism spectrum disorders (ASD) to engage in social and communicative behavior have traditionally employed low-tech approaches. Among these, the Picture Exchange Communication System (PECS) has extensive support as an approach for effectively teaching these skills. New and evolving technology (i.e., tablets, applications) has resulted in cheaper and more affording forms of speech-generating devices (SGD) and these SGD are increasingly used in practice. Despite early adoption of these newer methods, there are relatively few guidelines for using these devices to teach social and communicative behavior. To date, no studies have rigorously compared the relative effectiveness of high-tech and low-tech Augmentative and Alternative Communication (AAC) with randomized assignment, and it is also unclear as to whether a particular device may be better matched to certain individuals.

Objectives: A mobile application and associated custom teaching protocol was developed and systematically compared to PECS in a community-based randomized controlled trial (RCT). The objectives of the trial were to: 1) compare the effectiveness of high-tech and low-tech AAC approaches for teaching requesting skills; 2) compare the effectiveness of high-tech and low-tech AAC approaches for teaching queried requesting skills; and, 3) compare the effectiveness of high-tech and low-tech AAC approaches for teaching queried social responding.

Methods: Thirty-five school-aged participants assigned randomly to either a high-tech or low-tech AAC group. AAC intervention was provided in the schools of participants and trained therapists provided participants with either high-tech (n = 18) or low-tech (n = 17) forms of communication training. Trial participants were assessed before and following four months of AAC intervention. This trial was developed to examine the relative effectiveness of both types of AAC intervention for teaching social and communicative behavior to individuals with ASD. A repeated measures analysis of variance was used to systematically compare improvements in the two approaches. Time was included as a within-subjects factor and Type (i.e., high-tech, low-tech) was included as a between-subjects factor.

Results: The results from repeated measures analyses of variance indicated significant effects for Time for both types of requesting, but not for general social behavior. There was no significant effect for Type in any form of communication. These results indicate that the two approaches produced substantial benefit and that the benefits of these two approaches did not differ significantly.

Conclusions: The results from this community-based RCT suggest that high-tech AAC approaches, when implemented with a comprehensive teaching protocol, can be effective for teaching social and communicative impairments to children with ASD. While these results are supportive of the use of high-tech AAC with ASD, additional study is required to confirm similar outcomes when participants have more greater levels of impairment (i.e., ASD with comorbid intellectual disability). The results of this trial highlight how open-sourced technology can be combined with clinician-driven assessments and individualized intervention.

182 **146.182** A Fundamental Motor Skill Intervention Using a Dynamic Systems Apporach

A. M. Colombo-Dougovito[1] *and M. E. Block*[2], *(1)Kinesiology, Health Promotion, & Recreation, University of North Texas, Denton, TX, (2)University of Virginia, Charlottesville, VA*

Background: Autism spectrum disorder (ASD) is a complex neuro-developmental disorder characterized by deficits in social communication and pervasive repetitive behaviors (American Psychiatric Association, 2013). In addition to the hallmark characterizations of this condition is a growing body of research (Lloyd, MacDonald, & Lord, 2013; Liu, Hamilton, Davis, ElGarhy, 2014; Staples & Reid, 2010) that suggests that individuals with ASD also demonstrate delays in the development of gross motor skills. Despite mounting evidence of delay, few interventions have targeted gross motor skills as an outcome (Staples, MacDonald, Zimmer, 2012). Three recent studies (Bremer, Crozier, & Lloyd, 2016; Bremer & Lloyd, 2014; Ketcheson, Hauck, & Ulrich, 2016) demonstrate the increasing awareness of this issue; however, continued theory-based research is needed to build an effective motor intervention for children with ASD.

Objectives: The purpose of this parallel, convergent mixed methods design study was to test the validity and effectiveness of a fundamental motor skill (FMS) intervention for children with ASD that uses dynamic systems theory (DST; Newell, 1986). The intervention was based on intentional manipulations of task constraints—hereafter referred to as task modifications—to build FMS. This presentation will focus on the quantitative results, which focus on the fundamental motor intervention.

Methods: A purposive sample of 5 children (4 boys, 1 girl; Mage=7.92, SD=1.09) with ASD—in addition to two comparison (one age-matched and one developmentally-match) groups of children without ASD—completed a 6-week fundamental motor intervention with a retention assessment at 4 weeks post-intervention. Participants were provided instruction on one locomotor and one manipulative skill, based on pre-assessment of the Test of Gross Motor Development, 3rd ed. A repeated-measures ANOVA was done to analyze data collected during the intervention.

Results: Overall, a significant difference was found in motor scores across time, *F*(1.65,19.76) = 874.09, *p* < .001, partial n2 = .99, and between groups across time, *F*(1.65,19.76) = 874.09, *p* < .001, partial n2 = .99. A post hoc Tukey's pairwise comparison using a Bonferonni procedure was done to evaluate group differences. Significant differences were found between the ASD group and the developmental-match (*p* = .004) and age-match (*p* < .001) groups. Dependent *t*-tests using only data from the ASD group to understand how changes occurred over time found a significant increase between the pre- and post-assessments, *t*(4) = 4.98, *p* = .008, a significant decrease between the post- and retention assessments, *t*(4) = 4.52, *p* = .011, and a nonsignificant result between pre- and retention assessments, *t*(4) = 1.94, *p* = .124 (See Figure 1)

Conclusions: Data revealed that a motor intervention based on DST may: (a) significantly improve gross motor performance of children; (b) provide an effective means to build motor skills in children with ASD; and (c) allow for a high level of engagement and successful practice. Further, evidence reaffirms previous suggestions of significant motor delays in children with ASD and provides evidence that children with ASD may learn motor skills at rates closer to peers half their chronological age.

183 **146.183** A Randomised Feasibility Trial of a Low Intensity Intervention for Depression in Adults with Autism: The Autism Depression Trial (ADEPT)

A. Russell[1], *S. Barton*[2], *K. Cooper*[3], *I. Ensum*[4], *D. Gaunt*[5], *J. Horwood*[5], *B. Ingham*[6], *D. Kessler*[5], *C. Metcalfe*[5], *J. R. Parr*[7], *D. Rai*[8] *and N. Wiles*[5], *(1)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)Newcastle University, Newcastle, United Kingdom, (3)University of Bath, Bath, United Kingdom, (4)BASS, Avon and Wiltshire Mental Health Partnership NHS Trust, Bristol, United Kingdom, (5)University of Bristol, Bristol, United Kingdom, (6)Northumberland Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (7)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (8)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom*

Background:

High rates of co-occurring depression have been reported in Autism. Clinical guidelines recommend 'low intensity' psychological treatment based on cognitive behaviour therapy (CBT) as an effective treatment for mild-moderate depression. If adapted, CBT has been found to be effective in treating anxiety problems in children and adults with Autism if adapted. There has been less research into the usefulness of CBT as a treatment for co-occurring depression in Autism; several studies of group CBT showing mixed findings and no randomised controlled trials of individual, low-intensity CBT. There is a need to consider the feasibility of low intensity CBT for depression adapted for adults with Autism before investigating the effectiveness and efficacy of the intervention.

Objectives:

As part of a commissioned call by the NIHR HTA, this was a feasibility study for a large-scale Randomised Controlled Trial (RCT) that would determine the clinical and cost-effectiveness of a low intensity intervention for co-occurring depression in adults with autism.

Methods:

The feasibility study comprises a randomised controlled trial (RCT) and nested qualitative evaluation in preparation for a future definitive RCT. Participants are adults with Autism (n=70), aged 18 years or over with a PHQ-9 score ≥ 10, randomised to Guided Self-Help (GSH): a low intensity psychological intervention based on Behavioural Activation adapted for ASD or Treatment as Usual (TAU). Outcome measurement at 10, 16 and 24 weeks post randomisation is blind to group allocation for those measures that are not self-administered. Measures include standardised measures of depression symptoms, anxiety, social function, and service use. The analysis will aim to establish the rates of recruitment and retention for a larger scale RCT as well as the most appropriate measure of depression to serve as primary outcome.

Results:

At the time of writing, 70 eligible participants had been recruited and randomised; 35 were allocated to Treatment as Usual (TAU) and 35 to Guided Self-Help (GSH), across the two trial sites. The average PHQ-9 score at baseline was 16, indicating a severe level of depression. 23 of the 35 participants allocated to GSH had completed their treatment, which is 92% of those who had reached their ten week follow-up. At 10 week follow-up, 43 participants had completed outcome measures. At 16 week follow-up, 34 had completed outcome measures. At 24 week follow-up, 23 participants had completed measures. There had been four adverse events, none related to trial participation. One participant in the GSH arm had withdrawn, and seven in the TAU arm had withdrawn, with an additional TAU participant lost to follow-up.

Conclusions:

There is a need for evidence based psychological interventions in people with autism and co-occurring depression. This feasibility study considers if it is possible to conduct an effectiveness study of a newly developed, low intensity intervention for depression based on the principles of CBT for autistic adults.

184 **146.184** A Randomized Controlled Trial of the Korean Version of the Program for the Education and Enrichment of Relational Skills for Young Adults (PEERS®-YA-K) for Adults with Autism Spectrum Disorder

M. Oh[1], *J. Kim*[2], *K. Lee*[3], *J. Kim*[4], *S. Lee*[5], *G. Bong*[6], *S. Cha*[7], *I. H. Cho*[8], *H. J. Yoo*[9], *Y. S. Lee*[10], *M. S. Kim*[11], *D. W. Han*[12] *and C. Y. Shin*[13], *(1)Psychiatry, Seoul National University Bundang Hospital, Sungnam, Korea, The Republic of, (2)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, Republic of (South), (3)Special Education, Dankook University, Yongin, Korea, Republic of (South), (4)Seoul National University center for campus life and culture, Seoul, Korea, Republic of (South), (5)University College London, London, United Kingdom, (6)Psychiatry, Seoul National University Bundang Hospital, Seungnam, Korea, Republic of (South), (7)Smiletogether Foundation, Seongnam, Korea, Republic of (South), (8)Dr. Cho's Child & Adolescent Psychiatric Clinic, Seongnam, Korea, Republic of (South), (9)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, The Republic of, (10)Department of Physiology, Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea,* *Republic of (South), (11)Department Applied Chemistry, Kyung Hee University, Seoul, Korea, Republic of (South), (12)Dept. of Stem Cell Biology, School of Medicine, Konkuk University, Seoul, Korea, Republic of (South), (13)Department of Neuroscience, School of Medicine, Konkuk University, Seoul, Korea, Republic of (South)*

Background: The evidence-based social skills intervention for young adults are limited, though social difficulties in autism spectrum disorder (ASD) persist after transition to adulthood. Program for the Education and Enrichment of Relational Skills for Young Adults (PEERS®-YA-K) is one of the evidence-based interventions effective in improving relational skills for young adults with ASD.

Objectives: The objectives of this study are, 1) examining feasibility of the PEERS-YA® through cross-cultural modification for Korean language and culture, and 2) validation of the Korean version (PEERS-YA®-K) using a randomized controlled trial (RCT) design, for efficacy in improving social skills of young adults with ASD.

Methods: 1) Cultural adaptation: The original version of the PEERS-YA® treatment manual was translated. Focus group interview was performed for 29 typical adults recruited from advertisement in the community. We asked 33 questions regarding dating etiquettes of young adults and 14 questions about social groups/activities and bullying. The interview questions consist of “whether the contents of the manual are different in Korea”, and “how to modify the differences if we implement it.” We modified the didactic lessons and role play scripts into more culturally sensitive and linguistically appropriate way. 2) Young adults diagnosed with ASD (18~35 years of age, IQ>70) and their social coaches were recruited for RCT. The subjects were randomly assigned to a treatment group (TG, n=19) or waitlist control group (CG, n=19). Primary outcome measures included questionnaires and direct observations quantifying social ability and problems directly related to ASD. Secondary outcome measures included scales for depressive symptoms, anxiety, and other behavioral problems. The effects of the intervention were analyzed by paired samples *t*-test and repeated measures ANOVA.

Results: 1) Based on focused group interview, several etiquettes for dating have been modified, including rules for follow up call and “blind dating”, examples of appropriate/inappropriate places for dating, conventions for compliments and controversies about online dating. Culturally unique characteristics of romantic relationship are added, and examples of social groups/activities were also modified. 2) Thirty eight young adults (age 23.50±3.89, IQ 99.34±15.01, all male) were participated in RCT. Attrition rate was 10.5% (4 subjects) due to diminishing motivation of the adults, social anxiety and major depressive episode). After the 16 weeks of treatment, participants showed significant improvement in social skills knowledge measured by Test of Adolescent Social Skills Knowledge Recised (TYASSK-R, t=-6.14, $p < 0.01$), decreased anxiety symptoms on Beck Anxiety Inventory (t=2.19, $p < 0.05$), and maladaptive behavior on Asperger Syndrome Diagnostic Scale (t=2.41, $p < 0.05$), ‘Offers Information’ item in language and communication domain score on the Autism Diagnostic Observation Schedule (ADOS, t=3.46, $p < 0.05$). When we compared TG and CG, TG showed significant difference in TYASSK-R (F=24.69, $p < 0.01$) and state and trait anxiety (F=5.78, $p < 0.05$).

Conclusions: After modest cultural adaptation focusing on dating sessions and social activities, implementation of PEERS®-YA-K was feasible to Korean community. We observed improvement in social knowledge and skills, as well as decrease in anxiety in the participants of PEERS®-YA-K.

185 **146.185** A Randomized Waitlist Controlled Trial of Cognitive Behavior Therapy to Improve Emotion Regulation in Children with Autism

J. A. Weiss[1], *K. M. Thomson*[2], *P. Burnham Riosa*[3], *C. S. Albaum*[1], *V. Chan (Ting)*[1], *A. L. Maughan*[1], *P. Tablon Modica*[1] *and K. R. Black*[1], *(1)Psychology, York University, Toronto, ON, Canada, (2)Applied Disability Studies, Brock University, St. Catharines, ON, Canada, (3)Brock University, St. Catharines, ON, Canada*

Background: Mental health problems are common among individuals with autism spectrum disorder (ASD), and difficulties with emotion regulation processes may underlie these issues. Cognitive behavior therapy (CBT) is considered an efficacious treatment for anxiety in children with ASD specifically; however, additional research is needed to examine the efficacy of a transdiagnostic treatment approach. The intervention in question, *Secret Agent Society: Operation Regulation* (SAS:OR) is an individually provided spy-themed manualized intervention using cognitive behavioral strategies. Systematic exposures, affect education, and strategies are applied across multiple emotions with a focus on practicing adaptive emotion regulation processes. Sessions progress from teaching basic skills, such as recognizing and labeling emotions in self and others (i.e., *affect education*) to more complex skills, such as adjusting responses to difficult emotions using relaxation strategies (*response modulation*), combined with planned systematic exposure to increasingly distressing family-informed situations. A parent is involved throughout each session; they follow along in their own manual, provide support to the child and therapist, and later, help the child transfer skills to school and home environments.

Objectives: The purpose of the present study was to examine the efficacy of SAS:OR with children with ASD, using a randomized waitlist controlled trial.

Methods: Sixty-eight children (M age = 9.75, SD = 1.27) and their parents participated in the study, randomly allocated to either a treatment immediate (n = 35) or waitlist control condition (n = 33). Parent-, child-, and clinician-reported measures of emotion regulation and mental health were administered at baseline, post-intervention, and at 10-week follow-up.

Results: Treatment integrity was high (85.8%) across sessions. Overall, children demonstrated good in-session engagement and program adherence. Results from ANCOVA revealed a significant treatment effect on two primary emotion regulation outcome measures: the parent-report Lability/Negative subscale of the Emotion Regulation Checklist (p = .03), with a medium effect, and the Emotion Regulation and Social Skills Questionnaire, with a large effect. Significant medium to large treatment effects were also found on parent reports of child adaptive behavior (p = .001) and behavioral symptoms (p = .04), overall Anxiety Disorder Interview Schedule Overall Severity (p = .04), and on blind clinician judgement on the Clinical Global Impression Scale-Severity (p = .01), and -Improvement (p = .003). Treatment gains were maintained at follow-up.

Conclusions: This study is the first transdiagnostic CBT efficacy trial for children with ASD. Additional investigations are needed to further establish its relative efficacy compared to more traditional models of CBT for children with ASD and other neurodevelopmental conditions.

186 **146.186** Acting out in Public School: How a Theatre Program Can Impact Imitation Skills in Children with ASD

S. Paterson[1], *M. D. Lerner*[2], *T. R. Goldstein*[3], *T. S. Toub*[4], *R. Golinkoff*[5] *and K. Hirsh-Pasek*[6], *(1)Department of Psychology, Temple University, Philadelphia, PA, (2)Psychology, Stony Brook University, Stony Brook, NY, (3)Department of Psychology, George Mason University, Fairfax, VA, (4)Psychology, Temple University, Ambler, PA, (5)University of Delaware, Newark, DE, (6)Temple University, Ambler, PA*

Background:
Does theater arts improve social emotional skills in ASD children? A growing body of work suggests that it might, with improvement in social behavior (Lerner et al., 2011), emotional recognition (Lerner & Mikami, 2012; Mehling et al., 2016), peer interaction (Guli et al., 2013; Corbett et al., 2015), theory of mind (Corbett et al., 2013; 2016), and anxiety (Lerner et al., 2012), Notably, however, most of these studies have been done on select samples of children who have the opportunity to go to specialized programs. Few investigate the effects of programs that are available to the wider community. Further, most of these studies examine only student outcomes rather than focusing on the stakeholder's perception of the effectiveness of that curriculum. In this study, we investigate the impact of an ongoing theatre arts program in a public school, incorporating the views of stakeholders (e.g.,teachers, administrators, paraprofessionals) into our measurement of students' performance

Objectives:

To assess children's social, emotional, and motor imitation skills before and after participation in an already existing school-based theatre arts program, evaluating those aspects of functioning stakeholders involved in the program thought were important.

Methods:

76 participants (74% male), aged 8-18 years old took part in a naturalistic study of a theatre arts program in a New York City public school for children with special needs. The program lasted for 40 sessions and was part of the regular school curriculum. Parent report of autism symptoms (SRS) was assessed. In person measures of imitation included the Rogers Battery (Rogers et al.,2010), Imitating Hand Position from NEPSY, and imitation trials of a Simon Says task. In person measures also assessed executive function (Simon Says) and social-emotional functioning (SEL-Web). Measures were chosen based on previous work with stakeholders working in the program (Goldstein et al, 2017) and were administered at the beginning of the academic year (Time 1) before participation in the program and again at year end (Time 2).

Results:

Standard scores on Imitating Hand Position significantly increased from Time 1 to Time 2, indicating improvement in core motor imitation skills. ($t(29) = -2.34$, $p<.026$). In addition, higher imitation skills on the Rogers battery positively predicted change on the SEL-Web ($b = .299$, $p<.01$).

Conclusions:

Stakeholders have endorsed imitation as an important outcome for children with ASD likely because it represents a potential portal for developing social skills. Indeed, imitation scores predicted change in social-emotional skills. Further, the fact that imitation skills improved in a public, not selective, school environment from Time 1 to Time 2 suggests that theater arts might be a conduit for the development of these foundational skills. Although significant differences were not seen in social-emotional skills per se from Time 1 to Time 2, these small gains in imitation are encouraging and provide an important step in more fully understanding school-based theatre interventions.

187 **146.187** Age As a Predictor of Treatment Outcome in Youth with ASD Following the PEERS® Social Skills Intervention

M. Jolliffe[1], *R. Ellingsen*[2], *N. E. Rosen*[3] *and E. A. Laugeson*[3], *(1)Psychiatry, UCLA PEERS Clinic, Los Angeles, CA, (2)Psychiatry, University of California Los Angeles, Los Angeles, CA, (3)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA*

Background: Prior research shows that psychiatric disorders may be triggered by stress in adolescence, and that social stress in particular is thought to have a disproportionate impact during this time (Anderson & Teicher 2008). It has also been suggested that while early childhood is a sensitive time for sensory, motor, and language development, adolescence may be a second "window of opportunity" in brain development, particularly for improving social skills (Fuhrmann, Knoll, Blakemore 2015), a factor that is known to be associated with better psychiatric outcomes (Hawker & Boulton 2000). However, there is a dearth of research comparing social skills treatment outcomes across different developmental stages to examine age as a predictor of success in social skills training.

Objectives: The purpose of this study was to compare differences in treatment gains from a parent-assisted social skills intervention across three age groups (preschool, adolescent, young adult). We hypothesized that the adolescent group would demonstrate the greatest treatment gains across these three conditions.

Methods: Participants included 28 preschoolers (85.71% male; mean age=4.50, SD=0.75), 181 adolescents (79.9% male; mean age= 13.73, SD= 1.80), and 76 young adults (77.6% male; mean age= 20.92 , SD= 2.34) with Autism Spectrum Disorder (ASD), presenting for treatment through the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®; Laugeson & Frankel, 2010), an evidence-based, parent-assisted social skills program. All participants had clinically elevated ASD symptoms at baseline, as determined by a Total Score ≥ 60 on the Social Responsiveness Scale-Second Edition (SRS-2; Constanino 2012). Treatment gains were assessed using parent-reports on the SRS-2 pre- and post-treatment. Results were examined using repeated measures ANOVA to compare changes in SRS-2 Total Scores across groups.

Results: Paired samples t-tests revealed significant decreases in SRS-2 Total Scores pre- to post-treatment in all three age groups: preschool (t=2.48, p<.001), adolescent (t=10.17, p<.001), and young adult (t=6.87, p<.001). A repeated measures ANOVA compared change in SRS-2 Total Scores between groups and revealed a significant difference in amount of change between the adolescent and young adult groups (F=5.02, p<.01), such that SRS-2 Total Scores improved more in the adolescent group than the young adult group, supporting the original hypothesis. However, there were not significant differences in amount of change between the preschool group and the adolescent group or the preschool group and the young adult group.

Conclusions: These results suggest that the adolescent group did benefit more from treatment than the young adult group. This is consistent with the research advocating adolescence is a critical age for social skills development. This study demonstrates the importance of social skills treatment during adolescence. Future research might examine other social skills gains following the PEERS® intervention to determine if these differences are consistent across other domains.

188 **146.188** Are Children Severely Affected By ASD Underrepresented in Treatment Studies?: An Analysis of the Literature

A. Stedman[1], *M. Erard*[2] *and M. Siegel*[3], *(1)Spring Harbor Hospital, Westbrook, ME, (2)Maine Medical Center Research Institute, Portland, ME, (3)Maine Medical Center - Tufts School of Medicine, Westbrook, ME*

Background: Despite significant advances in the field of autism research, many experts have noted that those severely affected by Autism Spectrum Disorder (ASD) appear to have been understudied, particularly as the ASD phenotype has broadened over time. The extent to which this is true, and how severity is represented in the literature, has not been quantified. This question may exert its most proximal effects in the arena of treatment studies, which inform current clinical practices.

Objectives: We aimed to evaluate the degree to which the more severely affected population of children with ASD has been included in treatment studies, how severity is measured and represented, and if there have been changes in these areas over the past two decades in the autism literature.

Methods: A comprehensive literature search was conducted encompassing all autism research articles published from January 1991 to March 2013. Inclusion criteria for our analysis were peer-reviewed treatment studies with a sample size greater than one of pediatric subjects with ASD. Review of the articles based on these criteria yielded a final sample of 367 publications. The following was extracted from the full text of each article: publication year, sample size, age and sex of subjects, study design, type of treatment, and treatment target. To assess severity of participants in each study, information was extracted regarding communication level, IQ/level of intellectual disability (ID), and adaptive behavior, noting whether each was reported and with what measures. To determine overall presence of severely affected subjects, we evaluated each study based on severity cut-off scores on measures used in three domains (communication, IQ/ID, adaptive behavior). If an article included severely affected subjects in at least one domain, it was categorized as having evidence of inclusion of the severely affected population.

Results: Of the three severity domains, information regarding IQ/level of ID was most commonly reported (in 65.7% of papers, n=241), followed by communication (42.2%, n=155) and adaptive behavior (21.8%, n=80). Forty-nine percent of the studies (n=180) demonstrated evidence of inclusion of the severely affected population by our criteria. Notably, when examining the inclusion of the severely affected population over time, there was a significant decrease in the proportion of studies that included severely affected subjects (X^2 (8, n=367) = 36.7, $p<0.001$). Of the assessed papers published 1990-1994, 90% (n=18) included the severely affected population, whereas only 36.2% (n=42) of papers published 2010-2013 included the severely affected.

Conclusions: In reviewing treatment studies of children with ASD, it is clear that even by our liberal criteria of needing just one reported domain (IQ, communication, adaptive) to fall within the severe range, children severely affected by ASD were increasingly underrepresented in the literature over time. Particularly notable, in a disorder with a core feature of communication deficits and typically lowered adaptive functioning, was the underreporting of both domains. Future research could examine possible factors related to the underrepresentation of those severely affected by ASD, such as relative lack of gold-standard measures for communication and challenges in accessing more severely affected samples for outpatient studies.

189 **146.189** Assessment of Treatment Gains Following Social Skills Intervention: Parent and Adolescent Perceptions of Social Anxiety and Social Engagement

E. Veytsman[1]*, Y. Bolourian*[2]*, R. Ellingsen*[3]*, J. Blacher*[1] *and E. A. Laugeson*[4]*, (1)Graduate School of Education, University of California Riverside, Riverside, CA, (2)University of California - Riverside, Riverside, CA, (3)Psychiatry, University of California Los Angeles, Los Angeles, CA, (4)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA*

Background:

The use of multiple informants in the assessment of treatment gains is critical in obtaining a better understanding of treatment progress. Some studies show inconsistencies between youth and parent report of socioemotional functioning among youth with Autism Spectrum Disorder (ASD) (e.g., Knott et al., 2006). The Program for the Education and Enrichment of Relational Skills (PEERS), an evidence-based social skills intervention, has been effective in improving adolescent social engagement and lessening social anxiety (Laugeson et al., 2012; Laugeson et al., 2009; Schohl et al., 2014). Previous correlational findings showed increased agreement between adolescent and parent ratings of adolescents' social anxiety and social engagement after participation in PEERS. However, the effect of informant ratings on treatment gains has yet to be examined.

Objectives:

The current study examines the association of parent and adolescent ratings on improvements of social anxiety and social engagement following an evidence-based social skills intervention.

Methods:

Participants included 133 adolescents (males=110; females=23) 11-18 years of age (M=14.02, SD=1.79) with ASD who attended 14 sessions of a weekly 90-minute social skills group (PEERS) with their parents. In order to assess adolescent social anxiety, parents and adolescents completed the *Social Anxiety Scale* (SAS; La Greca 1999) at pre- and post-test. The SAS Total Score was utilized in analyses. Parents and adolescents also completed the *Quality of Socialization Questionnaire* (QSQ; Frankel & Mintz 2008) at these two time points to assess the frequency of hosted and invited get-togethers in the previous month.

In order to determine the magnitude of change in adolescent social anxiety and social engagement by rater over time, gain scores on the SAS and QSQ were computed, and analyses of variance (ANOVA) were utilized with rater (parent vs. adolescent) as the independent variable. A significant omnibus test indicates that the mean change from pretest to posttest is not the same by rater.

Results:

Paired sample t tests revealed significant improvements on the SAS and on both domains of the QSQ as per parent and adolescent ratings ($p < .05$). ANOVAs of gain scores yielded no significant difference between raters on the SAS Total Score, F (1, 215) = .28, $p > .05$, or on the number of invited get-togethers on the QSQ, F (1, 218) = .33, $p > .05$. However, a significantly greater increase in hosted get-togethers per adolescent ratings (M = 2.20, SE = .27) was detected as compared to parent ratings (M = 1.38, SE = .27), F (1, 219) = 4.59, $p < .05$.

Conclusions:

Consistent with previous findings, parents and adolescents reported improvements on measures of social anxiety and engagement following the PEERS intervention. Analyses of gain scores were utilized to determine if treatment gains differed by parent and adolescent ratings. Overall, findings suggest that parents and adolescents perceive similar rates of improvement. However, adolescents reported a greater increase in the number of hosted get-togethers. This discrepancy in parent and adolescent report may be socially normative as adolescents become less socially anxious and more socially engaged and independent in planning their own get-togethers.

190 **146.190** Assistive Social Skills and Employment Training (ASSET) Program for Transition Youth with Autism Spectrum Disorder

K. White[1], *C. Sung*[2] *and G. Leader*[3], *(1)National University of Ireland, Galway, Galway, Ireland, (2)Department of Counseling, Educational Psychology and Special Education, Michigan State University, East Lansing, MI, (3)National University of Ireland, Galway, Ireland*

Background: Youth with autism spectrum disorder (ASD) face disappointing employment outcomes, including high unemployment and underemployment rates, following high school. This holds true for individuals with ASD without intellectual disability (ID) who have average intellectual abilities, but often have significant difficulty navigating the demanding social interactions in the workplace. While interventions targeting social skills in the larger ASD population have become increasingly prevalent, the majority of studies are atheoretical and focus on the needs of children. Research has not systematically examined work-related social skills interventions as evidence-based practices for transitioning youth with ASD. In addition to this area of need, recent legislative initiatives, including the Workplace Innovation and Opportunity Act in U.S., which mandates significant emphasis on pre-employment training for transition youth with disabilities, highlight the need for work-related social skills interventions to promote successful transition outcomes.

Grounded in social cognitive career theory and developed using a developmental iterative process, the Assistive Social Skills and Employment Training (ASSET) program, consists of ten 90-minute sessions offered in a community-based setting. One trained facilitator led sessions with 6 to 8 transition youth. Using multidisciplinary collaboration and community-based participatory design, curriculum was developed to meet the end-users needs, while emphasizing its appropriateness for practical and clinical utility. Topics covered included: communication, attitude and enthusiasm, teamwork, networking, problem-solving and critical thinking, and professionalism.

Objectives: This study aims to contribute to the evidence base by validating a work-related social skills training intervention, namely ASSET, for transition age youth with ASD (without ID) designed to improve social skills and social self-efficacy.

Methods: Twenty-seven transition youth with ASD participated in the pilot study of the ASSET program between 2014 and 2016 in the U.S. Preliminary findings included 17 high school and college students ranging from 19 to 23 years (M = 20.08; SD = 2.03) with ASD without ID (IQ M = 98.21; SD =16.78). All participants reported a previous diagnosis of an ASD according to DSM-IV-TR criteria.

Results: Findings revealed that 90% of a sample of 17 transition youth with ASD demonstrated significant improvements in social skills (d = .69) and social self-efficacy (d =1.58), as well as in secondary outcomes such as adaptive skills (d = .21) and self-reported levels of anxiety (d = .49) (Sung et al., in preparation; Connor & Sung, in preparation). Qualitative reports indicated that more than 80% reported that overall satisfaction rate was very high (rating between 8 to 10) on a 10 point-Likert scale with 10 being the highest satisfaction.

Conclusions: This study offers preliminary evidence for the efficacy of a work-related social skills training on social skills, self-efficacy, job readiness, adaptive functioning, and mental health for transition youth with ASD. The ASSET program is currently being piloted as a multi-site randomized control trial in two U.S. states, as well as being adapted and implemented in Ireland highlighting its potential for broader national and international collaboration, as well as its practicality and utility in community-based settings. Implications for research and practice, and lessons learned will be discussed.

191 **146.191** Autism Summer Employment Program Improves Job-Readiness and Employment Prospects in ASD Post-Secondary Students

J. Doidge[1], *A. Porthukaran*[2], *I. Yusupov*[1], *S. Konanur*[1], *M. Segers*[1] *and J. M. Bebko*[1], *(1)York University, Toronto, ON, Canada, (2)Psychology, York University, Toronto, ON, Canada*

Background: Entering the workforce and obtaining employment is an important goal for students in contemporary society, and a challenge for many young students with Autism Spectrum Disorder (ASD) who seek to transition into the workforce. Recently, studies have begun to show the effectiveness of supported employment programs for individuals with ASD and have demonstrated that employment programming for ASD participants can raise employment rates up to 35% (Garcia-Villamisar & Hughes, 2007;García-Villamisar, Wehman, & Navarro, 2002; Hillier et al., 2007; Lawer et al., 2009; Morgan & Schultz, 2012). Yet because of the length of time and expenses, these programs are often not feasible for many vocational centers, or student service centers. Similarly, many students with ASD may not utilize these programs since they are looking for summer or short-term employment.

Objectives: We explored a shortened and specialized Autism Summer Employment Program (ASEP) for post-secondary students with ASD with limited or no prior employment experience. We then examined how ASEP affected students' employment success, job-related knowledge and skills, as well as program satisfaction amongst ASEP participants.

Methods: 18 Canadian post-secondary students with ASD who were currently enrolled in university were recruited for the study. The program took place at a Canadian university, and used employment workshops specific to the ASD population for job searching, plus mock interviews with participants that were videotaped, in addition to ongoing job-related support. Job-readiness was evaluated with the Job-Readiness Questionnaire (JRQ).

Results: Overall, a significant increase in students' post-program scores compared to their pre-program scores, was found on the JRQ, indicating that students perceived an improvement in their job skills ($p < 0.001$). Students of the ASEP also reported a significant increase in their interview skills ($p = .03$), and confidence ($p = .01$), across the two time points, as well as high program satisfaction. Significant gains were also made in terms of employment goals and communication skills from pre- to post-program evaluations. As for employment, 100 percent of the students achieved employment positions; 14 participants accessed paid employment and 4 had volunteer positions. Of the 14 employed students, 100 percent maintained employment for the duration of their jobs. It seemed that smaller size workplaces sites were beneficial to individuals with ASD for several related reasons: such sites may be less intimidating, friendlier, and more flexible than large-scale workplaces.

Conclusions: These results demonstrated that the ASEP was helpful for obtaining and sustaining summer employment, often the first real work experience for the students. The program provided university students with ASD the opportunity to increase their employment skills in a safe and supported setting for a short duration and with limited costs. Students reported a significant increase in their job-related skills, knowledge, and confidence, and had generally positive work experiences during the program. The ASEP may be a viable support for post-secondary students with ASD in finding not just paid summer employment but also better preparation for full-time employment in the future.

192 **146.192** Best Practices in Supporting Social Participation of Young Adults with Autism Spectrum Disorder (ASD) : A Systematic

Review.

E. L. Bussières[1]*, J. Trépanier*[2]*, O. Laverdière*[3]*, M. H. Poulin*[4]*, D. St-Laurent*[5]*, J. Berbari*[6]*, C. Dumont*[7] *and M. Couture*[8]*, (1)Psychology, Université du Quebec à Trois-Rivières, Trois-Rivières, QC, Canada, (2)Faculté de médecine et des sciences de la santé, Université de Sherbrooke, Sherbrooke, QC, Canada, (3)FAculté de Médecine et des sciences de la santé, Université de Sherbrooke, Sherbrooke, QC, Canada, (4)Psychoeducation, UQAT, Rouyn-Noranda, QC, Canada, (5)Psychoeducation, UQAT, Royn-Noranda, QC, Canada, (6)FAculté de médecine, Unviersité de Sherbrooke, Sherbrooke, QC, Canada, (7)Rehabilitation, UQTR, Trois-Rivières, QC, Canada, (8)Rehabilitation, Universite de Sherbrooke, Sherbrooke, QC, Canada*

Background: The majority of ASD studies focuses on early childhood and early intervention (Howlin, 2008) while the challenges associated with autonomy and independent living is a major issue for avdults with ASD
Objectives:

The purpose of this systematic review (SR) is to document the effectiveness of interventions to support social participation of young adult with autism (16-40 years old). In this review, social participation is defined by three domains: social relations, employment and independent living.

Methods:

A comprehensive literature search was conducted to identify published articles and unpublished dissertations, using the following databases ProQuest, Medline, PsycInfo, Cinhal, ERIC. The research covered the period from 1 January 2000 to 1 June 2016. Two persons independently screened articles for eligibility. Studies were included if they: 1) include more than 10 participants ; 2) focuses on at least one aspect of transition to adulthood, including social relations, employment and independent living. Critical appraisal of included studies was done independently by two persons, using the Scientific Merit Rating Scale (National Autism Center, 2015).

Results:

Fourteen studies were retained, evaluating work-related interventions (10 studies), independent living programs (3 studies) and a leisure program (1 study). Methodological quality varies greatly across studies. Among high quality studies, three different interventions appear promising: a leisure program and two programs related to work, including a virtual training to job interviews, and a school-based employability program including an internship.

Conclusions: This SR suggests that interventions targeting transition to adulthood may be beneficial; it also highlights the need for more research, especially regarding the effectiveness of programs targeting independent living.

193 **146.193** Building from Strengths: A Curriculum to Help Adolescents with ASD Develop Creative Technology Skills and Succeed in STEM Fields

A. Riccio[1]*, M. Hossain*[2]*, B. Rosenberg*[3,4] *and K. Gillespie-Lynch*[5]*, (1)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (2)Hunter College, CUNY, New York, NY, (3)Tech Kids Unlimited, Brooklyn, NY, (4)Technology, Culture, Society, New York University Tandon School of Engineering, Brooklyn, NY, (5)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: People with ASD are chronically underemployed (Burgess & Cimera, 2014) despite their often heightened interest in computers (Wei et al., 2013) *and* the growing need for professionals who specialize in computing. Despite a deeply problematic gap between the potential of youth with ASD and their employment outcomes, evidence-based services to bridge this gap remain very limited (Taylor & Seltzer, 2011). Tech Kids Unlimited (TKU), a not-for-profit, aims to provide students with ASD and other learning differences with opportunities to build from their strengths to obtain meaningful careers.
Objectives: We aimed to gain insights about the interests/goals of teens with ASD and their perspectives about TKU to inform curriculum adaptations.

Methods: Throughout seven weeks of summer programming, twenty students with ASD (13-20 years; $M = 15.6$) participated in structured interviews at the beginning and end of each week-long workshop. After achieving reliability, the lead author coded students' responses. Optional Likert scale surveys were distributed at the end of the week to parents and instructors of all students who participated in summer programming.

Results: When asked what they were looking forward to at the beginning of the week, most students indicated excitement about technology (68%), 26% reported anticipation of social opportunities. When asked what social skills they hoped to learn at TKU, 36% of students did not know or did not feel they needed social skills supports. When asked what job they would like, 79% of students indicated STEM careers. Only 26% of students identified specific job-related skills they hoped to learn. Few students (35.29%) provided a specific employment-preparation strategy.

When asked what they had learned, most (82%) students indicated technological skills, 24% indicated social skills. When asked what they had learned which could help them get a job, most students (47%) indicated technological skills, 24% indicated social skills. When asked how their instructor made activities interesting for them, 56% of students described hands-on activities and 31% described playful humor/games.

In post-test surveys, instructors indicated that all program participants (n=42) developed technological skills (M= 5.59 out of 7) and were engaged with the curriculum (M= 5.49) and other teens (M= 5.05). Parents (n=23) indicated that students gained skills needed to obtain employment (M= 5.48 out of 7), technological skills (M= 5.45), social-emotional skills (M= 5.14), and friendships (M=5.21).

Conclusions: Students', parents' and instructors' indicated that adolescents with autism gained technological and social skills at TKU. Students and parents reported that skills learned could help students obtain jobs. In order to help students transition into careers aligned with their interests, TKU's innovative curriculum should increasingly emphasize activities to help students identify goals and monitor progress developing job-related soft skills (e.g., planning and collaboration). Given that teens with ASD reported that hands-on, playful, technology-based activities are a central aspect of their enjoyment of TKU, curricular adaptations should continue building on these strengths.

194 **146.194** Community-Based Intervention Research for Adolescents and Young Adults with ASD Is Uneven across Designs, Diversity & Domains: A Review

T. M. Girolamo[1] *and S. F. Warren*[2]*, (1)Child Language, University of Kansas, Lawrence, KS, (2)Speech-Language-Hearing: Sciences and Disorders, University of Kansas, Lawrence, KS*

Background: Little is known about community-based intervention (CBI) research on adolescents and adults with Autism Spectrum Disorders (ASD). Yet, research suggests adolescents and adults with ASD face adverse outcomes upon exiting public education. CBI may be an effective way to provide support across the life span.

Objectives: The aim of this study was to summarize the state of research on CBI for adolescents and adults with ASD, particularly with regard to: demographics of participants in CBI research, development of the literature as a whole, and domains targeted by interventions.

Methods: This study included all peer-reviewed journal articles from 1980–2015. Inclusionary criteria were: (1) an explicitly identified CBI; (2) taking place in a real world setting outside of a residential setting or school; (3) targeting one or more adolescents and/or adults, of 14 years of age or older; (4) a diagnosis of autism or demonstration of the characteristics of autism under the DSM-4 or DSM-5. This criterion includes individuals from earlier studies who did not have an ASD diagnosis, but demonstrated symptoms consistent with ASD.

ERIC, GoogleScholar, Medline, and PsycInfo searches were conducted with the following terms in all permutations: (adolescents OR adults) AND (community-based OR community based OR community OR vocational) AND (autism OR asperger) AND (treatment OR intervention OR training). Reference lists of articles were also checked. Fourteen studies were identified that met the inclusionary criteria.

Articles were evaluated using a template developed by a NIMH work group. Phase I research is formulation and systematic examination of intervention techniques. Phase II research involves protocol development and manualization. Phase III research consists of randomized controlled trials. Phase IV research is community effectiveness studies.

Results: 13 of the 14 eligible studies were Phase I studies. Of the 13 Phase I studies, 11 were single-subject designs, and 2 were pre-/post-test designs. Challenges to strong single-subject designs included: sufficient intervention duration, changes in level and trend to claim treatment effect, as well as generalization. No studies explicitly qualified as Phase II. Only one study qualified as Phase III. No studies qualified as Phase IV.

Second, most studies focused on the vocational domain. Nearly 60% had vocational goals, 20% behavioral goals, 14% social skills goals, and 7% activities of daily living goals. Interventions targeting language were wholly absent from the CBI literature.

Third, studies may lack diversity. Information on participant race/ethnicity was obtained for 85% of participants overall and for 9/14 studies. 70% of participants were Caucasian, 22% African American, 4% Asian, and 3% Hispanic. No participants were Alaska Native/Native American.

Conclusions: The literature suggests that CBI research for adolescents and adults with ASD has stagnated over the past 35 years. Most studies are Phase I studies focusing on the vocational domain. It is unclear how interventions might vary with culturally and linguistically diverse participants. The paucity of research may be tied to a lack of funding and advocacy for this age group. Future research should focus on replication, especially with diverse participants, and CBI targeting other domains, including language.

195 **146.195** Constructing Successful in-Home Oral Care Habits in Latino Children with and without Autism

D. H. Como[1]*, L. I. Florindez*[1] *and D. C. Florindez*[2]*, (1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)University of Southern California, Los Angeles, CA*

Background:

Dental care is the most prevalent unmet health need in US children (Stella et al., 2002). Children who are from an underrepresented, underserved minority population, like Latinos, or have a special health care need such as Autism (ASD), are at increased risk for experiencing oral health disparities (Fisher-Owens et al., 2013). When intersected, Latino children with ASD face unique and unresearched oral care challenges. Performing routine dental activities can be especially difficult for a child with ASD due to their unique set of sensory sensitivities (Stein et al., 2012). Most literature discussing oral health disparities recognizes a need for further research to mitigate the inequalities, but little focuses on promoting successful home-based oral care strategies like tooth brushing and flossing.

Objectives:

The purpose of this qualitative study is to use videos recorded by parents to explore and compare how 18 Latino children with and without Autism perform in-home oral care routines, note both successful aspects of their routines and areas for improvement, and summarize findings into suggestions for practitioners working with these families.

Methods:

This study employed a qualitative approach to analyzing oral care videos. Eighteen Latino families (8 families with a typically developing child ages 6-12 and 10 families with a child with ASD ages 6-12) were interviewed to identify the factors that impact their in-home oral care routines, including how the presence of ASD may alter their child's habits. Each family was asked to film their child performing their typical oral care routine for 3 days. A research assistant blindly coded 61 videos (n=30 from a child with ASD and n=31 from a typically developing child) using a checklist of dental behaviors (amount of toothpaste, duration of brushing, etc.), in addition to making notes about unique aspects of the oral care routines. Videos were discussed and co-coded by the research team to decide on final themes.

Results:

From the videos, three themes pertaining to successful oral care practices were observed. The first, *Parent Involvement*, identifies parents as partners in the oral care process, helping facilitate the activity physically or with verbal cues. The next, *Wait, there's more,* describes that tooth brushing was often the only routine performed by the child; noticeably absent were flossing and mouthwash habits, which were often described by parents as too difficult to incorporate into their child's routine. Finally, *Sensory modifications* describes being aware of the sensory needs of the child, and modifying the activity to meet those needs, including altering the environment where the activity takes place, or using timers to help establish routines.

Conclusions:

Understanding in-home oral care routines may address oral care disparities in Latino children. This involves addressing the occupation of oral care itself, while also considering the influence of the cultural contexts, family and child descriptors, performance patterns, and systemic restrictions on the activity. By synthesizing components of oral care routines into suggestions for successful practice, we hope to begin the discussion on effective oral care for Latino children.

196 **146.196** Delivery of ABA to Children in Rural Communities Via Teleconsultation and Rethink Autism

J. Viskochil[1]*, W. Jenson*[2]*, W. M. McMahon*[3]*, P. Carbone*[4]*, J. Davis*[2] *and J. Hood*[5]*, (1)Utah Autism Research Program, Salt Lake City, UT, (2)Educational Psychology, University of Utah, Salt Lake City, UT, (3)Psychiatry, University of Utah, Salt Lake City, UT, (4)University of Utah, Salt Lake City, UT, (5)Carmen B. Pingree Autism Center of Learning, Salt Lake City, UT*

Background: Applied Behavior Analysis (ABA) is an effective intervention for individuals with ASD, and parents can be trained to provide ABA intervention in their home. Families in rural areas face a lack of nearby ABA service providers, thus parent training for this population is imperative. Developments in telehealth and teleconsultation may further increase ABA training opportunities for these rural communities. Rethink Autism is an online, video-based treatment program designed to provide parents with the training to implement ABA with their children at home. Although online parent training programs confer multiple benefits, therapist-assisted modalities show greater outcomes than self-directed use. Contact with a trained interventionist could bridge some of the common barriers in online parent training.
Objectives: The purpose of the present study was to evaluate outcomes of an online, ABA-based intervention with video modeling delivered to children with ASD in rural areas and supplemented by teleconsultation. This model may provide the education, training, and scaffolding needed for parents to implement behavioral interventions with their children. Outcome measures of import included the following: child behavioral gains; parent ABA skill development; fidelity of the ABA programming and implementation integrity; and generalization of ABA skills to novel behaviors. Additionally, this study reviewed access to evidence-based intervention in rural communities, cost-effective delivery of intervention, and the utility and social validity of behavioral teleconsultation.

Methods: A non-concurrent multiple baseline design was used across three rural families. Following an in-vivo orientation, three phases were completed remotely through Rethink and teleconsultation. The baseline phase involved novice participants implementing ABA using only a one-page lesson printout. This was followed by successful completion of four Rethink ABA training modules. During the intervention phase, participants had access to Rethink's high definition video modeling and coaching delivered via teleconsultation. The generalization phase replicated baseline conditions with a never-before-seen lesson; participants had only the lesson printout without coaching or video modeling.

Results: Outcomes reveal large effect sizes for parent increases in ABA implementation integrity from baseline to generalization (Tau-*U* = 0.82), coupled with child skill gains in their ABA lesson programming (Tau-*U* = 0.80). Both Rethink and teleconsultation were rated with high acceptability and perceived effectiveness. Cost analyses show financial benefits of Rethink and teleconsultation in terms of ABA programming (annual savings = $18,051 per child), logistical expense (average travel of 49 driving hours over 2,900 miles), and ABA consultation costs (average savings by teleconsultation = $300.16).

Conclusions: This study supports the use of digitally delivered intervention to increase child skills via targeted ABA lesson programming. These gains were achieved with relatively short duration (three months) and with low intensity (four hours/week). Parents were able to develop ABA implementation skills over the course of the study through the completion of online training modules and coaching received over teleconsultation sessions. These skills were critically demonstrated in the generalization phase to a novel behavior. This model of service delivery is apropos for families living in rural geographies, elegantly addressing limitations in service access and economic burdens.

197 **146.197** Developing Self-Reflection: A Novel Social Skills Intervention Using First-Person Video Recording Eyeglasses

S. Hurwitz[1]*, D. P. Kennedy*[2]*, T. Ryan*[3]*, K. Quest*[4]*, B. Schmitt*[4] *and A. Zero*[4]*, (1)Special Education, Indiana University, Bloomington, IN, (2)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (3)Special Educaiton, Indiana University, Bloomington, IN, (4)Indiana University, Bloomington, IN*

Background:
Autism Spectrum Disorder (ASD) is a neurodevelopmental condition characterized by profound and lifelong impairments in social relationships and communication. Social-communication deficits are important targets for intervention because proficiency is critical for successful functioning within society.

Objectives:

This study takes a novel approach to social skills development by improving participants' ability to self-reflect. In this context, self-reflection is the capacity to think about one's own behavior during social interactions and consider whether it was appropriate. Using first-person-perspective video recordings as a tool, participants with autism learned to reflect upon their conversational behavior, learn from their mistakes and successes, and improve future social interactions.

Methods:

Participants: Four adolescent males with autism (diagnosis confirmed by ADOS-2), ages 12-16 years-old, with average IQs (as measured by WISC-V) and fluent spoken language, participated in this study.

Study design: Single-case design; multiple-baseline across participants, replicated across four individuals.

Measures: The following measures were administered to all participants and/or their parent. ADOS-2, WISC-V, Autism Social Skills Profile (ASSP-II), Social Responsiveness Scale (SRS-2), Social Skills Improvement System (SSIS), Self Reflection and Insight Scale (SRIS), a social validity questionnaire.

Intervention approach: Each session consisted of a 10-minute, unstructured, naturalistic conversation between the participant with ASD and an interventionist (i.e. a trained school psychology doctoral student or a principal investigator). Both members wore first-person, video capture eyeglasses that recorded the conversation from their viewpoint. Baseline sessions involved a 10-minute conversation (nothing else). Intervention sessions involved a conversation and then the participant was asked to, "Think back about how the conversation went." Video clips were viewed so the participant could see himself from the outside (e.g. the expression on his face, the gaze of his eyes, the topics he brought up) and the interventionist (e.g. to see the puzzled look or smile on her face). Sometimes, clips showed the table or floor because the participant had looked down during much of the conversation. Participants identified moments of conversational strength and imperfection.

Videos of the participants were coded for behavioral changes by trained graduate students. A randomization procedure was used to reorder videos before coding began so coders were blind to treatment condition. IOA was completed for 30% of videos to an average level of 93%.

Results:

Each participant engaged in 14-23 conversational sessions (this number varied due to the multiple-baseline study design), and two generalization sessions six weeks later. Participants improved in at least one conversational measure. These target skills were individualized, as some participants developed their eye contact, while others talked less about restrictive-interests and asked more questions. Participants and parents completed a feedback survey; learned new skills, recommended the study to others. Effect sizes and visual analyses will be presented.

Conclusions:

First-person video recording eyeglasses can be used as a tool to improve some conversational behaviors for adolescents with ASD. Nonverbal communication skills (like eye contact, facial affect, and physical orientation) were easy for participants to self-identify from videos. Conversational skills, like perseverating on restrictive interests or initiating new topics, were more difficult for participants to recognize independently.

198 **146.198** Development of Immersive Gaze-Controlled Video Game Therapy for Children with Autism Spectrum Disorder

L. Cordero[1]*, Z. M. Dravis*[1]*, B. Farber*[2]*, L. Robinson*[2]*, M. Farber*[3] *and J. D. Herrington*[4]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)BioStream Technologies, LLC, Boston, MA, (3)BioStream Technologies, LLC, Philadelphia, PA, (4)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background:

Existing interventions for children with autism spectrum disorder (ASD) require significant therapist or educator time, with an estimated annual cost of more than $11B. As such, there is a pressing need for affordable and accessible tools to evaluate and treat children with ASD. In collaboration with the University of Pennsylvania and the Children's Hospital of Philadelphia, BioStream Technologies, LLC (“BioStream”) is developing a commercial-quality immersive 3D video game to augment social skill training for children with ASD. BioStream’s game leverages behavioral and educational principles used in applied behavior analysis, such as discrete trial training and differential reinforcement, to shape behavior and drive positive outcomes. To inform game design, BioStream has developed a proprietary research platform (“BioStream Platform”), which uses state-of-the-art software to collect and interpolate synchronized biosensor data and enable programmatic adaptation of player experiences in real time.

Objectives:

1) To determine that the BioStream Platform can collect accurate synchronized physiological and behavioral metrics. 2) To qualitatively evaluate BioStream’s game that includes tasks designed to facilitate social abilities (eye contact and facial expression recognition).

Methods:

This observational pilot study is actively recruiting children between the ages of 6 and 17 targeting 50 children with ASD and 20 typically developing children. To date, BioStream’s game has been administered 36 times over 13 children (10 ASD and 3 TDC) (mean age = 12.25 years, 83% Male). The wide age range aids in further identifying a target demographic of those who may benefit most from the game. Study visits include computer game play while wearing biosensors including ECG, EDA/GSR, EEG, and use of eye trackers (table-top and eyeglass-mounted depending on the task). Participants are also recorded with front facing cameras to analyze facial expressions. After a physiological baseline is obtained via a 3 minute long fractal video with no sound, participants engage in a three minute dyadic conversation. Next, they move on to play BioStream’s game, which includes repeatedly administered discrete trials that require participants to attend to specific contents on a computer screen (i.e., eyes within a face), and provides immediate, rewarding feedback upon success. The use of real-time eye tracking data is essential to truly evaluating eye contact and providing effective differential reinforcement.

Results:

To date, the BioStream Platform and BioStream’s game have proven to be safe and well tolerated by participants. The gaze-contingent eye tracking portion of the game has worked successfully for all children. Quality assurance and basic analyses are presently underway for the remaining biosensor data.

Conclusions:

BioStream’s game and platform have been well received by participants and the platform effectively collects simultaneous biosensor and behavioral data among children with varying abilities. In addition to the value of the BioStream Platform in developing interventions, present data suggest that it provides a convenient method for researchers to simultaneously measure multiple data streams during dyadic communication, gameplay training and social skills assessments. By INSAR 2018 Annual Meeting we will have implemented analyses on data from each biosensor (including eye tracking), as well as on child ratings of the game.

199 **146.199** Employment Interventions for Individuals with ASD, DD, & ID: A Meta Analysis of Single Case Research

J. Davis[1]*, K. Mendenhall*[2]*, T. Glad*[2]*, M. Walkingshaw*[3] *and W. M. McMahon*[4]*, (1)Educational Psychology, University of Utah, Salt Lake City, UT, (2)University of Utah, Salt Lake City, UT, (3)University of Utah, Salt lake City, UT, (4)Psychiatry, University of Utah, Salt Lake City, UT*

Background:

Individuals with autism spectrum disorder (ASD), intellectual disabilities (ID), and/or other developmental disabilities (DD) often face challenges when transitioning from school based services to competitive employment in adulthood. Many individuals in this population enter adulthood without the necessary skills to independently acquire a competitive job or maintain a position. At this crucial transition point, needed are effective intervention practices to support individuals on the path to gainful employment.

Objectives:

The objective of this study is to review and analyze the available literature to better understand the current state of intervention research that supports individuals with ASD, ID, and or DD in the process of obtaining and maintaining competitive employment.

Methods:

A comprehensive literature review was conducted that resulted in a pool of 3,372 studies. After reading the title and abstract of each of the identified articles, the number of included studies was reduced to 544. Additional inclusion criteria included 1) studies that had utilized Single Case methodology, 2) studies that targeted an individual with ASD, ID or DD, and 3) studies that targeted outcomes related to pre-employment skills or specific job skills. Following the application of additional inclusion criteria, 21 studies were identified and coded for relevant variables.

Each study was coded based on the following variable 1) quality of research design 2) Intervention method, 3) Participant Characteristics (age & diagnosis), and 4) Setting of Intervention. For the current study, the Tau-U ES was used to determine intervention effects. Tau-U is a method for measuring data non overlap between two phases (A and B). Statistical significance between variables was assessed using the Kruskal-Wallis H test with the Dunn post-hoc test.

Results:

The current study found an overall TauU effect size = .79 CI95 [.72, .81]. These results include 67 effect sizes from 21 studies with 50 unique participants. Sixteen studies employed a high quality single case research design. Three studies utilized technology mediated interventions (TauU = .81 CI95 [.77, .85]), three studies targeted social skill interventions (TauU = .65 CI95 [.62, .68]), one study investigated interviewing skills (TauU = 1.0 CI95 [.77, 1.00]), and 14 studies targeted specific job skills (TauU = .80 CI95 [.77, .83]) as outcomes. No significant differences between studies were found based on age, diagnosis or setting of intervention.

Conclusions:

The current study examined intervention research for individuals with ASD, ID, and DD in the areas of employment and pre-employment skill development. Much of the research in this area centers around training specific skills for specific jobs. Relatively few studies target job preparation skills (e.g. interviewing, application development, etc.). While several high quality single case studies exist that promote effective practices for developing employment skills with this population, more research is needed to support individuals with ASD, ID, and /or DD in the process of obtaining jobs and maintaining employment opportunities.

200 **146.200** Examining the Effectiveness of a Mind Reading Emotion Intervention for Children with Autism Spectrum Disorders

D. Davidson[1]*, E. Hilvert*[2]*, M. Giordano*[1] *and I. Misiunaite*[3]*, (1)Psychology, Loyola University Chicago, Chicago, IL, (2)Loyola University, Chicago, IL, (3)Loyola University Chicago, Chicago, IL*

Background: Emotion processing plays a pivotal role in the maturation of social interactions and communication in children with Autism Spectrum Disorders (ASD). Although interventions that target emotion processing have the capacity to improve these social deficits, only a handful of technology-based emotion interventions have been designed and implemented with children with ASD.

Objectives: The goal of the present study was to examine the effectiveness of the software: *Mind Reading: The Interactive Guide to Emotions* (Baron-Cohen, Golan, Wheelwright, & Hill, 2004) on improving accurate recognition of basic and self-conscious emotions from facial and contextual stimuli in children with ASD.

Methods: Eighteen children with ASD (M_{age} = 12;02) participated in a four-week technology-based emotion intervention using the *Mind Reading* software (Baron-Cohen et al., 2004), which aims at improving emotion recognition abilities and social behaviors. All children had an IQ > 75, and were mainstreamed in their school district (see Table 1 for additional demographics).

Before the intervention began, children completed two tasks to assess their emotional development. The first was a measure of facial emotion recognition where children viewed pictures of happy, sad, angry, and fearful faces presented at varying expression intensities (0%, 50%, 100%). In the second task, children were read short stories and asked to identify the character's emotions from the situational context that elicited either a basic (i.e., happiness, sadness, fear) or self-conscious (i.e., pride, guilt, embarrassment) emotional reaction.

Two months after this initial assessment, all children participated in the Mind Reading intervention at their schools for three hours twice a week for four weeks. The Mind Reading software consists of three modules: the emotions library, learning center, and game zone. In the emotions library, children were exposed to over 400 basic and complex emotions through videos, recordings, and mini-stories. In the learning center, children completed lessons and quizzes on these emotions. In the game zone, children played games that tested their emotion recognition skills. Children spent the majority (~70%) of each session working in the emotions library and learning center, and at the end, they worked in the game zone. During each session, an intervention facilitator ensured students stayed on task. Children were then re-assessed two weeks later using the same battery of emotion tasks.

Results: After the intervention, children with ASD showed improvement in basic and self-conscious emotion processing skills. With regards to facial recognition, we found improvements in children's ability to detect happy and fearful facial expressions, subtle facial expressions (at 50% expression intensity), and their ability to specifically recognize basic emotions on male faces. On the situational emotion task, we found that after the intervention, children were better able to identify subtle and intense expressions of self-conscious emotions, especially guilt, from situational contexts (see Table 2).

Conclusions: These findings provide support for the efficacy of the Mind Reading program. Additional assessment of this intervention across various settings and with different emotion outcome measures will be essential to further establish its utility.

201 **146.201** Fidelity with Flexibility: Implementing Evidence-Based Interventions to Enhance Child Outcomes through Telehealth Parent Training

S. M. Egan, ***M. S. Torres-Viso*** *and M. D. Powers, The Center for Children with Special Needs, Glastonbury, CT*

Background:

In recent years, advances with telehealth technology have improved the opportunity for families of children diagnosed with Autism Spectrum Disorders (ASDs), living in areas with resource shortages, to collaborate with providers. As this distance consultation model becomes more prevalent, clinicians must adapt their service delivery repertoire to incorporate a fidelity with flexibility approach to training a parent acting in the role of practitioner. Best practices for children with ASD indicate that interventions must concurrently target decreasing challenging behavior which impair functioning and increasing the child's adaptive and functional repertoire. When utilizing telehealth technology, it is essential that added emphasis be placed on developing interventions which embed family and cultural values into evidence-based treatment. This will lead to culturally-sensitive interventions which incorporate variables that are meaningful to the family's values, and consequently improve child functioning within their cultural context.

Objectives:

The efficacy of telehealth-delivered, evidenced-based methodology on interfering and functional adaptive behaviors for children diagnosed with

ASD using a parent training model was evaluated. Modifications made to the implementation of best-practice strategies to match the needs of families and educators in a manner that maintains the integrity of evidence-based services are also discussed.

Methods:

Telehealth consultation was delivered to parents of three school-aged children (ages 5, 10, and 15) with ASD to manage disruptive behavior and teach appropriate, functional skills in response to child-specific adaptive challenges. The families were located in Europe and Asia with participants living in England, Norway, and Sri Lanka. Regularly-occurring telehealth consultations provided the parents with training by a clinician via didactic instruction with role plays/review of video, development of protocols for parent practice and electronic sharing of data. Data were collected by the parents on interfering behaviors and replacement responses.

Results:

Participant 1's avoidant feeding behavior decreased from 100% of trials met with refusal when target foods were presented at baseline to 3% of trials met with refusal after intervention. Additionally, his repertoire of food consumed increased by 25 foods with intervention. For participant 2, the weekly average of episodes of aggressive behavior decreased by total of 77%, from 3 episodes per week at baseline to <1 episode per week after intervention. Participant 3, demonstrated a decrease in voiding accidents from 48 per week at baseline to 7 per week after intervention and increased the frequency of initiation requests from 0 per week at baseline to 34 per week following intervention.

Conclusions:

Parent training delivered through telehealth was an effective intervention in reducing interfering behaviors and increasing parent-identified adaptive responses. Additionally, as the child’s interfering behaviors decreased, their availability to access family and community-based activities increased. Following the reduction in interfering behavior, intervention for each participant was advanced to incorporate assessment of additional adaptive skills and develop instructional protocols that further promoted community participation and family functioning. By incorporating a family’s cultural variables into the development of a strong distance consultation framework, the needs and resources of families were meaningfully embedded into intervention strategies which promoted generalization of successful outcomes and prevented consultative failures.

202 **146.202** Ideas: Inventing, Designing and Engineering on the Autism Spectrum

K. P. Koenig[1], *W. Martin*[2], *R. Vidiksis*[2] *and Y. L. Chen*[1], *(1)Occupational Therapy, New York University, New York, NY, (2)EDC, New York, NY*

Background: Preparation for a career as an inventor, designer, or engineer requires that students not only learn disciplinary knowledge, but also to engage in scientific and engineering practices. These abilities are difficult for most students to master, but they can be particularly challenging for students with ASD, who often struggle with peer interactions, critical reflection, executive function, and communication yet have a high interest in the STEM fields. The overarching goal for this project is for a collaborative team of researchers, program developers, ASD educators and students to create an inclusive design and engineering program for middle-school students with ASD and general education peers
Objectives: To explore preliminary indicators of positive social behavior during a high interest inclusive STEM club for middle school students with and without an autism spectrum disorder (ASD).

Methods: A 10-week afterschool program (Maker Club) was conducted in a large urban district in three pilot schools with six teachers and 37 students (14 with ASD and 23 without). Researchers conducted structured observations of every program session (n=50), a mid-year focus group with all six teachers, and post-implementation focus groups with the two teachers at each of the three pilot schools (N=6), to gather data about their experience at different stages in the program. As a result of this initial data collection, a Behavioral Coding Scheme will be used (Bauminger, 2002) during the Fall of 2017 to code social initiation and response in 3 main behavioral categories: positive social interaction, negative social interaction, and low-level social interaction. Observations and coding will be made in two 15-minute periods (2 before treatment 2 after treatment in the study) and data will be coded for presence of behavior in 1-min intervals.

Results: Initial results from the focus groups and structured observations indicate that over the 10 week period, students with ASD showed an increased frequency of social initiations that included a) asking for help from their peers, b) direct questioning of their peers for information about their projects, c) initiation of spontaneous conversations while working on Maker activities, and d) increased social initiations with students without an ASD. As a result of these findings a behavioral coding scheme will be used in the fall of 2017 to examine social interaction systematically and these findings will be presented along with the preliminary data from structured observations and focus groups.

Conclusions: An after school STEM club that is designed and implemented by a collaborative team of general education and special education teachers, engineering students and science museum personnel shows promise in generating a higher frequency of social initiations and duration of social interactions for students with ASD. By starting from a place of strength and interest rather than remediation, students can be motivated to internalize and integrate practices that are difficult for them—namely, those that support development of social and functional skills.

203 **146.203** Impact of Vigorous Exercise on Behavior Problems and Academic Engagement Among Adolescents with Autism Spectrum Disorder

A. C. Woodman[1], *M. Evans*[2], *R. Golden*[3], *J. Maina*[4] *and Y. Mori*[1,4], *(1)University of Massachusetts Amherst, Amherst, MA, (2)EdTogether, Inc., Boston, MA, (3)Boston Children's Hospital, Boston, MA, (4)Boston Higashi School, Randolph, MA*

Background: Children with autism spectrum disorder (ASD) experience less active lifestyles than their peers without ASD, which may place them at risk for poor mental and physical health outcomes. Regular, vigorous exercise may reduce these health risks and improve behavior and academic engagement for students with ASD. Few studies have examined the impact of exercise on well-being for adolescents with moderate to severe autism. Moreover, much of the past research has relied on subjective measurements of activity, such as heart rate and flushed faces, and small samples.
Objectives: The goal of the present study is to extend our understanding of the impact of vigorous exercise on behavioral and academic outcomes for adolescents with moderate to severe ASD, using objective measures of activity (Metabolic Equivalent Tasks or METs). We hypothesized that more vigorous (6-9 METs), but not strenuous (9+ METs), activity would predict fewer problematic behaviors and greater academic engagement during the school day.

Methods: The sample consisted of 21 junior high students (2 female) with ASD, recruited from four classrooms in a school for children with ASD in the Northeast. Mean age was 15.67 years (*SD* = 0.73). A research assistant reliable on the Autism Diagnostic Observation Schedule conducted ADOS-2 assessments and teachers completed the Child Behavior Checklist (CBCL/6-18) at baseline. Two of the classrooms were randomly assigned to jog outside for 20 minutes at the start of each school day for weeks 1 and 2, while the remaining two classrooms walked, stretched, and engaged in less vigorous activity at the same time (also outside). The conditions were counterbalanced in weeks 3 and 4. Immediately following the exercise period, students were videotaped during a standardized Basic Study lesson for 20 minutes. Students wore an Omron 750C accelerometer on their waist band during the school day that tracked METs at 10 second intervals. Teachers completed student behavior logs (e.g., tantrums, noncompliance, aggression) and a modified version of the Problem Behavior subscale of the Scales of Independent Behavior-Revised (SIB-R) on a randomly selected "target day" each week. Research assistants blind to student condition coded on and off task behaviors during Basic Study using the Behavioral Observation of Students in Schools (BOSS) on each student's "target day".

Results: The number of minutes of vigorous activity was significantly higher for students in the jogging condition, $t(20) = -8.09$, $p < .001$. Hierarchical linear modeling was used to examine the impact of vigorous exercise on outcomes. Analyses controlled for week number (Level-1), autism symptoms and externalizing behavior problems measured at baseline (Level-2). Greater vigorous exercise predicted significantly fewer behavior problems (Table 1). Students spent a significantly higher percentage of their time on task during the Basic Study lesson on days with greater vigorous activity.

Conclusions: Findings from the present study suggest that school-based exercise programs for adolescents with ASD may improve student outcomes by minimizing disruptive behaviors in the classroom and improving academic engagement. This is the first study to our knowledge to examine the effects of vigorous exercise in adolescents with ASD.

204 **146.204** The Effect of Music on Exercise Intensity Among Children with Autism Spectrum Disorder

A. C. Woodman[1]*, E. Breviglia*[2]*, Y. Mori*[3]*, R. Golden*[4]*, J. Maina*[3] *and H. Wisniewski*[2]*, (1)University of Massachusetts Amherst, Amherst, MA, (2)Psychological and Brain Sciences, University of Massachusetts Amherst, Amherst, MA, (3)Boston Higashi School, Randolph, MA, (4)Boston Children's Hospital, Boston, MA*

Background: Children with autism spectrum disorder (ASD) are at risk for obesity and other health problems as a result of insufficient exercise. Past research suggests that vigorous exercise can yield immediate improvements in challenging behavior, sleep, and academic engagement as well as physical and mental health over the life course for people with ASD. To date, little research has identified strategies to motivate children-particularly young children-with ASD to engage in levels of physical activity analogous to their peers.

Objectives: The present study aimed to extend this limited body of literature on motivation and exercise by examining the effect of music on exercise intensity in elementary school children with ASD. It was expected that exercise intensity would be greatest when fast music was playing, followed by slow music then no music. Potential moderating factors (e.g., student gender, age, body mass index, adaptive skills, behavior problems, autism symptom severity) were explored.

Methods: The sample consisted of 13 elementary school children (2 female) with ASD, recruited from a school for children with ASD in the Northeast of the United States. The mean age was 9.31 years (*SD* = 2.25), with a range from 5 to 13 years. Teachers completed a baseline booklet of questionnaires about participating children, including measures of adaptive skills (Waisman Activities of Daily Living Scale, Maenner et al., 2013), behavior problems (Problem Subscale of the Scales of Independent Behavior Revised, Bruininks et al., 2016), and autism symptom severity (Autism Spectrum Quotient-Children's Version, Auyeung et al., 2007). Child age, gender and body mass index were obtained from the nurse's office with parents' permission. Data on exercise intensity were collected on six days within a 16-day period. Each morning, students jogged alongside their teachers for 20 minutes (structured exercise period). Later in the morning, students were encouraged to jog again for 20 minutes around a circle of cones in the gymnasium, with minimal prompting from teachers (unstructured exercise period). On each of the six days of data collection, students listened to either fast music, slow music, or no music across both jogging periods (two days for each condition). Accelerometers were placed on students' waistbands to measure exercise intensity every 10 seconds as Metabolic Equivalent Tasks (METs). Vigorous exercise was operationalized as the percentage of 10-second intervals within the exercise period that exceeded 6 METs, in line with current definitions from the World Health Organization.

Results: A one-way repeated measures ANOVA with post-hoc tests was conducted with music condition as the independent variable and vigorous activity as the dependent variable. Music condition had a significant effect on vigorous activity in the unstructured, but not structured, exercise period. Vigorous exercise was significantly higher during the slow music condition, compared to the no music condition. This effect was significantly moderated by adaptive behavior, such that only children with low or average levels of adaptive skills showed heightened vigorous exercise in response to slow music.

Conclusions: Music may be a helpful tool for school-based exercise programs to motivate youth with ASD to engage in vigorous exercise.

205 **146.205** Impacting Real World Social Outcomes: An Examination of Changes in Social Engagement and Friendships Associated with START Program Participation

S. J. Cohen[1]*, T. W. Vernon*[1]*, J. A. Ko*[1]*, A. Miller*[2]*, A. Barrett*[1] *and E. McGarry*[1]*, (1)University of California Santa Barbara, Santa Barbara, CA, (2)University of California, Santa Barbara, Santa Barbara, CA*

Background: Adolescents diagnosed with Autism Spectrum Disorder (ASD) frequently have difficulty making and sustaining friendships, which can lead to adverse consequences later in life (Mazurek, 2014). Group-based social skills interventions, have been shown to be effective in helping teens with ASD improve their performance on a variety of social skills (e.g. Laugeson et al., 2012; Vernon et. al., 2016). The ultimate aim of improving social competencies is to create a pathway towards meaningful change in the social lives of the participants; however, the extent to which program participation impacts real-life social success, such as making friends and engaging in social outings and activities on a regular basis, remains largely unknown.

Objectives: The purpose of the present study was to use self- and parent-report data collected in a randomized control trial of the Social Tools And Rules for Teens (START) intervention to provide insight into the impact of the program on real-life social outcomes. Specifically, the investigators sought to determine if participants and their parents independently endorsed increases in, (1) telephone contact with others, (2) extended and received invitations for get-togethers, (3) structured and unstructured social activities, and (4) number of friendships.

Methods: A randomized control trial (RCT) was conducted with 35 participants. Data were obtained from 16 participants in the treatment condition and 19 in the waitlist condition. Participants in the treatment condition (and later the waitlist group) engaged in a 20-week social skills group with a structured curriculum, covering a variety of key social skills including introductions and initiations, conversation skills, and higher order social skills such as sportsmanship, humor, and social media use. In addition to standardized measures and observational conversation skill data (reported elsewhere), all participants and their parents were asked to complete pre- and post-intervention surveys regarding frequency of phone communication, invitations for get-togethers, social activities, and reported friendships. Data were analyzed using a mixed group x time MANOVA with follow-up ANOVAs to identify specific survey items with significant differences.

Results: Results revealed a significant Time x Group interaction in the total number of friends reported by the adolescent participants (p = 0.025), as well as a trend in number of participant-reported invitations received (p = 0.067). Analyses also revealed a significant Time x Group interaction in parent reports of total number of friends (p = 0.001), as well as a trend for number of unstructured social activities (p = 0.084).

Conclusions: Results suggest that there were measurable real-world differences that occurred as a result of participation in the START intervention program. Most notably, an increase in the total number of friends reported by both the parents and adolescents suggest that the skills gained in the START program may generalize to other settings and result in meaningful change in the lives of these adolescents. Overall, the results suggest that the START program successfully targets social competence and motivation barriers that impede optimal social success in adolescence.

206

146.206 Improvement in Social Functioning Following Participation in TUNE in, a Novel Cognitive-Behavioral Treatment Program – Results from a 2nd Cohort of Adults with ASD

A. A. Pallathra[1], *J. Day-Watkins*[2], *M. E. Calkins*[3], *B. B. Maddox*[3], *J. S. Miller*[4], *J. Parish-Morris*[5], *J. D. Herrington*[4], *S. Kangovi*[3], *R. Tomlinson*[6], *T. A. Creed*[7], *C. M. Kerns*[8], *W. Bilker*[9], *F. Handy*[3,10], *J. Connell*[11], *G. S. Dichter*[12], *D. S. Mandell*[13], *R. T. Schultz*[5] *and E. S. Brodkin*[14], *(1)Department of Psychiatry, Catholic University of America, Washington, DC, (2)Drexel University, Philadelphia, PA, (3)University of Pennsylvania, Philadelphia, PA, (4)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (5)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (6)Temple University, Philadelphia, PA, (7)Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA, (8)University of British Columbia, Vancouver, BC, Canada, (9)Univ of Pennsylvania, Phila, PA, (10)School of Social Policy and Practice, University of Pennsylvania, Philadelphia, PA, (11)AJ Drexel Autism Institute, Philadelphia, PA, (12)Psychiatry, University of North Carolina, Chapel Hill, NC, (13)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (14)Department of Psychiatry, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

Background: Impairments in social functioning—the ability to navigate the social world and form and maintain relationships in community settings—are among the most critical challenges faced by individuals with autism spectrum disorder (ASD). Social functioning difficulties become particularly problematic in adulthood, when expectations for skillful social functioning increase. However, there are few evidence-based social functioning treatment programs for adults with ASD beyond their early twenties (Bishop-Fitzpatrick et al., 2013, Spain and Blainey, 2015). TUNE In (Training to Understand & Navigate Emotions and Interactions) is an integrated, three-part cognitive-behavioral intervention, which targets the multiple behavioral categories underlying social functioning (social motivation, social anxiety, social cognition, social skills) in adults with ASD, and has components to generalize new social understanding and social skills to community settings. In a first group of adults with ASD to complete TUNE In, we reported significant improvements in overall social functioning, as measured by the Social Responsiveness Scale-2 (SRS-2) and the Social Network Index – Number of People in Social Network Subscale (SNI) (Pallathra et al. 2017, IMFAR). We hypothesized that a second cohort of adults with ASD would show the same improvements in SRS-2 and SNI following TUNE In treatment.
Objectives: To assess the effects of TUNE In on social functioning in adults with ASD.

Methods: Adults with ASD and without intellectual disability were recruited for the study. TUNE In consists of 17 weekly sessions divided into three consecutive components addressing (1) social motivation/anxiety, (2) social cognition/social skills, and (3) generalization of skills to community settings (Pallathra et al. 2017, IMFAR). Participants underwent assessments of social functioning before starting (Time 1) and after completing (Time 2) TUNE In. Based on our previous results (Pallathra et al. 2017, IMFAR), we tested the hypothesis that this second cohort would also show an improvement in the SRS-2 (informant-report) and the SNI (Cohen, 1991), a self-report assessment of social network size. A paired analysis was performed to assess changes in outcome measures between Time 1 and Time 2, using the nonparametric Signed Rank Test, because the data were not normally distributed.

Results: Fifteen adults were enrolled into this second treatment group, of which 13 completed TUNE In (Table 1). Results demonstrate evidence of social functioning improvements from Time 1 to Time 2 as reflected by a significant reduction in the SRS-2 score (z=2.76, p<0.01, Cohen's effect size, d=0.44) (Figure 1a) and a significant increase in the SNI score (z=-2.25, p<0.05, d=0.38) (Figure 1b).

Conclusions: Data from this study replicate the findings of improvement in social functioning, as reflected by the SRS-2 and SNI, following participation in TUNE In. These results suggest there are benefits to the integrated service strategy of TUNE In that targets multiple behavioral domains underlying social functioning and provides opportunities for skill generalization. A randomized control trial of TUNE In with a larger sample size and with greater inclusion of women, minorities, and older age groups is warranted in order to address the urgent need for evidence-based treatments targeting social functioning in adults with ASD.

207

146.207 Improving Conversational Fluidity in Adults with Autism Spectrum Disorder

D. Tagavi[1], *R. L. Koegel*[2] *and L. Koegel*[3], *(1)University of California, Santa Barbara, Santa Barbara, CA, (2)Stanford Medical School, Stanford, CA, (3)Stanford University School of Medicine, Palo Alto, CA*

Background: Young adults with ASD often demonstrate significant challenges in their social conversation skills, including difficulty with conversational fluidity (reciprocal, to-and-fro conversation) and social pragmatics. Previous research has demonstrated that with appropriate intervention, these individuals can make significant improvements in this area. In particular, video-based interventions may be useful for this population because of frequently observed strengths in visual perception skills and sustained attention with this medium (Sherer et al., 2001; Bellini & Akullian, 2007). Video-feedback, which involves the viewing and evaluating of a client's previously filmed performance, has shown promise as an effective means to improve social initiations and general social communication skills in individuals with ASD (Koegel, Ashbaugh, Navab, & Koegel, 2016; Maione & Mirenda, 2006), but it is unclear if this type of intervention can improve conversational fluidity in high-functioning adults, specifically.

Objectives: This study evaluated the merits of using a tailored video-feedback intervention to improve conversational fluidity and overall social conversational desirability in young adults with ASD.

Methods: Three adults ages 19–26 participated in this study. Each adult had a diagnosis of ASD according to current criteria of the DSM-5. Participants demonstrated difficulties with social communication skills and conversational fluidity, as noted by the referring agency, direct observations, and self-report. A multiple baseline design across participants was used to assess the effects of the video-feedback intervention on level of conversational fluidity and social desirability. During baseline sessions, participants engaged in a 10-minute, video-taped conversation, in which the conversational partner purposely created an unnatural (three second) pause at least once per minute. During intervention sessions, participants were shown video clips of opportunities for conversational fluidity. Each participant was instructed to think of filler words or follow-up or novel questions they could have communicated to fill the gap in the conversation. The participant and clinician role played the exchange to ensure the participant could effectively implement the skills. Video-recorded conversation probes with novel peers were collected every session. Dependent measures included (1) level of conversational fluidity, defined as the percentage of minutes in the conversation with no pauses lasting three seconds or more; and (2) rating of social desirability, as rated by age-matched peers who were blind to study aims and time point.

Results: Preliminary results indicate that all participants increased their conversational fluidity and ratings of social desirability in the context of a multiple baseline design. Participants increased from a mean of 15% of conversationally fluid intervals to 90% of intervals (an increase indicative of a large effect size). Participants also increased their rating of social desirability from an average score of 1.5 (“undesirable”) to 4 (“desirable”). These effects generalized one month after completion of the intervention.

Conclusions: Results of this study demonstrate the promise of video-feedback interventions to improve conversational fluidity and other social communication skills among adults with ASD. The results highlight the utility of implementing these interventions in practice and suggest that future research on improving reciprocal conversation in adults with ASD may be highly lucrative.

208 **146.208** Improving Daily Living Skills in College Students with Autism Spectrum Disorder Using a Peer-Mediated Daily Living Checklist Intervention

E. Engstrom[1]*, R. L. Koegel*[2] *and M. Higgins*[3]*, (1)Koegel Autism Center, UCSB Koegel Autism Center, Santa Barbara, CA, (2)Stanford Medical School, Stanford, CA, (3)UCSB Koegel Autism Center, Santa Barbara, CA*

Background:

Research suggests individuals with Autism Spectrum Disorder (ASD) have difficulties with daily living skills that affect adaptive behavior, which are a major barrier to success in higher education settings and beyond. Few interventions target the improvement of daily living skills within this population, with even fewer targeting college students. Since interventions that integrate motivational and peer-mediated components have improved social communication in college students with ASD, it is possible that incorporating these methods into a daily living checklist, a type of self-management intervention, may lead to greater improvements in daily living skills for this population as well.

Objectives:

The purpose of this study is to assess whether the use of peer-mediated motivational components would increase the number of daily living tasks completed per week. In addition, data will be collected to systematically examine if this intervention will improve overall adaptive behavior, mental health, quality of life, and academics.

Methods:

Participants included three adults between 18 and 26 years diagnosed with ASD according to DSM-5 criteria. Participants were full time students in a four-year university, had average intellectual functioning, and demonstrated difficulties in daily living skills.

A multiple baseline across participants with reversals design was used, in which a baseline condition with a self-management daily living checklist without peer-mediation was compared to a peer-mediated intervention condition where individualized prompts were provided to complete the self-management daily living checklist.

The primary dependent measure was the total number of daily living tasks completed per week. Additionally, secondary data was collected for the following measures pre and post intervention: (1) Vineland Adaptive Behavior Scales- 3rd Edition (2) Beck Depression Inventory-II; (3) Beck Anxiety Inventory; (4) Quality of Life Assessment for Adults with ASD; and (5) quarterly grade reports.

Results:

Preliminary data from two participants suggest that a peer-mediated daily living checklist intervention is effective in increasing frequency of daily living skills in college students with ASD. At baseline, Participant 1 completed an average of 5 tasks per week. After the peer-mediated intervention began, Participant 1 increased the number of completed tasks to an average of 13.5 tasks per week. At baseline, within the context of a reversal design, Participant 2 completed an average of 13.5, 20, and 24 tasks per week, respectively. After the intervention began within the reversal design, Participant 2 increased the number of completed tasks to an average of 33, 30, and 40 tasks per week, respectively. Preliminary data show medium to large effect sizes. Follow up data will be completed one month after the completion of the intervention. Additional analyses will confirm these findings in three participants and across pre-post measures.

Conclusions:

Preliminary results show promise that this peer-mediated intervention may be more effective in improving daily living skills among college students with ASD than without peer-mediation. The results suggest that future research on improving daily living skills for college students with ASD may be highly profitable.

209 **146.209** Improving Emotion Regulation in Teens with Autism through Mindfulness

S. W. White[1]*, C. M. Conner*[2]*, K. B. Beck*[3] *and C. A. Mazefsky*[2]*, (1)Psychology, The University of Alabama, Tuscaloosa, AL, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Rehabilitation Science & Technology, University of Pittsburgh, Pittsburgh, PA*

Background: Research indicates that impaired emotion regulation (ER), or the ability to modulate one's arousal and emotional state, underlies many of the co-occurring psychiatric and behavioral concerns that are frequently seen in ASD (Mazefsky & White, 2014). The majority of psychosocial treatment research in ASD has focused on the remediation of anxiety in children via cognitive-behavioral therapy (CBT). While largely efficacious, response has been variable with effect sizes lower than in non-ASD youth (Kreslins et al., 2015); further, anxiety protocols generally do not address other common problems such as explosive behavior, meltdowns, irritability, anger, and depression that stem from impaired ER. ER impairments may magnify the developmental vulnerability of adolescence for those with ASD who do not have co-occurring intellectual disability. Adolescents with ASD face a critical gap in empirically based treatment options to support the transition to adulthood. To address this significant treatment need, we developed the *Emotion Awareness and Skills Enhancement* (EASE) Program. EASE is a 16-session individual therapy program for verbal adolescents and young adults with ASD designed to improve ER capacity.

Objectives: We sought to develop and evaluate a novel treatment targeting ER impairment in adolescents and adults with ASD. EASE emphasizes awareness of one's own emotional responses as a foundational skill that promotes the ability to manage intense negative emotions, which is taught through mindful awareness. Mindfulness may be ideally suited for improving ER, as it involves cultivating awareness of emotional states and distress tolerance, and an open and accepting attitude through the use of meditative practices and activities (Kabat-Zinn et al. 1985).

Methods: We utilized a participatory action framework for manual development. After development of the first draft of materials, we sought input from individuals with ASD, therapists experienced in MBIs, ASD, and manualized intervention trials, and parents of children with ASD. Refinements to the treatment were made based on feedback received. In a pilot, two-site open clinical trial, eligible participants (i.e., 12-17 years old, confirmed diagnosis of ASD, IQ > 80) received the treatmentulti-method data were collected at pre, post, and three-month follow-up.

Results: Pilot data support feasibility (20 eligible participants enrolled within less than six months), acceptability to consumers (based on quantitative and qualitative data and high retention rates), and viability of dissemination (high treatment fidelity across 8 therapists and 2 sites). Preliminary analyses suggest that EASE is associated with statistically significant improvements with moderate to large effect sizes. Clinical Global Impressions-Improvement (CGI-I) scores (made by an independent rater) that take functioning across environments and overall symptom impairment into account correspond to a mean of "Much Improved" and 100% of participants demonstrated at least some improvement. Declines in emotional reactivity, irritability, and depression were also observed.

Conclusions: EASE is a new mindfulness-based intervention, developed for adolescents and adults with ASD. The primary treatment target is improved emotion regulation, which should have downstream positive effects on socialization, mental health, and more global and functional outcomes.

210 **146.210** Improving Social Motivation, Competency, and Empathy in Young Adults with ASD: Results from a RCT of the START Adult Program

T. W. Vernon*, J. A. Ko, E. McGarry, A. Chiu, R. Graef, E. Prado, C. Torres, K. Chuor, S. Said, J. Littleton and A. Huerta, University of California Santa Barbara, Santa Barbara, CA*

Background: Individuals with ASD often face tremendous challenges during the transition to adulthood (Barnhill, 2007; Engstrom, Ekstrom, & Emilsson, 2003; Howlin, 2000; Hurlbutt & Chalmers, 2004). Specifically, a sharp increase in social and independent living demands are often paired with an equally jarring reduction is crucial support services. The transition to post-secondary and vocational settings requires a number of interrelated social readiness skills, including adequate social motivation and competency to successfully navigate interactions across novel situations and settings. Fortunately, there is a growing recognition of the need to address the unique socialization difficulties of this burgeoning population (Williams-White et al, 2007). Intervention programs specifically designed to equip young adults with a variety of socialization strategies may hold promise for improving their experienced success during this daunting time of transition and change.

Objectives: To evaluate preliminary outcomes associated with participation in the Social Tools And Rules for Transitions (START) Program for Young Adults in the context of a randomized controlled trial.

Methods: A randomized controlled trial was used to investigate outcomes associated with the START for young adults group intervention model. The participants were young adults (aged 18-25) with an ASD diagnosis who had a verbal IQ over 70 and fluent language use. Participants were randomly assigned to immediate or waitlist control groups for 20 weeks. Those in the immediate treatment group participated in the START program for young adults, a weekly 90-minute peer-facilitated experiential socialization program based loosely on the structure of the adolescent model (Vernon, Miller, Ko, Barrett, McGarry, 2017). Program components included a weekly social outing with a same-aged peer, free socialization periods, an interactive social topic discussion, structured games and activities, and individual check-in and check-out sessions. Weekly topics included crucial conversation skills, relationship maintenance, dating and romantic relationships, social momentum, employment, and shared living space considerations. Measures included the Social Motivation & Competency Scale (SMCS), Empathy Quotient (EQ), Behavior Assessment System for Children Third Edition (BASC-3) – College Self-Report, and Social Responsiveness Scale (SRS). Data is being analyzed with a mixed Group X Time mixed MANOVA with follow-up ANOVAs for individual variables.

Results: Data from 22 participants analyzed thus far are indicative of significant Group X Time differences on both the SMCS and EQ Scores. Additional analyses of the BASC-3 subscales and SRS scores are currently underway.

Conclusions: Preliminary results are indicative of significant improvements in START participants' social motivation, competencies, and empathy. These data indicate that this comprehensive socialization intervention may hold promise for improving the complex, multifaceted social vulnerabilities of young adults with ASD. During a time in which social demands shift dramatically, this program appears to significantly improve social motivation to engage with peers, the competencies to facilitate successful interactions, and empathy to foster deeper personal and professional relationships.

211 **146.211** Internet-Based Psychoeducational Intervention for Youths with ASD

A. Backman[1,2]*, A. Mellblom*[2]*, E. Norman-Claesson*[2]*, G. Keith-Bodros*[2]*, S. Bolte*[3] *and T. Hirvikoski*[2,4]*, (1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden, (2)Habilitation & Health, Stockholm County Council, Stockholm, Sweden, (3)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (4)Karolinska Institutet, Stockholm, Sweden*

Background: The recommended support for youths with ASD include interventions to facilitate coping with life challenges and improving social skills, as well as treatment of psychiatric comorbidity, by using e.g. cognitive behavioral therapy. The number of intervention trials with satisfactory quality is low, especially regarding transitioning youths with ASD. Psychoeducation has been recommended as a first-line post diagnostic intervention. Only a couple of previous studies have described psychoeducational interventions for individuals with ASD. However, these studies have shown preliminary promising results in teaching the participants about ASD. Internet-delivered treatment options for youths with ASD have scarcely been developed and evaluated. This may be considered surprising, considering the possible reservations among youths with ASD to participate in traditional interventions from health care organisations, as well as the group´s good capacity and willingness to utilize computer-mediated communication.

Objectives: The objective of the open feasibility study was to evaluate feasibility, treatment credibility and satisfaction, as well as preliminary efficacy of an internet-based psychoeducational intervention named SCOPE (Spectrum COmputerized PsychoEducation), for youths with autism spectrum disorder (ASD without intellectual disability), in an outpatient clinical context of disability services in Sweden.

Methods: The internet-based psychoeducational intervention, consisting of eight ASD themed modules, was developed in cooperation with youths with ASD. The internet-based delivery was chosen to utilize the interactive pedagogical potential of the Swedish national platform for internet-delivered treatment. The intervention includes weekly contact with an experienced clinician via a message-function. The youths (16 – 25 years of age; n=28) completed self-rating scales measuring knowledge about ASD, mental well-being, as well as acceptance of their diagnosis and quality of life.

Results: Treatment feasibility was good in the clinical context: 79% of the participants completed at least 6 out of 8 modules in the program. Treatment credibility was good and increased from pre- to post-treatment. Participants' knowledge about ASD increased significantly from pre- to post-treatment, and the increase in knowledge was not associated with negative effects on psychological well-being. The three-month follow-up showed that the participants had retained their knowledge, and also had improved acceptance of diagnosis.

Conclusions: Internet-delivered psychoeducation is a promising, new treatment method for youths with ASD. An ongoing randomized controlled study will generate further evidence concerning the SCOPE intervention.

212 **146.212** Is Eye Movement Desensitization and Reprocessing Effective in Adults with an Autism Spectrum Disorder and Comorbid Post Traumatic Stress Disorder?

S. Piening[1]*, A. van Dijk*[1]*, N. Mirzaeva*[1]*, P. Huizinga*[1]*, M. Vieira Rocha*[1]*, S. P. Dijkstra*[1] *and I. D. van Balkom*[1,2]*, (1)Autism Team Northern Netherlands, Jonx (Lentis), Groningen, Netherlands, (2)Lentis Psychiatric Institute, Zuidlaren, Netherlands*

Background:

People with an autism spectrum disorder (ASD) are more likely to experience traumatic events and to develop post traumatic stress disorder (PTSD). Eye Movement Desensitization and Reprocessing (EMDR) is an effective treatment option for PTSD, but its effect on adults with ASD and comorbid PTSD is largely unknown.

Objectives:

To study the effectiveness of EMDR in adults with ASD and comorbid PTSD.

Methods:

In this before-after study, adults with ASD and comorbid PTSD (diagnosed according to DSM criteria) filled out Dutch versions of three self-report questionnaires: the Impact of Event Scale (IES-R; assessing trauma symptoms); the Social Responsiveness Scale Adult (SRS-A; assessing ASD symptoms) and the World Health Organization Disability Assessment Scale 2.0 (WHODAS 2.0; assessing social functioning). Treatment was given by experienced and qualified psychologists. Repeated measures ANOVA were performed to assess any significant differences in total scores of the questionnaires. A distinction was made between patients with single versus multiple traumas.

Results:

To date twelve service users have been included in the study (n=3 females; aged 18 to 41; five participants with multiple traumas). Preliminary results show that EMDR reduced PTSD symptoms significantly at group level (F(1,11)=7.76, p=0.02). Half of the participants did not meet the PTSD criteria anymore after EMDR treatment. ASD characteristics and social functioning did not improve significantly at group level (F(1,11)=0.01, p=0.92) and F(1,11)=0.10, p=0.76), respectively). However, a significant improvement in social functioning was observed for the single trauma group (F(1,4)=27.24, p=0.006). When looking at individual results, scores for ASD-characteristics improved in 8 of 12 participants and social functioning improved in 9 of 12 participants.

Conclusions:

EMDR appears to be effective in reducing PTSD symptoms, but not ASD symptoms and social functioning in patients with ASD and comorbid PTSD. Data collection will continue to facilitate a more reliable conclusion regarding the effect of EMDR in patients with ASD and comorbid PTSD.

213 **146.213** Long-Term Social Skills Group Training in Children and Adolescents with Autism Spectrum Disorder Indicates a Dose-Response Relationship: A Randomized Controlled Trial

S. Bolte[1]*, N. Choque Olsson*[2]*, U. Jonsson*[3]*, K. Tammimies*[4]*, S. Berggren*[3] *and C. Coco*[3]*, (1)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (2)Clinical Neuroscience (CNS), Karolinska Institutet, Stockholm, Sweden, (3)Karolinska Institutet, Stockholm, Sweden, (4)Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Background: Social skills group training (SSGT) is widely used for intellectually able children and adolescents with autism spectrum disorder (ASD). Previous studies indicate small to moderate effects on social communication capacities. Objectives: We hypothesized that an extended training program would result in larger effects. Methods: This randomized controlled trial compared 24 weekly sessions of the SSGT program KONTAKT with standard care alone. The SSGT combined a previously evaluated 12 session version of KONTAKT with 12 additional sessions designed to facilitate generalization of acquired skills to real-world settings. A total of 50 participants with ASD (15 females; 35 males) aged 8-17 years were included. The study was conducted at two child and adolescent psychiatry outpatient units in Sweden. The primary outcome was the

Social Responsiveness Scale -2 (SRS-2) rated by parents and blinded teachers. Secondary outcomes included parent- and teacher-rated adaptive behaviors, trainer-rated global functioning and clinical severity, and self-reported child and caregiver stress. Assessments were made at baseline, post-treatment, and at 3-months follow-up. Results: Parent-rated SRS-2 scores indicated large effects post-treatment (-19.2; 95% CI, -29.9 to -8.5; *p* < .001, effect size [ES] = 0.76), which were maintained at follow-up (-20.7; 95% CI, -31.7 to -9.7; *p* < .0001, ES = 0.82). Conclusions: These estimates indicate substantially larger improvement than previously reported for shorter SSGT. However, the effects on teacher-rated SRS-2 and most secondary outcomes did not reach statistical significance. These preliminary results indicate a dose-response relationship, and imply that service providers can reach better results by optimizing the length of SSGT.

214 **146.214** Managing Anxiety in Autism: A Pilot Trial of Newly Developed Psychoeducation Toolkits

R. Kent[1]*, S. Carruthers*[2]*, L. Bridge*[3]*, A. Ozsivadjian*[4] *and E. Simonoff*[5]*, (1)Institute of Psychiatry, Psychology and Neuroscience, Kings College London, London, United Kingdom of Great Britain and Northern Ireland, (2)King's College London, London, United Kingdom of Great Britain and Northern Ireland, (3)Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (4)St. Thomas Hospital, Evelina London Children's Hospital, london, UNITED KINGDOM, (5)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom*

Background: Additional psychiatric disorders are common in individuals with ASD especially co-occurring anxiety, with around 40% of individuals meeting diagnostic criteria for an anxiety disorder and 80% experiencing symptoms (White et al., 2009). Although modified cognitive behavioural therapy has been shown to be effective at reducing anxiety in young people with ASD (Sukhodolsky et al., 2013), it is likely that not all people with ASD and milder anxiety require specialist one to one therapy. Furthermore, such specialist interventions may not be universally available. Self-help programmes have the benefits of wide accessibility and availability without a referral. Effectiveness of self- or parent-facilitated programmes based on CBT principles have been demonstrated for anxiety in people without ASD (Lucksted et al., 2012) but have been understudied in ASD populations.

Objectives: To develop and evaluate a set of psychoeducation self- or parent-led toolkits in collaboration with clinical professionals aimed at recognising and managing anxiety in young people with ASD.

Methods: Young people with ASD experiencing clinically significant anxiety, as measured at baseline using the Screen for Anxiety and Related Disorders (SCARED; Birmaher et al., 1999), were recruited from mental health services in South London, UK. Thirty four participants aged 8-18 years old were randomised to receive the psychoeducation intervention either immediately or after a 4 week delay. Parents completed questionnaires at baseline, at Time 1 four weeks later (post-intervention for the immediate start group) and at Time 3 eight weeks later, young people also completed questionnaires where possible. The primary outcome was a study-specific measure of parental knowledge and confidence and secondary outcomes were total anxiety (SCARED) and quality of life scores (KidScreen-10 index; Ravens-Sieberer et al., 2010). All measures were completed at the three time points.

Results: Intention to treat analyses explored effect sizes at Time 2 for primary and secondary outcomes, with the recognition that small sample sizes would likely render results non-significant, which was the case. Cohen’s d effect sizes (ES) revealed small effects of the randomisation group on knowledge and confidence score (0.26; 95% CI: -0.46 – 0.98) and anxiety symptoms (-0.22; 95% CI: -0.94 – 0.50) and a moderate (but non-significant) ES for quality of life (-0.40; 95% CI: -1.12 – 0.33). At the end of the intervention, all but one parent said they would recommend the toolkit to other families with 63% being very likely to recommend. Ninety three percent of parents reported their knowledge improved, 96% that it was useful in helping them understand their child’s anxiety and 61% said there was improvement in their child’s anxiety after 4 weeks.

Conclusions: Statistical analyses were limited due to the small sample size of the pilot trial. From qualitative feedback, it is likely that four weeks was too short to read the toolkits and implement the suggested management strategies. The study-specific knowledge and confidence questionnaire was not tested for sensitivity to change and many parents reported high baseline levels, leaving little room for improvement. Acceptability of the toolkits was positive and supports further development and evaluation of the materials.

215 **146.215** Meta-Analysis of Group Social Skills Interventions Using the SRS in Children with High Functioning Autism Spectrum Disorders

J. Wolstencroft[1]*, W. Mandy*[2] *and D. H. Skuse*[3]*, (1)UCL GOS ICH, London, United Kingdom, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland, (3)Behavioural and Brain Sciences Unit, Population Policy and Practice Programme, UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom*

Background:

Social skills deficits are an important target for intervention for children with Autism Spectrum Disorders (ASD) because they have a significant impact on academic, adaptive and psychological functioning. Group social skills interventions (GSSIs) are one of the most popular treatments recommended for children with high functioning ASD. Previous meta-analyses of GSSIs have evaluated the efficacy of GSSIs by combining the scores of different social skills assessments, despite evidence that these tools may be measuring different underlying constructs. As a high proportion of GSSIs now use the Social Responsiveness Scale (SRS), this presents an opportunity to examine which domains of social skills are changed by intervention.

Objectives:

Conduct a meta-analysis of multimodal GSSI randomised controlled trial studies using the SRS as parent-report outcome measure.

Methods:

Online electronic searches were conducted on four databases. The search used medical subject heading key terms including ‘social skills’ and ‘group interventions’. Two independent reviewers rated the abstracts against the eligibility criteria (1) age (6-25years), (2) no intellectual disability, (3) multi-modal GSSI, (4) conducted and assessed in English, (5) used Social Responsiveness Scale (SRS). The Cochrane Collaboration tool Risk of Bias (RoB) v2 tool was used to assess bias. Authors were contacted for unpublished total scores and subscale scores for the meta-analysis.

Results:

The initial electronic search returned 593 articles after duplicates were removed. 9 studies that met criteria for eligibility were retained for RoB analysis, after which one study was excluded from the meta-analysis due to poor study methodology. SRS total and subscale scores were available from 7 studies following correspondence with authors.

Participants that received a GSSI obtained better outcomes than the control group on the total standardised score (SMD= -0.85, 95% CI [-1.12,-0.59], Z= 6.35, p=0.000) and all the SRS subscales. The effect sizes on the social communication (SMD= -0.89, 95% CI [-1.2,-0.59], Z= 5.71, p= 0.000) and ritualised and repetitive behaviours subscales (RRB; SMD= -0.9, 95% CI [-1.23,-0.57], Z=5.4, p=0.000) were large. The effect sizes for the social awareness (SMD= -0.57, 95% CI [-0.87,-0.28], Z= 3.78, p= 0.000), social cognition (SMD = -0.53, 95% CI [-0.98,-0.09], Z= 2.34, p= 0.019) and social motivation subscales (SMD= -0.55, 95% CI [-1.02,-0.07], Z= 2.27, p= 0.023) were moderate.

Conclusions:

Large and significant effect sizes in the SRS on social communication as well as the RRB subscales suggests that GSSIs had the largest impact on these domains. Improvements on the RRB subscale were unexpected, as the teaching materials of GSSIs do not explicitly target the reduction of these behaviours. One hypothesis might be that the cognitive and emotional skills taught during GSSIs such as cognitive flexibility, problem solving or controlling emotional impulses are mediating this change. It may be that these skills help to make the participants more confident and less anxious in social situations, which in turn reduces their restrictive and repetitive behaviours.

216 **146.216** Mindfulness-Based Program for Autism Spectrum Disorder: A Qualitative Study of the Experiences of Children and Parents

A. Ridderinkhof[1], *E. I. de Bruin*[1], *R. Blom*[2] *and S. M. Bögels*[1,3], *(1)Research Institute of Child Development and Education, University of Amsterdam, Amsterdam, Netherlands, (2)Child and adolescent psychiatric center Karakter, Zwolle, Netherlands, (3)Academic outpatient child and adolescent treatment center UvA minds, Amsterdam, Netherlands*

Background: Effective psychosocial intervention options for children with autism spectrum disorder (ASD) are sparse. Mindfulness-based programs for children with ASD and for their parents are a potentially promising approach to improve their quality of life. However, research in the field of mindfulness for ASD is in the beginning stages worldwide. Mindfulness is primarily an internal experience. The way people relate to their internal thoughts, feelings, bodily sensations, and action tendencies is the target of mindfulness trainings. Therefore, it seems valuable to include a qualitative approach to investigate the experiences of children and parents.

Objectives: This study explores what children with ASD and their parents perceive as benefits of a mindfulness-based program with parallel sessions for children and parents, and how they explain the processes that lead to these benefits. Thereby, our aim is to contribute to theory development on how mindfulness-based programs might work for this population from a participants' perspective.

Methods: Participants were 11 children with ASD, aged 9 till 17 years old, and 22 parents (mothers and fathers) that took part in the mindfulness-based program MYmind. MYmind consisted of nine weekly parallel sessions for children and parents of 1.5 h. After two months a booster session took place. The program consisted of educating theory, practicing meditations, and discussing experiences. Thereby, participants trained to pay attention to the present moment with a non-judgmental attitude, including awareness of bodily sensations, feelings, and thoughts, and to cultivate an accepting and compassionate stance towards experiences. Interviews were conducted within six weeks after the booster session and lasted between 30 and 60 minutes. Children and parents were interviewed separately. The interviews were transcribed and incorporated into ATLAS.ti. Guidelines of grounded theory are followed to analyze the data.

Results: Main categories that emerged from the preliminary analyses are acknowledging feelings and thoughts, taking a moment for mindfulness in daily situations, increased calmness, and improved relating to the needs of the child. Several processes seem to lead to the benefits of mindfulness. Participants describe that acknowledging feelings or thoughts leads to choosing how to respond rather than responding automatically, which leads to responding more calmly. Also, acknowledging feelings towards themselves leads to acknowledging feelings of and towards others, which leads to more constructive solutions in the interaction between children and parents. Furthermore, taking a moment for mindfulness leads to increased calmness, which helps to respond less emotionally, to improve school work, or to better fall asleep. Children seem to describe the same constructs as their parents, but with less depth in their explanations.

Conclusions: Children with ASD and their parents are able to give insights into the processes of change following from a mindfulness-based program. This study provides a participants' perspective on how mindfulness-based programs might work for children with ASD and their parents.

217 **146.217** Mindfulness-Based Program for Children with Autism Spectrum Disorder and Their Parents: Direct and Long-Term Improvements

A. Ridderinkhof[1], *E. I. de Bruin*[1], *R. Blom*[2] *and S. M. Bögels*[1,3], *(1)Research Institute of Child Development and Education, University of Amsterdam, Amsterdam, Netherlands, (2)Child and adolescent psychiatric center Karakter, Zwolle, Netherlands, (3)Academic outpatient child and adolescent treatment center UvA minds, Amsterdam, Netherlands*

Background: Children with autism spectrum disorder (ASD) experience difficulties in social interaction, restrictive behavior patterns, and neurocognitive deficits. Also, children with ASD are more stressed and suffer more frequently than typically developing children from comorbid anxiety, depression, and attention problems. In addition, their parents experience increased parenting stress, which leads to mental health problems and deteriorated parenting behavior. Previous research shows that mindfulness-based programs could decrease mental health- and attention problems in various populations, and is hypothesized to improve social communication. A previous pilot study showed that a mindfulness-based program was beneficial for adolescents with ASD and their parents.

Objectives: In this study we investigated a mindfulness-based program for children with ASD and their parents. In doing so, we examined whether this intervention is beneficial for children with ASD with a broad age range, whether social communication problems and common comorbid problems are reduced, whether it is beneficial for their parents, and whether effects last up to one year later. Furthermore, on a neuropsychological level we explored whether children's attention is improved.

Methods: Forty-five children referred with ASD, aged 8 till 19 years old, and their parents participated. The mindfulness-based program MYmind consisted of nine weekly sessions of 1.5 h with parallel sessions for children and parents. The program consists of meditation practices, educating theory, and inquiry of participants' experiences. Repeated measures of children's and parents' social communication problems, emotional and behavioral functioning, mindful awareness, and of parenting were conducted pre-intervention, post intervention, 2-month follow-up, and 1-year follow-up. Children also completed the Attention Network Test (ANT) to index their alerting, orienting, and executive attention networks. In addition, children's and parents' experienced changes as reported on open-ended questions were explored qualitatively.

Results: Children's social communication problems decreased over time, and their emotional and behavioral functioning improved. However, children did not report significant changes in mindful awareness. Results were inconsistent across occasions; improvements reported by children were most substantial at 2-month follow-up and only partly remained at 1-year follow-up, while all children's improvements as reported by parents were present on all occasions. Parents reported about themselves improved emotional and behavioral functioning, improved parenting, and increased mindful awareness on all occasions. Parents' social communication problems were only reduced at post intervention. Most improvements were supported by the themes emerging from the qualitative analysis. Preliminary results on the ANT showed an increase for the alerting score, a reduction for the executive score, and no change for the orienting score after MYmind.

Conclusions: This study suggests that children with ASD with a wide variety of ages and their parents can benefit from a mindfulness-based program by improving children's ASD symptoms and common comorbid problems, parents' mental health problems, parenting, and parental mindful awareness. Most improvements seem to last on the long term. However, differences in the attention network are conflicting. Overall, the results imply that a mindfulness-based program may support families in coping with the demanding consequences of ASD.

218 **146.218** On the Feasibility of Rt-fMRI Neurofeedback Training in ASD: A Clinical Trial Study

***S. Mouga**[1,2], B. Leitão[3], A. Sayal[4], I. Bernardino[5], M. Simoes[4,6,7], G. Oliveira[2,8,9,10] and M. Castelo-Branco[11], (1)IBILI - Institute for Biomedical Imaging and Life Sciences, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, (2)Centro Hospitalar e Universitário de Coimbra - CHUC, Coimbra, Portugal, (3)University of Coimbra, Coimbra, Portugal, (4)Institute of Nuclear Sciences Applied to Health, University of Coimbra, Coimbra, Portugal, (5)Institute for Nuclear Sciences Applied to Health (ICNAS), Coimbra, Portugal, (6)IBILI - Institute for Biomedical Imaging and Life Sciences, Faculty of Medicine – University of Coimbra, Portugal, Coimbra, Portugal, (7)Center for Informatics and Systems, University of Coimbra, Coimbra, Portugal, (8)Faculty of Medicine, Institute for Biomedical Imaging and Life Sciences (IBILI) and Center for Neuroscience and Cell Biology (CNC), University of Coimbra, Coimbra, Portugal, (9)University Clinic of Pediatrics, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, (10)Centro de Investigação e Formação Clínica – Hospital Pediátrico – Centro Hospitalar e Universitário de Coimbra (HP-CHUC), , Portugal, Portugal, (11)CIBIT & IBILI - Institute for Biomedical Imaging and Life Sciences, Faculty of Medicine – University of Coimbra, Portugal, Coimbra, Portugal*

Background: The posterior superior temporal sulcus (pSTS) has been previously identified as part of the face processing core network. It also plays a key role on basic aspects of social information processing, with some imaging studies reporting abnormal function and structure in Autism Spectrum Disorder (ASD).
Advances in functional Magnetic Resonance Imaging (fMRI) allow to feedback *quasi* real-time information about the brain function to the participant (rt-fMRI-neurofeedback). In this sense, the participant learns to volitionally self-modulate the activation of a specific brain region. It has been demonstrated that neurofeedback training alters neural activity and preliminary studies suggest that the approach may represent a viable neurorehabilitation tool.

Objectives: We investigated the feasibility of a neurofeedback-based intervention in ASD, targeting a brain region involved in social cognition - the pSTS.

We aim to a) evaluate patients' acceptability and recruitment over multiple sessions, b) assess preliminary efficacy measures derived from neuropsychological evaluation and imaging data.

Methods: 15 participants (mean age 19y11m) with high-functioning ASD (mean full-scale IQ 103) were invited to enroll in a single-arm feasibility clinical trial. The intervention structure consisted of an initial eligibility screening, pre-intervention (first week of study, baseline measures), 5 sessions rt-fMRI-NF intervention process (4 weekly sessions, fifth one month later), post-intervention, and follow-up (at 6 months).

Each neurofeedback session lasted for approximately 1 hour. During this time, the participants were asked to imagine different facial expressions (as a strategy for volitional control of pSTS activity), while looking at a representation of their own brain activity. The primary outcome measure is the FEEST - Hexagon test - and the secondary outcome measures are the Autism Treatment Evaluation Checklist (ATEC) and Vineland Adaptive Behaviour Scale (VABS). Mood and depression state were also assessed. Regarding imaging data, we assessed a general linear model in our region-of-interest (ROI-GLM) throughout the intervention.

Results: 10 out of 15 patients improved in global ability to recognize expressions according to FEEST. The results present a 13% average decrease in total ATEC (Z=-2.076, p=0.038) rated autism symptoms (23% in Sensory/Cognitive Awareness, Z=-2.446, p=0.014; 21% in Health/Physical/Behaviour, Z=-2.176, p=0.030); 6% average improvement in Adapted Behaviour Composite (Z=-2.768, p=0.006) and in all VABS subareas: 6% in Communication (Z=-2.366, p=0.018), 4% in Daily Living Skills (Z=-2.324, p=0.020), 5% in Socialization (Z=-2.491, p=0.013); 9% average decrease in Total Mood Disturbance (Z=-2.103, p=0.035), 44% in Tension (Z=-2.313, p=0.021); 82% in Depression (Z=-2.139, p=0.032), 64% in Anger (Z=-2.286, p=0.022) and 43% average decrease in mood disturbance/depression, Z=-2.421, p=0.015.

The ROI-GLM analysis suggests that pSTS modulation is possible (42.67% of the runs were successful according to two-tailed t-tests, P-val<0.05). We further explored the data, with an individual assessment of the event-related averages curves, and found evidence for heterogeneity (e.g. participants modulated either positively or negatively to distinct regulation conditions).

Conclusions: These findings support the hypothesis that neurofeedback may represent a viable neurorehabilitation tool. Tailored strategy optimization may represent an important aspect in future studies.

Results emphasize the need to proceed to a two-arm randomized clinical trial to validate the reported preliminary efficacy findings.

219 **146.219** Outcome Evaluation of Personalized Multidimensional Interventions on Children with Low-Functioning ASD through an Innovative Machine Learning System: A Proof of Concept Study.

***K. Hall**[1] and E. Grossi[2], (1)Autism Research Unit, Villa Santa Maria, Tavernerio, Italy, (2)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy*

Background:
Evaluating treatments outcome in children with low-functioning autistic disorder requires the utilization of specific but manageable instruments, both for patients and for their environment (parents, educators, doctors). Few studies so far have focused how use multidimensional data for outcome assessment in residential health settings.

Objectives:

The aim of this study is to highlight the possible outcome prediction of personalized plans of intervention for low-functioning ASD subjects using innovative machine learning systems enabling also to understand which treatment factors are significantly involved.

Methods:

In this pilot observational study, twelve consecutive new patients with low-functioning autism (range of age 3-13 years) have been enrolled between November 2015 and October 2016. Four complementary assessment instruments (*Vineland Adaptive Behavior Scales*, a 540-item questionnaire which evaluate personal and social autonomy, communication and motoric competences; *SDQ-Strenghts and Difficulties Questionnaire-*, a 25-item questionnaire useful to screen emotional, behavioral and social problems in children aged 4-16 years; The *HoNOSCA-Health of Nation Outcome Scale for Children and Adolescents-*, a 15-item clinical assessment scale used as part of the routine outcome monitoring in mental health services, which measures global functioning in patients aged 3-18 years through 4 different areas: behavioral, impairment, symptoms, social functioning; *DC-GAS -Disability Child Global Assessment Scale-*, a dimensional scale used by the clinician to evaluate global functioning in disabled children and adolescents) have been used at the patients first access in the neuropsychiatric clinic and after 6 months of intensive personalized treatment. Vineland Scales and SDQ questionnaire have been completed by educators and parents; HoNOSCA and DC-GAS have been completed by the clinician. Increase of at least 4 points in the DC-GAS total score between baseline evaluation and the assessment after 6 months the has been individuated as main outcome measure. Ninety four variables related to demographic, familiar, therapeutic, pharmacological, medical and checkup information represented the input for preprocessing. An evolutionary algorithm (TWIST system-Semeion) has been used to subdivide the dataset into training and testing set and select features yielding the maximal amount of information. After this pre-processing, 21 input variables were selected and different machine learning systems have been used to develop a predictive model based on a training-testing crossover procedure.

Results:

Eight out of twelve subjects have shown an improved global functioning at the end of the follow-up. The best machine learning system (three-layers feed- forward neural network with 8 hidden nodes) obtained a global accuracy of 83.3% (91.7 % sensitivity and 75% specificity) with a ROC of 0.89. The variables selected for the predictive model included previous pharmacological and non-pharmacological treatments, actual treatment plan, and baseline scores of different subscales of Vineland, SDQ, HoNOSCA and DC-GAS.

Conclusions:

Machine learning systems shows a promising potential in predicting the outcome of personalized multidimensional interventions in low-functioning ASD subjects. Accurate data collection, considering multidimensional aspects, and the use of a complex and complete statistical analysis, as the machine learning systems, could be useful in order to highlight predictable positive treatment factors.

220 **146.220** Parent- Assisted Social Skills Training: The UCLA Peers® (Programs for the Education and Enrichment of Relational Skills)-Thai Version for Adolescents with Autistic Spectrum Disorders in Bangkok, Thailand

N. Sittanomai[1,2]*, V. Boonyasidhi*[2]*, S. Chantaratin*[2]*, J. Tarugsa*[2]*, D. Sainampran*[2]*, V. Sathirangkul*[2]*, S. Apinantanakul*[2] *and N. Songrujirat*[2]*, (1)Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand, (2)Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand*

Background:

Social impairment is one of the challenging problems among high- functioning autistic teenagers worldwide and requires social skills interventions. Programs for the Education and Enrichment of Relational Skills (PEERS®) is a manualized, parent- assisted social skills training for high- functioning adolescents with Autistic Spectrum Disorder (ASD) developed by Semel Institute for Neuroscience and Human Behavior, UCLA, which the effectiveness was proved in western countries. In Thailand, there have been no previous studies regarding any parent- assisted social skills interventions before. Given social and cultural difference between Thailand and the country where PEERS® program was developed, cultural adaptation is one of essential elements of success and acceptance of the intervention among Thai autistic teenagers and their families.

Objectives:

To study the feasibility and effectiveness of The UCLA PEERS® (Programs for the Education and Enrichment of Relational Skills)- Thai Version delivered as an outpatient service for high- functioning adolescents with ASD at Division of Child and Adolescent Psychiatry, Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand. Adaptation of the program to Thai social and cultural context was highlighted.

Methods:

In a retrospective study , 12 high- functioning autistic adolescents were referred from their responsible child psychiatrists for the program in 2015. Parents completed the division intake form. Pre-intervention Clinical Global Impression- Severity (CGI-S) was assessed. The PEERS® - Thai Version was 10- weekly parent- assisted social skills training program with one booster session at 4 months, adapted from the original 14- session program regarding Thai culture. The program was led by a Thai certified PEERS® provider. Pre and post intervention Vineland Adaptive Behavior Scales (Survey Form), Children's Depression Inventory (CDI), Thai version, Clinical Global Impression- Improvement (CGI-I) and parents' behavioral report and satisfactory survey were evaluated. The data was analyzed by descriptive statistics, independent t test and chi-square test.

Results:

The participants' mean age was 14.8±1.99 years, 83.8% were male, and average IQ was 94.7±20.21. All participants studied in regular classes, grade 5- 12. 58.3% were moderately ill, 33.3% were mildly ill and 8.3% were borderline ill. Overall, there was no attrition. The attendance rate of each session was ≥ 80%. Individual attendance rate was ≥ 70%. There were 7 in 10 social skills delivered in the program which at least half of parents reported improvement. Eight skills remained being reported the improvement four months after interventions. Eleven children were clinically improved (1 very much improved, 5 much improved and 5 minimally improved). In regard to Vineland Scales, there were significant increase in raw score for communication, domestic, community, daily living skill, play and social domain as well as decrease in maladaptive behavior domain standard score ($p<0.05$). No significant change demonstrated in CDI. Parents' satisfaction survey was 81.92%.

Conclusions: The UCLA PEERS®- Thai Version is a feasible and promising social skills intervention among Thai adolescents with high- functioning ASD.

221 **146.221** Peer Mediated Intervention for Minimally Verbal Children with Autism Spectrum Disorders; Strength of Evidence and

Future Directions

M. O'Donoghue[1]*, N. Kennedy*[1]*, J. Forbes*[2] *and C. A. Murphy*[1]*, (1)Clinical Therapies, University of Limerick, Limerick, Ireland, (2)Graduate Entry Medical School, University of Limerick, Limerick, Ireland*

Background: Peer mediated intervention (PMI) involves engaging peers in intervention to improve social communication and/or educational outcomes for people with autism spectrum disorder. A number of reviews and meta-analyses have established PMI as an evidenced-based practice for young people with autism (Wong et al 2015; Chan et al 2009; Zhang and Wheeler 2011; Chang and Locke 2016). The majority of research published in this area is with participants who use verbal language to communicate. The evidence base for PMI with minimally verbal children with autism spectrum disorder has not been examined. This group are underrepresented in the research base in general, with Tager-Flusberg and Kasari (2013) describing minimally verbal school-aged children with autism as “the neglected end of the spectrum”. Between 25% and 30% of children with ASD can be classified as minimally verbal (Rose et al 2016). As schools become more inclusive more minimally verbal children are attending mainstream schools. Interventions that foster increased personal contact, such as PMI, may have an important part to play in fostering positive attitudes and creating opportunities for social interaction. This review aims to inform future research on PMI with minimally verbal children by investigating the current evidence base and gaps therein.

Objectives: 1) Investigate studies that implement PMI with minimally verbal children with autism. 2) Evaluate the quality of these studies. 3) Identify the outcomes targeted in these studies. 4) Consider the impact on peers involved in the studies. 5) Identify implications for practice and directions for future research.

Methods: The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) methodology was utilised. Systematic searches of the following databases were conducted: Scopus, Web of Science, Embase, ERIC, PsychInfo and PubMed. There were no restrictions on publication date or language. Studies were included in the review if their method included PMI, the participants were children who were diagnosed with autism and were minimally verbal, and it was an original piece of research; not a review, meta-analyses or commentary. Single case and group-design studies were included. Data on study description, participant characteristics, components of intervention and outcomes, and quality of evidence were extracted from included full texts and narrative synthesis was undertaken.

Results: We present the findings in terms of eligible studies and the quality of the presented evidence. Variation in participant characteristics and processes that were used to select peer participants in the included studies are identified. Findings address details on the components of PMI as described in the studies, and the primary and secondary outcomes. We also consider the impact on the peers involved in the interventions where reported.

Conclusions: This study determines whether PMI can be considered an evidence based practice for minimally verbal people with autism. This will inform future research on PMI with this population, an area determined to require further research (Chang and Locke 2016; Watkins et al 2015).

222 **146.222** Pilot Evaluation of an Adaptive Virtual Reality Based Social Intervention for Teens with ASD

J. W. Wade[1]*, E. Bekele*[1]*, D. Bian*[2]*, A. Swanson*[3]*, A. S. Weitlauf*[4]*, Z. Warren*[5] *and N. Sarkar*[1]*, (1)Vanderbilt University, Nashville, TN, (2)Electrical Engineering & Computer Science, Vanderbilt University, Nashville, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, NASHVILLE, TN, (4)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (5)Vanderbilt University Medical Center, Nashville, TN*

Background: Deficiency in social communication is a core characteristic of individuals with Autism Spectrum Disorder (ASD). Interventions designed to address these deficits, especially those based on innovative technology, show evidence of outcome improvement. However, currently available systems do not fully leverage the ability of technology to utilize sensor-based biofeedback in a manner that is adaptive and individually tailored. Atypical patterns of gaze in individuals with ASD are related to processing and cannot be directly addressed through exclusively performance-based systems. Thus, there is a need to develop and evaluate social intervention technologies capable of utilizing such biofeedback in real time to enhance current approaches.

Objectives: We created and pilot tested a novel social intervention technology called Multimodal Adaptive Social Interaction in Virtual Environments (MASI-VR). In this system, conversations between users and avatars are mediated by a virtual facilitator who gives feedback designed to guide users towards ideal conversational exchanges (i.e., those that are reciprocal and on topic). We hypothesized that MASI-VR would lead to improved emotion recognition accuracy and that group differences would emerge with regards to visual attention.

Methods: MASI-VR consists of a 3D virtual high school cafeteria populated by animated avatars, with whom users verbally communicate using a built-in speech recognition module. Two modes of MASI-VR were developed and tested: one in which task progression depends solely on performance in conversational tasks, and another in which task progression depends on both performance and attention directed towards the emotionally expressive elements of avatars' faces. N=18 teenagers (M=15.24 years of age, SD=1.68) with a clinically verified diagnosis of ASD took part in an IRB-approved study to evaluate the novel system. Subjects were randomly assigned to groups using one of the two modes described above (9 in each group). Training consisted of 30 minutes of exposure to MASI-VR at three different time points. Changes in performance were assessed at two time points (pretest and posttest) using a novel system designed to quantify users' abilities to recognize the seven universally accepted emotions described by Ekman (1993) as presented on animated faces (i.e., fear, joy, surprise, anger, sadness, disgust, and contempt).

Results: All but one participant completed the study. Performance on the emotion recognition task increased significantly in both the performance-based ($p < .05$; 12.05% increase) and gaze-sensitive ($p < .05$; 12.95% increase) groups. With regards to gaze measures, blink rate decreased significantly from pretest to posttest ($p < .05$), and durations of fixation on the mouth decreased while durations of fixation on the forehead and entire face increased (all $p < .05$).

Conclusions: We implemented and pilot tested a novel system for social intervention in teens with ASD. Training with this system demonstrated significant improvements in social skills as measured by accuracy in emotion recognition. Additionally, we found significant changes in patterns of visual attention related to processing of the emotional faces. These results show promise for the use of an adaptive technology in training social skills and warrant further investigation into the use of our novel system.

223 **146.223** Professionals’ Perspective on Using a New Strengths and Interests-Based Intervention Model with Autistic Children and Adolescents

C. Jacques[1]*, S. M. Fecteau*[2]*, J. Ruel*[3]*, C. Normand*[4] *and L. Mottron, M.D.*[5]*, (1)University of Quebec in Outaouais, Gatineau, QC, Canada,* *(2)Psychoéducation et psychologie, Université du Québec en Outaouais, St-Jérôme, QC, Canada, (3)Science de l'éducation, Université du Québec en Outaouais, Gatineau, QC, Canada, (4)Psychoéducation et psychologie, Université du Québec en Outaouais, Gatineau, QC, Canada, (5)University of Montreal Center of Excellence for Pervasive Developmental Disorders (CETEDUM), Montreal, QC, Canada*

Background: Interventions in autism mostly target deficits (McConachie et al., 2017). However, a strength–based approach has been recommended by NIH guidelines (Kendall et al., 2013), parents and young autistic adults (McConachie et al., 2017) as well as critical reviews (Mottron 2017). An innovative intervention model using strengths and interests was therefore developed through action-research, and implemented with autistic children and adolescents.

Objectives: To evaluate the feasibility of implementing a Strengths and Interests-Based Intervention Model according to professionals' experience.

Methods: The research was conducted over a period of 10 months. Ten professionals (psychoeducators), whose main caseload was in autism intervention, received a two-day training session on a Strengths and Interest-Based Intervention Model (Jacques et al., unpublished) under the supervision of four of the authors (CJ, JR, SMF and CLN). A section of the training was dedicated to the use of a new questionnaire specifically designed to evaluate strengths and interests of autistic children and adolescents. Consecutively, these professionals implemented the intervention model with 16 autistic youths (8 to 17 years). Four telephone interviews were then conducted with each psychoeducator during implantation of the intervention model. One focus group, facilitated by two of the authors (CJ and JR), brought together all participants. Exchanges were recorded, transcribed and imported to NVivo, for content analyses. The effective use of strengths and interests in each component of the intervention model (needs assessment, interventions with the youth, parental guidance, and evaluation of the outcomes of the interventions) was evaluated using a qualitative analysis of the themes evoked during the interview and the exchanges of the focus group.

Results: Four major themes were extracted from the thematic analysis of the data collected through interviews and focus group: 1- the strengths and interests' questionnaire is more suitable for youth with high-functioning autism; 2- this questionnaire allows professionals to improve their awareness of strengths and interests among autistic youth; 3- a shift of focus on strengths and interests requires time to be mastered; 4- although interests are commonly used as reinforcement, professionals find it difficult to design interventions, or guide parents, focusing on the children's strengths and interests. The interviews also showed that, with time, the psychoeducators seem more at ease in using a Strengths and Interests-Based Intervention Model.

Conclusions: The intervention model allowed the participating psychoeducators to consider strengths and interests in addition to the challenges of autistic youths. However, participants underlined the necessity to have more time and support measures in order to adequately implement this new focus. Further steps will enable us to improve the Strengths and Interests–Based Intervention Model for future applications by providing mentoring to new users, as well as developing tools that foster knowledge sharing between professionals and parents, and that allow professionals to measure their use of strengths and interests in their evaluation of and intervention with autistic children and adolescents.

224 **146.224** Project Evo: Feasibility and Initial Efficacy of an Interactive Digital Treatment to Improve Attention in Autism Spectrum Disorder

***B. E. Yerys** and J. R. Bertollo, Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Children with autism spectrum disorder (ASD) and co-morbid attention deficit/hyperactivity disorder (ADHD) symptoms experience significant impairments in attention and executive function skills. These children also demonstrate lower adaptive functioning skills, more severe maladaptive behaviors, poorer responses to social skills treatment, and less successful transitions to independence as adults. Relative to an ADHD population, frontline medications for ADHD, such as stimulants, have a lower success rate and greater rates of side effects in ASD. Thus, there is a need to develop alternative treatments targeting attention and executive function.

Objectives: To examine the feasibility and initial efficacy of an interactive, multi-tasking training "app" for attention and executive function.

Methods: 42 children between the ages of 9 and 15 years enrolled in the study. If children met screening criteria, they were assigned to either an adaptive multi-tasking training condition in a game-like environment or an alternative non-multi-tasking training in a game-like environment. Children accessed the treatment in twenty ~30-minute sessions over four weeks. Pre-treatment testing occurred on Day 0 and post-treatment testing occurred within 3 days of Day 28. Feasibility variables included acceptability (percentage of prescribed sessions played) and consumer satisfaction obtained from post-treatment surveys. The primary outcome was measured with the Attention Performance Index (API) from the Test of Variable Attention (TOVA), and secondary outcomes included validated measures of executive function and parent ratings across several domains of function.

Results: 19 of 42 children met the screening criteria. Nineteen children failed to meet the TOVA API entry criterion, three did not meet the IQ criteria, and one withdrew. Overall, excluded children were significantly older (12.14 years) than included children (10.75 years; Hedges' g=0.83). Of the 19 children enrolled, 11 completed the multi-tasking treatment and 8 completed the alternative, non-multi-tasking treatment. Acceptability was high and similar across groups (Table 1). Satisfaction surveys revealed that children were impressed with the graphics and rewards in the multi-tasking treatment, but expressed moments of frustration with the training. In both conditions, parents believed the treatment had potential to improve attention and executive function skills.

Given the small samples, only within-group effects were examined. At post-treatment, the multi-tasking treatment group showed a moderate-to-large improvement on the TOVA's API, and large effects in parent ratings, but weaker effects on other measures. The alternative treatment group showed a worsening effect on the TOVA's API, and other effects were approximately half the size of those observed in the multi-tasking treatment group (Figure 1).

Conclusions: The high exclusion rate is consistent with prior Project: EVO studies. This 'personalized' treatment approach ensures that treated children have impairments in the targeted skills. Acceptability measures indicate high engagement with both treatments, and that the alternative treatment is comparable with respect to child engagement and parent belief of treatment potential. The initial efficacy findings from the TOVA for the multi-tasking treatment are in line with effect sizes from prior Project EVO studies. This finding plus the large parent-reported effects for multi-tasking over the alternative treatment condition, suggest Project: EVO may plausibly improve attention in ASD.

225 **146.225** Promoting Self-Advocacy Skills through Leadership Opportunities: A Participatory Peer-Mentorship Program for

Neurodiverse College Students

D. DeNigris[1], E. Hotez[2], A. Riccio[3], A. Cosenza[4], V. Lee[5], W. Long[5], P. J. Brooks[6], M. Hossain[7], J. D'Onofrio[8] and K. Gillespie-Lynch[9], (1)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ, (2)City University of New York, Hunter College, New York, NY, (3)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (4)College of Staten Island, City University of New York, Staten Island, NY, (5)Psychology, College of Staten Island, CUNY, Staten Island, NY, (6)Psychology, College of Staten Island, Staten Island, NY, (7)Hunter College, CUNY, New York, NY, (8)Center for Student Accessibility, College of Staten Island, CUNY, Staten Island, NY, (9)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY

Background: Although increasing numbers of autistic students are entering college, many face challenges adapting to college, including social difficulties, challenges self-regulating and engaging in self-advocacy, and mental health issues (Schindler et al., 2015). Interventions to help autistic students are often neither evidence-based nor informed by the perspectives of autistic students (Barnhill, 2014). In response to the need for programming that directly aligns with the needs and interests of autistic students (White et al., 2017), we developed a *participatory mentorship program* (Project REACH), in which neurodiverse students play leadership roles in developing, delivering, and evaluating curriculum. *Autistic students* have the opportunity to become *mentors* and *researchers,* whereby they develop leadership skills and shape the program with their unique perspectives.

Objectives: We examined strengths and challenges experienced by autistic and non-autistic students, perspectives of mentors with and without disabilities, and perceived benefits of programming.

Methods: As part of an initiative to help autistic students succeed in college, we developed the Project REACH mentorship program in 2013 (Gillespie-Lynch et al., 2017). Project REACH is open to students with diverse disabilities because a number of autistic students were disinterested in participating in a program solely for autistic people and exposure to diverse peers is likely beneficial. Students participate in weekly hour-long mentor-led group meetings with a structured curriculum and/or hour-long one-on-one meetings. Mentees are encouraged to become mentors and provided with scaffolding to facilitate this transition. Increasingly, autistic students have transitioned into becoming mentors/researchers (and co-authors of this report). Mentees/mentors completed optional semi-structured qualitative interviews at the beginning and end of each semester. Interviews with 26 autistic students (6 mentors), 7 students with other disabilities (4 mentors), and 14 neurotypical students (all mentors) were qualitatively coded after obtaining reliability.

Results: At the end of the term, we asked students which classes/assignments they found easiest and hardest and what non-academic challenges they experienced (Table 1). When asked about goals post-graduation, 46% of autistic students and 33% of non-autistic students indicated employment; 21% of autistic students and 56% of non-autistic students indicated further education. When asked what they gained from mentorship, most indicated social relationships (52% autistic; 47% non-autistic), academic skills (22% autistic; 13% non-autistic), and self-advocacy skills (17% autistic; 20% non-autistic). When asked why they wanted to become a mentor, most mentors indicated that they wished to help others (Table 2). While mentors without disabilities frequently indicated that they had prepared for mentorship by planning, mentors with disabilities often described preparing by maximizing responsiveness to their mentee. Mentors often hoped that their mentee had become empowered through mentorship.

Conclusions: The current study provides a model of a participatory peer-mentorship program for neurodiverse college students. Although research about autistic college students is increasing, autistic students are rarely invited to take on leadership roles in programming. Participatory programming helps align services to the needs of students, provides autistic college students with opportunities to develop communication and teamwork skills, and encourages students with disabilities more generally to become empowered community members.

226 **146.226** Psychiatric Outcomes in an Addressing Disparities Comparative Effectiveness Trial for Elementary Students with ASD or ADHD

C. E. Pugliese[1], L. Anthony[2], B. J. Anthony[2], A. Verbalis[1], A. B. Ratto[1], S. Seese[1], J. Safer[3], A. C. Armour[1], Y. Myrick[1], D. Limon[1], M. F. Skapek[4], M. D. Powers[5] and L. Kenworthy[1], (1)Children's National Health System, Washington, DC, (2)University of Colorado, Denver, Aurora, CO, (3)Georgetown University, Washington, DC, (4)Psychological Sciences, University of Connecticut, Storrs, CT, (5)Children's National Health System, Rockville, MD

Background: Executive functions have been linked to real world behaviors, such as learning, adaptive behavior, and adult outcome. Cognitive flexibility, specifically, has been robustly linked to anxiety and oppositional defiant behavior in typically developing children and children with autism spectrum disorders. Clinical trials are natural vehicles for testing whether executive function mediates psychiatric outcomes, as well as to see whether effects vary based on diagnosis or intervention type offered.

Objectives: This study presents secondary analyses of change in psychiatric symptoms from a larger comparative effectiveness trial of two executive function interventions that targeted cognitive flexibility in a sample of youth diagnosed with ASD and ADHD who also had primary impairments in inflexibility.

Methods: The trial compared Unstuck and On Target (UOT) to Contingency Behavior Management (CBM) in 21 Title I (low-income) elementary schools in 3 school districts for students with ASD (n=43) or ADHD (n=79). All participants had an FSIQ above 70 (range: 70-138) on the WASI-2, and diagnoses were verified using gold standard diagnostic measures (the Autism Diagnostic Observation Schedule for ASD and the MINI-Kid for ADHD). Both interventions targeted executive functioning skills in the classroom. Participants were divided into four groups based on diagnosis (ASD vs. ADHD) and intervention received (CBM vs. UOT). Paired sample *t*-tests were used to measure change from baseline to endpoint via parent report on the CBCL within each group (Anxiety Problems, Oppositional Defiant, Rule Breaking, Attention Problems, ADHD Problems). Within diagnostic groups, there were no significant differences in age, gender, full-scale IQ, race, income, or percentage of parents attending at least one training across diagnostic groups (see Table 1).

Results: CBM treatment reduced Attention Problems in students with ASD (t=2.91, p=.008) and Attention Problems (*t*=2.06, *p*=.047), Anxiety Problems (*t*=2.43, *p*=.020), and Oppositional Defiant Problems (*t*=-2.08, *p*=.045) in students with ADHD. UOT reduced Rule Breaking (*t*=2.53, *p*=.021) behavior in ASD and Attention (*t*=2.81, *p*=.007) and ADHD Problems (*t*=3.29, *p*=.002) in students with ADHD.

Conclusions: Overall, both treatments were effective in reducing psychiatric symptoms, though the pattern of improvement differed in regards to diagnosis and intervention type. CBM is an evidenced based practice well-known for improving attention in ADHD, and this was replicated in the ASD group in this study. Benefits also extended past improving attention to decreasing anxiety and oppositional behaviors in the ADHD group. UOT, which has been shown to be effective in improving EF in youth with ASD, had a broader impact on externalizing rule breaking in ASD. In the

ADHD group, UOT improved attention-related problems.

227 **146.227** Qualitative Evaluation of a Low Intensity Psychological Intervention for Depression in Adults with Autism: The Autism Depression Trial (ADEPT)

*J. Horwood[1], **K. Cooper**[2], H. Harvey[3], L. Evans[2] and A. Russell[4], (1)University of Bristol, Bristol, United Kingdom, (2)University of Bath, Bath, United Kingdom, (3)Newcastle University, Newcastle, United Kingdom, (4)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom*

Background:
High rates of co-occurring depression are reported in Autism Spectrum Disorder (ASD). Cognitive behavioural interventions adapted for ASD have been effective for anxiety problems. There have been evaluation studies of group CBT for co-occurring depression, but no randomised trials investigating low intensity psychological interventions as recommended in clinical guidelines for mild-moderate depression.

Objectives:

This study was a nested qualitative evaluation of the acceptability and feasibility of the ADEPT pilot randomised controlled trial. Participants (with a prior diagnosis of ASD and current depression as measured by PHQ-9 score ≥ 10) were randomised to Guided Self-Help (GSH): a low intensity psychological intervention based on Behavioural Activation adapted for ASD, or Treatment as Usual (TAU).

Methods:

Interviews in two locations in the United Kingdom were conducted with 18 trial participants and 4 therapists. Purposive sampling was used to select participants in order to capture maximum variation in views and experiences. Data were digitally recorded, transcribed verbatim and analysed thematically supported by qualitative data analysis software NVivo10.

Results:

Trial participants and therapists considered the intervention and trial to be acceptable and feasible. All participants welcomed an ASD focused intervention for depression due to the current lack of provision in mainstream services. For therapists the training and supervision was well received and all felt confident delivering GSH. Therapists felt GSH was appropriate to meet the needs of the majority of trial participants. Trial participants who received GSH appreciated the therapists having a good understanding of ASD and were positive towards the aim and structure of the GSH intervention. Suggested improvements that may have enhanced trial participants' engagement in the GSH therapy included session alterations, more regularly checking progress with therapy goals, and increasing the personalisation and presentation of materials.

Conclusions:

The findings support the proposal to carry out a larger scale randomised controlled trial, and also provide evidence to refine the trial design to increase feasibility and acceptability to both trial participants and therapists.

228 **146.228** Randomized Control Trial of Compass for Improving Transition Outcomes of Students with Autism Spectrum Disorder

***L. A. Ruble**[1], J. H. McGrew[2], C. Snell-Rood[3] and M. Toland[1], (1)University of Kentucky, Lexington, KY, (2)Psychology, Indiana University - Purdue University Indianapolis, Indianapolis, IN, (3)Berkeley, Berkeley, CA*

Background:
Despite federal law that requires public schools to provide a coordinated set of results-oriented activities that lead to successful post-secondary outcomes, research indicates that current processes to ensure a seamless movement from school to post-school activities are insufficient. The postsecondary outcomes of individuals with ASD are significantly worse than peers with other disabilities, including intellectual disability. One problem is the lack of empirically-supported transition planning interventions to guide services and help produce better outcomes.

Objectives:

To determine if COMPASS for transition planning and implementation improves IEP goal attainment outcomes for students with ASD.

To assess consultant fidelity in delivering the modified version of COMPASS and teacher adherence in providing evidence-based instruction in COMPASS.

Methods:

Public school special education teachers and a randomly selected student with ASD (research verified) from their caseloads were recruited. Students' mean age was 18.2 years (*SD* = 1.1). Ninety percent of the students were male, 70% White, 15% Black, 5% Asian, and 10% multi-racial.

A total of 150 teacher-child pairs were assessed for eligibility (Figure 1); 20 teachers and 20 students and their parents participated. Following a baseline assessment, teacher-child dyads were randomized into groups, 11 in the experimental condition and 9 in the placebo condition.

Four measures (cognition, adaptive behavior, social/emotional functioning; autism severity) were administered at Time 1 to verify group equivalency (Table 1).

Three reliable adherence measures were utilized: (a) consultant fidelity to the initial COMPASS consultation and (b) to the teacher coaching sessions; and (c) teacher adherence to the implementation of the teaching plans.

Idiographic assessment using psychometrically equivalence tested goal attainment scaling (PET-GAS) was used to evaluate IEP progress because each student had different goals, different baseline skill levels associated with the goals, and different teaching plans. Interrater agreement (two-way Random) as measured using the sample ICC for single measures was .94 at baseline and .86 at final evaluation. The final evaluator was unaware of group assignment.

The intervention consisted of a 3-hr parent-teacher consultation and four 1-1.5 hr teacher coaching sessions.

All consultations were conducted at the school. Prior to consultation, students (4 out of 11), parents, and teachers completed a COMPASS assessment questionnaire, which was summarized into a joint form used for discussion of post-secondary goals and about the student's personal and environmental challenges and supports associated with social, communication, and independent/adaptive skills at school and home.

Results:

Results replicated findings with younger students with ASD that IEP outcomes were higher for COMPASS compared to the placebo control group (d = 2.1; Table 2). Also, consultant fidelity to the consultation and coaching protocols was high (92%) and teacher adherence improved over time, replicating the importance of ongoing teacher coaching.

Conclusions:

In their critical review of the key elements of the transition process for students with ASD, Wehman and colleagues (2014) were unable to identify any studies that tested a transition planning intervention using experimental methods. Thus, to our knowledge, this is the first experimental trial of a transition planning and monitoring intervention for students with ASD.

229 **146.229** Recall with Concept Mapping: Effects on Young Children's' Responses to Science Text

E. Jackson, *Florida State University, Tallahassee, FL*

Background: Effective reading instruction is vital for children to become independent readers (Boulineau et al., 2004). The high proportion (about 33%) of children with autism spectrum disorder (ASD) who struggle with reading comprehension exceeds that of their typically developing peers (7-10%), (Lucas & Norbury, 2014). An extensive amount of research has been published in reading instruction; however, less published research is available on reading comprehension instruction, particularly for students with ASD. Although some work has been published documenting the effectiveness of RECALL (Whalon, Delano, & Hanline, 2013; Whalon, Martinez, Shannon, Butcher, & Hanline, 2015; Whalon, Hanline, & Davis, 2016), there have been no studies using RECALL with nonfiction text

Objectives: This poster will describe findings from a reversal design study including two participants with ASD ages five using RECALL visuals with concept maps while using science texts. The importance of this study is highlighted by the fact that students with ASD choose majors in science, technology, engineering and math (STEM) at higher rates than students in the general population (Wei et al., 2013).

Methods: During all phases, the interventionist read a science book aloud while asking 5 scripted fact and inference questions. Following the reading, participants responded to a post-test assessment (i.e., a combination of 5 fact and inference based questions). Intervention differed from baseline with the addition of a prompting hierarchy that incorporated RECALL visuals and a concept map (i.e., main topic and four related topics about the book). The dependent variable was the number of correct responses to the five post-test questions without the use of the RECALL visuals or concept map.

Results: Results indicate both participants benefited from the concept map and the use of RECALL strategies to increase their ability to answer fact and inference based comprehension questions relating to science text.

Conclusions: As students with ASD are being included in general education classes with their peers (Kluth & Darmody-Latham, 2003), content area instruction is essential. This pilot study assessed the effect of a concept map on the comprehension of science text for ASD using RECALL strategies with two five-year-old boys. Only one other study has used both concept mapping (Roberts & Joiner, 2007) and science text with individuals with ASD. Therefore, this study adds to our knowledge that the use of visual supports and a visual map with effective RECALL strategies can increase listening comprehension skills of children with ASD.

230 **146.230** Reduced Levels of Anxiety, Depression, and Stress in Parents of Children with ASD Following Participation in Pivotal Response Treatment

C. C. Kautz[1], *R. L. Gruen*[1], *E. A. DeLucia*[1], *A. Pomales*[1], *L. L. Booth*[1] *and P. E. Ventola*[2], *(1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Parents of children with autism spectrum disorder (ASD) are more susceptible to psychological stress, depression, and anxiety than parents of typically developing children and parents of children with other disabilities (Dunn, Burbine, Bowers, & Tantleff-Dunn, 2001; Miodrag & Hodapp, 2010; Taylor & Warren, 2012). Past research found 33%-59% of mothers of children with autism report depressive symptoms warranting psychiatric evaluation and nearly 40% express clinically significant levels of parenting stress (Feinberg et al., 2014). The prevalence of mental health challenges facing parents of children with autism highlights the importance of evaluating how treatment interventions for children could impact parental mental health.

Objectives: We investigated levels of anxiety, depression, and stress in parents of children with ASD. Then, we evaluated the changes in parents' symptom severity after their children participated in a 16-week trial of Pivotal Response Treatment (PRT).

Methods: Thirty-seven parents, twenty-two mothers, participated in a study of PRT for children with ASD aged 4-8. PRT is a naturalistic behavioral treatment focused on improving children's social communication skills. Treatment included 7 hours of weekly individual work with the child and parent training over 16 weeks. Both at the beginning and end of the 16-week treatment, parents completed the Beck Anxiety Inventory (BAI), Beck Depression Inventory (BDI), and Parental Stress Index (PSI). Scores greater than 21 indicate moderate anxiety on the BAI. On the BDI, scores above 13 indicate mild depression, and scores of 14-19 indicate moderate depression. Total scores greater than 109 on the PSI indicate high or critically high stress levels.

Results: At baseline, 2.7% of parents showed moderate-level anxiety as measured by the BAI. On the BDI, 16.7% of parents showed mild depression and 13.9% showed moderate depression. The PSI showed 2.7% of parents had stress in the high range and 8.1% had stress in the critically high range. Mothers showed significantly higher symptoms of depression at baseline than fathers (mothers mean=12.00, fathers mean=4.07, p<.05), but did not differ significantly on any other scale at baseline.

Conclusions: These findings indicate that parental anxiety, depression, and stress were significantly reduced following a 16-week trial of PRT. Additionally, with the exception of depression, mothers' and fathers' symptoms did not differ significantly at baseline. These results are promising in that although parents did not receive direct treatment, their wellbeing was improved following the trial. The parent-training component likely provided parents a sense of empowerment, and their symptoms also may have been reduced as a result of their child's improvements in skills and behaviors.

231 **146.231** Reduction in Restricted and Repetitive Behaviors Following Pivotal Response Treatment

A. Pomales[1], *D. G. Sukhodolsky*[2], *E. A. DeLucia*[1], *C. C. Kautz*[1], *R. L. Gruen*[1], *L. L. Booth*[1] *and P. E. Ventola*[2], *(1)Yale Child Study Center, Yale School of*

Medicine, New Haven, CT, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT

Background: Restricted and Repetitive Behaviors (RRBs), one of the central symptoms of autism spectrum disorder (ASD), consist of diverse factors – such as repetitive sensory motor behaviors and insistence on sameness – that interfere with social interactions. Previous research on interventions for RRBs indicates resistance to pharmacological treatments and behavioral interventions (Harrop et al., 2015). Additionally, pharmacological interventions have notable side effects.
Pivotal Response Treatment (PRT) is a naturalistic behavioral treatment targeting social communication and social motivation. Preliminary work demonstrates PRT effectively reduces RRBs (Ventola et al., 2016).

Objectives: The present study evaluated changes in severity of RRBs in children with ASD following a 16-week trial of PRT.

Methods: The sample consisted of 45 children with ASD, 4-7 years-old. Thirty-five children received 16-weeks of PRT, consisting of 7 hours of weekly individual treatment and parental training. The sample was combined from an open-label trial of PRT and a RCT of PRT. Ten children were in a non-treatment control condition. RRBs measures were collected at baseline and endpoint using Repetitive Behavior Scales-Revised (RBS), Aberrant Behavior Checklist (ABC), and Social Responsiveness Scale (SRS). To evaluate changes in RRBs severity, paired-samples t-tests were conducted to compare baseline and endpoint scores on each measure.

Results: Independent samples t-test indicated no significant differences between the PRT and control group at baseline (RBS total: $t(35)=-1.545$, $p=.131$; ABC stereotypy: $t(27)=.775$, $p=.444$; SRS RRB: $t(39)=-1.584$, $p=.121$). Additionally, there were no significant IQ differences at baseline (Differential Abilities Scale, General Conceptual Abilities: $t(42)=-.186$, $p=.854$.)

Paired-samples t-tests revealed a significant overall reduction in RRBs severity following 16 weeks of PRT (RBS total: pre-PRT M=28.71, SD=19.637; post-PRT M=20.11, SD=12.029, $t(27)=3.808$, $p<.001$). This reduction is consistent across RBS subdomains: stereotyped ($p=.002$), self injurious ($p=.014$), compulsive ($p=.020$), ritualistic ($p=.021$), sameness ($p=.005$), and restricted ($p=.009$). Additionally, there was a significant decrease in SRS RRB-subdomain pre-PRT (M=14.80, SD=6.202) and post-PRT (M=12.57, SD=7.496; $t(34)=2.557$, $p=.015$), as well as in ABC stereotypy scores pre-PRT (M=11.97, SD=10.61) and post-PRT (M=8.58, SD=7.97; $t(30)=2.814$, $p=.009$).

Children in the control group did not exhibit significant reduction in RRBs severity during the 16-week period (RBS total: baseline M=41.22, SD=25.528; endpoint M=30.78, SD=15.189, $t(8)=1.584$, $p=.152$). RBS subdomain scores did not change significantly: stereotyped ($p=.059$), self injurious ($p=.128$), compulsive ($p=.300$), ritualistic ($p=.272$), sameness ($p=.684$), and restricted ($p=.081$). Similarly, there were no significant differences in ABC stereotypy at baseline (M=7.75, SD=5.377) and endpoint scores (M=4.75, SD=4.573; $t(3)=1.009$, $p=.387$), and SRS RRB at baseline (M=19, SD=4.382) and endpoint scores (M=18.17, SD=7.33; $t(5)= .362$, $p=.732$).

Conclusions: While PRT focuses on improving social communication skills, it has a secondary effect on RRBs severity. Results suggest a significant reduction in severity across a variety of RRBs following a 16-week PRT trial. This could possibly result from incorporating parent training and using circumscribed interests to motivate, and consequentially, increase reciprocal interactions. Future studies may examine follow-up data to assess the longevity of the effects of PRT on RRBs, as well as use diverse measures to evaluate RRB severity. Additionally, a larger sample is needed to measure generalization of this effect.

232 **146.232** Sex Differences in Outcomes of a Social Skills Intervention for Children with ASD

B. L. Ncube[1], *J. M. Bebko*[2], *M. Thompson*[3], *N. Bardikoff*[3] *and M. Spoelstra*[3], *(1)Psychology, York University, Toronto, ON, Canada, (2)York University, Toronto, ON, Canada, (3)Autism Ontario, Toronto, ON, Canada*

Background: Research is mixed regarding whether or not girls with autism spectrum disorder (ASD) present differently from boys (Lai et al., 2015). Although some studies show no differences between boys and girls with ASD (e.g., Sutherland et al., 2017), other studies have found differences between the two in age of diagnosis and symptom presentation (Lai et al., 2015). Little and colleagues (2017) found that parents of young girls (2- to 11-years-old) reported fewer concerns regarding their children's social difficulties. Importantly, although Hiller, Young, and Weber (2014) found that girls performed better on a number of metrics of interpersonal interaction (e.g., ability to maintain a reciprocal conversation), their ability to maintain friendships remained impaired. Unfortunately, few studies have explored whether girls with ASD have similar outcomes to boys following participation in a structured social skills intervention targeting ASD. Children's Friendship Training (CFT) is a manualized parent-assisted social skills intervention for children with ASD in grades 2 -5. Autism Ontario has been running CFT at sites across Ontario, Canada for the past three years.

Objectives: The present study examines sex-differences in the outcomes of children with ASD who participated in the CFT program.

Methods: Participants were 42 children with ASD (33.3% female) between the ages of 7 and 12 (M = 9.59, SD = 1.40) who participated in the CFT program in Toronto between April 2016 and June 2017. Parents and children were asked to complete a number of measures before and after participation in the program. Measures evaluated social skills (measured by the SSQ-P and SSQ-PU), social anxiety (measured by the SASC-R), and the number of play dates the child hosted or was invited to in the past month. No differences existed between boys and girls in baseline scores on the above measures.

Results: In the male sample, both parent-report ($t(23) = -5.385$, $p < .001$) and boys' self-report ($t(11) = -5.358$, $p < .001$) indicated a significant increase in social skills from pre- to post-CFT participation. By contrast, neither parents of girls ($p = .074$) nor girls themselves ($p = .219$) reported a significant change in social skills from pre- to post-CFT participation. A similar pattern emerged regarding ratings of social anxiety. While parents of boys reported a significant decrease in their child's social anxiety from pre- to post-CFT participation, $t(21) = 2.989$, $p = .007$, parents of girls did not report a significant change in social anxiety ($p = .871$). Neither parents of boys ($p = 1.000$) nor parents of girls ($p = .075$) reported a significant change in how many play dates their child was invited to. However, while parents of boys reported no change in how many play dates their child hosted ($p = .677$), parents of girls reported a significant increase in how many play dates their child hosted, $t(13) = -3.322$, $p = .006$).

Conclusions: Prior to conducting this research, we found no data detailing specific outcomes of girls with ASD in CFT. Our results point to the need for more research on this topic.

233 **146.233** Social Gains Are Maintained at 4-Month Follow-up Evaluation of Pivotal Response Treatment for Children with Autism

R. L. Gruen[1], *C. C. Kautz*[1], *A. Pomales*[1], *E. A. DeLucia*[1], *L. L. Booth*[1] *and P. E. Ventola*[2], *(1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Pivotal response treatment (PRT) is a naturalistic behavioral approach to treating autism that targets core deficits in social motivation. PRT is an evidence-based treatment which has been shown to foster improvements in social interaction, language skills, and adaptive behavior in children with autism (e.g., L. K. Koegel, Koegel, Harrower, & Carter, 1999; R. L. Koegel, Koegel, & McNerney, 2001). However, there is limited research examining whether these treatment effects are maintained over time, after treatment is concluded.

Objectives: In a sample of children with autism spectrum disorder (ASD) who had participated in a 16-week PRT treatment program, we examined the maintenance of treatment effects 16 weeks following the completion of treatment.

Methods: Twenty children, nine girls, (mean IQ 97.32; SD 19.42; range 55-128) completed a 16-week trial of PRT with a follow-up visit 16 weeks post-treatment. This study was part of a larger randomized controlled trial of PRT, but only a subset of the children--those in the PRT condition--completed the follow-up assessment measures. The trial included 7 hours per week of individual work with the child and parent training. Primary clinical outcome was assessed at baseline, endpoint, and follow-up using the SRS-2, a parent report measure of social communication.

Results: Children gained social communication skills over the course of the trial (baseline to endpoint) and, importantly, gains were maintained through the 16-week follow-up period. Over the course of PRT, children demonstrated significant improvements on the SRS Total Score and the SRS Social Communication scale (SRS Total Score baseline mean=87.471, post-treatment mean=72.235, p<.01; SRS Social Communication baseline mean=32.294, post-treatment mean=25.647, p<.01). Furthermore, skills at follow-up remained significantly improved from skills at baseline (SRS Total Score baseline mean=87.471, follow-up mean=76.118, p<.05; SRS Social Communication baseline mean=32.294, follow-up mean=27.588, p<.05). Gains made from endpoint to follow-up visit were not significant (p>.05). The remaining subscales of the SRS, including Social Awareness, Social Cognition, Social Motivation, and Autistic Mannerisms followed this pattern, but results were not significant (p>.05).

Conclusions: We aimed to investigate maintenance of social communication skills following a 16-week trial of PRT. Children in the trial made significant gains over the course of the treatment, and these gains were maintained at the follow-up time-point (16 weeks after the conclusion of treatment). These results suggest that PRT can have lasting effects on children's development. It is likely that the parent-training component allowed parents to continue to implement PRT principles after participation in the active phase of treatment concluded. There were some limitations to this study; namely, the SRS is a parent report measure of social skills and the control group did not participate in the follow-up portion of the study, as treatment was not delayed this additional period of time.

234 **146.234** Social Game Interactivity Levels As Active Ingredients in Performance-Based Intervention for Adolescents with Autism Spectrum Disorder (ASD)

C. E. Simson[1], *S. L. Sommer*[1], *L. A. Santore*[1], *E. Kang*[1] *and M. D. Lerner*[2], *(1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY*

Background: Adolescents with autism spectrum disorder (ASD) have core social deficits that make peer interactions challenging (Picci & Scherf, 2014). Research suggests that non-didactic interventions using intrinsically engaging structured social activities to promote peer interaction (performance-based interventions) may be effective in improving social skills and peer interactions for adolescents with ASD (Corbett, et al., 2017; Lerner et al., 2011). Structured social activities (social games) have also been shown to promote spontaneous *in vivo* peer interactions (Dolan et al., 2016; LeGoff et al., 2006). Social game structures include various interactive components, such as one-to-one or group formats, verbal and/or non-verbal imitation and communication, and physical activity (Guli et al., 2013). Thus, those containing more components require more interactivity – levels of which are a plausible "active ingredient" in such interventions. However, little research has examined such ingredients in performance-based interventions (Lerner et al., 2012), and none has examined relative levels of interactivity in social games as one that may potentiate spontaneous in vivo peer interaction.

Objectives: This study aimed to assess the differential efficacy of levels of interactivity in three social games for eliciting spontaneous peer interactions. We hypothesized social games with higher interactivity levels would elicit more *in vivo* spontaneous peer interactions.

Methods: 25 adolescents (M_{age}= 14.98, SD_{age}= 1.48, 19 male) with confirmed ASD diagnoses (ADOS-2; Lord et al., 2012) completed a performance-based social skills intervention, Socio-Dramatic Affective-Relational Intervention (SDARI; Lerner et al., 2011). Participants were placed in groups of 5-9 and met for ninety-minute sessions once per week for ten weeks where they engaged in targeted social activities (Lerner & Levine, 2007). Groups were video recorded and multiple blinded raters reliably coded participation in three core SDARI activities (ICC = 0.71; 134 observations): Mirror, Round of Applause, and Walkabout (see *Table 1*). A separate team of blinded raters reliably coded peer interactions (SIOS; Bauminger, 2002; ICC = 0.79; 440 observations) during a thirty-minute free-time immediately after the activities. Hierarchical linear modeling analysis (Level 1: within-person between-session; Level 2: between person) were used to examine session-level relations between activity participation and peer interaction.

Results: Increased participation in Walkabout (i.e., high interactivity) significantly predicted increased observer-rated peer interaction (β = 5.23; *p* = 0.001). However, increased participation in Mirror (i.e., low interactivity) significantly attenuated peer interaction (β = -4.29; *p* = 0.032). Round of Applause (i.e., medium interactivity) had no effect on peer interactions (*p* = 0.29; see *Figure 1*).

Conclusions: These results suggest participation in social games with different levels of interactivity elicit varied amounts of spontaneous in vivo peer interactions. These results suggest a linear, bimodal relation between social game activity level and immediately subsequent peer interactions, such that low levels of interactivity may actually exert an iatrogenic effect. This likewise suggests the possibility of an *interactivity threshold effect,* wherein a certain level of interactivity may be required to elicit spontaneous peer interactions. These findings may help explain the heterogeneity in outcomes of social interventions (Gates et al., 2017), and provide guidance to increase their efficacy.

235 **146.235** Social Networks: Supporting College/University Students with High Functioning ASD

B. Cook *and D. Weiss, Communication Disorders, Southern Connecticut State University, New Haven, CT*

Background: Social networks that college students develop with faculty, staff, peers, friends, and mentors are strongly linked to student success, e.g., satisfaction, persistence, etc. (Kuh, Kinzie, Buckley, Bridges & Hayke, 2012). The development of these social networks may be especially challenging for individuals with autism. A number of studies have explored variables related to developing social networks that may impact college success among individuals with autism (Neville & White, 2011). Increasing awareness of autism and related social communication challenges amongst similar aged peers may support an increase in the development of social networks. Additionally, the inclusion of peer

mentors as models and supports in the development of peer social networks is a promising key approach (Hart, Grigal, & Weir, 2010). A specially-designed program to increase opportunities for peer mentors and peer networks was developed and assessed by the authors.
Objectives: Identify outcomes related to social interaction and development of peer networks for both individuals with autism and typical development related to participation in a specially-designed university program consisting of a university-level course and participation in a small group orientation experience.

Methods: *Participants:*Consenting course participants: 19 individuals who self-identified as having autism and 10 individuals who indicated no diagnoses. *Intervention:*Participation in a university-level, 1 credit course with a focus on social communication and cognition. In addition to the course, participants with autism attended small group orientation and experiential activities that targeted objectives related to the use of social communication to navigate various university entities such as the library, registrar, student involvement center, etc.

Results: Data have been collected over 3 iterations via multiple sources: 1) pre- and post- Likert rated surveys related to comfort with individuals with autism and and willingness to develop peer networks; 2) pre- and post-systematic observation of social interaction behaviors between course participants; and 3) focus interviews 6 months post program with all participants to determine the effect of the program on the knowledge, awareness, and acceptance of autism, as well as the changes in social interactions with the members of the class across time. Data are currently being analyzed; preliminary results include: an increase in peers' awareness and greater levels of comfort with interactions among the participants of the course ($p < .05$); a minimum of a 50% increase in observed social interaction behaviors among group members from the first to the final course session; and report of maintained peer connections between some students from each group.

Conclusions: These results provide preliminary evidence of the benefit of developing an inclusive university level course that addresses the key challenge of social interaction and communication faced by individuals with autism. The course provides a context that allows for the development of peer relationships, both as peer mentor/mentee, and can lead to a peer network for the individuals with autism. The addition of the small orientation group appears to enhance these outcomes. The intended outcome of these results is to encourage university faculty and staff to develop a similar program to support individuals with autism.

236 **146.236** Supervising Individuals with ASD in the Workplace: A Managerial Perspective

***V. Martin**, École de psychoéducation, Université de Montréal, Montreal, QC, Canada*

Background: Individuals with ASD often experience difficulties in finding and maintaining employment. Employment specialists can assist employees with ASD and their manager during the initial integration period.
Objectives: The purpose of our study was to examine the experience of managers who supervise employees with ASD receiving services from an employment specialist during the initial integration period.

Methods: We interviewed five managers who hired individuals with ASD from a specialized employment community program and supervised them during at least three months. During 30- to 60-min individual interviews, managers responded to open-ended questions on hiring, training, adjustment, relationship with colleagues, perception of higher management and support from human resource management professionals. We qualitatively analyzed the data within a post-positivist, pragmatic and realist paradigm (Miles & Huberman, 2003). We recorded interviews for coding line by line and then conducted categorization to identify themes. We also wrote narrative cases for each experience. Themes were tabulated to facilitate comparison. A theoretical framework was used to organize the key themes identified. To verify the trustworthiness of the analysis, we compared our results with the scientific literature and presented them to employment specialists for individuals with ASD.

Results: Time was an important theme in all interviews. Employees with ASD required more time to integrate in a new job than the majority of other employees. Managers also devoted more time to their employee with ASD on a day-to-day basis. Another important theme was how managers had to pay attention to the way they communicated information and instructions to their employee with ASD. This change in the manager's behavior led to improvement in their communication skills towards their other employees. To improve the performance of their employee with ASD, managers selected the context they perceived to be a better fit such as shifts when they were fewer customers or when colleagues that were more flexible were present. Most managers had a personal motivation, outside of their work environment, to hire an employee with ASD, such as knowing a person with ASD or the desire to participate in a project that had a social impact. The employment specialist support was instrumental in understanding the employee with ASD and their behaviour, and in resolving issues. The employment specialists provided support to improve the productivity of the individuals with ASD to achieve a sufficient level of work performance. These results felt gratifying for the managers that perceived themselves as better supervisors.

Conclusions: Employment specialists offer essential services to managers to become successful in supervising individuals with ASD. Theses specialists can explain the needs of this population and offer strategies to communicate, preventing and resolving issues related to the ASD in the workplace. Understanding the experience of managers of employees with ASD helps create better services aimed at supporting adults with ASD in long-term employment. Future research should include managers whose experience was negative (e.g., the employee was fired) in order to further our understanding of the experience of managers supervising employees with ASD.

237 **146.237** Supportive School Services for Youth with ASD and Their Relation to ASD Symptoms, Intellectual Functioning, and Co-Occurring Psychiatric Symptoms

***T. Rosen**[1], C. Spaulding[1], J. A. Gates[1], K. Gadow[1] and M. D. Lerner[2], (1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY*

Background: It is often presumed that greater ASD symptom severity necessitates more intensive supportive school-based services (SSS; e.g., Goin-Kochel et al., 2007). However, ASD symptoms vary in presentation of severity by context, highlighting the need for multiple perspectives to understand complexity of symptom presentation (Lerner et al., 2017). Nonetheless, little research has taken a multi-informant perspective on symptom severity in relation to SSS. In addition, the contribution of intellectual functioning and psychiatric comorbidity to SSS has been relatively understudied (Narendorf et al., 2011; White et al., 2007), though ~32% of youth with ASD have intellectual disability (Christensen et al., 2016), and ~70% have co-occurring psychiatric conditions (Simonoff et al., 2008). Moreover, no study has examined the relation of ASD severity, intellectual functioning, and psychiatric comorbidity in tandem to parse their relative and joint contributions to SSS delivery.

Objectives: Examined the relative contributions of parent, teacher, and clinician ratings of ASD symptom severity and psychiatric comorbidity, and IQ, in relation to SSS for ASD youth.

Methods: 283 youth (233 males) ages 6-18 ($M_{age} = 10.5$) with ASD were assessed with parent and teacher versions of the Child and Adolescent Symptom Inventory-4R (Gadow & Sprafkin, 2005), and clinical evaluation via the ADOS, to index co-occurring psychiatric and ASD symptom severity. FSIQ scores were obtained from case record review. Parents reported on SSS; *Presence* of common SSS refers to receipt of ≥1 of three SSS ASD youth most commonly use (Goin-Kochel, et al., 2007; speech/language, occupational therapy, social skills training). *Total* SSS includes both common SSS *and* any other SSS (e.g., adaptive physical education, counseling, etc.). *Frequency* of services refers to average weekly SSS receipt.

Results: Parent, teacher, and clinician ratings of ASD severity correlated with common ASD and total SSS frequency (see Table 1). Importantly, when controlling for all 3 sources of severity and age, only clinical evaluation related to common SSS presence ($OR = 1.19$, $p < .01$), whereas both clinical evaluation and teacher-report of ASD severity related to common (both $B = .04$, $p < .05$) and total SSS frequency ($B_{Clinical\ Evaluation} = .07$, $p < .001$; $B_{Teacher\text{-}report} = .02$, $p < .05$).

IQ was negatively associated with common and total SSS frequency, whereas parent-reported internalizing symptoms were negatively correlated with common SSS frequency (Table 1). After accounting for IQ and psychiatric comorbidity, clinical evaluation related only to total SSS frequency ($B = .04$, $p < .05$), whereas teacher-report related only to common SSS frequency ($B = .03$, $p < .05$). Moreover, lower IQ predicted higher frequency of common ($B = -.02$, $p < .01$) and total SSS ($B = -.01$, $p < .05$), while parent-reported externalizing symptoms predicted lower likelihood of common SSS presence ($OR = .93$, $p < .01$).

Conclusions: Overall, clinical evaluation and teacher-report of ASD severity showed the strongest and most consistent associations with SSS frequency. Results highlight the importance of indexing ASD severity via multiple sources, and accounting for intellectual functioning and psychiatric comorbidity, when examining correlates of SSS for youth with ASD.

146.238 The Effect of TUNE-in Treatment on Naturalistic Conversation in Adults with ASD: Speaking Rate Is a Temporal Marker of Rapport

J. Parish-Morris[1], *A. A. Pallathra*[2], *E. F. Ferguson*[3], *L. Bateman*[3], *M. Cola*[1], *S. Uh*[1], *Z. M. Dravis*[1], *A. Zoltowski*[4], *A. Pomykacz*[5], *K. Bassanello*[1], *J. Day-Watkins*[6], *B. B. Maddox*[7], *J. S. Miller*[8], *G. S. Dichter*[9], *J. Connell*[10], *D. S. Mandell*[11] *and R. T. Schultz*[1], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Department of Psychiatry, Catholic University of America, Washington, DC, (3)The Center for Autism Research/CHOP, Philadelphia, PA, (4)Vanderbilt University, Nashville, TN, (5)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (6)Drexel University, Philadelphia, PA, (7)University of Pennsylvania, Philadelphia, PA, (8)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (9)Psychiatry, University of North Carolina, Chapel Hill, NC, (10)AJ Drexel Autism Institute, Philadelphia, PA, (11)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: Social communication impairment is a core feature of autism spectrum disorder (ASD; APA, 2013) but contributors to natural conversation problems in adults with ASD remain poorly understood. For example, individuals with ASD are more likely to use unusual words (Volden & Lord, 1991), and engage less in shared conversational topics (Adamson, Bakeman, Deckner, & Nelson, 2012) than typical individuals, potentially leading to unnatural conversational flow. Beyond word-level differences, sometimes the *sound* of speech is off; individuals with ASD may talk too slowly, produce unusual pitch characteristics, or pause differently than typical peers (Parish-Morris et al., 2016a,b). These differences, while subtle, may contribute to the feeling of an odd conversational interaction. In this study, we test whether one subtle temporal feature that has been associated with ASD – slower than average speaking rate – improved after a 17-week cognitive-behavioral intervention.

Objectives: Determine whether Training to Understand and Navigate Emotions and Interactions (TUNE-In) treatment improves speaking rate during natural conversation in adults with ASD.

Methods: Twenty-one adults with ASD (age M=28y, IQ M=104) underwent Training to Understand and Navigate Emotions and Interactions (TUNE-In), which consists of components to improve social motivation, anxiety, social cognition, and social skills (Pallathra et al., 2017). At pre- and post-intervention visits, participants were given the Contextual Assessment of Social Skills (CASS, Ratto et al., 2011). The CASS includes two 3-minute conversations with undergraduate students (confederates) acting interested or bored. Here we report results from the “interested” condition only. Eleven different confederates contributed to the “interested” condition, and participants never spoke to the same confederate twice. Videotaped conversations were scored for overall rapport (e.g., combined effect of positive affect, social affect, involvement, vocal expressiveness, etc), by independent evaluators blinded to intervention status. The primary dependent variable of interest, speaking rate, was calculated by dividing the sum of all speech segments (not including inter-turn or intra-turn pauses) by the total number of words produced by each speaker. Speaking rate indexes how quickly a person says words, and has been found to be low in participants with ASD relative to typical controls (Parish-Morris et al., 2016a,b).

Results: Two separate linear mixed-effects regression models with participant ID and confederate ID as random effects and intervention stage (pre/post) as fixed effects revealed significant increases in speaking rates from pre- to post-intervention in participants with ASD, but not in confederates (Table). Participants who spoke more quickly post-intervention were rated as having significantly better rapport with confederates by independent evaluators (Spearman $r = .65$, $p = .002$; Figure).

Conclusions: Natural conversation is a significant challenge for individuals with ASD, but the specific contributors to awkward conversations are subtle and may be hard to specify. In this study, we found that one temporal feature of conversation, speaking rate, increased after TUNE-In and was associated with improved conversational rapport in adults with ASD. Speaking rate may thus be a feature that indexes the “goodness” of natural conversations, and may hold promise as a yardstick for evaluating the effectiveness of social skills interventions.

239

146.239 The Effects of a Peer Supported Physical Activity Intervention for College Students with Autism Spectrum Disorder

N. Miodrag[1], *T. Todd*[2], *S. Colgate*[3], *E. V. Perez*[4], *M. Salazar*[5] *and B. Endinjok*[5], *(1)Child and Adolescent Development, California State University Northridge, Northridge, CA, (2)Kinesiology, California State University, Northridge, CA, (3)California State University Northridge, Northridge, CA, (4)Psychology, California State University Northridge, Northridge, CA, (5)Kinesiology, California State University Northridge, Northridge, CA*

Background: A growing body of evidence shows that individuals with Autism Spectrum Disorder (ASD) often lead sedentary lives and have a higher prevalence of being overweight and obese than the general population. Engaging in regular physical activity (PA) can improve health and help prevent obesity (US Department of Health and Human Services). Physical activity levels decrease in adolescence and remain low throughout adulthood. To date, there is a lack of PA interventions for young adults with ASD. As the number of adults with ASD increases, it is important to develop evidence-based interventions that improve physical activity and fitness before chronic health issues become a major burden for individuals, families, and public health.

Objectives: The aim of this study was to engage college students with ASD in regular, sustained PA and increase levels of fitness. Specifically, we examined the effects of a 10-week exercise program on cardiovascular fitness, muscular endurance, flexibility, as well as perceived anxiety and motivation to participate.

Methods: IFiT (*I*nto *Fi*tness *T*ogether) is a 10-week, individualized peer supported physical activity program tailored to address the motor and social barriers to PA among college students with ASD. A total of 16 participants with ASD (13 males, 3 females) between the ages of 18 and 28 years ($M = 22.38$) participated in this study. Each student was paired with a college Kinesiology student (i.e., Peer Mentor). Dyads met twice a week for 10 weeks for a minimum of 120 minutes of PA of their choice and 30 minutes to plan activities for the coming week. Anthropometric, fitness, anxiety, and motivation measures were taken at pre- and post-intervention. Fitness measures included the timed 1-mile walk for VO^2 max (the maximum amount of oxygen used during intense physical activity), sit-ups and push-ups for muscular endurance, and flexibility assessed using the sit and reach box. Self-reported anxiety was measured using the Beck Anxiety Inventory and motivation using the MPAM-R.

Results: Fifteen of the sixteen participants had BMI scores in the overweight to obese range. The results for cardiovascular fitness (1-mile walk) showed significant differences in VO^2 from pre ($M = 32.58$) to post-intervention ($M = 36.97$), $p < .05$. There was a significant increase in sit and reach post scores ($M = 10.78$) compared to sit and reach pre scores ($M = 9.66$), $p < .05$. Muscular Endurance was assessed using the push-up test measuring endurance in the upper extremity muscles, while the YMCA half sit-up test measured endurance in the core muscles. A statistically significant increase was found in the push-up post scores ($M = 16.0$) compared to the push-up pre scores ($M = 12.81$), $p < .05$. Significance was not found in core muscular endurance measured by sit-ups. There were no significant changes from pre- to post-intervention for perceived anxiety or motivation to participate.

Conclusions: Regular participation in a 10-week peer supported physical activity program resulted in significant fitness benefits to college students with ASD. These findings indicate that participants with ASD sustained PA to meet national guidelines with peer support.

240 **146.240** The Effects of Social Training Games on Visual Gaze to Social Stimuli

G. A. Alvares[1]*, N. T. Chen*[2,3]*, L. Notebaert*[2]*, J. Granich*[4] *and A. J. Whitehouse*[1]*, (1)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (2)School of Psychological Sciences, University of Western Australia, Perth, Australia, (3)School of Psychology and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (4)Telethon Kids Institute, Telethon Kids Institute, Subiaco, Australia*

Background: There is accumulating interest in the gamification of social-communication skill development for children with autism spectrum disorder (ASD). To date, many games have targeted older individuals with average to high-average cognitive/language abilities, or have limited experimental controls. Our previous research has found that a more inclusive game rewarding attention to faces over objects increased eye-gaze to faces in children after 15 minutes of gameplay. However, it is unknown whether extended gameplay can maintain this effect.

Objectives: This study tested the effects of social training games on visual attention in children with ASD.

Methods: Participants included 65 children (10 females) diagnosed with ASD (mean age=8.59, SD=2.16, range=5-12 years) randomly allocated to play either a training (n=33) or control (n=32) set of games. No exclusion criteria related to cognitive, language, or functional ability were applied. Children were asked to play the games for at least 15 minutes/day for seven days. In each game, children were rewarded for correctly sorting emotions (Emotion Recognition), following a character's eyes (Joint Attention), or selecting faces over objects (Social Attention). Each game embedded these socially-oriented goals into a child-friendly format, with visual rewards and sounds to maintain engagement, and no written or verbal instructions to enable accessibility for children with minimal receptive language. A control version was designed to ensure equivalent exposure to the visual game components, but without active training contingencies programmed. Children completed eye-tracking pre- and post-gameplay, measuring attention to (1) eye regions of faces, (2) directed eye gaze, and (3) faces relative to objects. Qualitative data from children were collected on their game experiences.

Results: On average, children played an equivalent amount of time in either condition ($t(63)=0.46$, $p=.65$), however control games were passed significantly more frequently; suggesting that control games were easier, but time engaging in games were relatively comparable. Compared to before playing the game, children in the training group exhibited no significant changes in visual attention across all eye-tracking tasks after playing the game, relative to the control group (all p values>.05). Daily game usage indicated that 16 (24.6%) children did not engage in one or more of the games for more than one day after returning home; once these children were excluded pair-wise from eye-tracking analyses, there was a borderline significant interaction in gaze following ($F(1, 47)=4.15$, $p=.05$, partial $eta^2=.08$); this indicated that children playing the Joint Attention training game significantly increased the speed at which they could follow gaze directed to an object post-gameplay. No other changes in eye-gaze were observed. Qualitative data indicated that the games were well received, with high acceptability ratings.

Conclusions: Games represent an acceptable format to engage children with ASD in social-communication development. Our results suggest that, while engagement with these games was acceptable, specific transfer to changes in visual gaze was limited. These results may be partially influenced by the heterogenous nature of the sample included and variability in gameplay. However, qualitative data supported overall acceptability and highlighted feasibility of designing games for a range of functional, cognitive, and language ability levels.

241 **146.241** The Positive Effects of Assistance Dogs in Families of Children and Adolescents with ASD

V. Simard[1]*, M. A. Aubry-Guzzi*[1]*, I. Chapleau*[1]*, M. Carrier*[1]*, F. Zerrouki*[1]*, M. M. Blouin*[1] *and N. Champagne*[2]*, (1)Universite de Sherbrooke, Longueuil, QC, Canada, (2)Mira Foundation, Sainte-Madeleine, QC, Canada*

Background: Sleep disorders are highly prevalent among children and adolescents with an autism spectrum disorder (ASD). Two studies (Fecteau et al., 2017; Viau et al., 2010) have reported the effect of assistance dogs on the cortisol awakening response of children with ASD and of their parents. They have explained their findings by an effect of the dog on sleep, although they did not measure this variable.

Objectives: To assess the effect of well-trained assistance dogs on 1) sleep of the child/adolescent with ASD and of their parents, and on 2) autonomy and 3) sensory modulation of the child/adolescent.

Methods: This study follows a pre-test/post-test pre-experimental design. Thirteen families with a child/adolescent with ASD (5 to 16 years old; 9 boys) participated in two home visits, the first within one month of receiving the assistance dog (pre-test) and the second, two months after it's arrival (post-test). The sleep of the child/adolescent was assessed using both actigraphy (wrist-worn accelerometer) and mother-reported sleep diary. The sleep of parents was assessed using self-reported sleep diaries. All sleep measures were taken on five consecutive 24-hour periods. Autonomy was assessed with the corresponding subscale of the ABAS-II (Harrison & Oakland, 2003), and sensory modulation, with the Sensory Profile (Dunn, 1999). All measures were taken at pre-test and post-test. One week after each visit, a research assistant collected at home the actigraph, and the completed sleep diaries and questionnaires.

Results: Most (63.6%) children and adolescents were sleeping with the dog in their room every night, and 45.5% were even bed-sharing every night. Sleep of the child/adolescent and of the father did not significantly improve after the dog's arrival. However, self-reported nighttime sleep duration of the mother improved between pre-test (M=6.36±.80 hours) and post-test (M=7.01±.64 hours; F(1, 12)=5.56, p=.036), representing a large effect size (η^2=.32). A shorter pre-test sleep duration of the mother was associated with a greater increase in this parameter between time points (r(11)=-.79, p=.001). Autonomy of the child/adolescent also significantly improved after the dog's arrival in the family (t(12)=-2.26, p=.045), a greater improvement in autonomy being associated with a greater proportion of nights of room-sharing (r_s(11)=.75, p=.013) or bed-sharing (r_s(11)=.69, p=.029) with the dog. Finally, the introduction of the assistance dog was associated with increased socio-emotional responsiveness (F(1, 12)=6.34, p=.03) and attention (F(1, 12)=7.93, p=.017) on the Sensory Profile, with large effect sizes (η^2=.37 and .42).

Conclusions: Results from this ongoing study provide preliminary evidence that an assistance dog, trained specifically for work with youngsters with ASD, may have several benefits. The dog's arrival was associated with increased sleep duration of mothers, especially for those who were more sleep deprived. It also appears to benefit youngsters in their socio-emotional and everyday functioning. Moreover, a greater proximity of the child/adolescent with the dog (i.e., room-sharing) was associated with increased benefits in terms of gained autonomy, suggesting that the better the child-dog bonding, the better the outcome. The limited sample size may have prevented the finding of other clinically significant benefits of the assistance dog.

242 **146.242** Use of Positive Reframing to Reduce Negative Statements in Adolescents with ASD - 1 Year Follow up

***J. Hai**, Education, UC Santa Barbara, Santa Barbara, CA*

Background:

Individuals with Autism Spectrum Disorder (ASD) often experience impaired social communication skills. With these difficulties, social isolation can occur which may lead to comorbid disorders such as depression and anxiety (Shtayermman, 2006; Ryden & Bejerot, 2008). Current research indicates that children with ASD are also susceptible to comorbid disorders such as depression and anxiety (Strang, J., F., Kenworthy, L., Daniolos, P., Case, L., Wills, M., C., Martin, A., & Wallace, G., L., 2012). Very few studies target these comorbid disorders in this younger population (Simonoff, E., Pickles, A., Charman, T., Chandler, S., Loucas, T., Baird, G., 2008). These increased levels of negative affect and commenting may create difficulties in social conversation and establishing meaningful relationships. Positive reframing is the ability to perceive something previously viewed as negative in a positive light (Lambert, Fincham, & Stillman, 2012). It is empirically validated as a beneficial treatment for a range of psychological conditions, including; Depression (Lambert, 2010), Anxiety disorders (Goldin et al., 2012), Depression/anxiety in parents of children with ASD (Benson, 2010).

Objectives:

To use positive reframing to effectively decrease the use of negative statements while reframing into neutral or positive statements during social conversations for adolescents with ASD. A second objective included if collateral improvements would be gained in affect/interest during social conversation.

Methods:

Participants included 3 adolescents, ages 9, 11, and 14, diagnosed with ASD. Selection criteria included making excessive negative comments to conversational partner during at least 20% of intervals in 10-minute conversational probes. A multiple baseline design was used along with partial interval recording. Behavioral measures included; negative/positive/neutral statements and affect. Self-report measures included: The beck depression inventory for youth, the beck anxiety inventory for youth, and social validity measures. For intervention, a combination treatment package was implemented. This included defining reframing, in-vivo prompting from a clinician and self-management of reframing.

Dependent Measures

Negative statements: utterances made by participant that reflected, sadness, anger, or anxiety (i.e., "I can't wait for school to be over"). For each 30-second interval in social conversation, a plus (+) was recorded if there was a negative statement in the interval, and a minus (-) was recorded if there were no negative statements made. The percentage of intervals with negative statements for the 15-minute conversation probe was then calculated.

Positive statements: utterances made by participant that reflected happiness or excitement in the content of speech, independent of affect. Neutral statements were defined as utterances made by the participant that reflected an absence of negative or positive content of speech, independent of affect. Positive or neutral statements were merged into one variable for comparison to negative statement purposes.

Results: Findings indicate that it is possible for each adolescent with ASD to effectively decrease the use of negative statements while reframing during social conversation with peers (Ex. Participant 1 neg statements 24% with mod depression/severe anxiety decreased to 5% and increased pos from 0% to 14%). One year follow-up data was also collected and found generalization of new skills.

Conclusions: N/A

243 **146.243** Using Multiple Schedules to Decrease Vocal Stereotypy of Students with ASD in Classroom Settings

***B. Cavanaugh**[1], S. Iadarola[1], R. J. Martin[2], C. M. Anderson[2], R. Iovannone[3] and T. Smith[1], (1)University of Rochester Medical Center, Rochester, NY, (2)May Institute, Randolph, MA, (3)University of South Florida, Tampa, FL*

Background: Stereotyped behaviors such as repetitive vocalizations are a defining feature of autism spectrum disorder (ASD) and can disrupt classroom instruction. Behavioral interventions have been shown to reduce stereotypy but are seldom implemented in schools because they are often designed for one-to-one settings and involve specialized teaching techniques. Structured, collaborative coaching models for teachers may help bridge this research-to-practice gap. Students with Autism Accessing General Education (SAAGE) is a modular intervention approach to address core features of ASD in educational settings. Within SAAGE, teachers are presented with guidelines for selecting and individualizing interventions (via individual “modules”), and receive coaching to implement these interventions. One SAAGE module focuses on vocal stereotypy, with intervention options that include a “Now/ Not Now” intervention, which aims to bring stereotypy under stimulus control using multiple schedules of reinforcement (e.g., Rapp et al., 2009).
Objectives: (1) Evaluate the effectiveness of a teacher-implemented multiple schedule intervention package for reducing vocal stereotypy. (2) Evaluate teacher fidelity within naturally occurring, academic instructional periods.

Methods: Two teachers worked collaboratively with their SAAGE coach to create a “Now/Not Now” intervention package for two students with ASD. For student 1, intervention included the following components: (a) visual instructions of the intervention, (b) multiple schedule visual (red/green card), (c) differential token reinforcement of low-rate (DRL) behavior during the “not now” condition, and (d) response interruption during the “not now” condition. For student 2, intervention included: (a) a social story, (b) multiple schedule visual, and (c) response cost with a visual during the “not now” interval. Following intervention development, the coach provided in-vivo skills-training to teachers and collected teacher fidelity data. Teachers observed the frequency of vocal stereotypy during academic instruction and completed the 29-item Usage Rating Profile (URP), rated from 1 (strongly disagree) to 6 (strongly agree), which assessed teacher perception of the SAAGE intervention. We used a quasi-experimental interrupted time series design (with reversal for student 2) to evaluate the intervention.

Results: For student 1, vocal stereotypy decreased to 0 during the “not now” interval and the interval was successfully increased to 5 minutes. For student 2, vocal stereotypy decreased to near-zero rates and the “not now” interval was successfully increased to 30 minutes. Teacher intervention adherence and quality were 85.19 and 100 percent for student 1, respectively, and M(SD)=88.19(10.29) and M(SD)=93.06(12.19) percent for student 2. On the URP, mean ratings for teacher 1 and teacher 2, respectively, were 6.00 and 5.67 for Acceptability, 6.00 and 6.00 for Understanding, and 6.00 and 5.67 for Feasibility.

Conclusions: Both multiple schedule intervention packages brought vocal stereotypy under stimulus control and decreased stereotypy to zero or near-zero rates during the “not now” intervals. Teachers selected the intervention over other intervention options and implemented it with fidelity. They also rated the SAAGE process as acceptable and feasible. Results provide preliminary evidence that teachers can learn to use behavioral interventions for stereotypy and that, with teacher input, the interventions can be practical to implement throughout the classroom routine, making this a potentially effective and feasible intervention option.

244 **146.244** Visual Supports at Home for Children with ASD: Using Parent and Staff Experiences to Develop and Pilot a Brief Intervention

M. Rutherford[1,2]*, J. Baxter*[3]*, L. Johnston*[3] *and Z. Grayson*[2]*, (1)Health Sciences, Queen Margaret University, Edinburgh, United Kingdom, (2)Speech and Language Therapy Department, NHS Lothian, Edinburgh, United Kingdom, (3)Additional Support for Learning Service, City of Edinburgh Council, Edinburgh, United Kingdom*

Background:
Visual Supports are one of the evidence based psychosocial interventions recommended in clinical guidelines for ASD and commonly used in school settings to support individuals with ASD to understand expectations, to reduce anxiety and to participate purposefully in daily life. Their use is reported across intervention paradigms. However, there is very little evidence about how parents and carers of children or adults with ASD are or should be, supported to access and use these at home or in the community. There is also a lack of comprehensive, evidence based guidance or ready-made resources for professionals.

Objectives:
We aim to:

1. explore experiences of parents, carers and staff in relation to access to relevant visual supports
2. explore how practical knowledge of home visual supports is shared with families in ways that enables use
3. develop and evaluate a *Home Visual Support Project* model for practice

Methods:
Following a systematic literature review, questionnaires and focus groups were conducted with parents/ carers of children with ASD (aged 2-12 years) and a multi-professional group of staff working in specialist roles with children with additional support needs and their families (n=22).

The results of the questionnaires (n=101) informed the content of the focus group discussion. This centred around challenges and solutions related to timely access to the right visual supports and reasonable support to start and maintain their use. Focus group data were transcribed and thematic analysis undertaken. Outcomes were used to develop resources and a model for practice, which could be easily delivered within current UK public service provision.

Results:

1. Key themes generated between families and professionals were remarkably similar and were:

- Participation focussed
  - Considering child’s opportunities and motivation
  - Providing supports relevant to the child within their environment
- Knowledge and understanding
  - Information
  - Training for families and staff

- Resources
    - Accessibility of a range of visual supports
    - Means of creating individualised resources
    - Need for a forum to discuss how to adapt to needs as they change over time
- Support to families
    - Individualised support and planning
    - Timely support
    - Structured processes to gather information
    - Developmentally appropriate visual supports, linked to current priorities for the child and family
    - Consistency between home, school and community settings

2. Parent and Staff resources (for 3 stages of development) and a model for practice were developed and these will be available for demonstration at the conference.

3. Pilot evaluation results for 30 parents using qualitative and quantitative parent measures will be reported.

Conclusions:

The mixed methodology provided an effective means of identifying challenges and solutions to the mismatch between provision of visual supports in home, school and community settings. Key themes generated were used to develop resources for practice, which were participation focussed; share knowledge and information; provide access to practical resources and support to families. The methodology and results from this research may be used to inform low-cost service provision in other countries.

245 **146.245** 'Gaming Seriously!': A Systematic Review and Meta-Analysis of the Influence of Serious Game Elements on the Effectiveness of Social-Emotional Computer Based Interventions in Autism

J. Tang[1,2]*, N. T. Chen*[3,4]*, M. Falkmer*[5,6,7]*, S. Bolte*[8,9,10,11] *and S. J. Girdler*[2,4]*, (1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)School of Psychological Sciences, University of Western Australia, Perth, Australia, (4)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (5)Curtin University, Bentley, Australia, (6)School of Occupational Therapy and Social Work, Curtin University, Perth, Western Australia, Australia, (7)School of Education and Communication, CHILD programme, Institute of Disability Research, Jönköping University, Jönköping, Jönköping County, Sweden, (8)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (9)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (10)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Australia, (11)Child and Adolescent Psychiatry, Center for Psychiatry Research, Stockholm County Council, Sweden*

Background:

The utility of Serious Games as a tool to target social emotional skills of individuals on the autism spectrum is increasingly explored in research. Current application of Serious Game features in computer-based interventions (CBI) in autism are heterogeneous, likely attributed to the limited frameworks outlining the most salient autism specific design features. Further understanding is required to examine the potential application of Serious Game design principles in improving the effectiveness of social emotional CBI for individuals on the autism spectrum.

Objectives:

This review aimed to evaluate the potential impact of Serious Game design in enhancing the effectiveness of social emotional CBI in autism. The objectives were to (1) develop an assessment tool to quantitatively evaluate the design of Serious Games based on an existing framework by Whyte et al. (2014), (2) provide a conceptual systematic review of the design quality of social emotional CBI in autism, (3) and to evaluate the potential moderating influence of Serious Game design principles in improving social emotional outcomes for individuals on the autism spectrum.

Methods:

The Serious Game Assessment Tool was developed through reviewing the five Serious Games principles previously outlined by Whyte et al. (2014). The five principles included motivating storyline, goal-directed learning, rewards and feedback, progression in levels of difficulty and individuation. Operational definitions and a grading system for each Serious Game principles were developed and tested for reliability. Five electronic databases were then searched with the main keywords "autism", "social", "emotion", and "computer" to retrieve relevant experimental studies evaluating social emotional CBI for individuals on the autism spectrum. With the developed Serious Game Assessment tool, a conceptual review and summary of the design features of social emotional CBI was conducted. Dependent measures relating to social emotional outcomes; close generalisation, distant generalisation, transferability to other skills, maintenance and engagement were extracted. Effect sizes were calculated and analysed using random effects model. Meta-regressions were conducted to examine the moderating influence of Serious Game design principles on social emotional outcomes.

Results:

A total of 28 experimental designs evaluating 18 existing CBI were retrieved. The application of Serious Game design was heterogeneous between interventions and few consistently incorporated Serious Game design elements (average percentage of Serious Game design application was 47%). Fifteen experimental design studies with a control group were retrieved for meta-analysis. Results indicated significant effects for CBI improving the social emotional skills for individuals on the autism spectrum (close generalisation: g = 0.69, CI =0.49-0.88, p<.001; distant generalisation: g = 0.48, CI =0.11-0.85, p<.001; transferability: g = 0.36, CI =-0.00-0.72, p=.05). Of central interest, a moderating influence of Serious Game design principles enhancing CBI-related distant generalisation outcomes was found (g = 0.33, p =.03).

Conclusions:

The findings demonstrate the importance of considering Serious Game design principles for the development of CBI in autism. The Serious Game Assessment Tool developed as part of this review may provide helpful guidance for the systematic evaluation of existing CBIs and for the prospective development of social emotional interventions.

Oral Session - 6A
Social Cognition and Social Behavior

1:45 PM - 2:35 PM - Grote Zaal

1:45 **149.001** Heart Rate Orientation Responses to the Shifts in Gaze Direction - a Follow-up Study of Low-Functioning Young Children with ASD

T. M. Helminen[1]*, M. Muuvila*[2]*, J. Lauttia*[3]*, J. M. Leppanen*[1]*, K. Eriksson*[4] *and A. Kylliainen*[1]*, (1)Tampere University, Tampere, Finland, (2)Tampere University Hospital, Tampere, Finland, (3)University of Tampere, Tampere, Finland, (4)Tampere University and Tampere University Hospital, Tampere, Finland*

Background: Reduced use of eye contact is a prominent characteristic of individuals with autism spectrum disorder (ASD). In a recently published study (Helminen et al., 2017) we showed that while young, 2-5-year-old children without ASD showed stronger heart rate deceleration response, indicative of physiological orientation, to gaze shifts to direct vs averted direction, young low-functioning children with ASD did not. The result indicated that direct gaze (or gaze shifts in overall) does not attract the attention of the children with ASD, which could lead to reduced eye contact behavior.
Objectives: The objective was to follow-up the developmental course of the heart rate orientation response to direct vs. averted gaze over the 2-year period in children with and without ASD. Furthermore, the study aimed at investigating whether the heart rate orientation response could be used as a psychophysiological outcome measure for interventions aiming at increasing the children's ability to use the eye contact in social interaction.

Methods: Twenty children with ASD (2.5 – 5.3 years, developmental age 1.2 – 4.2 years), 20 typically developing children and 18 children with developmental delay participated in the original study, and 18 ASD, 17 typically developing and 12 developmentally delayed children in the follow-up after two years. A series of facial pictures creating an illusion of dynamic gaze shifts to direct and averted gaze directions were presented, while the heart rate and eye movements were recorded. After the initial measurement, half of the children in the ASD group received a 4-months intervention based on parental guidance, aiming at increasing the children's motivation to use the eye contact in social interaction. The experiment was repeated after intervention and after a two-year follow-up period with the same participants.

Results: In the first follow-up, the control children responded to both gaze directions with a heart rate deceleration, while the ASD children showed no heart rate deceleration to either gaze condition [ANOVA Gaze x Time after gaze shift x Group, main effect of the Group p=.009). However, according to our preliminary analysis, the children with ASD in the intervention group showed a tendency to respond to gaze shifts with a heart rate deceleration after the intervention (ANOVA Session x Time x Intervention, p=.076). In the two-year follow-up, the ASD group as a whole showed similar orientation responses to shifts in gaze direction as the non-ASD control children (ANOVA Gaze x Time x Group, main effect of time p=.003, no effects of Group).

Conclusions: The preliminary results indicated that the effect of short-term eye contact intervention might be seen in enhanced psychophysiological orientation response to the shifts in gaze direction in young children with ASD. In addition, during the course of development, also the children with ASD who receive treatment as usual, might start to show similar orientation responses to the shifts in gaze direction as non-ASD children with or without developmental delay. The potentiality of the heart rate orientation response as a psychophysiological outcome measure in the intervention studies will be discussed.

1:57 **149.002** Social Attention in ASD Females: The Same, Yet Different

C. Harrop[1]*, D. R. Jones*[2]*, S. Nowell*[3]*, S. Zheng*[4]*, R. T. Schultz*[5] *and J. Parish-Morris*[5]*, (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Texas at Dallas, Richardson, TX, (3)University of North Carolina at Chapel Hill, Carrboro, NC, (4)Psychiatry, University of California, San Francisco, San Francisco, CA, (5)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Differences in attention to social stimuli are a hallmark feature of ASD and have been extensively studied using eye-tracking. Chevallier et al. (2015) found that some stimuli are better at capturing social attentional differences in children with ASD than others, with dynamic videos generating the largest group differences.
Due to a sex imbalance in ASD diagnoses, very few studies have used eye-tracking to examine sex differences in social attention. Emerging literature suggests that girls with ASD socialize differently than boys (Dean et al., 2017) and experience heightened social motivation (Sedgewick et al., 2016), mirroring some of the differences found in typically developing girls and boys. Therefore, a dynamic eye-tracking paradigm may reveal differences in social attention and motivation in girls with ASD.

Objectives: The purpose of this study was to examine whether behavioral and clinical differences in ASD males and females were mirrored in their distribution of attention to social, dynamic stimuli – particularly faces – using a validated eye-tracking paradigm.

Methods: 65 children aged 6 to 10 years were included in the study [37 ASD (16 female); 28 typically developing (TDC; 14 female). Children completed a Visual Exploration eye-tracking paradigm that included 22 silent video clips of 11 sibling pairs of school-aged children playing together (Joint condition) or in parallel (Parallel condition; Chevallier et al., 2015). Our primary dependent variable of interest was the proportion of gaze duration to faces relative to gaze duration toward the full screen, overall and by condition. We also compared the proportion of gaze duration to hands playing with objects, background objects, and the "space between" people and objects, overall and by condition.

Results: Diagnosis (ASD vs. TD) and sex (Male vs. Female) predicted a number of indices of social attention. Children with ASD spent proportionally less time attending to faces overall and across conditions (Joint and Parallel; all ps <0.02, η^2_p .08 to .17). However, sex also differentiated fixation to faces overall and in the joint play condition (ps <.05, η^2_p .06 & .08) with females allocating proportionally more attention to faces than males. Within the ASD group, ASD females spent proportionally more time attending to faces (t= -2.24, p =.03), particularly in the parallel play condition (t=-2.51, p =.01). Diagnostic groups looked equally at background objects and hands with toys, but the ASD group gazed longer at the "space between" AOIs than the TD group (ps<.01, η^2_p .07 to .15; no effect sex or interaction).

Conclusions: Using a validated, ecologically valid, eye-tracking paradigm we found both similarities and differences between ASD males and females. Our data reveal that while ASD females demonstrate enhanced social attention compared to boys with ASD, their overall pattern of attention, particularly to areas of the scene not portraying social or non-social information (“space between”), was comparable to their male counterparts. This disjointed pattern of attention aligns with clinical and behavioral reports of ASD females, with reported heightened social motivation and desire for friendships, yet similar rates of actual friendships and social success to ASD males.

2:09 **149.003** Interpersonal Coordination and Its Role in Social Functioning in ASD

C. J. Zampella[1] *and L. Bennetto*[2]*, (1)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Clinical and Social Sciences in Psychology, University of Rochester, Rochester, NY*

Background: Interpersonal coordination (IC) is the tendency for social partners to nonconsciously align their behaviors. It is a well-established phenomenon from infancy, and has been shown to foster connectedness, enhance processing of social cues, and play an important role in development. A small body of research has begun to suggest atypical IC in autism spectrum disorder (ASD). This study augments that research by evaluating differences in both nonverbal and verbal IC as contributors to social symptoms in ASD.

Objectives: (1) To quantify the degree to which children with and without ASD engage in IC; (2) To identify the extent to which engaging in IC relates to aspects of social functioning impaired in ASD.

Methods: Participants were 20 well-characterized children (ages 9-16) with ASD and 17 matched typically developing controls (TDC). Children participated in conversational tasks with their mothers and an unfamiliar research assistant. IC during these tasks was coded from recordings by blinded raters, using two established coding systems. The first captured temporal coordination among interaction partners’ movements (*movement coordination)*; the second captured IC in terms of the verbal content of interactions (*content coordination;* e.g., mutual focus, conversational equality). Interrater reliability was adequate for all codes (*ICC*s .77-.96). Children’s everyday social functioning was also assessed with standardized measures completed by mothers, in the domains of general social skills, communication skills, empathy, and perspective-taking.

Results: Movement and content coordination were analyzed separately with mixed design ANOVA. There was a significant main effect of group for both movement coordination, $F(1,34)=17.65$, $p<.001$, $\eta_p^2=.34$, and content coordination, $F(1,34)=7.21$, $p=.01$, $\eta_p^2=.18$. In both cases, children with ASD were rated as displaying significantly less IC with their interaction partners than TDC children. Neither within-subjects effects of familiarity level nor interaction terms were significant. Within the ASD group, both movement coordination, $r(17)=-.64$, $p=.003$, and content coordination, $r(17)=-.59$, $p=.01$, were significantly correlated with symptom severity as measured by ADOS-2 calibrated severity scores. Linear regression analyses across all children indicated that movement coordination predicted scores on standardized measures of general social skills, communication skills, empathy, and perspective-taking, even when controlling for content coordination (all $\beta s \geq .39$; $ps<.05$). Content coordination, however, did not predict any social outcome domain when controlling for movement coordination (all $\beta s \leq .15$; $ps>.05$). Finally, movement coordination partially mediated the relationships between diagnostic status and both general social skills and communication skills.

Conclusions: Results demonstrate reduced nonverbal (movement) and verbal (content) IC in children with ASD, suggesting atypicality in their ability to engage in a social process that is automatic and fundamental in normative development. Results also strongly link IC to primary areas of social impairment in ASD. Lower IC was associated with more severe ASD symptoms, suggesting a relationship with core diagnostic deficits. Moreover, movement coordination specifically predicted functioning across several key social domains, raising the possibility that a failure by individuals with ASD to coordinate movements with social partners may help explain social difficulties. Findings thus highlight atypical IC as an important, understudied process in ASD, which may be a mechanism driving social and communication impairments.

2:21 **149.004** Characterizing Temporal-Contextual Effects on Social and Object-Directed Attention in ASD Via High-Density Video Coding

A. Rozga[1]*, A. Southerland*[1]*, M. McCall*[1]*, E. A. Stubbs*[1]*, M. R. Silverman*[2]*, E. Ajodan*[2]*, K. Chanda*[1]*, E. Chong*[1]*, J. Rehg*[1] *and R. M. Jones*[3]*, (1)Georgia Institute of Technology, Atlanta, GA, (2)Sackler Institute for Developmental Psychobiology, New York, NY, (3)Weill Cornell Medicine, New York, NY*

Background: Atypical patterns of gaze in social interactions remain among the earliest behavioral red flags for autism and are commonly targeted in treatment. Observational studies typically examine global frequencies of behaviors such as eye contact and joint attention. Eye-tracking technologies have enabled more detailed characterization of gaze dynamics in laboratory “screen tasks,” but such high-density measurements have rarely been applied to more ecologically valid “live” social interactions.

Objectives: We used high-density video coding to characterize patterns of social and object-directed gaze, along with temporal-contextual factors, during live play interactions in children with autism (ASD) and typically developing (TD) children.

Methods: 56 ASD and 58 TD children were administered the Early Social Communication Scales, videotaped with a camcorder as well as a camera embedded in a pair of glasses worn by the examiner that captured the child’s looks to the examiner’s eyes. A subset of the sessions – the six ESCS toy-spectacle tasks for 21 ASD (mean age 45.1mo, SD=10.6; mean VIQ=74, SD=33; 71% male) and 38 TD (mean age 27.4mo, SD=5.3; 63% male) participants – were coded at the frame level for the onset/offset of each instance of (1) child looking to the examiner’s eyes; (2) child looking at the toy; (3) examiner activating the toy, (4) the toy inactive and out of the child’s reach, and (5) the toy in the examiner’s vs. child’s possession.

Results: Dependent variables were not normally distributed; hence, we report the results of nonparametric tests. Compared to TD children, the ASD children spent less time making eye contact with the examiner when the toy was inactive (p=.001) and in their possession (p=.01), with no group differences during toy active periods (p=.06). The ASD group produced fewer shifts of attention from the toy to the examiner’s eyes across toy active (p=.01), toy inactive ($p<.001$), and child possession (p=.005) periods. Within-group analyses indicated that during periods of examiner toy possession, both groups spent more time making eye contact with the examiner and less time looking at the toy when it was inactive compared to when it was active (all p’s<.0001). They also engaged in more attention shifts when the toy was inactive compared to when it was active (ASD p=.-001; TD p<.0001). Children in both groups spent more time looking at the toy when it was in their possession vs. the examiner’s possession (p’s <.0001), with no effect of possession on amount of eye contact and rate of gaze shifts (p’s>.1).

Conclusions: These results confirm previous findings of decreased eye contact and lower rates of joint attention gaze shifts in children with ASD, but indicate that temporal context matters for the pattern of group differences observed. Importantly, our analyses revealed that children with ASD modulated their gaze across toy active/inactive and child/examiner possession periods similarly to TD children, indicating they were sensitive to the temporal context of the interaction. These results have implications for measurement of social and object attention in research studies aiming to characterize early behavioral markers of ASD, and for treatment outcome measures.

Oral Session - 6B
Social Cognition and Social Behavior
150 - Human-robot interactions and ASD
2:40 PM - 3:30 PM - Grote Zaal

2:40 **150.001** Could Human-Robot Interactions Facilitate Joint Attention of Children with Autism Spectrum Disorder (ASD)?

W. Cao[1], W. Song[2], X. Li[3], S. Zheng[4], G. Zhang[5], Y. Wu[3], S. He[2], ***H. Zhu***[6] *and J. Chen[7], (1)South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (2)Centre for Optical and Electromagnetic Research, South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (3)School of Psychology, South China Normal University, Guangzhou, China, (4)School of Physics and Telecommunication Engineering, South China Normal University, Guangzhou, China, (5)Caihongqiao children rehabilitation and service center of Panyu district, Guangzhou, China, (6)Child Developmental & Behavioral Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (7)School of Electrical Engineering and Computer Science, KTH Royal Institute of Technology, Stockholm, Sweden*

Background:
Impaired social communication is one of the core symptoms of the autism spectrum disorder (ASD). Some studies have shown that the children with ASD might have developmental deficits on joint attention, which was one of the basic forms of social interactions. Meanwhile, in recent years humanoid robots showed a potential to be a social partner of ASD and were introduced to involve in interventions. Nevertheless, few researches have focused on the difference of interacting with human agents and robots within ASD population. It remains a question whether human-robot interactions facilitate joint attention of children with ASD.

Objectives:

To address the aforementioned question, the study aimed to investigate the difference between the ASD and typically-developing (TD) children when viewing human-robot interactions compared to human-human interactions. By combining a commercial humanoid robot NAO with the Tobii X3-120 eye-tracker system, this study measured the eye movement patterns towards the interactions between two figures, including two types, namely human-robot vs. human-human.

Methods:

6 ASD (mean age: 4.84±0.41) and 12 age-matched TD children (4.63±1.05) participated in the eye-tracking tests. Video stimuli depicted the interaction between one female and one agent (a male or a robot). Each video clip contained four stages: Greeting (two figures say “Hi” towards the screen); Looking at each other (two figures looked at each other); Leading by gazing (two figures turned their head towards the common target); Leading by pointing (two figures moved their fingers to point towards the target). First fixation time, total fixation duration and fixation time percentage were collected to measure the attention distribution among different areas of interests (AOIs): head, body, hand, target and background.

Results:

Data analysis showed that participants fixated faster in the human-human interaction condition in the stage with leading by gazing, but the total fixation time was shorter in the human-robot interaction condition. On the other hand, in the stage with leading by pointing, the participants made faster fixation in the human-robot interactions, but the total fixation time was shorter during human-human interactions. Meanwhile, compared to the human-robot interaction condition, in the human-human interaction condition the participants spent less time on the agent’s head, but spent more time on head and hand of the agent in the stage with leading by gazing, and on the target in the stage with leading by gazing. Furthermore, ASD spent more time on the male body, TD spent more time on human hand in leading by pointing stage of human-human interaction condition, but TD spent more on human body in leading by gazing stage, more on human head in leading by point stage of human-robot interaction condition.

Conclusions:

This research showed that the human-robot interaction might have a different feature compared to the human-human interaction. Although the robot could attract the attention of ASD children in some conditions, the children with ASD could not well understand and follow the intentions of social robots, which implied that the social robot might have difficulty to facilitate the education or intervention of ASD children.

2:52 **150.002** Robot-Assisted Learning-By-Teaching Pedagogy for Improving Social Skills

L. Boccanfuso[1]*, E. Barney[2], M. Mademtzi[3], C. Foster[3], Q. Wang[3], B. Scassellati[4], P. E. Ventola[5] and F. Shic[2], (1)Vän Robotics, LLC, Irmo, SC, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Yale University, New Haven, CT, (5)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background:
An increasing number of children with autism spectrum disorder (ASD) are attending mainstream schools. The majority of these children receive regular interventions that provide opportunities to practice social skills within group settings, one-on-one intervention with an educator or targeted therapy with a specialist. However, it is still uncommon for a child with autism to have the opportunity to develop the social skills acquired during interventions and foster a deep, generative understanding of these skills by engaging others in peer tutoring. The learning-by-teaching pedagogy offers these children a number of potential social benefits that may facilitate long-term learning and improved outcomes but there are numerous challenges make the deployment of peer tutoring difficult in practice.

Objectives: In this first study, we evaluated the potential benefits of a novel robot-assisted, learning-by-teaching approach for advancing social skills using a set of well-defined social skills tasks for school-aged children with ASD. We investigated the feasibility and comparative benefits of implementing the paradigm in a child-to-robot context versus a child-to-human-confederate scenario. Further, we examined the relative differences in engagement between conditions and potential performance implications correlated to higher engagement in each study condition.

Methods: Ten children between 6-10 years of age (*m=8.75 yrs.*) who were diagnosed with ASD based on evaluation with gold standard DSM-5 criteria and met or surpassed a minimum threshold (>=80) for IQ, as determined by the Differential Ability Scales-General Conceptual Ability (DAS-GCA) assessment (*m=107.5*), were invited to participate in this randomized control trial. We empirically evaluated performance on a set of social

skills tasks and engagement level during two study conditions: robot and human-confederate. We computed Pearson bi-variate correlations to evaluate potential connections between IQ, performance and engagement and performed Fisher's z-transformation on correlations to investigate the significance of differences between resulting correlations. Finally, we conducted multiple linear regression to examine the predictive value of age, IQ and engagement for predicting performance in both study conditions.

Results: Results show that 80% of study participants performed better in the robot condition (*mean performance: robot=63%, confederate=37%*) and 90% of all participants were significantly more engaged in the robot condition (*mean engagement: robot=61%, confederate=32%*). Verbal IQ and IQ were significantly correlated with overall performance in the confederate condition (*r=0.794, p<0.05 and r=0.726, p<0.05, respectively*), but no correlation resulted in the robot condition between Verbal IQ/IQ and overall task performance or in any individual script. Multiple linear regression was conducted to predict overall performance from IQ, age and engagement. Although age, IQ and overall engagement did not predict performance in the confederate condition, these variables statistically significantly predicted overall performance in the robot condition, F(3,6)=5.399, p<0.05, R2=0.730.

Conclusions: Results from this study confirm the feasibility of this new robot-assisted intervention and support the significant potential of this approach for promoting social skills. These findings further underscore the attentional value of employing a robot in an autism intervention and the potential therapeutic benefit of employing a social robot as a peer student.

3:04 **150.003** Do Children with Autism Spectrum Disorder Learn to Distrust and Deceive a Social Robot?

Y. Zhang[1]*, W. Song*[2]*, Z. Tan*[3]*, J. Chen*[4]*, H. Zhu*[5] *and* ***L. Yi***[6]*, (1)Peking University, beijing, China, (2)Centre for Optical and Electromagnetic Research, South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (3)South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (4)School of Electrical Engineering and Computer Science, KTH Royal Institute of Technology, Stockholm, Sweden, (5)Child Developmental & Behavioral Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (6)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China*

Background:

Children with autism spectrum disorder (ASD) display difficulty in understanding other people's mental states (Baron-Cohen, 2001) and learning complex social rules in interpersonal interaction (Jones et al., 2013). For example, children with ASD showed difficulty in learning the social rules to distrust and deceive an adult who repeatedly deceive them (Yi et al., 2014). However, little is known about how children with ASD learn social rules from social robots.

Robots can offer children with autism spectrum disorder (ASD) a safe and predictable environment and help develop social skills (Dautenhahn et al., 2004). Studies on using interactive robot in therapy that helps children with ASD learn social skills have shown promising outcomes (Feil-Seifer et al., 2008; Kozima et al., 2007; Stanton et al., 2008). In our study, we attempt to use social robot to teach hidden social rules to children with ASD in the trust and deception games.

Objectives:

To examine how children with ASD learn social rules to distrust and deceive a social robot.

Methods:

Twenty-one 5 to 8-year-old children with ASD and 21 age-matched typically-developing (TD) peers participated in the trust and deception tasks with a social robot to try to win as many tokens as possible. In the trust task, children were asked to find a token in three identical cups, while the robot providing misleading information about the location of the token (pointing to an empty cup). This procedure repeated for 10 trials. In the deception task, children were asked to switch the roles with the robot, i.e., the children hid the token and the robot looked for it. With this manipulation, we aimed to investigate whether children would deceive the robot. Children had to hide the token and then indicate a location of the token for the robot to find over another 10 trials.

Results:

The analysis of the overall performance across 10 trials indicated that: (a) children with ASD showed a trust bias towards the robot (t = -3.77, p = .001); (b) they were also less likely to deceive the robot (t = -2.47, p = .02). This finding replicated the difficulty of children with ASD in distrusting and deceiving a human experimenter in the previous research (Yi et al., 2014).

The survival analysis based on the trial-by-trial data, as shown in Figure 1, further indicated the learning process over the 10 trials in both groups. Results showed that in the trust task, the ASD group learned slower than the TD group to distrust the robot (p < .001). The group difference in the deception task were marginally significant (p = .064).

Conclusions:

Our study indicated that when confronting the social robot, children with ASD showed a trust bias and difficulty engaging in deception compared to the TD children. However, it does not mean inferring mental states from the robot is more difficult than that from the human. Therefore, it might still be promising to develop intervention protocol using robots based on this paradigm to teach the social rules to children with ASD.

3:16 **150.004** A Randomized Controlled Trial of the Effectiveness of Pivotal Response Treatment with and without Use of a NAO Robot in Young Children with ASD

I. Smeekens[1,2]*, M. De Korte*[2,3]*, M. Van Dongen - Boomsma*[2]*, J. C. den Boer*[4]*, I. J. Oosterling*[2]*, J. K. Buitelaar*[5,6]*, W. G. Staal*[1,2,7]*, E. I. Barakova*[8]*, T. Lourens*[9] *and J. C. Glennon*[3]*, (1)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Department of Cognitive Neuroscience, Nijmegen, Netherlands, (2)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (3)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands, (4)Karakter Child and Adolescent Psychiatry, Ede, Netherlands, (5)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (6)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (7)Institute for Brain and Cognition, Leiden University, Leiden, Netherlands, (8)Faculty of Industrial Design, University of Technology, Eindhoven, Netherlands, (9)TiViPE, Helmond, Netherlands*

Background: Pivotal Response Treatment (PRT) is a promising intervention effective in promoting "pivotal skills" in children with autism spectrum disorder (ASD) (Bozkus-Genc & Yucesoy-Ozkan, 2016). However, evidence is lacking on which treatment components contribute to higher gains in generalized social communication skills and general clinical functioning and to diminished ASD symptoms. The use of robots within the treatment of ASD is hypothesized to contribute to higher treatment gains, since robots are intrinsically appealing to many children with ASD and robots may generate motivation for social interaction (Scassellati, 2007) and engagement in interventions (Boccanfuso et al., 2017). However, contemporary research on using robots in ASD interventions often lacks 1) methodological rigor (Begum, Serna, & Yanco, 2016), 2) evidence on generalization of treatment effects and follow-up (Pennisi et al., 2016) and 3) insight into how robots can be of additional value to established interventions (Diehl, Schmitt, Villano, & Crowell, 2012).

Objectives: The present study aims to examine the effectiveness of using a humanoid (NAO) robot within parent-mediated PRT for diminishing ASD-related symptoms and improving general clinical functioning in young children with ASD compared with PRT (without robot) and treatment-as-usual (TAU).

Methods: A randomized controlled trial (RCT) design was used to compare 1) parent-mediated PRT with using the NAO robot (PRT+robot), 2) parent-mediated PRT, and 3) TAU in 74 young children (3-8 years) with ASD. PRT consisted of 20 weekly therapy sessions, including 14 parent-child sessions and 6 parent sessions. In both PRT conditions, parents were trained in use of the PRT techniques and in the PRT+robot condition, the robot was added in all parent-child sessions to train the child with programmed scenarios incorporating PRT techniques. At baseline, week 10, 20 and 3-month follow-up, the child's ASD-related symptoms were assessed with the Social Responsiveness Scale (SRS, Roeyers, Thys, Druart, De Schryver, & Schittekatte, 2011) completed by parents and teachers. Clinically significant improvement was examined using the Clinical Global Impression-Improvement Scale (CGI-I, Guy, 1976) completed by a blinded child psychiatrist.

Results: Repeated measures analysis using the GLM approach indicated a significant main effect of time ($F(3,147) = 14.53$, $p < .001$) and a time x group interaction effect ($F(6,147) = 2.78$, $p = .018$) on the SRS completed by parents, reflecting steeper decrease of ASD-related symptoms over time in the PRT+robot condition (see Figure 1). Furthermore, the percentage clinical responders (*much* and *very much improved* on the CGI-I) was significantly higher in the PRT+robot condition (66.7%) compared with both the PRT (36.4%) and TAU condition (36.4%) ($\chi^2(1) = 4.22$, $p = .040$) at week 20, but not at follow-up (PRT+robot (63.2%) vs PRT (50.0%): $\chi^2(1) = 0.67$, $p = .408$; PRT+robot (63.2%) vs TAU (40.0%): $\chi^2(1) = 2.09$, $p = .148$).

Conclusions: Results of this study provide a first indication that the use of robotics in PRT may be an effective treatment component in diminishing ASD-related symptoms and improving general clinical functioning in young children with ASD. Implications for clinical use of robotics in PRT and future research will be discussed.

Oral Session - 7A
Family Issues and Stakeholder Experiences
151 - Family Issues and Stakeholder Experience
1:45 PM - 2:35 PM - Willem Burger Zaal

1:45 **151.001** Play with Me: Sibling Interactions of High-Risk Infants with Their Older Brother or Sister with Autism Spectrum Disorder

P. Warreyn[1]*, C. Bontinck*[2]*, E. Demurie*[1]*, S. Van der Paelt*[1] *and H. Roeyers*[1]*, (1)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (2)Department of Experimental-Clinical and Health Psychology, Ghent University, Gent, Belgium*

Background:

The social experience and social context of infants in their first years of life play an important role in shaping their future social interactions. In infant siblings of children with ASD, who have an increased risk of developing ASD or related social-communicative problems themselves, these social interactions may be even more important. Recently, there is increased attention for parent-child interactions in these high-risk (HR) siblings. Another important aspect of early social experience has however been largely overlooked so far: the interaction with older siblings. In the case of HR siblings, at least one of these older siblings has ASD, which will have an impact on the interaction between both children, and most probably also on the social learning opportunities of the youngest child. Therefore, this study was the first to focus on sibling interactions between HR siblings and their older brother or sister with ASD, in a longitudinal design.

Objectives:

1) To compare sibling interactions of HR siblings and their older sibling with ASD with those of low-risk (LR) control dyads and 2) to explore the possible predictive value of these interactions for the later development of HR infants.

Methods:

28 HR dyads and 34 LR dyads were seen when the youngest sibling was 18, 24 and 36 months old, as part of a larger follow-up study. Sibling interactions were observed during a naturalistic free-play session filmed at home, and positive and negative initiatives and responses of both interaction partners were coded afterwards. At 24 and 36 months, the Mullen Scales of Early Learning and the ADOS-2 were administered.

Results:

At 18 months, HR siblings responded more often in a negative way to the initiatives (both positive and negative) of their interaction partners, and so did their older brother or sister with ASD. There was no difference in the amount of positive initiatives or responses. At 24 months, HR siblings made fewer initiatives, especially positive ones, compared to the LR infants. By 36 months, the number of initiatives did not differ anymore between the groups, but both HR infants and their older sibling with ASD responded less often positive to an initiative of the interaction partner. In general, infants of both groups showed more initiatives at 36 months than at 18 and 24 months. Responsiveness of the HR infants decreased over age, while this was not the case in LR infants.

A lower number of initiatives made by the HR infants (and a lower number of responses by their older sibling with ASD) at 18 months predicted a higher ADOS score at 24 months.

Conclusions:

Sibling interactions of HR infants with their older brother or sister were characterised by more negativity and/or less positivity. In addition, in HR infants there was a decrease in responsivity over time. Sibling interaction at 18 months predicted ADOS scores at 24 months in the HR group. 36-

month outcome is currently being collected, and the extent to which this is predicted by peer interaction variables will also be presented at the meeting.

1:57 **151.002** Mental Healthcare Experiences of Autistic Adults: Using First-Hand Perspectives to Inform a Clinician Training Program

B. B. Maddox[1], *S. R. Crabbe*[1] *and D. S. Mandell*[2], *(1)University of Pennsylvania, Philadelphia, PA, (2)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: Many autistic adults struggle with psychiatric disorders; however, little is known about their personal experiences navigating the mental healthcare system and their satisfaction with services. Oftentimes, these adults face a “services cliff” when they exit high school, with limited options for treatment. A shortage of trained clinicians is one of the most commonly reported barriers to quality mental healthcare for adults on the spectrum. No prior studies have interviewed autistic adults about their recommendations for improving the mental healthcare system to meet their needs.

Objectives: The objective of this community-partnered study is to learn from autistic adults about their experiences with mental healthcare, in order to inform a training program for clinicians working with this population. We aimed to obtain an in-depth understanding of specific clinician characteristics and actions that contribute to negative or positive mental healthcare experiences for adults on the spectrum.

Methods: To date, we have completed semi-structured interviews with 15 autistic adults spectrum (12 male; mean age 36 years, age range 19-56 years). By December 2017, we will have a final sample of 20 adults; this target sample size is considered more than sufficient to reach thematic saturation in qualitative research. All participants are age 18 years or older with the verbal abilities to complete a one-hour interview. The interview questions ask about the adult’s experiences and needs related to mental health treatment, along with recommendations for training clinicians to better serve this population. All interviews are audio-recorded and professionally transcribed for analyses. Analyses are guided by grounded theory, which provides a rigorous, systematic approach to collecting and analyzing qualitative data.

Results: Participants expressed varying degrees of satisfaction with their mental healthcare experiences. Preliminary data provide important insights into difficulties with finding quality psychiatric treatment, particularly in community mental health settings. A common theme is the perception that clinicians rely too much on pharmacological treatment. Participants offered recommendations for clinicians to improve their interactions with adult clients on the spectrum, including modifying the environment to account for sensory sensitivities, using concise and direct language, being comfortable with silence as the client may need additional time to process information, and providing more psychoeducation about emotions. Almost every participant shared stories about not feeling understood, validated, or respected by mental health providers. For example, according to one young woman: “I think a lot of people that I know on the spectrum have this experience of feeling really invalidated. The therapist thinks that the way to go is to make us more typical. . . That's not helpful.”

Conclusions: This study is one of the first to obtain first-hand perspectives from autistic adults about navigating the mental healthcare system. These findings directly inform priority training needs for clinicians working with this population, with a focus on better understanding how core autism symptoms affect in-session interactions and treatment progress. Effective mental health services could significantly improve the quality of life for many adults on the autism spectrum.

2:09 **151.003** Videogame (Over)Use in Children and Adolescents with Autism: Exploring Parental Concerns, Attitudes, and Mediation Strategies

S. S. De Pauw[1], *J. Van Brabandt*[1], *L. Tiberghien*[1], *L. De Clercq*[1] *and L. M. Dieleman*[2], *(1)Department of Special Needs Education, Ghent University, Ghent, Belgium, (2)Department of Developmental, Personality, and Social Psychology, Ghent University, Ghent, Belgium*

Background:

Playing videogames is one of the most favourite leisure activities for many children and adolescents with Autism Spectrum Disorder (ASD). Their parents, however, frequently have mixed feelings about these screen-based activities and their children’s level of engagement with it. On the one hand, accumulating studies suggest that youth with ASD is at significantly greater risk of problematic use of videogames, compared to peers without ASD or with other disabilities. On the other hand, many parents also endorse that videogames serve a significant number of emotional, social, and intellectual needs of their child with ASD.

Objectives:

Given the parents’ pivotal role in accommodating their child’s leisure behaviours, this study aims to better understand (1) videogame (over)use in Flemish youth with ASD, (2) the concerns and attitudes of parents about this videogame (over)use, and (3) the mediation parenting strategies that parents adopt to manage their children’s screen-based activities.

Methods:

Parents of 244 children and adolescents with ASD (M_{age} child= 12.03, 7-17 year olds) completed a comprehensive online survey. In the first part, parents reported on the frequency, duration, game characteristics and child preferences, and measures evaluating both the negative (Problem Videogame Playing Test, PVGT; obsessive passion; concern about gaming; negative evaluation of life domains, ill-being) and positive (harmonious passion; positive evaluation of life domains; social engagement; well-being) impact of videogame use. In the second part, parents reported on their use of active, restrictive or social strategies in parental game mediation, and on the extent these mediations are exerted in an autonomy-supportive or controlling manner. Parents also evaluated their own attitudes and concerns about the videogaming of their child, in addition to dimensional ASD-symptoms of the child (Social Responsiveness Scale).

Results:

In line with international estimates, Flemish youth with ASD spent an average of 2.45 hours/day playing videogames. However, Flemish parents reported significantly higher PVGT-scores on their children (M=56.6) than similar research in the U.S. (M=41.2; Mazurek & Engelhardt, 2013; d=1.2). Gender (boys) and a preference for the most popular genres (adventure, action, and violence) were associated with more negative outcomes. The quality of passion for gaming, however, yielded two separate patterns: a problematic, obsessive passion-pattern (with excessive PVGT-scores, more ill-being, parental concerns and negative attitude towards gaming) versus a non-problematic, harmonious passion-pattern (more hours/day, but not related to ill-being, parental concerns or negative outcomes). Surprisingly, no associations between gaming and positive outcomes were

found.

Parents of younger children exerted more social, active and restrictive mediation than parents of older children. Notably, we did not find associations between parental concerns or negative perceptions and restrictive or controlling mediation strategies. Social mediation (i.e., playing together), however, turned out to be significant 'buffering' factor for negative gaming outcomes. Moreover, an autonomy-supportive style fostered harmonious passion for gaming.

Conclusions:

This study demonstrates the importance of distinguishing obsessive versus harmonious passion for gaming in youth with ASD. It also gives practical tools, suggesting that playing together (i.e., social mediation) and an autonomy-supportive parental style may protect children with ASD from the negative outcomes of excessive gaming.

2:21 **151.004** The Bi-Directional Association between Sleep Problems and Autism Spectrum Disorder Symptoms: A Population-Based Cohort Study

*M. E. Verhoeff[1], L. Blanken[2], D. Kocevska[3], V. Mileva-Seitz[4], V. Jaddoe[5], T. White[6], F. Verhulst[3], **M. Luijk**[7] and T. Henning[8], (1)Department of Child and Adolescent Psychiatry/Psychology, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands, (2)Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, (3)Department of Child and Adolescent Psychiatry/Psychology, Erasmus University Medical Center–Sophia Children's Hospital, Rotterdam, Netherlands, (4)Department of Child and Adolescent Psychiatry/Psychology, Erasmus Medical Center, Rotterdam, Netherlands, (5)Department of Pediatrics, Erasmus University Medical Center –Sophia Children's Hospital, Rotterdam, Netherlands, (6)Child and Adolescent Psychiatry, Erasmus University Medical Centre, Rotterfdam, Netherlands, (7)Department of Psychology, Education and Child Studies, Erasmus University Rotterdam, Rotterdam, Netherlands, (8)Department of Psychiatry, Erasmus MC-University Medical Center, Rotterdam, Netherlands*

Background:

Sleep difficulties are prevalent in children with Autism Spectrum Disorder (ASD), occurring in 40-80% of cases across all ages. The association between sleep problems and ASD can be of two forms. First, sleep problems may precede and worsen the behavioural outcome of ASD. Second, sleep problems may occur as a consequence of the underlying disorder. Because longitudinal studies are lacking, the temporal nature of the association between sleep problems and ASD is unclear.

Objectives:

Our aim is to clarify whether sleep problems precede and worsen autistic traits and ASD or occur as a consequence of the disorder. This enables us to gain more insight in the course of sleep problems in children with ASD over time which can be beneficial for parents and for clinical practice.

Methods:

Repeated mother-reported sleep measures were available at 1.5, 3, 6, and 9 years of age in 5151 children participating in the Generation R Study, a large prospective birth cohort in the Netherlands. Autistic traits were reported by the mother using the Pervasive Developmental Problems score (PDP) of the Child Behavior Checklist (CBCL) at 1.5, 3, and 6 years and the Social Responsiveness Scale (SRS) at 6 years. This cohort included 81 children diagnosed with ASD by a clinician who we compared with the rest of the sample.

Results:

Sleep problems in early childhood were prospectively associated with a higher SRS score, but not when correcting for baseline PDP score. By contrast, a higher SRS score and an ASD diagnosis were associated with more sleep problems at later ages, even when adjusting for baseline sleep problems. Likewise, a trajectory of increasing sleep problems was associated with ASD.

Conclusions:

Sleep problems and ASD are not bidirectionally associated. Sleep problems do not precede and worsen autistic behaviour, but rather co-occur with Autistic traits in early childhood. Yet, as supported by our trajectory analyses, the severity and frequency of sleep problems decreases in typically developing children, whereas sleep problems worsen over time in children with ASD. This strongly suggests that the pathology underlying ASD on the behavioural sequelae, determines the development of sleep problems. A possible mechanism for why sleep problems in children with ASD persist could be that social problems associated with ASD may worsen the day-night rhythm in these children and play a crucial role in the development of sleep problems. Socialization of day-night rhythm by parents, such as bed time routines, night time rituals, and family regularity, are important in young children as they can act as social zeitgebers and thereby contribute to the development of a healthy sleep pattern and the prevention of the occurrence of sleep problems. Children with ASD have difficulty to adequately respond to the social zeitgebers and therefore may struggle to develop a healthy sleep pattern. More research is needed to unravel the socialization of day-night rhythm in children with ASD and the linkage with the development of sleep problems. Future studies should emphasize bed time routines and family regularity when investigating children with ASD and sleep problems.

Oral Session - 7B
Family Issues and Stakeholder Experiences
152 - Involving Autistic People and their Families in Autism Research
2:40 PM - 3:30 PM - Willem Burger Zaal

2:40 **152.001** Including Autistic People and Relatives in Planning, Designing and Undertaking Longitudinal Research: An Evolution from Consultation and Advice to Participatory Research

***J. R. Parr**, Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background: Little guidance exists regarding ways for autistic people and researchers to work together effectively. During the first years of the Autism Spectrum Cohort-UK (ASC-UK) longitudinal cohort project, and the broader Autism Lifecourse and Ageing research programme, we worked with autistic adults in various ways.

Objectives: 1. To disseminate information about how a stakeholder-informed research approach moved toward participatory research in a longitudinal cohort study and research programme; 2. Show how this process benefitted researchers and autistic people – and what might have been done differently.

Methods: The participatory research approach evolved over 5 years. Initially around 50 autistic adults and relatives advised on their research priorities, and project methods and materials. From 2014, autistic people and relatives were consulted and advised on the research process. The team then moved toward an approach where autistic people and relatives were part of the research team, and named on funding applications. Later discussions focussed on the positive experiences, and the limitations of people's roles, and how in retrospect autistic people might have been involved differently from the outset. This informed the next phase participatory research regarding ASC-UK, and associated projects.

Results: *Consultation before and during initial research phases*: Initial involvement of autistic people involved three autistic adults attending a research prioritisation meeting, being paid as research advisors, and a relative being recruited to the research team. A broader group of autistic people and relatives (30 people) attended separate larger consultation meetings about methods and materials. Autistic people supported the research team to develop appropriate strategies for before, during and after meetings. For example, telephone conferences were discounted, and meetings were face-to-face. Materials were sent well before the meeting, with clear topics for discussion on an agenda that was not altered subsequently. Opportunities to make the environment appropriate were an additional focus (e.g., discussion about the room to be used, accepting low natural light surroundings). A 'model' of how to conduct meetings with autistic advisors, and those attending consultation groups was created so each type of meeting was undertaken similarly. Payments for autistic advisors time were agreed; the research team arranged and funded travel and accommodation.

Moving from consultation and advice to participatory research: During the research, as new projects commenced, the research team and autistic people discussed opportunities for them to be research collaborators and co-applicants. Other autistic people joined project-based research groups, and became part of community-based participatory research. Autistic people gained a greater understanding of the different research roles and responsibilities (for example, consultant, advisor, collaborator, and co-investigator). The importance of a 'menu' of roles for people working with the research team was discussed. Most recently, research workshops including autistic people, relatives and researchers led to refinement of community research priorities.

Conclusions: Autistic people and researchers initially used an advisory model, and through shared mutual respect, evolved into an effective participatory research team; the journey continues, and new ways of working together will continue to be identified. This approach has resulted in effective research with significant impact.

2:52 **152.002** Predicting Attrition in a Longitudinal Study of Children with Autism Spectrum Disorder

A. E. Richard[1], *I. M. Smith*[2], *E. Duku*[3], *M. G. Hayes*[4], *T. Vaillancourt*[5], *C. Waddell*[6], *J. Volden*[7], *P. Mirenda*[8], *L. Zwaigenbaum*[7], *T. Bennett*[9], *S. Georgiades*[3], *M. Elsabbagh*[10], *W. J. Ungar*[11] *and P. Szatmari*[12], *(1)Autism Research Centre, IWK, Halifax, NS, Canada, (2)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (3)McMaster University, Hamilton, ON, Canada, (4)Dalhousie University, Halifax, NS, Canada, (5)University of Ottawa, Ottawa, ON, Canada, (6)Simon Fraser University, Vancouver, BC, Canada, (7)University of Alberta, Edmonton, AB, Canada, (8)University of British Columbia, Vancouver, BC, Canada, (9)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (10)McGill University, Montreal, PQ, Canada, (11)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (12)Centre for Addiction and Mental Health, Toronto, ON, Canada*

Background: Attrition is considered an inescapable reality of longitudinal studies. Nonetheless, little research has carefully examined predictors of attrition in studies of children, in which an interplay of child and parent variables may influence participation. Notably, attrition has not been systematically explored in longitudinal observational studies of children with neurodevelopmental disorders such as autism spectrum disorder (ASD). Identifying predictors of attrition in such studies may improve quality of research as well as families' experiences of participation.

Objectives: We examined how the rate of attrition varied across assessment points in an inception cohort of preschoolers with ASD followed over a nine-year period, and investigated which child and parent characteristics predicted attrition.

Methods: Data were drawn from the multi-site Canadian Pathways in ASD study, which followed 421 children with ASD and their caregivers. This study was divided into two phases. Phase I followed participants from diagnosis at age 2 to 4 years (M_{age} = 38.2 months [SD = 8.7]; M_{IQ} = 50.9 [SD = 28.7]; M:F = 356:65) until age 6 years, and Phase II, from the age of 7.5 to 11 years. Participation involved psychometric assessment of children and completion of interview and questionnaires by parents and teachers to identify child, family, and community predictors of child outcome. We used discrete-time survival analysis to identify baseline predictors of attrition.

Results:

One hundred and eighteen families (28%) ceased participation over nine years in this longitudinal study. The attrition rate was relatively stable in Phase I, with 2-6% of participants ceasing participation at each assessment point. Participant loss peaked at the start of Phase II, with 10% of participants not consenting to this second phase. Interestingly, of those who consented to Phase II, only 3% left the study over the subsequent three-year period. Competing discrete-time survival analysis models were fit and compared based on AIC and BIC. The final model included age of the primary caregiver, family income, general distress of the parent, a measure of severity of child's restricted and repetitive behavior, and child IQ, as predictors of attrition ($\chi^2_{model}(18) = 103.1$, $p < 0.001$). Age of the caregiver (Wald statistic(1) =8.24, p =0.004), family income (Wald statistic(1) =7.02, p =0.008), and severity of restricted and repetitive behaviour (Wald statistic(1) =7.19, p =0.007) were the most important predictors. Whereas lower family income, younger age of the parent, and lower IQ of the child *increased* the risk of attrition, self-reported general distress of the parent and more severe ASD symptoms were associated with a *reduced* risk.

Conclusions:

The rate of attrition in this study of children with ASD was commensurate with observational studies of children at risk for, or with, a medical condition, and influenced by both child and parent variables. These findings suggest that addressing parent-perceived challenges to participation and emphasising relevance of participation may improve retention rates and thereby increase the representativeness of longitudinal data. In particular, reviewing the study aims and renewing participants' commitment may offer a compelling approach to increasing participant retention.

3:04 **152.003** A View through a Different Lens: Capturing the Sibling Experience of Children with a Diagnosis of Autism Via Photo Narratives

G. Pavlopoulou[1] *and D. Dimitriou*[2], *(1)Lifespan Learning and Sleep Lab, UCL.IOE,Lilas Lab, london, United Kingdom of Great Britain and Northern*

Ireland, (2)Lifespan Learning and Sleep Laboratory (LILAS) UCL, Institute of Education, London, United Kingdom

Background: Much of siblings' research has focused on siblings' adjustment and relies on parental reports. Although researchers have started exploring typically developing siblings' perspectives on their relationships with a brother or sister with autism, there is still a lack of research on the perspective of the child with a diagnosis of autism.
Objectives: This is the first study to utilise, a modified version of a participatory methodology, Photovoice, combined with phenomenology to understand siblings' everyday lived experience and to investigate opportunities for wellbeing in the environment of their families, schools and the wider local community.

Methods: 10 autistic siblings were recruited, aged 7 to 11, from 3 rural counties in Greece. Background information were collected using a number of psychometric tests. Siblings were involved by collecting data by themselves, determining the content of the data, and analysing and interpreting the data that consist of their observations, experiences and reflections as well as how they negotiate and construct reality through their every day interactions in their familiar environments over a period of 19 weeks. In this innovative approach, interpretation of the photographs was primarily in the hands of the children through photovoice groups, while interpretation of the narratives from the 1-1 interviews was the responsibility of the authors employing Interpretative Phenomenological Analysis.
Results: Our methodology facilitated dialogue and the collection of an array of data including 140 transcription pages and 95 usable photos. Sibling-driven content analysis identified five major categories: shared time at home (27.06%), sensory difficulties (25.04%), special interests (20.40%), supportive family members (16%) and pets (11.05%). Interpretative Phenomenological Analysis identified important topics. Three master themes emerged: (i) typicality in siblings' relationships such as feelings of love and support, (ii) the perceived difficulties in siblings' relationships with their family members such as sensory overload and siblings' conflicts, (iii) copying strategies including animals as a source of companionship and special interests to cultivate positive emotions throughout the day.

Conclusions: A key challenge in current research and intervention is the inclusion of the voice of disadvantaged groups such as the children with a diagnosis of autism. Photo voice, as a methodological choice, facilitated the expression of the participants' experiences by equalizing the research process and expose take for granted views on siblings' experiences. Through eliciting sibling voice directly, we hoped to reveal positive aspects, as well as, previously unconsidered challenges in the life of children with a diagnosis of autism. A strong sense of love and pride of their autistic identity was expressed throughout the interviews, and this builds into an optimism that can be a crucial part of interventions that help to lift and further develop resilience, wellbeing and a life that is possible while planning for what remains to be difficult such as sensory and sleep difficulties. Such information around contemporary and lifecycle issues in the life of siblings is central to the goal of designing proactive empowering interventions by clinicians, communities such as school and other agencies, and by policymakers in relation to both quality improvement and cost containment.

3:16 **152.004** An International Autism Portfolio Analysis By United States (IACC-NIH), United Kingdom (Autistica) and Canada (Canadian Government)

S. Daniels[1], *J. Rava*[2], *J. Cusack*[3] *and G. Warner*[4], *(1)National Institute of Mental Health (NIMH), Rockville, MD, (2)National Institute of Mental Health, Office of Autism Research Coordination (OARC), Rockville, MD, (3)Autistica, London, United Kingdom of Great Britain and Northern Ireland, (4)Autistica, London, United Kingdom*

Background: In this talk, the Office of Autism Research Coordination (OARC) of the U.S. National Institutes of Health (NIH), Autistica of the U.K., and the Canadian Government will present findings from a ground-breaking *International Portfolio Analysis* that describes autism research investments spanning government and private funders in the U.S., U.K., and Canada.
OARC/NIH manages the Interagency Autism Coordinating Committee (IACC) a federal advisory body that provides advice to the U.S. government on issues related to ASD. OARC conducts an annual portfolio analysis of U.S. research projects to help guide the IACC's strategic planning efforts. Autistica is the national autism research charity in the UK. The Canadian Institutes of Health Research (CIHR) Institute of Neurosciences, Mental Health and Addiction (INMHA) supports research on biomedical, clinical, health services, and population research related to the neurosciences, mental health, and addiction.

These three international partners collected and analyzed data from research projects funded by government and private funders in their respective countries and analyzed it according to the seven general categories of research described in the IACC *Strategic Plan for ASD*.

Objectives: By taking an international perspective centered on universal research topic areas, the portfolio analysis presented in this talk should improve knowledge of international research efforts in the seven research areas adapted from the *IACC Strategic Plan* and identify potential gaps or areas of opportunity for future research endeavors and collaborations. The international partners plan to continue the analysis as an annual exercise and aim to encourage participation from more countries to demonstrate global progress in the field of autism research.

1:45 **153.001** Examining “Turning Points” in Trajectories of Symptom Severity in Children with Autism

S. Georgiades[1], *P. A. Tait*[1], *V. Bierling*[1], *M. P. Gallaugher*[1], *P. D. McNicholas*[1], *E. Duku*[1], *T. Bennett*[2], *M. Elsabbagh*[3], *P. Mirenda*[4], *I. M. Smith*[5], *W. J. Ungar*[6], *T. Vaillancourt*[7], *J. Volden*[8], *C. Waddell*[9], *L. Zwaigenbaum*[8], *E. Fombonne*[10], *S. E. Bryson*[11] *and P. Szatmari*[12], *(1)McMaster University, Hamilton, ON, Canada, (2)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (3)McGill University, Montreal, PQ, Canada, (4)University of British Columbia, Vancouver, BC, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (7)University of Ottawa, Ottawa, ON, Canada, (8)University of Alberta, Edmonton, AB, Canada, (9)Simon*

Fraser University, Vancouver, BC, Canada, (10)Psychiatry, Pediatrics & Behavioral Neurosciences, Oregon Health & Science University, Portland, OR, (11)Dalhousie University, Halifax, NS, Canada, (12)The Hospital for Sick Children, Toronto, ON, Canada

Background: Autism Spectrum Disorder (ASD) is a complex neurodevelopmental disorder characterized by variability in symptom presentation and outcome. To date only a small number of studies have examined the longitudinal course of ASD symptom severity (Gotham, Pickles & Lord, 2012; Szatmari et al., 2015). In Szatmari et al. (2015) we reported two distinct trajectory groups of autistic symptom severity: Group 1 (11.4% of the sample) had less severe symptoms and an improving trajectory; Group 2 (88.6% of the sample) had more severe symptoms and a stable trajectory. Those results were based on data collected during the preschool years so new studies are needed to explore how variability in autism severity unfolds beyond the key transition point of entry into school.

Objectives: To extend our longitudinal investigation of symptom severity into the early school years and identify possible key “turning points” in the developmental trajectories of children with ASD.

Methods: Data were drawn from the Canadian Pathways in ASD study and included 360 children with ASD. Autistic symptom severity was indexed by the Autism Diagnostic Observation Schedule (ADOS) standardized severity score. Trajectories were plotted using data from four time points collected between the time of diagnosis and age 11. Three-way clustering methods consisting of variables and observations over time modelled as matrix variate data were used to identify homogeneous groups of children. Our matrix variate data comprised ADOS severity score and associated variables such as the child’s age at assessment, child’s sex, and adaptive functioning skills (indexed by the Vineland Adaptive Behavior Scales; VABS II). These variables were identified via boosted regression trees, a predictive modeling method. Missing data were imputed using median imputation combined with normal noise. A finite mixture of skewed matrix variate distributions (Gallaugher and McNicholas, 2017) was used for clustering.

Results: Using the Bayesian Information Criterion, a 3-group model was selected as the best fit to the data. Symptom severity scores for children in Group 1 (54% of the sample) and Group 3 (14% of the sample) decreased over time and then plateaued. However, symptom severity scores for children in Group 2 (32% of the sample) increased over time. A “turning point” (or “elbow”) at around 54 months of age – a time that for many children coincides with transitioning into the school system – was identified in two trajectory groups. Specifically, at that point, severity scores for children in Group 3 stopped decreasing and leveled out; severity scores for children in Group 2 stopped decreasing and started to increase. Groups differed by sex and had different linear associations with ADOS, VABS and age at diagnosis.

Conclusions: Study findings provide further evidence for the heterogeneous nature of symptom severity in children with ASD. The identification of key “turning points” in these trajectories supports the idea that symptom severity does not unfold in a linear way. Child, family and contextual factors associated with “turning points” in symptom severity will be discussed within the longitudinal research and clinical practice frameworks.

1:57 **153.002** Predictors of Longer-Term Language Development in Language Delayed Children with ASD

V. Hus Bal[1], *M. Fok*[2], *I. M. Smith*[3], *P. Mirenda*[4], *P. Szatmari*[5] *and C. Lord*[6], *(1)STAR Center for ASD & NDD; Dept of Psychiatry, University of California, San Francisco, San Francisco, CA, (2)Graduate School of Applied and Professional Psychology, Rutgers University-New Brunswick, Piscataway, NJ, (3)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (4)University of British Columbia, Vancouver, BC, Canada, (5)Centre for Addiction and Mental Health, Toronto, ON, Canada, (6)University of California Los Angeles, Los Angeles, CA*

Background:
Approximately 40-60% of children with ASD are language delayed, but only 30% remain minimally verbal (MV; Pickles et al., 2014). Preschool expressive abilities, nonverbal cognition, joint attention and motor skills have been shown to predict language development in broad samples including children with and without language delay. There is a need for studies focused on language-delayed children to better understand factors that predict whether or not a child will remain minimally verbal and their language development beyond the preschool years. One challenge to this area of research is the limited availability of longitudinal cohorts with a sufficient number of language-delayed children to examine predictors of longer-term language outcomes.

Objectives: Identify factors that predict expressive language development in language-delayed preschoolers using two independent longitudinal cohorts of children with ASD.

Methods: Age 3 predictors of young adult language level were explored using CART in the Early Diagnosis cohort (N=125 followed from 2 to 19 years of age). Five Mullen subscales (Gross Motor, Fine Motor [FM], Visual Reception, Expressive Language, and Receptive Language) and two ADOS items (joint attention, motor imitation) were entered as age 3 predictors. Language delayed at 3 and MV at 19 were defined as not yet using phrases on the ADOS. Linear mixed models were then used to examine the effect of CART-identified predictors on Vineland expressive language trajectories from ages 3 to 19 for children not yet using phrases (n=81). Findings were replicated in an independent sample of 361 children followed from 3 to 10 years of age (Pathways) using ADOS language level and the Merrill Palmer FM and cognitive subscales as predictors of Vineland as expressive language trajectories.

Results: CART indicated that significantly delayed FM skills (i.e., T-score<20) were the strongest predictor of MV status at age 19. Within children with delayed FM, lower expressive language and visual reception abilities further predicted sustained language impairment. Linear mixed models indicated main effects of time (p<.001), and age 3 language level (p<.001) and FM skills (p=.002), as well as significant time x language (p<.001) and time x FM (p=.02) interactions. Visual receptive abilities at age 3 did not emerge as a significant predictor (p=.47; Figure 1). While age 3 language level did not differentiate expressive trajectories of children with the greatest language impairment (i.e., nonverbal or using fewer than five words), a main effect of FM (p<.005) and time x FM interaction (p<.05) remained significant (Figure 2). Findings were highly similar in the Pathways cohort, with the Merrill Palmer FM, but not cognitive scale, emerging as a significant predictor of expressive language from ages 3 to 10.

Conclusions: Findings from two independent cohorts using different assessment instruments suggest that significantly delayed fine motor skills may be predictive of sustained language impairments in language-delayed preschoolers with ASD. Future studies are needed to better understand the association between fine motor and language impairments. Fine motor skills may be reflective of other child characteristics that interfere with language development (e.g., reduced interest in interacting with objects) or a broader neurological vulnerability.

2:09 **153.003** Parsing the Heterogeneity of Multidimensional Adaptive Behavior Profiles over Time in ASD

C. Farmer[1], *A. Thurm*[1], *E. Duku*[2], *P. Szatmari*[3], *T. Bennett*[4], *M. Elsabbagh*[5], *P. Mirenda*[6], *L. Swineford*[7], *I. M. Smith*[8], *W. J. Ungar*[9], *T. Vaillancourt*[10], *J. Volden*[11], *C. Waddell*[12], *L. Zwaigenbaum*[11] *and S. Georgiades*[2], *(1)National Institute of Mental Health, Bethesda, MD, (2)McMaster University,* *Hamilton, ON, Canada, (3)Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (5)McGill University, Montreal, PQ, Canada, (6)University of British Columbia, Vancouver, BC, Canada, (7)Speech and Hearing Sciences, Washington State University, Spokane, WA, (8)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (9)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (10)University of Ottawa, Ottawa, ON, Canada, (11)University of Alberta, Edmonton, AB, Canada, (12)Simon Fraser University, Vancouver, BC, Canada*

Background: The trajectory of development, versus static point-in-time estimates of skills, may serve as a useful phenotype among individuals with ASD (Georgiades, Bishop, & Frazier, 2017; Lord, Bishop, & Anderson, 2015). Extant studies of the developmental trajectory of adaptive behavior in ASD have focused on either separate specific subdomains or on an omnibus estimate of overall adaptive ability (e.g., Baghdadli et al., 2012; Bal, Kim, Cheong, & Lord, 2015; Szatmari et al., 2015). This may mask some of the variability manifest in the adaptive behavior profiles of individuals with ASD, including the interplay between adaptive behaviors closely linked to core ASD deficits and other problems in daily living.

Objectives: To further expand our knowledge of the course and pace of development of adaptive behavior in ASD, our objective was to characterize the jointly modeled trajectories of three pertinent domains of adaptive behavior (Socialization, Communication, and Daily Living Skills) as measured by the Vineland Adaptive Behavior Scales, Second Edition.

Methods: Data from two longitudinal studies of ASD were combined for analysis using growth mixture models (GMM). The first study, an accelerated longitudinal natural history study performed in the Eastern United States, comprised 106 children with ASD (82% male) who began the study between the ages of 2 and 7 years and were assessed up to five times at 6-month or 12-month intervals. The second study was a multisite longitudinal investigation of an inception cohort of 406 preschool children with ASD (84% male) from across Canada. These children were enrolled between the ages of 2 years and 4 years, 11 months, and were assessed up to six times. GMM is a statistical technique used to parse heterogeneity in developmental trajectories within a latent variable framework, by specifying an unobserved grouping variable that is explained by the pattern of scores over time. First, standard latent growth curves are fit to determine the shape of the average trajectory, and to serve as the baseline model against which the GMMs are compared. Next, a series of GMMs of increasing complexity are fit, each with up to six classes. The average age equivalents in each of three domains (Socialization, Communication, and Daily Living Skills) were jointly modeled.

Results: The available data were restructured into 6-month intervals beginning at 36 months (±3 months) and ending at 138 months (±3 months), for a total of 2,212 assessments (see **Figure 1** for data coverage). The best-fitting latent growth curve models had a quadratic shape for both Communication and Daily Living Skills, but the linear model was best fit to the Socialization data. In all cases, the overall model fit was poor (e.g., large and significant residual variance, large and significant chi-square test of model fit), suggesting that GMM may be better-suited to the data. The results of the joint trajectory model will be presented at the meeting.

Conclusions: The heterogeneity in development of adaptive behavior skills, both within-domain/across-individuals and across-domain/within-individuals, may be examined in order to provide a precise representation of the complexity of autism.

2:21 **153.004** Loss of Social-Communication Skills and Outcomes during Childhood in a Large General Population Cohort

Background:

Developmental regression, especially the loss of previously acquired social-communication skills, is often described as specific to autism spectrum disorder (ASD). However, studies of regression have largely been conducted in samples ascertained for diagnosed or suspected ASD. Therefore, little is known about the prevalence and correlates of regression in the general population. Furthermore, while studies have primarily relied on retrospective reporting, parental recall may be unreliable (Ozonoff et al., 2017). Prospective studies of regression as a predictor of longer-term neurodevelopmental outcomes has been limited by study periods restricted to the early developmental period.

Objectives:

We examined whether prospectively-reported loss of social-communication skills is associated with 1) parental recall of regression, and 2) concurrent and later neurodevelopmental functioning.

Methods:

Data were from the Norwegian Mother and Child Cohort Study (MoBa) and the Autism Birth Cohort, a study nested within MoBa. Preliminary analyses included 48,550 children (49% girls, born 1999-2009) with parent ratings of 15 social-communication skills at age 18 months (SD=0.55, range 15-29) and 36 months (SD=0.76, range 34-47). We included early-emerging skills (i.e., expected to be attained by 18 months) such as pointing and showing, from screeners for social-communication deficits in children. Prospectively-reported loss was defined as the reported absence at 36 months of any skills that were reported as attained at 18 months. Parents were also asked at 36 months to generally recall if their child had lost any social abilities. Follow-up questionnaire data were available for n=29,928 at 5 years and n=23,586 at 8 years. ASD diagnosis was available from the nationwide patient registry.

Results:

The majority of children (n=33,565, 69.13%) attained all social-communication skills by 18 months and maintained all at 36 months, while 17.67% (n=8,577) showed delayed attainment of at least one skill without any loss. Loss of at least one skill was observed in 13.20% (n=6,408). In contrast, few parents recalled any social loss ("yes":n=400, 0.83%; "not sure":n=590, 1.22%; missing n=83).

Correspondence between prospectively-reported and recalled loss was very low (kappa 0.02). Among parents who prospectively reported loss, only 2.03% (n=130) recalled a loss (an additional 3.16%, n=202, reported being "not sure"). Conversely, prospectively-reported loss was observed in 32.50% (n=130) of those who recalled a loss (34.24%, n=202, in the "not sure" group).

Prospectively-reported loss was associated with higher odds of a range of concurrent and later developmental delays (Fig.1-2), epilepsy (Fig.3), emotional and behavioral problems (Fig.4-5), functional impairments (Fig.6), and ASD symptoms and diagnosis (Fig.7).

Conclusions:

Loss of previously attained social-communication skills was prospectively reported for a substantial minority of children. However, these parents rarely recalled a general loss of social abilities, suggesting that rates of loss in retrospective studies may be underestimated.

Prospectively-reported loss was associated with later ASD symptoms and diagnosis, but also with neurodevelopmental problems not specific to ASD, highlighting the need to consider social-communication regression in a broader perspective. Repeated parent ratings of the same skill in prospective population-based cohorts may be valuable in increasing our understanding of the emergence of social-communication deficits in neurodevelopmental disorders.

Oral Session - 8B
Interventions - Non-pharmacologic - Preschool & Infant
154 - Early Intervention

2:40 PM - 3:30 PM - Willem Burger Hal

2:40 **154.001** Child Behavioral Outcomes from a Randomized Controlled Trial of Pivotal Response Treatment

G. W. Gengoux[1], *J. M. Phillips*[2], *C. Ardel*[1], *M. E. Millan*[2], *R. K. Schuck*[3], *T. W. Frazier*[4] *and A. Y. Hardan*[2], *(1)Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA, (2)Psychiatry and Behavioral Sciences, Stanford University, Stanford, CA, (3)Psychiatry and Behavioral Sciences, San Jose State University, Palo Alto, CA, (4)Autism Speaks, New York, NY*

Background: Pivotal Response Treatment (PRT) is an evidence-based naturalistic behavioral intervention which is traditionally delivered via a parent training model. Support for its use in improving language abilities has historically come from single-case studies using primarily behavioral observation measures. There is a critical need for examination of objective outcome measures from larger samples. Furthermore, identification of behavioral factors which are associated with treatment response will be essential for individualizing treatment.

Objectives: This presentation will review behavioral outcomes from a randomized controlled trial comparing a Delayed Treatment Group (DTG) to a PRT package treatment (PRT-P) which combines parent training with clinician-delivered in-home treatment. Our aim is to highlight new data demonstrating how objective measures of social communication can be used to assess and predict treatment response in clinical trials.

Methods: Participants include 48 children with ASD and significant language delay, ages 2-5 years (M=46.3 ± 13 months). Children were randomly assigned to DTG or PRT-P, which involved weekly parent training and 10 hours per week of in-home therapist-delivered treatment for 3 months, followed by a less-intensive phase with 5 hours per week of in-home treatment and monthly parent training sessions. Dependent measures included ratings by trained raters blinded to treatment condition including functional verbal utterances [ICC (2,1) = 0.827] and parent fidelity of implementation [ICC (2,1) = 0.893] from Structured Laboratory Observation (SLO), Clinical Global Impression Improvement (CGI-I), as well as standardized parent questionnaires. Children in both groups continued stable community treatments during the trial (average of 9 hours/week in-home Applied Behavior Analysis).

Results: Examination of changes with PRT-P reveal that children in the active group demonstrated greater improvement between baseline (M=49.52 ± 32.1) and week 24 (M=70.57 ± 29.6) in frequency of functional utterances during the SLO compared to controls (BL: M=52.84 ± 24.6; Wk 24: M=54.16 ± 29.52; F(1,38)=4.517 p=0.040). Eighty-three percent of parents receiving PRT-P training met PRT fidelity of implementation criteria (80% fidelity) at week 24. Change in Total Utterances was significantly correlated with Parent Fidelity of PRT Implementation (r=.407, p=0.005). CGI-I ratings indicate that the PRT-P group showed more improvement in communication compared to controls (X^2(3, N=40)= 17.50; p=0.001). Specifically, 4 children were rated as very much improved (0 in DTG), 10 children rated as much improved (2 in DTG), 4 children rated as minimally improved (12 in DTG) and one child rated "no change" (5 in DTG). Stronger baseline social communication skill on SRS-2 was associated with greater improvement in total utterances by week 24 (r=-0.387, p=0.007).

Conclusions: These data suggest that the PRT package approach was effective in increasing functional communication skills and the majority of parents were able to learn PRT during the trial. Child treatment response was associated with parent fidelity and baseline social communication skill. Benefits and challenges of a combined parent training and clinician-delivered early intervention approach will be discussed, with a focus on factors which can predict an individual child's response to treatment and aid clinicians in personalizing care.

2:52 **154.002** Randomized Trial of Early Intervention for Spoken Communication in Autism Spectrum Disorder

C. Kasari[1], *T. Smith*[2], *R. Landa*[3], *S. Y. Shire*[4], *W. I. Shih*[1], *D. W. Mruzek*[2], *D. Herman*[5] *and D. Senturk*[6], *(1)University of California, Los Angeles, Los Angeles, CA, (2)University of Rochester Medical Center, Rochester, NY, (3)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (4)University of Oregon, Eugene, OR, (5)Kennedy Krieger Institute, Belcamp, MD, (6)UCLA, Los Angeles, CA*

Background: Applied behavior analysis interventions, including at least some discrete trial teaching (DTT), are often considered the standard of care for preschoolers with autism spectrum disorder (ASD) and limited language. DTT is a highly structured, adult-led teaching format that focuses on directly teaching sounds and words. A second category of approaches apply naturalistic, developmental behavioral interventions (NDBIs). These approaches focus on increasing social engagement by providing learning opportunities in the context of back-and-forth interpersonal interaction, often involving child-led play.

Objectives: To compare DTT to an empirically supported NDBI, the Interpersonal Developmental Approach (IDA) consisting primarily of JASPER.

Methods: Participants were 161 children with ASD, age 33-54 months at baseline, with limited language (<30 initiated spoken words during behavior observations). They were randomized to DTT (n=82) or IDA (n=79), and received one-hour intervention sessions five days per week for six months. Outcomes were assessed at baseline, end-of-treatment, and six-month follow-up. Outcome measures included the Reynell

Developmental Language Scales and the Mullen Scales of Early Learning (MSEL), both assessing expressive and receptive language, and the Early Social Communication Scales (ESCS), an observational measure of nonverbal communication behaviors, including frequency of initiations of joint attention (IJA). Generalized linear mixed models (GLMM) were fitted with log link function for count outcomes and identity link function for Gaussian outcomes. Hurdle models were used for Reynell expressive language and IJA; this model examined whether or not each participant displayed the behavior (binary process) and, if so, how many (zero-truncated Poisson process).

Results:

Children in both DTT and IDA significantly improved from baseline to post-intervention and follow-up.

Reynell receptive language yielded non-significant post-intervention and follow-up differences between groups, F(1,308)=1.06, p=0.305, and F(1,308)=1.62, p=0.204, respectively. For expressive language, there were no significant post-intervention or follow-up difference between groups in either the binary, F(1,162)=0.06, p=0.799, or the truncated Poisson model, F(1,162)=0.06, p=0.799. On the MSEL, children in both IDA and DTT demonstrated significant gains in both expressive and receptive language from baseline to post-intervention, F(1,304)=185.97, p<0.001, and F(1,304)=156.36, p<0.001, respectively, and follow-up, F(1,304)=339.37, p<0.001, and F(1,304)=353.0, p<0.001, respectively. There were no significant treatment differences between IDA and DTT in the rate of improvement in both expressive and receptive language from baseline to post-treatment, F(1,304)=0.23, p=0.635, and F(1,304)=0.86, p=0.354 respectively.

For IJA, there was no significant treatment or maintenance in the binary model, F(1,159)=0.07, p=0.793; however, IDA was superior to DTT in the truncated Poisson model, F(1,159)=4.44, p=0.037. Children who displayed IJA at baseline made greater improvement in IJA if they received IDA than if they received DTT.

Conclusions: Participants in both DTT and IDA improved, and the groups did not significantly differ on most outcome measures. IDA did produce larger gains in IJA for participants who already demonstrated some joint attention skills when they began intervention. The similar improvements observed in approaches that differ markedly in intervention content and method suggest that it may be advantageous to pinpoint efficacious components of each approach and identify ways to match components to the needs of individual children with ASD.

3:04 **154.003** Identifying Predictors of Successful Peer Engagement for Toddlers with Autism

__W. I. Shih__[1], S. Y. Shire[2] and C. Kasari[1], (1)University of California, Los Angeles, Los Angeles, CA, (2)University of Oregon, Eugene, OR

Background: Deciding how and when to combine interventions are everyday questions faced by community programs. Yet to date, intervention research provides few answers regarding how best to tailor individual children's programming. This study aims to respond to such questions posed by a community center-based program for toddlers with autism that offers two social communication interventions: a 1:1 social communication intervention (JASPER: Kasari et al., 2004) and adapted JASPER that includes a peer (jasPEER). It's possible that toddlers may need 1:1 intervention to best succeed in group jasPEER. This study aims to explore whether children's baseline skills may inform such questions.

Objectives: To explore predictors of successful peer engagement for children who received the jasPEER intervention in order to inform future services.

Methods:

Participants. Fifty toddlers (mean age 32.6 months, 80% male, and 84% minority) who received jasPEER were included.

Teacher-Child Interaction (TCX): Ten-minute teacher-child interactions were coded for children's time in engagement states: unengaged, person (e.g. engaged with another person only), object (e.g. engaged only with objects), joint engagement (e.g., notices teacher and shared activity). Verbal/nonverbal joint attention initiations (JA), and percentage of time in play levels (simple, combination, pre-symbolic, and symbolic) are also coded from the TCX.

Mullen Scales of Early Learning (MSEL): Expressive and receptive language subscales (age equivalency) were collected by independent assessors.

Peer Observation. Five-minute unsupported child-peer interactions were coded for engagement in 1 minute intervals. Children were considered "successfully engaged" with peers if they demonstrated awareness (parallel aware) or coordination of the peer (joint engagement) for at least 20% of time.

Results:

Random forest (Breiman, 2001), a machine learning technique, was used to identify potential predictors of successful peer engagement. While random forest has been shown to provide high level of prediction accuracy, the forest cannot provide objective decision rules or criteria needed to inform clinicians in determining which type of children would have successful peer engagement. Hence, decision rules were identified using the Classification and Regression Tree (CART: Breiman et al., 1984), a statistical learning technique designed to develop decision rules based on recursive partitioning of predictors, and generate cutoff values within predictors.

MSEL expressive language was the strongest predictor of successful peer engagement (accuracy 78%; p<0.001) where children who had >18.5 months of expressive language were more likely to show peer engagement while children who demonstrated <10% combination play were less likely to show peer engagement. Further, children who showed >10% combination play, and who spend less than 14% time object engaged are more likely to demonstrate peer engagement (accuracy 84%, p<0.001).

Conclusions: Expressive language remains the best predictor of peer engagement for toddlers with autism. However, the presence of functional play skills is also important. Children who struggled with basic combination play or who become overly focused on toys to the exclusion of others were less likely to share a play interaction with peers. Children with this profile may benefit from 1:1 intervention to ready them for peer interactions.

3:16 **154.004** Parent Training for Feeding Problems in Young Children with Autism Spectrum Disorder

C. R. Johnson[1], S. Hyman[2], K. Brown[3], L. Levato[4], C. A. Aponte[4], B. Schmidt[4], V. Evans[5], M. Brooks[6], H. Eng[6], T. Sax[6] and __T. Smith__[3], (1)Clinical and Health Psychology, University of Florida, Gainesville, FL, (2)Pediatrics, University of Rochester School of Medicine, Rochester, NY, (3)University of Rochester, Rochester, NY, (4)University of Rochester Medical Center, Rochester, NY, (5)University of Florida, Gainesville, FL, (6)University of Pittsburgh, Pittsburgh, PA

Background: Many children with autism spectrum disorder (ASD) have feeding problems including idiosyncratic food selectivity and food refusal, mealtime rituals, and disruptive behaviors at mealtime. Although preliminary evidence suggests that behavioral interventions can reduce these problems, the interventions have not been well tested in randomized clinical trials and are typically delivered in highly specialized settings (inpatient or day treatment centers) by feeding experts with little parental involvement or attention to nutrition. Reports have focused on short-term effects on specific target behaviors such as the number of bites that a child accepts, without systematically measuring nutritional sufficiency or parent perception of behavior. Given the prevalence of ASD, there is a great need for feeding interventions that are more widely available, efficient, cost-effective and capable of producing generalized improvements. Behavioral parent training may be a promising approach because of its success in managing other problem behaviors in children with ASD

Objectives: This three-site project (University of Florida, University of Rochester, University of Pittsburgh) further developed an alpha version of a 9-session, individually delivered manualized behavioral parent training program for feeding problems (PT-F) in children with ASD and conducted an initial test in a 20-week, randomized, waitlist controlled trial. PT-F is innovative in that it is time-limited, takes place in an outpatient setting with ongoing parent engagement, and involves an interdisciplinary collaboration of specialists

Methods: Forty-two young children with ASD were randomized in equal numbers to either PT-F or waitlist control. The sample was predominately male (95%) with a mean age of 5.2 years. The primary outcome measure was the Brief Autism Mealtime Behavior Inventory (BAMBI). Secondary outcomes included a rating by a blinded independent evaluator (Clinical Global Impression – Improvement; CGI-I) and the parent-rated About Your Child's Eating (AYCE), Irritability subscale of the Aberrant Behavior Checklist (ABC), and Home Situation Questionnaire (HSQ). All outcome measures were administered at baseline and Week 20. Wilcoxon rank-sum tests were calculated for continuous variables (BAMBI, ACYE) and chi-square tests for the categorical variable of responders (participants with CGI-I ratings of much or very much improved) vs. nonresponders (all other participants).

Results: Compared to children in the waitlist control, children whose parents participated in PT-F showed statistically significant reductions on the BAMBI (p = 0.007), AYCE (p = .004) and CGI-I (p =0.000). For the CGI-I, 48% of participants completing PT-F were responders compared to none in waitlist. However, overall disruptive and noncompliant behaviors were not decreased on the ABC-Irritability (p= 0.447) or HSQ (p = 0.179).

Conclusions: Our initial test of efficacy of PT-F in a small RCT yielded promising results on key outcome measures of feeding, eating and mealtime behaviors. Parents reported improvement in their child's mealtime behaviors and eating habits. In addition, an independent evaluator, masked to treatment group, rated many children in the PT-F group as improved compared to none of the children in the waitlist group. The encouraging outcomes in this small RCT support further investigation in a larger, definitive trial that is powered to explore predictors and moderators.

Oral Session - 9A

155 - Early Language Development
1:45 PM - 2:35 PM - Jurriaanse Zaal

1:45 **155.001** Synchrony at 15 Months, Children's Risk Status, and the Relationship to Later Language Ability at 24 Months.

H. L. Fipp-Rosenfield[1]*, A. C. Dowd*[2]*, B. G. Davidson*[3] *and A. R. Neal-Beevers*[2]*, (1)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)The University of Texas at Austin, Austin, TX, (3)Pediatrics, University of Miami Miller School of Medicine, Miami, FL*

Background: Synchrony is defined as the degree to which parent nonverbal and verbal communication follows their child's focus of attention and action during play (Siller & Sigman, 2002). It has been established that early synchrony in the mother-infant dyad plays a supportive developmental role in later language and communication abilities (Yirmiya et al., 2006). It has also been observed that the use of gesture in the mother-infant dyad has a positive influence on infants' later language abilities (Iverson et al. 2005). However, it is unclear how these developmental relationships vary across children at high-risk (HR) and low-risk (LR) for autism spectrum disorders (ASD).

Objectives: In this study, we hypothesized that mother-infant synchrony at 15 months would be positively associated with 24-month vocabulary scores. We also hypothesized an interaction between synchrony and risk, such that the influence of synchrony on vocabulary development will be weaker in HR infants.

Methods: 13 HR and 15 LR infants and their mothers were recruited as part of a larger longitudinal study. During their 15-month visit, each mother-infant dyad engaged in a 15-minute unstructured play session with a standardized set of toys. The video-recorded play sessions were coded for synchrony yielding the proportion of: (1) maternal indicating behaviors (e.g., pointing, showing, etc.) synchronized with infant's attention (MS1), (2) maternal utterances synchronized with infant's attention (MS2), and (3) maternal utterances synchronized with infant's attention & action (MS3; Siller & Sigman, 2002). Twenty percent of all videos were randomly selected and double-scored to establish ongoing interrater reliability. Intraclass correlations suggested excellent reliability (α = .86 - .98). Child expressive vocabulary was assessed at 24 months using the MacArthur-Bates Communicative Development Inventories: Words and Sentences Long Form (MCDI; Fenson et al., 2007).

Results: Hierarchical regression equations were used to predict language from: (1) gender (2) risk status, (2) synchrony and (3) risk by synchrony interaction. Separate regression equations were conducted for each language outcome and each synchrony predictor (see Table 1). Results of the regression analyses revealed that the model using MS2 to predict the number of words reported on the MCDI (MCDI_Number) approached significance and the model using MS3 to predict MCDI_Number was significant, accounting for 27% and 33% of the variance in MCDI_Number, respectively. In both models, gender was a significant predictor such that being female predicted higher MCDI_Number. Furthermore, MS3 predicted higher MCDI_Number. A marginally significant interaction suggested that the predictive relationship between MS3 and MCDI_Number was stronger for LR infants. Similar direction interactions were observed in other models, although none were statistically significant (see Figure 1).

Conclusions: Preliminary data from this prospective study support previous findings linking stronger mother-infant synchrony to enhanced language development. Specifically, we found that infants who were female and whose mother-infant interaction was characterized by greater verbal synchrony at 15 months had larger expressive vocabularies at 24 months. These preliminary findings also point to a possible interaction between verbal synchrony and risk status, such that the relation between synchrony and expressive language appears stronger for LR compared to HR infants.

1:57 **155.002** Is Early Verbal and Nonverbal Language Gain Related to Autism Spectrum Disorder' Symptomatology in Infants at Risk?

M. Franchini[1], *E. Duku*[2], *V. Armstrong*[3], *J. A. Brian*[4], *S. E. Bryson*[5], *N. Garon*[6], *W. Roberts*[7], *C. Roncadin*[8], *L. Zwaigenbaum*[9] *and I. M. Smith*[10], *(1)Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (2)McMaster University, Hamilton, ON, Canada, (3)IWK Health Centre / Dalhousie University, Halifax, NS, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Dalhousie University, Halifax, NS, Canada, (6)Mount Allison University, Sackville, NB, Canada, (7)isand, Toronto, ON, Canada, (8)Autism Spectrum Disorder Service, McMaster Children's Hospital - Hamilton Health Sciences, Hamilton, ON, Canada, (9)University of Alberta, Edmonton, AB, Canada, (10)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA*

Background: Early communication impairment represents one of the most-reported early concerns in parents of young children with autism spectrum disorder (ASD). Moreover, verbal and nonverbal communication impairments are strongly associated with ASD symptomatology from the first years of life. Trajectory groups were examined in siblings at high risk (HR) for ASD and in children at low risk (LR) during the two first years, a period in which word and gesture learning show substantial gains and considerable intra-individual variability.

Objectives: We first aim to define distinct developmental trajectories for early language and gesture acquisition in siblings at HR for ASD and in LR children using an extensive parent-report questionnaire. Our second purpose is to identify early predictors and clinical and cognitive outcomes related to the derived trajectory groups based on verbal and nonverbal communication gains.

Methods: We used Group Based Trajectory Models (GBTM) to derive early communication trajectory groups. Data for language (expressive and receptive) and gesture acquisition were collected with the MacArthur Communicative Development Inventory-Infant Form (M-CDI) at 9, 12, 15, 18, 21 and 24 months of age. The sample was composed of 660 HR and LR infants (482 HR siblings, 361 males in the total sample). Clinical and cognitive measures were also collected before and after this period (at 6 and 36 months respectively). Predictors and outcomes were further examined according to the trajectory groups derived for each of the three measures. Finally, membership in each trajectory groups was analyzed with regard to the diagnostic outcome at 36 months.

Results: Analysis revealed three distinctive trajectory groups for the receptive language and gesture gain measures, and two groups for the expressive language acquisition measure. Pairwise comparisons between trajectory groups for the estimates of quadratic slope revealed significant differences for all comparisons (all p<.001) except for slopes 1 and 2 for gestures (p=.14). Intercepts for verbal expression and gestures did not differ significantly between trajectories (all p>.17), except for receptive language (all p<0.01). For each measure (expressive language, receptive language, and gestures), assigned trajectory groups were strongly related to clinical and cognitive outcomes. Children with an ASD diagnosis were less likely to be in the trajectory groups with the fastest language/gesture acquisition for all three measures. Clinical and cognitive measures at 6 months predicted trajectory group membership for receptive language and gesture gains. Global motor functioning was the only predictor for expressive language trajectory membership.

Conclusions: Our results confirm substantial variability in communication gains in the early development of both HR and LR infants. The results also suggest that this variability predicts further ASD symptomatology and is related to very early risk factors. Beyond communication-related behavioral features, predictors include motor skills and cognitive functioning. The current study has clinical implications in pointing out relevant language-related targets for early intervention.

2:09 **155.003** Preliminary Report: Predicting Expressive Language Abilities at Age 2 from Fine-Grained Infant Vocalization Codes at 12 Months

A. Faggen[1], *S. Plate*[1], *J. Brown*[1], *N. Libster*[2], *R. F. Slomowitz*[3], *J. Wood*[1], *J. Maldarelli*[3], *J. Pandey*[1], *R. T. Schultz*[1], *J. Parish-Morris*[1] *and .. The IBIS Network*[4], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)University of North Carolina, Chapel Hill, NC*

Background: Language delays and differences are evident as early as 12 months of age in children who ultimately develop autism spectrum disorder (ASD; Lazenby et al., 2016). To evaluate emergent language in young infants, clinicians use tools like parent report measures, semi-structured observations, and standardized assessments. In this project, we developed a finer-grained method of vocalization coding during infancy and toddlerhood that we hope will contribute to existing models of early language development. Accurate models are especially important for high-risk infant populations, as divergence from the expected trajectory can highlight potential treatment targets. In this preliminary report, we examine whether fine-grained vocalization coding at 12 months of age adds value to standardized test scores, when predicting expressive language abilities 1 year later.

Objectives: Determine whether vocalization coding adds significant explanatory variance to models of language ability from 12 to 24 months, in a sample of children at high- and low-risk of developing ASD.

Methods: Thirty-six children were assessed at 12 and 24 months as part of a longitudinal study of brain development (IBIS; Estes et al., 2015). The first group had an older sibling with ASD and were ultimately diagnosed with ASD (HR-ASD, N=10, 1 female). The second group had an older sibling with ASD but did not receive an ASD diagnosis (HR-neg, N=14, 6 female). The third group had a typically developing older sibling and were not diagnosed with ASD (LR-, N=12, 3 female). At each time point, participants were administered the Communication and Symbolic Behavior Scales (CSBS; Wetherby & Prizant, 2002), and Mullen Scales of Early Learning (MSEL; Mullen, 1995). Reliable annotators blind to risk status segmented and coded videotaped administrations of the CSBS at 12 months, and categorized infant vocalizations as speech- or speech-like (e.g., babbles, words) or non-speech (e.g., growls, squeals). The relative duration of speech- vs. non-speech vocalizations was explored as a potential predictor of language ability at 24 months (MSEL Expressive Language t-scores).

Results: After controlling for 12-month MSEL Expressive Language t-scores, the relative duration of speech- or speech-like vocalizations (vs. non-speech vocalizations) during the CSBS at 12 months accounted for significant additional variance (ΔR^2) in 24-month Expressive Language ability, $\Delta F(1,33)=4.51$, $p=.04$, $\beta=.30$. Overall, the combined model accounted for 34% of the variance in 24 month scores, $F(2,24)=18.59$, $p<.001$. Adding information about 12-month CSBS scores (total scores and standard scores for speech, communication, and words subdomains) did not significantly improve model fit, $\Delta F(4,28)=.59$, $p=.67$.

Conclusions: The results of this preliminary exploration suggest that fine-grained vocalization coding in a heterogeneous sample adds additional explanatory variance to language predictions from 1 to 2 years of age, above and beyond what can be learned from standardized assessments. Our next steps are to increase our sample size, and include an additional time point with vocalization coding (6 months) to test the power of change in speech-like vocalizations from 6 to 12 months to predict 24-month language ability within separate diagnostic/risk groups.

2:21 **155.004** High-Dimensional Gesture Coding for Use in Prospective Gene-Brain-Behavior Studies of ASD

N. Libster[1]*, J. Brown*[2]*, S. Plate*[2]*, A. Faggen*[2]*, R. F. Slomowitz*[3]*, J. Wood*[2]*, J. Maldarelli*[3]*, J. Pandey*[2]*, R. T. Schultz*[2]*, J. Parish-Morris*[2] *and .. The IBIS Network*[4]*, (1)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (4)University of North Carolina, Chapel Hill, NC*

Background: Early gestures predict later social communication skills, including language, prosocial behavior, and peer play (Mundy et al., 1990; Sigman & Ruskin, 1999), and infants and toddlers with autism spectrum disorders (ASD) display gesture impairments by 12 months of age (Wetherby et al., 2007). Siblings of children with ASD, who are at heightened risk for developing an autism spectrum disorder, also demonstrate social communication deficits, often in a mild form (Yirmiya et al., 2006). However, most children with ASD are not diagnosed until ~4 years old (CDC, 2016). Research on social communication deficits in children under three therefore has important implications for improving early identification. In addition, gene-brain-behavior research has been hindered by behavioral metrics that are insufficiently granular. In this exploratory study, we compare fine-grained communicative gesture codes in 2-year-old children at high familial risk for ASD who received a diagnosis (HR-ASD), to those at high risk that did not receive a diagnosis (HR-neg), and those at low risk who did not develop ASD (LR-).
Objectives: Determine whether high-dimensional gesture coding of the Communication and Symbolic Behavioral Scales (CSBS; Wetherby & Prizant, 2003) differentiates diagnostic/risk groups in overall gestures, and in subcategories of behavior regulation, joint attention, and social gestures.

Methods: Trained clinicians administered the CSBS to 44 2-year-olds (LR-: 22, 6 female; HR-neg: 11, 4 female; HR-ASD: 11, 1 female) participating in the longitudinal Infant Brain Imaging Study (IBIS; Estes et al., 2015). Videos were segmented and coded for CSBS communicative gestures by 4 independent annotators. Coders were not informed of participant diagnostic status, and all coding discrepancies were resolved by consensus. Single gestures were summed into groups: Behavior Regulation (give, reach, open hand), Joint Attention (point, show), and Social Interaction (wave, high five, nod head, shake head).

Results: Overall gestures per 10 minutes differentiated the HR-ASD group from the LR- and HR-neg groups (*p*s<.001, Fig.1), but did not differentiate the LR- and HR-neg groups from each other. The same pattern was evident in the Behavior Regulation and Joint Attention subcategories (*p*s<.01). In the Social category, gestures per 10 minutes differentiated the LR- group from the HR-ASD group (*p*<.05), but did not distinguish the HR-neg group from the other two groups.

Conclusions: This project lays the foundation for dimensional gesture coding that can be used in genetic and imaging research, as well as to track developmental change and treatment response. Of note, our study does not address the issue of how gestures are defined and conceptualized. Although we were able to code over 1,700 individual gestures, they may fail to capture the full extent of communicative gestures in children with ASD. In addition, we only coded fully formed gestures – developing and partially formed gestures were coded in the “other” category; our findings may therefore not capture children’s emerging skills. Our next steps include distinguishing between gestures that do and do not carry communicative intent, increasing our sample size, and coding gestures in the same infants at 12 months for use in longitudinal analyses.

Oral Session - 9B
Early Development (< 48 months)
156 - Early Screening - New Methods / Approaches
2:40 PM - 3:30 PM - Jurriaanse Zaal

2:40 **156.001** Diminished Rate of Response to Name in Autism Spectrum Disorder: Using a Smartphone Application to Provide a Quantitative Measure of Behavior

R. P. Thomas[1]*, W. Guthrie*[1]*, L. A. Wang*[1]*, J. Miller*[2]*, W. Struebing*[2]*, J. W. Pennington*[3] *and J. S. Miller*[1]*, (1)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (2)Department of Biomedical and Health Informatics, The Children's Hospital of Philadelphia, Philadelphia, PA, (3)Department of Biomedical and Health Informatics, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Previous research suggests that children with autism spectrum disorder (ASD) show limited response to their name, though they may orient easily to other sounds (Dawson et al., 2004). A child’s response to name (RtN) is included in most screening and diagnostic tools because of its high sensitivity as an early indicator of ASD (Miller et al., 2017). However, current measures of RtN rely on parent report that only allows for yes/no ratings or on brief clinical observation of 1-5 name calls. A quantitative measure of RtN can provide information on the *rate* of response, which may improve screening or help us measure treatment response.
Objectives: To use a novel smartphone application to systematically measure RtN within a child’s natural environments and to generate a quantitative measure of a child’s rate of RtN.

Methods: Participants were parents of 83 children between 18-48 months (*M*= 35.68 months, *SD*= 8.82), reported to have a diagnosis of ASD (n=29), a developmental delay/disorder (DD; n=24), or typical development (TD; n=30). Through the RtN app, parents were instructed to complete up to 30 name call trials over 1-2 weeks. The app prompted parents to stand 5 feet behind the child, call the child’s name, and then rate yes/no on the app to indicate whether the child responded to his/her name. Parent ratings and video recordings of the child’s response were both collected through the app, allowing the team to examine parent accuracy. Cumulative rate was calculated after 1-5, 10, 15, and 20 trials.

Results: Rate of RtN plateaued near 15 trials for all groups (Fig. 1). Significant group differences were not observed in the first trial; ASD, DD, and TDC groups showed similar rates of response (77%, 97%, and 92% respectively), suggesting that a small number of trials may not be sufficient for detecting statistically significant differences in RtN. After 3 trials, the ASD group showed a significantly lower rate of RtN than the TDC group (62% vs 84%, *p*=.02), though differences for the DD group (79%) were not significant. Significant differences between the ASD and DD groups did not emerge until 10 trials (50% vs 73%, *p*=.005), and remained through 20 trials (*p*=.007).

Conclusions: Results indicate that one name call trial was not sensitive enough to detect group differences; most (77%) children with ASD responded to the first trial. In fact, none of the children with ASD showed a complete lack of response to name, as the average response rate after 20 trials was ~50%. Instead, differences were observed in the ASD group's *rate of response* rather than whether a child responded to an individual bid. These results, and use of a smartphone app to generate quantitative data, have important implications for how RtN is measured during clinical observations and through parent report questionnaires. A scalable measurement tool, such as this app, could open new horizons to community-based studies of ASD by providing a feasible way to screen large samples and identify infants at risk of developing ASD because of a low RtN rate.

2:52 **156.002** What Happens after Early Autism Screening? Factors That Predict Evaluation Attendance

R. K. Ramsey[1]*, J. Donelan*[2]*, T. Hamner*[3]*, D. A. Fein*[2]*, L. B. Adamson*[4] *and D. L. Robins*[5]*, (1)Georgia State University, Atlanta, OH, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)AJ Drexel Autism Institute, Philadelphia, PA, (4)Psychology, Georgia State University, Atlanta, GA, (5)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Autism spectrum disorder (ASD) can be detected in toddlers prior to 24 months (Baranek et al., 2009, Pierce et al., 2011), which helps families access early intervention. However, age of diagnosis and participation in follow-up can differ by screening age, sex, race, ethnicity, and maternal education (Dietz et al., 2007, Giarelli et al., 2010, Khowaja et al., 2015, Mandell et al., 2009).
Objectives: This study examines evaluation attendance by parents of toddlers who screened at-risk for ASD at 12, 15, or 18 months, and analyzes the relation between evaluation attendance and demographic factors.

Methods: The sample included 710 (M_{age}=15.95 mos, *SD*=2.76) toddlers who screened at-risk for ASD at well-child visits. Children were screened at 12 months (Infant Toddler Checklist (ITC) and First Year Inventory-Lite (FYI-L)); 15 months (FYI-L and Modified Checklist for Autism in Toddlers, Revised, with Follow-Up (M-CHAT-R/F)); or 18 months (M-CHAT-R/F). Pediatrician ASD concerns also denoted risk at each age. Parent-reported demographics included the child's sex, race, ethnicity, and mother's education. Families of at-risk children were invited for a free evaluation that resulted in a diagnosis of ASD, other developmental disorders (DD) or no diagnosis (ND).

Results: There was a significant difference in evaluation attendance between age groups: 30.9% attended at 12 months, 19.1% attended at 15 months, and 35.3% attended at 18 months, $\chi^2(2, N=710)=17.20$, $p<.001$. Evaluation attendance did not differ between males (30.2%) and females (28.7%), $p=.378$, or between low (28.9%) and high (29.8%) maternal education groups, $p=.438$. However, significantly more minority race families (34.9%) attended evaluations compared to White families (27.4%, $\chi^2(1, N=597)=3.89$, $p=.030$), and significantly fewer Hispanic/Latino families (25.2%) attended compared to non-Hispanic/Latino families (35%, $\chi^2(1, N=518)=4.82$, $p=.017$). Across age groups, 203 children completed an evaluation ($N_{ASD}=51$, $N_{DD}=90$, $N_{ND}=62$). There were significant differences in diagnoses across age groups, $\chi^2(4, N=203)=36.93$, $p<.001$. At 12 months, 23.7% were ASD, 32.2% were DD, and 44.1% received ND. At 15 months, 4.3% were ASD, 43.5% were DD, and 52.2% received ND. At 18 months, 35.7% were ASD, 52% were DD, and 12.2% received ND.

Conclusions: Overall, attendance was lower than expected, although not inconsistent with research examining screening prior to 18 months (Dietz et al., 2007). Race and ethnicity related to evaluation attendance. Lower income and minority families often experience barriers to care (Liptak et al., 2008), and thus may have a greater need for accessible resources, making them more likely to attend a free evaluation. Hispanic/Latino families may be less likely to attend due to concern for language barriers (Zuckerman et al., 2009). Attendance seemed most impacted by screening age, with parents less likely to attend at 15 months compared to 12 or 18 months. Parents and pediatricians may have had less confidence in 15 month screen positive results, leading to lower attendance rates. Differential rates of diagnosis by age suggest lower accuracy in screening at 15 months: only 4.3% of at-risk 15-month-olds met criteria for ASD and a majority had no diagnosis. Future research may be able to refine screening thresholds at 15 months.

3:04 **156.003** Phenoscreening: A Developmental Approach to Rdoc-Motivated Sampling

J. T. Elison*, University of Minnesota, Minneapolis, MN*

Background: The Research Domain Criteria (RDoC) initiative has formalized research strategies for parsing the heterogeneity/variability inherent to the etiology, phenotypic presentation, and treatment response of major psychiatric disorders, but has not effectively integrated developmental considerations. Identifying multi-dimensionally-determined profiles of risk via data driven computational approaches represents one potential avenue to 1) improve early identification of at-risk phenotypes and 2) select unbiased samples for various research questions.
Objectives: The primary objective of this research is to derive multiple "high-risk" phenotypes, while remaining agnostic to traditional DSM categories, by leveraging multiple dimensional constructs and a data-driven computational strategy during a developmentally sensitive period. A secondary aim is to verify the prognostic utility of the risk profiling approach.

Methods: Parents of 17-25 month-old toddlers (n = 1570), drawn from a community-based sample, completed the MCDI, the Video-Referenced Rating Scale for Reciprocal Social Behavior (vrRSB; Marrus et al., 2015), and the Repetitive Behavioral Scales for Early Childhood (RBS-EC; Wolff, Boyd, & Elison, 2016). To identify discrete developmental phenotypes, we used factor mixture modeling (FMM), a statistical method for parsing population heterogeneity that identifies groups of empirically testable entities (i.e., latent classes). Statistically, FMM mixes factor analysis, used to estimate unobserved continuous variables, with latent class analysis, used to estimate latent categorical groups. Conceptually, FMM is a person-centered statistical approach that focuses on similarities and differences among profiles to identify homogenous subgroups of individuals, with each subgroup possessing a unique set of characteristics that differentiates it from other subgroups. To validate the predictive utility of these risk profiles, a subsample of toddlers (n = 107) was assessed on a distal, independent outcome (the Infant Toddler Social Emotional Assessment; ITSEA) at an average of 10 months after the initial assessment.

Results: FMM results, based in part on 2 factors derived from seven dimensional manifest variables, identified five asymmetrically sized subgroups (ranging from n = 4 to n = 1230). One percent of the sample (17/1570), captured by two subgroups, was characterized by increased repetitive behaviors and social communicative impairments. An additional 5% of the sample fell into a nominally moderate risk group (79/1570), whereas the remaining toddlers fell into 2 nominally low-risk clusters. Follow-up analyses on a subsample of 107 infants confirmed the predictive validity of the risk profiles, showing significant differences between high-, moderate-, and low-risk groups on internalizing, externalizing, and dysfunctional behavior as assessed by the ITSEA. Comparison of high- and low-risk groups revealed large effect sizes for internalizing (d = 1.39), externalizing (d = 0.83), and dysregulation (d = 1.87).

Conclusions: A data-driven computational approach yielded 5 homogenous subgroups of n = 1570 community-ascertained toddlers, the clinical utility of which was corroborated by outcomes measured longitudinally. Data-driven approaches, leveraging multiple developmentally appropriate dimensional/quantitative constructs holds promise for future efforts aimed toward early identification of at-risk-phenotypes. Further, we expect this method to inform a more personalized approach to clinical recommendation/intervention, as compared to the binary approach of traditional screening/sampling schemes.

3:16 **156.004** A Multimedia Screening System to Predict ASD Symptoms in Diverse Community Settings: Preliminary Convergent and Concurrent Validity

S. Macari[1], *K. Chawarska*[1], *M. Wilkinson*[1], *E. Barney*[2], *J. C. Snider*[3], *E. S. Kim*[4], *Q. Wang*[1], *Q. A. Yang*[3], *C. A. Wall*[5], *B. Li*[3,6], *M. Mademtzi*[1], *C. Foster*[1], *D. Macris*[1], *F. E. Kane-Grade*[7], *A. Milgramm*[8], *P. Heymann*[1], *E. Hilton*[1], *A. Zakin*[1], *H. Neiderman*[1], *K. Villarreal*[1], *K. K. Powell*[1], *S. Fontenelle*[1], *M. Lyons*[1], *A. Giguere Carney*[1], *K. Bailey*[1], *M. Kim*[3], *Y. A. Ahn*[3], *M. C. Aubertine*[9] *and F. Shic*[2], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Seattle Children's Research Institute, Seattle, WA, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)Department of Psychology, University of South Carolina, Columbia, SC, (6)Computer Science and Engineering, University of Washington, Seattle, WA, (7)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (8)Center for Autism and Related Disabilities, Albany, NY, (9)Seattle Children's Hospital and Research Institute, Seattle, WA*

Background:

Earlier identification of ASD leads to earlier, more effective treatment. Many infants and toddlers with ASD would not be identified, however, without formal screening (Miller et al., 2011). ASD-specific screening, increasingly routine in well-child pediatric visits (Arunyanart et al., 2012), may benefit from new generations of tools that improve accuracy in the youngest children and decrease time burden. Furthermore, disparities exist in screening accessibility in racially- and economically-diverse populations (Herlihy et al., 2011). Electronic multimedia applications can provide remote administration of video illustrations to improve clarity, usability, and accessibility across diverse cultural and socioeconomic groups. The Yale Adaptive Multimedia Screeners (YAMS-One and YAMS-Toddler) were developed to fill these needs.

Objectives:

To evaluate preliminary convergent and concurrent validity in a pilot of the YAMS system in multiple community pediatric primary care sites.

Methods:

200 families from three urban community pediatric locations and 48 families attending a research clinic participated by completing age-appropriate versions of the YAMS via iPad: 1) the YAMS-One (for 10-16-month-olds; n=51 community infants, M_{age}=14m) along with a text-only version of the Communication and Symbolic Behavior Scales Infant-Toddler Checklist (CSBS-ITC; Wetherby & Prizant, 2002); or 2) the YAMS-Toddler (for 17-33-month-olds; 149 community toddlers, 48 research clinic toddlers, M_{age}=26m) accompanied by a text-only version of the M-CHAT-Revised/Follow-Up (Robins et al., 2014). Children in the research clinic sample were concurrently administered the ADOS-2 Toddler Module. The community sample was racially- and ethnically-diverse (88% non-white, 44% Hispanic) with a range of SES backgrounds: 51% of mothers had a high school degree or less. The research clinic sample was less diverse (20% non-white; 22% Hispanic) and more highly-educated (87% of mothers had a college degree or more). We used Pearson's r to examine associations between the YAMS-One/CSBS-ITC scores and the YAMS-Toddler/M-CHAT-R/F scores, respectively, to test preliminary convergent validity. To examine concurrent validity, Pearson's r measured the relationship between YAMS-Toddler scores and ADOS-Toddler Social Affect scores.

Results:

Pearson correlations showed high positive correspondence between YAMS-Toddler scores and M-CHAT-R/F final scores in both community (*r*(149)=.617, *p*<.001) and research clinic samples (*r*(48)=.825, *p*<.001). YAMS-One scores were marginally associated with CSBS-ITC Composite Scores, including Social Composite (*r*(51)=-.245, *p*=.08) and Symbolic Composite (*r*(51)=-.248, *p*=.08) but not Speech Composite (*p*=.66) in the community sample. In the research clinic sample, there was a significant correlation between YAMS-Toddler scores and ADOS SA scores (*r*(46)=.662, *p*<.001).

Conclusions:

Results suggest good convergent and concurrent validity for YAMS-Toddler in both diverse community samples and research clinic samples. YAMS-One (infant version), was only modestly associated with CSBS-ITC scores. The latter is a broadband screener for social-communication delays, while the YAMS-One taps into attention and emotion regulation constructs as well as social communication, all of which may characterize prodromal symptoms of ASD around the first birthday. Longitudinal follow-up will yield information on the predictive power of the YAMS-One for later autism severity. The YAMS system shows promise as a valid ASD screener that capitalizes on modern technology to enable more efficient screening, using video supports to broaden accessibility across socioeconomic and cultural barriers.

Oral Session - 10A
Medical and Psychiatric Comorbidity
157 - Suicide and Bullying in ASD
1:45 PM - 2:35 PM - Arcadis Zaal

1:45 **157.001** Emotion Reactivity and Bullying in Adolescent Boys with Autism; Bi-Directional Longitudinal Outcomes

C. Rieffe[1], *S. Novin*[2] *and E. Broekhof*[1], *(1)Leiden University, Leiden, Netherlands, (2)Utrecht University, Utrecht, Netherlands*

Background: Bullying is a worldwide concern for everyone involved. Bullying involves repeated and intentional harm to someone over a longer period of time, causing long-lasting negative effects on the victim's mental health and social development, but in fact, everyone involved is negatively affected, including the bully. Adolescents with autism are more often involved in bullying than adolescents without autism, and although emotional functioning is important in this respect, we do not yet know the causality of these relationships.

Objectives: Fear is more often related to victimization in normal development, but we found that anger was more dominant in victims with autism in an earlier, cross-sectional study. In this study, we longitudinally examined these relationship again, to establish their causality. Based on parents' feedback and clinical observations, we expected that more victimization in adolescents with autism could cause a stronger anger reaction, since it seems that trying to gain control over socially difficult and unpleasant situations often causes an uncontrollable emotional arousal.

Methods: A total of 185 adolescent boys (89 with autism) were tested, age range was 10 to 15 years old. The participant filled out self-report questionnaires on Bullying, Emotion Reactivity (from which we only used the scales for Anger and Fear). Background information was derived from their parents and schools. Informed consent for participation was provided by all parents and participants.

Results: In order to examine the contribution of emotions on Bullying and Victimization and vice versa, General Linear Model (GLM) analyses with clustered bootstrapping were performed. The outcomes showed that being bullied caused higher levels of shame and fear in boys with and without autism, but also more anger in boys with autism specifically. Higher levels of anger, in turn, caused more victimization in both groups. More fear contributed more strongly to more victimization in boys without autism.

Conclusions: The outcomes of this longitudinal study show a bidirectional relationship between emotion reactivity and victimization in adolescents boys with and without autism. Adolescents who are more bullied, develop more negative emotions, anger and fear, over time, which may not come as a surprise. Unfortunately, however, these stronger levels of negative emotions can, in turn, be a trigger for bullies who now see that their bullying is effective. Consistent with the literature on adolescents from a community population, fear is the most dominant emotion related to bullying. Yet, adolescents boys with autism seem to predominantly react with anger when being bullied, supporting the viewpoint that socially unpleasant situations cause uncontrollable arousal. These new insights might offer important strategies for prevention and anger management in adolescents with autism.

1:57 **157.002** Suicide Screening in Neurodevelopmental and Autism Clinics: Early Data and Implications

S. Rybczynski[1,2], *P. H. Lipkin*[3,4,5] *and R. A. Vasa*[6], *(1)Kennedy Krieger Institute, Baltimore, MD, (2)Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD, (3)Medical Informatics, Kennedy Krieger Institute, Baltimore, MD, (4)Johns Hopkins University School of Medicine, Baltimore, MD, (5)Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, (6)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD*

Background: Children and adults with neurodevelopmental disabilities, including autism spectrum disorder (ASD), are reported to be at increased risk for suicidality. However, no studies have screened for suicidal ideation in this population when presenting to outpatient clinics. In 2015, The Joint Commission, an international healthcare accreditation organization, issued a "Sentinel Event Alert" mandating health care facilities to implement suicide screening in all healthcare settings. This study presents preliminary data on suicide screening in medical outpatient clinics at The Kennedy Krieger Institute, a large university-based center for neurodevelopmental disabilities.

Objectives: (1) To determine the overall rates of past suicidal ideation, prior suicide attempts and current suicidal ideation in individuals presenting to 27 distinct outpatient neurodevelopmental medical clinics (2) To compare rates of suicidality in patients with ASD to patients with other neurodevelopmental conditions.

Methods: All individuals greater than 9 years of age were screened during August and September 2017. There was no upper age limit for screening. Suicide screening instruments included the "Ask Suicide Screening Questions" (ASQ) (ages 9 to 18 years) and the "Ask Suicide-Screening Questions to Everyone in Medical Settings" (ASQ'em) (over age 18 years). Nurses performed the screenings during the initial intake. Patients and caregivers were given the option to opt out of the screening. Patients or their caregivers could respond to the questions. We reviewed results for patients presenting to all clinics. We then compared patients presenting to autism and related disorders clinic with those presenting to the center for development and learning, and neurology and developmental medicine clinics. The latter two clinics collectively see patients with a variety of neurodevelopmental disorders, including ADHD, intellectual disability, learning disabilities, epilepsy and other neurological diagnoses.

Results: A total of 2054 patient visits were eligible for suicide screening. Patients were screened at each visit. A total of 522 (25.4%) of the 2054 eligible patients declined screening. Of those screened in all clinics (1532 distinct visits), 99 (6.5%) screened positive for past or present suicidal ideation or prior attempted suicide, and 1433 (93.5%) were negative screens. In our autism clinic, 317 patients were eligible for screening and 106 (33.4%) declined screening. Among those who were screened (211 patients), 29 (13.7%) had positive screens and 182 (86.3%) negative screens.Of the 555 patients eligible for screening in the center for development and learning, 101 (18.2%) declined screening. Of the patients screened (454 patients), 23 (5.1%) screened positive and 431 (94.9%) screened negative.In the neurology and developmental medicine clinic, 237 patients were eligible for screening of which 72 (30.4%) declined screening. Of the patients screened (165 patients), 9 (5.5%) screened positive and 156 (94.5%) had negative screens.

Conclusions: Individuals with neurodevelopmental disabilities are at risk for suicidal ideation. In our sample, patients with ASD had higher rates of suicidality compared to patients with developmental and neurological conditions. A substantial number of individuals declined screening. Further studies are needed to determine outcomes for patients who screen positive and examine reasons for why screening was declined.

2:09 **157.003** Suicidality and Familial Liability for Suicide in Autism: A Population Based Study

T. Hirvikoski[1], *M. Boman*[1], *Q. Chen*[1], *B. D'Onofrio*[1], *E. Mittendorfer-Rutz*[1], *P. Lichtenstein*[1], *S. Bolte*[2] *and H. Larsson*[3], *(1)Karolinska Institutet, Stockholm, Sweden, (2)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (3)School of Medical Sciences, Örebro University, Örebro, Sweden*

Background: Studies on the individual risk and familial co-aggregation of suicidal behaviour in autism spectrum disorder (ASD) are lacking.

Objectives: This study aimed to explore the gender specific risk of suicide attempt and suicide in ASD individuals with (ASD+ID) and without intellectual disability (ASD-ID), as well as the potential role of familial liability.

Methods: Swedish national registers were used to conduct a matched case-cohort study applying conditional logistic regression models. We identified 54168 individuals with ASD (ASD-ID n = 43570; ASD+ID n = 10598) recorded from January 1, 1987, to December 31, 2013, and 270840 controls matched for gender, age and residential information. We also compared risk of suicidal behaviour at three levels of family relatedness in 348192 relatives of individuals with ASD and 1740960 matched control relatives.

Results: Individuals with ASD-ID had an increased risk of both suicide attempt and suicide, even after adjustment for depression and attention-deficit hyperactivity disorder (ADHD). Females with ASD-ID had higher risk of suicide attempt and suicide as compared to males with ASD-ID. The risk was also increased in ASD+ID group regarding both attempted suicide and suicide, although to a lesser degree as compared to ASD-ID group. In comparison to controls, relatives of individuals with ASD had an increased risk of suicidal behaviour. First-degree relatives of individuals with ASD had significantly higher risk estimates of suicidal behaviour than second- and third-degree relatives.

Conclusions: Individuals with ASD are at increased risk of suicidal behaviour, in particular females without intellectual disability. Psychiatric comorbidities and shared familial risk factors are important explanations to the increased risk of suicidal behaviour in ASD. Clinicians treating patients with ASD should be vigilant for suicidal behaviour and consider treatment of psychiatric comorbidity.

2:21 **157.004** Suicidality and Non-Suicidal Self-Injury in Adults with Autism Spectrum Conditions

S. A. Cassidy[1,2], *L. Bradley*[3], *R. Shaw*[4] *and S. Baron-Cohen*[2], *(1)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (3)Coventry University, Coventry, United Kingdom, (4)NHS Coventry and Warwickshire Partnership Trust, Warwickshire, United Kingdom*

Background: Recent research has shown significantly increased risk of suicidality in Autism Spectrum Conditions (ASC). However, previous studies have utilised clinical samples, lacked validated measures and failed to explore risk or protective factors. Non-suicidal self-injury, unemployment and psychiatric conditions have all been identified as risk factors for suicide in the general population. People with ASC also describe camouflaging their ASC in order to fit in in social situations, at great potential cost to their mental health. However, no study has yet explored all these factors in relation to suicidality in ASC. This is crucial to inform new suicide prevention strategies for this group.

Objectives: 1) To compare the prevalence of suicidality and NSSI between those with and without ASC; and 2) To explore risk and protective factors for suicidality in those with ASC.

Methods: A comprehensive online survey was co-designed with the help of a steering group of adults with ASC who had experienced mental health problems and/or suicidality. Adult males and females with ASC, and control females without ASC or suspected ASC, completed the survey online. Measures included the Suicide Behaviour Questionnaire-Revised (SBQ-R), the Non-Suicidal Self-Injury Assessment Tool (NSSI-AT), and the Autism Spectrum Quotient (AQ). Participants also provided details of diagnosed developmental and mental health conditions, experiences of attempting to camouflage their ASC in order to fit in in social situations, employment, education, treatment and support.

Results: The ASC group comprised 168 adults (67 male, 101 female), and 108 control females without ASC or suspected ASC, aged 20-60 years old, recruited from online adverts and the University of Cambridge Autism Research Database. Significantly more ASC females reported lifetime experience of NSSI (81.8%) than ASC males (55.4%), and control females without ASC (27.6%) (all $p < .001$). In the ASC group, mean SBQ-R (10.31 *SD* 4.2) was significantly higher than the recommended cut off for psychiatric populations (>=8); 69.8% of the ASC group scored at or above this cut off. After statistically controlling for age, education, occupational status, living arrangements, co-morbid developmental and mental health conditions, ASC females scored significantly higher on the SBQ-R than control females (10.61 (*SD* 4.16) vs 6.27 (*SD* 3.18)). In the ASC group, history of NSSI, at least one mental health condition, unemployment, and camouflaging ASC were associated with significantly higher scores on the SBQ-R (all $p < 0.05$).

Conclusions: Results showed that a majority of ASC adults had experienced NSSI, and scored significantly above the recommended cut off for suicide risk in psychiatric populations. After controlling for a number of factors such as mental health conditions, unemployment and living situation, ASC females scored significantly higher in suicidality than control females. Results suggest that the factors underlying increased risk of suicidality in ASC compared to the general population goes beyond co-morbid psychiatric conditions and demographic risk factors. One new autism-specific risk factor for suicidality identified was the tendency to camouflage their ASC in an attempt to cope in social situations. Implications for suicide prevention are discussed.

Oral Session - 10B
Medical and Psychiatric Comorbidity
158 - Symptoms, Traits and Biomarkers: The Search for Stratification

2:40 PM - 3:30 PM - Arcadis Zaal

2:40 **158.001** Emotional and Behavioural Problems in Adolescents with ASD Are Associated with Alterations in Neural Indices of Perceptual Processing

V. Carter Leno[1], *P. White*[1], *I. Yorke*[1], *S. Chandler*[1], *G. Baird*[2], *A. Pickles*[3], *T. Charman*[4] *and E. Simonoff*[1], *(1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, (3)Biostatistics and Health Informatics, King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:

Many young people with autism spectrum disorder (ASD) exhibit co-occurring emotional and behavioural problems. The development of effective interventions requires greater knowledge of the causes of these problems. One approach is to explore whether variation in specific neurocognitive processes, thought to be impaired in individuals with ASD, is also associated with additional psychopathology. Perceptual/sensory processing atypicalities are often reported in ASD, but how these relate to co-occurring emotional and behavioural problems is not well explored.

Objectives:

To test the association between neural indices of perceptual processing, and emotional and behavioural problems, in a well-characterised sample of adolescents (11-15 years) with ASD (n=43; 29 males, 14 females) with a wide-range of IQ (27-129).

Methods:

Event-related potentials (ERPs) were recorded in response to both deviant (8% probability, 1200Hz) and standard tones (92% probability, 1000Hz) in an auditory oddball paradigm.

Analyses focused on perceptual sensitivity, measured by the response to deviant, as compared to standard tone (mismatch negativity; MMN), and the differential ERP response to the first (S1), second (S2) and third (S3) standard tone presented directly after the deviant tone. Multivariate regression tested the association between ERPs and parent-reported emotional and behavioural problems. Primary analyses used the ADHD, emotional and conduct problems sub-scales of the Strengths and Difficulties Questionnaire (SDQ), and the Affective Reactivity Index (ARI). Secondary analyses used the Developmental Behaviour Checklist (DBC) total behaviour problem score.

Age, sex, IQ, and ASD severity were used as covariates. Sensitivity analyses excluded those taking psychotropic medication (n=5), and then separately excluded those with epilepsy (n=2).

Results:

No association was found between MMN amplitude and SDQ sub-scales or ARI. An association was found between MMN amplitude and DBC total behaviour problem score ($p<0.05$), and this remained at a trend level when controlling for age, sex and IQ ($p=0.07$), but became non-significant when controlling for age, sex, IQ and ASD severity ($p=0.11$). The association remained in unadjusted sensitivity analyses ($p<0.05$).

A selective association was found between ERP response (N2) to S1 and SDQ emotional problems ($p<0.05$). No associations were found to S2 or S3. This pattern of results remained in all co-variation and sensitivity analyses ($ps<0.05$). Follow-up analyses showed participants who scored positively on the Social Communication Questionnaire (SCQ) item indexing repetitive behaviours had a greater ERP response to S1 as compared to those who did not ($p<0.05$). No association was found between ERP response and the summed score of SCQ items indexing social impairment.

Conclusions:

Results regarding the association between MMN amplitude and DBC extend prior work, which has found comparable associations between behavioural problems and perceptual hyper-sensitivity using care-giver ratings of perceptual sensitivity.

Results regarding the selective response to S1 suggest a higher initial orienting response following deviant stimuli was linked to both internalising and repetitive behaviours, and thus are interpreted within the 'intolerance of uncertainty' framework.

Overall, findings suggest that perceptual processing atypicalities should be investigated in aetiological models of psychopathology in ASD, and ultimately the assessment of perceptual sensitivities may be helpful in individuals with co-occurring emotional and behavioural problems.

2:52 **158.002** Sleep Disturbance in Children and Adults with ASD in the EU-AIMS LEAP Cohort: Association with Symptomatology, Comorbidities, Quality of Life, and Intellectual Ability

A. San Jose Caceres[1], *D. V. Crawley*[1], *B. Oakley*[1], *E. Simonoff*[2], *T. Charman*[3], *J. K. Buitelaar*[4], *D. G. Murphy*[5], *E. Loth*[1] *and J. Tillmann*[6], *(1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)King's College London, London, United Kingdom of Great Britain and Northern Ireland*

Background: Rates of sleep problems in individuals with ASD range between 40%-80% (Johnson et al. 2009). Recent studies report the importance of sleep in the manifestation of ASD core symptoms (e.g. repetitive behaviours and communication; Park, et al., 2012; Tudor, et al., 2012) and sensory abnormalities (Mazurek et al., 2015). Psychiatric comorbidities have also been shown to be associated with sleep problems in neurodevelopmental conditions (e.g. challenging behaviours are more likely to co-exist in individuals with ASD who suffer from sleep disturbances; Lundqvist, 2013), ultimately impacting family life. Although some studies have shown sleep problems throughout the life span (e.g. Øyane, & Bjorvatn, 2005), to date, most of the studies focus on children and little attention has been given to the continuity and impact of these problems in adulthood.

Objectives: 1) To investigate the type and severity of sleep problems in individuals with and without ASD in relation to age, and ability level; 2) To study the associations of sleep problems on ASD core symptoms and psychiatric comorbidities (i.e. depression, anxiety, ADHD) as well as quality of life and adaptive functioning.

Methods: 294 individuals with ASD and 204 individuals with typical development or mild intellectual disability, with IQ ranging from 40-148 and aged 6-30 years were recruited as part of the multi-centre EU-AIMS Longitudinal European Autism Project (Charman et al., 207; Loth et al., 2017). Autism symptomatology was characterized with the ADOS, ADI-R, Social Responsiveness Scale, Short Sensory Profile, and Repetitive Behaviours Scale. Sleep disturbances were studied with the Child Sleep Habits Questionnaire (parent report version for 6-11 years-olds) or the self-report adolescent version in individuals over 11 years of age of IQ above 75, and parent reported for those below. Quality of life was measured with the Columbia Impairment Scale, and adaptive functioning with the Vineland adaptive behaviour interview. Comorbidities were characterized using the ADHD DSM-5 checklist, and Beck questionnaires for Anxiety and Depression.

Results: Children with ASD showed significantly greater overall sleep disturbances than controls, in particular, anxiety around sleep time, quality of waking (e.g. feeling rested, difficulties waking up, etc.), parasomnias, and daytime sleepiness (all $p_{corrected} < .037$). Adolescents and adults with ASD reported poorer quality of waking than controls ($p_{corrected} = .004$). Repetitive behaviours and sensory abnormalities correlated moderately with the total sleep time across ages, as reported by parents (all $r > .44$, all $p_{corrected} < .004$), but not on self-reports. In children, sleep correlated to adaptive behaviour ($r = -.35$, $p_{corrected} = .005$). Across ages, the total sleep time was moderately correlated to anxiety, depression and ADHD (all $r > .42$, all $p_{corrected} < .005$), as well as quality of life (all $r > .36$, all $p_{corrected} < .004$), but only on individuals of IQ > 75.

Conclusions: Sleep problems are linked to ASD core symptoms and adaptive behaviour in children with ASD, but sensory anomalies, and frequent comorbidities across the ages. Future analyses will examine whether the effect of sleep on clinical symptoms may be mediated by differences in cognitive or emotional processes.

3:04 **158.003** Sensory over-Responsivity Is Associated with Anxiety Disorders in Preschoolers with Autism and Typical Development

K. L. Carpenter[1], *J. Lorenzi*[1], *L. DeMoss*[2], *H. Riehl*[3], *E. Glenn*[3], *L. Beyer*[3], *J. Emerson*[3], *K. L. Williams*[4], *V. Smith*[5], *H. L. Egger*[6], *G. Baranek*[7] *and G. Dawson*[8], *(1)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (2)Rhode Island Consortium for Autism Research and Treatment, Brown University, East Providence, RI, (3)Duke Center for Autism and Brain Development, Durham, NC, (4)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (5)Duke University, Durham, NC, (6)Department of Child and Adolescent Psychiaty, New York University Langone Health, New York, NY, (7)Chan Division of Occupational Science and*

Occupational Therapy, University of Southern California, Los Angeles, CA, (8)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC

Background: Around 50% of individuals with autism spectrum disorder (ASD) have a comorbid anxiety disorder. Despite the fact that anxiety disorders are common and impairing in individuals with ASD, we know little about the early risk factors for anxiety in ASD, especially in the preschool period. One such risk factor is sensory over-responsivity - a set of symptoms characterized by heightened and unusual reactivity to sensory stimuli.
Objectives: We conducted an in-depth study of the relationship between sensory over-responsivity and anxiety symptoms in preschool age children with ASD as compared to typically developing (TD) children.

Methods: Ninety-six 3-6 year old children (65 ASD, 31 TD) participated in this study. ASD was diagnosed using the ADOS and ADI-R by research reliable examiners. Sensory challenges were assessed via parent report using the Sensory Experiences Questionnaire v3.0 (SEQ). Anxiety disorders, including generalized anxiety disorder (GAD), separation anxiety disorder (SAD), social anxiety disorder, and specific phobia, were assessed with the Preschool Age Psychiatric Assessment (PAPA). The relationship between sensory over-responsivity and anxiety was tested with Pearson correlations. The relative odds of meeting criteria for anxiety disorders given mean sensory over-responsivity score was tested with logistic regression. In the TD group, exact logistic regression was used to account for limited sample size.

Results: Forty-six children (71%) with ASD and 11 TD children (35%) met both symptom and impairment criteria for at least one anxiety disorder. Further, 39 children (60%) with ASD and 4 TD children (13%) fell 2SDs above typically developing norms for sensory over-responsivity. Overall, there was a significant correlation between mean sensory over-responsivity score and number of anxiety symptoms in all children (r^2=0.68, p<0.0001), as well as in both groups separately (ASD: r^2=0.60, p<0.0001; TD: r^2=0.44, p=0.01). This relationship translated into a 5-fold increased chance of anxiety in children with high levels of sensory over-responsivity in the ASD group (OR 5.5, 95% CI: 1.72, 17.56, p<0.01) and a 7-fold increase in the TD group, though it was not statistically significant in the TD group (OR 7.1, 95% CI: 0.64, 79.24, p=0.1). In the ASD group, sensory over responsivity significantly increased the odds of GAD by a factor of 6 (OR 6.6, 95% CI: 1.69, 25.55, p<0.01) and SAD by a factor of 3 (OR 3.6, 95% CI: 1.26, 10.32, p=0.02). In the TD group, sensory over responsivity increased the odds of SAD by a factor of 15 (OR 14.96, 95% CI: 0.952, 942.9 p=0.056), but was not associated with other types of anxiety.

Conclusions: Results suggest sensory over-responsivity is strongly associated with anxiety disorders in preschoolers with ASD, as well as TD preschoolers. In preschoolers with ASD, sensory over-responsivity is associated with both GAD and SAD. In TD preschoolers, preliminary results suggest it is associated with SAD only. Identifying early child characteristics, such as sensory over-responsivity, that confer risk for anxiety may set the stage for the development of targeted treatment strategies that can reduce or prevent anxiety before it emerges in young children.

3:16 **158.004** Biomarkers As Intermediate Indicators of Improvement in ASD: A RCT with OMEGA-3

C. Moreno[1] *and M. Parellada*[2]*, (1)Hospital Gregorio Maranon, Madrid, Spain, (2)Fundación Investigación Biomedica Gregorio Marañon, Madrid, Spain*

Background: A high ω6/ω3 ratio [fatty acid (FA) index] in the cell membrane has been associated with inadequate brain development. It has started to be used as a biomarker of treatment efficacy in human diseases.
Objectives: The aim of this study was i) to investigate if omega-3 supplementation improves erythrocyte membrane ω6/ω3, plasma antioxidant status (TAS) and autistic behaviors ii) to identify markers of response (i.e. baseline TAS, baseline ω6/ω3 ratio, age subgroups, etc.)

Methods: A randomized, crossover, placebo-controlled study was designed to investigate the effect of 8 weeks of supplementation with ω3 (962mg/d and 1155mg/d for children and adolescents, respectively). Sixty-eight children and adolescents with Autism Spectrum Disorders (ASD) completed the full protocol. Primary outcome measures were erythrocyte membrane FA composition and TAS. Secondary outcome measures were Social Responsiveness Scale and Clinical Global Impression-Severity.

Results: Treatment with ω3 improved the erythrocyte membrane ω6/ω3 ratio (treatment effect p<0.008, d=0.66; within subjects effect p<0.007, d=0.5) without changing TAS. There was a within subjects significant improvement in Social Motivation and Social Communication subscales scores, with a moderate to large effect size (p=0.004, d=0.73 and p=0.025, d=0.79 respectively), but no treatment effect (treatment-placebo order). Carryover effects cannot be discarded as responsible for the results in behavioral measures. When the sample was stratified into those with higher baseline antioxidant status and those with lower antioxidant status (<p50 vs p>50), the group with higher antioxidant status showed a greater benefit. In this group, there was a within-subject improvement in antioxidant capacity after supplementation with PUFAs (p<0.001, ηp2=0.247, large effect size); the ω3/ω6 ratio showed a treatment effect in both groups, as it does the whole sample (with a larger effect size in those with more baseline antioxidant stress (ηp2=0.194 vs ηp2=0.0.092). A further subdivision of the samples was conducted, with 2 groups, those with lower ω3/ω6 (percentile <50) (n=32) and those with higher ω3/ω6 (n=33). For the lower half of the sample, ω3/ω6 and AA/DHA showed a treatment effect (as did the whole group) (p=0.04 and p=0.02, respectively); a within-subjects effect was clear only in the lower ω3/ω6 group (p<0.001). All effect sizes were large. Further post-hoc analyses are being conducted in order to identify subgroups of patients that better respond to the intervention administered in this study.

Conclusions: In conclusion, supplementation with ω3 FA might be studied as an add-on to behavioral therapies in ASD. Optimal duration of treatment requires further investigation. With regard to side effects, the effect of this supplementation on the lipid profile needs monitoring.

Panel Session
Diagnostic, Behavioral & Intellectual Assessment

159 - The Female Autism Phenotype: New Methods, New Discoveries

3:30 PM - 5:30 PM - Grote Zaal

Panel Chair: William Mandy, *University College London, London, United Kingdom of Great Britain and Northern Ireland*

Discussant: Christopher Gillberg, *Gillberg Neuropsychiatry Centre, Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

There is a burgeoning interest amongst researchers, clinicians, and members of the autism community in the 'female autism phenotype', i.e., a female-typical pattern of core and associated autistic characteristics. This is driven by the realisation that autistic females are often excluded from clinical care and research, because they do not fit the stereotypical conceptualisation of autism, which is largely based on male cases. To reverse this sex/gender-based inequality we need a better, evidence-based understanding of autism in girls and women. In this panel a combination of leaders in the field and early career researchers will present diverse methodologically innovative approaches to studying the female autism phenotype; and report on the discoveries these have yielded. The talks cover an in-depth, phenomenological investigation via qualitative research; new measures of the female autism phenotype; twin and family pedigree designs; and longitudinal epidemiological investigations. The panel will be of interest to autism scientists and clinicians, as it is designed to: (1) offer new insights into the female autism phenotype; (2) explain how these can be translated into practice to improve care for autistic females; (3) and point towards new, fruitful ways of conducting research in the area.

3:30 **159.001** Understanding the Health Care Experiences of Girls and Women on the Autism Spectrum

Y. Hamdani[1]*, Y. Lunsky*[1]*, C. Kassee*[1]*, F. Nafeh*[2]*, B. Gladstone*[3]*, N. Bardikoff*[4]*, S. Ameis*[5]*, A. Sawyer*[1]*, P. Desarkar*[5]*, P. Szatmari*[1] *and M. C. Lai*[1]*, (1)Centre for Addiction and Mental Health, Toronto, ON, Canada, (2)Centre for Addiction and Mental Health, Toronto, Canada, Toronto, ON, Canada, (3)Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, (4)Autism Ontario, Toronto, ON, Canada, (5)Department of Psychiatry, University of Toronto, Toronto, ON, Canada*

Background:

Diagnosing autism spectrum disorder (ASD) in females may be challenging because their social behaviours present differently than males. Many girls and women are undiagnosed, misdiagnosed or diagnosed late in life. Their health care needs are often unrecognized, or unmet compared to males with ASD. Many experience mental health, self-identity, and gender-related challenges, and inadequate or insufficient health care and support. Systematic research that explores female experiences of ASD is lacking. Research that integrates a gender analysis, which involves identifying socio-cultural themes related to gender in data, can contribute to enhanced understandings of the health care experiences of autistic girls and women.

Objectives:

Our objective was to understand the ASD and health care experiences of girls and women. Research questions included:

1. How do girls and women experience autism and the process of being diagnosed with ASD?
2. How does being a girl or a woman with ASD affect access to health care?
3. What are girls' and women's experiences of both ASD-specific and general health care?

Methods:

A qualitative descriptive design (Kahlke, 2014) was adopted, which involved conducting individual and focus group interviews with three groups of participants: girls with ASD (12 to 18 years old), women with ASD (18 years and older), and parents/guardians. Our minimum target was 11 participants per category. A project advisory group of girls, women and parents provided ongoing recommendations about the methods and results. Thematic analysis methods proposed by Braun and Clarke (2006) were used to identify patterns in the data related to ASD, gender, and health care experiences. Interview transcripts were read and discussed by five research team members to develop a coding scheme by consensus. The interviewer's post-interview memos were incorporated into the data set for analysis. A research assistant then coded the transcripts and memos using NVivo software to organize the data for the purpose of further analysis. Key themes were generated, reviewed and refined by the larger research team.

Results:

To date, 17 women and 6 parents have participated in the study. Recruitment of girls is in progress. Preliminary results indicate that there are specific presentations of ASD in females compared to males, and that gender-related factors contributed to females being undiagnosed and having unmet health care needs. Key themes included: 1) feeling different from others at an early age; 2) being diagnosed with mental health conditions and overlooked for ASD; 3) experiencing exhaustion from managing ASD in daily social life; 4) being socialized differently than boys and men; and, 5) lacking access to health, education, employment and social services and supports. Gender and ASD identities and expressions were entwined and influenced how girls and women experienced health care and social interactions.

Conclusions:

Understanding the health care experiences of girls and women with ASD can inform: 1) the development of diagnostic and health care practices that are tailored to their specific health care needs; 2) the training of health professionals; and, 3) pathways to improve access to both general health and ASD-specific services and supports.

3:55 **159.002** It Gets Better? Sex/Gender Differences in Social Camouflaging in Autistic and Non-Autistic Adults

L. Hull[1]*, W. Mandy*[1]*, C. Allison*[2]*, P. Smith*[3]*, S. Baron-Cohen*[2]*, M. C. Lai*[4] *and K. V. Petrides*[5]*, (1)University College London, London, United Kingdom of Great Britain and Northern Ireland, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (3)University of Cambridge, Cambridge, United Kingdom, (4)Centre for Addiction and Mental Health, Toronto, ON, Canada, (5)London Psychometric Laboratory, London, United Kingdom*

Background:

Social Camouflaging (i.e., behaviours performed by autistic individuals to compensate for and/or mask their autism during social interactions) has increasingly become the focus of research attention as it may contribute to risk and resilience across an individual's lifespan. However, almost all work to date on this topic has been qualitative, reflecting the lack of validated measures of camouflaging. This exploratory work has suggested that that autistic women and girls camouflage to a greater extent than men and boys, and that camouflaging may be associated with reduced wellbeing; but these ideas have yet to be formally tested. Further, no research to date has compared camouflaging behaviours in autistic and non-autistic people, or looked at whether camouflaging behaviours remain constant across the lifespan. To address these gaps in knowledge, the newly validated Social Camouflaging in Autism Questionnaire (SCAQ) has been developed as the first measure of self-reported camouflaging behaviours.

Objectives:

This study aimed to assess camouflaging behaviours using the SCAQ in men and women with and without a diagnosis of an autism spectrum condition. The study also aimed to identify the relationship between autistic traits, number of years since diagnosis, and camouflaging in autistic men and women.

Methods:

284 autistic adults (104 men, 180 women) and 448 non-autistic adults (193 men, 255 women) completed an online survey including the SCAQ and a standardised measure of autistic traits, amongst other measures.

Results:

In this sample the SCAQ had high reliability ($\alpha = 0.94$) and demonstrable convergent and discriminant validity. A significant interaction between gender and diagnostic status was found for total camouflaging behaviours. Autistic women camouflage at significantly higher levels than autistic men ($p < .001$, $d = 0.60$); non-autistic men camouflage at moderately higher levels than non-autistic women ($p = .03$, $d = 0.25$). For autistic women, autistic traits predicted greater camouflaging behaviours ($B = .65$, $p < .001$), while years since diagnosis (controlling for age) predicted fewer camouflaging behaviours ($B = -0.86$, $p = .001$). For autistic men, autistic traits predicted greater camouflaging behaviours ($B = 0.47$, $p < .001$), whereas years since diagnosis (controlling for age) did not significantly predict camouflaging behaviours ($B = 0.40$, $p = .19$). Age did not significantly predict camouflaging for either gender.

Conclusions:

The newly developed Social Camouflaging in Autism Questionnaire is a reliable and valid method to measure self-reported camouflaging behaviours amongst autistic adults. Autistic adults of both genders camouflage at significantly higher levels than non-autistic adults, and autistic women camouflage to a greater extent than autistic men. The more time since an autistic woman was diagnosed, the less likely she is to camouflage, perhaps suggesting greater acceptance of autistic behaviours by herself or others around her. In contrast, this effect was not observed in males.

4:20 **159.003** Examining Autism Sex/Gender Differences in Presentation and Mental Health across a Range of Research Designs

F. Happé[1]*, L. Livingston*[1]*, E. Colvert*[2] *and E. Yarar*[3]*, (1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Institute of Psychiatry, KCL, London, United Kingdom of Great Britain and Northern Ireland, (3)King's College London, London, UNITED KINGDOM*

Background:

Women and girls on the autism spectrum have often been excluded from research. This has likely led to male-biased information on which theory and clinical practice are based. New approaches are needed to address this inequality in autism science, to insure our diagnostic and intervention efforts are fair to females.

Objectives:

Four approaches to researching autism gender differences will be described, with illustrative data from recent studies. The aim is to examine possible autism gender differences in presentation and mental health, and to highlight strengths and weaknesses of different approaches.

Methods:

Four contrasting approaches will be described, examining sex differences in: a) adults presenting for diagnosis of autism at a specialist clinic (N=90 ASD, 46 non-ASD, m age 40 years); b) twins (m age c.13 years) meeting diagnostic criteria for ASD (N=135), their non-ASD co-twins (N=55) and comparison twins (N=144); c) twins high in autistic traits, identified from an on-going population-based study (N c.8,000, data from age 8 & 12 years); and d) grandparents (N=43, m age 70 years) of offspring with ASD, hence enriched for the broader autism phenotype. Data from diagnostic (e.g. ADI, ADOS) and trait measures of ASD (e.g., CAST, BAPQ), and mental health (e.g. SDQ, HADS) will be considered across the different designs.

Results:

Strengths and weaknesses of different approaches will be contrasted. Although females in general scored lower than males on autistic trait measures, few sex differences emerged across our different samples in mental health or quality of life. In some cases, sex-differences seen in neurotypical samples were not seen in ASD samples. Our actively ascertained and population-based samples did not show the gender differences in IQ expected from previous clinic-based data.

Conclusions:

Research on gender differences in autism currently relies on diagnostic measures largely designed from and for males. Research with diagnosed samples alone may therefore risk circularity. Examination of trait scores in population-based samples may help us move research forward. A major challenge exists, however, if ASD in females presents very differently from ASD in males, given that ASD is currently a purely behavioural diagnosis with no reliable biomarkers.

4:45 **159.004** Sex/Gender Differences across Contexts and Reporters

J. L. Taylor[1]*, L. E. Smith DaWalt*[2]*, S. Odom*[3]*, K. Hume*[3]*, B. Kraemer*[4] *and L. J. Hall*[4]*, (1)Vanderbilt Kennedy Center, Nashville, TN, (2)University of Wisconsin-Madison Waisman Center, Madison, WI, (3)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)Special Education, San Diego State University, San Diego, CA*

Background:

Women with autism spectrum disorder (ASD) have a more difficult time than men maintaining post-secondary employment/educational positions, though they obtain these positions at similar rates. One hypothesized explanation for this difference is that social deficits associated with ASD have a greater impact on the day-to-day functioning of women with ASD, given that social behavior is generally more important for societal interactions of females versus males. The present study explores this hypothesis in a sample of high school-aged students with ASD.

Objectives:

This study has two objectives: 1) to test for sex differences in parent- and teacher-reported autism symptoms; and 2) to examine sex differences in patterns of social interactions for high school students with ASD.

Methods:

Participants include 547 adolescents (76 Females, 471 Males) between 13 and 20 (M=16.2, SD=1.4), who all have an educational diagnosis of ASD and are part of a larger longitudinal study of 60 high schools in 3 states (CA, NC, WI). The sample was diverse with 45.7% of students being from a racial or ethnic minority group. Parent-reported lifetime autism symptoms were assessed using the Social Communication Questionnaire. Teacher-reported current autism symptoms were measured using the Social Responsiveness Scale-II. Parents and teachers answered questions regarding the student with ASD's social behavior, including how frequently they interacted with typically-developing and disabled peers in schools, and how often they interacted with peers outside of school by phone, over the internet, and in person.

Results:

Analysis of variance was used to test for sex differences in autism symptoms and social participation. Although parents rated lifetime autism symptoms as nearly identical for males versus females (M=20.67, SD=7.66 for males; M=21.15, SD=7.42 for females), F=0.20, p=.65, teachers rated autism symptoms as more severe in the females (M=69.18, SD=11.13 for males; M=78.00, SD=15.84 for females), F = 33.33, p < .001. Sex differences were also noted in some aspects of social participation – both in and out of school. Teachers reported that females spent a greater percentage of time compared to males interacting with typically-developing peers, F=7.76, p<.01, although there were no sex differences in percentage of time interacting with peers with disabilities, F=3.25, p=.07. Despite more time interacting with peers without disabilities, females were no more likely than males to have a single person that they interacted with at least 5 times in a week (a regular social partner), F=.79, p=.375. Outside of school, females were more likely than males to interact with peers using technology (e.g., calling/texting/internet), F=6.87, p < .01, but there were no sex differences in in-person interactions with peers (e.g., getting together with friends outside of school), F=2.40, p=.12

Conclusions:

Discussion will touch on possible explanations for discrepancies in teacher versus parent findings on sex differences in autism symptom severity, including: 1) autism symptoms that become less severe over time for males versus females (lifetime versus current symptoms); and 2) similar symptom presentations that appear more impairing in females due to societal expectations or unsuccessful peer interactions.

Panel Session

Cognition: Attention, Learning, Memory

160 - Linking Behavioral and Neurobiological Perspectives to Examine Executive Function in ASD and Their Impacts on Social, Academic and Adaptive Outcomes

3:30 PM - 5:30 PM - Willem Burger Zaal

Panel Chair: So Hyun Kim, *Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

Discussant: Elizabeth Pellicano, *Macquarie University, Sydney, Australia*

This panel combines cutting-edge behavioral phenotyping and electrophysiology to examine executive function (EF) in children with ASD. EF is one of the strongest predictors of academic, social, adaptive, and mental health outcomes. Recent behavioral and neurobiological evidence suggests that difficulties in EF skills may emerge early on in children with ASD. However, the current scope of research is limited by a lack of 1) valid, child-friendly tasks targeting core EF skills specifically designed for ASD, 2) studies examining the underlying neurobiological mechanisms of EF, and 3) longitudinal investigations elucidating long-term impacts of early problems with EF. To address these gaps, the first presentation examines the patterns of EF in children with ASD based on highly-usable, innovative, tablet-based EF games that incorporate both social and non-social stimuli. The second and third presentations investigate electrophysiological markers of EF in relations to achievement, symptom severity and other clinical features in children with ASD. The last presentation examines the link between preschool EF and long-term outcomes in ASD symptom severity and adaptive functions based on a 12-year longitudinal study. These findings provide a further step towards advancing our understanding of early neurobiological and behavioral patterns of EF and their impacts on longer-term outcomes.

3:30 **160.001** A Mobile Game Platform for Studying Social Influences on Executive Function in ASD: Towards Accessible Remote Measurement

M. C. Aubertine[1], *B. Li*[2], *M. Kim*[3], *M. Mademtzi*[4], *S. A. A. Chang*[5], *E. Barney*[6], *C. Foster*[4], *T. St. John*[7], *A. Atyabi*[8] *and F. Shic*[6], *(1)Seattle Children's Hospital and Research Institute, Seattle, WA, (2)Computer Science and Engineering, University of Washington, Seattle, WA, (3)Seattle Children's Research Institute, Seattle, WA, (4)Child Study Center, Yale University School of Medicine, New Haven, CT, (5)Yale University, New Haven, CT, (6)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (7)University of Washington, Seattle, WA, (8)Seattle Children's Research institute University of Washington, Seattle, WA*

Background:

Mobile applications and games offer an accessible, often highly acceptable, method for assessing skills and developmental ability in special populations (e.g. young children), potentially facilitating data collection from the large sample sizes needed to parse and study clinically-relevant heterogeneity. Here, we present a mobile game that uses social and nonsocial stimuli to examine executive functioning skills, a known vulnerability for children with ASD.

Objectives:

1. Design a fun tablet-based game targeting areas of executive function.
2. Compare game performance and play patterns between diagnosis groups (ASD, typically developing (TD)) across stimuli (social, nonsocial).
3. Assess the predictive value of game performance to IQ and a validated measure of executive function, the Behavior Rating Inventory of Executive Function (BRIEF).

Methods:

Three games were created to assess: shifting, working memory, and inhibitory control. The shifting game showed four images (happy or angry faces, red or blue fractals) and required users to guess which image fit the unwritten rule. The working memory task required users to memorize one to four images and then choose the correct objects. The inhibitory control game required users to touch as many pictures as possible, but stop when a stop sign or angry face appeared. Each game had two social blocks and two nonsocial blocks that alternated (three counterbalanced orders). Participants were sixty-five children (ASD, N=33; TD, N=32) ages 2 to 17 years. Experimenters placed the tablet in front of participants seated at a table. Directions were presented on the screen and read aloud. Participants were allowed to engage with the tablet in any way they preferred.

Results:

A one-way ANOVA revealed, in the shifting game, participants with ASD made more mistakes than TD children in social (p=.015) and nonsocial conditions (p=.021). Children with ASD also touched more targets than TD children during the stop period of the inhibitory game in the nonsocial condition (p=.021), but not the social condition (p=.411). Inhibitory game performance was the only predictor of IQ (social, r=.345, p<.05; nonsocial, r=.456, p<.001). A one-way ANCOVA controlling for IQ and age revealed children with ASD were less accurate than TD children in the working memory game for social (p=.024) and nonsocial (p=.01) conditions. Partialling for IQ and age, significant relations were found between the BRIEF shifting subscale and shifting game duration (r=.467, p=.044) and correct guesses (social and nonsocial, r=.472, p=.035). Planning/organization subscale was correlated with nonsocial learning latency for the shifting game (r=.504, p=.028). In the inhibitory game, nonsocial accuracy was correlated with self-monitoring (r=-.421, p=.041) and emotional control (r=-.402, p=.05) subscales.

Conclusions:

In support of previous findings, children with ASD showed several EF deficits compared to their TD peers. In some areas, these deficits may interact with the sociality of the task. Mobile games, including the game presented here, have the potential to predict valuable clinical indicators such as IQ. While some facets of the BRIEF correlated with some game outcomes, more exploration is necessary to elucidate these relationships.

3:55 **160.002** Neurobiological Mechanisms of Executive Function (EF) As a Predictor of Social and Academic Outcomes in More-Able Kindergarteners with ASD

S. H. Kim[1]*, L. C. Shuffrey*[2]*, N. Benrey*[3]*, Y. B. Choi*[4]*, N. H. Brito*[5]*, W. P. Fifer*[2] *and C. Lord*[6]*, (1)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY, (2)Division of Developmental Neuroscience, Columbia University Medical Center, New York, NY, (3)Weill Cornell Med School, New york, NY, (4)Psychiatry, Weill Cornell Medical College, White Plains, NY, (5)Department of Applied Psychology, New York University, New York, NY, (6)University of California Los Angeles, Los Angeles, CA*

Background: Although past studies have shown atypical electrophysiological patterns of response monitoring and inhibitory control in ASD, these investigations have been limited to older school-age children and adults with ASD. This calls for more in-depth examinations of neurobiological mechanisms of EF in young children with ASD.

Objectives: We examined behavioral and electrophysiological patterns of EF skills and their impacts on concurrent social and academic outcomes in more-able kindergarteners with ASD.

Methods: We integrated innovative behavioral and event-related potential (ERP) tasks to target EF in 43 more-able kindergartners with ASD (no cognitive/structural language delays; mean age=64 months, SD=6). Novel computerized EF tasks were administered on a touch-screen tablet ("EF Touch"; Willougby et al., 2010) to assess inhibitory control ("Spatial Conflict Arrows [SCA]"), working memory ("Pick the Picture"), and attention shifting ("Something's the Same [STS]") based on proportions of correct trials. EF-related ERP components, Error Related Negativity [ERN], Correct Related Negativity [CRN], error positivity (Pe), N2 and P3 were elicited with a newly validated child-friendly Go/No-go ERP task ("Zoo Game"; Grammer et al., 2014) for a subset of children (*n*=17). Social and academic achievement were measured by the Brief Observation of Social Communication Change (BOSCC; Grzandinsky, Lord et al., 2016) and Woodcock Johnson Achievement Test (WJ). Regression analyses were conducted to examine the significant effects of EF on social/academic skills. Non-parametric correlations were used to examine the associations between ERPs and social/academic outcomes.

Results: Significant effects of inhibitory control (EF Touch SCA) and attention shifting (STS) on math achievement (WJ Applied Problems) emerged while controlling for age, gender, and maternal education ($p<0.05$). Additionally, when IQ was controlled, the effect of inhibitory control on math achievement still remained significant. The Zoo Game successfully elicited ERP components related to response monitoring (ERN/CRN, Pe) and inhibitory control (N2, P3; **Figure 1**). Larger No-go P3 amplitudes were significantly associated with worse achievement in reading (WJ Letter Word Identification [r_s=-.66]; Passage Comprehension [r_s=-.59], $p<0.05$). Greater No-go N2 amplitudes were significantly associated with more social communication impairments (BOSCC, r_s=0.71, $p<0.05$). Larger CRN was marginally correlated with worse achievement potentially due to a small sample size (WJ Passage Comprehension, r_s=-.48, p=0.08).

Conclusions: Preliminary data with recent cohorts of 43 more-able kindergarteners with ASD showed potential links between EF and concurrent academic and social outcomes. Results also showed that less efficient inhibitory processing related to larger N2 and P3 may be associated with poorer academic and social outcomes. This is in line with previous findings showing that children with ASD may require more neural resources for inhibitory control. Similarly, hyperactive response monitoring related to larger CRN (similar to findings in those with anxiety) may be linked to more limited academic skills. These findings might shed light in examining functional mechanisms of atypical neural activities related to EF deficits in young children with ASD, which will be critical for the development of more focused behavioral interventions targeting EF skills prior to school entry. The data collection is currently underway, and we hope to expand our analyses to a larger, longitudinal sample.

4:20 **160.003** Event-Related Potentials Linked to Executive Function Predict Concurrent School Functioning Among School-Aged Children with ASD

S. Faja[1]*, R. Golden*[1]*, R. Gilbert*[1]*, A. Vaidyanathan*[2]*, D. Hyatt*[3] *and L. J. Nelson*[4]*, (1)Boston Children's Hospital, Boston, MA, (2)The Banyan Academy of Leadership in Mental Health, Mugappair west, Chennai, India, (3)Medicine, University of Illinois Chicago, Chicago, IL, (4)Boston University, Boston, MA*

Background: Executive function (EF) is often reduced among individuals with ASD, even in the absence of more generalized cognitive difficulties. EF underlies the ability to manage complex problems, respond to novel situations, and strategically approach goals. Evidence suggests that it is comprised of inhibition, set-shifting, and working memory by mid-childhood. Understanding the neural profile that underlies EF in children with

ASD is critical because EF is linked to academic success and the ability to successfully navigate social situations in children without ASD. The N2 event-related potential (ERP) has been linked to inhibition of conflicting information or responses. We previously reported that children with ASD had greater overall N2 amplitudes than children without ASD and amplitude differences between congruent and incongruent flanker conditions related to EF behavior (Faja et al., 2016). Little research has examined the link between neural signatures of EF and academic and social functioning in ASD.

Objectives: To examine individual differences in ERPs during two inhibitory EF tasks with respect to academic, executive, and social functioning in the classroom.

Methods: As part of a larger clinical trial of EF intervention, 75 children (10 female), aged 7-11 years, with ASD and a full-scale IQ of 107 (range: 80-150) participated. Teachers responded to surveys about EF (BRIEF) and social functioning (SRS-2 and SSIS). Parents responded to the CBCL Academic Competence scale. Electrophysiological recordings were collected to examine the N2 during Flanker and Go/Nogo tasks. Mean amplitude and latency were computed for each condition (congruent/incongruent, go/nogo). Larger ERP difference scores suggest more effortful or slower processing for the condition requiring greater inhibition. Sixty-nine children provided adequate ERP data for the Flanker task (33 with teacher surveys) and 37 for the Go/Nogo task (18 with teacher surveys).

Results: During the Flanker task, greater overall N2 amplitude uniquely predicted lower Academic Competence beyond age and IQ (F_{change}=5.68, *p*=.02). More negative N2 amplitude for incongruent trials related to more teacher-reported problems with Organization of Materials (BRIEF; *r*(32)= -.38, *p*=.03). During the Go/Nogo, longer nogo versus go N2 latencies related to more teacher-reported problems with Shifting, *r*(18)= .62, *p*=.006, Monitoring, *r*(18)= .47, *p*=.05, and Behavioral Regulation, *r*(18)= .51, *p*=.03. Socially, larger go/nogo N2 latency differences related to more difficulties with Social Awareness (SRS-2; *r*(18)= .49, *p*=.04) and reduced Social Engagement (SSIS; *r*(17)= -.52, *p*=.03) at school. Larger differences between go and nogo amplitudes also related to lower teacher-reported Social Communication ability, *r*(17)= .57, *p*=.02, Cooperation, *r*(17)= .54, *p*=.03, and Social Responsibility, *r*(17)= .59, *p*=.01.

Conclusions: Neural responses during inhibitory EF tasks predict functioning at school. Specifically, children who exert more neural effort to suppress interfering stimuli (i.e., incongruent flankers), have worse general functioning and organization at school. Additionally, children with slower neural responses to cues to inhibit a dominant response were less flexible, less careful, and more dysregulated. Those who required more neural effort and responded more slowly to inhibitory signals also had reduced social functioning at school. The results of an EF training intervention on teacher-reported EF skills will also be presented.

4:45 **160.004** Childhood Executive Function Predicts Later Adaptive Functioning and Autistic Features: A 12-Year Longitudinal Study

E. Pellicano[1,2]*, S. Cribb*[3] *and L. Kenny*[4]*, (1)Macquarie University, Sydney, Australia, (2)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom, (3)School of Psychology, University of Western Australia, Nedlands, Australia, (4)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland*

Background:

Long-term follow-up studies show that the developmental outcomes of autistic individuals are highly variable, even for individuals at the more able end of the autism spectrum. While some cognitively-able individuals go on to live independently and obtain qualifications, the majority fail to achieve independence, to attain full-time employment or to enjoy friendships. Explaining this variability is of critical importance: to discover why developments take place in some areas and not in others, and especially in some individuals and not in others.

Objectives:

This study sought to test the potential sources, namely theory of mind (ToM) and executive function (EF), of the variability in developmental outcomes in a cohort of autistic children assessed at two follow-up time-points, 3 years (Time 2) and 12 years (Time 3) after initial intake (Time 1).

Methods:

Thirty-seven autistic children (4 girls) were assessed on two key components of EF (planning and cognitive flexibility) and on a battery of ToM tasks (1st- and 2nd-order false-belief understanding) at Time 1 (M age = 5 years; 7 months) and Time 2 (M = 8 years; 4 months), as well as a measure of autistic features (ADOS-G). Of these 37 participants, 28 (2 girls) were assessed again at Time 3, 12 years later (M age = 17 years; 7 months), in terms of their adaptive behaviour (Vineland Adaptive Behaviour Scales – 2nd edition) and core autistic features (ADOS-2).

Results:

At Time 2 (3-year follow-up), early EF skills were longitudinally predictive of change in children's ToM test performance, independent of age, language, nonverbal intelligence, and early ToM skills. Predictive relations in the opposite direction were not significant. Individual differences in early EF but not ToM skills also predicted variation in children's social communication and repetitive behaviors and interests at the 3-year follow-up. At Time 3 (12-year follow-up), early EF *and* ToM skills predicted significant variance in autistic adolescents' autistic features (ADOS severity scores) but only early EF skills predicted unique variance in young people's adaptive behaviour at the 12-year follow-up.

Conclusions:

These longitudinal findings clearly demonstrate that EF measured in early childhood has predictive power: it uniquely predicts autistic children's developing ToM and their behavioural features 3 years later, *and* their behavioural outcomes (autistic features, everyday adaptive functioning) 12 years later. Together, these findings provide compelling reasons to suggest that individual differences in the developmental trajectories of autistic children's EF skills might well explain some of the variability in children's functional outcomes, both in the shorter term and in the longer term, and underscores their importance as a key target for early intervention. -p

Panel Session
Interventions - Non-pharmacologic - School-Age, Adolescent, Adult
161 - Psychosocial and Demographic Moderators of Intervention Outcomes for Youth and Young Adults with ASD
3:30 PM - 5:30 PM - Willem Burger Hal

Panel Chair: Alan Gerber*, Stony Brook University, Stony Brook, NY*

Discussant: Matthew Lerner, *Psychology, Stony Brook University, Stony Brook, NY*

Social deficits are a defining characteristic of youth with autism spectrum disorder (ASD); however, symptom presentation is often highly heterogeneous (Georgiades et al., 2013). While research on interventions to remediate such deficits among individuals with ASD has recently proliferated, results remain similarly variable (Gates et al., 2017). This variability begs the fundamental questions of "for whom" do current treatments work (Kazdin, 2007). Likewise, in parallel to effort across child psychopathology (Ng & Weisz, 2017), there have been calls to individualize interventions in ASD in order to maximize benefits for participants (Lerner et al., 2012). The question remains, though: where – among the vast array of potential factors – to begin? In fact, basic psychosocial and demographic information is available in nearly all intervention datasets that contains under-explored factors that may be used to constrain heterogeneity of outcomes and potentially individualize interventions. This panel will synthesize findings from several social-focused interventions to explore when and how widely-available key moderators – age, gender, language, and comorbid diagnoses – may similarly and differentially impact outcomes. An integrative discussion will address both person- and treatment-level factors that may drive variability in moderator effects and provide concrete direction for the future of ASD social interventions.

3:30 **161.001** Examining the Influence of Age on Social Skills Intervention Outcomes: Does Age Moderate Social Improvements in ASD?

A. J. McVey[1], *H. K. Schiltz*[1], *A. D. Haendel*[2], *B. Dolan*[3], *K. Willar*[4], *A. Carson*[5], *F. Mata-Greve*[6], *C. Caiozzo*[7] *and A. V. Van Hecke*[8], *(1)Marquette University, Milwaukee, WI, (2)Speech-Language Pathology, Concordia University Wisconsin, Mequon, WI, (3)Medical College of Wisconsin, Milwaukee, WI, (4)Children's Hospital Colorado, Aurora, CO, (5)Pediatrics, Autism Center, Baylor College of Medicine/Texas Children's Hospital, Houston, TX, (6)Marquette University, Shorewood, WI, (7)Psychiatry and Behavioral Sciences, Children's Hospital of Philadelphia, Philadelphia, PA, (8)Psychology, Marquette University, Milwaukee, WI*

Background: Although social skills interventions exist for children, adolescents, and adults with autism spectrum disorder (ASD; Palmen, Didden, & Lang, 2012; Reichow & Volkmar, 2010; White, Keonig, & Scahill, 2007), very few studies have examined the influence of age on the outcome of receiving such an intervention (e.g., Tse, Strulovitch, Tagalakis, Meng, & Fombonne, 2007). Literature demonstrates that ASD is a lifetime condition, that is, children do not "age out" of ASD symptomology. In both clinical and research domains, however, a small proportion of youth who receive intervention have been shown to experience "optimal outcome," that is, amelioration of ASD symptoms to a non-clinical level (Fein et al., 2013). It may be that there are "ideal" times, or sensitive periods, during development when the receipt of a social skills intervention may be most helpful.
Objectives: The present study examined the relation between age and social knowledge and behavior among adolescents and young adults with ASD before and after receiving a well-validated social skills intervention, the Program for the Education and Enrichment of Relational Skills (PEERS®). It was hypothesized that older age would be associated with better social knowledge prior to the intervention and that younger and older age would show less malleability across the intervention, both in terms of social knowledge and social behavior.

Methods: One-hundred seventy-nine adolescents and young adults with ASD aged 11-28 participated in this study (EXP = 88; WL = 91). Participants received the PEERS® or PEERS® for Young Adults intervention, corresponding with their age. Self-report or caregiver-report of social knowledge (TASSK/TYASSK), direct interactions (QSQ), and social behavior (SRS, SSIS) was collected before and after intervention.

Results: The EXP and WL groups did not differ by age $t(177) = 1.42$, $p = .16$. Pearson correlations were conducted to examine the relation between participant age and each of the social knowledge and behavior variables at both pre- and post-intervention. Results indicated positive associations between age and TASSK/TYASSK at both pre- ($r = .48$, $p < .001$; all participants) and post- (EXP: $r = .24$, $p = .02$; WL: $r = .39$, $p < .001$), as well as age and QSQ at pre- ($r = .17$, $p = .02$; all participants) but not post-; neither the SRS nor SSIS showed significant associations with age at either time point. Multiple linear regressions were employed to examine the potential moderating role of age in intervention outcome. Results indicated that there was no significant age by group interaction for any outcome measure.

Conclusions: Our hypotheses were partially supported. The current study provides some evidence that, while younger participants demonstrate lesser PEERS® knowledge than their older counterparts, both before and after intervention, and have fewer direct social contacts prior to intervention, age itself does not appear to moderate intervention response. That is, seemingly regardless of age, adolescents and young adults benefit from the intervention.

3:55 **161.002** Gender and Psychiatric Comorbidity Moderate Outcomes of a Community-Delivered Group Social Skills Intervention for Youth with ASD

A. H. Gerber[1], *E. Kang*[1], *C. E. Simson*[1], *E. J. Libsack*[1] *and M. D. Lerner*[2], *(1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY*

Background: The most widely used treatment for social competence in youth with autism spectrum disorder (ASD) is group social skills interventions (GSSIs; McMahon et al., 2013); however, effect sizes are variable (Gates, Kang, & Lerner, 2017). One empirically supported GSSI for youth with ASD that has been successfully delivered in both controlled and "real world" community-based settings is socio-dramatic affective-relational intervention (SDARI; Lerner et al., 2011). A major challenge in implementing empirically-supported GSSIs in the "real world," however, is the complex clinical heterogeneity exhibited by youth with ASD in the community (Wood et al., 2015), which can lead to considerable variability in outcomes for community-delivered interventions (Perry et al., 2008). Thus, it is particularly important to identify individual difference factors (i.e., potential moderators) among participants in community-delivered interventions to optimize their effectiveness. In particular, three variables that have particularly strong theoretical promise – yet little previous examination – as moderators of GSSIs (Lerner & White, 2015): gender, psychiatric comorbidity, and psychotropic medication use.
Objectives: Based on prior research (Lerner & White, 2015), we hypothesized that female participants, as well as those with comorbid anxiety, would demonstrate larger treatment gains, but those with ADHD would experience attenuated effects. Given the limited research on medication use, we conducted exploratory analysis of its effects.

Methods: Seventy-five youth, ages 9 to 17 years (M=12.86 years, SD=2.19; 59 male; 86.7% parent-reported ASD) participated in a 6-week community-based summer GSSI in groups of 5-9. Parents completed pre-post measures of broad psychopathology (BASC-2; Reynolds & Kamphaus, 2004), ASD symptomatology (SRS; Constantino & Gruber, 2007), and social skills (SSRS; Gresham & Elliot, 1990). Participants completed a computer-based emotion recognition task (DANVA-2; Nowicki, 2004). We utilized generalized estimating equations (GEE) in an ANCOVA-of-change framework to account for nesting within groups.

Results: Participants with unitary anxiety displayed *greater improvements* in ASD symptom severity and vocal emotion recognition relative to those without anxiety or with multiple comorbidities (see Table 1). Additionally, participants with unitary ADHD demonstrated *greater* gains in adaptive skills compared to those without. Multiple comorbidity of ADHD and anxiety was associated with *limited improvements* in ASD symptom severity and social skills, and a *decrement* in vocal emotion recognition (see Figure 1) relative to all other participants. Additionally, females experienced greater improvements in facial emotion recognition, while males experienced greater improvements in vocal emotion recognition. There were no effects of medication.

Conclusions: This is among the first studies to examine the impact of outcome moderators in a community-based GSSI. Extending prior work (Antshel et al., 2011), we found that participants with both ADHD and anxiety made the *fewest* gains and, in fact, experienced no gains and even iatrogenic effects across several measures. Given the complexity of comorbidity in youth with ASD (Simonoff, 2008), this illustrates the importance of a thorough assessment of comorbid symptomatology. We also found evidence that gender moderated the effects of a GSSI when other studies have not (McVey et al., 2017). This again highlights the impact of phenotypic heterogeneity in community-based interventions on treatment effectiveness.

4:20 **161.003** Gender Differences Among the Social Conversational Profiles of Adolescents with ASD Participating in the START Socialization Program Clinical Trial

***J. A. Ko**, A. R. Miller, T. W. Vernon, A. Chiu, M. Allison, R. Graef, E. Prado, A. Barrett and E. McGarry, University of California Santa Barbara, Santa Barbara, CA*

Background: Researchers have increasingly focused on exploring gender differences associated with autism presentation and treatment response. Previous research relying on parent- and self-report measures indicates that females with ASD may demonstrate unique profiles of social-communication symptoms compared to males (Head et al., 2014; Lai et al., 2011). However, there is very limited research investigating gender differences in the context of a clinical trial. Even fewer studies have examined gender differences in video-recorded social behaviors and interactions (e.g. McMahon, Vismara, & Solomon, 2013). Direct observation of social behaviors during live social interactions may provide a more objective and ecologically valid means to understand how gender influences social presentation both before and after participation in a socialization intervention.

Objectives: The present study examines gender differences in the use of verbal and nonverbal social interaction skills following participation in the START socialization intervention for adolescents with ASD.

Methods: Participants were 32 adolescents with ASD (22 males and 10 females ages 12-17 years) who completed the Social Tools And Rules for Teens (START) program. The START program is a 20-week experiential social competence and motivation intervention. Each weekly group session consisted of an individual check in, socialization time, discussion of a weekly social topic, group activity, and a check-out that involved the parent. At pre- and post-intervention time points, participants engaged in two five-minute video-recorded conversations with unfamiliar, similarly-aged peers (one with a male and one with a female). Trained raters naïve to project hypotheses and the time point of each video coded these conversations for verbal and nonverbal social interaction skills (i.e. question asking, responding to questions, mutual engagement, eye contact, positive facial expressions, and listening behaviors). Two video coders coded each behavior and reliability was established for a minimum of 30% of the videos.

Results: Analysis of Covariance (ANCOVA) methods were performed to examine if females and males possessed similar or different patterns of socialization in response to the START intervention. To take into account pre-group differences, pre-intervention values of the video-recorded social behaviors were used as a covariate. When controlling for baseline scores, gender was found to have a significant impact on treatment outcome for question asking and positive facial expressions. More specifically, females had significantly improved at asking questions (p = 0.01; large effect) and showing positive facial expressions (p = 0.47; medium-large effect) during the brief conversations compared to males. There are ongoing analyses on the other verbal and nonverbal social skills.

Conclusions: Results indicate that there are clear gender differences in adolescents with ASD across verbal and nonverbal social skills in the context of the START socialization program. Findings from the present study may help inform how socialization interventions and treatment strategies can be tailored to meet the specific needs of different demographic subgroups.

4:45 **161.004** An Exploration of Possible Moderators in an Addressing Disparities Comparative Effectiveness Trial for Elementary Students with ASD or ADHD

***L. Anthony**[1], B. J. Anthony[1], A. Verbalis[2], D. Naiman[3], A. B. Ratto[2], S. Seese[2], J. Safer[4], M. F. Skapek[5], M. D. Powers[6], M. Troxel[1] and L. Kenworthy[2], (1)University of Colorado, Denver, Aurora, CO, (2)Children's National Health System, Washington, DC, (3)Applied Mathematics and Statistics, Johns Hopkins University, Baltimore, MD, (4)Georgetown University, Washington, DC, (5)Psychological Sciences, University of Connecticut, Storrs, CT, (6)Children's National Health System, Rockville, MD*

Background: As we grapple with the importance of determining patient-centered outcomes, those of us conducting intervention research with individuals who have neurodevelopmental disorders need to explore the possible moderating effects of important variables such as age, IQ, language(s) spoken in the home, income level and ethno-racial identity.

Objectives: This study presents the exploratory analyses of possible moderating variables from a larger comparative effectiveness research (CER) trial that may be used for hypothesis generation for future studies.

Methods: The trial compared Unstuck and On Target (UOT) to Contingency Behavior Management (CBM) in 21 Title I elementary schools in three school districts for students with ASD or ADHD. Both interventions targeted executive functioning skills in the classroom. The primary outcome for these analyses are academic classroom observations on the following behaviors: demonstrates social reciprocity, follows rules, transitions appropriately, gets stuck, displays negativity, and participates in class (total raw scores ranging from 0 (worst) to 6 (best)). IQ was measured by the WASI-II. Family income ranged from $8,796-400,000 and was split into tertiles (<35,000; 35,000-100,000; >100,000).

Results: Diagnosis is an important moderator, with ADHD students making significant treatment gains in both interventions (d=.45-.70), while ASD students only showed a positive effect in UOT (d=.42-.60). Importantly, age (r=-.033; p=.69), IQ (r=.165; p=.055) and income (r=.062; p=.495) do not significantly correlate with change in classroom behavior. This lack of significance remains true when analyzed separately by ADHD and ASD. There are three categories for language spoken at home: English only, Spanish only, and More than one language spoken. To be included in the study, parents needed to be able to understand parent trainings, handouts and parent questionnaires in either English or. Overall, language spoken in the home does not moderate the effectiveness of UOT as measured by blinded classroom observations (F=.001), but it does a little bit more with CBM, with the children whose families spoke English only in the home making the *least* amount of progress, though again, this change was not statistically significant (F=.191; see Table 1).

When looking at potential descriptive differences by race/ethnicity and intervention, it appears that Other (primarily reported as mixed race) students change the most, followed by Black students in UOT, Latino students in either intervention, with White students in both interventions and Black students in CBM making the smallest positive changes. None of these results were statistically significant on t-tests.

As stated above, there is not a significant linear relationship between income and change. However, because income was the specific disparity that this CER trial was designed to address, further exploration is warranted. Descriptively, high- and low-income students changed the most, though these differences are not significant (F=.185).

Conclusions: Overall, there may be some important moderators of effectiveness that could be explored in future large-scale effectiveness trials. It is particularly interesting that the hypotheses generated from these descriptive analyses include speaking languages other than English at home, being non-White and not from a middle-income family may predict greater change in hypothesis-, treatment-, and diagnosis-naïve classroom observations.

Panel Session
Miscellaneous

162 - Tracking Innovation: Catching Up with Recent Winners of the Slifka /Ritvo Innovation in Autism Award

3:30 PM - 5:30 PM - Jurriaanse Zaal

Panel Chair: Shafali Jeste, *University of California, Los Angeles, Los Angeles, CA*

For nearly a decade, the Alan B. Slifka Foundation has partnered with INSAR to offer the Slifka-Ritvo Innovation in Autism Award. This Award promotes innovative autism research designed to catalyze novel treatments and improvements in quality of life, as well as transformative insights into etiology. This panel offers an opportunity to review the outcomes of these efforts, providing summaries from Slifka-Ritvo Award winners (from 2014 – 2016) of their projects and impact on subsequent research. Dr. Naples will summarize his project developing improved methods for studying the social neuroscience of autism across the spectrum, and where these efforts will lead next. Dr. Hoekstra will review findings regarding understanding and reporting on autism in Ethiopia, with implications for capturing the broader landscape of autism around the world. Dr. Shcheglovitov will share progress on the use of human-derived induced pluripotent stem cells into mouse models to better understand functional connectivity differences in autism. Dr. Libertus will present results of his efforts to remotely and cost-effectively assess early motor development in infants with high likelihood of developing autism. The Chair will lead an integrative discussion on the impact of these projects and implications for the future of autism research.

3:30 **162.001** Human iPSC-Derived Neurons and Organoids for Studying Cortical Development, Synapses, and Synaptopathies

O. Shcheglovitov, *University of Utah, Salt Lake City, UT*

Background: Human cerebral cortex is a complex brain structure associated with many human-specific behaviors and disorders. Many genes important for the development and wiring of this structure have been found mutated in the individuals with autism spectrum disorders (ASDs). It has previously demonstrated that cerebral organoids generated from induced pluripotent stem cells recapitulate many important aspects of human cortical development. The main issue, however, has been reduced reproducibility and impaired functional maturation of neurons in these structures.

Results: To improve experimental reproducibility and neuronal maturation, we developed a new method enabling generation of three-dimensional cortical organoids from single induced pluripotent stem cell (iPSC-) derived neural rosettes – neural tube-like structures in vitro. We demonstrate that single-rosette-derived cortical organoids grow large in suspension culture, reaching 4-5 mm in diameter by 4 months while maintaining a single internal lumen, and consist of different types of neuronal cells, including cortical neural progenitors, deep and superficial cortical excitatory neurons, inhibitory neurons, and different glial cells, organized around the lumen. Using slice patch-clamp electrophysiology, we also show that many neurons in slices from single-rosette-derived cortical organoids fire repetitive action potentials, receive excitatory and inhibitory synaptic inputs, exhibit typical pyramidal-like morphologies, and have dendritic spines.

Conclusions: Our results indicate that human cortical organoids generated from single iPSC-derived neural rosettes could be useful for studying and modeling human cortical development in health and disease.

3:55 **162.002** Novel Paradigms for Studying Brain Activity across the Autism Spectrum

A. Naples, *Child Study Center, Yale University School of Medicine, New Haven, CT*

Background

Individuals with ASD experience profound difficulty in social interactions. These challenges are most evident in dynamic, interactive contexts; however, most brain research in ASD has studied neural response in unrealistic social contexts, such as passive viewing of static faces on a computer monitor. Furthermore, it is estimated that 30% of individuals with ASD are minimally verbal, a characteristic associated with poorer prognosis across academic, economic, and socio-emotional domains. Despite having the most significant need for support, most neuroscience research excludes these individuals from participation.

Objective

We have developed methods to measure brain activity during reciprocal interactions. Integrating highspeed eye-tracking (ET; measuring where a person looks on a computer screen) and electroencephalographic recording (EEG; measuring brain response) enables simulation of social interactions with animated faces that respond to a participant's gaze (faces that "look back" or smile in response to gaze). Importantly, these methods allow us to characterize attention and brain activity in the absence of explicit instructions and task demands. The experimental paradigms are driven by non-verbal behavior, and participants are "self-paced" in their completion of the task. We have capitalized on these technological advances to explore brain activity and attention in individuals with autism with varying levels of cognitive and language abilities, including individuals who may have difficulty following explicit experimental instructions. Our goal is to evaluate the efficacy of these methods for minimally verbal individuals and to explore brain activity in this sample.

Method

We collected co-registered high-speed EEG and eye-tracking data from individuals with ASD with IQ<70 during simulated social interactions. Onscreen faces responded to participant gaze by opening their eyes or mouths when looked at, or by looking towards or away from the participant. Importantly, the gaze-contingent nature of the experiment guaranteed attention to the eyes or mouth of onscreen faces during all facial movement, ensuring that brain activity reflected the locus of visual attention. We explored the P100 and the N170, temporally early neural indices of face processing, and pupil diameter.

Results

Preliminary data from four children with ASD showed modulation of brain activity in response to gaze-contingent facial movement such that reciprocal eye-contact elicited more negative and earlier activity at the N170 than mouth movement (mean difference=-1.85mv [Cohen's d=1.49], 21ms [Cohen's d=1.38]). A marginally significant effect was observed for P100 latency, such that eye movement was processed faster than mouth movement (t=-2.49, p=.08). Data collection is ongoing, and analyses are exploring the effects of gaze change and modulation of pupil diameter.

Discussion

Our preliminary data show efficacy for interactive neuroscience methods in this sample, with expected modulation of brain activity to social stimuli. Innovative experimental designs that are accessible to participants with a wide range of developmental and functional levels will reduce barriers to participation in clinical neuroscience research.

4:20 **162.003** Remote Assessments of Motor Skills in Infants at High Familial Risk for ASD

***K. Libertus**, Psychology, University of Pittsburgh, Pittsburgh, PA*

Background: The emergence of foundational motor abilities have implications for the development of several key behaviors during infancy. Specifically, attaining motor milestones, such as reaching, sitting, or walking, provides the child with new learning opportunities about the social and physical world (Gibson, 1988; Libertus & Hauf, 2017). However, in clinical contexts, early motor development is typically neglected unless motor problems are severe enough to interfere with daily living skills. For example, the often noted but mild motor delays observed in Autism Spectrum Disorders (ASD) are not considered diagnostic. This is surprising, given recent reports of delayed postural control and gross motor skills in infants at familial risk for ASD (Flanagan, Landa, Bhat, & Bauman, 2012; Nickel, Thatcher, Keller, Wozniak, & Iverson, 2013). Further, research with typically developing infants has noted far-reaching developmental cascades that are initiated by self-produced motor acts (e.g., Libertus & Needham, 2010, 2011; Soska, Adolph, & Johnson, 2010). Therefore, more research is needed to better understand the emergence of early motor skills and their impact on development across domains as well as their potential role in ASD where subtle differences in motor ability might affect subsequent social-cognitive development.

Objectives: Design and implement a remote observation protocol to study early motor development.

Method: A total of 43 infant-parent dyads provided longitudinal data on grasping and sitting development over an 8-week period starting at 3-months of age. Assessments were conducted in the family's own home using videoconferencing. On 3 follow-up occasions when the child was 10, 14, and 18-months of age, parents completed language and motor skill questionnaires about their child. Correlation and regression were used to examine the relation among motor skills and with subsequent language development (CDI) at 10 and 14 months.

Results: Results revealed that the emergence of sitting and grasping skills in early infancy do not correlate with each other, suggesting that the child focuses at one skill at a time. Further, only grasping skills seemed impacted by maturational factors. Regression analyses showed that early motor skills did indeed predict language development at 10 and 14 months of age, but not at 18 months of age. However, vocabulary size at both 10 and 14 months were significant predictors of language skills at 18 months. Consequently, early motor skills may indirectly influence language development at 18 months of age.

Conclusions: The current study demonstrates that early motor skills can be assessed remotely via videoconference and provides empirical support for interactions between motor and language development starting in early infancy. Benefits of the remote assessment protocol include its cost efficiency and wide potential participant base. Preliminary observations with infants at high-familial risk for ASD have been started and will be discussed.

4:45 **162.004** The Face of Autism in Ethiopia: The Expression, Recognition, Reporting and Interpretation of Autism Symptoms in the Ethiopian Context

***R. A. Hoekstra**[1], F. G. Bayouh[2], B. T. Gebru[1], M. Kinfe[2], A. Mihretu[2], W. Adamu[2], E. Carmo[1] and C. Hanlon[3], (1)Department of Psychology, King's College London, London, United Kingdom, (2)Department of Psychiatry, School of Medicine, College of Health Sciences, Addis Ababa University, Addis Ababa, Ethiopia, (3)Addis Ababa University and King's College London, Addis Ababa, Ethiopia*

Background: To improve identification and intervention for children with autism worldwide a better understanding is needed of the cultural-specific expression of autism symptoms and of how these symptoms are recognised, reported and interpreted by caregivers. A good understanding of these cultural factors is essential to inform adaptations of existing autism screening tools and autism interventions to non-Western and low-resource settings.

Objectives: To explore the expression, recognition, reporting and interpretation of autism symptoms in Ethiopia.

Methods: Audiotaped semi-structured interviews were conducted with fifteen Ethiopian caregivers of a child with autism and with nine local clinical professionals with autism experience. Informants were asked to describe the child's strengths and difficulties, and the caregivers' main concerns. Probes included autism characteristics listed in international diagnostic criteria. Data were analysed using framework analysis, and compared and contrasted with findings from two previous studies by our group: i) a situational analysis describing the current service provision for children with autism in Ethiopia (Tekola et al., 2016); and ii) a structured survey in caregivers of children with developmental disorders, exploring their explanatory models, unmet needs and challenges (Tilahun et al., 2016).

Results: Most caregivers identified strengths of their children; several indicated their child ‘greets other well’ (social greetings are ritualised in Ethiopia and carry great significance). Clinicians and caregivers together provided locally prevalent examples of all main diagnostic symptoms. Problems with social communication were highlighted most: the majority of caregivers indicated they don’t understand their child’s wants or needs. Reported examples of restricted repetitive behaviours and activities included repetitive play (e.g. splitting grass); sensory sensitivity (e.g. to loud noises) and insistence on sameness (e.g. eating only injera). Most caregivers found their child’s inability to communicate the most challenging; several also mentioned lack of self-help skills or challenging behaviours. While caregivers could easily describe their primary concerns, some core autism symptoms remained unrecognised: ‘I only start thinking about this [non-verbal communication problems] now that you raised it. ...We never thought of that’.

Several caregivers’ comments suggested that symptom interpretation and reporting may be affected by beliefs and stigma. These results corroborate our previous findings, indicating that autism families experience severe stigma (Tilahun et al., 2016) and social exclusion (Tekola et al., 2016), and that caregivers often attribute their child’s condition to spiritual causes and believe it can be cured (Tilahun et al., 2016).

Conclusions: This exploratory study from Ethiopia suggests the expression of core autism symptoms does not differ markedly from reports in Western countries. However, due to local belief systems, cultural norms and low levels of awareness some symptoms may be missed when using a standard Western autism tool. In order to avoid low sensitivity, prevailing caregiver-reported screening tools will require careful cultural adaptation. Moreover, existing autism interventions will require adaptation to local context and culture. The studies reported here have informed our current endeavour, adapting and piloting the World Health Organization’s Caregiver Skills Training for use in Ethiopia, leading to the first intervention available for children with developmental disorders living in rural Ethiopia.

Poster Session
164 - Cognition: Attention, Learning, Memory

5:30 PM - 7:00 PM - Hall Grote Zaal

1 **164.001** A Meta-Analysis of Working Memory in Individuals with Autism Spectrum Disorders

A. Habib[1]*, C. Melville*[2]*, F. E. Pollick*[3] *and L. Harris*[2]*, (1)University of Glasgow, Glasgow, United Kingdom of Great Britain and Northern Ireland, (2)University of Glasgow, Glasgow, United Kingdom, (3)School of Psychology, University of Glasgow, Glagow, United Kingdom*

Background: Autism spectrum disorders (ASD) are lifelong neurodevelopmental disorders. Numerous studies have shown that individuals with Autism spectrum disorder (ASD) are associated with working memory (WM) deficits, however, the findings from research on WM impairments in ASD has been inconsistent and it is not clear whether WM deficits are commonly experienced by individuals with ASD.
Objectives: To determine whether individuals with ASD experience significant impairments in WM and whether there are specific domains of working memory that are impaired.

Methods: We conducted a comprehensive systematic review and a meta-analysis using four electronic databases EMBASE (OVID), MEDLINE (OVID), PsychINFO (EBSCOHOST), and Web of Science, to examine the literature to investigate whether people with ASD experience impairments related to WM. Meta-analyses were conducted separately for phonological and visuospatial domains of WM. Subgroup analyses investigated age and intelligence quotient as potential moderators.

Results: A total of 29 papers containing 34 studies measuring phonological and visuospatial domains of WM met the inclusion criteria. WM scores were significantly lower for individuals with ASD compared to typically developed (TD) controls, in both the visuospatial domain when investigating accuracy (d: -0.73, 95% CI -1.04 to -0.42, $p < 0.05$) and error rates (d: 0.56, 95% CI 0.25 to 0.88, $p<0.05$), and the phonological domain when investigating accuracy (d:-0.67, 95% CI -1.10 to -0.24, $p>0.05$) and error rate (d: 1.45, 95% CI -0.07 to 2.96, $p=0.06$). Age and IQ did not explain the differences in WM in ASD.

Conclusions: The findings of this meta-analysis indicate that across the lifespan, people with ASD demonstrate large impairments in WM across both phonological and visuospatial WM domains when compared to people without ASD.

2 **164.002** Adaptive Behavior in Preschoolers with Autism Spectrum Disorder: The Role of Executive Function

J. R. Bertollo[1]*, A. S. Nahmias*[2]*, S. R. Crabbe*[3]*, L. Kenworthy*[4]*, D. S. Mandell*[5] *and B. E. Yerys*[1]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)MIND Institute, UC Davis Medical Center, Sacramento, CA, (3)University of Pennsylvania, Philadelphia, PA, (4)Children's National Health System, Washington, DC, (5)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: Adaptive behavior, the ability to function independently, is a well-measured concept that relates closely to functional outcomes in individuals with autism spectrum disorder (ASD). Even in the preschool years, children with ASD demonstrate poorer adaptive behavior than those with Down syndrome, a group with impaired cognitive ability, suggesting that cognitive ability alone does not explain the discrepancy in these skills. Research also suggests that adaptive behavior impairment increases with age, warranting research on which factors explain adaptive behavior, as well as its change over time. Some studies have demonstrated the importance of executive function skills, such as shifting and organization, in predicting adaptive behavior in individuals with ASD. However, this research has focused on school-age youth with average to above-average intelligence. Less work has extended into younger samples or those with a broader range of cognitive abilities, so it is not known whether the same skills are implicated across the ASD population and across development.
Objectives: To examine the association between executive function and adaptive behavior in preschoolers with ASD.

Methods: Ninety-one preschoolers with ASD (mean age=52.1 months; 81% male) from two sites were included in this analysis. At one site, teacher report on the Behavior Rating Inventory of Executive Function – Preschool (BRIEF-P) and the Adaptive Behavior Assessment System-II (ABAS-II) were used to assess executive function and adaptive behavior respectively. The other site relied on caregiver report on both the BRIEF-P and the Vineland Adaptive Behavior Scales, Second Edition (Vineland-II). We standardized measures of adaptive behavior by focusing only on adaptive practical and socialization skills. “Adaptive practical skills” were either Vineland-II Daily Living Skills Standard Score or ABAS-II Practical Composite Standard Score. Depending on site, cognitive or developmental functioning level (hereinafter, “nonverbal IQ”) was measured by either a nonverbal subtest of the Differential Ability Scales-2 or Wechsler Preschool and Primary Scale of Intelligence-III, or Visual Reception on the

Mullen Early Learning Scales. Stepwise regressions were conducted for each adaptive behavior domain to determine the unique variance contributed by the BRIEF-P scales, above and beyond nonverbal IQ (Table 1). Site was also entered as a covariate of no interest to minimize confounding effects from site differences, including rater and measure differences.

Results: For adaptive practical skills, nonverbal IQ and site accounted for 28.4% of variance. The BRIEF-P scales explained 8.0% of variance in practical skills and the model comparison was marginally significant; Plan/Organize scale was statistically significant. For adaptive socialization skills, the covariates predicted 13.5% of variance, but only nonverbal IQ was significant. The BRIEF-P scales explained an additional 12.0% of variance in socialization skills, with the Shift scale reaching statistical significance.

Conclusions: These results show that specific executive function skills play an important role in explaining variance in different aspects of adaptive behavior in early development, extending prior literature into preschoolers with ASD. Future research should replicate these findings with longitudinal designs and performance-based measures to sharpen our understanding of executive function in preschoolers with ASD, which may provide insight for adapting interventions to improve functional outcomes.

3 **164.003** Adults with High Autistic Traits Are Reluctant to Trade Accuracy for Monetary Reward: A Probabilistic Reasoning Experiment

H. Lu[1,2]*, H. Zhang*[2,3,4] *and L. Yi*[5]*, (1)Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China, (2)Peking-Tsinghua Center for Life Sciences, Peking University, Beijing, China, (3)School of Psychological and Cognitive Sciences, Peking University, Beijing, China, (4)PKU-IDG/McGovern Institute for Brain Research, Peking University, Beijing, China, (5)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China*

Background:

Information processing has been considered as a cause of dysfunctions in autism spectrum disorders (ASD; e.g., van de Cruys et al., 2014). Different empirical studies, however, provided seemingly contradictory findings on whether and how autistic people differ in probabilistic reasoning (Brosnan, Chapman, & Ashwin, 2014; Jänsch & Hare, 2014). What were confounded in previous studies are the abilities to judge probabilistic information and to use the information for decision-making.

Objectives:

To investigate how people with various autistic traits are driven by accuracy (the goal of judgment) and monetary reward (the goal of decision-making) to different extents by introducing monetary reward into a probabilistic reasoning task. In certain experimental conditions, accuracy and reward formed the opposing forces: pushing expected accuracy over a point would reduce expected reward.

Methods:

We recruited forty-eight 18- to 28-year-old college students and measured their autistic traits with Autism-Spectrum Quotient (AQ) on a 4-point scale (0, 1, 2, and 3). Participants played a computerized Bead Task, in each trial of which they saw two bead jars. One of the jars had a blue-to-pink beads ratio of 80%:20% or 60%:40%, and the other had the opposite ratio. Participants were told that one jar had been randomly chosen and their task was to judge which jar was chosen. For each correct judgment, participants could win up to 10 game points. Before judging, they could draw 0 to 20 beads sequentially from the chosen jar and stop sampling at any time. This information gathering could incur a cost: 0, 0.1, or 0.4 points for each bead drawn. There were 288 trials with three cost conditions blocked and two ratio conditions randomly mixed in each block.

Results:

We divided the participants evenly into three groups based on AQ scores (IQ-matched) and performed an ANOVA (Group × Cost × Ratio) on the jump-to-conclusion rate (the percentage of the trials with no more than two beads drawn). Jump-to-conclusion was not an optimal choice when the sampling cost was low, but could be more rewarding when the sampling cost was high. We found a three-way interaction (Figure 1): in the 80%:20% ratio condition where accuracy and reward were rarely in conflict, all the groups adequately adapted to the change of the cost. However, in the 60%:40% ratio condition, the high-AQ group was less likely than the other two groups to trade accuracy for expected reward when the cost climbed.

The distribution of the reaction time was bimodal. Consistent with our findings in the number of beads drawn, the reaction time gradually shifts from the shorter to the longer in the low- and middle-AQ groups with the drawing cost rising, while the shift in the high-AQ group seemed somewhat cost-resistant (Figure 2).

Conclusions:

In sum, we found that autistic traits influence how people use probabilistic information for decision-making. People with high autistic traits are highly driven by the accuracy of judgment even though pursuing the accuracy means costing their expected reward, while people with low autistic traits are more adaptively driven by expected reward.

4 **164.004** Alterations in Global and Local Visual Processing Is Associated with Autism and Autistic Traits – a Twin Study.

J. Neufeld[1]*, A. Hagström*[2]*, A. van't Westeinde*[3]*, K. Lundin*[2]*, E. Cauvet*[4]*, J. Isaksson*[2] *and S. Bolte*[5]*, (1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Srockholm, Sweden, (2)Karolinska Institutet, Stockholm, Sweden, (3)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden, (4)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (5)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Background:

Autism Spectrum Disorder (ASD) has long been suggested to be associated with altered local and global sensory processing. However, the nature of such alterations remains controversial with theories ranging from a reduced drive to integrate information into a coherent 'gestalt' ("*weak central coherence*"=WCC; Frith, 1989) to *enhanced perceptual functioning* in local information processing (Mottron et al., 2006) or a more *detail-focused processing style* (Happé, 1999) in ASD. Findings are largely contradictory, with reports of superior local processing or no differences compared to TD in high-functioning individuals with ASD (Muth et al., 2014) and no local advantage but slower global processing in more heterogeneous ASD-samples (van der Hallen, 2015).

Objectives:

In the light of these contradicting findings the current study aimed to gain more conclusive results by testing alterations in global and local visual processing in association with ASD and autistic traits for the first time in a large and well characterized sample of monozygotic (MZ) and dizygotic (DZ) twins, discordant or concordant for ASD or autistic traits. Using this approach, we implicitly controlled for a vast number of confounding factors – including family background, sex and age. Furthermore, we assessed the impact of genetic vs environmental contributions to this link by comparing MZ (100% genetically identical) and DZ twins (50% shared genes).

Methods:

134 same-sex twin pairs (N=268, 53%male, 63.5%MZ, mean age=16.5+/-5.5, 64 diagnosed with ASD) selected from the Roots of Autism and ADHD Twin Study Sweden (RATSS, Bölte et al., 2014) were included.

The Fragmented Pictures Test (FPT) was used to test the ability to construct a gestalt from incomplete visual information (global processing), measured by amount of visual information needed. The Embedded Figures Test (EFT) was used to test the ability (speed) to detect details while ignoring global information (local processing). Autistic traits were assessed with the Social Responsiveness Scale-2 (SRS). Clinical consensus diagnosis of ASD was supported by diagnostic tools, such as the Autism Diagnostic Interview – Revised (ADI-R), the Autism Diagnostic Observation Schedule Second Edition and medical history.

Conditional linear regressions were conducted to assess the within-twin pair relationships between visual tasks and ASD diagnosis/autistic traits, while controlling for general intellectual abilities using the Wechsler Intelligence Scales.

Results:

Both, ASD diagnosis (Z=2.19, p=0.028) and higher autistic traits (Z=1.97, p=0.048) were associated with the need for more visual information to construct a gestalt in the FPT. There was no difference between MZ and DZ sub-cohorts in this relationship. In contrast, speed of local processing in the EFT was only associated with autistic traits within DZ twins alone (Z=-2.15, p=.031), with twins with higher autistic traits being faster.

Conclusions:

Consistent with the WCC hypothesis, our results confirm the notion of altered global processing (need for more visual information) in ASD and individuals with high autistic traits while implicitly controlling for a large number of confounding factors. In contrast, an association between faster local processing and higher autistic traits was only seen within DZ but not MZ pairs, indicating that the latter effect is under genetic control.

5 **164.005** An Eye-Tracking Study on Biological Motion Perception in Children with High-Functioning Autism Spectrum Disorder

C. H. Chiang[1], *W. J. Lin*[2] *and J. L. Tsai*[3], *(1)Department of Psychology, National Chengchi University, Taipei City, Taiwan, (2)Taipei Student Counseling Center, Taipei, Taiwan, (3)Psychology, National Chengchi University, Taipei, Taiwan*

Background: Literature had been demonstrated that children with autism spectrum disorder (ASD) revealed atypical perceptual pattern in biological motion with eye-tracking paradigm. However, some methodological issues such as subject characteristics and the strategy of data analysis are needed to explore.

Objectives: This study investigated the preferential attention and attentional processing on the basic motion perception, animal biological motion perception, and human biological motion perception in children with High-Functioning ASD (HFASD). It aimed to explore the processing of biological motion perception in children with HFASD. Moreover, concerning the heterogeneity within ASD, the study examined the biological motion perception in intellectually gifted children within HFASD.

Methods: Fifty children aged 7 to 10 years with HFASD and twenty-five children with typically development（TD） matched on age and IQ were recruited. The current study utilized preferential looking paradigm and motion point-light displays, demonstrating three visual comparisons: (1) basic motion perception: object motion paired with scrambled motion; (2) animal biological motion perception: animal motion paired with object motion; (3) human biological motion: human motion paired with animal motion. Eye-tracking techniques were applied to measure proportion of dwell time and time course of fixation probability on each motion stimuli.

Results: In basic motion perception, children with TD and HFASD preferentially attend toward scrambled motion. In biological motion perception, generally, children with TD and HFASD preferentially attend toward animal motion and human motion. Time-course analysis revealed that children with TD and HFASD attended toward animal motion and human motion at the same time window. Moreover, in animal biological motion perception, children with HFASD showed lower preferential interest in animal motion than children with TD at the early stage of time course, and there were no significant difference between groups at the late stage of time course. In human biological motion perception, children with TD and HFASD showed similar level of preferential interest in human motion at the early stage of time course; however, children with TD maintained preferential interest in human motion across time, but children with HFASD reduced preferential interest in human motion across time. At the late stage of time course, children with HFASD showed significantly lower level preferential interest in human motion than children with TD. Concerning the heterogeneity within the study sample of HFASD, results indicated that there was no difference on the level of preferential interest in animal motion between intellectually gifted HFASD (IG-HFASD) and TD group; however, in human biological motion perception, IG-HFASD and nonIG-HFASD group reduced preferential interest in human motion across time course compared to TD group.

Conclusions: Findings suggested that children with HFASD exhibit the equivalent preferential interest and speed of attending to biological motion as did TD children. However, children with HFASD reduced referential interest in human biological motion across time course compared to TD children, and not influenced by the intellectually gifted advantage with compensation. The results implicated that biological motion perception may play an important role to understanding the social deficit in children with ASD.

6 **164.006** Attention Allocation during Visual Search in ASD: Results from the ABC-CT Feasibility Study

T. Tsang[1], *E. Barney*[2], *A. Naples*[3], *R. Bernier*[4], *G. Dawson*[5], *S. Jeste*[1], *J. McPartland*[3], *C. A. Nelson*[6], *M. Murias*[7], *C. Sugar*[1], *S. J. Webb*[4], *F. Shic*[2] *and S. Johnson*[1], *(1)University of California, Los Angeles, Los Angeles, CA, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (5)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (6)Boston Children's Hospital, Boston, MA, (7)Duke Center for Autism and Brain Development, Department of Psychiatry and*

Behavioral Sciences, Duke University, Durham, NC

Background: Attenuated attention to social stimuli is a hallmark characteristic of autism spectrum disorder (ASD), and visual search tasks have been used to address salience of social stimuli such as faces (Gliga et al., 2009). 7-14-month-old infants who later developed ASD demonstrated a face “pop-out” effect, much like their typically-developing (TD) peers (Elsabbagh et al., 2012). However, older children with ASD attended to faces less than TD controls in the presence of competing non-social stimuli (Sasson et al., 2008). Visual search may potentially monitor changes in social functioning, and restrictive and repetitive behaviors (Sasson et al., 2008). Here, we evaluated the possibility that visual search tasks can aid in the detection of reliable biomarkers of social impairments in children with ASD.

Objectives: The current study aimed to evaluate whether visual search can reveal reliable differences in attention between children with ASD and TD controls, and to relations between visual search performance, and social and repetitive behavioral features of the autism phenotype. This study is part of a larger project on creating objective measures of treatment gains in clinical trials.

Methods: 46 children (23 ASD, 23 TD; 4.01-11.40 years) participated in the visual search task (adapted from Gliga et al., 2009). Stimuli comprised six circular arrays of five colored images (face, cell phone, vehicle, bird, and scrambled face). Participants viewed each array for 20 s while gaze patterns were recorded using a SR Eyelink 1000 Plus eye tracker. The primary dependent variable was percentage of time spent looking at the face; additional dependent variables included on-screen looking time and number of fixations to each target. Participants also completed a battery of behavioral assessments of social and cognitive development. Eye-tracking data were analyzed using linear mixed-effects modeling with repeated effects of trial; diagnosis, trial, and their interaction were included as fixed effects, and full-scale IQ as a covariate. Associations between social and cognitive measures, and visual search performance were determined with Spearman correlations.

Results: On-screen looking time did not differ by diagnosis status ($F_{1, 49.689}$=1.304, *p*=0.26) or trial ($F_{1,44}$=1.56, *p*=0.19), suggesting no between-group difference in overall visual engagement. Children with ASD looked less at faces ($F_{1,43.55}$ =13.130, *p*=0.001) than TD controls, over and above effects of full-scale IQ and trial. Similarly, children with ASD made fewer fixations within the face than TD controls ($F_{1, 36.381}$=6.027, *p*=0.019at non-face, object targets did not differ by diagnosis status ($F_{1, 41.193}$=0.255, *p*=0.616), suggesting a specific attenuation in attention to social stimuli. Greater fixation to the face was associated with higher Vineland Communication Standard Scores (rho=0.374, *p*=0.011).

Conclusions: Faces captured and held attention less for children with ASD, suggesting that the visual search task is sensitive to differences in social attention between diagnostic groups. In addition, attention to faces was associated with better functional communication skills, implying that visual search performance indexes a relevant domain of social functioning in ASD. Visual search tasks may help to objectively address changes in social functioning or treatment response in clinical trials.

7 **164.007** Attention to Faces in Toddlers Showing Early Signs of Autism Spectrum Disorder: A Marker of Early Risk

A. T. Marin[1]*, H. Yu*[2]*, E. Baker*[3]*, B. Nguyen*[4]*, M. Ware*[5]*, E. Pompan*[6]*, N. M. McDonald*[3]*, A. Gulsrud*[7]*, C. Kasari*[8] *and S. Jeste*[8]*, (1)UCLA Center for Autism Research and Treatment, University of California, Los Angeles, Los Angeles, CA, (2)School of Medicine, Nankai University, Tianjin, China, (3)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (4)Center for Autism Research and Treatment, UCLA, Los Angeles, CA, (5)UCLA, Los Angeles, CA, (6)University of California Los Angeles, Los Angeles, CA, (7)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (8)University of California, Los Angeles, Los Angeles, CA*

Background: Lack of attention to faces is considered one of the earliest and most reliable indicators of risk for Autism Spectrum Disorder (ASD; Dawson et al., 2005; Wetherby et al., 2004). These abnormalities in social attention during early development may contribute to the underlying heterogeneity that characterizes ASD. Using eye tracking methodology, the measurement of time spent examining faces provides an objective marker of dynamic eye gaze that can quantify characteristics of attention in toddlers showing early behavioral signs of ASD. This sensitive measure could provide utility as an outcome marker of social attention in clinical trials for early social communication interventions.

Objectives: We examined: 1) whether fixation time on faces differentiates toddlers who are showing behavioral signs for ASD (HR-ASD) and age-matched typically developing controls (TD), and 2) whether this marker of social attention relates to social communication and cognitive skills.

Methods: Two age-matched groups of HR-ASD (n=64;$M_{\text{age-months}}$=18.5,SD_{age}=2.5) and TD (n=21;$M_{\text{age-months}}$=17.4,SD_{age}=2.3) toddlers participated in a visual paired comparison eye-tracking task (Tobii Systems, Inc.). Toddlers in the HR-ASD group fell within the mild-to-moderate or moderate-to-severe ranges of concern on the Autism Diagnostic Observation Schedule, Toddler Module (ADOS–T). Toddlers viewed two fixed images of faces that were presented in juxtaposition to one another four times each with an on-screen duration time of ten seconds per trial, while eye fixation data was recorded. One image consisted of the child’s primary caregiver and the other of a stranger who was matched based on similarity of physical appearance. Areas of interest (AOI; mouth, eyes, face) were drawn for each image, and eye fixation time in milliseconds per AOI was obtained. An independent sample *t*-test was used to examine risk group differences in percent time looking at the face (i.e., time fixation on face/total fixation time). Correlations between percent eye fixation to the face and non-verbal/verbal developmental quotient (NVDQ/VDQ) were also examined (Mullen Scales of Early Learning).

Results: HR-ASD toddlers did not differ from TD toddlers in percent looking time at familiar/unfamiliar faces, or at the eyes/mouth (all *p*’s>.37). However, HR-ASD toddlers spent significantly less time looking at the face than TD toddlers (*t*(77.2)=3.09,*p*=.016; see Figure 1). Whole-group correlations revealed the percent time looking at the face positively related to VDQ (r_T(83)=.23,*p*=.003) and NVDQ scores (r_T(83)=.17,*p*=.024), but did not correlate with the ADOS-T total score (r_T(63)=-.12,*p*=.186).

Conclusions: Our results indicate that toddlers showing early signs of ASD spent less time looking at faces than TD toddlers. Moreover, HR-ASD toddlers who spent more time looking at faces had higher cognitive abilities, yet no relationships were found with ASD symptoms. Figure 1 depicts a great deal of heterogeneity within the HR-ASD group, suggesting that this may be a promising marker of which toddlers may benefit most from intervention. Null findings with regards to the familiar/unfamiliar face and mouth/eyes suggests these contrasts are developmentally inappropriate within this age group. Ongoing research will examine attention to faces as an outcome measure and predictor of response to intervention in an eight-week clinical intervention designed to target early social communication skills.

8 **164.008** Attentional Disengagement in School-Age Children with ASD and Relationship to Phenotype: Results from the ABC-CT Feasibility Study

Q. Wang[1]*, E. Barney*[2]*, R. Bernier*[3]*, G. Dawson*[4]*, S. Jeste*[5]*, K. Chawarska*[1]*, J. McPartland*[1]*, C. A. Nelson*[6]*, M. Murias*[7]*, C. Sugar*[5]*, S. J. Webb*[3]*, A. Naples*[1] *and F. Shic*[2]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle*

Children's Research Institute, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (5)University of California, Los Angeles, Los Angeles, CA, (6)Boston Children's Hospital, Boston, MA, (7)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC

Background: Children with Autism Spectrum Disorder (ASD) exhibit atypicalities in attentional disengagement compared to controls. However results have been inconsistent with some groups noting longer (Elsbbagh et al, 2009, 2013, Kawakubo et al. 2007, Landry and Bryson 2004) while others observe shorter disengagement times (Chawarska, et al, 2003, 2010), or no difference (Kawakubo, et al., 2011, Fischer et al., 2014). Furthermore, little is known about relationships between atypical disengagement and phenotypic characteristics in both typically developing (TD) children and children with ASD.
Objectives: 1. Analyze group differences in reaction times during a gap overlap paradigm (including gap, overlap, and baseline phases). 2. Examine the association between engagement on screen and reaction times with behavioral characterization.

Methods: Participants were children with ASD (n=24, age = 7.9±2.2) and TD controls (n=26, age = 6.6±2.0). Paradigms were adapted from Elsbbagh et al (2009, 2013) with in-house trial randomization and no gaze contingency. Dependent measures were percentage of valid looking time (%Valid) and reaction time to the peripheral stimulus (RT). Data were analyzed using linear mixed models (LMM) with diagnosis, condition and their interaction as factors, covarying for full scale IQ (FSIQ). For RT, a natural base logarithm transformation was used. Spearman's rank correlations were applied to compare T scores from the Social Responsiveness Scale (SRS) to the eye-tracking measures in children with and without ASD respectively.

Results: A LMM of %Valid showed a main effect of group (d = 0.98, p = 0.038), with the ASD group looking less than TD, and no effect of task condition, interaction, or FSIQ. Similarly, a LMM of RT showed a main effect of group (d = 0.28, p =0.048), with shorter RTs in the participants with ASD than TD. Condition effects were observed (p < 0.001), with fastest RTs in the gap condition, then baseline, and slowest in overlap. The interaction and FSIQ were not significant.

A negative correlation was observed between %Valid and SRS Autistic Mannerisms in participants with ASD (r(23) = -0.50 p = .015). In the TD group, a negative correlation was observed between %Valid and SRS Social Awareness (r(26) = -0.53, p = 0.005) and Social Cognition (r(26) = -0.62, p = 0.001). In the TD group, RT in the overlap condition was correlated with SRS Social Cognition (r(26) = 0.45, p = 0.02), while no correlation between the RT and SRS was found for children with ASD (ps>0.1).

Conclusions: Lower overall attention, which was associated with more severe autism symptoms indicated by SRS, was observed in children with ASD. Children with ASD showed faster disengagement times compared to TD children, suggesting greater bias for exogenously driven salient cues, limited processing of the central stimulus, or greater efficiency in visual exploration in ASD. In TD children, slower disengagement was associated with social cognition difficulties, contrary to continuum-based expectations that children with ASD should be slowest of all. These results suggest that a simple deficit model of attentional disengagement in ASD may not adequately describe our observed results.

9 **164.009** Attentional Performance in Adolescents with ASD in Normal Range of Intelligence

M. Pudło[1] *and E. Pisula*[2]*, (1)University of Warsaw, Faculty of Psychology, Warsaw, Poland, (2)University of Warsaw, Warsaw, Poland*

Background: The results of previous studies on individuals with ASD mostly regard only one type of attentional process such as orienting attention. However, it is essential to examine the performance of various attentional processes in adolescents with ASD. There is evidence of impaired bottom-up attentional at individuals processes. On the other hand, some researchers postulate the poor executive attentional control and atypical attentional processing e.g. overselectivity in individuals with ASD. In addition, the developmental and educational challenges during adolescence require efficient alerting, orienting, and executive processes of attention. As a result, the knowledge of what kind of attention processes the adolescents with ASD manifest decreased and increased performance could be useful for interventions and education.
Objectives: The aim of the research was to assess the efficacy of numerous attentional indicators in adolescents in the normal range of intelligence. The performance at attentional processes was examined such as: alerting, orienting to spatial cues, solving cognitive conflicts, visual-spatial search, concentration performance, and selectivity.

Methods: The following tests were used in the study: The Attention Network Test (ANT), Test of concentration d2 and The Color Trails Test (CTT). The participants were 37 adolescents with ASD, 12-20 years of age, selected from a larger sample, with a Wechsler IQ in the normal range ≥75, and 37 controls. The groups (ASD and control) were matched by chronological age and Full-Scale IQ. The psychiatric diagnosis of autism and Asperger Syndrome was based on the ICD-10 criteria. The diagnosis of ASD was confirmed with use of ADOS-2 and ADI-R.

Results: The results of ANOVA showed significant differences in reaction times between the groups for seven conditions in the ANT: No cue, double cue, spatial cue, center cue, and flanker conditions: Congruent, incongruent, and neutral. The differences in the effects of ANT (alerting, orienting and executive attention) between groups were not revealed. The differences were present between participants with ASD and their counterparts in the Test of Concentration d2 on two indicators: Their ability on Concentration-Performance and Fluctuation Rate. No significant differences between the groups in CTT were found. The second step in the analysis was to select attentional tasks, which would differentiate the most adolescents with ASD from typically developing counterparts. The discriminant function analysis showed that adolescents with ASD differed the most from the control group in the task with the center cue condition in ANT and the task with incongruent flanker. Individuals with ASD reacted slower with these two conditions than their counterparts from the control group. However, the ASD group manifested high efficacy at the indicator from the Test of concentration d2: Total corrected processed.

Conclusions: The results of the discriminant analysis are consistent with the hypothesis of enhanced perceptual capacity and overselectivity for individuals with ASD. Decreased efficacy at orienting attention is typical for children with ASD, however as discriminant analysis shows, adolescents from the study did not seem to differ significantly from typically developed counterparts in orienting attention.

10 **164.010** Atypical Visual Attention Patterns to Social and Non-Social Stimuli in the Broad Autism Phenotype

N. Maltman[1]*, K. Nayar*[2]*, G. E. Martin*[3]*, N. J. Sasson*[4] *and M. Losh*[5]*, (1)Northwestern University, Evanston, IL, (2)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (3)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (4)University of Texas at Dallas, Richardson, TX, (5)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Differences in attention to social stimuli have been repeatedly observed in eye-tracking studies of individuals with autism spectrum disorder (ASD), particularly in the context of competing information, such as objects associated with circumscribed interests (Sasson et al., 2008; 2011). Evidence of subtle differences in visual attention to social stimuli (e.g., faces) has also been reported in parents of individuals with ASD, and among those parents who display subclinical features of the broad autism phenotype (BAP) in particular (Spezio et al., 2007; Adolphs, et al., 2008). The BAP is a constellation of subclinical traits (pragmatic language, personality features) related to the core features of ASD. This study built on this work by applying eye tracking during a passive viewing paradigm, adapted from Sasson et al. (2008), to examine patterns of visual attention to social, neutral, and circumscribed interest stimuli in parents with and without the BAP.

Objectives: This study examined whether visual attentional patterns to social and nonsocial images in parents of individuals with ASD are similar to those observed in ASD, and whether these differences are related to features of the BAP.

Methods: Thirty parents of individuals with ASD, and 9 controls viewed 12 separate visual arrays on a Tobii T60 eye tracker for 10 seconds each. Each visual array included 12 luminance-matched gray-scale images drawn from both public domain and Sasson et al. (2008) of four image types: smiling people, neutral objects (e.g., table, gloves), objects associated with high interests in ASD (e.g., trains, electronic devices), and those associated with personality features of the BAP, such as rigid or perfectionistic qualities (e.g., calendar, folded clothes). Image types were presented in randomized order to control for potential order effects. Analyses evaluated visual exploration (number of images explored over time) and perseveration (amount of time spent on each image). BAP status (positive + or negative -) was determined using the Modified Personality Assessment Scale (MPAS; Tyrer, 1988).

Results: Visual attention differed across parent groups, and in relationship to BAP features. Similar to patterns reported in ASD (Sasson et al., 2008), parents of children with ASD demonstrated reduced exploration (*p*s<.05) and increased perseveration (*p*s<.05) with all image types across slides, relative to controls. These findings were driven by the BAP+ parents, who showed decreased exploration (*p*s<.04), and increased perseveration (*p*s<.05) on slides containing ASD-related high interest images, compared to those without BAP features and controls.

Conclusions: Differences in visual attention to social and nonsocial stimuli observed in BAP+ parents bear striking resemblance to patterns observed in ASD, and may suggest key differences in attentional biases related to genetic liability to ASD.

11 **164.011** Autistic Children at the Age of Diagnosis Are More Interested in Letters Than Typical Children

A. Ostrolenk[1], *B. Forgeot d'Arc*[2] *and L. Mottron, M.D.*[3], *(1)Université de Montréal - Department of Psychiatry, Montréal, QC, Canada, (2)Département de Psychiatrie, Université de Montréal, Montréal, QC, CANADA, (3)University of Montreal Center of Excellence for Pervasive Developmental Disorders (CETEDUM), Montreal, QC, Canada*

Background:

Hyperlexia is defined by advanced reading skills relative to comprehension, acquired at an early age in the absence of explicit teaching, concurrent with a strong orientation toward written material, and accompanied by a neurodevelopmental disorder. Hyperlexia is the most common special ability reported in autism. Ostrolenk et al.'s (2017) literature review of 82 individual cases of hyperlexia and 22 group studies (including 315 hyperlexic subjects) showed that the reported prevalence of hyperlexia in autism varies between 6 and 21%. Furthermore, Ostrolenk et al., (2017) found that of the published hyperlexic case studies reviewed, a significant proportion (84%) were on the autism spectrum. However, within this literature, there are no group studies specifically investigating children's *interest* in written material.

Objectives:

Our objective was to **estimate the prevalence of atypical interest for written material** in a representative population referred for an autism diagnosis assessment.

Methods:

Participating families were referred to our clinic after autism was suspected in their child. They were administered a six-minute questionnaire by the psychiatrist; questions about the child's interest in written material, their related skills and behaviours, as well as questions about their comprehension and oral language level were included. The parents of 79 children answered the questionnaire at intake, of which 40 subsequently received an autism diagnosis at the end of the evaluation (50.63%). The children were 28 to 86 months old (mean = 46.29; SD = 12.26). The two groups (autism diagnosis and no diagnosis) did not differ in their age. The children's interest in written material was rated using 4 categories, coded with numbers 1 to 4; 1 - *None* < 2 - *Moderate* < 3 - *Intense* < 4 - *Exclusive*.

Results:

Children later diagnosed with autism had a mean interest for written material that was superior to the non-diagnosed group (means: 2.20 vs. 1.69 out of 4). An ANCOVA analysis using age as a covariate, demonstrated a significant interaction between diagnosis and interest for letters (p=.013). Significantly more autistic children had an *intense* or *exclusive* interest in written material compared to non-autistics (42.50% vs. 20.51%). For those who had an interest in written material, the mean age of the interest onset was similar in both groups (29.51 months).

Conclusions: Our study demonstrates the existence of an association between autism and an early interest in written material, with a significantly larger portion of autistic toddlers demonstrating an intense interest compared to non-autistic toddlers. These findings confirm the need for more research on hyperlexia in autism, the factors involved in its emergence, and its possible uses during diagnosis assessment and intervention.

12 **164.012** Binding in Short-Term Memory across Modalities in Younger and Older Adults with Autism Spectrum Disorder

M. Ring[1], *B. Guillery-Girard*[2], *P. Quinette*[2], *S. B. Gaigg*[3] *and D. M. Bowler*[4], *(1)Department of Child and Adolescent Psychiatry, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany, (2)Inserm—EPHE, Université de Caen-Normandie, Unité E0218, Laboratoire de Neuropsychologie, CHU Côte de Nacre, 14033 Caen Cedex, France, Caen, France, (3)City, University of London, London, United Kingdom, (4)Autism Research Group, City, University of London, London, United Kingdom*

Background:

Adults with Autism Spectrum Disorder (ASD) show difficulties in long-term memory which are assumed to result from altered relational binding (Bowler et al., 2011). Relational binding is the process by which elements of an episode are related to form a coherent episodic representation and to enable flexible retrieval. There is some evidence that short-term memory can also be impaired in ASD, for example when asked to remember the temporal order of item presentation such as digits, words (Poirier et al., 2011) or locations in a grid (Bowler et al., 2016). Similar to ASD individuals TD older adults (TD OA) present an associative deficit (Naveh-Benjamin, 2000) and, therefore, they show lower memory especially in relational tasks compared to younger TD individuals, which was found for long-term (Rotblatt et al., 2015) and short-term memory (Lecouvey et al., 2015). The ageing analogy of ASD describes similarities in memory in ASD and TD OA (Bowler, 2007) in that the memory difficulties ASD individuals show at younger age are similar to that of TD OA. This was confirmed for order memory (Ring et al., 2016).

Objectives:

This study aimed to compare systematically short-term memory across different modalities to investigate whether it is impaired in ASD similarly to long-term memory when it depends on relational binding and to test which task is most difficult. In addition, the ageing analogy was tested. It was predicted that short-term memory in ASD would be reduced compared to TD adults and that age would have a significant negative effect on TD but not ASD memory.

Methods:

Fifty-three ASD and 54 typically developing (TD) participants matched on gender, chronological age (CA; $M_{CA} = 43.19$), and intelligence quotient (IQ; $M_{FIQ} = 111$) were tested with three tasks testing verbal (sequence of letters), visuo-spatial (sequence of crosses in the cells of a grid) and multimodal short-term memory span (sequence of letters in the cells of a grid).

Results:

TD participants had a significantly longer span compared to ASD individuals in all tasks ($F = 12.24$, $p < .01$, $\eta_p^2 = .10$). The multimodal task was hardest for both groups, followed by the visuo-spatial task ($F = 47.97$, $p < .0001$, $\eta_p^2 = .31$). ASD participants made more mistakes than TD participants ($F = 6.37$, $p < .05$, $\eta_p^2 = .06$). Whereas age had a significant negative effect on TD individuals' memory ($R^2 = .13$, $F(1,52) = 8.05$, $p = .006$), short-term memory in younger and older ASD individuals did not differ significantly ($R^2 = .01$, $F(1,51) = 0.53$, $p = .47$).

Conclusions:

Similar to long-term memory, ASD individuals show difficulties in relational short-term memory that are similar across the verbal, visuo-spatial and multimodal domain. The analysis of the effect of age on short-term memory found confirmation for the ageing analogy. Age had a significant negative effect on TD but not ASD individuals' relational short-term memory. ASD might be protective against the effects of age on memory.

13 **164.013** Children and Adults with Autism Detect Rapidly Presented Temporal Information More Accurately Than Typically Developing Individuals

***J. Kopec**, A. M. Prawl, E. P. McKernan, E. A. Kaplan, E. L. Koelmel and N. Russo, Psychology, Syracuse University, Syracuse, NY*

Background: Individuals with autism spectrum disorders (ASDs) experience enhanced or more efficient visual perception abilities in spatial visual search tasks in comparison to IQ and age-matched typically developing (TD) individuals.

Objectives: The goal of this study was to extend the notion of enhanced visual search to the temporal domain and across development in individuals with autism.

Methods: We tested children (n = 21) and adults (n = 4) with autism, as well as mental-age matched TD children (n = 21) and adults (n = 4) in two rapid serial visual presentation (RSVP) tasks at six different presentation rates (13, 26, 39, 65, 91, 195 ms/item). In the Color task, participants detected a purple target letter amongst black letter distractors, while in the Category task, participants detected a black letter amongst black number distractors.

Results: Across all groups and both tasks, slower presentation rates resulted in higher accuracy. In the Color task, adults with ASD were more accurate than TD adults at shorter presentation rates, but similar at longer presentation rates. Children with ASD showed comparable performance to TD adults at shorter presentation rates and outperformed TD children across presentation rates. In the Category task, all adults were more accurate than children except at the shortest presentation rates. Children with ASD were more accurate than TD children across the majority of presentation rates, while no significant differences were found between adults with ASD and TD adults.

Conclusions: These results suggest that both children and adults with ASD experience enhanced visual processing in the temporal domain, particularly in tasks involving temporal binding of stimulus features (i.e., binding a color to a letter).

14 **164.014** Creativity Assessment in ASD: Mathematical and Non-Mathematical Thinking Processes

***O. E. Hetzroni**[1], M. Leikin[2] and H. Agada[3], (1)University of Haifa, Haifa, Israel, (2)Department of Special Education, University of Haifa, Haifa, Israel, (3)Special Education, University of Haifa, Haifa, Israel*

Background: Creativity has been identified as a creation of an object, action, or idea that is new and valuable within it's time and frame. Creativity can be evaluated using fluency, flexibility, originality, and details/expansion as performance parameters. Research investigating creativity among individuals with ASD incorporated mostly traditional creative thinking processes such as art, writing, and, music. Mathematical and science creative thinking were not evaluated among individuals with ASD.

Objectives: The goal of this study was to investigate traditional and mathematical creative thinking processes among individuals with and without ASD, and to evaluate the relations between creative thinking and cognitive processes namely verbal and spatial working memory, and inhibition.

Methods: Participants included two groups of 20 children with HFASD and with typical development (TD) ages 9-11, matched based on Raven's IQ test. Participants were asked to participate in five sets of tests: mathematical and pictorial tasks developed to evaluate creativity in multiple solutions to problems using the four parameters performance scale developed to evaluate creativity; the Stroop color-word test, the Wechsler's letter-number sequencing test, and the Corsi block task.

Results: There were no significant differences based on gender, IQ or age among all participants. There were no significant differences in inhibition and spatial working memory, but there was a significant difference in verbal memory test results between the two groups. In the mathematical creativity test, results demonstrate a significant difference in fluency and in flexibility, with the group of children with ASD presenting more solutions to the problems, with a larger variability in the solutions. However, there was no significant difference in the general level of creativity. In the pictorial problem solving test, results demonstrate a significant difference in fluency and originality, and a close to significant difference in the general level of creativity. In this test, the group of children with TD presented more solutions to the problems, with a larger variability in the solutions. There were negative correlations between the mathematical problem solving abilities and the results in the Stroop test among both groups, and positive correlations between the pictorial problem solving abilities and the Raven's IQ results. Specific results in the ASD group demonstrated negative correlations between the mathematical fluency and the originality levels and the Stroop, and between the pictorial fluency and the flexibility levels and all the math creativity results.

Conclusions: Results demonstrate that children with HFASD and children with TD did not differ in their general creativity when solving mathematical problems. Yet, children with HFASD showed more fluency and flexibility in the math task, while children with TD showed more flexibility and originality in the pictorial test. These results might indicate a tendency for higher levels of creativity in mathematical thinking in comparison with non-mathematical creativity among children with ASD. Cognitive measures were similar across both groups, except for the verbal working memory that was significantly lower than the control group. Further conclusions and comparisons will be discussed in the presentation in relation cognitive performance and specific creativity parameters among both groups.

15 **164.015** Data-Gathering Style in Autism and Its Relationship with Paranoia

K. Bennert[1]*, A. Russell*[2]*, A. Canning*[3]*, M. Brosnan*[4] *and G. Roberts*[5]*, (1)Bristol Autism Spectrum Service, Bristol, United Kingdom of Great Britain and Northern Ireland, (2)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (3)Fromeside Secure Services, Avon and Wiltshire Mental health Partnership, Bristol, United Kingdom, (4)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (5)Bristol Autism Spectrum Service, Bristol, United Kingdom*

Background: Individuals with Autism Spectrum Conditions (ASC) have been found to experience higher levels of paranoia than the general population. However, cognitive mechanisms involved in the development and maintenance of paranoia may differ from those proposed for typically developed (TD) individuals with persecutory ideation. A reasoning bias in the form of reduced data-gathering ('jumping-to-conclusions', or JTC bias) is regarded as contributory factor for paranoia in people with psychosis and non-clinical populations.

Objectives: To examine data-gathering style and its association with paranoia in individuals with ASC and TD controls. To elucidate conflicting previous research findings regarding presence /absence of a JTC bias in individuals with ASC.

Methods: Data-gathering style was investigated in 39 adults with ASC and 64 typically developed controls using two probabilistic reasoning tasks: the classic Beads Task paradigm, traditionally employed to evidence reduced data-gathering in paranoid schizophrenia, and an emotionally salient equivalent.

Results: Despite higher levels of paranoia, the ASC group requested significantly more information (>3 beads) and were significantly less likely to show a JTC bias than the TD group. Task design was not found to significantly affect performance for either group and there was no difference between groups with regard to degree of confidence at point of decision-making. Paranoia did not correlate with amount of data-gathering for either group.

Conclusions: Results suggest that data-gathering style may not be a contributory factor for paranoia in autism, consistent with the proposal of a differential cognitive structure of paranoia in individuals with ASC. Cognitive behavioural interventions for individuals with ASC and paranoia may need to be adapted to address alternative cognitive mechanisms involved in its development and maintenance.

16 **164.016** Decreased Experience-Driven Optimization of Eye-Movement Patterns in People with Autism Spectrum Conditions

M. E. Krol*, Faculty of Psychology II, SWPS University of Social Sciences and Humanities, Wroclaw, Poland*

Background:

Pellicano and Burr (2012) proposed that predictive coding theory may help to understand the mechanism behind the cognitive phenotype of autism, i.e. the diminished ability to generate and employ predictions in the processing of sensory data. In other words, people with autism may see the world without the "glasses of experience"- and in consequence may have difficulty ignoring noise inherent in sensory input and distinguishing signal from noise. This may also manifest itself in the difficulty with the generalization of experience and inflexibility of thinking. Predictive coding account of autism also explains enhanced sensory discrimination abilities (a consequence of very realistic sensory experience), local information bias at the expense of global information or diminished susceptibility to perceptual illusions, which are caused by strong top-down expectations distorting the perception of certain images.

Objectives:

We wanted to investigate the ability of participants with ASC (autism spectrum conditions) to use top-down expectations to optimize their eye-movement patterns. In a previous study with typically developing participants, we showed "economies of experience" in eye-movement patterns, i.e. optimization of eye-movement patterns aimed at more efficient and less costly visual processing. We showed that eye-movement dispersion, velocity, and the number of fixations decreased with each stimulus presentation. This suggests that eye-movement patterns can evolve to facilitate the optimal processing of a given stimulus via experience-driven perceptual learning. The aim of this study was to test whether this experience-driven optimization would be present to a similar extent in participants with ASC.

Methods:

21 participants with ASC diagnoses confirmed by ADOS, and 23 age-, IQ- and gender-matched typically developing (TD) participants took part in the study. Participants' eye movements were recorded using a remote eye-tracking device SMI RED250Mobile, with a sampling rate of 250 Hz. Participants looked at Mooney-type, degraded stimuli that were difficult to recognize without prior experience, but easily recognizable after exposure to their undegraded versions, in a design similar to a Loth, Gómez and Happé (2010) study. Participants first saw the degraded version of the stimulus, which was used to record the eye-movements without prior experience of the stimulus. Next, participants saw the original, disambiguated photograph, immediately followed by the degraded version again. These presentations were used to disambiguate the degraded stimulus and enable perceptual learning, to make sure that the participants would be able to link the degraded and undegraded stimuli. Finally, after a delay, participants saw the degraded version again, interspersed with other stimuli, which was used as a measure of perception with prior experience and the outcome of perceptual learning.

Results:

We compared the first presentation (pre-experience) and the last presentation (post-experience). We performed a mixed-model analysis, controlling for intelligence, age and ASC diagnosis, of several eye-tracking measures. We found that participants with autism used their experience to optimize their eye-movement patterns to a smaller degree compared to TD participants.

Conclusions:

This study provides evidence in support of the predictive coding account of autism and identifies atypical perceptual learning in people with ASC, who may underuse top-down expectations to optimize eye-movement patterns.

17 **164.017** Developing and Piloting a New Parent-Report Measure of Executive Function for Use with Children with ASD

*L. Ledger-Hardy[1], **W. Mandy**[2], D. H. Skuse[3] and P. Burgess[4], (1)University College London, London, United Kingdom, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland, (3)Behavioural and Brain Sciences Unit, Population Policy and Practice Programme, UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom, (4)UCL, London, United Kingdom*

Background:

Although executive function difficulties are well documented amongst individuals with autism spectrum disorder (ASD), there is no consensus on how best to assess these in clinical practice and research. Studies using performance-based measures (i.e., cognitive tests) often demonstrate relatively modest effect sizes and inconsistencies between studies are apparent. These findings lack ecological validity, as they do not reflect the fact that severe difficulties with planning and organisation are commonplace in the day-to-day lives of children with ASD. A widely used parent-report questionnaire measure, the Behaviour Rating Inventory of Executive Function (BRIEF), was designed to have greater ecological validity than traditional performance-based measures. A review of the literature reveals that the average score on the BRIEF for children with ASD is close to the maximum score on the BRIEF, indicating the presence of a ceiling effect.

Objectives:

The aim of this study was to develop and pilot a new parent-report measure of executive function, specifically for use with children with ASD. This measure was intended to have good ecological validity and be sensitive to variability across the full range of day-to-day executive function difficulties experienced by children with ASD.

Methods:

This research was completed in two parts. Study 1 focused on the development of the measure and Study 2 focused on its initial validation. In Study 1, parents and professionals underwent in-depth interviews about the nature of executive function difficulties in children with ASD. These interviews were analysed using qualitative methods and this directly informed the development of the new measure, thereby maximising its ecological validity. The measure was then piloted online with parents of children with ASD (N = 44) and parents of TD children (N = 55), enabling preliminary examination of its psychometric properties.

Results:

A thematic analysis of the nature of executive function difficulties in children with ASD revealed widespread executive function difficulties across multiple domains. The new measure was named the A-POD (Autism Planning and Organisation Difficulties) and initially contained 48 items. Piloting of the A-POD online revealed a large difference between the ASD and TD groups (*r* = .79), indicating that children with ASD were reported to have substantially greater levels of executive dysfunction. The A-POD demonstrated good test-retest reliability (r=.82) and internal consistency (α=.98). The items with the weakest reliability were removed and the final version of the A-POD contained 38 items. Preliminary positive evidence of its criterion and construct validity was found.

Conclusions:

Day-to-day executive function difficulties are substantial and widespread amongst children with ASD. The A-POD is a promising measure of these difficulties, demonstrating encouraging psychometric properties. Both parent-report and performance-based methods of assessment should be used to gain a comprehensive picture of a child's executive function ability.

18 **164.018** Differences in Attentional Disengagement in Preschoolers at Risk for ASD and with FXS

***C. A. Wall**[1], Q. Wang[2], B. Tonnsen[3], K. E. Caravella[4] and J. E. Roberts[5], (1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Psychological Sciences, Purdue University, West Lafayette, IN, (4)University of South Carolina, Columbia, SC, (5)Psychology, University of South Carolina, Columbia, SC*

Background:

Early visual attention is critical to shaping learning opportunities. Although attentional problems are not core features of neurodevelopmental disorders such as fragile X syndrome (FXS) and autism spectrum disorder (ASD), much work has highlighted atypical attention patterns in young children in these populations (Tonnsen, Grefer, Hatton, & Roberts, 2014). Many studies utilize eye-tracking to measure low-level differences in attention at young ages in children with ASD and FXS. One example is attentional disengagement, indexed by the gap-overlap paradigm. Longer latencies to attentional disengagement may suggest attention difficulties, and increased latency of disengagement has been shown to discriminate infant siblings who go on to develop ASD from those who do not (Elsabbagh et al., 2013). Little work has examined performance on the gap-overlap task in very young children with FXS although some studies suggest attentional disengagement is impaired in older individuals (Shelton et al., 2014). Given the high rate of comorbidity of ASD with FXS and the mounting interest in neurodevelopmental pathways to common and divergent phenotypes in childhood disorders, the examination of early visual attention in these populations offers an important avenue for current research.

Objectives:

To evaluate differences in attentional disengagement between typically developing (TD) preschoolers and those at risk for developing ASD due to 1) FXS or 2) heritable factors due to an older sibling with ASD.

Methods:

Data were taken from a longitudinal study of neurodevelopment in children with disabilities. Assignment to risk groups was made at recruitment. The sample included 21 ASIB preschoolers (n_{males}=15; M_{age}=5.09 years), 19 with FXS (n_{males}=14; M_{age}=5.11 years), and 21 TD (n_{males}=15; M_{age}=4.46 years).

Groups did not differ by age (*p*=.274). Participants viewed the gap-overlap eye-tracking task using the SR Eyelink system, and saccadic reaction times (RT) for gap, overlap, and baseline conditions were recorded. Disengagement was calculated as the difference in RT between the overlap and baseline conditions. Given the small within-group sample and heterogeneity characteristic of at-risk populations, nonparametric methods were utilized to test differences in median disengagement time.

Results:

Median disengagement times for each group were: q_{ASIB}=88.8 ms, q_{FXS}= 119.5 ms, and q_{TD}=74.3 ms. Results of the Independent-Samples Kruskal-Wallis test suggest that the groups differ (H(2) = 6.0, *p*=.050) with pairwise comparisons showing a difference between TD-ASIB (*p*=.049) and TD-FXS (*p*=.025), but not for ASIB-FXS (*p*=.748).

Conclusions:

Consistent with previous findings, the present study found longer disengagement latencies in the ASIB and FXS groups relative to TD but no differences between ASIB and FXS preschoolers. Results suggest that atypical visual attention patterns observed in both of these risk groups are similar and present in early childhood. These findings provide important information regarding ASD risk and the convergent developmental pathways that lead to an ASD diagnosis. Impaired attentional control could be related to ASD features in both groups, particularly as it relates to executive functioning deficits, anxiety, or atypical social learning. Continuing longitudinal research will examine earlier attentional vulnerabilities among these etiological risk groups earlier in life and their relation to ASD diagnostic outcomes as those data become available.

19 **164.019** Diminished Spontaneous Social Orienting in School-Age Children with ASD: ABC-CT Feasibility Study

***K. Chawarska**[1], A. Naples[1], J. McPartland[1], S. J. Webb[2], M. Murias[3], C. Sugar[4], R. Bernier[2], G. Dawson[5], S. Jeste[4], C. A. Nelson[6] and F. Shic[7], (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (4)University of California, Los Angeles, Los Angeles, CA, (5)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (6)Boston Children's Hospital, Boston, MA, (7)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Deficits in spontaneous orienting to social (SSO) stimuli have been reported as early as at 6 months in infants who are later diagnosed with ASD (Chawarska et al., 2013; Shic et al., 2014) as well as in toddlers newly diagnosed with ASD (Chawarska et al., 2012; 2016). Young children with ASD have the greatest orienting difficulties in the presence of ostensive cues for engagement such as eye contact and speech (Chawarska et al., 2012; Shic et al, 2014) expressed in lower level of attention to the social scene and to the face of an interactive partner. Early individual differences in SSO have been linked with social and language outcomes 2-3 years later (Campbell et al., 2014). It is not clear however, if SSO deficits are also present later in development and if they follow the same pattern as those observed in the early stages of autism.

Objectives: To evaluate if school-age children with ASD display impairments in SSO. We hypothesized that school-age children with ASD will show diminished attention to faces (%Face) in conditions involving ostensive cues for engagement and lower attention to social scenes (%Scene) in general.

Methods: Children with ASD (n=23) and typically developing (TD) controls (n=25) age 4 to 11 years completed the free-viewing SSO eye-tracking task validated previously in infant and toddler studies (Chawarska et al., 2012; 2013) as part of their participation in the Autism Biomarker Consortium for Clinical Trials (ABC-CT) study. Four conditions were presented in which actress: spoke directly to the camera (Speech), initiated Joint Attention (JA), made sandwich (Sandwich), and looked at moving toys (Toys). Group differences were analyzed using linear mixed models (LMM) with diagnosis and condition as factors and IQ as a covariate.

Results: A LMM analysis of %Face indicated effects of diagnosis (p=.009), condition (p<.001) and their interaction (p<.003) as well as IQ (p<.001). Compared to TD controls, children with ASD had lower %Face in the Speech and JA conditions (p<.001, p=.018), but not in the Toys and Sandwich conditions (p=.099, p=.860). LMM analysis on %Scene indicated no effect of diagnosis (p=.25), but significant condition (p<.001) and diagnosis x condition interactions (p<.001). Within subject comparisons indicated that, in the TD group, attention to the scene in the Speech condition was either *comparable* (JA and Toys) or *higher* (Sandwich) than in other conditions. In the ASD group, attention to the scene during the Speech condition was *comparable* to JA condition, but *lower* than in Toys and Sandwich conditions. Lower %Scene and %Face during the SSO task was associated with higher total SRS scores in the ASD group (Pearson r(22)=-.5 and r(22)=-.45, ps < .05).

Conclusions: Increasing attentional capacity in school-age children resulted in less pronounced differences in the overall attention to the scene. However, this increased capacity did not eliminate ASD-specific impairment in attention to faces of interactive partners. The study replicates and extends earlier findings and suggests that the SSO task represents a promising biomarker for ASD from prodromal stages of the disorder to early school age.

20 **164.020** Examining Distraction and Avoidance Information Processing Mechanisms Among Children with Autism Spectrum Disorder

***A. J. Harrison**[1] and M. M. Slane[2], (1)Educational Psychology, University of Georgia, Athens, GA, (2)University of Georgia., Athens, GA*

Background:

Research ubiquitously supports that children with ASD demonstrate impairments in social attention such as a reduction of attention to social stimuli in the majority of contexts (Guillon, Hadjikhani, Baduel, & Rogé, 2014). Less is known about the mechanisms that contribute to diminished social attention in ASD. The social motivation theory posits that individuals with ASD simply find social stimuli less rewarding and do not show the same preference for social stimuli that typically developing children do (Chevallier, Kohls, Troiani, Brodkin, & Schultz, 2012). Other research suggests that competition from circumscribed interests (Cis) may better explain the emergence of the social attention deficit in ASD (Sasson, Turner-Brown, Holtzclaw, Lam, & Bodfish, 2008).

Objectives:

Use an information-processing paradigm (commonly used to examine attention biases in individuals with internalizing disorders) to examine profiles of attention in children with ASD. Evaluate whether children with ASD demonstrate a causal mechanism accounting for diminished social attention more in line with avoidance of social stimuli as compared to distraction by circumscribed objects.

Methods:

The current study compared attentional allocation patterns in children ages 6 to 17 years diagnosed with ASD (n = 16) to a typically developing (TD) control group (n = 19). The study utilized an ASD-specific passive viewing task to examine information processing styles (Harrison & Gibb, 2014). The task was designed so that each quadrant or area of interest (AOI) depicted two social images, a familiar face (FS) and a control face (NFS), and two objects, a parent identified CI (FCI) and an unfamiliar control object (UFO). This presentation allows for the examination of the proportion of attentional allocation across stimulus type.

Results:

Initial analyses using a 2 (diagnostic group: ASD, TD) x 4 (AOI: FS, NFS, FCI, UFO) repeated measures ANOVA to examine differences in mean dwell time for each of the four stimulus types. Results from this study did not reveal a diagnostic group by stimulus type interaction. However, children with ASD and TD children demonstrated systematic differences in attentional allocation. More specifically, children with ASD demonstrated less attention than TD children to all stimulus types: CI objects, $F(1, 33) = 5.21$, $p = .03$, control objects, $F(1, 33) = 10.77$, $p = .002$, familiar faces, $F(1, 33) = 4.52$, $p = .04$ and unfamiliar faces, $F(1, 33) = 12.24$, $p = .001$.

Conclusions:

These initial results demonstrate that children with ASD are attending to all stimuli less than TD children; however, information regarding which mechanism is contributing to diminished attention was not revealed from these analyses. Follow-up analyses will examine group by stimulus type interactions using several other dependent eye tracking variables. More specifically, rather than examining overall total dwell time, an adjusted estimate of attentional allocation will be calculated for each participant to take into account individual variation in total attention. The proportion of time spent looking at each quadrant or AOI as compared to total attention across each trial will allow for an examination of individualized patterns of attentional allocation.

21 **164.021** Executive Function in More-Able Kindergartners with ASD Predicts Concurrent Academic, Social, and Behavioral Outcomes

Y. B. Choi[1], *N. Benrey*[2], *E. S. Sheridan*[1], *C. Lord*[3] *and S. H. Kim*[4], *(1)Psychiatry, Weill Cornell Medical College, White Plains, NY, (2)Weill Cornell Med School, New york, NY, (3)University of California Los Angeles, Los Angeles, CA, (4)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

Background: Impairments in executive function (EF) in ASD may emerge as early as preschool years, but studies examining EF skills in young children with ASD are limited. More in-depth examinations of EF skills as predictors of academic and social outcomes in young children with ASD will help us examine when and how impairments in school readiness skills emerge prior to school entry and build treatment programs targeting these skills beginning as early as the preschool years.

Objectives: We used innovative, recently-validated EF tasks in order to examine the association between EF skills and concurrent academic achievement, peer connections, and externalizing/internalizing problem behaviors in more-able kindergarteners with ASD.

Methods: Participants included 42 more-able children with ASD (no cognitive and structural language delays; *mean age* =63.7 months; SD=6.0). Working memory (Pick the Picture [PTP]), inhibitory control (Arrows [ARR]), and attention shifting (Something's the Same [STS]) were assessed based on child-friendly, tablet-based EF tasks, EF Touch (Willoughby et al., 2010) and behavioral regulation was assessed based on a well-established, highly engaging, Head Toes Knees Shoulders (HTKS) task (Ponitz et al., 2008; *n*=28). Academic achievement was measured based on the Woodcock Johnson achievement test (WJ), internalizing/externalizing behaviors based on the Child Behavior Checklist (CBCL), and peer connections based on the Penn Interactive Peer Play Scale (PIPPS). Regression analyses were conducted to examine whether EF skills significantly predicted subsections of WJ–letter word identification (LW), passage comprehension (PC) and applied problem (AP), CBCL internalizing, and externalizing behaviors and PIPPS interaction and disconnection during peer play, while controlling for age, gender, race and maternal education. For a subset of children (*n*=27, *mean age* = 60.6 months; *SD*=3.8); analyses were repeated while controlling for FSIQ as an additional covariate.

Results: Regression analyses indicated significant effects for following variables ($p<0.05$). Accuracy for attention shifting (STS) from EF Touch significantly predicted performance on the WJ math achievement (AP) the PIPPS interaction and CBCL internalizing problem sub-scores. Accuracy for working memory (PTP) was significantly associated with performance on all three sections from WJ as well as interaction and disconnection sub-scores from the PIPPS. Accuracy for inhibitory control (ARR) from EF Touch significantly predicted WJ reading achievement (PC) and CBCL internalizing problems. Response time for the EF ARR task was also a significant predictor of WJ AP and the PIPPS play interaction. Last, behavioral regulation (HTKS) was significantly predictive of scores for reading (WJ-LW). When IQ was controlled, the effects of attention shifting (STS) on WJ-AP and inhibitory control (ARR) on CBCL internalizing behaviors remained significant.

Conclusions: Our results demonstrate the potential link between impairments in EF skills and academic and social success as well as other clinical features in more-able kindergarteners with ASD. The most robust effects were found for one's ability to shift attention and inhibit responses on math achievement and internalizing problems respectively. These findings provide preliminary evidence of EF deficits in children with ASD and implications for incorporating EF training into intervention prior to school entry.

22 **164.022** Exploring the Conditions of Typical and Atypical Social Attention in Autism: A Gaze Contingent Eye Tracking Study

J. S. Black[1] *and M. Bindemann*[2], *(1)School of Psychology, University of Kent, Canterbury, United Kingdom of Great Britain and Northern Ireland, (2)School of Psychology, University of Kent, Canterbury, United Kingdom*

Background:

Attending to faces is extremely important for understanding social cues and it is thought that atypical social attention may contribute to social difficulties in Autism Spectrum Disorder (ASD). However, research findings are mixed as to whether faces have the same special status in attention for people with ASD as in typical development. Methodological differences across studies make it hard to reach a consensus about social attention in ASD and why it may appear typical or atypical in experimental studies. Additionally, the Social Motivation Theory of autism predicts that individuals with ASD will attend to non-social objects of particular interest to them, rather than faces, and previous research has found that objects of Circumscribed Interest (CI) may disrupt social attention when co-occurring with people in a scene.

Objectives:

The present study employed visual scenes containing people and objects of CI to which adults with ASD have previously been found to attend atypically. A novel gaze contingent window technique explored the allocation of attention across these scenes among adults with and without ASD. This technique provides a measure of top down allocation of attention by removing opportunities for automatic attentional capture in peripheral vision.

Methods:

In Experiment 1, a gaze contingent window in a black screen revealed 4° visual angle around the point of fixation of a scene containing people and CI objects. Regions of interest (ROIs) corresponding to faces, bodies, CI objects, and background were defined. In Experiment 2, participants saw an array of gift boxes, which, upon fixation, revealed a different image of either a face, an object of CI, or a neutral object. Measures of fixation duration and number of fixations within each area were recorded. Participants also later rated how much they liked each image and how interesting they found it to explore explicit interest in the stimuli.

Results:

Experiment 1 found that all participants had longer fixations to face regions of scenes than any other region, with no group differences in the percentage of fixations in each ROI. However, in Experiment 2, whilst there were no group differences in mean fixation duration to each object category, participants in the TD group made a higher proportion of fixations to faces than the ASD group.

Conclusions:

Experiment 1 showed that when background information is removed from a scene, social attention appears typical in adults with ASD, with faces holding attention longer than other objects once fixated. However, Experiment 2 found suggested reduced social attention in participants with ASD. This could be because social cues are more important to establish context within natural scenes as in Experiment 1, than in Experiment 2 where images were displayed in isolation without context. Therefore, adults with ASD may be able to preferentially allocate information to social information when it may be informative, but lack the motivation to do so when it is not. Further time course analyses will help to elucidate these results.

23 **164.023** Face Recognition and Processing in Children with Autism

***C. Wang**, Nankai University, Tianjin, China*

Background: It was reported that typically developing (TD) children are able to recognize the familiar faces and voices when they are four years old and they also prefer to focus on the more socially revealing features of face, such as eyes rather than mouth; in contrast, individuals with ASD seem to lack these early social predispositions, and have problems to recognize the familiar faces (Boucher, et al, 1998) and unfamiliar faces (Wilson, et al, 2007).

Objectives: This study aims to explore the influence of familiarities on the background and faces during face recognition and processing in children with autism.

Methods: Nineteen children with ASD ages from three to seven (M=5.34, SD=1.10, M:F=16:3) and nineteen age-matched TD (M=5.04, SD=0.36, M:F=10:9) were recruited and required to watch a set of pictures. Their gaze behaviours were measured via an integrated Tobii TX300. These pictures contained faces with three different familiarity degrees (familiar, repeatedly unfamiliar, unfamiliar) and backgrounds (familiar and unfamiliar). A multi-factor, repeated measurement ANOVA with factors areas of interest (AOI: whole face, eyes, mouth and background), faces, backgrounds and groups (ASD, TD) was applied to gaze fixation durations.

Results: The results showed that TD children spent longer viewing familiar faces than unfamiliar faces (F(2,36)=16.449, p=0.000). Both TD and ASD children spent longer time viewing familiar background than unfamiliar background (TD: F(1,18)=24.915, p=0.000; ASD: F(1,18)=21.989,p=0.000). Compared to familiar faces, both ASD and TD children had increased fixation duration on backgrounds when viewing unfamiliar faces (ASD: F(1,18)=24.883, p=0.000; TD: F(1,18)=5.411, p=0.032). While watching familiar faces, ASD children spent longer time viewing eyes and mouth (Mouth: F(2,36)=6.800, p=0.003; Left eye: F(2,36)=8.169, p=0.001; Right eye: F(2,36)=11.144, p=0.000).

Conclusions: In summary, ASD showed impairments on face cognition and processing. Both ASD and TD showed preference to familiar faces and backgrounds.

24 **164.024** Global Motion Perception in ASD: A Meta-Analysis

***R. Van der Hallen**[1,2,3], C. Manning[4], K. Evers[2,3,5] and J. Wagemans[3,6], (1)Department of Psychology, Education and Child Studies, Erasmus University of Rotterdam, Rotterdam, Netherlands, (2)Laboratory of Experimental Psychology, Department of Brain and Cognition, KU Leuven, Leuven, Belgium, (3)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium, (4)Department of Experimental Psychology, University of Oxford, Oxford, United Kingdom, (5)Parenting and Special Education Research Unit, KU Leuven, Leuven, Belgium, (6)Laboratory of Experimental Psychology, Brain & Cognition, KU Leuven, Leuven, Belgium*

Background: Visual perception in individuals with autism spectrum disorder (ASD) is often characterized by enhanced perception of local elements and impaired perception of global patterns. Deficits in global motion perception, mostly coherent motion and biological motion, seem to support this characterization, although the evidence is inconsistent. A proper quantitative review of the available data, in which the overall effect size of each study is assessed and the influence of potential moderators is investigated, is lacking. Yet, it is of critical importance to understand performance of global motion in order to evaluate theories of perception in ASD.

Objectives: To evaluate all experimental data on global motion perception, and (a) assess whether the available data are in favor of the hypothesis of enhanced perception of local elements or the hypothesis of impaired global perception in individuals with ASD compared to typically developing controls, and (b) evaluate which moderator variables rule the diversity within the literature.

Methods: A large meta-analysis was conducted, combining 48 articles on biological motion and coherent motion, including approximately 1,000 individuals with ASD and controls. All data were coded and transformed to the standardized mean difference metric d and used in a linear three-level random effects model, accounting for random sampling fluctuation, between-outcome variance and between-study variance. Differences in paradigm, task, stimulus and participant characteristics were taken into account and evaluated as potential moderators.

Results: The results revealed a small mean effect of -0.30, with 95% confidence limits from -0.17 to -0.44, indicative of global motion processing difficulties in ASD. This mean negative effect was apparent for both biological motion as well as coherent motion paradigms, and appeared to be independent of the paradigm, task, dependent variable, age or IQ of the groups.

Conclusions: The results of our meta-analysis indicate that individuals with ASD are less sensitive to global motion perception, as present in both coherent motion and biological motion paradigms. However, the differences in neural mechanisms that might underlie this behavioral difference remain unclear. Recommendations for future motion research are made in the hope of refining current theories on vision in ASD and atypical development in general.

25 **164.025** Habituation in Children with Traits Related to Autism Spectrum Disorder (ASD)

I. Arora[1], *A. Bellato*[2], *D. Ropar*[3], *T. Gliga*[4], *C. Hollis*[5] *and M. Groom*[6], *(1)University of Nottingham, Nottingham, United Kingdom, (2)The University of Nottingham, Nottingham, United Kingdom of Great Britain and Northern Ireland, (3)University of Nottingham, Nottingham, United Kingdom of Great Britain and Northern Ireland, (4)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (5)School of Medicine, University of Nottingham, Nottingham, United Kingdom, (6)Faculty of Medicine and Health Sciences, University of Nottingham, Nottingham, United Kingdom*

Background: Abnormalities in habituation have been documented in ASD (McDiarmid, Bernardos and Rankin, 2017). These atypicalities have been attributed to sensory hyperresponsivity and hyperarousal in the literature. However, behavioural studies in the literature are inconsistent, possibly due to the diversity in stimuli used, alongside heterogeneity in the population being tested. Further, evidence suggests that there might be atypical salience of social information in individuals with ASD-related traits.

Objectives: This study investigated whether children with lower social skills show reduced habituation as compared to children with higher social skills. Further, we measured habituation to different types of stimuli to assess the stimulus-dependence of these effects.

Methods: 64 children between the ages of 4 to 12 years (mean age= 108.32 months, SD=21.696, 33 males and 31 females) took part in the study. The children were recruited as part of a local science event at the University Of Nottingham, U.K. and had no known diagnosis. We used an eye-tracking paradigm that measured participants' attention to a repeating stimulus and a novel stimulus, presented alongside each other across multiple trials (adapted from Vivanti et al., 2016). Building on their paradigm, which used simple dynamic shapes (*baseline condition*), we added a *social condition* (with faces breaking into smiles) and a *non-social condition* (clocks with moving arms) to match the social condition in complexity and localized movement. We measured participants' verbal ability using the British Picture Vocabulary Scale (BPVS). Social skills were measured using the Social Aptitude Scale, a parent-report measure sensitive to risk of ASD (Liddle, Batty and Goodman, 2009). The median SAS score in the sample was used to divide the sample into groups of higher and lower social ability.

Results:

Preliminary analyses have been conducted on this data. First, a repeated-measures mixed-design ANOVA was conducted to investigate individual differences in information sampling as measured by number of fixations to the screen. Results revealed a significant interaction: Gender x Condition (F(2, 45)= 3.766, p= 0.031). Follow-up analyses revealed that females demonstrated significantly more looking than males in the social condition only (t (62)= -2.047, p= .045). There was also a significant Gender x SAS group effect (F(1, 46)= 4.462, p= 0.040). Follow-up analyses revealed that only in females, lower social ability was associated with significantly lower number of fixations to the screen across conditions (t (25)= -2.601, p= .015). Given these differences in fixations, only proportion scores (ratio of looking towards the new versus repeating stimulus) were used to analyse habituation. Preliminary analyses did not reveal any differences in habituation based on stimulus type, gender, verbal or social ability.

Conclusions: Results indicate differences in information sampling based on gender, wherein social stimuli appear to be more salient for females than males. Further, social ability impacts information sampling differently in females than in males. While preliminary analyses indicate no differences in habituation based on social ability for different types of stimuli. In the poster, I will present a more fine-grained analysis of the habituation parameters. Further, data from clinical samples will also be presented.

26 **164.026** Higher Autism Traits in the General Population Are Related to Reduced Intuition and Reduced Reasoning Bias.

M. Lewton[1], *C. Ashwin*[2] *and* ***M. Brosnan***[3], *(1)University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background:

A defining feature of being human is the ability to think rationally, however, typically humans have a propensity to base judgements on prior beliefs and experiences, rather than on a more logical and complete reasoning process. Dual Process Theory proposes both intuitive 'Type 1' and deliberative 'Type 2' processing. Type 1 (intuitive) processing is autonomous and typically involves rapid, effortless, parallel, non-conscious processing that is independent of working memory and cognitive ability. Type 2 (deliberative) processing, on the other hand, involves slower, effortful, sequential, conscious processing and is heavily dependent on working memory and related to individual differences in general cognitive ability. Within Dual Process Theory, Type 1 processing is assumed to yield default responses unless intervened upon by Type 2 reasoning processes. However, The Dual Process Theory of Autism proposes that both those with autism and those with higher autistic-like traits from the general population have a relative predisposition towards Type 2 processing.

Objectives:

To identify the relationship between autistic-like traits and two assessments of judgements based on intuition and prior beliefs and experiences.

Methods:

206 British adult participants aged between 18 and 62 years (M = 27.25, SD = 8.89) took part in the study, comprising 105 males and 99 females. Autistic-like traits were assessed using the original 50-item version of the Autism Spectrum Quotient (AQ). The Cognitive Reflection Task (CRT) has 3-items each of which has a potentially intuitive and deliberative answer. Eight syllogistic reasoning problems were presented, four of the problems had correct answers consistent with real world validity – congruent, and four problems had answers inconsistent with reality - incongruent. A 'Belief Bias' was calculated by subtracting the incongruent total from the congruent total. General non-verbal cognitive ability was assessed through Raven's matrices.

Results:

A linear multiple regression was run under 2 models with AQ as the dependent variable: 1) with the demographic variables of sex, age and general non-verbal cognitive ability as the predictors; and 2) adding intuition (CRT) and Belief Bias as predictors. Both models were significant (F=8.22, p<.001; F=12.42, p<.001; respectively). Age was a significant variable in both models, older people having higher AQ scores (t=4.89, p<.001; t=3.83, p<.001; respectively). In addition in Model 2, both Belief Bias (t=-3.74, P<.001) and Intuition (CRT: t= -2.44, p<.05) were significant, higher AQ scores being predicted by lower intuition and lower belief bias. General non-verbal cognitive ability was not a significant predictor (t=1.13, ns).

Conclusions:

This is the first study to show that higher autistic-like traits in the general population relate to a reduced propensity to base judgements on intuitive prior beliefs and experiences. This is consistent with the Dual Process Theory of Autism, which proposes that higher autistic traits (and autism) are related to a reduced default to Type 1 processing and greater predisposition to Type 2 (deliberative) processing. AQ was not significantly predicted by general non-verbal cognitive ability, highlighting that higher autistic-like traits may relate to a predisposition to engage in deliberative reasoning, but not to reasoning ability per se.

27 **164.027** How Young Adults with Autism Spectrum Disorder (ASD) Spontaneously Attend to Real-World Scenes: Use of a Change Blindness Paradigm and Eye-Tracking

M. Hochhauser[1] *and O. Grynszpan*[2]*, (1)Ariel University, Ariel, Israel, (2)LIMSI CNRS UPR3251, Université Paris-Sud, Orsay, France*

Background: Change blindness paradigms involve tasks that hinder automatic visual detection of change. The detection of changes in the environment is typically dependent on attentional processes. Studies in autism spectrum disorder (ASD) have demonstrated mixed evidence of strengths in change detection tasks. To our knowledge, eye-tracking has never been used before to investigate this issue.

Objectives: a) Compare performances of TD and ASD young adults when detecting marginal versus central change; b) Use eye-tracking to compare first fixations and total fixation time on change between the groups.

Methods: Twenty ASD and 20 matched TD young adults aged 19- 25 years viewed 36 pairs of digitized real-world images. The images in a pair differed by only one item and were displayed in a 'flicker paradigm' whereby this item alternately appeared and disappeared. This item was either a central or a marginal detail of the scene. Upon change detection, response times were collected and visual fixation on the changing item were recorded by an eye-tracker.

Results: ASD young adults were significantly slower in response time and time to first fixation than TD young adults but did not have significantly longer fixation duration.

Conclusions: ASD young adults showed reduced processing speed and did not outperform TD young adults in attention to marginal details in real-world scenes nor demonstrate different gaze behavior, challenging current theories on higher abilities of ASD individuals to process local details.

28 **164.028** Illusion Strength and Associated Eye Movements in Children with Autism Spectrum Disorder While Viewing Shepard and Ebbinghaus Illusion Displays

O. Landry[1]*, K. Royals*[1]*, I. Sperandio*[2]*, S. Crewther*[3] *and P. Chouinard*[1]*, (1)La Trobe University, Bendigo, Australia, (2)University of East Anglia, Norwich, United Kingdom, (3)La Trobe University, Bundoora, Australia*

Background: Previous research examining visual illusion susceptibility in ASD has found inconsistent results. Chouinard et al (JADD, 2016) demonstrated that illusions with strong within-object relational properties (e.g. the Shepard's tabletops) were associated with reduced susceptibility as a function of AQ, whilst illusions with strong between-object relational properties (e.g. Ebbinghaus) were not. Chouinard et al. (Front Hum Neuro, 2017) also demonstrated that eye-movements moderate illusion strength. From these results, the authors speculated that individuals with ASD may exhibit reduced susceptibility to specific types of illusions, and that differential scan patterns may underlie these differences.

Objectives: To investigate whether participants with ASD show reduced susceptibility to the Shepard illusion, while simultaneously showing typical levels of susceptibility on the Ebbinghaus illusion, and whether individual differences in scan patterns relate to illusion strength.

Methods: The participants included 18 individuals with ASD (12 males, mean age = 11.4 yrs, age range = 6.5 to 15.5 yrs) and 18 typically developing participants (12 males, mean age = 11.4 yrs, age range = 6.0 to 14.7 yrs), matched on age and Raven's Progressive Matrices raw scores. The participants completed four trials of each illusion, in pseudorandom order (Shepard's tabletops and Ebbinghaus illusions). Presentation was computerized, with participants adjusting one stimulus to match another. Eye-tracking was used to measure scan patterns while participants completed the task. To allow meaningful comparisons between illusions, we computed normalised indices of susceptibility for each illusion as: ((Perceived Size of Stimulus B - Perceived Size of Stimulus A) / (Perceived Size in Stimulus A + Perceived Size of Stimulus B)); B denoting the stimulus one would expect participants to make larger judgements in perceived size. Participants also completed control tasks to measure basic abilities in visual acuity and discrimination.

Results: The children with ASD (M = .14, SD = .10) were less susceptible to the Shepard's tabletops illusion than the typically developing children (M = .20, SD = .05), t (28) = 2.41, p = .043. There were no differences between groups on the Ebbinghaus. There were no differences between groups on any eye-tracking measures (saccade time, saccade distance, average saccade velocity, average saccade count, average pupil size, average block duration, time spent fixating). A medium strength correlation (r = .62, p = .024) was found between time spent fixating on the standard and illusory susceptibility to the Shepard, but only among participants with ASD.

Conclusions: We conclude that reduced illusory susceptibility in ASD is confined to certain types of illusions, particularly those with strong within-object relational properties. We suggest, based on the absence of evidence for differences in eye-tracking measures, that differences in illusion strength in ASD depend on perceptual mechanisms required to experience visual illusions.

29 **164.029** Imitation of Atypical Biological Kinematics in Autistic Adults Is Associated with Sensorimotor Integration

M. Andrew*, S. J. Bennett, D. P. Clowes and S. J. Hayes, Research Institute Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, United Kingdom*

Background: Novel sensorimotor actions are learned during voluntary imitation. Over repeated imitation attempts, a sensorimotor action model is configured by processes that represent the executed observed biological kinematics. Although voluntary imitation is functional from early development, autistic individuals generally show low-fidelity imitation of novel actions (DeMyer et al., 1972; Hayes et al., 2016). Notably, in these studies the imitation stimuli (e.g. typical and atypical kinematics) were presented in a random trial order. This non-predictable trial order was suggested to underpin low-fidelity imitation by attenuating the integration of sensorimotor information between trial *n*, and trial *n+1*. To this end, we attempted to influence imitation of biological kinematics in *Experiment 1* by presenting stimuli in a constant trial order that is known to facilitate sensorimotor integration between trials. To further examine sensorimotor integration in *Experiment 2*, a visuomotor-interference task was introduced between trial *n*, and trial *n+1,* to interfere with inter-trial sensorimotor processing.
Objectives: Examine the contribution of sensorimotor integration processing during voluntary imitation in autism.

Methods: Autistic, and control, adults observed single point-light models moving horizontally on a monitor and imitated using a stylus on a digital graphics tablet. A control model contained typical biological kinematics and displayed a bell-shaped (peak velocity occurs at 44% of the movement trajectory) velocity profile. An experimental model contained atypical biological kinematics and displayed peak velocity that occurred earlier (18%) in the movement trajectory. In *Experiment 1* (autistic, n = 15; control, n = 15) and *2* (autistic, n = 15; control, n = 15), the typical (30 trials) and atypical (30 trials) models were presented in a constant trial order, counterbalanced across participants. In *Experiment 2*, participants performed an additional incongruent (continuous circle drawing) visuomotor task in the inter-trial period.

Results: The discrete (time to peak velocity) and continuous (root mean square error) kinematic data in *Experiment 1* indicated autistic adults significantly (*ps* < 0.05) adapted imitation by reducing error across the imitation trials. We showed no adaptation effect in *Experiment 2* when autistic participants performed a secondary visuomotor interference task in the inter-trial period.

Conclusions: These data indicate functional voluntary imitation in autistic adults, and importantly that the reported deficits (DeMyer et al., 1972; Hayes et al., 2016) in voluntary imitation in autism may have been associated with an imitation context that prevented sensorimotor integration and adaptation across trials. The finding from the secondary task supports the suggestion that atypical imitation and motor learning in autism (Haswell et al., 2009) is associated with atypical sensorimotor integration.

30 **164.030** Intact Orientation Perception Bias in Autism Speaks Against the Decreased Divisive Normalization Model

S. Van de Cruys[1]*, S. Vanmarcke*[1]*, J. Steyaert*[2] *and J. Wagemans*[3]*, (1)Laboratory of Experimental Psychology, Brain & Cognition, KU Leuven, Leuven, Belgium, (2)Katholieke Universiteit Leuven, Leuven, Belgium, (3)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium*

Background: One recent, promising account of Autism Spectrum Disorders (ASD) situates the cause of the disorder in an atypicality in basic neural information processing, more specifically in how activity of one neuron is modulated by neighboring neurons. The canonical neural computation that implements such contextual influence is called divisive (or suppressive) normalization. The account proposes that normalization is reduced in ASD. This idea is inspired by the excitatory/inhibitory imbalance hypothesis of ASD, and by findings of decreased contextual influences in perception and cognition in this population.
Objectives: We tested one fundamental prediction of this model for low-level perception, namely that individuals with ASD would show reduced cross-orientation suppression (leading to an illusory tilt perception).

Methods: 11 young adults with an ASD diagnosis and 12 age-, gender-, and IQ-matched control participants performed a psychophysical orientation perception task with compound grating stimuli. Their illusory tilt perception was derived from psychometric function fits used as a measure of the strength of the divisive suppression by context.

Results: Suppression did not differ significantly between groups, indicating typical divisive normalization in individuals with ASD. In fact, all individuals with ASD showed a considerable orientation bias. There was also no correlation between illusory tilt perception and autistic traits as measured by the Social Responsiveness Scale.

Conclusions: These results provide clear evidence against the decreased divisive normalization model of ASD in low-level perception, where divisive normalization is best characterized. We evaluate the broader existing evidence for this model and propose ways to salvage and refine the model.

31 **164.031** Learning from Digital Media: The Effects of Social Engagement

L. A. Bird *and M. L. Allen, Lancaster University, Lancaster, United Kingdom of Great Britain and Northern Ireland*

Background:
Digital learning is revolutionising education, it's increasing prevalence in the classroom has inspired new approaches to teaching. Many language interventions for children with autism spectrum disorder (ASD) are now being delivered via digital technology, such as tablet-devices, due to their accessibility and easily tailored functions. Despite the extensive use of digital learning evidence of its effectiveness remains scarce and contradictory. Furthermore, how children potentially engage with technology, and the effect this has on learning has not yet been explored, which is particularly important for children with ASD whom characteristically struggle with social functioning.
Objectives:

The present research compared how children with ASD engage with iPads and traditional storybooks, and examined the effect this had on the learning and retention of novel words.
Methods:

Two groups of children between 4-11 years participated, 21 children with ASD (10 iPad, 11 book) and 21 children with other developmental disorders (DD; 10 iPad, 11 book). Both groups were matched on receptive vocabulary age equivalents (ASD iPad M: 6.1 years, book M: 6.76 years; DD iPad M:6.39 years, book M: 6.17 years). During a story book interaction presented as either a traditional book or on the iPad, participants heard 2 novel words 4X times each. Word learning was then assessed using a picture based referent selection task immediately, and again after a 24-hour delay. Social engagement with the task and experimenter was also assessed using observations of experimental footage.
Results:

A mixed factor analysis showed no difference in word learning performance between presentation medium ($F(1, 37) = .040$, $p = .843$, $\eta p^2 = .001$), suggesting neither books or iPads are a superior instrument, nor detrimental to learning. Further validation of this was provided by a non-significant interaction between task delay*group*condition (F(1, 37) = .385, p = .539, ηp² = .010) also suggesting both groups learned and retained words at a similar rate. However, controlling for disengagement from the task revealed an advantage of iPad-based learning across the test delay (F(1, 36) = 4.481, p = .041, ηp² = .111).

Social engagement was analysed using a multivariate analysis which showed a significant effect of presentation medium (V = .179, F(8, 30) = 2.286, p = .048, ηp² = .379, observed power = .777). Closer inspection revealed increased engagement via medium-directed attention with the iPad (M = 46.24) compared to the book (M = 18.25). However, medium-directed pointing revealed the opposite effect, with children in the book condition (M = 1.68) pointing towards the medium more than children in the iPad condition (M = .15).

Conclusions:

Word learning occurred at a similar level between books and iPads for both participant groups. However, an advantage for iPad-based learning over traditional books was found when disengagement from the task was controlled for. Social engagement measures revealed an increase in medium-directed attention towards the iPad, but an increase in pointing towards the book; suggesting children are more focused when content is presented on an iPad, however engage more socially when using traditional books.

32 **164.032** Learning in a Probabilistic Environment in the EU-AIMS LEAP Cohort: How Do Individuals with Autism Spectrum Disorder Perform and How Does This Relate to Restricted, Repetitive Behaviour and Associated-ADHD Symptomatology?

D. V. Crawley[1], *L. Zhang*[2], *H. den Ouden*[3], *J. Ahmad*[1], *C. H. Chatham*[4], *E. J. Jones*[5], *A. San Jose Caceres*[1], *J. Tillmann*[6], *T. Charman*[7], *J. K. Buitelaar*[8], *D. G. Murphy*[9] *and E. Loth*[1], *(1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)F. Hoffmann-La Roche AG, Basel, Switzerland, (3)Donders Institute for Brain Cognition and Behaviour, Nijmegen, Netherlands, (4)Neuroscience, Ophthalmology, and Rare Diseases (NORD) Roche Pharma Research and Early Development. Roche Innovation Center Basel, Hoffmann La Roche, Basel, Switzerland, (5)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (6)King's College London, London, United Kingdom of Great Britain and Northern Ireland, (7)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (8)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (9)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:

Cognitive flexibility denotes the ability to shift thoughts and actions in response to changes in the environment. It requires learning from reinforcement and adapting to new situational demands. Impairments in cognitive flexibility have been proposed to underlie restricted, repetitive behaviour (RRB) in ASD, and to explain some behavioural deficits seen in often co-occurring ADHD. Yet, evidence for cognitive inflexibility in ASD and its relationship with symptomatology is mixed. Probabilistic reversal learning (PRL) tasks examine choice behaviour in an unstable environment, and perseverative errors (PEs) are frequently used to index cognitive inflexibility. Computational models add critical information beyond composite scores like PEs, to reveal how individuals learn over time, and the strategies they use.

Objectives:

1. To examine case-control differences in PRL task performance in a large cohort;
2. To study learning trajectories across development and quantify differences in cognitive mechanisms using computational models;
3. To investigate the relationship between PRL task measures and RRB and associated-ADHD symptomatology.

Methods:

Participants were 317 ASD individuals aged 6-30 years and 250 age-matched typically developing (TD) individuals recruited as part of EU-AIMS LEAP (Charman et al., 2017). They were split into: children (6-11), adolescents (12-17) and adults (18-30). Participants learned to choose the 'most often' rewarded stimulus, from a choice of two, with an 80:20 reward/punishment ratio. Feedback contingencies were reversed at the task midpoint. Win-stay lose-shift scores were calculated in both phases (acquisition/reversal); PEs were derived from the reversal phase (den Ouden et al., 2013). Hierarchical Bayesian analysis was then used to fit 3 computational models using the R-based package, hBayesDM: Reward-Punishment, Experience-Weighted Attraction (EWA) and Fictitious-Update. IQ scores were covaried in each model after z-transform. RRBs were assessed using the Repetitive Behaviour Scale-Revised. ADHD symptomatology was measured using the DSM-5 ADHD rating scales.

Results:

There was an overall group effect, whereby ASD individuals made significantly more PEs than controls and showed less win-stay and more lose-shift behaviours (all p<.001, d=0.23-0.33), however post-hoc analyses revealed this was only significant in adolescents (all p<.005, d=0.38-0.54). Model comparisons revealed the best estimate for children in both groups and ASD adolescents was the Fictitious-Update model; for TD adolescents the Reward-Punishment model outperformed the others; while for adults in both groups the EWA model was superior. Learning rates of each age group's winning model significantly correlated with PEs (all r_s=.34-.68, all p<.001). The only significant relationship between PRL task measures and symptomatology to survive multiple comparisons was that of lose-shift behaviours and both hyperactivity/impulsivity and inattention in ASD adults (Figure 1; both r_s=0.32, $p_{corrected}$<.003).

Conclusions:

Impairments in cognitive flexibility were only found in ASD adolescents. Combined with the model comparisons, findings suggest that different strategies are employed by different age groups when learning in a probabilistic environment, and that these strategies transition during adolescence, with potentially different developmental trajectories for ASD and TD individuals. The relationship between task performance and ADHD symptoms in ASD adults has important implications – a better understanding of how learning cognitive flexibility develops in ASD and its relationship with symptomatology will inform effective interventions.

33 **164.033** Local and Global Face Identity Discrimination in Children, Adolescents and Adults with Autism Spectrum Disorder

K. Ainsworth[1], *D. Tullo*[1], *M. Pietracupa*[1], *J. Guy*[1,2] *and A. Bertone*[1], *(1)McGill University, Montreal, QC, Canada, (2)Experimental Psychology, University of Oxford, Oxford, United Kingdom*

Background:

Autism Spectrum Disorder (ASD) is differentiated from other neurodevelopmental disorders by its unique perceptual phenotype (Bertone et al, 2010), defined by a relative facility for processing non-social, spatial information with concurrent difficulty in perceiving complex, socially laden information exemplified by face perception (Simmons et al., 2009). Some suggest that atypical face perception in ASD has a perceptual origin, resulting from abnormally local or detailed processing strategies (Behrmann et al., 2006) that change with age (Guy et al., 2016). The ability of high-functioning autistics to discriminate facial identities is selectively decreased when access to local facial cues is minimized (Morin et al., 2015). However, these results, are based on autistics who score average or higher on IQ tests; therefore, little information is available for individuals who are 'lower functioning'.

Objectives:

The objectives of this study were twofold:

1. When access to local cues are diminished, do autistics who are 'low functioning' exhibit an atypical performance profile?
2. Does identity discrimination ability differ as a function of age, and if so, are such differences related to the differential use of local vs. global facial processing?

Methods:

Nineteen autistics (17 male, 2 female), aged between 9 and 21 years, completed the Wechsler Abbreviated Scale of Intelligence (WASI-2) as well as the Social Responsiveness Scale (SRS-2). Participants then completed a simple, 2AFC facial identity discrimination task where they answered 'same' or 'different' to two synthetic face stimuli (Wilson et al, 2002) presented simultaneously on a computer screen. First, face pairs were presented front-facing, allowing for identity judgements to be based on local facial cues (e.g., comparing noses). The second condition presented a stimulus view-change, where face pairs had one front facing and one side facing stimulus (20 deg.), resulting in a decreased access to local information, and a greater reliance on a global analysis to complete the task.

Results:

A 3 x 3 ANOVA (condition x developmental group) revealed a significant effect of condition (F (2, 32) = 38.4, $p <0.001$), suggesting that autistics found the front-front condition (facilitating local strategies) significantly easier than the front-side condition (facilitating global strategies). A significant correlation was found between chronological age and performance in the front-front condition (r = 0.49, n = 19, $p = 0.03$) despite no significant correlation with IQ or SRS scores.

Conclusions:

Results reveal a similar performance profile for individuals on the 'lower functioning' spectrum of ASD compared to individuals who are 'high-functioning' (e.g. Guy et al 2016). Thus, this study contributes to understanding face perception in autistics with low IQ: a group who are less well defined in ASD visual perception research. Results indicate a divergent developmental trajectory, upon which, locally-oriented face perception improves as a function of age while global processing does not. Eye tracking data was also collected for this study and so future developments of this project will seek to assess whether atypical face perception in ASD may have a non-social origin by examining these data in conjunction with objective viewing strategies.

34 **164.034** Lower-Level and Top-Down Processing Underpins Motor Contagion in Autism Spectrum Disorders

N. C. Foster[1], *S. J. Bennett*[2], *J. Causer*[1] *and S. J. Hayes*[2], *(1)Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, United Kingdom, (2)Research Institute Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, United Kingdom*

Background: A person becomes significantly more variable when performing a horizontal movement if they concurrently observe another person executing a vertical (incongruent) arm movement, compared to a horizontal (congruent) arm movement. Increased movement variability is a consequence of the observed movement properties interfering with the sensorimotor processes controlling the ongoing movement (Kilner et al., 2003). The interference effect is called 'motor contagion' and is underpinned by a sensorimotor system directly linking perception and action (Prinz, 1997). Motor interference effects have been reported in autism and indicate intact lower-level sensorimotor processing (Sowden et al., 2016) and top-down control (Hamilton et al., 2007). In the present study, we further examined motor contagion in autism to establish if lower-level and top-down processes operate within an embedded system that leads to combined additive interference effects.

Objectives: (1) examine the contribution of end-point and trajectory information on motor contagion.

Methods: Twenty-two autistic adults and twenty-two matched control participated in the study. The autistic adults were diagnosed by a clinical assessment and ADOS, and the study was approved by the local ethics committee. Participants performed cyclical horizontal arm movements whilst simultaneously observing different stimuli. The stimuli were horizontal (congruent end-points and trajectory), vertical (incongruent end-points and trajectory), and curvilinear (congruent end-points and incongruent trajectory). Mean data for *deviation* and *peak position* were submitted to separate 2 group x 3 stimulus repeated measures ANOVA. Alpha was set at $p < 0.05$.

Results: Although *deviation* was significantly greater in the autism group than the control group ($p < 0.05$), both groups demonstrated motor contagion. *Deviation* and *peak position* were significantly higher in the vertical compared to the horizontal conditions (*ps* < 0.05), with additional significant increases in *deviation* and *peak position* between the curvilinear compared to the vertical condition (*ps* < 0.05).

Conclusions: The observation of vertical incongruent arm movements during motor execution led to motor contagion in autistic and control adults. Increased *deviation* and *peak position* is underpinned by sensorimotor processes representing the observed movement properties in the sensorimotor system at a similar time as the motor commands are controlling the executed horizontal movement. Importantly, increased *deviation* and *peak position* was found when viewing a curvilinear stimulus that had an incongruent trajectory, but congruent end-points. The additive contagion effects found in the curvilinear condition indicated motor interference was modulated by combined processing of the movement trajectory and end-points. These findings indicate lower-level sensorimotor, and top-down, processing is intact in autism.

35 **164.035** Making Sense of the Perceptual Capacities in Individuals with and without Autism

A. Remington *and J. Brinkert, UCL Centre for Research in Autism and Education, London, United Kingdom*

Background:

Recent studies report that, for autistic people, perceptual capacity (the amount of sensory information processed at any one time) is increased in the auditory (Remington et al., 2016) and visual domains (e.g. Remington et al., 2012). This increase in capacity may be responsible for both positive (superior auditory perception skills) and negative (increased distractibility) aspects of the condition. The question remains, however, whether this increase in capacity is associated with the real-life sensory experiences of autistic individuals. Those on the autistic spectrum often have altered sensory experiences compared to their neurotypical peers. In particular, sensory hypersensitivity is often reported to be distressing and uncomfortable by autistic individuals. Several theories (e.g. Baron-Cohen et al., 2009; Dunn, 1997) have proposed that sensory symptoms, in particular hypersensitivity - the heightened acuity of sensory experiences – may be linked to altered attention patterns. We hypothesise that increased perceptual capacity may be one such process underlying the atypical sensory sensitivities seen in the condition.

Objectives:

The current study aimed to explore the relationship between perceptual capacity and sensory hypersensitivity. Understanding this association may help inform the creation of therapeutic interventions to minimise sensory distress.

Methods:

Eighteen autistic and 19 neurotypical participants between 18-35 years, matched in age and cognitive ability took part in an auditory test of perceptual capacity (developed by Fairnie et al., 2016). The task, a dual-task paradigm, involved performing an auditory search task in the presence of varying numbers of distractors, while also performing a secondary detection task. Participants also completed a self-report sensory questionnaire (the Sensory Perceptual Quotient by Tavassoli et al., 2014) to quantify overall sensory symptoms in daily life (e.g. "I would be able to hear the sound of a vacuum cleaner from any room in a two-storey building.").

Results:

In line with initial predictions, a positive correlation (r_s= .42, p=.01) between level of perceptual capacity and sensory sensitivities was found. This shows that extra perceptual ability is related to the sensory perception of real-life events.

Conclusions:

The findings indicate that an increased perceptual capacity is associated with increased levels of sensory responsiveness in every-day life. Crucially, this allows a reframing of increased sensory sensitivity in terms of the increased perceptual capacity, rather than a filtering deficit or an insufficient focus. This offers a target for interventions, education and therapy and could assist in the development of improved sensory environments which are adapted to a persons' perceptual capacity.

164.036 Personification in Autism: This Abstract Will be Very Sad If You Don't Read It.

***A. Remington*[1]**, *O. Negri[2] and R. C. White[3], (1)UCL Centre for Research in Autism and Education, London, United Kingdom, (2)UCL Centre for Research in Autism & Education, London, United Kingdom, (3)Department of Experimental Psychology, University of Oxford, Oxford, United Kingdom*

Background:

In online forums, autistic individuals describe a special relationship with objects. They report, for example, that papers in a filing cabinet feel unloved, or that the last crisp in a packet is lonely. Given that approximately half of all autistic individuals experience alexithymia (Bird & Cook, 2013), a condition characterised by difficulties identifying one's own emotions, the suggestion that object personification may be a feature of autism seems almost paradoxical. Why would a person experience sympathy for objects, when they struggle to understand and verbalise the emotions of other people as well as their own?

Objectives:

This study investigated whether descriptions of object personification seen in online forums were representative of a large subset of the autistic population. Furthermore, it sought to understand and compare the experiences of autistic and non-autistic personifiers.

Methods:

An online survey was used to assess autistic traits (Autism Quotient, Allison, Auyeung, & Baron-Cohen, 2012) and tendency for personification (Anthropomorphism Questionnaire, Neave, Jackson, Saxton, & Honekopp, 2015, with a bespoke questionnaire designed for the current study). Follow-up interviews were carried out with a subset of respondents – eight autistic and eight non-autistic adults – who reported high levels of personification. Participants were asked about their experiences of personification, both positive and negative.

Results:

350 adults completed the survey, 87 with a professional diagnosis of autism and 263 who reported being non-autistic. There were significantly more personifiers in the autistic group (56%) than in the non-autistic group (33%, χ^2 = 12.9, p < .001). Autistic personifiers reported experiencing the phenomenon more often (31% reporting daily personification) than non-autistic personifiers (16% daily, χ^2 = 4.73, p = .03). Overall scores for the Anthropomorphism Questionnaire were higher in the autistic group (t(312) = 2.34, p = .02) and the pattern across the two subscales revealed group differences. On the Childhood Subscale the average scores were very similar (t(312) = .67, p = .50) however the autistic group more strongly endorsed statements from the General Subscale (t(312) = 3.97, p < .001), suggesting that anthropomorphism more commonly persists into adulthood for autistic individuals than for those without the condition.

Interview data indicated that all participants felt that personification was an automatic process. Additionally, individuals from both groups described personifications as comforting, promoting a sense of safety and friendship with agents of personal significance, as well as experiencing concern and feelings of sympathy and empathy toward agents. For some, these feelings caused distress, and were considered intrusive. Autistic individuals stressed the important role personified agents played in their life, particularly when growing up, easing loneliness and helping with developing an understanding of emotions and relationships.

Conclusions:

Together, our results indicate that object personification occurs commonly among autistic individuals, and perhaps more often (and later in life) than in the general population. However, the lived experiences of personifiers with and without autism seem similar. Given that in some cases, these experiences are negative, it is important to now consider the reasons for the increased personification, and identify structures for support.

37 **164.037** Memory Deficits, Communicative Ability, and Self-Monitoring Limit Utility of Existing Forensic Interviewing Methods for Youths with High Functioning Autism Spectrum Disorder

***J. L. Johnson**, G. S. Goodman and B. De Vault, Psychology, University of California, Davis, Davis, CA*

Background: Individuals with Autism Spectrum Disorder (ASD) exhibit deficits in autobiographical memory, and, in legal application eyewitness memory, compared to typically developing individuals (TD), particularly on free recall tasks (e.g., "Tell me what you remember about X"). Such free recall accounts in ASD are reportedly sparse, lack coherence, and include irrelevant or idiosyncratic details. In eyewitness memory, free recall accounts are the preferred statements used by legal investigators. Interview protocols, derived from TD memory abilities, which aim to elicit accurate accounts, may be ineffective as they rely on cognitive and social abilities that may be diminished in ASD (e.g., narrative ability, pragmatic understanding, self-monitoring, and use of organizational frameworks at encoding/retrieval).
Objectives: This study compared memory for details (events, people, actions, and setting/object) in youths with and without high functioning ASD (HFASD) as well as compared the efficacy of two forensic interview protocols for use with ASD samples.

Methods: Forty-eight youths [age: 13.96(2.47)] experienced a semi-distressing event involving four confederates. Half of the participants had a diagnosis of HFASD (n = 24). Two to three weeks later, they returned for a memory interview, half receiving the Cognitive Interview and other half the 10-Step (shortened NICHD derivative version) protocols to aid in retrieving details. Parents rated youths' language (pragmatic difficulties) and executive functioning (self-monitoring ability). Free recall details were scored as general theme events, or more specific people-, action-, or setting/object-related.

Results: Controlling for age, working memory, and attempt duration, a 2 (Diagnosis: TD vs. HFASD) x 2 (Interview Protocol: CI vs. 10) ANCOVA revealed deficits for the HFASD group on proportion of events remembered, F (1, 41) = 8.37, p < .01, η_p^2 = .17. Planned comparisons revealed these differences for the CI groups only, F (1,41) = 6.44, p = .02, η_p^2= .14. For detail categories, a 2(Diagnosis) x 2 (Interview Protocol) x 3 (Detail: people, actions, objects/setting) repeated measures ANCOVA, revealed diagnostic group differences, F (1,41) = 21.61, p < .001, η_p^2 = .35 as well as a within Detail effect for both groups, F (1, 41) = 26.41, p < .001, η_p^2 = .39. Both groups demonstrated the lowest and greatest accuracy for details related to actions and people, respectively, F's (2,40) ≥ 84.70, p's < .001, η_p^2 = .81-.83. Regression models predicting detail accuracy revealed that pragmatic ability ($\beta \leq -.41$, p <.01) and self-monitoring X Interview Protocol ($\beta \geq .39$, p <.05) predicted a substantial portion of the variance in the proportion scores for actions (R^2 = .58, F = 11.78, p <.001) and setting/objects actions (R^2 = .51, F = 8.78, p <.001).

Conclusions: While deficits were observed, HFASD group did exhibit similar memory trends for type of detail reported relative to TD peers, and remembered most events. Lower accuracy was associated with pragmatic difficulty and receiving the CI while having low levels of self-monitoring. Moreover, the HFASD group did not seem to benefit from either protocol's strategies. Results are discussed with legal implications in terms of modifying cognitive demands of existing protocols.

38 **164.038** Modulating Attentional Biases of Adults with Autistic Traits Using Transcranial Direct Current Stimulation: A Pilot Study

***M. C. English**, E. Kitching, M. T. Maybery and T. A. Visser, School of Psychological Science, University of Western Australia, Perth, Australia*

Background: Pseudoneglect is the propensity for neurotypical individuals to over-attend to the left-side of centrally-presented visual stimuli and is driven by relatively greater lateralization of spatial attention to the right hemisphere (RH) than the left. However, this attentional bias appears to be reduced or absent for individuals with autism spectrum conditions relative to healthy controls, and for neurotypical individuals with high levels of autistic-like traits (ALT) relative to those with low levels of ALT. This reduced bias likely reflects a reduction in the lateralization of spatial attention to the RH for these individuals.
Objectives: The aim of the present study was to determine whether non-invasive transcranial direct current stimulation (tDCS) delivered to the right posterior parietal cortex (PPC) could alter attentional biases in High ALT individuals, such that attentional bias is relatively more comparable to that reported in Low ALT individuals. If tDCS does influence attentional biases in High ALT individuals, this would 1) provide evidence for reduced RH lateralization for spatial attention in High ALT individuals; and 2) indicate that attentional biases, and therefore relative levels of hemispheric activation, are not resistant to modulation via external stimulation.

Methods: The Autism Spectrum Quotient (AQ) was administered to an undergraduate student cohort (n=702), and 38 students invited to participate in the study from the initial pool. Students were categorized as Low ALT (n=18) or High ALT (n=16) if their Autism Spectrum Quotient scores fell below or above the median AQ score for the entire cohort (Median AQ = 107). In separate sessions, participants received approximately 10 minutes of anodal, cathodal, and sham tDCS, while completing the greyscales task – a task that provides an index of attentional lateralization.

Results: The main outcome of the study was that tDCS over the right PPC was particularly effective at modulating attention biases in our High ALT group, but ineffective at inducing attentional changes in the Low ALT group. Critically, a repeated measures ANOVA found an interaction between ALT Group and Stimulation Type, F(2,34)=7.00, p<0.01. Follow-up tests revealed a significant increase in leftward bias as a result of anodal tDCS relative to sham levels in the High ALT group, t(15)=4.09, p<0.001, while no such change was evident in the Low ALT group, t(17)=0.58, p=0.57. The effect of cathodal tDCS on attentional biases was substantially weaker, with the High ALT group falling just short of significant levels, t(15)=2.05, p=0.06 and Low ALT group showing no effect of stimulation, t(17)=0.95, p=0.35.

Conclusions: This study has shown that relatively lower levels of pseudoneglect expressed by High ALT individuals can be increased to a level that is more comparable to what is seen in Low ALT individuals. This finding is important as it suggests that if attention can be modulated using tools like tDCS, other aspects of attention relevant to autism (i.e. global processing, face processing) that are also linked to relative levels of hemispheric activation might also stand to benefit from similar techniques.

39 **164.039** Patterns of Attention to Non-Social Stimuli in Children with Autism Spectrum Disorder

***Y. J. Chen**[1], C. Harrop[2], M. Sabatos-DeVito[3], J. Bulluck[2] and G. Baranek[1], (1)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background: Aberrant attention patterns in Autism Spectrum Disorder (ASD) have been widely reported. Eye-tracking offers a non-invasive way to examine visual attention; however, most ASD studies have focused on attention to social stimuli (e.g. Jones & Klin, 2013) with very few studies

examining attention to non-social stimuli. The impact of low-level sensory features (e.g. motion, modality) on attention patterns in ASD has not been comprehensively studied.
Objectives: In this eye tracking study, we aimed to test how the sensory properties of non-social stimuli impacted the allocation of attention in ASD and how patterns of attention associate with clinical sensory profiles.

Methods: Forty children [15 ASD, 15 Typically Developing children (TD) and 10 Developmental Delay excluding ASD (DD)] ages 4 to 13 years were included. Parents provided data on child sensory response patterns via the Sensory Experiences Questionnaire, Version 3.0 (SEQ-3; Ausderau et al. 2014). Children completed a passive-viewing eye-tracking task designed to measure attention to non-social stimuli; six novel, objects with interesting visual and auditory qualities were presented in the center of the screen in either unimodal (static or dynamic) or multimodal (dynamic+auditory) format. Stimuli were shown on the screen one at a time for 15 seconds in a random order.

Results: There were no group (ASD/TD/DD) differences in total attention to stimuli (F(2, 79)=1.48, p=.23). However, there was a condition effect: all subjects spent more time attending to dynamic and dynamic+auditory stimuli compared to static (F(2, 79)=8.94, p<.001). There were no group or condition effects for time to first fixation, suggesting initial orientation was similar across groups and conditions. However, first fixations were longer to both dynamic and dynamic+auditory stimuli compared to static (F(2, 79)=23.43, p<.001). There was no condition effect for the number of individual fixations, however children in the ASD group fixated fewer times overall than DD and TD controls (F(2, 79)=9.89, p<.001). Associations between clinical sensory response patterns and attention were found in the ASD group only; Hyperresponsivness correlated positively with both total fixation duration (r=.57 to77, all p's<.05) and mean fixation duration (r=.61 to.79, all p's <.01) across all conditions. Time to first fixation for dynamic and dynamic+auditory stimuli correlated negatively with hyperresponsiveness scores (both p's<.05).

Conclusions: Children in all three groups had comparable rates of overall attention and initial orientation to non-social stimuli in our study, with more attention to dynamic and dynamic+auditory versus static stimuli. Thus, sensory attributes (e.g. motion) appeared similarly salient to children regardless of diagnosis. Our findings using non-social stimuli are partially consistent with Chevalier et al. (2015) showing no group differences in static and dynamic stimuli when presented independent of social interaction. We conclude that overall attention and initial orientation to non-social stimuli is comparable across groups, with some sensory qualities, such as motion, producing a facilitatory effect on visual attention for all children. However, we found enhanced attention (i.e. looking more quickly and for longer periods to non-social stimuli) was only associated with clinical measures of hyperresponsiveness in children with ASD, suggesting the need for future mechanistic research.

40 **164.040** Planning and Efficiency on the Tower of London Test in ASD

L. C. Baxter[1]*, A. Nespodzany*[2]*, B. B. Braden*[3] *and C. J. Smith*[4]*, (1)Radiology, Barrow Neurological Institute, Phoenix, AZ, (2)Barrow Neurological Institute, Phoenix, AZ, (3)College of Health Solutions, Arizona State University, Tempe, AZ, (4)Southwest Autism Research & Resource Center, Phoenix, AZ*

Background: Planning is a critical component of executive functioning that facilitates the proper execution of goal-directed behavior. Deficits in executive functioning can underlie many of the challenges faced by individuals with autism spectrum disorder (ASD), and many studies show that individuals with ASD exhibit poor planning compared to neurotypical (NT) individuals.
Objectives: To investigate the effect of ASD on planning ability in adults.

Methods: Participants were recruited through the community and underwent screening for ASD prior to cognitive assessments. Inclusion/exclusion criteria included IQ > 80, male, and general good health. NT participants (n = 38, age 18-64, M = 38, SD = 15.24) were age- and IQ-matched to individuals in the ASD group (n = 52, age 18-70, M = 38, SD = 17). Participants performed a Tower of London test, a commonly used neuropsychological test requiring planning. The test requires participants to arrange beads on pegs in specified patterns in as few moves as possible, where consecutive trials get progressively more difficult. Total moves, initiation time (time spent planning), execution time, and total number of correct trials (completed without making extra moves) was recorded. SPSS (v19) was used to test mean differences between ASD and NT groups, and linear regression modeling was conducted to test the relationship between initiation time and number of trials completed correctly for each group.

Results: NT subjects completed significantly more correct trials than did their ASD counterparts, and the ASD group made significantly more moves across all trials. The two groups did not show significant differences in the amount of time they used to plan moves. However, linear regression revealed that there was a significant and negative relationship between planning time and total move count for the ASD group, but not for the NT group. Thus, for individuals with ASD, more time spent planning moves resulted in the making of fewer unnecessary moves.

Conclusions: Compared to healthy controls, adults with ASD displayed deficits in planning on a Tower of London task. While both ASD and NT groups showed similar variability in time spent planning, planning time was an important determinant of correctly completing the task for only the ASD group. In summary the study indicates that though some individuals with ASD had difficulty in motor planning, those who utilized longer planning periods had the best performance. NT individuals completed the task with more ease than did the ASD individuals, with little to no benefit from longer planning periods. Since no instruction was given regarding using planning as a strategy, it is difficult to know whether the use of planning was incidental or deliberate. This study suggests that increased emphasis on planning may improve some aspects of executive functioning in individuals with ASD.

41 **164.041** Probabilistic Learning in a Volatile Environment in Individuals with and without Autism Spectrum Disorder

L. Lemmens[1,2]*, J. Wagemans*[1,2] *and S. Van de Cruys*[1,2]*, (1)Laboratory of Experimental Psychology, Brain & Cognition, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium*

Background: Predictive coding has recently been proposed as a framework to understand Autism Spectrum Disorder (ASD). It assumes that the human mind processes information by making and testing predictions, and that violations to these predictions result in prediction errors. One possible explanatory account argues that individuals with ASD tend to ascribe High and Inflexible Precisions to Prediction Errors (HIPPEA), irrespective of the context. Ascribing high weights or precisions to all prediction errors could be an advantageous strategy for probabilistic learning within a stable environment, but would hamper learning in a volatile and unstable environment.
Objectives: In order to gain insight into these mechanisms of precision-setting in an unstable environment in individuals with ASD, we administered a Probabilistic Learning Task in a Volatile Environment (PLTVE). Based on the Probabilistic Reversal Learning task of Behrens et al.

(2007), the PLTVE is designed to evaluate whether ASD individuals can estimate the volatility of the context and use this estimate to flexibly adjust their precision-setting of prediction errors. To investigate the influence of noise on precision-setting in ASD, we extended this task by adding variability in irrelevant dimensions of the presented stimuli. Based on the HIPPEA framework, we hypothesize differences in probabilistic learning to be more pronounced when variability in irrelevant dimensions is present.

Methods: In a behavioral experiment we presented the PLTVE to an ASD group (11-27 y) and a typically developing (TD) group (13-26 y). The PLTVE is a two-alternative forced choice task, in which the probabilistic rule about which feature out of three potentially relevant dimensions is rewarded, changes unannounced. The number of (ir)relevant dimensions and whether the relevant dimension was cued or not was manipulated in three experimental phases (uncued unidimensional - cued three-dimensional - uncued three-dimensional).

Results: Overall, no differences in consistency on the PLTVE task were found between the TD and the ASD group over all 3 phases. In phase 1 and phase 2, the average consistency of both groups approximated the reward probabilities. In phase 3, average consistency was lower than the reward probability for both groups. However, results revealed an interaction effect of group and lose-shift/win-stay strategy, with TD participants making more use of the win-stay strategy and ASD participants making more use of the lose-shift strategy. In addition, participants in the ASD group were more likely to give up trying to find the correct rule in phase 3, compared to participants in the TD group.

Conclusions: The present results suggest that individuals with and without ASD can adapt to a more volatile environment. When variability was increased, both TD and ASD individuals had more difficulties with probabilistic learning. Interestingly, our results reveal that individuals with ASD make less use of positive feedback (i.e. prediction confirmation) and more use of negative feedback (prediction error) in their choice for the next trial, indicating that they do assign different weights to most recent trials. In addition, individuals with ASD seem to withdraw more frequently when confronted with high amounts of uncertainty (phase 3).

42 **164.042** Pupillary Responses to Manipulations of Stimuli Type and Synchrony in Children with Autism Spectrum Disorder

M. Segers[1], *J. M. Bebko*[1], *B. L. Ncube*[2] *and R. A. Stevenson*[3], *(1)York University, Toronto, ON, Canada, (2)Psychology, York University, Toronto, ON, Canada, (3)Western University, London, ON, Canada*

Background: Individuals with ASD have been shown to have a decreased sensitivity to the timing of multisensory inputs that are linguistic in nature, but not to simple, non-social stimuli. These difficulties have been theoretically and empirically linked to speech perception and communication difficulties. It is unclear if difficulties with socio-linguistic processing are a *social* or a *linguistic* issue. Pupillary responses (dilation and constriction) are reliable indices of cognitive operations including preference, mental load, and incongruity.
Objectives: The current study is the first to measure pupillary responses to dynamic, temporally manipulated audio-visual stimuli to infer cognitive processes involved in perception of non-social, social, and social-linguistic stimuli. The aims of the current study were threefold:

1) Determine if differences between pupillary responses to non-social and social-linguistic information are the result of difficulties in *social* or *linguistic* processing.

2) Determine if processing of asynchronously presented stimuli can be indexed through pupillary change, and if responses differ between typical development (TD) and ASD.

3) Determine if pupillary responses to stimuli relate to clinical symptomatology in ASD.

Methods: Participants included 39 children with ASD (Age; M=12.3, SD=3.2) and 32 TD children (Age; M=12.4, SD=3.0) who were matched for chronological and mental age using the WASI-II (Wechsler, 2011). Each participant was presented with audiovisual stimuli in 6 conditions in a 2x3 design. Stimuli were one of three types, non-social (a video of the children's game Mousetrap), social non-linguistic (a video of an actress making verbal, non-speech sounds), and social-linguistic (the same actress speaking). Each of these stimulus types were presented synchronously or asynchronously (1000ms delay, collapsed across visual-leading and auditory-leading). Pupillary responses were captured and recorded using a Tobii X60 eye-tracker. Participants' parents completed the Autism Quotient- Child Version as a measure of symptom severity.

Results: Children with ASD showed smaller pupillary responses to social information than TD children for both the social-linguistic (*p*=.009) and social non-linguistic (*p*=.005) conditions. However, there was no group difference in pupillary response between groups for the non-social condition (*p*=.376; Figure 1). Analysis of temporal processing was more equivocal. No significant Group x Stimulus x Synchrony interaction was apparent in the mean pupillary responses. However, more in-depth waveform analyses showed significant effects of synchrony in both the social non-linguistic and the socio-linguistic conditions (p's<0.001), but not in the non-social condition (Figure 2). Furthermore, responses to asynchronous stimuli were significantly correlated with symptom severity in the social non-linguistic (*p*=.01) and social-linguistic (*p*=.03) conditions, but not the non-social conditions (*p*=.16) such that smaller pupillary responses were associated with more severe symptomatology.

Conclusions: These data suggest that the atypical response to socio-linguistic sensory information in individuals with ASD is a result of the *social* components of the information. This held for both overall processing differences seen with synchronous stimuli, and differences observed in multisensory temporal processing. Finally, differences in multisensory temporal processing of social stimuli were significantly correlated with symptom severity, providing convergent evidence that differences in early-stage physiological processing (i.e., pupillary change) may contribute to symptomatology, including communication issues.

43 **164.043** Reduced Competition and Visual Field Asymmetries in a Dual-Stream Attentional Blink Paradigm in Individuals with High Levels of Autistic Symptomatology

J. L. Ringo[1], *L. Jefferies*[2,3] *and J. Burack*[4], *(1)Educational and Counselling Psychology, McGill University, Montreal, QC, Canada, (2)School of Applied Psychology, Griffith University, Gold Coast, Australia, (3)Menzies Health Institute Queensland, Southport, Australia, (4)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: The attentional blink (AB) paradigm has been used to explore the temporal and spatial dynamics of visual attention (Raymond, Shapiro, & Arnell, 1992). In a typical AB paradigm, two target letters are embedded in a rapid stream of digit distracters. Although identification accuracy of the first target is normally very high, identification of the second target is impaired when it appears in close temporal proximity to the first. A notable exception to this occurs when the second target is presented directly after the first target (at the ordinal position known as Lag 1). Using a dual-stream AB paradigm, in which two streams of distractors are displayed, one to the left and one to the right of fixation, Verleger et al.

(2009) showed that when T1 and T2 are presented in opposite streams, T2 is identified more accurately when it is presented in the left visual field. This left visual field advantage did not occur when T1 and T2 were presented in the same stream. They conclude that this is evidence for a right-hemisphere advantage when singling out targets in time.
Objectives: English, Maybery, and Visser (2015) showed a tendency in individuals with autistic traits to attend less to the left side suggesting a reduction in right hemisphere activation. Accordingly, we used a dual-stream AB paradigm, to further assess the nature of visual field asymmetries in individuals high in autistic traits.

Methods: Eighty-two young adults were allocated to either High-AQ or Low-AQ groups based on scores on the autism-spectrum quotient (AQ; Baron-Cohen, 2001). Each participant completed a dual-stream AB task in which two target letters were embedded in streams of digit distracters. One stream was presented to the left of a central fixation point, the second stream appeared to the right of fixation. The two targets appeared randomly and unpredictably in either the same stream as one another or in opposite streams. On a third of trials, the second target appeared immediately after the first (Lag 1); on another third of the trials the targets were separated by a single digit distracter (Lag 3); on the remaining trials, the targets were separated by 8 distracters (Lag 9). The stimulus onset asynchrony between items in the stream was 80 ms.

Results: The Low-AQ grouped showed the anticipated differences, and T2 was identified more efficiently in the left than right visual field. Visual field differences were markedly absent for the High-AQ group, who identified T2 equally well in both hemifields.

Conclusions: Individuals with High- as compared to Low-AQ scores displayed the lack of an attentional bias for the left visual field, extending evidence of diminished neural asymmetry in autism. This suggests that enhanced perceptual processing or snappy attentional gating might eliminate hemispheric competition leading to similar results in the same and different streams, regardless of the visual field in which T2 appeared. The apparent absence of hemispheric asymmetry that is characteristic of typical individuals may reflect a cognitive strength in right hemisphere functioning, leading to similar perceptual processing in both visual fields.

44 **164.044** Reduced Perceptual Narrowing in Autism: Evidence from the Other-Race Face Effect

__S. Schwartz__ and B. S. Hadad, University of Haifa, Haifa, Israel

Background: Over development, the perceptual system becomes more efficient and specialized for the stimuli at hand in its close environment. This perceptual narrowing is a fundamental process, emerging already in infancy for several types of stimulation, such as faces, language, and music. Specifically, for faces, advantage is seen for processing faces from one's own race, over faces from other races. Despite the adaptive value of this narrowing in perception, recent evidence implies for reduced narrowing in individuals with ASD. The findings, however, are inconsistent, in particular for faces.
Objectives: Our research purpose was to explore other-race effect (ORE) in autism, looking for both quantitative differences in the magnitude of the effect, and for qualitative differences in the way own-race versus other-race faces are processed. We hypothesized that individuals with ASD would exhibit (a) lower processing advantage for own-race faces, and (b) comparable inversion effect for own- and other-race faces, indicating similar type of processing for the two races and reduced specialization to the more frequent faces.

Methods: Participants (24 TD and 19 high-functioning ASD adults) were simultaneously presented with two faces and were asked to indicate whether the two faces were same or different (see Figure 1). Discrimination was tested for each face race (Caucasian vs. Asian) on separate blocks. Within each race, morphed faces were created to manipulate discrimination difficulty, and orientation was manipulated to examine inversion effect.

Results:

Quantitative differences in ORE: The results for the upright faces showed that although ORE was exhibited for both groups, it was smaller for the ASD group [$F(1,42)=7.32$, $p<0.009$]. As can be seen in Fig. 2, this pattern resulted specifically from the reduced specialization to the own-race faces in the ASD group.

Qualitative differences in ORE: Comparing inversion effect for the two race-faces revealed that while inversion effect was larger for the Caucasian faces in the TD group [$F(1, 23)= 4.23$, $p<0.05$], no such differences in the sensitivity to orientation between the two races were observed in the ASD group [$F<1$].

This pattern of results was obtained for the relatively easier morph levels but did not reach significance for the more difficult morph levels (20% and 40%), presumably because of an overall extremely low performance under these conditions.

Contrary to recent views, individuals with ASD also showed overall lower sensitivity in perceptual discrimination of faces [$F(1, 42)=4.62$, $p<0.037$], as well as an overall reduced inversion effect [$F(1, 42)= 3.85$, $p<0.056$], suggesting both qualitative and quantitative differences in face perception between the two groups.

Conclusions: The present data suggests that contrary to prevailing views, perceptual discrimination of faces is overall weaker in ASD compared to TD individuals, and demonstrates lower sensitivity to orientation effects. But more importantly, the data indicates that the perceptual system in autism does not become specialized, to the same extent seen in typicals, in processing the more frequent faces it encounters.

45 **164.045** Relation of Anxiety on Attentional Flexibility and Attentional Disengagement in Children with Autism Spectrum Disorder: Results from the ABC-CT Feasibility Study

__E. Baker__[1], E. Pompan[2], B. Nguyen[3], P. Renno[2], Q. Wang[4], S. J. Webb[5], F. Shic[6], A. Naples[4], C. Sugar[7], M. Murias[8], R. Bernier[5], G. Dawson[9], C. A. Nelson[10], J. McPartland[4], S. Jeste[7] and S. Johnson[11], (1)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)Center for Autism Research and Treatment, UCLA, Los Angeles, CA, (4)Child Study Center, Yale University School of Medicine, New Haven, CT, (5)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (6)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (7)University of California, Los Angeles, Los Angeles, CA, (8)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (9)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (10)Boston Children's Hospital, Boston, MA, (11)UCLA, Los Angeles, CA

Background:
Attentional flexibility has been shown to differentiate infants at high risk for autism spectrum disorder (ASD) from infants at low risk for ASD

(Elsabbagh et al., 2009). Similarly, children with anxiety have deficits in attentional flexibility, including difficulty disengaging attention between tasks (Eysenck & Calvo, 1992). Approximately 40% of children with ASD have a co-occurring anxiety disorder, a rate significantly higher than the 2.4% estimated in the general population (Costello et al., 2003). Despite the increased prevalence, little is known about factors that contribute to heightened rates of anxiety in children with ASD. Measuring attentional flexibility in school-aged children with a diagnosis of ASD and anxiety symptoms may inform how early attentional deficits contribute to the phenotype.

Objectives:

Our primary objective was to evaluate group differences in attentional flexibility and determine how anxiety symptoms in children with ASD relate to disengagement of attention.

Methods:

Typically developing (TD) children (n=26, M_{years}=6.6 *SD*=1.98) and children with ASD (n=19, M_{years}=8.25 *SD*=2.03), recruited from study NIMH# 1U19MH108206-01—PI: McPartland, viewed a central stimulus with an animated peripheral (target) stimulus as eye movements were recorded using an SR EyeLink 1000 Plus eye tracker. The following conditions were presented: 1. Baseline Condition, where the central stimulus disappears at precisely the same time as the appearance of the target stimulus; 2. Gap Condition, where the central stimulus disappears 200 ms before the target stimulus appears; and 3. Overlap Condition, where the central stimulus and target stimulus are presented at the same time. The principal dependent variable was average reaction-time (RT) of the first fixation toward the target. RT was log-transformed to normalize the spread of distribution. Anxiety symptoms were measured using the *Behavior Assessment System for Children, Version 3* (*BASC-3*).

Results:

The ASD group had elevated scores of anxiety symptoms when compared to the TD group (*t*(43)= 3.44, *p*<.01). Average RT to the target stimuli in the ASD group (Baseline_*M*=5.46 Baseline_*SD*= .20, Gap_*M*=5.31 Gap_*SD*=.14, Overlap_*M*=5.63 Overlap_*SD*=.29) was faster than the TD group (Baseline_*M*=5.57 Baseline_*SD*=.17, Gap_*M*=5.42 Gap_*SD*=.19, Overlap_*M*=5.74 Overlap_*SD*=.23) in all conditions, with a marked speed in the baseline and gap conditions (Baseline_t(43)= -2.14, *p*=.04; Gap_t(43)= -2.14, *p*=.03; Overlap_t(43)= -1.4, *p*=.17). In the ASD group, anxiety symptoms negatively correlated with RT baseline average (*r*= -.5, *p*=.03).

Conclusions:

The ASD group had faster RTs to the target stimulus than the TD group in all three conditions, with particular speed in the baseline and gap conditions, suggesting temporal facilitation of attentional disengagement. Increased anxiety symptoms were related to faster engagement to the target stimulus in the baseline condition for the ASD group. This may be due to elevated rates of anxiety symptoms and thus increased vigilance and awareness of the overall environment. Further examination of attentional flexibility in children with anxiety and ASD may provide insight into the cognitive mechanisms of anxiety in this population and increased prevalence.

46 **164.046** Relational Memory in High-Functioning Children with Autism Spectrum Disorders

R. H. Mogensen[1], *M. B. Hedegaard*[2], *L. R. Olsen*[3], *J. Skewes*[4] *and L. Gebauer*[5], *(1)Center for Music in the Brain, Department of Clinical Medicine, Health, Aarhus University and Aarhus University Hospital, Aarhus, Denmark, (2)Department of Psychology and Behavioural Sciences, Aarhus University, Aarhus, Denmark, (3)Cognitive Science, Aarhus University, Aarhus, Denmark, (4)Interacting Minds Centre, School of culture and society, Aarhus University, Aarhus, Denmark, (5)Center for Music in the Brain, Department of Clinical Medicine, Aarhus University and Aarhus University Hospital, Aarhus, Denmark*

Background: Individuals with Autism Spectrum Disorders (ASD) show both memory strengths and weaknesses. As an example, individuals with ASD seem to have intact memory for single features but diminished relational memory (i.e. memory for information consisting of combinations of different features). A number of studies have identified such pattern in memory performance in adults with ASD (e.g. Bowler, Gaigg, & Gardiner, 2009; Bowler. Gaigg, & Gardiner, 2014). However, only few studies have examined, whether this pattern also is present in children with ASD, and the results from these studies are not clear-cut (Lind, Bowler, & Raber, 2014; Maister, Simons, & Plaisted-Grant, 2013). Further, diminished relational memory in ASD might be related to an enhanced perceptual focus on local information, but this relationship has not yet been addressed directly.
Objectives: The aim of this study was to examine, whether children with ASD show impaired memory for relational information, i.e. combinations of two features: an object and its location.

Methods: 15 high-functioning children with ASD (Mean age: 13.0 years) and 16 typically developed (TD) children (Mean age: 12.4 years) participated in the study. Diagnoses were confirmed using ADI-R, and WISC-IV was used to measure verbal comprehension and working memory. Relational memory and memory for single features was examined by use of a computer-based paradigm inspired by Bowler et al. (2014). This paradigm included two tasks measuring memory for single features (objects or locations) and one task measuring memory for relational information (combinations of objects and locations). Each memory task consisted of a series of study-phases followed by corresponding test-phases, during which the participants were asked only to click on previously studied and recognised stimuli (objects, locations, or combinations of objects/locations). Perceptual style was measured using the Children's Embedded Figure Test (CEFT), in order to examine the relation between local processing style and a diminished ability to encode and recognise relational information.

Results: In the relational memory task, we found no between-group difference on how many correct and previously studied combinations of objects and locations the two groups were able to recognise. However, the children with ASD clicked on significantly more unstudied (incorrect) combinations of objects and locations than the TD group in this task. The groups performed equally well on the two single-feature memory tasks, which confirms previous findings of intact memory for single features in individuals with ASD. We did not find any group difference in degree of local processing style as measured with the CEFT, and processing style did not predict performance on the three memory tasks in any of the groups.

Conclusions: The ASD group gave significantly more incorrect answers in the relational memory task compared to the TD group, indicating that the children with ASD applied a less precise mnemonic strategy when solving this task. These findings represent important knowledge on altered basic memory processes in children with ASD. Difficulties in encoding and recognising relational information may affect these children's foundation for picking up and recalling new information, and may ultimately affect both social and non-social learning.

47 **164.047** Rhythm Perception in Music By Adolescents with Autism Spectrum Disorder

C. Rimmer[1], *H. Dahary*[1], *T. Fernandes*[2], *S. Sivathasan*[2] *and E. M. Quintin*[2], *(1)McGill University, Montreal, QC, Canada, (2)Educational & Counselling*

Psychology, McGill University, Montreal, QC, Canada

Background:

Individuals with Autism Spectrum Disorder (ASD) have demonstrated strength in perceiving musical stimuli, with most studies focusing on pitch and melody perception and memory (Heaton, 2009). Few studies have assessed musical rhythm perception of individuals with ASD (Lim, 2009; DePape, Hall, Tillmann, & Trainor, 2012) and found typical performance when processing and producing simple and complex rhythms, which seems associated with visual perceptual skills (DePape et al., 2012). However, rhythm perception has not been investigated in relation to ASD symptomology. Further, previous studies have focused on individuals with high cognitive functioning. Thus, the relationship between rhythm perception, ASD symptomology, and cognitive skills remains to be investigated across levels of functioning.

Objectives:

The purpose of this research is to assess whether ASD symptomology is related to musical rhythm perception and to examine the influence of varying levels of cognitive functioning on performance of a music rhythms task.

Methods:

Twenty-seven adolescents older than 12 years old with ASD and varying levels of cognitive functioning (WISC-V Visual Comprehension Index: 45-111; Visual Spatial Index: 57-144) completed a rhythms perception task: an adapted version of the Beat Alignment Test (Iversen & Patel, 2008). Participants listened to short musical excerpts with overlaid beeps (on or off the musical beat) and identified whether the beeps matched the musical beat. Performance was analysed by calculating Hits (number of correct responses for off beat trials/number of off beat trials) minus False Alarms (number of incorrect responses for on beat trials/ number of on beat trials) (HiFA as per Tillman, Schulze, & Foxton, 2009). Teachers completed the *Social Responsiveness Scale-2* (SRS-2, Constantino, 2012) questionnaire as a measure of ASD symptomology.

Results:

The participants' performance, based on HiFA, was significantly better than chance, $p<.01$. A regression analysis revealed that VSI but not VCI predicted task performance. Regression coefficients indicated that individuals with a lower VSI score performed the Beat Alignment Test less accurately than those with a higher VSI score, $p<.01$. A regression also showed that scores on the SRS-2 Social Motivation Scale predicted performance on the Beat Alignment Test, such that higher difficulties in social motivation resulted in less accurate performance, $p<.05$.

Conclusions:

Our results are consistent with previous findings showing preserved rhythm perception for individuals with ASD, and that this ability is related to visual spatial skills. Given previous reports of musical strengths, we suggest music intervention including a rhythmic component as a strength-based approach for this population. Our results support previous research showing that there is a perceptual association between auditory rhythm and visual spatial frequency in the typical population (Sherman, Grabowecky, & Suzuki, 2013). These results also suggest that music interventions should be approached differently when working with individuals with ASD that have varying symptomology and lower cognitive skills compared to those with higher cognitive skills, particularly in terms of visual spatial skills. The current findings could also help guide the development of music interventions that target cognitive functioning; for example improving rhythmic skills may be associated with improvement in visual spatial abilities.

48 **164.048** Study of Working Memory in Children with Autism Spectrum Disorders

A. M. Bartolini girardot[1], *C. Clarisse*[2], *M. Viellard*[2] *and F. Poinso*[3], *(1)Autism Resources Center, Marseille, France, (2)psychiatry, autism resources center, Marseille, France, (3)Autism Resource Center, Marseille, France*

Background:

Several studies describe an alteration of executive functions in children with ASD with consequences on their functioning. However, few research demonstrate a profile of working memory on both the auditory and visual side, and examines correlations with social and behavioral alterations.

Objectives: The purpose of our study is to reveal a profile of auditory and visual working memory in children with ASD. Then, to study the correlations between the working memory capacities and the alterations of communication, social interactions and adaptive behaviors

Methods:

The population of this research is composed of 27 children with Autism Spectrum Disorders. Patients were recruited from the « *Autism Resource Centre* » of Child Psychiatric Unit of Hospital in Marseille (France).The average chronological age of the group is 10 years and 4 months, the average cognitive level is 105. Children's parents were assessed with the ADI-R (Autism Diagnostic Interview Revised). The children were assessed with ADOS-2, the Vineland 2 and the WISC 5.

Results:

Comparative analyzes demonstrate a better visual working memory than auditory working memory. The profile of the auditory memory shows that the immediate auditory memory is the most efficient. The results show that the more auditory working memory has to mentalize information manipulation the less it performs.

The correlation analyzes reveal positive correlations between auditory and visual work memories and autonomy abilities in everyday life. There is also a positive correlation between immediate auditory memory and communication abnormalities. The results show negative correlations between visual working memory and anomalies in social interactions, and a negative correlation between mental manipulation abilities and behavioral abnormalities

Conclusions:

These results demonstrate a specific working memory profile in ASD with a visual memory more powerful than the auditory memory. In general, working memory seems to be particularly related to the autonomous capacities of everyday life. The results also show specific links between the type of working memory, the possibilities of adaptations and the anomalies of communication, social interactions and behavior.

49 **164.049** Supporting Eyewitness Testimony By Individuals with Autism through Witness-Directed Interviews

K. L. Maras[1], *C. Dando*[2], *S. B. Gaigg*[3], *H. J. Stephenson*[1] *and S. Anns*[4], *(1)Psychology, Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)Psychology, University of Westminster, London, United Kingdom, (3)City, University of London, London, United Kingdom,* *(4)Psychology, City, University of London, London, United Kingdom*

Background:

Adults with autism may be more likely to be interviewed in the criminal justice system as a witness, victim or a suspect, yet they also experience specific memory difficulties that can impact their ability to recall episodic information in a coherent, relevant and complete narrative. Previous research has shown that current police interviewing techniques are ineffective in supporting these difficulties to obtain detailed, accurate memory recall from them. We developed the 'Witness-Aimed First Account' (WAFA) interview specifically with the aim of supporting executive function, social demand, narrative and episodic memory difficulties in autism to improve the quality of their accounts within a legally appropriate, non-leading framework and without constraining recall. In contrast to current police interviewing techniques, where uninterrupted and unbound, parameter-free recall from the outset is the gold standard, WAFA was developed to diminish socio-cognitive demands by encouraging participants to generate and direct their own discrete, parameter-bound topics from the video in phase 1, before freely recalling information within each parameter-bound topic in turn in phase 2.

Objectives:

The primary aim of this research was to test this new method of interviewing (WAFA) for eliciting detailed, yet accurate, eyewitness accounts from individuals with autism. A second aim was to explore whether differences between autistic and typically developing (TD) witnesses' recall would be diminished when the narrative structure of the to-be-remembered event was lost (i.e., whether TD witnesses would appear more autistic in their recall, ameliorating the relative disadvantage by autistic participants).

Methods:

This study adopted a 2 (Group: Autism vs Typically Developing) x 2 (interview: WAFA vs. Control standard 'achieving best evidence' police interview) x 2 (Video: Scrambled vs. Unscrambled) mixed design, where Video was within participants. Specifically, participants were interviewed about their memory for two specially developed videos depicting criminal events. One video was 'scrambled' whereby clip segments were re-ordered, thus removing the narrative structure of the video; the other video was watched intact (the order in which videos were presented and whether video A or B was scrambled was counterbalanced between participants). Participants were interviewed using the same interview (WAFA vs. Control) for both videos. In WAFA interviews, rather than having a free flow verbalization of the entire event – which is difficult and inevitably results in underperformance by autistic adults – participants self-segmented their free narrative recollection right from the beginning. Once complete, they then revisited each of the self-directed free narrative topics in turn, in the order that they were recalled. Interviews were transcribed and coded according to the types of details recalled (e.g., persons, actions, surroundings, objects), completeness (i.e., number of correct details recalled), and accuracy (i.e., errors/all details recalled).

Results:

Data collection is still underway but preliminary results are promising. Although witnesses with autism recall fewer person and action details compared to TD witnesses overall, tentatively, WAFA interviews appear to ameliorate this difference, whilst also increasing the accuracy of autistic witnesses' accounts without compromising completeness.

Conclusions:

Witnesses with autism can make reliable witnesses if their socio-cognitive difficulties are supported appropriately at interview.

50 **164.050** Testing the Ecological Validity of Executive Function Assessment in Autism with a Novel 'Tea-Making' Task

***L. Kenny**[1], A. Remington[2] and E. Pellicano[3], (1)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland, (2)UCL Centre for Research in Autism and Education, London, United Kingdom, (3)Macquarie University, Sydney, Australia*

Background: People on the autism spectrum often struggle to achieve personal and occupational outcomes commensurate with their intellectual potential. One possible explanation for this mismatch could be difficulties with executive function (EF): a collective term for the higher-order cognitive skills that facilitate goal-directed behavior. Over 250 peer-reviewed papers have reported on EF assessments of autistic people but the findings have been markedly inconsistent. One criticism levelled at current EF assessment is that it lacks ecological validity. Indeed, research testing the ecological validity of these assessments in autism is severely limited and so it is unknown if the relationship between performance on neuropsychological EF tasks and everyday executively demanding tasks differs in autism compared with non-autistic people. Further, it is relatively unknown the extent to which current EF tasks are empirically related to the personal and occupational outcomes that have been so widely documented in autism.

Objectives: The current study sought to test the ecological validity of current neuropsychological EF assessment in autism in two ways. First, we tested the verisimilitude of EF by comparing the performance of autistic and non-autistic adolescents on two measures of EF: a battery of common EF tasks (National Institutes of Health (NIH) Examiner battery) and a novel, ecologically-valid 'tea-making' task. Second, we assessed the veridicality of EF by testing whether performance on the NIH battery was related to autistic participants' quality of life and level of disability.

Methods: Data collection is ongoing. Participants assessed so far include autistic (n=20) and non-autistic (n=19) adolescents, between 12 and 19 years, group-matched by age (*p*=.15) and IQ (*p*=.30). A composite EF variable was generated by the NIH battery. The tea-making task involved preparing food and materials for a group study session while a researcher rated the number of executive errors committed (e.g. boiling the kettle extra times, failing to adapt to a change in task instructions). Performance on both tasks was scaled and standardized such that higher scores were indicative of better EF ability. Parents also completed The Pediatric Quality of Life Inventory (PedsQL) and The World Health Organization Disability Assessment Schedule (WHODAS-2).

Results: A 2x2 repeated-measures ANOVA comparing group (autistic and non-autistic) and EF assessment type (NIH and 'tea-making' task) yielded a significant main effect of group, $F(1,36)=8.00$, $p=.008$, $\eta_p^2=.18$. Autistic participants showed, on average, more EF difficulties compared to non-autistic participants. There was, however, no main effect of EF assessment type, $F(1,37)=.001$, $p=.99$, $\eta_p^2<.001$ and no significant group x EF assessment type interaction, $F(1,37)=.29$, $p=.59$, $\eta_p^2=.008$. There were also no significant correlations between performance on the NIH battery and PedsQL, $r(16)=-.28$, $p=.26$ or WHODAS-2, $r(16)=.23$, $p=.36$, scores when age and IQ were controlled for among autistic participants.

Conclusions: Both the neuropsychological and ecological assessments of EF employed here were sensitive to group differences. This study demonstrated that, for autistic people, the verisimilitude of EF assessment is comparable with typical development. Yet, the absence of any relationship with parent reported quality of life or level of disability draws into question the veridicality of EF assessment in autism.

51 **164.051** The Ability to Retell a Story: Children with ASD in Comparison to Typical Development

Y. Kimhi[1,2]*, L. Kadosh*[2]*, G. Tubul-Lavy*[3] *and N. B. Bauminger-Zviely*[4]*, (1)Levinsky College of Education, Tel Aviv, Israel, (2)Bar Ilan University, Ramat Gan, Israel, (3)Ono Academic College, Kiryat Ono, Israel, (4)School of Education, Bar Ilan University, Ramat Gan, Israel*

Background:

Oral retelling is the restating of a text that was heard or read. Retelling demonstrates one's ability to identify relevant information of the previously heard (or read) text and integrate these ideas into a coherent narrative. Examining oral story retelling abilities enables delineating different levels of comprehension and is therefore an efficient strategy for discovering whether a child understands what he or she has heard or read. Impaired reading comprehension has been reported for children with ASD (Autism Spectrum Disorder) yet, research regarding oral retelling abilities in ASD is scarce.

Objectives:

1. To examine group differences (ASD/TD) in oral story retelling abilities (macrostructure and microstructure characteristics) in both channels (reading and listening).
2. To examine within group differences regarding oral story retelling abilities in the different channels (after reading / after listening).
3. Correlations between ToM and story retelling abilities.

Methods:

Participants included 40 third grade school-age children: 20 cognitively able children with ASD and 20 children with typical development. Groups were matched on SES, VIQ, CA and gender. VIQ was assessed by the PPVT-III (Dunn & Dunn, 1997). Story retelling was compared in two tasks: retelling following listening to the text and retelling following individual reading of the text. The Katzenberger Hebrew Language Assessment (KHLA; Katzenberger, 2016) was used to assess the children's ability to retell the story they read / listened to. The KHLA is a standardized in-depth norm-referenced test of language for children in the elementary school age range. Two major KHLA dimensions were measured: essential (equivalent to macrostructure) and optional (equivalent to microstructure) characteristics. ToM was assessed by two second-order false-belief tasks; (a) "The Ice Cream Van Task" (Perner & Wimmer, 1985); (b) ToM faux pas task (Baron-Cohen, O'Riordan, Stone, Jones, & Plaisted, 1999).

Results:

Main findings showed that cognitively able school-age children with ASD demonstrated difficulties in comparison to their typically developing peers when retelling the story that they read / listened to, only in relation to one aspect of the macrostructural essential components (relation between text events), and not for the microstructural optional components. No differences emerged between the channels (reading / listening) in both groups, and retelling the optional microstructure components was easier than retelling the macrostructural essential components in both groups. ToM scores were positively correlated with the macrostructural essential components.

Conclusions:

This study presents an in-depth examination of the macro (essential) and microstructure (optional) story retelling abilities of cognitively able children with ASD in comparison to their typically developing peers. The contribution of this study is two-fold: the assessment of the abilities in relation to the different channels – reading and listening, and the analysis of the relation between story retelling abilities and ToM. These findings are important when considering classroom accommodations and modifications. Story retelling is considered an effective literacy and language enhancement strategy, and therefore crucial for developing academic abilities. Considering the academic difficulties typical of children with ASD, all strategies that may advance these abilities are important to study and develop.

52 **164.052** The Development of EF and Its Relationships with Social Function and Behavior Problem in the Children with High-Functioning Autism Spectrum Disorder

P. Yeh[1]*, C. H. Chiang*[2] *and Y. A. Lin*[3]*, (1)Psychology, National Chengchi University, Taipei, Taiwan, (2)Department of Psychology, National Chengchi University, Taipei City, Taiwan, (3)Tri-Service General Hospital, Taipei, Taiwan*

Background: Individuals with autism spectrum disorder (ASD) have diverse deficits in executive and social functioning. This is difficult to identify the core impairments that cause their problems.

Objectives: The study aimed to examine different domains of executive functions (EF) with heterogeneity of high-functioning ASD (HFASD) in relations to their symptom severity, adaptive behavior and social problems.

Methods: seventy-four 7- to-10-year-old HFASD and 44 typically developing (TD) controls were measured three domains of EF tasks: working memory (i.e., Leiter-R and subtest of WISC-III), inhibition(i.e., subtest of NEPSY-III and Flanker task) and flexibility abilities (i.e., subtest of NEPSY-III). Parent-reported were also assessed for children's executive functions and self-regulations (BRIEF), social communication (i.e., SRS, RBS-R, SCQ) and adaptive behavior (i.e., CBCL, VABS).

Results: HFASD group had worse performance on all EF tasks compared to TD group, particularly for inhibition tasks, showed the largest group differences. When intelligence was considered, the HFASD with non-intelligence (non-IG-HFASD, 70<FIQ<115) were weak in inhibition and flexibility abilities than TD group. However, these comparisons were not obviously observed between HFASD with high-intelligence (IG-HFASD, FIQ>115) and TD groups. In addition, there are respective impairments on inventory-based EF scales in the IG-HFASD and Non-IG-HFASD participants. Regression analysis revealed the problems of inhibition and shift abilities can predict restricted and repetitive symptoms as well as internalizing (e.g. anxiety) and externalizing symptom (e.g. attack).

Conclusions: Children with HFASD having better inhibition abilities are likely to have more disturbance of internalizing problems. The specific patterns of deficits in execute functions related to social behavior can be observed for HFASD with and without high-intelligence. The results highlight the uniqueness and universality of executive functions interpret heterogeneity in the cognitive profiles of children with HFASD, implying the possibilities for early intervention.

53 **164.053** The Dual Process Theory of Autism, Systemizing and Formal Logical Reasoning.

C. Singleton[1]*, C. Ashwin*[2] *and M. Brosnan*[3]*, (1)University of Bath, Bath, United Kingdom, (2)University of Bath, Bath, United Kingdom of Great Britain* *and Northern Ireland, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background:

Autism Spectrum Disorder (ASD) has been characterised by a drive or bias towards deliberative, systematic processing relative to intuitive, social-emotional processing – the opposing bias typically being seen in the general population. Two cognitive theories provide a framework for considering relatively preserved or enhanced logical reasoning in people with ASD and people from the general population with high levels of autistic-like traits. Hyper-systemizing accounts, propose these groups are high in systemizing, which is characterized by a drive towards understanding and predicting rule-based systems. The Dual Process Theory of Autism on the other hand, proposes that autistic people and people high in autistic-like traits bias towards deliberative processing, which is characterised as slow, effortful, sequential, conscious processing that is heavily dependent on working memory and related to individual differences in general cognitive ability. This is contrasted with a bias away from intuitive processing which is characterised as autonomous processing which is typically rapid, effortless, parallel, and non-conscious, that is independent of working memory and cognitive ability. Sex differences have been reported inconsistently in these capabilities.

Objectives:

To identify sex differences in, and correlates of, self-reported systemizing, deliberation and intuition with a behavioural assessment of logical thinking in a general population sample.

Methods:

104 participants (52 male, 52 female, ages 18-66, mean 22, sd 6) from the general population completed an online assessment comprising the Systemizing Quotient-short (SQ) to measure self-reported drive to systemize and the Rational Experiential Inventory to measure self-reported deliberative and intuitive reasoning ability and engagement. The Test of Logical Thinking (TOLT) was then undertaken to behaviourally measure formal reasoning ability.

Results:

There were significant sex differences, with males scoring higher, in SQ (t=4.88, p<.001), deliberative ability (t=2.02, p<.05) and deliberative engagement (t=2.34, p<.05). There were no significant sex differences in intuitive reasoning ability and engagement or on the TOLT. A partial correlation (controlling for sex) identified that TOLT significantly correlated with deliberative ability (r=.26, P<.01) and deliberative engagement (r=.25, p<.05) but not the SQ nor intuitive ability or engagement. The SQ significantly correlated with deliberative ability (r=.36, p<.001) and deliberative engagement (r=.45, p<.001) but not intuitive ability or engagement. There were no significant correlates of age.

Conclusions:

In a general population sample, those who self-report a higher levels of deliberative ability and engagement also perform better on a test of logic and formal reasoning ability. This is consistent with the Dual Process Theory of Autism. Self-reported systemizing did not correlate with the test of logic and formal reasoning ability. The SQ has been characterised as assessing systemizing drive, which is higher in autism, as is deliberation. Consistent with this, the strongest correlation was between SQ and deliberative engagement. Sex differences were identified in self-reported deliberative ability and engagement, but were not reflected in actual performance. It may be, therefore, that self-assessments of such capabilities are vulnerable to response biases in the general population. The Dual Process Theory of Autism proposes autism is also associated with reduced intuition, suggesting this bias would not be evident in autism.

54 **164.054** The Effects of Stimulus Complexity and Social Realism on Emotion Recognition in Children with ASD.

***T. Hutchins**, UVM, Burlington, VT*

Background: The use of visual supports is a common strategy for facilitating social cognition and the understanding of emotions in children with autism spectrum disorder (ASD). Yet, while the processing of visual information is considered a relative strength in ASD, the deficits in processing social information are well-documented. Furthermore, very little is known about the stimulus characteristics that support (or impede) the understanding of social imagery. The purpose of this study was to examine the effect of stimulus complexity and social realism on emotion recognition in ASD and typical development.

Objectives: This study compared the ability of typically developing (TD) children and children with ASD (ages 6 – 12 years) to identify emotions (happy, sad, mad, scared, disgust, surprise) when presented with face stimuli that systematically varied in complexity (i.e., the amount of detail and the intricacy of the lines, patterns, and colors in the image) and social realism (i.e., how realistic an image). Our exploratory research questions were:

1) Is there a difference between TD and ASD groups in the ability to identify emotions when complexity and social realism vary?

2) Which stimulus characteristics predict better emotion recognition for each group?

Methods: Nineteen TD children and 18 age- and gender-matched children with ASD participated. Children viewed face stimuli (presented in counterbalanced order) on a video monitor. Face stimuli were carefully manipulated using photoshop to make incremental adjustments in stimulus complexity and social realism: two levels (low, high) for each dimension were developed using a 2x2 approach. Each image was presented for 4 seconds and children were asked to “tell me what emotion you see”.

Results: Data for each emotion were submitted to six 2 (group) x 2 (social realism) X 2 (complexity) mixed model ANOVAs. A main effect of social realism was found such that higher social realism was associated with more accurate emotion recognition. When verbal ability was controlled, this main effect disappeared. A group X emotion interaction approached significance for ‘mad’ faces such that the ASD group performed best under conditions of low realism and the TD group continued to perform best under conditions of high realism.

Conclusions: Better performance by both groups in conditions of high social realism could be explained by higher ecological validity. Alternatively, our ‘social realism’ condition may actually have captured ‘prototypicality’ or how well an image represents its category. Although the ability to extract prototypes is thought to be disrupted in ASD, some researchers have argued that it is not the ability to extract the prototype but to apply it flexibly. Thus, both the ASD and TD samples may have experienced an emotion recognition advantage under conditions of higher prototypicality in this experiment. Finally, ‘mad’ faces may be particularly dependent on configural processing and there is an atypical tendency in ASD toward part- rather than whole-processing.

55 **164.055** Which Visual Supports Work Best? an Examination of Visual Attention to Photograph and Cartoon Stimuli in Children with ASD.

T. Hutchins[1] *and C. Sedeyn*[2]*, (1)UVM, Burlington, VT, (2)Center for Childhood Communication, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: The use of visual supports is a common strategy for facilitating receptive language, enhancing communication, and increasing appropriate behaviors among children with autism spectrum disorder (ASD). At the same time, ASD is often accompanied by atypical visual attention to social stimuli. Specifically, several studies have documented an atypical tendency in ASD to look more at the mouth region of the face at the expense of the eye region of the face. To complicate matters, some researchers have argued that children with ASD demonstrate strengths when processing visual information from cartoons, whereas others have argued that photographic stimuli confer benefits.

Objectives: This study used eye tracking to assess children's visual attention when presented with Social Stories that employed either photographs or BoardMaker (BM) images. Social Stories were chosen (as were these two stimulus types) because they represent one of the most popular interventions in ASD and, hence, have great ecological validity. Our exploratory research questions were:

1) Is there a difference between TD children and children with ASD in how they attend to faces (i.e., eye region, mouth region, and background regions of a scene) in BM and photographic stimuli in the context of a Social Story?

2) Do group differences in visual attention to stimuli correlate with age, autism severity, executive function (attention shifting), intellectual functioning, or weak central coherence?

Methods: Nineteen TD children and 18 age- and gender-matched children with ASD participated. Children viewed two Social Stories (presented in counterbalanced order) on a eye tracking screen-capture monitor. The stories were identical with the exception that one used photographs and one used BM images. The BM and photograph stimuli were carefully controlled so that the images were as similar as possible with regard to semantic content, size, color, and orientation of people and objects. Each 'page' of the Social Story was presented for 4 seconds and the number of fixations and fixation time were assessed for eye, mouth, and 'other' (background) areas of interest.

Results: With one exception, we found no differences between groups when viewing images of faces. The exception involved one instance in which the image represented a person’s full body as well as a range of objects (i.e., the other scenes depicted only faces). For this more complex scene, an interaction was observed such that the TD and ASD groups were no different in their looking patterns in the BM condition but they were different in the photograph condition. Moreover, we found that in ASD, a shift toward more mouth-looking in the photograph condition was negatively associated with attention shifting and verbal IQ and that a shift toward more background-looking was negatively associated with attention shifting, age, and central coherence.

Conclusions: Children with ASD demonstrate typical visual attention patterns to both BM and photographic stimuli representing faces but children with ASD employ an atypical scanning strategy when presented with photographic stimuli representing more complex social scenes. Professionals should consider the potential benefits of simple, cartoon-like imagery when presenting complex images in the conduct of intervention.

56 **164.056** The Influence of Genes and Environments on the Gap-Overlap Task

M. Siqueiros Sanchez[1]*, D. P. Kennedy*[2]*, E. Pettersson*[3]*, S. Bolte*[4]*, B. D'Onofrio*[2]*, P. Lichtenstein*[5] *and T. Falck-Ytter*[6]*, (1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Institutionen för kvinnors och barns hälsa (KBH), Karolinska Institutet, Stockholm, Sweden, (2)Psychological and Brain Sciences, Indiana University, Bloomington, IN, (3)Department of Medical Epidemiology and Biostatistics (MEB), Karolinska Institutet, Stockholm, Sweden, (4)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (5)Karolinska Institutet, Stockholm, Sweden, (6)Karolinska Institutet & Uppsala University, Uppsala, Sweden*

Background: Atypicalities in attention are often found in neurodevelopmental disorders, including autism. The “gap-overlap task” is an eye-tracking paradigm that assesses the ability to disengage attention from a stimulus and orient toward a new one (visual disengagement). Although related, visual disengagement is thought to be a distinguishable construct from basic oculomotor control. Support for this thesis mostly comes from animal studies and a few small studies in humans using electroencephalogram (Csibra, Johnson, & Tucker, 1997). By studying the degree of genetic and environmental influences to individual differences in the gap-overlap task, we can assess if visual disengagement is an etiologically distinct construct. This can be done with multivariate analysis of twin data, which allows for establishing the relative influence of shared versus unique contributions of genes and environments to the measure.

Objectives: To study genetic and environmental influences on the gap-overlap task.

Methods: Classical twin design. The sample consisted of 492 twins (120 monozygotic pairs; 126 dizygotic pairs) from the general population, ranging in age from 9-14 years, recruited from the Child and Adolescent Twin Study in Sweden (CATSS). The gap-overlap task was performed using a Tobii T120 eye tracker. In this task a central stimulus (CS) appears on a screen and is followed by a new stimulus that appears on the periphery (PS). The task has three conditions: (1) “The gap” where the CS disappears before the PS appears, (2) “The baseline” where the CS disappears simultaneously as the PS appears, (3) “The overlap” where the CS remains on screen when the PS appears. The dependent variable was the median saccadic latency of gaze arrival at the PS. Multivariate twin modelling was used to analyze the genetic and environmental contributions to the variances and covariance among saccadic latencies.

Results: A common pathway model provided the best fit for the data. The covariance between the conditions was best explained by one shared factor with a primarily genetic background (63%). Significant unique genetic effects were found for the baseline (17%) and the overlap (15%) conditions, but not for the gap condition. Shared environment did not influence the experimental conditions (neither common nor unique).

Conclusions: Performance in the gap-overlap paradigm is primarily influenced by genetic effects, most of which are shared between the three conditions. This is expected since all conditions engage basic oculomotor functions (shifting the gaze from one stimuli to another). We found unique genetic effects in the overlap condition, which is in line with the view that this condition captures a distinct attentional function in addition to oculomotor control. We found no unique genetic effects in the gap condition. Surprisingly, we found unique genetic effects in the baseline condition, suggesting that it may be problematic to operationalize “the disengagement effect” as the difference between the overlap and the baseline conditions (resulting in a less clean comparison due to different genetic factors influencing each condition), as it sometimes done, at this age. This study illustrates how twin studies can enrich our understanding of experimental measures frequently used in autism research.

57 **164.057** The Modality Shift Effect in Autism: Exploring Speed Accuracy Trade-Off and the Time Course of Crossmodal Switching.

D. Poole[1], *E. Gowen*[2] *and E. Poliakoff*[2], *(1)Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (2)Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom*

Background: Previous research in neurotypicals (NTs) has shown that people can selectively attend to a sensory modality (vision, touch, hearing). This is reflected in switch costs during experimental tasks in which participants typically respond more slowly and less accurately to a target stimulus preceded by a stimulus in a different modality (crossmodal) relative to a target preceded by a stimulus in the same modality (ipsimodal). There are findings suggesting that shifts in attention between visual and auditory information are less effective in autism, reflected in increased switch costs compared with NTs (Courchesne et al., 1994; Williams, Goldstein, & Minshew, 2013). There are also contradictory findings suggesting audio-visual switch costs are comparable to NTs (Haigh et al., 2016; Murphy, Foxe, Peters, & Molholm, 2014).
Objectives: This study investigated automatic crossmodal switching between visual, tactile and auditory targets in autism for the first time. The time course of crossmodal switching was investigated; we expected that participants with autism would not show a reduction in switch costs with increased duration between the targets based on previous evidence of impaired disengagement of attention. We also sought to characterise any differences in speed- accuracy trade-offs during crossmodal switching using Drift Diffusion modelling (Ratcliff and Mc Koon, 2008).

Methods: Autistic adults (n =24) and NT controls (n = 24) matched for age, IQ, gender and handedness completed a speeded discrimination task (pulsed vs continuous) to visual, tactile and auditory targets. Targets were separated by 1,000, 1,250 or 2,000ms inter trial intervals (ITIs). For each target, reaction times were compared for ipsimodal and crossmodal trials across the three ITIs. The EZ diffusion model (Wagenmakers, van der Maas, & Grasman, 2007) was used to extract estimates of drift rate (quality of information extracted from the target), boundary separation (response conservativeness) and non-decision time (time taken to encode the target and prepare a response).

Results: Clear switch costs were observed in the reaction time data for each target modality, but did not differ between the groups. Against our expectations, switch costs were not reduced with increasing ITI for either group. For visual and auditory targets, switch costs were apparent in increased drift rates and reduced non-decision time. For visual targets, participants with ASC exhibited an increased boundary separation. Furthermore, participants with ASC required longer non-decision times when responding to tactile targets preceded by auditory.

Conclusions: Switch costs did not statistically differ between the groups and were not reduced with increased ITI. The importance of considering speed accuracy trade-offs in ASC was highlighted by differences in diffusion model parameters. In particular, the increased non-decision time when switching from auditory to tactile information suggests that the interaction between these sensory modalities may be affected in ASC and warrants further investigation.

58 **164.058** Time Perception and Autistic Spectrum Condition: A Systematic Review

D. Poole[1], *M. Casassus*[2], *E. Poliakoff*[2], *E. Gowen*[2] *and L. Jones*[2], *(1)Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (2)Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom*

Background: Problems with timing and time perception have been suggested as key characteristics of Autism Spectrum Condition (ASC). Studies and personal accounts from clinicians, parents, caregivers and self-reports from autistic people themselves often refer to problems with time. Although a number of empirical studies have examined aspects relating to time in autistic individuals, there remains no clear consensus on whether or how timing mechanisms may be affected in ASC.
Objectives: A systematic review was conducted in an attempt to summarise the extant literature. This review considered a wider range of timing behaviours than previous reviews (e.g. Allman and Falter, 2015; Stevenson, et al. 2015). We also incorporated more information from the theories and cognitive models of timing developed in neurotypicals (NTs).

Methods: In March 2017, five databases were consulted. From an initial 597 records, 45 were selected and reviewed. These studies were organised according to different timing abilities tested: time sensitivity (the ability to discriminate stimuli based on temporal characteristics), perception of duration and higher-order time perception (referring to the capacity to think about time as a concept, where events take place within it, and the ability to be aware of one place in time and plan for events in the future).

Results: There was a tendency for studies in timing sensitivity to display differences in children, whereas adult performance was comparable to NTs. This may suggest at a developmental delay in time sensitivity in ASC. However, in many studies it is not possible to determine whether differences are the result of a true timing deficit, or instead reflect differences in decision criterion or in the attention to socially relevant stimuli. Perception of duration studies have also generated mixed findings, but studies which investigated memory effects on timing performance have highlighted divergent performance from NTs. To date, the few studies that have investigated higher order timing in ASC (e.g. concepts of time) have consistently observed differences from NT performance.

Conclusions: It remains unclear whether there is a timing deficit in ASC. Divergent performance on timing tasks could reflect differences in cognitive mechanisms unrelated to timing in ASC. Additionally, studies have tended to involve varied methods and sample characteristics which likely contribute to the heterogeneity of findings. A proposed schedule of work to address these issues will be presented.

59 **164.059** The Role of Attention in Maths and Reading Achievement for Children with and without an Autism Spectrum Disorder

M. Hanley[1], ***E. McDougal***[2] *and D. M. Riby*[3], *(1)South Road, Durham University, Durham, United Kingdom of Great Britain and Northern Ireland, (2)Psychology, Durham University, Durham, United Kingdom of Great Britain and Northern Ireland, (3)Department of Psychology, Durham University, Durham, United Kingdom*

Background:
Attention abilities provide the gateway for learning in all domains, including reading and maths. Although not a core feature of Autism Spectrum Disorder (ASD), attention atypicalities have been well-documented (Ames & Fletcher-Watson, 2010). However, little research has investigated the role of attentional atypicalities in academic achievement in ASD.

Objectives:

The purpose of this study was to (1) investigate the role of attention in maths and reading achievement for children with and without ASD, and (2) to characterise profiles of academic achievement in relation to attention in children with and without ASD.

Methods:

Twenty-seven children with ASD aged between 6 and 16 years (M = 10.75) and 61 typically developing children aged between 6 and 11 years (M = 8.94) completed standardised assessments, including the Wechsler Abbreviated Scale of Intelligence-II (WASI-II), the Test of Everyday Attention for Children (TEA-Ch), and the Wechsler Individual Attainment Test-II (WIAT-II), providing measures of FSIQ, selective, sustained, and divided attention, and reading and maths achievement.

Results:

Correlational analyses showed that attention abilities were related to reading and maths achievement, but differently for children with and without autism. For typically developing children, sustained attention was related to reading achievement (r = .216, p = .05), but for children with autism divided attention was related to both reading (r = .591, p = .002) and maths achievement (r = .729, p < .001). A hierarchical cluster analysis was performed to examine whether there were sub-groups within the data reflecting different profiles of achievement relating to attention. This produced a three-cluster solution that grouped children according to ability – a group with good divided attention and good reading/maths achievement; average divided attention and average reading/maths achievement; and poor divided attention with correspondingly poor reading and maths achievement. Seventy nine per cent of children in the poor achievement group were children with autism. Inspection of the profile of this group indicated that although FSIQ was in the average range (M = 86) as was reading achievement (M = 81), these children appeared to have a relative weakness with maths achievement (M = 73).

Conclusions:

Overall, the results highlight that attention abilities are important for academic achievement. The findings suggest that the ability to divide attention between two tasks (in this case, auditory and visual) may be more important than sustained or selective attention skills for academic achievement. They also show that divided attention may be particularly important for children with autism in relation to maths achievement. Identifying attention skills important for achievement in different domains can help with future interventions. Further exploration is needed in a real world context, using real-time measures of attention and learning, to gain a deeper understanding of how attention abilities support or constrain learning and achievement.

164.060 The Role of Prior Knowledge in Perceptual Inference Is Preserved in Autism Spectrum Disorder

J. Van Overwalle[1,2]*, S. Vanmarcke*[1,2]*, I. Van de Put*[1]*, J. Wagemans*[1,2] *and S. Van de Cruys*[1,2]*, (1)Laboratory of Experimental Psychology, Brain & Cognition, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium*

Background:

Several researchers have exploited the Bayesian framework to propose an imbalance between bottom-up (sensory) and top-down (prior) information processing in Autism Spectrum Disorder (ASD). One recent Bayesian account about ASD is the ‘weak priors’ hypothesis. This hypothesis can be traced back to principles of older perceptual theories about ASD (Enhanced Perceptual Functioning and Weak Central Coherence), suggesting that perception of individuals with ASD is more determined by sensory input instead of by prior knowledge. However, studies empirically testing the ‘weak priors’ theory have generated contradictory results and alternative accounts of ASD exist that do not assume impaired acquisition of prior knowledge per se.

Objectives:

Here we aim to provide clear evidence for or against the ‘weak priors’ hypothesis by obtaining a distinct measurement of prior knowledge using Mooney images. On first viewing, Mooney images are experienced as meaningless black and white patches. After exposure to the source image however, prior knowledge causes the patches to (re)organize and be perceived as a meaningful whole. Hence, we can investigate the role of priors in Typically Developing (TD) individuals varying in ASD-like traits (study 1) and ASD individuals (study 2) by looking at improvements in recognition accuracy for Mooney images, before and after exposure to their source image.

Methods:

In the first study, 282 TD individuals (40 males, mean age 18.6 ± 1.91) performed the experiment and the Autism-Spectrum Quotient (AQ) questionnaire. In the second study, the experiment was completed by 23 adolescents with ASD (19 males, mean age 14.04 ± 1.49) and 24 matched TD individuals (20 males, mean age = 14.38 ± 1.28). The experiment in both studies consisted of six experimental blocks, each made up by three phases of 10 trials (10 different Mooney images). In the first phase, participants were asked to identify the object in the Mooney images (open response). Then the source images were presented in random order. After this exposure phase participants were presented with the same Mooney images as in the first phase and again had to try to recognize the image.

Results:

Participants of the first study had an average AQ score of 17.73 (range of 3-43), comparable with other studies, but there was no difference between the accuracy data of individuals with lower and higher AQ. Results of the second study also showed no difference between the accuracy data of TD and ASD individuals. GLMM analyses confirmed both findings.

Conclusions:

Our findings consistently did not support a difference in the impact of prior knowledge in perception, as a function of varying ASD-like traits or a clinical ASD diagnosis. These findings, thus, suggest that the fast formation and application of priors is preserved in ASD and go against the ‘weak priors’ hypothesis. Earlier studies reporting an intact use of priors in ASD are consistent with this result, while other studies do claim to have found evidence for weaker priors in ASD. Future research will have to systematically evaluate the differences in settings and priors concerned.

61

164.061 The Self-Reference Effect on Perception: Undiminished in Adults with Autism and No Relation to Autism Traits.

D. M. Williams[1]*, C. Grainger*[2] *and T. Nicholson*[3]*, (1)University of Kent, Canterbury, United Kingdom, (2)Stirling, Edinburgh, United Kingdom, (3)University of Kent, Canterbury, England, United Kingdom*

Background: It is widely agreed that the self plays an important role in human cognition and perception, exerting influence across a range of domains and situations. The clearest empirical demonstration of this influence is the "self-reference effect" (SRE; Rogers et al., 1977), whereby information encoded in relation to the self has a mnemonic advantage over information encoded in other ways. This effect is apparent in a number of different paradigms and across different domains of processing. This SRE in *memory* appears diminished in ASD and related to the number of ASD traits manifested by neurotypical individuals (the fewer ASD traits, the larger the SRE). Here, we report the first experiments exploring the relation between ASD and the SRE in *perception*.
Objectives: To investigate the role of self-reference on perception in ASD.

Methods: Using a "Shapes" Task (Sui et al., 2012), participants learned to associate three different shapes (triangle, circle, square) with three different labels representing self, a familiar other, or an unfamiliar other (e.g., "you", "mother", "stranger"). Participants then completed trials during which they were presented with one shape and one label for 100ms, and made judgements about whether each shape-label pairing matched the learned contingency. Participants also completed measures of mentalizing (Reading the Mind in the Eyes and Animations tasks) and ASD traits/severity (Autism-spectrum Quotient). Bayesian analyses were employed to complement null hypothesis significance testing ($BF_{10} < 1$ = evidence for the null; $BF_{10} > 3$ = evidence for the alternative hypothesis).

Results: In Experiment 1, neurotypical participants (*n*=124) showed the expected SRE, detecting self-related matches more reliably and quickly than matches involving the familiar or unfamiliar other (all *p*s<.001, *d*s>0.97, BF_{10}>100). Most important, number of ASD traits was unrelated to the size of the SRE for either accuracy or RT (all *r*s <.10, *p*s >.27, BF_{10} <0.21). Hence, Bayesian association analyses strongly supported the null hypothesis. In Experiment 2, there were no differences between 22 adults with ASD and 21 age-, sex, and IQ-matched comparison adults in performance on the Shapes Task (see Figure 2). Despite showing large and significant mentalizing impairments (all *p*s <.01, *d*s >0.80, BF_{10} >23.00), participants with ASD showed the typical SRE for accuracy and RT, and there were no between-group differences in this respect (*p*s >.66, *d*s <0.13, BF_{10} <0.33). Moreover, there were no associations with ASD traits (measured using AQ or ADOS) in either group. Bayesian analyses favoured the null hypothesis.

Conclusions: These findings suggest that self-representation influences perception in a normal way in ASD. Considered alongside previous findings, the current results are relevant for theories about self-representation in ASD. Our interpretation is that first-order representations of self are typical in ASD and available to *bias* perception/cognition in a typical manner, contrary to the "experiencing-I" theory espoused by Millward et al. (2000). In contrast, we suggest that second-order (meta-) representations of self are impoverished among people with ASD (in keeping with the "absent self" theory; Frith, 2003), which leads to a diminished SRE on tasks that require reflections on/evaluations of self.

62 **164.062** The Use of Rewards at Home in Children with Autism Spectrum Disorders: A Parent Survey

A. Lambrechts[1], *E. Alonso*[2], *J. Cook*[3], *E. A. Ludvig*[4] *and S. B. Gaigg*[5], *(1)City, University of London, London, United Kingdom of Great Britain and Northern Ireland, (2)School of Mathematics, Computer Science & Engineering, Department of Computer Science, City, University of London, London, United Kingdom, (3)School of Psychology, University of Birmingham, Birmingham, United Kingdom, (4)Psychology, University of Warwick, Warwick, United Kingdom, (5)City, University of London, London, United Kingdom*

Background: Rewards act as a motivator for positive behaviour and learning. Although rewards are widely used in various settings and programmes with children with Autism Spectrum Disorder (ASD), it is unclear whether the same kinds of rewards are effective for children with and without ASD, in particular those children with complex needs.
Objectives: We investigated which rewards parents of ASD children use at home compared to parents of Typically Developing (TD) children and how effective they are.

Methods: In the context of a larger project on reward processing in autism, the parents of 33 ASD (age 4-15) and 22 TD children (age 5-8) completed a survey about 1) the tokens and activities they used as rewards at home 2) the toys, objects and activities that their children generally enjoy. For each item endorsed, parents also rated how enjoyable they were for their children on a 1(little) to 5(very) scale. Items included tokens (gold stars, stickers), snacks, sensory toys and activities (sand, water play), toys and activities with a social feature (action figures and dolls, seeing a friend), time for watching TV or playing on the computer, social rewards (praising, high fives, cuddles), sports and outdoors activities (playground, swimming), etc.

Results: First, there was no difference in the average number of items endorsed by parents of TD and ASD children overall. There were however differences in the individual items endorsed in each group. Using praise as a reward was endorsed by more parents of TD than ASD children (TD: 100%, ASD: 73%, p=.002) and praising was rated twice as rewarding for TD than for ASD children (TD: 4.3/5, ASD: 2.5/5, p=.001). More parents of TD children reported action figures and dolls (TD: 82%, ASD: 18%, p<.001), stuffed animals (TD: 73%, ASD: 27%, p=.001), books (TD: 91%, ASD: 45%, p<.001) and drawing and painting (TD: 82%, ASD: 39%, p=.001) to be enjoyable compared to parents of ASD children. Action figures and dolls (TD: 2.9/5, ASD: 0.5/5, p<.001) and stuffed animals (TD: 2.8/5, ASD: 0.8/5, p<.001) were also rated as more rewarding for TD than ASD children.

Conclusions: Overall many items were endorsed as rewarding by parents of TD and ASD children equally. Praise however was used by fewer parents of children with ASD and rated as less rewarding by those who used it compared to parents of TD children. In the context of education, it might be good to substitute praise for other rewards such as smiling or high fives which might be more accessible and rewarding for ASD children. In line with previous literature, action figures and dolls which elicit symbolic play were deemed rewarding by fewer parents of ASD than TD children. Perhaps less expectedly, stuffed animals, books and drawing and painting were reported to be enjoyable by fewer parents of ASD than TD children. It might be important to consider the roles these toys and activities support beyond reward (e.g. comfort, learning, shared interaction, artistic development) to offer appropriate substitutes to children with ASD (e.g. sensory toy, tablet, music).

63 **164.063** Thinking in Black-and-White: Adults with High Autistic Traits Sharpen Vague Predicates

T. Loucas, *G. Baddeley, E. N. Carter and L. Mellor, University of Reading, Reading, United Kingdom*

Background: Thinking in autism spectrum disorders shows atypical cognitive flexibility and processing of local information independently of context. Recent evidence suggests that decision-making is also atypical, being more consistent and conventionally rational in adults with ASD and non-ASD controls with high autistic traits (Farmer et al., 2017). There does not appear to be any investigation of black-and-white, logical thinking that is reported clinically in ASD. Vagueness, a property of natural language, may provide a window on logical thinking. Vague predicates (e.g.,

"tall") admit borderline cases; those where it is not clear whether the predicate applies. Thus, the truth of a statement like "X is tall" is indeterminant. This contrasts with sharp predicates where classical bivalent logic applies. Truth-gap theories are a suggested solution to this problem, which minimise the divergence from classical logic. Alxatib and Pelletier (2011) (AP) found evidence for gap theories in a truth-judgment task. They argued that if the predicate "tall" was sharp, rather than vague, participants would be equally likely to accept '"X is tall" is True' as to reject '"X is not tall" is False'. However, they found participants were more likely to accept the statement '"X is tall" is False' than reject '"X is not tall" is True', which is consistent with the presence of a truth-gap.
Objectives: If black-and-white thinking is characteristic of ASD, the indeterminacy of vague predicates may be problematic. We investigated if individuals with high autistic traits may, therefore, treat vague concepts as sharp, implying a rejection of any divergence from the classical bivalent logical paradigm.

Methods: Participants recruited via social media participated in an online experiment, including the adult Autism Spectrum Quotient and AP's truth-judgment task. They were presented with a drawing of a police line-up showing five men, ranging in height from 5'4" to 6'6", with 5'11" as a borderline case. They responded "True", "False" or "Can't tell" to a series of statements (e.g., "#1 is tall"; "#1 is not tall") about each man, presented in random order.

Results: Data from 121 participants (median age = 27 (range = 18-80) years; Male = 26, Female = 95) were analysed. A median split of AQ score (median = 12 (range = 2-33)) was used to create low (N = 63) and high (N = 58) autistic traits groups. Cochran's Q tests were run to compare the frequency of truth judgments to "#x is tall" and "#x is not tall" statements in the low AQ and high AQ groups. For the critical borderline case, the low AQ group were more likely to reject the statement '"#2 is tall" (i.e., judge it False) than accept the statement "#2 is not tall" (i.e., judge it True) (Q(1) = 8.33, p = .004). This was not the case for the high AQ group (Q(1) = 1.00 , p = .317).

Conclusions: Participants with high autistic traits, in contrast to those with low autistic traits, treated vague concepts as sharp, appearing to reject any divergence from the classical bivalent logic.

64 **164.064** Towards a Clarification of Attention to Faces in Atypical Development: Sustained Attention to the Face Is Task-Dependent in Autism Spectrum Disorder

T. Del Bianco[1], *I. Landi*[1,2], *N. Mazzoni*[1], *A. Bentenuto*[1], *I. Basadonne*[1] *and P. Venuti*[1], *(1)Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)Bruno Kessler Foundation, Trento, Italy*

Background: Humans present a strong face-orienting response and a visual preference for faces from birth. Consistent evidence indicates that defective attention to faces and other humans characterizes Autism Spectrum Disorder (ASD).
Objectives: In our eye-tracking study, we aimed to investigate the face-orienting response and the subsequent attentive selection, by analysing the proportion of first looks to the face and the sustained attention to faces, in a group with atypical and typical development.

Methods: 20 young adults with ASD (mean age: 22.1, standard deviation: 3.8; mean IQ: 118, standard deviation: 10) and 24 young adults with typical development (mean age: 22.4, standard deviation: 3; mean IQ: 122.4, standard deviation: 8.1) participated our eye-tracking study. Each participant received three types of instructions in random order at the beginning of each trial, and watched scenes of a social interaction between three actors on the eye-tracker screen. The instructions identified three experimental conditions: free-viewing (FV), visual-search (VS) - where participants were asked to find an object - and gaze-reading (GR) - where participants were asked to identify which actor was paying attention to the conversation. We analysed and compared the Proportion of First looks from the centre to the face and the Proportional Looking Time to faces in the two groups.

Results: We found that the Proportional Looking Time to faces differed across groups (FV: W = 87, p-value < 0.001; VS: W = 36, p-value < 0.001; GR: W = 113, p-value = 0.002), with minor proportion in the ASD group in all conditions. Furthermore, Proportional Looking Time to faces was task-dependent in the ASD group only, with maximum proportion in the GR and minimum proportion in the VS condition (FV vs VS: W = 157, p-value = 0.002, FV vs GR: W = 13, p-value < 0.001, VS vs GR: W = 13, p-value < 0.001). The same measure did not significantly vary across conditions in the typical group. The face-orienting tendency was above chance in all groups and did not differ across groups and conditions.

Conclusions: Participants with ASD varied the time allocated to faces in a social scene depending on the instruction. This result cannot be explained by a lack of an initial bias to orient to the face, since the face-orienting tendency was similar in the ASD and the control group. We interpret the results with a possible delayed disengagement of attention from the item that the task-at-hand explicitly emphasized in the scene. Our finding suggests that persons with ASD may end disregarding relevant environmental stimuli, when their attention is explicitly directed to a specific element.

65 **164.065** Using the NIH Toolbox Cognition Battery to Characterize the Cognitive Profile of Children with Autism

D. R. Jones[1], *A. R. Dallman*[2], *C. Harrop*[2] *and B. A. Boyd*[3], *(1)University of Texas at Dallas, Richardson, TX, (2)University of North Carolina at Chapel Hill, Chapel Hill, NC, (3)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

Background: The NIH Toolbox Cognition Battery (NIH-TCB) is a clinically validated set of digital assessments for the assessment of several cognitive domains. While preliminary studies have implemented this measure in Intellectual Disability (ID), Fragile X syndrome, and Down syndrome (Hessl et al., 2016), to our knowledge, it has not been tested on children with autism spectrum disorder (ASD). Children with ASD are believed to possess an altered cognitive profile compared to typically developing children, characterized by executive dysfunction in several areas, including speed of processing, attention shifting, and cognitive flexibility, as well as increased detail orientation (Kenworthy et al., 2008).
Objectives: This study details preliminary data using the NIH-TCB to assess the cognitive domains of cognitive flexibility, processing speed, and attention shifting in children with and without ASD.

Methods: ASD children ages 3-17 and typically developing (TD) children matched on age are currently being recruited. This abstract details data from 18 children and adolescents with ASD (mean age = 9.4 years; SD = 3.9) and 14 TD controls (mean age = 7.1 years; SD = 2.8). TD children demonstrated a significantly higher IQ (mean IQ = 117.4; p=.01) than ASD children (mean IQ = 100.2), so this was controlled for in analysis. Children were administered an abbreviated version of the Stanford-Binet Intelligence Test, Fifth Edition (SB-5) and three NIH Toolbox Cognition assessments: 1) Flanker Inhibitory Control and Attention (Flanker); 2) Dimensional Change Card Sort (DCCS); and 3) Pattern Comparison Processing Speed (PCPS). These tasks were chosen in order to evaluate attention, cognitive flexibility, and speed of processing.

Results: Three ASD children were excluded from analysis, as they were unable to complete the assessment due to difficulties in attention or understanding the task. These children were all characterized by an IQ at or below the 5th percentile, although a select few children with an IQ in this range completed the assessment. ASD children exhibited cognitive deficits compared to TD children, with lower Age-Corrected Standard scores for the Flanker (t(27)= -2.9, p= .007), DCCS (t(27)= -3.6, p= .001), and PCPS (t(27)= -3.2, p= .004) assessments. IQ was strongly correlated with Age-Corrected Standard score for ASD (r= .69), but not TD children (r= .46) on the DCCS task. No significant correlations were found between IQ and Age-Corrected Standard score for the Flanker or PCPS tasks in either group. When controlling for IQ on the DCCS task, significant between-group differences continued to be observed in Age-Corrected Standard scores (F= 4.3, p= .047), supporting previous findings using the standard DCCS task in high-functioning autism (Faja & Dawson, 2014).

Conclusions: These preliminary findings replicate previously observed patterns of cognition in children with ASD. Children with ASD exhibited decreased cognitive flexibility, difficulties in attention switching and inhibition, and increased speed of processing compared to TD children. Although the current sample size is small, we anticipate 150 children with ASD and 75 controls by Spring 2018. These data support the potential of the NIH-TCB as a valid, integrated tool for the assessment of cognition in children with ASD.

66

164.066 Visual Preference to Repetitive and Biological Movements in Children with Autism Spectrum Disorder

T. Li[1]*, Y. Hu*[2] *and L. Yi*[1]*, (1)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China, (2)Peking University, Beijing, China*

Background:

Individuals with Autism Spectrum Disorder (ASD) exhibit reduced interest in social stimuli and biological motions (e.g., Klin et al., 2009). Meanwhile, they have also been reported, mainly based on parent report and clinical observations, to show excessive visual attention to repetitive movements (e.g., the rotating wheels, Leekam et al., 2011). However, the visual preference to repetitive and biological movements has rarely been compared within one paradigm.

Objectives:

In this study, we attempted to measure ASD children's visual preferences to repetitive and biological movements using a preferential looking paradigm. By carefully matching the properties of stimuli (e.g., color and shape), we aimed to investigate the preferences of children with ASD to the movements (repetitive, biological, and random) per se.

Methods:

We adapted the Social Attribution Task (SAT, Heider & Simmel, 1944), in which typical developing (TD) people could attribute geometric animation as a social story and perceived the intention enacted by the geometric shapes. The general setting, modified from SAT, was a little triangle moving in a location surrounded by a fence with several breaches. In the biological movements, the little triangle moved as it was trapped in the fence and intended to find an exit, it tried several breaches and succeed eventually. In the repetitive movements or random movements, the little triangle moved along an oval track or in random directions with the same speed.

Twenty-six 5- to 7-year-old high-functioning children with ASD and 22 age- and ability-matched TD peers participated in the experiment. Children were shown a pair of videos (approximately 35 s) selected from the three types of movements randomly. This procedure repeated for 12 trials. Children's eye-movements were recorded by a Tobii Pro X3-120 eye tracker during the whole experiment.

Using the looking time on random movements as the baselines, we calculated the average proportional looking time on the repetitive and biological movements as repetitive preference index (RPI) and biological preference index (BPI), respectively. When repetitive and biological movements were shown together, the average proportional looking time on the repetitive movements divided by the looking time on biological movements was defined as repetitive-biological ratio (RBR).

Results:

We found that (a) both group of children preferred the biological movements to random movements, with their BPIs significantly higher than the chance level (50%), see Figure 1; (b) the RPI of the ASD group was marginally higher than chance level, p = .06, while TD group shown no preference to repetitive movements compared to chance level, p > .1; (c) when repetitive movement and biological movement were displayed spontaneously, ASD group spent almost the same time on the two movements, and their RBR was significantly higher than their TD peers (Figure 2).

Conclusions:

Our study found that like TD children, children with ASD showed similar visual preference to biological movements relative to the random movements. However, compared with TD children, children with ASD still show the visual preferences to the repetitive movements. Our study provided evidence for the visual preference for the repetitive and biological movements in ASD.

67

164.067 Visual Working Memory in Adolescents with Autism Spectrum Disorder

K. R. Bellesheim[1]*, J. L. Sokoloff*[1]*, K. E. Bodner*[2]*, K. M. Boland*[1]*, N. Cowan*[1] *and S. E. Christ*[1]*, (1)Department of Psychological Sciences, University of Missouri, Columbia, MO, (2)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background: Impairment in working memory (WM) performance has been reported in individuals with Autism Spectrum Disorder (ASD; Geurts et al., 2014) though questions remain regarding which core processes of WM are impaired (e.g., capacity, attention, and/or filtering ability). A recent investigation (Bodner et al., in prep) found that visual WM performance was relatively spared in adults with ASD when memory load was low; however, at higher memory loads, ASD participants exhibited difficulty in optimally allocating WM capacity.

Objectives: The current research investigated whether this selective WM impairment extended to youth with ASD (ages 11 to 15) and whether differences existed in the neurocognitive profile of girls and boys with ASD.

Methods: Sixty participants [29 with ASD (12 females); 31 without ASD (17 females)] completed a computerized visual WM task assessing WM capacity and attentional control. Full-scale IQ for all participants fell at or above 75 (ASD mean = 100.6; non-ASD mean = 106.4). For each trial, participants were shown a visual array consisting of four or six colored circles and squares. After a short delay, memory for one of the stimuli was probed, and participants responded whether the shape was the same or different color from when first presented. Note that participants were informed beforehand that one of the shapes (e.g., circles; high-frequency probes) was more likely to be probed than the other shape (e.g., squares; low-frequency probes) – thus prompting participants to allocate their attention and memory capacity accordingly. Trial blocks were presented with 80% high-frequency and 20% low-frequency probes. Further, for half of the blocks, shapes in the visual array were presented simultaneously (all at once). For the other half, visual array shapes were presented serially (one at a time).

Results: Primary dependent variables were WM capacity (Cowan's *k*; Cowan, 2010) and attentional control. Preliminary analyses of WM capacity data revealed a significant three-way interaction between group (ASD, non-ASD), presentation type (simultaneous, serial), and memory probe (high frequency, low frequency) [$F(1,45)=4.94$, $p=.03$, $\eta_p^2=.10$]. In the simultaneous presentation condition, participants in the ASD group devoted relatively less capacity to high frequency probes as compared to participants in the non-ASD group. A main effect of group and group-by-sex interaction also trended towards significance ($p<.10$ in both instances). The non-ASD group had a higher capacity than the ASD group which was primarily driven by poorer WM performance in males as compared to females with ASD. No group differences or interactions were observed for attentional control ($p>.05$ in all instances).

Conclusions: Youth with ASD demonstrated selective impairment in WM capacity: when visual information was presented all at once, the ASD group was impaired on the high-frequency probes compared to the non-ASD group. Although preliminary, our data suggest that boys with ASD may display a different profile of WM capacity than girls. Future research should evaluate WM capacity and attention control across the lifespan as well as investigate the relationship between WM performance and everyday functioning.

68 **164.068** Visuospatial Cognition and Dimensions of Autistic Traits: Reduced Lateralization of Attention and Superior Search Relate Specifically to Social Difficulties

***M. T. Maybery**, M. C. English, D. W. Tan, I. Raiter and T. A. Visser, School of Psychological Science, University of Western Australia, Perth, Australia*

Background: Research has identified two visuospatial cognitive characteristics of individuals with high levels of autistic-like traits (ALT) – facility in embedded figures search and reduced left-visual-field (LVF) attentional bias – relative to individuals with low ALT levels. However, ALT are multi-dimensional, with social and non-social factors essentially independent for instruments such as the Autism-Spectrum Quotient (AQ). Therefore to advance understanding of atypical cognition on the autism spectrum and its likely neural correlates, we isolated contributions of two ALT dimensions.

Objectives: Our aims were to (1) check the independence of the Social Difficulties (SD) and Patterns/Interests/Details (PID) AQ factors; (2) investigate whether facility in embedded figures search and reduced LVF attentional bias can be attributed to elevated SD traits, elevated PID traits, or their combination; and (3) examine the relationship between search performance and LVF bias as potential support for a link to differences in right hemisphere function.

Methods: First, 702 volunteer undergraduate students were screened for SD and PID AQ scores. Next, volunteers were invited for further testing if their scores fell in the upper or lower 30% for each of the SD and PID distributions. This provided a 2 x 2 design (High SD-High PID [n=25]; High SD-Low PID [n=25]; Low SD-High PID [n=26]; Low SD-Low PID [n=25]), with the four groups matched on age and gender. These 101 participants (M_{age} = 20.61 years) then completed the Lueven Embedded Figures Test (L-EFT) and a greyscales task to assess LVF bias.

Results: Across the 702 screened students, SD and PID scores were independent, correlating $r = 0.02$, $p = 0.58$. On the greyscales task, High SD students showed a reduced LVF advantage (M=54.53%; SE=2.98% left responses) compared to Low SD students (M=61.94%; SE=2.16% left responses; $F(1,97)=4.00$, $p<.05$) whereas High and Low PID students did not differ in LVF bias ($p=.53$). Similarly, on L-EFT accuracy, High SD students (M=76.69%; SE=.96%) outperformed Low SD students (M=73.16%; SE=1.41%; $F(1,97)=4.24$, $p<.05$) whereas High and Low PID scorers were close in accuracy ($p=.58$). Finally, there was a trend for superior L-EFT performance to correlate with reduced LVF bias ($r = -0.17$, $p= .097$).

Conclusions: Facility in embedded figures search and reduced left-visual-field bias are characteristics of individuals who report pronounced social difficulties rather than of individuals who report pronounced attention to patterns, special interests or sensory details. The independence of the social and non-social dimensions of autistic traits, and their contrasting patterns of association with visual search and attentional bias, caution against investigating autistic traits as a single spectrum. The superior visual search and reduced attention to the left side of space associated with social difficulties support speculation that each effect reflects reduced involvement of the right hemisphere relative to the left in visuospatial cognition.

69 **165.069** A Unique Cognitive Profile of ASD Evident in Siblings, Parents, and Grandparents of Individuals with ASD

***M. Losh**[1], L. Bush[2], K. Nayar[3], M. Lee[4], G. E. Martin[5], M. Winston[3], S. Crawford[6], J. Sideris[7], D. Achorn[8], S. Lapham[8], C. Persico[9], J. Ferrie[10] and D. Figlio[4], (1)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)Northwestern Feinberg School of Medicine, Chicago, IL, (3)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (4)Northwestern University, Evanston, IL, (5)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (6)Communication Sciences and Disorders, Northwestern University, Chicago, IL, (7)Frank Porter Graham Child Development Institute, Chapel Hill, NC, (8)American Institutes for Research, Washington, DC, (9)University of Wisconsin-Madison, Madison, WI, (10)Economics, Northwestern University, Evanston, IL*

Background: Genetic liability to autism spectrum disorder (ASD) can be expressed in unaffected relatives through subclinical, genetically meaningful traits, or endophenotypes. Studying endophenotypes in unaffected relatives may help to decompose the complex ASD phenotype into more fundamental component features with clearer ties to underlying biology, which can be used to stratify families into biologically meaningful subgroups. This study makes use of three unique datasets of archival educational data available on siblings, parents, grandparents, and great-grandparents of individuals with ASD, to investigate cognitive profiles that may be related to ASD genetic liability.

Objectives: To explore the role of educational test data across multiple generations of individuals with autism and their family members, this study used archival test records from 1) a large population-based sample of children for whom later autism diagnostic information was available,

2) parents of individuals with and without autism, and 3) grandparents and great-grandparents of individuals with autism.

Methods: Three datasets comprising different archival academic test records were examined. First, individuals with ASD and their siblings were identified from a population-based sample of children attending kindergarten in Florida (n=292,407) who as preschoolers were administered a kindergarten readiness screener, the Dynamic Indicators of Basic Early Literacy Skills Kindergarten Readiness Test (DIBELS), which assesses letter and sound recognition. Academic testing for reading and math was also available at 3rd grade from children with and without ASD (n=1,281,005) from this sample. Childhood educational data from parents of individuals with ASD (n=144) and 75 controls were examined from the Iowa Tests of Basic Skills (ITBS), which assesses math, reading, and language from grades K-12. Childhood educational data from grandparents (n=19) and great-grandparents (n=2) of individuals with ASD was examined with data from Project Talent, a nation-wide study that assessed academic competencies, family background, and personal and educational experiences of high school students in 1960.

Results: Across all three samples and academic tests, a pattern of discordant skills was observed. In preschool age screening data, a discordant pattern of strong letter recognition and weaker sound recognition scores was strongly predictive of ASD (OR=2.74; *p*<.0001) and ASD-sibling status (OR=1.42; *p*<.0001). Later in development, greater discordance between reading and math scores was strongly predictive of ASD status (OR=2.03; *p*<.0001; sibling data will be processed and analyzed). In parents, results again revealed discordance between reading and math scores among ASD parents, where reading scores exceeded math scores. Multinomial regression predicted ASD-parent status with 74% accuracy and specificity of 95%. In grandparents and a small sample of two great-grandparents, 85% of the sample showed better reading vocabulary scores than math (with nearly 3/4 of the sample scoring below the 50th percentile on math). Greater discordance between reading vocabulary and math was associated with ASD endophenotypes in adulthood, with a small to medium effect size (*r*=.27; *p*=.31).

Conclusions: These findings suggest a unique cognitive profile of discordant cognitive skills evident in siblings, parents, and grandparents of individuals with ASD. This profile predicts endophenotypes in adulthood, and may be used to help inform understanding of the pathogenesis of ASD.

70 **165.070** AUT-Priori: A Web-Based Tool for Autism Gene Prioritization

A. J. Griswold[1], *D. Van Booven*[1], *E. R. Martin*[1], *M. L. Cuccaro*[1], *J. P. Hussman*[2] *and M. A. Pericak-Vance*[1], *(1)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (2)Hussman Institute for Autism, Catonsville, MD*

Background: Autism is highly heritable with a complex genetic etiology. Large scale genome and exome sequencing studies have implicated hundreds of genes with a range of genomic variation from common variants of small effects to pathogenic *de novo* coding loss of function variants. However, as the pace of functional genomic analyses in autism increases, such as large scale transcriptomic and epigenomic studies, a new challenge arises of defining which of the many possible candidate genes are truly related to autism but not previously identified with genetic variants. Reducing these sets of genes to a subset for critical follow-up examination can presently be a time-consuming and laborious task.

Objectives: To create a publicly available web-based resource to aide in prioritization of autism biology related genes utilizing tissue, cell specific, and developmental gene expression patterns as well as available genomic data.

Methods: The data underlying this application is populated from existing publicly available resources including adult tissue specific gene expression (GTEx), developmental and spatial time course of brain gene expression (Brainspan and Human Brain Map), and gene expression profiles of single neuronal cell types (scRNA-seq). Furthermore, we have retrieved genomic variation-based priority metrics including probability of intolerance from the Exome Aggregation Consortium and the Gene Scoring metrics from the SFARI Human Gene database. The expression and genomic variation data then feed into a support vector machine (SVM) that requires a background training dataset. By default this background training data is the SFARI VIP gene list, but a custom training set can also be user defined. Based on the output of the SVM, the genes are then prioritized in terms of likely genetic impact based on similarity to previously identified genes. This tool is implemented in an R environment based on the kernlab package (v0.9-25) with a graphical component coded in R Shiny. An alpha release is currently available at https://umiami-hihg-bioinf.shinyapps.io/autism-query-tool/

Results: Implementation of these techniques in a user-friendly environment produces a unique resource for the autism genetics research community. While each of the underlying data repositories are publicly available, AUT-PRIOIRI-GENE offers a synthesis of these in a single location. Furthermore, it is highly customizable as the user is able to enter a list of gene symbols (manually or by file upload), select tissue, region, or gender specificity from data sources where available, and define a training dataset for prioritization. The resulting hierarchical clustering and clustered expression heatmaps, annotation tables, and prioritization scores are all downloadable from the server. While optimization continues, this process takes less than a minute for a gene set of 200 genes.

Conclusions: AUT-PRIORI-GENE provides an easily accessible tool to prioritize a most likely autism-related gene from a user defined list. This is a critical downstream step for those engaging in high-throughput functional genomics studies to aide in unraveling the complex underlying genetics of autism.

71 **165.071** Clinical and Neurophysiological Phenotype of Phelan Mcdermid Syndrome: Communication Disorder or Autism?

L. Ponson[1], *M. Gomot*[2], *R. Blanc*[3,4], *C. Barthelemy*[5], *S. Roux*[6], *A. Munnich*[7], *N. Hernandez*[8], *E. Houy-Durand*[9], *S. Romana*[10], *V. Malan*[10] *and F. Bonnet-Brilhault*[11], *(1)CHRU Tours, Tours, France, (2)UMR 930 Inserm-Universite Francois Rabelais Tours, Tours Cedex 09, France, (3)Université Paris Descartes, Boulogne Billancourt, France, (4)psychology, Université Paris Descartes, Boulogne Billancourt, France, (5)UMR 930 Inserm-Universite Francois Rabelais Tours, Tours, France, (6)Université François-Rabelais de Tours, UMR INSERM U930, Tours, France, (7)Service d'Histologie-Embryologie et Cytogénétique, Université Paris Descartes Paris France, Paris, France, (8)Université François Rabelais de Tours, Tours, France, (9)UMR930 Inserm, Université François-Rabelais de Tours, Tours, France, (10)Université Paris Descartes Paris France, Paris, France, (11)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France*

Background:

The 22q13 deletion syndrome also known as Phelan-McDermid syndrome is a neurodevelopmental disorder characterized by hypotonia, global developmental delay with intellectual disability, severely delayed or absent speech and minor dysmorphia. Behavioral symptoms of Autism spectrum disorder (ASD) are reported for half of patients carrying this deletion of various size and encompassing *SHANK 3* gene. *SHANK3* haploinsuffisancy has been proposed as one of the more common monogenic causes of ASD and used for monogenic mouse models of autism spectrum disorders. However extensive clinical characterization of patients carrying this deletion is lacking whereas it is essential to understand genotype-phenotype correlation and to define an appropriate therapeutic program.

Objectives:

The aim of our study was to better characterize autistic behaviours in PD syndrome and to test whether they are related to atypical information process reported in autism by combining genomic, behavioural dimensional and neurophysiological explorations.

Methods:

Eighteen patients (8 males, mean age 12,7 years SD=9,2) with known 22q13 terminal deletions were fully explored with behavioural, language and cognitive standardized assessments. Neurophysiological indices previously reported to be altered in autism (ie Eye tracking in a social/non-social task, and Mismatch auditory evoked potentials) were also recorded. In parallel with these clinical and neurophysiological investigations carried out in the child psychiatry department of the CHU of Tours, cytogenetic analyses were carried out in the Cytogenetics Department of the Necker Enfants-Malades Hospital in Paris. All participants or the children participants' parents gave written informed consent according to institutional guidelines. The experiment was approved by an ethical committee.

Results:

Autism spectrum disorder clinical features reported by parents through ADI-R (Autism Diagnosis Interview based on the 4-5 years old period) found exceeding cut-off scores in 56% of cases. Using ADOS-2 (Autism Diagnosis Observation Schedule for current period), 50% met ASD clinical criteria exceeding cut-off scores. However only 39% remain positive when both ADOS-2 and ADI-R were required. All the patients had intellectual disability (mild, severe, profound) and language disability. Deletion size was significantly correlated with expressive and receptive language disorder but not with ADI-R nor ADOS or Developmental Quotient scores. Considering neurophysiological recordings, lack of pupil dilation for human faces which is typically described in ASD was not observed in these patients. Atypical shortened latency of Mismatch Negativity response previously reported in ASD was not observed either whereas N250 pattern, related to language, was affected.

Conclusions: The main genotype-phenotype correlation in 22q13 syndrome was related to language disorder. Combined with cognitive deficits this may lead to behavioral autistic symptoms but with different neurophysiological networks compared to typical autism. Our results should have consequences for research on animal models for which it should be verified that they involve the targeted networks. They also recall the need of precise stratification of patients in autism failing which the spectrum obscures the underlying pathophysiology. Finally, these results highlight the indication for early speech therapy rather than intensive autism program to treat patients with Phelan McDermid syndrome.

72 **165.072** Cord-Blood Based Methylome-Wide Association Study of the Social and Communication Disorders Checklist

A. T. Massrali[1]*, H. Brunel*[2]*, S. Baron-Cohen*[3] *and V. Warrier*[2]*, (1)Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)University of Cambridge, Cambridge, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Differentially methylated CpGs (DMCs) have been reported in both cortical tissues and in the blood in autistic individuals compared to non-autistic individuals. However, it is unclear if methylation of CpGs in cord blood is associated with scores on the Social and Communication Disorders Checklist (SCDC) – a measure that is phenotypically and genetically correlated with autism.

Objectives: We sought to investigate if: 1. There are significant DMCs that are associated with scores on the SCDC; 2. The SCDC methylome-wide association study (MWAS) is enriched for specific pathways, DMCs identified in the autism post-mortem cortical tissues, and transcriptionally dysregulated genes in the autism post-mortem cortex.

Methods: We conducted a MWAS on parent-reported SCDC scores in 701 8-year-olds from the Avon Longitudinal Study of Parents and Children. Enrichment analyses were conducted using modified hypergeometric tests and two-sided Kolmogorov-Smirnov Tests.

Results: MWAS did not identify any significant CpGs at a significant threshold < $5x10^{-8}$. However, after FDR correction, nominally significant CpG sites ($P < 0.05$) were enriched in 24 GO processes including neuronal projection and neuron part. Significant DMCs identified in the post-mortem anterior cingulate cortex in autism showed a significant tendency towards low P-values in the SCDC MWAS ($P = 7.7x10^{-9}$, two-sided Kolmogorov-Smirnov test). Nominally significant DMCs were replicably enriched for transcriptionally dysregulated genes in the autism post-mortem cortex in two independent samples.

Conclusions: Pathway specific enrichment identify several interesting pathways and propose an involvement of methylation signatures on neuronal pathways. The enrichment of transcriptionally dysregulated autism genes and DMCs in the post-mortem brain suggest an overlap in biological signatures between SCDC and autism.

73 **165.073** Distinct Sources of Genetic Risk for Autism from Social and Non-Social Domains

V. Warrier[1]*, N. The 23andMe Research Team*[2]*, N. iPSYCH-BROAD ASD Group*[3]*, T. Bourgeron*[4] *and S. Baron-Cohen*[5]*, (1)University of Cambridge, Cambridge, United Kingdom, (2)23andMe Inc, Mountainview, CA, (3)Aarhus University, Aarhus, Denmark, (4)University Denis Diderot Paris 7, Paris, France, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: Common genetic variation contributes to a substantial proportion of the variation in autism liability. There is considerable phenotypic and genetic heterogeneity within the autism spectrum. It is unclear how common genetic variation in social and non-social domains in the autism spectrum contribute to the liability in the condition.

Objectives: To investigate the genetic architectures of social traits (self-reported empathy, cognitive empathy, social and communication difficulties, and social relationship satisfaction) and non-social traits (systemizing) related to autism in large cohorts and map their contribution to autism liability.

Methods: We investigated the contribution of social and non-social traits for autism using GWAS for multiple traits (5000 > N > 140000) in three cohorts: ALSPAC, 23andMe, and the UK Biobank. Self-reported empathy was measured using the Empathy Quotient (EQ), cognitive empathy was measured using the Reading the Mind in the Eyes Test, Social and Communication Difficulties was measured using the Social and Communication Disorders Checklist, Social Relationship Satisfaction using two brief questionnaires: family relationship satisfaction and friendship satisfaction, and Systemizing was measured using the Systemizing Quotient-Revised (SQ-R).

Results: Using GWAS autism data from the iPSYCH consortium and the PGC, we identified a positive genetic correlation between autism and higher systemizing, lower social relationship satisfaction, and lower self-reported empathy. However, there is no genetic correlation between systemizing and the social traits i.e. social relationship satisfaction, self-reported empathy, and social and communication disorders. We further demonstrate that social autistic traits are positively genetically correlated with each other. Both social and non-social traits are genetically correlated with measures of intelligence, with significant negative genetic correlations between social traits and measures of intelligence and significant positive genetic correlations between systemizing and measures of intelligence. Finally, we demonstrate that the positive genetic correlation between systemizing and autism is independent of the genetic correlation with measures of intelligence.

Conclusions: Our results suggest that there are at least two independent sources of genetic liability for autism stemming from social and non-social traits. This is the first empirical evidence of distinct pathways to autism liability from common genetic variants.

74 **165.074** Epigenetic Alterations in Childhood Reflect Prenatal Exposure to Maternal Infection

M. Brucato[1]*, S. Andrews*[2]*, Y. Qian*[3]*, G. C. Windham*[4]*, D. Schendel*[5]*, L. Schieve*[6]*, C. J. Newschaffer*[7]*, A. P. Feinberg*[8]*, L. A. Croen*[3]*, M. D. Fallin*[9] *and C. Ladd-Acosta*[10]*, (1)Internal Medicine/Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD, (2)Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Division of Research, Kaiser Permanente, Oakland, CA, (4)Environmental Health Investigations Branch, California Department of Public Health, Richmond, CA, (5)Public Health, Aarhus University, Aarhus, Denmark, (6)Centers for Disease Control and Prevention, Atlanta, GA, (7)AJ Drexel Autism Institute, Philadelphia, PA, (8)Johns Hopkins University, Baltimore, MD, (9)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (10)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: Prenatal exposure to maternal immune activation (MIA), particularly infections and fever, has been linked with altered neurodevelopment in the offspring, yet we have a limited understanding of causal mechanisms.
Objectives: We sought to explore the potential biological consequences of prenatal exposure to maternal infections.

Methods: We examined 929 children, aged 2-5 years, in the Study to Explore Early Development, phase I (SEED I) with both genome-scale whole blood DNA methylation data, from the Illumina 450K array, and *in utero* infection exposure data, ascertained via structured maternal phone interview. We used linear models, adjusted for cell type composition, sex, ancestry, and other unwanted variation via estimated surrogate variables, to identify differentially methylated loci associated with prenatal exposure to any infection, at any time in pregnancy or during a specific trimester.

Results: We found one site in an intergenic region on chromosome 5 that was significantly (q-value = 0.005) hypomethylated in children whose mothers had an infection during the preconception period. We also identified 2 genomic loci, within the *IQSEC1* and *EPS8L3* genes, showing significant decreases in DNA methylation (q-value=0.014 for *IQSEC1* and q-value = 0.036 for *EPS8L3*) among children whose mother had an infection during her third trimester. The differences in percent methylation increased in magnitude when comparing children whose mothers reported infections in every trimester of pregnancy (n=56) to those whose mothers reported no infections during pregnancy (n=589). This may reflect a dose-response relationship between a cumulative prenatal infection exposure and methylation at the identified sites. Although we detected these differences in blood, reference datasets indicate that methylation at the intergenic locus on chromosome 5 is strongly correlated across blood and brain. This site is also predicted to be near an enhancer-like region in human astrocytes. *IQSEC1* is thought to be involved in synaptic transmission, as both a scaffolding and signaling protein. It is highly expressed in brain tissues, particularly the frontal cortex, as well as whole blood. *EPS8LS* is not well studied but is likely involved in actin regulation, which is important in neuronal structures like the postsynaptic density and dendritic spine.

Conclusions: Our findings suggest that epigenetic changes related to prenatal infection exposure can present in childhood samples, and can provide candidate loci for studies examining potential epigenetic mediation of prenatal MIA exposure and atypical neurodevelopment.

75 **165.075** Evidence for Widespread Associations between Broadly Expressed Genes in Blood Leukocytes and Neural Systems Response to Speech in Autism

M. V. Lombardo[1]*, T. Pramparo*[2]*, V. Gazestani*[2]*, L. Eyler*[2]*, K. Pierce*[2] *and E. Courchesne*[3]*, (1)University of Cyprus, Nicosia, Cyprus, (2)Univeristy of California, San Diego, La Jolla, CA, (3)Neurosciences, Univeristy of California, San Diego, La Jolla, CA*

Background: It has recently been suggested that complex phenotypes (e.g., ASD) may be understood through an omnigenic model, whereby a vast majority of genes may have some non-zero effect on the phenotype (Boyle, Li, & Pritchard, 2017, *Cell*). Genes broadly expressed across many tissues including the brain are numerous and may contribute significantly to the phenotype. This idea suggests broadly expressed genes measured in-vivo in non-brain tissue (e.g., blood) could be relevant for explaining variability in ASD neural phenotypes.
Objectives: To examine how widespread variation in the blood leukocyte transcriptome is associated with in-vivo neural systems response to speech in ASD subtypes and typical development. The omnigenic model predicts that association signals would be widespread across most of the transcriptome and that co-expression modules highly enriched in broadly expressed genes would harbor most of the ASD-relevant association signal.

Methods: Three age-matched groups of toddlers (mean age ~29 months) were investigated - two ASD subtypes classified as either good (n=40) or poor language outcome (n=41) (Lombardo et al., 2015, *Neuron)*, and n=37 typically developing toddlers. Neural systems response to speech was measured using fMRI during natural sleep using a story-language paradigm identical to prior work (Lombardo et al., 2015, *Neuron*). RNA was measured on all individuals using Illumina microarray chips as described in previous work (Pramparo et al., 2015, *JAMA Psychiatry*). Weighted gene co-expression network analysis (WGCNA) was used as feature reduction step. Partial least squares (PLS) analysis was used to reveal large-scale gene expression-fMRI associations. Association signal across modules was then tested for enrichment with tissue-specific or broadly expressed gene lists directly taken from Boyle et al.'s analysis of GTEx data.

Results: Only one latent variable gene expression-fMRI pair showed a statistically significant association between module eigengene variation and neural systems response to speech (LV1: d = 83.58, p = 9.99e-5). LV1 accounts for 20.7% of the covariance between gene expression and fMRI data and is spatially constrained to primarily prefrontal and temporal cortex. Reliable non-zero association signal in at least one group was present in 64% of modules (20/31) comprising 74% of all genes investigated. Of these 20 modules, 65% (13/20) were highly enriched for broadly expressed genes (OR = 57.57, p = 0.002). Of the 13 modules where a non-zero association was present in an ASD language outcome subtype, 84% (11/13) were highly enriched in broadly expressed genes (OR = 53.16, p = 0.0001). Other tissue-specific gene lists (e.g., brain, blood, lymphocyte) were not heavily enriched in many modules or over-represented within modules containing non-zero effects.

Conclusions: Rather than finding little to no association between blood leukocyte transcriptomic signal and neural phenotypes for ASD, this work demonstrates that widespread signals in the blood leukocyte transcriptome, particularly within genes broadly expressed across many tissues including the brain, are relevant to ongoing early pathophysiology at the neural systems level in living ASD toddlers. These insights suggest much translational research potential for in-vivo monitoring of such pathophysiology in clinically important contexts (e.g., treatment) in living patients with ASD.

76 **165.076** FMR1 mRNA in Blood As a Predictor of Intellectual Functioning and Autism Severity in Fragile X Syndrome: Is There a Difference between Sexes?

***E. K. Baker**[1], M. Arpone[2], S. Aliaga[2], L. Bretherton[1], M. Bui[3], C. Kraan[1], A. Alliende[4], V. Faundes[5], L. Santa Maria[5], C. Rogers[6], M. Field[7], D. Amor[8] and D. E. Godler[9], (1)Murdoch Children's Research Institute, Melbourne, Australia, (2)University of Melbourne, Melbourne, Australia, (3)Centre for Epidemiology and Biostatistics, University of Melbourne, Melbourne, Australia, (4)Molecular and Cytogenetics Laboratory, INTA University of Chile, Santiago, Chile, (5)Institute of Nutrition and Food Technology (INTA), University of Chile, Santiago, Chile, (6)Hunter Genetics, GOLD Service, Newcastle, Australia, (7)Hunter Genetics, Newcastle, Australia, (8)Victorian Clinical Genetics Service, Melbourne, Australia, (9)Genetics, Murdoch Children's Research Institute, Melbourne, Australia*

Background: Fragile X Syndrome (FXS) is a common single gene cause of intellectual disability and co-morbid autism spectrum disorder (ASD). FXS is caused by a large trinucleotide CGG expansion (>200 repeats), termed full mutation (FM), within the *FMR1* gene located on the X chromosome. FM alleles are associated with epigenetic changes that result in decreased production of *FMR1* mRNA and loss of the FMR1 protein FMRP, which is essential for normal neurodevelopment. While males with FXS typically present with a more severe phenotype compared to females, the molecular mechanisms that underlie differences in cognitive functioning and severity of ASD presentation in both sexes have not been defined.

Objectives: This study aimed to characterise gender differences in the relationships between levels of *FMR1* mRNA in blood and FXS phenotypes, including symptoms of ASD and intellectual functioning in males and females with FXS.

Methods: This study used a large international FXS cohort recruited through genetic testing centres and family support organisations in Australia and Chile. 128 individuals (28.1% female) with FXS aged between 1 and 43 years participated in the study. The Autism Diagnostic Observation Schedule-2nd Edition (ADOS-2) was used to assess symptoms associated with ASD while intellectual functioning (Verbal IQ [VIQ], Performance IQ [PIQ] and Full Scale IQ [FSIQ]) was assessed with the Mullen Scales of Early Learning for those < 3 years, and an age appropriate Wechsler scale for those aged ≥ 3 years. *FMR1* mRNA was analysed using the real-time PCR relative standard curve method in blood samples collected at the time of assessment.

Results: FXS females performed better than males on all cognitive domains ($p < .001$; Table 1). Similarly, only 16 (45.7%) FXS females met the cut-off for ASD on the ADOS-2 compared to 77 (82.8%) males ($p < 0.001$). Genotype-phenotype analyses showed that *FMR1* mRNA levels in blood were strongly associated with FSIQ ($p = 8.1\times10^{-11}$; $n = 41$), VIQ ($p = .0002$; $n = 50$) and PIQ ($p = 9.8\times10^{-9}$; $n = 50$) in males, but not in females (FSIQ: $p = .394$, $n = 24$; VIQ: $p = .170$; $n = 25$; PIQ: $p = .438$; $n = 25$). In contrast, *FMR1* mRNA levels were strongly correlated with total ($r_s = -.651$, $p = .001$), Social Affect (SA; $r = -.565$, $p = .008$) and Repetitive and Restricted Behaviours (RRB; $r_s = -.633$, $p = .002$) Calibrated Severity Scores in females, but not males (Total: $r_s = -.081$, $p = .537$; SA: $r_s = -.175$, $p = .178$; RRB: $r_s = -.002$, $p = .987$.

Conclusions: This study shows that *FMR1* mRNA levels in blood are associated with symptoms of ASD in females with FXS, but not with intellectual functioning. In contrast, in males with FXS *FMR1* mRNA levels in blood are associated with intellectual functioning, but not symptoms of ASD. This dissociation by gender in the relationships between *FMR1* expression with type and severity of cognitive and behavioural phenotypes (e.g., intellectual deficits versus ASD symptoms) warrants further study.

77 **165.077** Genetic Investigation of Insistence on Sameness in Autism

***M. L. Cuccaro**, S. Luzi, E. R. Martin, A. J. Griswold, D. Dykxhoorn, H. N. Cukier and M. A. Pericak-Vance, John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL*

Background: Restricted and repetitive behaviors (RRBs), in conjunction with social and communication problems, are defining features of the neurodevelopmental conditions that comprise the autism spectrum. The RRBs are generally grouped into two subdomains: insistence on sameness (IS) and repetitive sensory motor behaviors (RSMB). IS is the more robust of the domains and appears to be independent of developmental level, reducing potential overlap with intellectual disability phenotype. To date, there has been limited study of the genetic basis for the IS trait.

Objectives: For this study, we propose to test for genetic association with IS in a large sample of individuals with autism for whom we have targeted sequence data. We hypothesize that multiple genetic variants will be associated with the IS score.

Methods: Using Autism Diagnostic Interview-Revised (ADI-R) items, we calculated IS scores for our dataset of 1931 participants from the Hussman Institute for Human Genomics and Simons Simplex Collection. The items making up the IS trait include *difficulties with minor changes, resistance to trivial changes, abnormal response to sensory stimuli, circumscribed interests, compulsions/rituals, sensitivity to noise*. All individuals were sequenced with a 17Mb custom capture covering 681 genes within regions identified by GWAS of ASD. We conducted the SKAT-O gene-based test and single variant tests using IS scores as continuous outcomes. A Bonferroni correction for the number of genes tested was used as a significance threshold.

Results: For the gene-based test our top four results were: ATXN1, ARHGAP40, BICD1 and GCOM1 with p-values of 5.6E-03, 5.8E-03, 6.2E-03 and 7E-03, respectively. When only missense variants were analyzed, the top three genes were PANK1, TIMM22 and ZNF397with p-values of 1E-02, 1.2E-02 and 1.3E-02 respectively. ATXN1 is located on the short arm of chromosome 6, it is a protein coding gene and is associated with spinocerebellar ataxia type 1 (SCA 1). ZNF397 is located on the long arm of chromosome 18 and is part of the zing finger family. This gene is well established for its role in and has shown prior association with ASD. Overall, we identified 32 genes with p-values of less than 0.05.

Conclusions: We did not find genome-wide association to the IS trait in our dataset. Our top nominally significant results suggest a possible role of several genes in the modification of the IS trait in individuals with ASD but need further investigation. We propose that the current findings serve as a first step in dissecting the genetic basis of the IS trait in ASD. Within this group of individuals there is still substantial phenotypic heterogeneity which hinders our ability to detect association. With respect to the current results, we would propose follow up studies that focus on the sequence of the reported genes and surrounding areas. More generally, our results suggest the value of identifying genes associated with phenotypic traits that are a part of ASD as an alternative to using the broader ASD diagnostic phenotype.

78 **165.078** Genetic, Molecular, and Phentoypic Characterization of the Autism-Associated FOXP1 Syndrome

J. Buxbaum[1]*, S. De Rubeis*[2]*, M. P. Trelles*[3]*, R. Lozano*[4]*, A. Kolevzon*[3]*, E. Drapeau*[2]*, P. M. Siper*[3]*, A. R. Durkin*[5]*, D. Di Marino*[6] *and Y. Frank*[4]*, (1)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (4)Icahn School of Medicine at Mount Sinai, New York, NY, (5)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (6)Università della Svizzera Italiana, Lugano, Switzerland*

Background:

Haploinsufficiency of the forkhead-box protein P1 (*FOXP1*) gene leads to a neurodevelopmental disorder termed FOXP1 syndrome. Previous studies in individuals carrying *FOXP1* mutations and deletions have described the presence of autism spectrum disorder (ASD) traits, intellectual disability, language impairment, and psychiatric features.

Objectives:

The goal of the present study is to comprehensively and prospectively characterize the genetic and clinical spectrum of FOXP1 syndrome. In addition, gene expression studies of induced neurons (iNeurons) from patients and sibling controls are being characterized for gene expression and cellular changes.

Methods:

As of today, genetic and clinical data has been obtained and analyzed from 5 children and adolescents with mutations in *FOXP1* and 1 child with a duplication in the gene. Blood samples suitable for reprogramming into induced pluripotent stem cells (iPSC) were collected for 5 children and their unaffected siblings. Phenotypic characterization included gold standard ASD testing and norm-referenced measures of cognition, adaptive behavior, language, motor, and visual-motor integration skills. In addition, psychiatric, medical, neurological, and dysmorphology examinations were completed by a multidisciplinary team of clinicians. A comprehensive review of reported cases was also performed. All missense and in-frame mutations were mapped onto the three-dimensional structure of DNA-bound FOXP1.

Results:

We have identified 5 de novo mutations and 1 gene duplication. Reviewing prior literature, we found seven instances of recurrent mutations and another 34 private mutations. The majority of pathogenic missense and in-frame mutations, including all four missense mutations in our cohort, lie in the DNA-binding domain. Through structural analyses, we show that the mutations perturb amino acids necessary for binding to the DNA or interfere with the domain swapping that mediates FOXP1 dimerization. Individuals with FOXP1 syndrome presented with delays in early motor and language milestones, language impairment (expressive language > receptive language), ASD symptoms, visual-motor integration deficits, and complex psychiatric presentations characterized by anxiety, obsessive-compulsive traits, attention deficits, and externalizing symptoms. Medical features included non-specific structural brain abnormalities and dysmorphic features, endocrine and gastrointestinal problems, sleep disturbances, and sinopulmonary infections. Blood samples were reprogrammed into iPSC for 10 samples (5 cases and 5 unaffected siblings). iNeurons are being produced and characterized.

Conclusions:

This study identifies novel *FOXP1* mutations associated with FOXP1 syndrome, identifies recurrent mutations, and demonstrates significant clustering of missense mutations in the DNA-binding domain. Clinical findings confirm the role *FOXP1* plays in ASD and in development across multiple domains of functioning. As the in vitro studies progress, we will learn more about the pathobiology of this autism-associated syndrome.

79 **165.079** High-Resolution View of Genetic Architecture Underlying Autism

E. Larsen*, W. Pereanu and S. Banerjee-Basu, MindSpec Inc., McLean, VA*

Background: Over the last decade, several large-scale collaborative research initiatives have investigated genetic variations underlying ASD using genome-wide methodologies in well-defined cohorts. A complex genetic landscape has emerged with hundreds of genes and thousands of variants implicated in ASD revealing extreme heterogeneity.

Objectives: A central goal in autism research is to identify the core set of highly penetrant, causative ASD genes among the growing list of genes associated with the disorder. Towards this, we have conducted systematic assessment of a large set of genes curated in the autism genetic database (AutDB) to generate a ranked list of candidate genes.

Methods: Using a revised gene-scoring algorithm that relies on evaluation of individual variants (Larsen et al., 2016), we have analyzed a total of 11,287 variants in 921 genes associated with ASD that were annotated from 1383 research articles (AutDB data freeze of June 2017). Our assessment criteria included significance of genetic association, family structure (simplex, multiplex, multi-generational, or consanguineous), zygosity (heterozygous, homozygous, or hemizygous), inheritance pattern (de novo or transmitted), the type of variant (missense, nonsense, etc.), and the functional effect of the variant.

Results:

Here, we present the evidence score and categorization of all ASD-linked genes catalogued in AutDB. The level of evidence in terms of number and type of genetic variants are broadly distributed in this dataset delineating distinct categories of ASD genes. Importantly, we report the identification of a set of 21 ASD genes that occupies more than two standard deviations (SDs) above the mean score of genes analyzed in this study. Using integrated bioinformatics analyses we further characterize the top ranking ASD gene set for their convergent biological function. We show that mouse prenatal and postnatal lethality genes were found to be enriched in this top-ranking ASD gene set (hypergeometric distribution test; $p=3.0 \times 10^{-5}$ and $p=2.0 \times 10^{-8}$ respectively) replicating an earlier finding of involvement of essential genes in ASD.

Conclusions: The evidence-based classification of ASD genes presented here is anticipated to help interpret newly identified genes and variations in ASD individuals.

80 **165.080** Identification of Autism Spectrum Disorder with Salivary RNA

S. D. Hicks[1]*, M. Chroneos*[2]*, K. Wagner*[3]*, C. Tierney-Aves*[4] *and F. A. Middleton*[3]*, (1)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hershey, PA, (2)Penn State College of Medicine, Hershey, PA, (3)SUNY Upstate Medical University, Syracuse, NY, (4)Penn State Hershey Medical Center, Hershey, PA*

Background: Autism spectrum disorder (ASD) diagnoses rely heavily on parent-report measures and behavioral observations that lack specificity and can be influenced by situational variables. The identification of objective, accurate disease markers could improve clinicians' ability to diagnose and manage autism symptoms. Recent studies have demonstrated that epi-transcriptomic factors, including microRNA and other small RNAs, are altered in autism. Translation of these findings into clinical tools has been limited, in-part, by small sample sizes and older participants.
Objectives: This study characterized the oral micro-transcriptome of 179 children with autism spectrum disorder (ages 2-6 years) and 106 age-matched controls with typical development, to establish a panel of small RNAs with screening potential in autism spectrum disorder.

Methods: A prospective case-control design compared salivary RNA profiles of ASD (n=179) and TD (n=106) participants. ASD status was established by physician DSM-5 diagnosis and autistic traits were quantified with the Autism Diagnostic Observation Schedule, Second Edition. TD status was confirmed by physician assessment at a regularly scheduled well child visit. Adaptive behaviors were assessed in all participants with the Vineland Adaptive Behavior Scales, Second Edition. Salivary RNA was obtained in a non-fasting state with P157 swabs (DNA Genotek, Ottawa Canada) following oral tap-water rinse. RNA was quantified with high throughput sequencing on a NextSeq 500 Instrument (Illumina, San Diego, California). Human RNA reads were aligned in Partek flow using Refseq Transcripts v82 and miRBase v21 with the Shrimp2 algorithm. Microbial RNA was aligned to the human microbiome database using K-SLAM. RNA entities with read counts ≥10 in ≥10% of samples were interrogated for differential expression with Mann-Whitney U-test and RNA profiles were visualized with a partial least squares discriminant analysis (PLSDA). Thirty-five factors most crucial to PLSDA vector projection were used to construct a logistic regression model in the first half of samples (ASD=89, TD=53). This model was then tested in the remaining half of naïve "hold-out" samples (ASD=90, TD=53).

Results: Among the 285 samples, 1343 RNA factors were explored: 337 microRNAs, 85 small nucleolar RNAs, 170 mRNAs, and 751 microbial taxons. Seven RNA factors displayed significant differences between ASD and TD groups (FC>1.5; FDR<0.1). A PLSDA employing all 1343 RNA factors and 11 medical/demographic characteristics distinguished ASD and TD in two-dimensions while accounting for 7.5% of the variance in the dataset (Figure 1). The 35 factors with the highest variable importance in projection scores on PLSDA were used to create a logistic regression model of ASD status. This model included 14 microRNAs, 4 mRNAs, 13 microbial RNAs, and 1 small nucleolar RNA, while controlling for sex, disordered sleep, and gastrointestinal disturbance. It demonstrated an area under the curve (AUC) of 0.830 (95% CI: 0.733-0.913) in the training set and an AUC of 0.895 in the hold-out set on receiver operator characteristics curve (Figure 2).

Conclusions: Salivary RNA profiles represent a non-invasive, objective, and accurate source of biomarkers that may aid in ASD screening or diagnosis.

81 **165.081** Inherited and Multiple De Novo Mutations in Autism Risk Genes Suggests a Multifactorial Model

H. Guo[1,2]*, T. Wang*[2]*, H. Wu*[1]*, M. Long*[1]*, B. P. Coe*[2]*, R. Bernier*[3]*, E. E. Eichler*[2] *and K. Xia*[1]*, (1)Central South University, CHANGSHA, China, (2)Department of Genome Science, University of Washington, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: Large-scale, genome-wide and targeted sequencing analyses are dramatically accelerating the discovery of candidate genes associated with autism spectrum disorders (ASD), establishing dozens of novel high-risk genes. Despite these advances, only a small fraction of the genetic risk has been defined, the penetrance of most mutated genes is unknown, and genotype–phenotype correlations are only beginning to be understood.
Objectives: To better understand the genetic architecture, penetrance, and genotype–phenotype relationships of ASD mutations.

Methods: We targeted 188 autism candidate genes for sequencing in 2,926 families from the Autism Clinical and Genetic Resources in China (ACGC) cohort using a modified molecular inversion probe (MIP) method, which enables ultra-low-cost candidate gene resequencing in very large cohorts.

Results: We validated recurrent *de novo* likely gene-disruptive (LGD) mutations in 13 genes and identified three potential novel risk genes (*ZNF292*, *GRIA2* and RALGAPB) as well as genes associated with macrocephaly (*GIGYF2* and *WDFY3*). During this analysis, we identified transmission of private gene-disruptive mutations in genes predominantly associated with *de novo* mutations (DNMs) (e.g., *CHD8* and *KMT5B*) and showed that clinical reevaluation of carrier parents revealed mild neurodevelopmental or related endophenotypes. We also identified families with DNMs in two or more candidate genes. Combining available exome sequence data, we identified 10 such "double-hit" families involving well-known autism risk genes (*SCN2A*, *CHD8*, etc.). We show that such oligogenic cases occur more frequently in probands associated with more severe phenotypes, including social impairments and seizure burden.

Conclusions: Our data suggest a multifactorial model of multiple high-impact mutations in some ASD patients indicating that monogenic models may be too simplistic. Disease risk of genes associated with DNMs requires a much more comprehensive understanding of the full spectrum of mutation as well as patient follow-up in larger number of affected families in order to accurately determine penetrance and the role of additional rare mutations in different genes in modifying the ASD phenotype.

82 **165.082** Linkage Analysis and Fine-Mapping in Autism Pedigrees Confirms and Refines Regions on Chromosomes 7 and 12

E. R. Martin*, S. Luzi, L. Gomez, P. Whitehead, J. Jaworski, A. J. Griswold, M. L. Cuccaro and M. A. Pericak-Vance, John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL*

Background: Autism is highly heritable with complex genetic architecture. While genetic studies to date have identified more than 100 candidate genes, they have failed to explain all of the underlying genetic risk. Recent studies have been association studies or rare-variant studies looking

for de novo variants in small families. These studies do not take advantage of the information that can be gained in linkage analysis of multiplex families. Previous linkage studies, while suggestive, failed to firmly establish linkage regions. Furthermore, recent advances in genotyping technology and growing reference panels from sequencing studies now allow for high-quality imputation of dense genotype data, which should improve our ability to identify linkage and fine-map autism genes using association.
Objectives: We hypothesize that using dense imputation in our sample of large of well-characterized multiplex families with autism, linkage analysis will be a powerful tool to identify genomic risk loci for autism.

Methods: We have ascertained 250 families of European ancestry: 165 families with sibling pairs and 85 with more distant relative pairs. Individuals were genotyped on either the Illumina HumanHap550 or Illumina Human1M genome-wide genotyping platforms. GWAS data were imputed from Haplotype Reference Consortium (HRC version r1.1) panel within the Michigan Imputation Server. Non-parametric multipoint linkage analysis was performed using the MERLIN software, followed by data cleaning (Merlin and Pedwipe), LD pruning (r2=0.16), and manual inspection for potential double recombinants using the Progeny software. Family-based SKAT (famSKAT) was used to test for significantly associated genes within the significant linkage regions.

Results: Non-parametric multipoint analysis identified two regions of significant linkage. The first was chromosome 7q11.23-21.11 (LOD=5.8). This linkage region spans 3Mb with ~40 genes including HSPB1, a gene that responds to environmental stress by translocating proteins, and the YWHAG gene, which is highly conserved and mainly expressed in the brain. The second region of linkage was chromosome 12q14 (LOD=4.5) spanning a 2Mb and 26 genes, including GRIP1, which is important for the function of synapses and previously reported associated with autism. FamSKAT analyses confirmed that several genes within both chromosome 7 and 12 are associated with risk of autism in our families. Both of these regions had been implicated previously as harboring autism risk genes.

Conclusions: We demonstrate the power of linkage analysis with imputed GWAS data in large pedigrees. Our results confirm previously suggestive linkage on chromosomes 12 and 7 with several potential candidate genes confirmed by association studies. Of particular interest is the GRIP1 gene on chromosome 12, previously implicated in autism, and the 7q11.23 region that is deleted in William syndrome and includes several autism candidate genes. The findings of several genes associated with autism, suggests a potential role of rare regulatory and non-regulatory variants accounting for the linkage signal within these regions.

83 **165.083** microRNAs and Gene-Environment Interactions in Autism: Prenatal Maternal Stress and the SERT Gene

D. Q. Beversdorf[1], *A. Shah*[2], *J. Noel-MacDonnell*[3], *P. Hecht*[4], *B. J. Ferguson*[5] *and Z. Talebizadeh*[2], *(1)University of Missouri, Columbia, Columbia, MO, (2)Children's Mercy Hospital, Kansas City, MO, (3)Children's Mercy Hospital and University of Missouri-Kansas City School of Medicine, Kansas City, MO, (4)University of Southern California, Los Angeles, CA, (5)Radiology & Thompson Center for Autism & Neurodevelopmental Disorders, University of Missouri, Columbia, MO*

Background: Both genetic and environmental factors may play critical roles in autism. However, there is less understanding of the potential environmental factors or gene X environment interactions (GxE). Recent evidence suggests that maternal stress exposure may be important in autism. By surveying for history and timing of prenatal psychosocial stressors, we found autism mothers to have a higher overall incidence of stressors as compared to the other groups, which was subsequently confirmed by larger epidemiological studies. In all of these studies, though, a significant proportion of stress-exposed mothers had unaffected children. To explain why prenatal stressors might result in autism in some cases but not others, we began to explore GxE. The serotonin transporter (SERT) gene is well studied for its role in stress reactivity. The most widely studied variation is an insertion/deletion within the promoter region, resulting in long (L) or short (S) alleles. The S-allele has been linked to autism in some but not all studies. These contradictory findings could, in part, be explained by the presence of a gene/stress interaction. We have subsequently demonstrated in two independent samples that the association between maternal stress exposure and autism is greatest with maternal presence of the S-allele. There is emerging evidence that microRNAs may play a regulatory role in the serotonergic pathway and in prenatal stress.
Objectives: To examine the microRNA profile in this GxE setting in maternal blood samples.

Methods: In the present study, we explored the role of epigenetic factors by profiling microRNA expression in blood samples (n=34) from mothers of children with autism, with known pregnancy stress history. The samples were divided into 5 groups based on SERT genotypes (LL, LS, and SS) and prenatal stress level (High and Low).

Results: Among the 2500 mature microRNAs examined, 5-way ANOVA showed significantly differential expression (DE) of 119 microRNAs, 90 (76%) of which showed a similar pattern of expression in High vs Low stress groups (i.e., stress-dependent microRNAs). Intriguingly, two of them, miR-1224-5p and miR-331-3p, were recently reported by our group to exhibit stress-dependent expression in rodent brain samples from embryos exposed to prenatal stress. Another stress-dependent microRNA found in our study, miR-145-5p, has been reported in association with maternal stress. To assess the role of SERT genotype, we conducted a 3-way ANOVA on three SERT genotype groups exposed to a high level of prenatal stress. This analysis showed a smaller number of significantly DE microRNAs (n=20), 5 (25%) of which were among the stress-dependent DE microRNAs. These 5 microRNAs may be candidates for stress X SERT genotype interactions. One of them, miR-663a, has been previously reported to be DE in response to the serotonin-specific reuptake inhibitor, fluoxetine. These findings are remarkable as these changes were detected in samples from mothers several years after stress-exposed pregnancies. Persistent microRNA changes have been observed previously in other conditions, such as after cessation of smoking.

Conclusions: Our study provides evidence for epigenetic alterations in relation to a promising GxE model (prenatal maternal stress X the SERT gene) in autism.

84 **165.084** Modifiers of Severity in Autism Spectrum Disorder

S. P. Smieszek, *R. Igo and J. Haines, Population and Quantitative Health Sciences, Case Western Reserve University, Cleveland, OH*

Background:
Autism Spectrum Disorder (ASD) comprises a complex of neurodevelopmental disorders primarily characterized by deficits in verbal communication, impaired social interaction and repetitive behaviors. The genetic architecture has proved to be complex and encompasses profound clinical heterogeneity, which poses challenges in understanding its pathophysiology.

Objectives:

There is accumulating evidence that ASD is caused by rare inherited or spontaneous genetic mutations, such as copy number changes and single nucleotide alterations. However, the genetic causes that have currently been found only in s small proportion of cases. We conducted a large scale association analysis of the MSSNG whole genome sequencing data to elucidate potential modifiers of ASD severity.

Methods:

Using the additive linear model method (PLINK) we have directly tested association between 6,198,166 SNPs (Quality Control: MAF > 0.05, HWE $P < 1 \times 10^{-6}$, Mendelian errors, removal of samples with dis-concordant sex status, twins, samples with unreported relatedness) and Vineland Adaptive Behavior Scale Scores.

Results:

Interestingly, the top variants direct us to a region (part of the biggest META-significant haplostretch of SNPs, n=132) containing multiple variants on chromosome 3 including a highly interesting nonsynonymous SNV rs11539148 within *QARS* (NM_001272073:c.A821G:p.N274S MAF=0.0391). Furthermore, to leverage the size of the data we conducted a pathway enrichment analysis of the set of highly significant results ($P < 1 \times 10^{-6}$) using PARIS and DAVID software. The most significant categories included brain development and structural component of myelin sheath pathways. Genes categorized a neurological, developmental and immune related constituted 65% of all the genes contributing in these pathways. We took variants from contributing genes from significantly over-represented categories to test how much variability in the VABS scores can be explained by the variants. The cumulative effect of the single top pathway enrichment alone on affection status is 2% ($P = 6.34 \times 10^{-6}$). Furthermore we inspected eQTLs for the region and reassuringly we detected lower expression across multiple data-sets, a result consistent with our hypothesis.

Conclusions:

We detect a region that may be a hallmark of severity in ASD. As genetic predisposition may be different for almost every ASD individual, understanding the common mechanisms for endo-phenotypes may help elucidate ASD causal mechanisms.

85 **165.085** Monogenic Disorders Associated with ASD in a Large Portuguese Sample

F. Duque[1,2,3]*, J. Rosmaninho-Salgado*[4]*, C. Café*[1]*, S. Mouga*[1,5]*, D. Sousa*[1]*, A. Oliveira*[1,2]*, S. Ferreira*[6]*, P. Maciel*[7]*, I. Carreira*[6]*, A. M. Vicente*[8] *and G. Oliveira*[1,2,3,9]*, (1)Centro Hospitalar e Universitário de Coimbra - CHUC, Coimbra, Portugal, (2)University Clinic of Pediatrics, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, (3)Faculty of Medicine, Institute for Biomedical Imaging and Life Sciences (IBILI) and Center for Neuroscience and Cell Biology (CNC), University of Coimbra, Coimbra, Portugal, (4)Serviço de Genética Médica do Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, (5)IBILI - Institute for Biomedical Imaging and Life Sciences, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, (6)Laboratório de Citogenética e Genómica, Faculty of Medicine, University of Coimbra, Coimbra, Portugal, (7)Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal, (8)Instituto Nacional Saude Doutor Ricardo Jorge, Lisbon, PORTUGAL, (9)Centro de Investigação e Formação Clínica – Hospital Pediátrico – Centro Hospitalar e Universitário de Coimbra (HP-CHUC), , Portugal, Portugal*

Background:

Autism spectrum disorder (ASD) is a challenging neurodevelopmental disorder, with a multifactorial origin and a complex inheritance. The great majority of ASD cases are “idiopathic” (without a known etiology). At present, the etiology of autism can only be explained in about 15-20% of the cases. The extreme heterogeneity of ASD further complicates our understanding of its biology and pathophysiology. Some individuals with ASD have an identifiable genetic etiology, for example, known rare single-gene disorders. Syndromic autism refers to genetically well-defined disorders in which ASD is observed at higher than expected frequencies. The most common of these syndromes associated with ASD is fragile X (*FMR1*), accounting for 2-5% of cases of ASD. Other monogenic disorders associated with ASD include tuberous sclerosis (*TSC1, TSC2*), neurofibromatosis (*NF1*), Angelman syndrome (*UBE3A*), Rett syndrome (*MECP2*) and PTEN mutations in patients with macrocephaly and autism, among others.

Objectives:

To report a subset of individuals with single-gene disorder associated with ASD in a large Portuguese sample.

Methods: Participants included 1608 children and adolescents, ranging in age from 2 to 18 years old (mean ± SD; 13.4 ± 6.2 years old) and a Male/Female ratio – 4.6/1. Subjects were seen as part of an outpatient clinic in a tertiary Pediatric Hospital between 1995 and 2016. To be included, all participants had to have ASD diagnosis, according to, at least positive score in two for ADI-R, ADOS and fulfilment of DSM-5 criteria. Associated medical or genetic condition that presumably is the cause of autism was considered after a detailed medical history, a carefully physical and neurologic examination and, if still there was no diagnosis, a thoroughly laboratory evaluation, which included routine testing procedures for fragile X mutations (FRAXA and FRAXE) and molecular cytogenetic abnormalities studied by comparative genome hybridization array and sequencing techniques. We also conducted a metabolic investigation. Moreover, these ASD children underwent intellectual and functional adaptive evaluations with Griffiths Mental Development Scale and/or Wechsler Intelligence Scale and Vineland Adaptive Behavior Scale (VABS), respectively.

Results:

Our findings revealed 40 Fragile X syndrome (*FMR1*) (2.48%) and a rare FRAXE mutation, seven Rett syndrome, six Tuberous sclerosis, four *PTEN* mutations, three *KCNQ3*-mutation, two individuals of each syndrome – Angelman, CHARGE and Pitt-Hopkins like syndrome 2 (*NRXN1*). With one case of each, we report a Cornelia de Lange and a Rubinstein-Taybi syndrome with ASD. Comprehensive genotype-phenotype description will be presented. Also, we highlight some interesting and published results: putative missense mutations were identified in the *NLGN4* gene in two separate, unrelated, autistic patients, *G99S* and *K378R* are described.

Conclusions:

Most of the known genetic causes of ASD are also causes of ID, implying that these two identities share common genetic basis. Comprehensive cognitive and behavior phenotyping revealed moderate to severe developmental delay/intellectual disability among syndromic ASD, in our study. Our findings are concordant with contemporaneous investigation, with extreme heterogeneity of ASD further complicates our understanding of its biology and pathophysiology.

86 **165.086** Patient and Provider Factors Influence Completion Rates of Genetic Testing for Autism Spectrum Disorders

N. Abreu[1], *M. Chiujdea*[1], *N. Huntington*[2] *and S. J. Spence*[1], *(1)Autism Spectrum Center, Boston Children's Hospital, Boston, MA, (2)Developmental Medicine Center, Boston Children's Hospital, Boston, MA*

Background: Genetic testing is standard medical care for children with autism spectrum disorder (ASD) as results can assist with providing diagnostic certainty, guide medical decision-making, influence family planning and help prognosticate on other medical issues in the affected child. Despite the American Academy of Pediatrics, American Academy of Neurology, American College of Medical Genetics and Genomics, and American Academy of Child and Adolescent Psychiatry writing consensus statements that chromosomal microarray (CMA) should be performed as first-line testing for all patients with non-syndromic ASD, previous survey-based research has identified low rates of testing, especially CMA completion (15-20%). While patient factors like intellectual disability and seizures are associated with increased yield of clinically significant results on CMA testing, it is unclear if this knowledge may affect ordering practices. Providers also have different approaches to genetic counseling in autism and it remains unknown how the provider's perspective influences completion of CMA testing.
Objectives: To evaluate completion of CMA testing using a prospective cohort of newly diagnosed children with ASD and investigate factors contributing to test completion . Patient factors include age, gender and medical comorbidities. Provider factors include specialty and CMA recommendation practice.

Methods: 343 patients with a new diagnosis of ASD made between 2/1/15 and 1/31/16 were identified. Cases were selected using a mandatory online institutional quality improvement questionnaire completed by providers at the time of initial diagnosis. Laboratory data were analyzed through 8/1/17, allowing for a minimum of 18 months for genetic testing to be performed. Patient and provider factors were extracted from billing data and chart review.

Results: The sample had 75% males and a mean age at diagnosis of 49 months (range: 16 months to 17.5 years). Epilepsy occurred in 3% and global developmental delay or intellectual disability (GDD/ID) occurred in 38%. Completion rate of CMAs was 40.2%. Higher rates of CMA completion were seen in individuals with GDD/ID (52% with v. 33% without, $p<0.001$). There was a negative correlation with age at time of diagnosis ($r = -0.27$, $p<0.01$). There was no effect of gender (48% males v. 38% females, $p=0.14$) or comorbid epilepsy (45% with v. 40% without, $p=0.72$).

Providers recommended genetic testing in 86% of initial diagnostic visits and also referred to Genetics in 6.4%. There was a lower overall CMA completion rate when providers did not recommend genetic testing at the first visit (15%) compared to when recommended by the provider (44%) or when recommended and referred to Genetics (45%, $p < 0.01$). Patients seen by providers in developmental medicine were more likely to have completed CMAs compared to patients seen by providers in neurology (46% v. 27%, $p=0.02$).

Conclusions: In this prospective cohort at a single center with institutional guidelines recommending routine CMA testing for all individuals with non-syndromic ASD, the CMA completion rate remains low. Certain patient-related factors (e.g., GDD/ID and age) and provider-related factors (e.g., specialty and recommendation made at first visit) significantly impact CMA completion rates. Further investigation is needed into specific provider practices, additional patient variables and family attitudes.

87 **165.087** Protecting DNA: Shortened Telomere Length Is Associated with Autism Spectrum Disorder

B. B. Braden[1], ***C. R. Lewis***[2], *K. Agrawal*[1], *S. Ringenbach*[1] *and M. Huentelman*[2], *(1)College of Health Solutions, Arizona State University, Tempe, AZ, (2)Translational Genomics Research Institute, Phoenix, AZ*

Background: Autism Spectrum Disorder (ASD) is a common neurodevelopmental disorder, but the etiology of symptoms in most cases is not well understood. Recently, two papers introduced preliminary evidence associating shortened telomere length with ASD. Telomeres are repetitive non-coding DNA nucleotides that protect genes by capping chromosome ends. They progressively shorten with each cell division, providing a biological measure of aging. Shortened telomeres have been associated with many adverse health and age-related outcomes such as cancer and Alzheimer's disease. How telomere length may underlie symptoms associated with ASD is not well understood.
Objectives: We aimed to replicate the association of shortened telomere length with ASD in a large, well-characterized sample of children. We hypothesized children with ASD would have shorter RTL than age-matched typically developing (TD) controls.

Methods: Using blood leukocytes, we investigated the association between relative telomere length (RTL) and childhood ASD in males (ASD: $n = 186$; TD: $n = 107$). We used an established quantitative polymerase chain reaction method, and designed telomere and single-copy reference gene primers from an established protocol. We assessed RTL between groups using independent samples t-test ($p < 0.05$; one-tailed).

Results: With a subset of the entire sample (ASD: $n = 31$; TD: $n = 28$), who were well matched in age (ASD: 5.79±2.12 years; TD: 5.93±2.71 years), preliminary findings demonstrate that the ASD group had shorter RTL length compared to the controls [$t(57) = 1.69$, $p = 0.04$]. Continued analysis of the entire sample and correlational analyses with behavioral measures are in progress.

Conclusions: Findings replicated other recent studies, providing additional evidence that ASD is associated with shortened telomere length. Further investigations aimed at understanding the relationship between telomere length and symptoms associated with ASD are planned and warranted. Telomere length may be an important biological mechanism in understanding the etiology of ASD, and providing a novel treatment target for future interventions.

88 **165.088** Quantification of Genetic Risk of ASD for a Planned Child Based on the Genomes of Its Parents

ABSTRACT WITHDRAWN

Background: A key question that many parents planning to start a family confront is: what is the probability that this child we are planning to conceive will develop ASD? While, many copy number variants (CNVs) and other genetic defects of high penetrance for ASD have been identified in the literature, and numerous genome wide association studies have identified sets of single-nucleotide polymorphisms (SNPs) that confer risk for ASD, no study that the author is aware of has attempted to quantify the overall genetic risk per genome. With a genetic risk per genome quantified, one could then go a step further and examine the question of what is the genetic risk of ASD in a child that has yet to be conceived.
Objectives: Given two genomes representative of potential biological parents, determine the risk that a child conceived from these two individuals will develop ASD.

Methods: A genome wide risk model was constructed to represent genetic risk of ASD given a specific genome. To start with, a review of the literature was conducted to determine a set of variants that confer ASD risk. Variants in this context included CNVs and SNPs. Full chromosomal duplications or deletions were excluded as they generally result from spontaneous mutation. The search was broad in the sense that it was conducted to include autosomal variants, X-chromosome variants, Y-chromosome variants, and mitochondrial variants. For each variant, measures of relative risk and prevalence were obtained from the medical literature or in some cases estimated. In the case of SNPs, the measure of prevalence used was the global mean effect size. A model of overall risk was constructed assuming risk associated with any given variant is independent of the risk of any other variants that do not affect the same segment of DNA. In other words, risks are generally assumed to be multiplicative. Care was taken in this model to avoid double counting risk of specific SNPs with risk of CNVs covering the same section of DNA. This model was calibrated for each sex based on the estimated prevalence of ASD per sex from the literature. Using this genome wide risk model, a separate model of ASD risk in progeny was constructed given two genomes (biological parents) as inputs. This progeny risk model calculates a risk of ASD for a child of each sex using the parents' genetic data, and data from the literature on the probability of spontaneous mutation resulting in CNVs. The overall ASD risk in the progeny was then computed as a weighted average of the ASD risk of each sex.

Results: The progeny risk model provides a seemingly reasonable quantification of ASD risk. It would be desirable to test it with out of sample data. Its limitations include: no adjustments for non-independent interactions between variants, and no adjustments for environmental or epigenetic risks.

Conclusions: This study provides a practical application of genetic risk to a real-world question that parents confront when they are considering conceiving a child.

89 **165.089** Rare Copy Number Variation As Predictors for Treatment Response to Social Skills Training in Children with Autism Spectrum Disorder

K. Tammimies[1]*, I. Rabkina*[1]*, D. Li*[1]*, S. Stamouli*[1]*, M. Becker*[1]*, S. Berggren*[2]*, U. Jonsson*[2]*, N. Choque Olsson*[3] *and S. Bolte*[4]*, (1)Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (2)Karolinska Institutet, Stockholm, Sweden, (3)Clinical Neuroscience (CNS), Karolinska Institutet, Stockholm, Sweden, (4)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Background: Social skills group training (SSGT) is one the most commonly used interventions for individuals with autism spectrum disorder (ASD). However, the response to SSGT can vary. Limited information exists of predictors of the SSGT treatment outcome. Chromosomal microarray (CMA), to analyze the presence of rare copy number variation (CNVs), is currently the recommended first-tier molecular diagnostic test for children with ASD. However, studies investigating the treatment outcomes in the individuals with CNVs are lacking.

Objectives: Analyze the association between rare CNVs and response to SSGT in children and adolescent with ASD

Methods: Saliva-derived DNA was used to genotype 207 consenting participants from the KONTAKT SSGT study (Choque-Olsson *et al.* J Am Acad Child Adolesc Psychiatry 2017; 56(7):585–592) using the Affymetrix Cytoscan HD microarray. CNVs were called using two different algorithms followed by annotation and selection of rare CNVs using population-based dataset. The rare CNVs were further stratified by size and gene context. The response to SSGT was measured using changes in the parental reported Social Responsiveness Scale (SRS-2) from baseline to post-treatment and 6-months follow-up. Secondary outcome measures included parental reported Adaptive Behavior Assessment System II (ABAS-II) and trainer reported Developmental Disabilities modification of the Children's Global Assessment Scale (DD-CGAS). Linear mixed models were used to test associations between rare CNVs and change in SRS-2 or other outcome measures. The outcome was considered first using data from all time points, then at the posttreatment or follow-up assessments specifically. We additionally investigated differences in the baseline phenotypic measures, such as full-scale IQ and ADOS-2 total scores, between individuals with and without rare CNVs

Results: A total of 101 rare CNVs or chromosomal abnormalities were identified in the participants. These included known microdeletion and duplication syndromes such as 7q11.23dup but also rare CNVs affecting newly identified ASD genes such as *CHD8*. Our analysis reveal that participants in the active KONTAKT SSGT group that were carriers of exonic CNVs had overall worse outcomes at all times point (β=12.1, p=0.018). This association was mainly driven by CNVs larger than 500kb, for which significant association was shown for both posttreatment (β=15.3, p=0.017) and follow-up (β=14.2, p=0.028). These results indicate a significant increase in the symptom severity after SSGT. Similar results were obtained for ABAS-II. However, no significant association was found for the trainer reported DD-CGAS outcome and rare CNVs. The individuals with rare CNVs had significantly lower IQ than non-carriers, but they did not differ in other baseline measures tested.

Conclusions: This is the first study to report that carriers with rare exonic CNVs had worse and even adverse outcome after completing SSGT. Our results suggest that currently used molecular diagnostic test CMA can potentially be used to pinpoint subgroup of individuals that do not benefit from SSGT. In the future, genomic testing will lead to recommendations on how to better tailor the limited resources in treatments for affected individuals thus enhancing the personalized medicine approach in ASD.

90 **165.090** SPARK (Simons Foundation Powering Autism Research for Knowledge): A US Cohort of 50,000 Families to Accelerate Autism Research

P. Feliciano*, L. Grosvenor, A. Daniels, W. K. Chung, L. A. Green Snyder and H. Zaydens, Simons Foundation, New York, NY*

Background:

The causes of autism spectrum disorders (ASD) and the cellular mechanisms leading to ASD are not completely understood. Clinical studies to understand the brain and behavior in ASD are challenged by lack of replicability, partly due to the heterogeneity of the condition and small sample sizes. These challenges have limited progress in the development of effective treatments for this condition, and there are currently no approved medications that treat the core symptoms of ASD. Although ~100 ASD genes have been identified from studies of thousands of individuals, larger studies are required to understand the genomic architecture of ASD and identify additional monogenic, oligogenic, polygenic and environmental risk factors and to enable research studies of more homogeneously defined groups of individuals with ASD.

Objectives:

To accelerate clinical research in ASD, we created SPARK (Simons Foundation Powering Autism Research for Knowledge) with the goal of recruiting and retaining at least 50,000 individuals with ASD and their family members into a longitudinal, recontactable research cohort in which individual genetic causes of autism are returned to participants.

Methods:

To date, we have enrolled over 30,000 individuals with ASD and over 50,000 of their family members. SPARK is recruiting approximately 1,000 additional participants with ASD each month, through a national network of 25 clinical sites and social and digital media campaigns. We have performed exome sequencing and SNP genotyping on the first 500 parent-affected offspring trios, and currently we are performing exome sequencing and genome-wide genotyping on 4,000 parent-affected offspring trios and 2,000 unaffected siblings.

Results:

Using exome sequencing of 500 ASD trios we identified *de novo* and inherited X- linked likely gene disrupting (LGD) variants in genes strongly associated with ASD in 4% of individuals and returned those results to participants using an innovative, centralized genetic counseling service. We have also identified *de novo* loss of function or damaging missense variants in 27 additional genes, including two *de novo* loss of function variants in *BSBK2*, a novel candidate gene for ASD.

Conclusions:

We have developed a large-scale research platform that is efficient and engaging and that can be applied to other human diseases. Data from this cohort of recontactable, genetically characterized individuals with ASD are available to the research community at https://sfari.org/resources /autism-cohorts/spark. Researchers can also apply to access to this unique cohort for recruitment into research studies. SPARK represents a new era of clinical research that combines online access to participants, ability to re-contact and recruit participants for new research studies, and genomic, environmental, and longitudinal behavioral and medical information on all participants. SPARK is founded on principles that emphasize a strong partnership between participants and researchers. SPARK is committed to providing aggregate and individual research results to participants to help keep the goals of research grounded in having a meaningful impact on the lives of individuals and families with ASD. We believe that the challenges and lessons learned from SPARK will be informative to a wide range of researchers working on other conditions.

91 **165.091** The Australian Autism Biobank: A National Initiative to Accelerate ASD Discovery Research

G. A. Alvares[1,2], *C. Dissanayake*[3,4], *V. Eapen*[4,5], *H. Heussler*[4,6], *F. J. Rose*[4] *and A. J. Whitehouse*[7], *(1)Telethon Kids Institute, University of Western Australia, Perth, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, QLD, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (4)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (5)School of Psychiatry, University of New South Wales, Sydney, Australia, (6)Mater Research Institute, The University of Queensland, Brisbane, Australia, (7)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia*

Background: The clinical (phenotypic) and genetic heterogeneity of Autism Spectrum Disorder (ASD) presents an enormous challenge to understanding etiological pathways and clinical outcomes. With significant advances in genetic and biological research alongside rapid-pace technological innovations, there is an increasing imperative to establish large and comprehensive bio-resources to support discovery research. To date, there has not yet been any single collective effort to establish such a resource in Australia, which has its own unique ethnic and cultural diversity.

Objectives: The Australian Autism Biobank was initiated by the Cooperative Research Centre for Living with Autism (Autism CRC). The aim of this initiative is to establish a large-scale repository of detailed phenotypic and biological information to facilitate future ASD discovery research.

Methods: Participants are children with a confirmed diagnosis of ASD ('probands'), aged between 2-17 years, at four national data collection sites in Australia. Biological parents and siblings are also invited to participate, as well as typically developing children ('controls') recruited from the general community. No exclusion criteria regarding language level, cognitive ability, or comorbid medical, psychiatric or genetic condition are applied to children diagnosed with ASD. All children complete cognitive or developmental assessments, with probands additionally completing an ASD diagnostic assessment. Parents/caregivers of probands are asked to complete questionnaires about medical history and current symptoms, along with an interview about early development. Physical measurements as well as blood, stool, urine, and hair samples are collected from all children; physical measurements and blood samples are collected from both parents, where possible. Samples are sent to a central processing site and placed in long-term storage at a specialised biobanking facility.

Results: With recruitment still ongoing, 691 probands (144 females) have been recruited to date, with an average age of 7.59 (SD = 3.95) years at assessment. In addition, 566 mothers (M = 39.37 years, SD = 6.67), 384 fathers (M = 42.27 years, SD = 7.53), and 124 siblings (M = 7.87 years, SD = 4.26) have been recruited, forming 415 (60.58%) complete 'trios' (a proband with biological mother and father) and 88 (12.74%) complete 'quads' (a proband with a sibling and both biological parents). 211 (30.54%) probands were from 99 multiplex families; that is, families comprising multiple children diagnosed with ASD (between 2 to 5 children). The current cohort also includes 11 concordant and 3 discordant twin pairs.

Conclusions: The establishment of this Australian biobank has resulted in a valuable resource of detailed clinical and biological information that will help accelerate the pace of ASD discovery research. Recruitment numbers to date support the feasibility of large-scale biological sample collection in children diagnosed with ASD with comprehensive phenotyping across a wide range of ages, adaptive functioning, and cognitive levels. The initial characteristics observed in this sample appear to be broadly in line with international surveillance efforts and suggest a representative sample of children across the four largest metropolitan areas in Australia. Recruitment is currently ongoing, with data access requests available in the near future.

92 **165.092** The Autism Speaks Mssng Whole Genome Sequencing Resource

Scherer*[1], *(1)The Hospital for Sick Children, Toronto, ON, Canada, (2)Deep Genomics, Toronto, ON, Canada, (3)Google, Mountain View, CA, (4)BioTeam inc, Middleton, MA, (5)University of Toronto, Toronto, ON, Canada, (6)Memorial University of Newfoundland and Eastern Health, St. John's, NF, Canada, (7)University of Alberta, Edmonton, AB, Canada, (8)McGill University, Montreal, QC, Canada, (9)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (10)isand, Toronto, ON, Canada, (11)Drexel University College of Medicine, Philadelphia, PA, (12)Autism Speaks, Princeton, NJ*

Background:

Autism Spectrum Disorder (ASD) is a highly heterogeneous disorder, both in clinical presentation and genetic architecture. There are many, perhaps hundreds, of loci associated with ASD with multiple forms of genetic variation contributing risk variants.

Objectives:

We are performing whole genome sequencing (WGS) of families with ASD to build a resource, named MSSNG, to enable the sub-categorization of phenotypes and underlying genetic factors involved.

Methods:

We have created a cloud database containing WGS data and clinical information which is accessible through an internet portal with controlled access. We have recently released new data to bring the total number of genomes to 7,235, including subjects who are part of the POND-network and Baby Siblings Research Consortium. Data are available for single nucleotide variants (SNVs), small insertion/deletions (indels) and copy number variants.

Results:

From the first 5,205 genomes, we detected on average 73.8 *de novo* SNVs and 12.6 *de novo* indels per ASD subject and identified 18 new candidate ASD-risk genes, such as *MED13* and *PHF3*. In total, by including *de novo* SNVs and indels and large copy number variants (CNVs), a molecular diagnosis could be determined for 11.2% of ASD cases (Nature Neurosciences, 2017). Analysis of the CNV data from these subjects found an average of 22.7 rare (<1% frequency) CNVs >1kb in size per individual sequenced on Illumina platforms, and 7.87 rare CNVs >2kb per individual sequenced by Complete Genomics. Of these, an average of 9.89 and 4.78, respectively, impacted protein-coding regions of genes. We are now analysing structural variant calls using multiple different tools; CREST, LUMPY, Manta and DELLY. The MSSNG phenotype database is also being expanded, and dozens of families are being added with multigenerational pedigrees, multiple affected siblings, and participants from clinical trials. Moreover, epigenetic analysis of DNA samples with data from methylation microarrays is adding additional functional data to the genomic information, and all of this is made available to the research community through a simple MSSNG user interface (portal).

Conclusions:

The Autism Speaks MSSNG project combines high quality WGS data with phenotype information to facilitate researchers of all backgrounds in studies of the genetic architecture of ASD.

93

165.093 The Clinical Relevance of Intragenic NRXN1 Deletions

N. Cosemans[1,2]*, L. Vandenhove*[1,2]*, S. Shen*[3]*, J. Fitzgerald*[4]*, L. Gallagher*[4] *and H. Peeters*[1,2]*, (1)Center for Human Genetics, University Hospital Leuven, KU Leuven, Leuven, Belgium, (2)Leuven Autism Research (LAuRes), Leuven, Belgium, (3)Regenerative Medicine Institute, School of Medicine, BioMedical Sciences Building, National University of Ireland (NUI), Galway, Ireland, (4)Trinity College Dublin, Dublin, Ireland*

Background: Neurexins (NRXNs) are involved in synapse formation, differentiation and function, which makes them important in brain development and function. Rare intragenic deletions affecting *NRXN1* have been associated with autism spectrum disorder, but also with other neuropsychiatric disorders, such as developmental delay, language disorders, epilepsy, schizophrenia and aspecific dysmorphic features. In fact, *NRXN1* deletions lack phenotypic specificity and are often inherited from a clinically unaffected parent. Therefore, it is challenging to determine to what extend a *NRXN1* deletion can explain the phenotype in a particular patient.

Objectives: The current study aims to gain insight in the genotype-phenotype correlation of intragenic *NRXN1* deletions.

Methods: First, an extensive literature study was performed that contains 629 heterozygous *NRXN1* deletions. The study cohort was assembled through data extraction from 73 literature reports and consists of 341 probands and 140 relatives from clinical cohorts or case reports and 148 individuals from control cohorts. All individuals are characterized by clinical data, position and size of the variant and family relationships. These data were used to study the prevalence, penetrance, inheritance, segregation and phenotypic specificity of *NRXN1* deletions. Second, we studied 44 additional cases with heterozygous *NRXN1* deletions identified at our center in Leuven to illustrate our findings by means of case based reasoning. Moreover, the exact breakpoints of these deletions were identified through targeted sequencing.

Results: Based on published unscreened control cohorts, the population prevalence of intragenic *NRXN1* deletions was estimated to be ~1/300 (0.312%; 99%CI [0.253%-0.370%]). However, 90% of these deletions were intronic, pointing out that the exonic deletions are very rare with a prevalence of ~1/3,000 (0.031%; 99%CI [0.013%-0.050%]). The observations from the extensive literature study allowed to distinguish three distinct parts in the *NRXN1* gene. First, exon 6-24 deletions, that were only present in two out of over 100,000 controls, often segregated with intellectual disability (ID) in families or were *de novo* in sporadic cases with ID. Genotype-phenotype data in the Leuven patient cohort illustrated this observation. Taken together, this lends support for an association of exon 6-24 deletions with mainly ID with high penetrance. Second, several intragenic deletions within intron 5 were founder deletions that did not show clear evidence for an association with neurodevelopmental or psychiatric disorders in the current study. These results were obtained by exact breakpoint determination in the Leuven cohort. Third, deletions affecting exon 1-5 are susceptibility variants that may have a very variable expression (from mild to severe phenotypes) and a variable penetrance. Penetrance is estimated to be rather low, however, it is difficult to estimate since these copy number variants are also present in screened and unscreened controls and may be overrepresented in the patient population because of reporting bias.

Conclusions: The current study revealed some important correlations between the position of *NRXN1* deletions on the one hand and the population prevalence, the segregation, the penetrance and the associated phenotype on the other hand. From these observations, clinical guidelines can be derived to improve the interpretation of a *NRXN1* deletion for a particular patient and family.

165.094 To Test or NOT to Test? Fragile X Premutation Analysis in Minors- Ethical and Medical Dilemmas and Considerations

L. V. Gabis[1] *and A. Raas-Rothschild*[2]*, (1)Pediatrics, Sheba Medical Center, Rehovot, ISRAEL, (2)Genetics, Sheba Medical center, Ramat Gan, Israel*

Background: Since 2013, Fragile X screening test has been included in Israeli general screening performed in healthy women above age eighteen. Since then new knowledge emerge on the point that women with premutation beyond the risk of childbearing an offspring with full mutation might face medical and emotional challenges during their life. It has become common knowledge that women with premutation face medical and emotional challenges during their life, beyond the risk of childbearing an offspring with full mutation. Fragile X-associated primary ovarian

insufficiency (FXPOI) is a primary cause of infertility and occasionally it may present at a young age, sometimes before the age of family planning. In addition, it seems that a phenotype of learning disabilities, neuropsychiatric issues, ADHD and endocrine dysfunction emerges as a continuum in patients with expansion mutation between the range of premutation and full mutation, both in male and female premutation carriers, as well as social communication awkwardness, possibly autism spectrum features and FXTAS in aging carriers.
Knowledge in regards to the Fragile X status of a child or a teenager might be actionable for the primary care physician and may influence parental attitudes. Minors in families at risk could be tested to benefice from more focused treatment of related impairments- such as learning disabilities, ADHD, ASD or other neuropsychiatric difficulties. On the other hand, physicians may have concerns that carrying a genetic disorder may have a negative impact in terms of emotional burden, social and insurance implications.

Objectives: Main aim was to assess Israeli medical personnel's attitudes in regards to testing Fragile X premutation status in minors. As a secondary aim we probed the knowledge in regards to premutation symptoms. A third aim was to promote knowledge and awareness.

Methods: We used an on- line 10 questions query (SurveyMonkey), including anonymous background information, knowledge and experience with Fragile X families and attitudes towards testing minors.

Results: To date 78 practitioners completed the study of which more than a half had more than twenty years in practice and 20% cared for 5-10 families with Fragile X and 18% for more than ten. 82% of practitioners answered that they would consider testing Fragile X in minors and 13% would test in girls only. In regards to the symptom list, more than 20% confused between symptoms related to permutation and full mutation, mainly in regards to fertility, intellectual impairment, autism and dysmorphic features.

Conclusions:

The permutation phenotype is not well recognized. However, most practitioners would test in minors, mainly if full mutation phenotype is present.

We suggest to individualize the decision in regards to testing carrier status in minors sibblings of affected children and to discuss the different options with the parents, while differentiating between general screening for non specific phenotype such as anxiety or ADHD, to permutation carriers with a family member with Fragile X Syndrome. Awareness of the risks and incidence of the various possible manifestations linked to the permutation status are mandatory for advising patients and their families.

95 **165.095** Translating the Complex ASD Genetic Architecture into Clinical Phenotype Using an Integrative System Biology Approach

M. Asif[1]*, H. Martiniano*[2]*, C. Rasga*[3]*, A. R. Marques*[4]*, J. Santos*[4]*, G. Oliveira*[5]*, F. M. Couto*[6] *and A. M. Vicente*[7]*, (1)Faculdade de Ciências da Universidade de Lisboa , Lisbon, Portugal, (2)Faculdade de Ciências, Universidade de Lisboa, Portugal, Lisbon, Portugal, (3)INSA, lisboa, Portugal, (4)INSA, Lisbon, Portugal, (5)Centro Hospitalar e Universitário de Coimbra - CHUC, Coimbra, Portugal, (6)Departamento de Informática, Faculdade de Ciências, Universidade de Lisboa, Portugal, Lisbon, Portugal, (7)Instituto Nacional Saude Doutor Ricardo Jorge, Lisbon, PORTUGAL*

Background: Autism Spectrum Disorder (ASD) is characterized by a wide spectrum of behavioral presentation, rendering ASD difficult to diagnose particularly in very young children. While many genetic factors are implicated in ASD, the architecture of genotype/phenotype correlations is still very unclear. Delayed diagnose leads to delay in applying behavioral therapies that may help to reduce symptoms, particularly when applied at young age.
Objectives: The aim of the study was to develop a novel machine learning-based integrative system biology approach to predict the clinical outcome from biological processes defined by rare Copy Number Variants (CNVs) in ASD children.

Methods: Agglomerative Hierarchical Clustering (AHC) was used to identify ASD phenotypic subgroups from the clinical reports from 2529 ASD patients recruited by the Autism Genome Project. Altered biological processes in the same ASD patients were inferred from rare CNVs targeting brain genes, by employing functional annotation analysis. To predict phenotypic clustering of patients from biological process disrupted by rare CNVs in brain genes, four different machine learning methods were trained and tested on the clustered patient and disrupted biological processes datasets, and performance of implemented methods were compared using “accuracy” measure.

Results: Analysis of clinical data using AHC identified two distinct phenotypic clusters that differed in overall adaptive behavior profiles, verbal status and cognitive abilities, defining more severe and less severe phenotypes. Clusters were highly stable for 1000-bootstrap iterations and clusters validation through the Silhouette method also indicated that both clusters were true and consistent. Cluster 1 represented the subgroup with the most severe clinical presentation, with all patients being non-verbal and presenting dysfunctional adaptive behavior profiles for all VABS subscales, as well as lower performance IQ. Cluster 2 individuals presented less severe ASD symptoms and milder deficits for all clinical variables. Enrichment analysis of rare CNVs targeting brain genes, followed by removal of redundant biological processes using Gene Ontology hierarchy, identified 18 statistically significant biological processes, generally consistent with reported literature for ASD. Support Vector Machine (SVM) outperformed the other three methods by achieving highest accuracy of 66.3% to differentiate between less and more severely affected individuals, thus allowing a reasonable prediction of clinical outcome from biological processes defined by genetic alterations.

Conclusions: To address the ASD heterogeneous phenotype which has hindered the identification of genotype/phenotype associations, ASD patients were clustered into two clusters with more and less severe phenotype that is consistent with a previously reported analysis. Functional annotation analysis showed that rare CNVs targeting brain genes from ASD subjects tend to aggregate in common biological processes that have been previously associated to ASD, such as nervous system development and protein polyubiquitination. The presented approach seeks to enhance our knowledge on ASD diagnosis and prognosis by elucidating the complex genotype/phenotype associations in patients, allowing earlier and more personalized intervention, and contributing to understanding the genetic basis of ASD clinical heterogeneity.

5:30 PM - 7:00 PM - Hall Grote Zaal

96 **166.096** A Meta-Analysis of the Efficacy of Immediate Release Methylphenidate to Reduce Hyperactivity in Children with Autistic Spectrum Disorder

A. Bratt[1], *B. Masanyero-Bennie*[2] *and S. P. Kelley*[3], *(1)Medway School of Pharmacy, Kent, United Kingdom of Great Britain and Northern Ireland, (2)Medway School of Pharmacy, University of kent & greenwich, Chatham, United Kingdom, (3)Medway School of Pharmacy, University of Kent & Greenwich, Chatham, United Kingdom*

Background: Psychostimulant medications, such as methylphenidate (MPH) have become mainstay treatments for Attention Deficit Hyperactivity Disorder (ADHD) symptoms, such as hyperactivity, impulsivity and inattention in children. Such symptoms frequently also co-exist in children with Autistic Spectrum Disorders (ASD), thereby complicating a differential diagnosis[1]. The presence of ADHD-like symptoms in children with ASD can have a significant detrimental impact on learning and social interaction, and can limit the outcome of behavioural interventions to address areas of core ASD difficulties. Therefore it is of clinical relevance and potential benefit to address the issue of effectiveness and tolerability / safety of stimulants such as methylphenidate in children with co-morbid diagnoses of ASD + ADHD.

Objectives: This study performed a meta-analysis of three randomised controlled trials (RCT's) homogeneously measuring the effect of immediate release methylphenidate (MPH) to reduce scores of hyperactivity in children with comorbid ADHD + ASD.

Methods: The following databases were searched to find studies / trials which used MPH in treating ADHD related symptoms in children & adolescents with ASD: PsychINFO, PubMed-MEDLINE, Cochrane Controlled Trials, and Web of Science. The search terms were variants of eg: Autism (Autistic Spectrum Disorders) / Methylphenidate/ Hyperactivity / Children. The primary homogeneous outcome measure extracted from each study was teacher / practitioner rated hyperactivity on the ABC scale[2].

Results: The findings showed that ir-MPH produces an overall moderate significant benefit to reduce hyperactivity in children with comorbid ADHD +ASD (Hedge's g value -0.581 & 95% confidence interval effect size -0.65). These results are best considered preliminary as they are based on 3 RCTs only, all with quite small sample sizes. Tolerability of methylphenidate appears to be a real issue, as a high number of adverse effects were experienced within the studies, which were severe enough to lead to frequent treatment discontinuation. Most frequent side effects reported were decreased appetite, difficulty initiating sleep, irritability and gastrointestinal discomfort.

Conclusions: Outcomes are discussed in relation to the risk / benefit question of medication use in this vulnerable population. Sleep disturbance, selective feeding and emotional lability are commonly observed inherently in the ASD phenotype, and these may all be exacerbated by methylphenidate use in a subset of children receiving medication. There is therefore a need to understand the clinical and biological variables which may predict which children are most likely to respond to treatment with stimulant medication and hence avoid exposure in those children who may experience an intolerable side effect profile.

97 **166.097** A Randomized, Double-Blind, Placebo Controlled Trial of 4 Weeks Intervention with Lactobacillus Plantarum PS128 in Autism Spectrum Disorder Boys in Taiwan

Y. W. Liu[1,2], *H. Y. Huang*[3], *W. S. Peng*[4], *Y. Y. Wu*[5] *and Y. C. Tsai*[2,6], *(1)Institute of Biochemistry and Molecular Biology, National Yang-Ming University, Taipei, Taiwan (Province of China), (2)Microbiome Research Center, National Yang-Ming University, Taipei, Taiwan, (3)Department of Psychology, National Taiwan University, Taipei, Taiwan, Taipei, Taiwan, (4)Bened Biomedical Co. Ltd., Taipei, Taiwan, Taipei, Taiwan, (5)YuNing Psychiatry Clinic, Taipei, Taiwan, (6)Institute of Biochemistry and Molecular Biology, National Yang-Ming University, Taipei, Taiwan*

Background: Targeting gut microbiota was reported to modulate behavioral abnormalities in animal models of neurodevelopmental disorders, like autism. *Lactobacillus plantarum* PS128 (PS128) was a psychobiotic which modulated the dopamine and serotonin levels in depression animal models.

Objectives: To investigate the effects of PS128 on boys with autism spectrum disorders.

Methods: Eighty male subjects diagnosed with autism spectrum disorder and confirmed with Autism Diagnostic Interview-Revised (ADI-R) were included in a 4-week, randomized, double-blind, placebo-controlled trial with PS128 or placebo (microcrystalline cellulose) intervention. The subjects took PS128 (3×10^{10} CFU) or microcrystalline cellulose (300 mg) orally twice daily. Several questionnaires were measured at baseline and day28 including Autism Behavior Checklist-Taiwan Version, (ABCT), Social Responsiveness Scale (SRS), SNAP-IV and child behavior checklist (CBCL). The principle of investigator measured Clinical Global Impressions (CGI)-severity scale was measured on day1 and Clinical Global Impressions (CGI)-improvement scale on day28. The primary outcome measure was ABCT. Fecal sample of subjects were collected on baseline and day28. Fecal levels of inflammatory molecules were analyzed by ELISA. Gut microbiota was analyzed by Next Generation Sequencing techniques. This study was registered on the Australian New Zealand Clinical Trials Registry (ANZCTR; Trial ID: ACTRN12616001002471).

Results: Four subjects of placebo group and 2 subject of PS128 group were dropped-out (drop-out rates is 7.5%) in this study. There is no adverse effect occurred in this study. There were no significant differences between in terms of subjects' age, education and their caregiver's education. It was also no significant difference with baseline performance between two groups with ADI-R, ABCT, SRS, SNAP-IV and CBCL scores. By the end of 4 weeks, the scores of Body and object use in ABCT and Rule-Breaking Behavior in CBCL were decreased significantly in PS128 group ($p < 0.05$). However, the placebo group was failed to improve significantly on any efficacy measure. Fecal levels of inflammatory molecules, myeloperoxidase and calprotectin, and gut permeability marker, zonulin, were similar in both groups on day1 and day28. NGS analysis results showed significant increasement of *Lactobacillus* was observed in PS128 group.

Conclusions: PS128 (3×10^{10} CFU) twice daily for 4 weeks significantly improved the scores of Body and object use in ABCT and Rule-Breaking Behavior in CBCL. Alteration of gut microbiota may contribute at least partially to the improvement.

98 **166.098** Cannabidiol Based Medical Cannabis in Children with Autism- a Retrospective Feasibility Study

A. Aran[1], *H. Cassuto*[2] *and A. Lubotzky*[1,3], *(1)Shaare Zedek Medical Center, Jerusalem, Israel, (2)Clallit and Leumit HMO, Jerusalem, Israel, (3)Department of Developmental Biology and Cancer Research, Hebrew University, Jerusalem, Israel*

Background: Anecdotal evidence of successful cannabis treatment in children with autism spectrum disorder (ASD) are accumulating but formal studies are lacking.
Objectives: This retrospective study assessed safety, tolerability and efficacy of cannabidiol (CBD) based medical cannabis, as an adjuvant therapy, for refractory behavioral problems in children with ASD.

Methods: 60 children with ASD (age = 11.8± 3.5, range 5.0-17.5; 77% low cognitive functioning; 83% boys) were treated with oral CBD and tetrahydrocannabinol (THC) at a ratio of 20:1. The dose was up-titrated to effect (maximal CBD dose -10mg/kg/d). Tolerability and efficacy were assessed using a modified Liverpool Adverse Events Profile, the Caregiver Global Impression of Change (CGIC) scale, the Home Situations Questionnaire–Autism Spectrum Disorder (HSQ-ASD) and the Autism Parenting Stress Index (APSI).

Results: Following the cannabis treatment, behavioral outbreaks were much improved or very much improved (on the CGIC scale) in 61% of patients. The anxiety and communication problems were much or very much improved in 39% and 47% respectively. Disruptive behaviors, were improved by 29% from 4.74±1.82 as recorded at baseline on the HSQ-ASD to 3.36±1.56 following the treatment. Parents reported less stress as reflected in the APSI scores, changing by 33% from 2.04±0.77 to 1.37±0.59. The effect on all outcome measures was more apparent in boys with non-syndromic ASD. Adverse events included sleep disturbances (14%) irritability (9%) and loss of appetite (9%).

Conclusions: This preliminary study support the feasibility of CBD based medical cannabis as a promising treatment option for refractory behavioral problems in children with ASD. Following this preliminary study, we launched a randomized double blind placebo controlled trial.

99 **166.099** Effect of a Combination of Carnitine, Coenzyme Q10 and Alpha-Lipoic Acid (MitoCocktail) on Mitochondrial Function and Neurobehavioral Performance in Children with Autism Spectrum Disorder

A. Legido[1]*, M. J. Goldenthal*[1]*, B. Garvin*[2]*, S. Damle*[1]*, K. Corrigan*[1]*, J. Connell*[2]*, D. Thao*[1]*, I. Valencia*[1]*, J. Melvin*[1]*, D. Khurana*[1]*, M. Grant*[1] *and C. J. Newschaffer*[2]*, (1)Drexel University, Philadelphia, PA, (2)AJ Drexel Autism Institute, Philadelphia, PA*

Background: Emerging research has suggested that mitochondrial (mt) dysfunction, causing secondary bioenergetic deficit and increase in oxidative stress, may play a role in the etiology of some patients with autism spectrum disorder (ASD) *(Legido A et al. Semin Pediatr Neurol 2013;20:163).*
Objectives: The hypothesis of this FDA-IRB approved open-label pilot trial was that patients with ASD and indications of mt dysfunction would improve clinically and/or biochemically following treatment with a combination of carnitine, coenzyme Q10 and alpha-lipoic acid *(MitoCocktail).*

Methods: To be eligible, participants had to fulfill DSM V diagnostic criteria for ASD and have abnormal buccal swab mt RCC (respiratory chain complexes) I and IV test results. RCC I and IV were measured through immunocapture and spectrophotometric procedures with values normalized to citrate synthase activity. A total of 11 patients (10M, 1F), aged 5-12 years completed the protocol. They received *MitoCocktail* daily for a 3-month period. Behavioral outcome data was collected from the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2), the Autism Spectrum Rating Scale (ASRS) and the Aberrant Behavior Checklist (ABC), administered at baseline (Time 1), three months into treatment (Time 2), and three months after treatment was discontinued (Time 3). Three separate scores (subscales and total) from the ADOS-2, three from the ASRS (subscales and total), and five (subscales) from the ABC were contrasted at Time 1 vs. Time 2. Those showing significant change were then examined for return toward baseline at Time 2 vs. Time 3. RCC I and IV levels were also compared across these time points. Paired t-tests were used to evaluate differences.

Results: Mean buccal complex I/IV activity ratio was significantly ($p<0.02$) reduced during *MitoCocktail* treatment compared to baseline. All subjects showed at least one specific sign of metabolic improvement, which waned 3 months post-treatment in 7 of the 11 participants. Of the 11 total or subscale scores considered, all showed change in means from Time 1 to Time 2. Statistically significant changes were observed for the Unusual Behavior subscale from the ASRS ($p<0.006$), the Lethargy subscale from the ABC ($p <0.01$), and the Inappropriate Speech subscale from the ABC ($p<0.02$). From Time 2 to Time 3, scores worsened on each of these three subscales with statistically significant changes on Lethargy ($p<0.01$) and Inappropriate Speech subscales ($p<0.007$).

Conclusions: The findings of this small pilot study provide preliminary support for the hypothesis that the use of *MitoCocktail* has a therapeutic benefit, improving maladaptive behavior and speech that correlate with changes in mt function. Larger placebo-controlled trials are needed to demonstrate efficacy.

100 **166.100** Effect of Vitamin A Supplementation on Gut Microbiota in Children with Autism Spectrum Disorders - a Pilot Study

J. Liu[1,2]*, X. Liu*[1]*, Q. X. Xiong*[3]*, T. Yang*[2]*, T. Cui*[2]*, L. N. Hou*[1]*, X. Lai*[2]*, S. Liu*[2]*, M. Guo*[2]*, H. X. Liang*[2]*, Q. Cheng*[1]*, J. Chen*[2] *and T. Li*[2,4]*, (1)Department of Child Health Care, Children's Hospital of Chongqing Medical University, Chongqing, China, (2)Children's Nutrition Research Center, Children's Hospital of Chongqing Medical University, Chongqing, China, (3)Pediatric Department of Clinical Medicine, Dazhou Vocational and Technical College, Chongqing, China, (4)Department of Child Health Care, Children's hospital of Chongqing medical university, Chongqing, China*

Background: Dysbiosis of gut microbiota are commonly reported in autism spectrum disorder (ASD) and may contribute to behavioral impairment. Vitamin A (VA) plays a role in regulation of gut microbiota.
Objectives: This study was performed to investigate the role of VA in the changes of gut microbiota and changes of autism functions in children with ASD.

Methods: Sixty four, aged 1 to 8 years old children with ASD completed a 6-month follow-up study with VA intervention. High-performance liquid chromatography was used to assess plasma retinol levels. The Autism Behaviour Checklist (ABC), Childhood Autism Rating Scale (CARS) and Social Responsiveness Scale (SRS) were used to assess autism symptoms. CD38 and acid-related orphan receptor alpha (RORA) mRNA levels were used to assess autism-related biochemical indicators' changes. Evaluations of plasma retinol, ABC, CARS, SRS, CD38 and RORA mRNA levels were performed before and after 6 months of intervention in the 64 children. Illumina MiSeq for 16S rRNA genes was used to compare the differences in gut microbiota before and after 6 months of treatment in the subset 20 of the 64 children.

Results: After 6 months of intervention, plasma retinol, CD38 and RORA mRNA levels significantly increased (all $P < 0.05$); the scores of ABC, CARS and SRS scales showed no significant differences (all $P > 0.05$) in the 64 children. Meanwhile, the proportion of *Bacteroidetes*/*Bacteroidales* significantly increased and the proportion of *Bifidobacterium* significantly decreased in the subgroup of 20 (all false discovery rate (FDR) $q < 0.05$).

Conclusions: *Bacteroidetes*/*Bacteroidales* were the key taxa related to VA. Moreover, VA played a role in the changes in autism biomarkers. It remains unclear whether the VA concentration is associated with autism symptoms.

101 **166.101** Management of Children and Youth with Neurodevelopmental Disorders (NDDs) in Community Settings Prior to Referral to a Tertiary Psychopharmacology Clinic

I. Kara *and M. Penner, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background:

The use of second-generation antipsychotic (SGA) medications to alleviate symptoms of irritability and aggression in children with autism spectrum disorder (ASD) has increased considerably in the past decade. Although efficacious, SGAs can be associated with significant cardiometabolic and neurologic risks. Given the increased susceptibility of the paediatric population to these adverse effects (AEs), the Canadian Alliance for Monitoring Effectiveness and Safety of Antipsychotics in Children (CAMESA) developed a set of guidelines in 2011 to provide physicians with clinical and laboratory testing recommendations for SGA monitoring. In this study, we undertake the first evaluation of CAMESA Guideline uptake amongst physicians to ensure that children with neurodevelopment disorders (NDDs) taking SGAs are receiving the current standard of care.

Objectives:

Primary: To determine how the introduction of the CAMESA Guidelines has impacted the frequency of clinical and laboratory investigations to monitor for AEs in children/youth with NDDs treated with SGAs.

Secondary:

1. Describe the sample of children/youth referred to a tertiary psychopharmacology clinic;
2. Determine rates of SGA prescription in the community and duration of treatment.

Methods:

A retrospective chart review was undertaken to compare rates of clinical monitoring of children/youth with NDDs treated with SGAs and referred to the Holland Bloorview psychopharmacology clinic before (2008-2011) and after (2013-2016) publication of the CAMESA Guidelines. Children on SGAs were divided into three categories based on reports of clinical monitoring: (1) Any investigations complete, (2) No investigations complete, and (3) Not specified. A Fischer's exact test was used to detect a statistically significant change in monitoring rates between the two time periods. Thoroughness of monitoring by CAMESA standards was also assessed. Descriptive statistics were used to address secondary objectives.

Results:

A total of 285 charts were reviewed (n=135 pre-CAMESA, n=150 post-CAMESA). The average age of children referred to the clinic was 10.4 years (range 2-18), with ASD as the most prevalent diagnosis amongst the population. The most common reasons for referral were aggression and hyperactivity/impulsivity. Forty-one percent of referred children were started on an SGA before arriving at the clinic, and median treatment duration was 17 months at the time of the first clinic visit. There is a nonsignificant difference (p=0.62) in the proportion of children on SGAs (n=48 pre-CAMESA, n=70 post-CAMESA) monitored for AEs before and after publication of the guidelines. Monitoring rates pre- and post-CAMESA were 35% and 44%, respectively. Of the children monitored, only 33% in the pre-CAMESA period and 63% in the post-CAMESA period underwent comprehensive investigations. This again represents a nonsignificant difference (p=0.11) in thoroughness of monitoring between the two time periods.

Conclusions:

We aim to provide novel insight into SGA monitoring practices and emphasize the importance of health risk minimization when prescribing these medications. Given that SGA monitoring rates did not significantly improve after CAMESA guideline publication, and that less than half of children on SGAs underwent monitoring, we have identified a gap in standard of care provision. There is a need to undertake future studies to identify barriers to guideline uptake and implement appropriate interventions to address them.

102 **166.102** Medical Cannabinoids for Patients with Autistic Spectrum Disorder: Parents Perspective

O. E. Stolar[1]*, D. Barchel*[2]*, T. De-Haan*[2]*, T. Ziv-Baran*[3]*, N. Saban*[4]*, G. Koren*[5,6] *and M. Berkovitch*[2]*, (1)Autism Center, Assaf Harofeh Medical Center, zerifin, Israel, (2)Clinical Pharmacology and Toxicology Unit, Assaf Harofeh Medical Center, zerifin, Israel, (3)Department of Epidemiology and Preventive Medicine, School of Public Health, Tel-Aviv University, Tel-Aviv, Israel, (4)Tikun Olam LTD, Tel aviv, Israel, (5)Maccabi Institute for Research and Innovation, Tel Aviv, Israel, (6)Research Institute, Maccabi Healthcare Services, Tel Aviv, Israel*

Background:

Parents to patients with autistic spectrum disorder (ASD) are in an endless search for treatment modalities to alleviate symptoms such as aggression, self- injury, restlessness, sleep disturbances, hyperactivity and other co-occurring conditions. In this study we report, for the first time, the experience of parents who administer oral oil-based cannabinoid extract to their child with ASD.

Objectives:

The aim of this study was to analyze parent's perspective on the usefulness of oral oil-based cannabinoid extract on their child with ASD.

Methods:

Patients with diagnosis of ASD were administered oral drops of oil-based cannabinoid extract, after getting license from the Israeli Ministry of Health. The cannabinoid oil solution was prepared by "Tikkun Olam" company, at a concentration of 30% and 1/20 ratio of cannabidiol (CBD) and Δ9-tetrahydrocannabinol (THC). During the first meeting, parents were instructed by a nurse practitioner how to administer the preparation. Thereafter, a weekly follow-up telephone interview was performed, where issues on efficacy and safety of the preparation were discussed. These reports were analyzed using statistical methods.

Results:

The parents of 53 patients with ASD and a mean age of 11.6 (4-22) years participated in this study. Mean duration of treatment was 66 (30-588) days. Mean daily CBD and THC dose were 102 (1.5 – 315) and 8.4 (0.5-49.5) [mean (range)]mg, respectively. Hyperactivity symptoms, reported among

38 patients, were improved in 26 patients (68.4%), not changed in 11 cases (28.9%) and worsened in 1 patient. Self-injury and rage attacks, reported among 34 patients, was improved in 23 cases (67.7%), not improved in 8 cases (15.1%) and worsened in 3 cases (8.8%), after the administration of the cannabis. Sleep disturbances, described in 21 patients, were improved in 15 patients (71.4%), not changed in 5 cases (23.8%), and worsened in 1 case. Anxiety and mood changes, reported in 17 patients, were improved in 8 cases (47.1%), not changed in 5 patients (29.4%), and worsened in 4 patients (23.5%). When parents were asked on overall change of ASD symptoms, 43.1% described a significant improvement, 31.4% mentioned any improvement, 21.6% described no change of symptoms, and worsening of symptoms was reported in 2 cases (3.9%). 5 families discontinued treatment. The most common reported adverse effects were somnolence and nausea, which resolved spontaneously.

Conclusions:

This study showed that cannabidiol is probably effective in improving ASD co-occurring symptoms, with few and transient adverse effects, however, the long-term effect and safety of these preparations should be evaluated in further large-scale, controlled studies.

103 **166.103** Mental Health Issues in Children and Youth with Autism Spectrum Disorder: Medication Use, Side Effects, and Monitoring

C. A. McMorris[1], *J. K. Lake*[2], *B. L. Ncube*[2], *R. Balogh*[3] *and T. Williamson*[4], *(1)Werklund School of Education, University of Calgary, Calgary, AB, Canada, (2)Psychology, York University, Toronto, ON, Canada, (3)Faculty of Health, University of Ontario Institute of Technology, Oshawa, ON, Canada, (4)Community Health Sciences, University of Calgary, Calgary, AB, Canada*

Background: Mental health issues are common in children and youth with autism spectrum disorder (ASD), and can cause significant interference in daily functioning. Approximately 70% of children and adolescents with ASD experience mental health symptoms, and 40% to 50% of these individuals meet diagnostic criteria for 2 or more mental health conditions. Psychopharmacological interventions are often used to manage or treat these mental health issues in children and youth with ASD, with as many as 39% taking a psychotropic medication (e.g., antipsychotic, antidepressant, etc.). There is also a small number of children and youth with ASD, that are taking more than three medications at the same time (polypharmacy). Despite the high prevalence of medication use and polypharmacy in this population, little is known about the potential side effects of a) using certain medications to treat mental health issues in this population; and b) using multiple medications concurrently. Similarly, it is unknown the degree to which these medications are monitored or managed by primary care physicians, essential information to minimize and prevent side effects and negative outcomes.

Objectives: The goal of the present study is to examine the: 1) prevalence of mental health issues in children and adolescents with ASD; 2) rates of medication use to manage these issues (class of medication prescribed, rates of polypharmacy, and associated side effects), and 3) service utilization patterns among children and youth with ASD and medical monitoring completed by their primary care physicians.

Methods: The cross-sectional study will involve secondary data analysis from the Canadian Primary Care Sentinel Surveillance Network (CPCSSN) database. CPCSSN is a multi-disease electronic medical record surveillance system that includes information from electronic medical resources of participating primary care providers across Canada. To be included in the study cohort, individuals must: 1) have had an encounter with a CPCSSN sentinel between January 1st, 2012 and December 31, 2014; 2) had two or more physician visits with an ICD-9 diagnostic code of ASD; and 3) be 18 years of age or younger.

Using descriptive statistics, we will identify the prevalence of mental health issues in this cohort. Next, we will determine the number of individuals with ASD prescribed medication to manage/treat co-occurring mental or physical health issues, as well as the class of drugs prescribed, rates of polypharmacy, and side effects of medication use. To further understand medical monitoring of medications, we will examine the service utilization patterns of those individuals with ASD prescribed medications.

Results: Data is already collected and analysis will begin in December 2017.

Conclusions: Mental health issues are highly prevalent in children and youth with ASD, and psychopharmacology is frequently utilized to manage and treat these issues. Although psychopharmacological intervention is quite common in this population, it is unknown the degree to which medication use is monitored by their primary health care provider. Implications for the prevention of adverse effects in the context of evidence-based clinical practice for children and youth with ASD and comorbid mental health issues will also be discussed.

104 **166.104** Multisite Randomised Controlled Trial of Fluoxetine Versus Placebo for the Treatment of Restricted Repetitive and Stereotyped Behaviours in Children and Adolescents with Autism

C. Marraffa[1,2], *D. S. Reddihough*[1,2,3], *M. O'Sullivan*[2], *F. Orsini*[2], *K. Lee*[2,3], *A. Mouti*[4], *P. Hazell*[5], *M. Kohn*[5,6], *D. R. Dossetor*[5,7], *N. Silove*[5,8], *J. Granich*[9], *A. J. Whitehouse*[10], *J. Wray*[11] *and P. J. Santosh*[12], *(1)Royal Children's Hospital, Parkville, Australia, (2)Murdoch Childrens Research Institute, Melbourne, Australia, (3)Paediatrics, University of Melbourne, Melbourne, Australia, (4)Sydney Children's Hospital Network, Sydney, AUSTRALIA, (5)University of Sydney, Sydney, Australia, (6)Sydney Children's Hospital Network, Westmead/Westmead Hospital/Centre for Research into Adolescent's Health (CRASH), Sydney, Australia, (7)Department of Psychological Medicine, Children's Hospital at Westmead, Sydney Children's Hospital Network, Westmead, Australia, (8)Sydney Children's Hospital Network, Sydney, Australia, (9)Telethon Kids Institute, Telethon Kids Institute, Subiaco, Australia, (10)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (11)State Child Development Service, Western Australia Department of Health, Perth, Western Australia, Australia, (12)Child Psychiatry, Institute of Psychiatry, Psychology & Neurosciences, King's College London, London, United Kingdom*

Background: Selective Serotonin Reuptake Inhibitors (SSRIs) have been used widely in clinical practice for children and adolescents with an autism spectrum disorder. These drugs are often prescribed off- license in children with limited evidence regarding effectiveness and safety. Two Cochrane reviews of the use of SSRIs in autism have been published, the last one in 2013. Fluoxetine has only been studied in clinical trials with small numbers of children. As this is a commonly prescribed SSRI in Australia, this trial was important to undertake. The only SSRI to be studied with sufficient power to answer the question about safety and efficacy is citalopram.

Objectives: Maladaptive repetitive activities, stereotypies and inflexibility have an impact on children's participation and function in their daily life. An adequately powered randomized double blind placebo controlled trial to establish whether there is a reduction in these troublesome behaviours was commenced in 2010. Low dose fluoxetine was compared to placebo.

Other aims of the study included frequency and type of adverse events and exploration of whether there is a relationship between the individual’s serotonin transporter genotype and response to treatment.

Methods: Patients aged 7 years 6 months to 17 years with a diagnosis of autism spectrum disorder were recruited in three states of Australia. We included children on stimulant medication for co-morbid attention deficit hyperactivity disorder. Exclusion criteria included being on any other psychotropic medications within 6 weeks prior to study entry, alternative therapies such as St John's Wort or co-morbid significant medical conditions such as cardiac, liver or kidney disease or uncontrolled epilepsy.

Detailed medical history and physical examination, an ADI-R and a number of rating scales were administered. Eligible participants were randomized to either placebo or active fluoxetine groups with medication being titrated upwards over a four-week period. Responses to medication were monitored on a weekly/fortnightly basis using the Clinical Global Impressions Scale (CGI). The primary outcome measure was the Children's Yale-Brown Obsessive Compulsive Scale- Modified for Pervasive Developmental Disorders (CYBOCS-PDD) at 16 weeks. Secondary outcome measures included the Aberrant Behaviour Scale (ABC), Spence Children's Anxiety Scale Parent version (SCAS-P) and the Repetitive Behaviours Scale (RBS-R) also at 16 weeks. Participants were also invited to undergo genetic testing for SLC6A4 allele variants via a cheek swab.

The primary outcome (total score on the CYBOCS-PDD at 16 weeks) will be compared for the active and placebo groups using unadjusted linear regression. Secondary outcomes will also be compared using unadjusted linear regression with proportions compared using unadjusted logistic regression.

Results: 146 patients were recruited to the study over a 7 year period. Our statistical analysis is currently being completed and will be available soon.

Conclusions: This trial has sufficient power to finally answer the question about whether the use of fluoxetine is safe and effective for troublesome symptoms in children and adolescents with autism spectrum disorder.

105 **166.105** One-Year Retention Effects of Multiple-Dose Oxytocin Treatment on Repetitive and Restricted Behaviors, Social Responsiveness and Attachment: A Randomized, Placebo-Controlled Trial

S. Bernaerts[1], *C. Dillen*[2], *J. Steyaert*[3] *and K. Alaerts*[1], *(1)Rehabilitation Sciences, University of Leuven, KU Leuven, Leuven, Belgium, (2)Department of Rehabilitation Sciences, KU Leuven, Leuven, Belgium, (3)Center for Developmental Psychiatry, KU Leuven, Leuven, Belgium*

Background:

Autism spectrum disorders (ASDs) are characterized by difficulties in social communication and repetitive and restricted behaviors. To date, no pharmacological treatment exists targeting the core symptoms of ASD, yet the past years, the pharmacological use of the neuropeptide oxytocin (OT), has gained increasing interest from the research community to explore its potential for elevating the core social deficits in ASD.

With our double-blind randomized placebo-controlled trial with thirty-nine young adult men with ASD (21 OT/18 Placebo (PL)) we previously showed that a four-week intranasal OT treatment (24 IU/day) improved repetitive behaviors, feelings of attachment and social responsiveness until one month post-treatment (poster presented at IMFAR 2017 ID#23322).

Objectives:

We conducted secondary analyses of this randomized trial to explore whether treatment-related behavioral improvements observed one month post-treatment were maintained at 12-month follow-up.

Methods:

We included thirty-one participants that completed the four-week treatment (OT or PL) and a follow-up session 12 months post-treatment (17 OT/14 PL). Behavioral outcome measures that showed improvements one month post-treatment were assessed again at 12-month follow-up, including assessments of treatment-related changes in repetitive behavior (Repetitive Behavior Scale–Revised(RBS-R)); feelings of attachment (State Adult Attachment Scale(SAAM)); and social functioning (self-report and informant-based Social Responsiveness Scale(SRS)). For each treatment group, the maintenance of behavioral improvements (from baseline) was assessed and difference-in-difference analyses were performed to assess whether the observed improvements were significantly larger in the OT, compared to the PL group.

Results:

At 12-month follow-up, improvements in self-reported repetitive behaviors were shown to be maintained in the OT group (t(16)=-1.78,p=0.05), not in the PL group (t(12)=0.31,p=0.76)(Fig.1a). The effect was most pronounced for the subscale assessing 'compulsive behavior' (t(16)=-3.27,p=0.005). Also in terms of state attachment, participants who received OT still reported to feel less avoidant towards others until 12 months post-treatment (t(16)=-1.91,p=0.04), whereas no significant improvement was observed in the PL group (t(13)=0.18,p=0.86)(Fig.1b). Albeit significant in the OT group, direct comparison of these effects to the PL group showed that the observed improvements were only tentatively more pronounced in the OT, compared to the PL group (RBS: t(28)=-1.58, p=0.06, Cohen's d=0.58; SAAM: t(29)=-1.59, p=0.06, Cohen's d=0.83) (Fig.1) (note that for the compulsive behavior scale, the effect was specific to the OT treatment (t(28)=-2.26, p=0.02, Cohen's d=0.83)).

In terms of social responsiveness, participants of the OT group still showed a tentative improvement in social responsiveness at 12-month follow-up (OT: informant-report: t(11)=-1.50,p=0.08; self-report: t(15)=-1.47, p=0.08)) (PL: informant-based: t(10)=0.59,p=0.30; self-report: t(13)=0.33,p=0.17). However, none of these tentative improvements were specific to the OT treatment (informant-based: t(21)=-0.44,p=0.33; self-report: t(28)=-0.33, p=0.37)(Fig.1c-d).

Conclusions:

Based on a subsample of participants that underwent a 4-week OT treatment and completed a 12-month follow-up session, we show that the observed behavioral improvements in repetitive behavior and attachment avoidance tended to persist until 12 months post-treatment. The observed beneficial effect of OT on social functioning was no longer significant at 12-month follow-up. Our findings provide first indications that continual OT treatment (four weeks) can induce long-lasting behavioral changes in individuals with ASD that last until 12 months after the actual treatment.

106 **166.106** Oxytocin Administration during Delivery and the Autism Spectrum Disorder

T. Brahim[1], *N. Gaddour*[2], *S. Missaoui*[3] *and L. Gaha*[3], *(1)PSYCHIATRY, UNIVERSITY OF MONASTIR, MONASTIR, Tunisia, (2)University Hospital F. Bourguiba, Monastir, Tunisia, (3)University of Monastir, Monastir, Tunisia*

Background:
The hypothesis of mediation by the oxytocin administrated to mother during labor to autistic behaviors had been elaborated from the effect observed on animals, and from the knowledge in the molecular level. However, the studies are scares and inconclusive.

Objectives:

to explore the relationship between administrating Oxytocin during labor to mother and the developing of Autism spectrum disorder by the offspring.

Methods: it is a cross sectional study. We included the first 150 child with diagnosed with ASD starting from Marsh 2015 April 2016, in the outpatient unit of child and adolescent psychiatry in Monastir. The 150 child with typical development were randomly chosen from kinder garden in the same region. We excluded from both group children with sensory abnormalities due to physical condition. The ASD diagnosis was done based on the DSM-5 criteria, the CARS and the clinical evolution of the child during the period of the study. The exposition to oxytocin during labor was explored by a direct yes/no question to the mothers. Analytic analysis were done using Chi-Square test and ANOVA.

Results:

the mean age of the ASD group was 2.66 years ± 0.55 years with a sex ratio of 3.2. Thirty-nine mother from the ASD group (27.1%) had received oxytocin during labor while only nine from the control group (6%) was exposed. The Chi-square test found a significant statistical relationship: $p<0.001$. After controlling of obstetrical complication, the relationship still significant $p=0.041$ [95% I.C (0.009-0.208)].

Conclusions: it seems that there is a possible relation between the use of oxytocin during labor in mother and the developing of ASD by the child. Further research should be undertaken.

107 **166.107** Vitamin A Improves the Symptoms of Autism Spectrum Disorders and Decreases 5-Hydroxytryptamine (5-HT): A Pilot Study

M. Guo[1], *J. Zhu*[1], *T. Yang*[1], *X. Lai*[1], *X. Liu*[1], *J. Liu*[1], *J. Chen*[2] *and T. Li*[3], *(1)Children's Hospital of Chongqing Medical University, Chongqing, China, (2)Children's Nutrition Research, Children's Hospital of Chongqing Medical University, Chongqing, China, (3)Department of Child Health Care, Children's hospital of Chongqing medical university, Chongqing, China*

Background: Autism spectrum disorders (ASD) are complicated neurodevelopmental disorders. Many studies have demonstrated that children with autism have multiple nutritional deficiencies and increased serum 5-hydroxytryptamine (5-HT) levels. In our previous study, 77.9% of autistic children were found to have vitamin A deficiency, and the concentration of vitamin A was negatively associated with the CARS score.
Objectives: In the present study, we sought to test whether vitamin A supplementation could improve autistic symptoms and decrease serum 5-HT levels.

Methods: The DSM-V criteria and CARS score were used for symptom description and symptom assessment of the patients, respectively, before and after vitamin A supplementation (VAS). Serum retinol and 5-HT levels, mRNA levels of RAR α, β, and γ and TPH1 expression were detected in autistic children before and after VAS and in normal children.

Results: Serum retinol levels in children with ASD were significantly lower than in control children. Serum 5-HT levels in children with ASD were higher than in control children, which was correlated with symptom severity of children with autism. After VA supplementation, the children with ASD exhibited significant improvements in autism symptoms. Serum retinol concentrations of children with ASD were significantly increased, and serum 5-HT levels were decreased. Moreover, statistically significant change were observed in mRNA expression levels of RAR α, RAR γ and TPH1 after VAS compared to baseline.

Conclusions: This study suggested that VA supplementation may improve symptoms and reduce 5-HT levels in children with ASD, indicating that VA supplementation is a reasonable therapy at least for a subset of children with autism.

5:30 PM - 7:00 PM - Hall Grote Zaal

108 **167.108** An Autism-Associated Signaling Network Differentiates Glutamate Receptor Inputs at Cortical Glutamatergic Synapses

S. E. Smith[1], *E. Brown*[2] *and J. Lautz*[2], *(1)University of Washington, Seattle, WA, (2)Seattle Children's Research Institute, Seattle, WA*

Background: The genomic revolution has revealed hundreds of genetic risk alleles for autism. Clustering these genes into functional groups using a variety of methods- gene ontology terms, mRNA co-expression networks, protein-protein interaction databases- has revealed that many risk genes are expressed at the neural synapse. Other genes participate in coupling synaptic activity to downstream homeostatic responses. Together, these genetic data suggest that ASD-linked genes constitute a molecular pathway that translates synaptic input into homeostatic responses.
Objectives: To test the hypothesis that ASD-linked genes are involved in the translation of extracellular inputs into cellular responses.

Methods: We used Quantitative Multiplex co-Immunoprecipitation (QMI), a flow-cytometry-based method that allows the simultaneous monitoring of hundreds of dynamic protein-protein interactions. We developed an experimental system to monitor the interactions among a network of synaptic proteins that have been genetically linked to autism, including NMDA receptors, mGluRs, Shanks, SynGAP, PSD95, and others. We stimulate cultured neurons with various excitatory chemicals (glutamate, high potassium, NMDA, DHPG, ect), and monitor the acute changes in our selected protein interaction network.

Results: We find acute, dynamic rearrangement of the targeted protein interaction network in response to activity-inducing stimuli. The majority of changes were dissociative: previously described reductions in co-associated Homer-mGluR5 were detected, as well as many previously undescribed changes largely centered on the scaffolding molecule Homer. Using weighted correlation analysis, we identified two correlated modules of co-regulated interactions. Using agonist and antagonist stimulation, we found that one of the modules responded to NMDA stimulation, while the other responded to mGluR stimulation. Glutamate stimulation resulted in simultaneous activation of both modules.

Conclusions: ASD-linked genes form a network of co-associated proteins at the synapse that responds to synaptic activity by changing its pattern of interactions. Information about the nature of the synaptic input seems to be encoded in the protein interaction network, with a set of interactions responding to mGluR stimulation and another set responding to NMDA. We hypothesize that many different autism risk alleles could convergently disrupt network-scale translation of synaptic input into homeostatic cellular responses, which has implications for LTP vs. LTD coordination, E/I imbalance and sensory hyperactivity phenotypes.

109 **167.109** A Novel Cost-Effective Approach to Derivation of Induced Pluripotent Stem Cells from Epstein-Barr Virus Immortalized β-Lymphoblastoid Cell Lines

S. J. Walker[1], *D. Mack*[2] *and A. Wagoner*[1], *(1)Wake Forest University Health Sciences, Winston Salem, NC, (2)University of Washington, Seattle, WA*

Background: Autism spectrum disorders (ASD) may be viewed as a collection of heterogeneous disorders that are currently diagnosed based upon DSMV criteria. The vast phenotypic differences that can exist from individual to individual suggest that the underlying etiologies are complex and likely involve multiple genetic and environmental inputs. Given that the availability of tissue, especially brain tissue, from ASD patients is extremely limited, the development of alternative tools to investigate molecular and neurobiological mechanisms is critically important. One key resource for ASD research is immortalized lymphoblastoid cell line (LCLs) banks generated from proband and family member blood samples. Induced pluripotent stem cells (iPSC), derived from these LCLs, can be to generate patient-specific neurons for use in downstream mechanistic studies.

Objectives: The objective of this study was to use LCLs to generate iPSCs for the downstream study of neurobiological aspects of ASD. The availability of a streamlined, standardized, reproducible, cost-effective, and efficient approach will render the use of well-characterized LCLs for ASD research a gold standard.

Methods: We obtained LCLs from two males (proband and sibling) from the Autism Genetics Resource Exchange (AGRE) and two males (proband and parent) from the NIMH Repository and Genomics Resource (Phelan-McDermid Syndrome [PMDS] patients). IPSCs were generated from all 4 EBV-LCLs by transfection with Epi5 Episomal iPSC reprogramming plasmids. For the first 7 days after transfection, cells were cultured on Matrigel-coated plates in N2B27 based medium. After 7 days, the reprogramming cells were cultured in Essential-8 medium until ready for passaging. PCR, RT-PCR, immunocytochemistry, and a novel assay, the Taqman® human pluripotent stem cell Scorecard™ Panel were used to fully validate endogenous pluripotency of all iPSC clones generated.

Results: IPSCs, generated via transfection with Epi5 Episomal iPSC reprogramming plasmids, were apparent as early as Day 8 post-transfection and ready for propagation as early as Day 18. IPSCs derived from LCLs obtained from the AGRE were propagated to passage 23 first, followed by the PMDS lines, which are currently at passage 10. Two clonal iSPC lines per original LCL were evaluated for normal karyotype, expression of pluripotency markers, and loss of OriP/EBNA-1 expression vectors. We have confirmed these iPSC clones are plasmid-free and EBV-free. Three of four clones had the expected expression of cell-autonomous pluripotency genes and normal karyotype. All clonal lines were allowed to spontaneously differentiate into embryoid bodies and were assayed for pluripotency markers and germline-specific transcripts using the Taqman® human pluripotent stem cell Scorecard™ Panel. Results indicated that all four iPSC lines are suitable for neuronal differentiation protocols.

Conclusions: This protocol describes a reproducible method to efficiently generate iPSCs with standardized and cost-effective reagents. IPSCs produced following this improved protocol can be used to generate and evaluate novel *in vitro* models to study a plethora of previously inaccessible neuronal cell types that underlie pathological mechanisms in ASD.

110 **167.110** Innate Versus Adaptive Immune Response Pathways in Peripheral Blood from ASD Children with Ileocolonic Inflammation

S. J. Walker[1] *and A. Krigsman*[2], *(1)Wake Forest University Health Sciences, Winston Salem, NC, (2)Pediatric Gastroenterology Resources of New York and Texas, Austin, TX*

Background: Gastrointestinal symptoms are a common co-occurring medical issue in ASD children. GI mucosal inflammatory infiltrates of both the small and large intestine have been noted in the setting of GI-symptomatic ASD and represent a potential etiology for many of the observed GI symptoms. Anecdotal and published reports of behavioral and cognitive improvement upon treatment of ASD-associated GI inflammatory disease supports the plausibility of a GI association for at least some of ASD behavioral and cognitive symptoms. We have previously described unique GI mucosal biomarkers specific for ASD-associated ileocolitis. It is not yet known whether these unique biomarkers are also present in the blood of these children. Identification of a validated blood-based biomarker of ASD-associated ileocolitis would allow for earlier identification of co-morbid GI disease and earlier GI intervention in affected patients. Moreover, it would provide insight into the relevant genes and biologic pathways in ASD-ileocolitis.

Objectives: The goal of these studies is to evaluate blood-based gene expression In GI-symptomatic ASD children with demonstrated histologic ileocolitis to identify the genes and biological pathways most affected.

Methods: The study cohort was comprised of whole blood from 22 ASD children undergoing clinically-indicated ileocolonoscopy for chronic GI symptoms, and 24 non-ASD (typically developing, TD) children undergoing ileocolonoscopy for a variety of GI symptoms. All ASD children had histologic inflammation of the ileum, colon, or both. The TD “controls” used for this study were selected based on absence of histologic inflammation anywhere in the GI tract and absence of a neurodevelopmental disorder. Differential gene expression in peripheral blood from ASD children (with ileocolitis) compared to TD children (without ileocolitis) was examined to identify differentially expressed transcripts that may serve as a proxy for GI inflammation.

Results: We reported in an earlier study (Walker *et al.*, PlosOne, 2013) that inflamed ileocolonic biopsy tissue from GI-symptomatic ASD children has a gene expression profile that overlaps with known inflammatory bowel disease. These earlier findings were apparent in inflamed ileocolonic mucosal tissue in this second cohort as well. In addition, we found that there is significant differential gene expression in peripheral blood of children with ASD and ileocolitis compared to TD children without GI inflammation. Two key immune-related pathways that were up-regulated in the blood of ASD cases are B cell receptor signaling and the Wnt signaling pathway, both important components of the *adaptive* immune response. In contrast, some of the key biological pathways that are coordinately down-regulated in the blood of the ASD (with inflammation) group are NOD-like receptor signaling, hematopoietic cell lineage, and Toll-like receptor signaling. Each of these pathways is important for pathogen recognition and for generating the host *innate* immune response.

Conclusions: Gene expression in peripheral blood from ASD children with ileocolitis reveals a down-regulation of the host defense mechanism (innate immune response) together with an up-regulation of pathways that constitute the adaptive immune response, a pattern seen in other inflammatory bowel diseases. Studies are ongoing to validate these findings in additional samples.

111 **167.111** Abnormal Crosstalk between Reelin-Dab1 and mTORC1 Signaling Pathways in Nonsyndromic Autism Spectrum Disorder

S. M. Sánchez-Sánchez[1], J. Magdalon[1], K. Griesi-Oliveira[1], V. Abreu[1], M. R. Passos-Bueno[2] and ***A. L. Sertie***[1]*, (1)Centro de Pesquisa Experimental, Hospital Israelita Albert Einstein, Sao Paulo, Brazil, (2)Centro de Pesquisas Sobre o Genoma Humano e Células-Tronco, Instituto de Biociências, Universidade de São Paulo, Sao Paulo, Brazil*

Background: Reelin-Dab1 and mTORC1 signaling pathways controls neuronal migration, layer formation, neurite outgrowth and plasticity of synapses in both the developing and the adult mammalian brain. Abnormal interplay between mTORC1- and Reelin/Dab1-signaling pathways has been implicated in the pathogenesis of syndromic Autism Spectrum Disorder (ASD). Recently, by using whole-exome sequencing in a subgroup of nonsyndromic ASD patients - in whom we found mTORC1 signaling hyperfunction, we identified rare and potentially damaging compound heterozygous variants in the gene encoding Reelin (*RELN*) in one patient (called as F2688). Although evidence from previous studies suggests that heterozygous loss-of-function variants in *RELN* can contribute to ASD, the molecular and cellular effects of *RELN* mutations identified in ASD patients are still poorly explored.

Objectives: To verify whether the variants we identified in *RELN* are functional and whether any crosstalk between Reelin-Dab1 and mTORC1 signaling pathways exists and potentiates neuropathological abnormalities.

Methods: We have generated iPSC-derived neural progenitor cells (NPCs) from patient F2688, from 5 idiopathic ASD patients (without *RELN* gene mutations) and from 5 control individuals. The gene expression levels of *RELN* were analyzed by RT-qPCR. The levels of Reelin protein in both whole NPC lysates and supernatants were analyzed by ELISA. Reelin and mTORC1 signal transduction was analyzed by RT-qPCR and western blot. Analysis of cell migration was performed using the Incucyte scratch wound cell invasion assay. F2688-derived NPCs were treated with rapamycin in order to verify whether an abnormal crosstalk exists between mTORC1 and Reelin-Dab1 pathways.

Results: We found that F2688-derived NPCs show impaired secretion of Reelin, impaired Reelin-Dab1 signaling (reduced levels of pDab1, pFyn and pSrc; and increased levels of total Dab1), hyperfunctional mTORC1 signaling (increased levels of *RPS6K1*, *RPS6*, pmTORC1 and pRPS6) and abnormal migration. Also, treatment of F2688-derived NPCs with rapamycin restored impaired Reelin-Dab1 signaling and migration.

Conclusions: Our results suggest that the variants we identified in the *RELN* gene are functionally relevant and suggest, for the first time, a dysfunctional interplay between Reelin-Dab1 and mTORC1 signaling pathways in nonsyndromic ASD.

112 **167.112** Complement System Dysregulation: A Contributing Factor for Autism Spectrum Disorder?

J. Magdalon[1], J. S. de Souza[1], K. Griesi-Oliveira[1], A. L. Teles e Silva[1], M. R. Passos-Bueno[2] and ***A. L. Sertie***[1]*, (1)Centro de Pesquisa Experimental, Hospital Israelita Albert Einstein, Sao Paulo, Brazil, (2)Centro de Pesquisas Sobre o Genoma Humano e Células-Tronco, Instituto de Biociências, Universidade de São Paulo, Sao Paulo, Brazil*

Background: Accumulating evidence points toward an important role of the complement system, a critical arm of the innate immune response, in normal brain development and connectivity. Complement cascade components expressed by neuronal and glial cells, such as C1q and C3, have been implicated in developmental pruning of rodent central nervous system synapses. Also, complement C3 fragments and their receptors were shown to positively regulate neurogenesis and neuronal migration in mice models. There is some evidence to suggest that improper complement activation can contribute to Autism Spectrum Disorder (ASD). Association between C4B null alleles and ASD was reported. Increased levels of C1q, complement factor H related protein, C3 and C3 fragments, as well as enhanced activity of complement factor I were found in the plasma of ASD patients. However, the involvement of the complement system in human neurodevelopment and in ASD is still poorly explored and understood.

Objectives: To compare the gene expression patterns of the main components of classical, lectin and alternative complement pathways in neural progenitor cells (NPCs), neurons and astrocytes derived from ASD patients and controls.

Methods: We have generated iPSC-derived NPCs, neurons and astrocytes from 7 patients with idiopathic ASD and from 4 control individuals. The expression levels of lineage specific markers were analyzed by immunofluorescence and RT-qPCR (TaqMan assays). The gene expression levels of complement cascade components (*C1QA*, *C1R*, *C1S*, *SERPING1*, *C3*, *C3AR1*, *C5*, *C5AR1*, *CD59*, *C7*, *C9*, *MBL2*, *MASP1*, *MASP2*, *CFB*, *CFD*, *CFH*) were analyzed by RT-qPCR (TaqMan assays). The mRNA expression levels of the target genes were normalized to the expression of the housekeeping genes *GAPDH*, *HMBS* and *HPRT1***.**

Results: We observed that: i) iPSCs were successfully differentiated into NPCs, neurons and astrocytes; ii) the gene expression levels of most complement components were higher in neurons than in NPCs and astrocytes; iii) ASD-derived NPCs showed significantly increased levels of *C1R* and *C7*, and significantly decreased levels of *MASP2* compared to control NPCs; iv) ASD-derived neurons showed significantly increased levels of *C3AR1* compared to control neurons; v) ASD-derived astrocytes showed significantly decreased levels of *C4* compared to control astrocytes.

Conclusions: Our results suggest that iPSC-derived neuronal and astroglial cells express a complete set of major complement components and therefore, constitute an interesting model to investigate the roles of the complement system in human neurogenesis and in ASD. Also, although further characterization and mechanistic investigation are required, our results point to abnormal complement regulation in ASD.

113 **167.113** Analysis of the Glutathione Cycle: A Comparison between Children with Autism, Healthy Controls, and Unaffected Siblings

S. C. Boland[1]*, E. K. Lecarie[1], M. B. Klein[2] and R. J. Jou[3], (1)Yale Child Study Center, New Haven, CT, (2)BioElectron Technology Corporation, Mountain View, CA, (3)Yale University, New Haven, CT*

Background:

Previous studies have demonstrated biochemical evidence of oxidative stress in children with autism spectrum disorder (ASD), including a subset with co-morbid mitochondrial dysfunction. Increased oxidative stress results in depletion of the endogenous cellular sulfur-hydride antioxidant system, including reduced glutathione and cysteine. Depletion of these sulfur-hydride metabolites leads to free radical-mediated cell injury and death, as well as other impairments in cellular function. Comparing the levels of key sulfur-hydride metabolites in children with and without ASD may improve understanding of underlying biochemistry and identification of candidate biomarkers and therapeutic targets.

Objectives: To compare plasma levels of key antioxidant metabolites in children with ASD to their unaffected siblings (UAS) and unrelated typically developing (TD) children.

Methods: This study consisted of 31 children between the ages of 4 and 12 years: 14 ASD (mean age = 7.79 ±2.91 years; 10 boys and 4 girls), 12 TD non-siblings (mean age = 8.08 ±2.35 years; 7 boys and 5 girls) and 5 UAS of proband participants (mean age = 7.40 ±2.88 years; 2 boys and 3 girls). Blood samples collected by venipuncture were separated into plasma and subsequently analyzed using a mass spectrometer and microflow, reversed-phase chromatography. Biomarker quantitation was performed using Multiple Reaction Monitoring (NRM) mode acquisition and with the aid of stable isotopically-labeled standards. The analytes evaluated include reduced cysteine (CysB), reduced glutathione (GSH), thiosulfate (TSH), cysteine persulfide (CyssB), glutathione persulfide (GSSB), ornithine, 5-oxoproline (PGA), and methionine. A total of the main sulfur species included CysB, GSH, TSH, CyssB, and GSSB. The following clinical data were collected: Social Responsiveness Scale (SRS), Vineland Adaptive Behavior Scales (VABS), and Differential Ability Scales (DAS). ASD diagnoses were confirmed using Autism Diagnostic Interview (ADI), Autism Diagnostic Observation Schedule (ADOS), and Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision. Correlation analyses between analyte levels and clinical measurements were also performed.

Results: A one-way ANOVA revealed significant differences between ASD and TD groups for CysB, CyssB, GSSB, ornithine and pooled sulfur analytes while differences in GSH approached significance. Significant differences between TD and UAS groups were found in PGA and ornithine. No differences were found between ASD and UAS groups. Across all subscales of the SRS, DAS (full-scale IQ), and all subdomains of the VABS, the ASD group significantly differed from both TD and UAS groups. No significant differences were found between the TD and UAS groups. There was a significant correlation between SRS and CysB, CyssB, GSSB, and pooled analytes.

Conclusions: This preliminary study demonstrates a differential biosignature across key components of the endogenous sulfur antioxidant system in children with ASD relative to TD children, suggesting that oxidative stress-associated sulfur depletion may play a role in the pathophysiology of autism. This is also supported by the significant negative correlations between SRS scores and analyte concentrations. However, the lack of significant differences between ASD and UAS groups in analyte levels suggests metabolite differences are also influenced by genetic factors and not solely driven by ASD symptomatology.

167.114 Autism Human Neural Precursor Cells (NPCs) Display Common As Well As Personalized Developmental and Molecular Phenotypes

S. Prem[1]*, M. Williams*[1]*, R. J. Connacher*[2]*, B. Dev*[3]*, C. Peng*[3]*, M. Mehta*[4]*, P. G. Matteson*[4]*, J. H. Millonig*[4] *and E. DiCicco-Bloom*[1]*, (1)Rutgers Robert Wood Johnson Medical School, Piscataway, NJ, (2)Rutgers University- New Jersey Medical School, Piscataway, NJ, (3)Rutgers University, New Brunswick, NJ, (4)Center for Advanced Biotechnology and Medicine, Rutgers Robert Wood Johnson Medical School, Piscataway, NJ*

Background:

Autism spectrum disorders (ASD) are neurodevelopmental disorders characterized by impaired social interaction and communication and the presence of repetitive behaviors. Human neuropathological and MRI studies of ASD reveal changes in brain size, neuronal-connectivity, and brain-architecture, which suggest dysregulation of multiple developmental processes. However, inability to directly study human neurons, limitations of animal-models, and disorder heterogeneity have thwarted discovery of underlying mechanisms. Now, induced- pluripotent-stem-cell (iPSC) technology has allowed the generation of neural precursor cells (NPCs) from individuals with neuropsychiatric disorders thereby allowing study of human development and disease. Using iPSCs we have generated NPCs from 8 boys with severe idiopathic autism (I-ASD) and their unaffected-brothers (Sib) as controls.

Objectives:

Our goals are to study developmental processes such as neurite-outgrowth and cell-migration in our ASD patient-derived NPCs. Our studies employ developmentally-relevant extracellular-factors (EFs) such as PACAP, 5-HT, and NGF to uncover both common and personalized developmental abnormalities. We also aim to identify signaling-pathway defects that contribute to the developmental abnormalities and could serve as targets for personalized medicine.

Methods:

NPCs were derived from 3 iPSC clones per individual. Two separate NPC derivations were conducted per clone. At least 2 experiments were conducted per NPC derivation per clone (minimum 12 expts/individual/assay).

<u>Neurite Assay:</u> 48 hrs after plating, the percentage of cells with neurites≥2 cell diameters were counted blind in 1 cm rows

<u>Neurosphere Migration:</u> Neurospheres generated from NPCs were plated for 48h on Matrigel. Migration = total neurosphere area-inner mass area.

Results:

Our studies indicate common reductions in neurite-outgrowth and cell-migration in two I-ASD individuals. Additionally, while Sib-NPCs exhibited 2-fold increases in neurite-outgrowth in response to PACAP, NGF, and 5-HT, both I-ASD NPCs failed to increase neurites in response to these EFs. Preliminary studies in I-ASD-NPCs from a 3rd patient also showed similar defects in EF response. Likewise, Sib neurospheres exhibited increased migration with PACAP yet I-ASD neurospheres were unresponsive. I-ASD NPCs in Family-1, which did unresponsive to PACAP, exhibited 4x-lower PACAP induced P-CREB levels compared to Sib-NPCs. Conversely, increasing I-ASD P-CREB levels using db-cAMP restored neurite-outgrowth and migration to levels of PACAP-treated Sib-NPCs. Surprisingly, Family-2 ASD-NPCs exhibited different signaling abnormalities. We next compared these I-ASD profiles to a genetically-defined subtype of ASD (three 16p11.2-deletion patients). Remarkably, both neurite-outgrowth and migration were also reduced, however, all three 16p11.2-del NPCs responded normally to EFs.

Conclusions:

Using iPSC technology, our studies identified common defects in neurite-outgrowth and migration in two distinct subtypes of ASD (I-ASD; 16p11.2-Del-ASD), suggesting the disorder may have a common underlying mechanism. Interestingly, while NPCs from I-ASD patients failed to respond to EFs, 16p11.2-del-ASD NPCs had typical EF responses, suggesting there are autism subtype-based differences. Within the I-ASD subtype, both NPCs showed defects in developmental phenotypes yet, only one depended on PKA pathway dysfunction, suggesting that common abnormalities may reflect personalized causative mechanisms. Thus, our studies illustrate the benefit of studying ASDs using iPSC techniques to obtain a personalized understanding of both common and unique neurodevelopmental abnormalities in affected individuals. Ultimately, this information could help develop personalized treatments for ASD.

115 **167.115** Characterizing PTGER4 As a Target Gene of Autism Protein E6AP

C. Amadei[1], *J. El Hokayem*[2], *Z. Nawaz*[3] *and M. Alessandri*[4], *(1)University of Miami Miller School of Medicine, Miami, FL, (2)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (3)Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL, (4)University of Miami, Coral Gables, FL*

Background: ASD has been found to be associated with duplication or triplication of the UBE3A gene, which encodes for E6-associated protein (E6AP, an E3 ubiquitin ligase and transcriptional coactivator). Mice with three copies of UBE3A exhibit core ASD features and humans with Dup15q share many symptoms with ASD. However, the few E6AP ubiquitination substrates found do not explain ASD pathology. Our lab has identified and characterized E6AP as a coactivator of steroid hormone receptor signaling. Estrogens (E2) affect learning, memory and many other brain processes via estrogen receptors, which are transcription factors.

Objectives: This study tests the hypothesis that deregulation of E6AP-mediated steroid hormone receptor transcriptional signaling in the brain leads to the development of ASD. The project aims are to identify steroid hormone-dependent E6AP target genes in neurons and to study the role of these target genes in the pathogenesis of ASD. Identification of new molecular pathways that are transcriptionally regulated by E6AP will broaden our understanding of ASD.

Methods: Potential E6AP target genes were identified by microarray of MCF-7 breast cancer cells. Cells from the mouse neuroblastoma Neuro2a cell line were cultured. Cells were transfected with E6AP or had E6AP knocked down by siRNA and then were treated with physiologically relevant doses of estrogen, the estrogen receptor antagonist tamoxifen, or vehicle. Assays included western blot, co-immunoprecipitation, qRT-PCR, and microscopy.

Results: 1) E6-AP and ER colocalize in mouse HPC neurons. 2) E6-AP and ERα translocate to the nucleus of Neuro2a (N2a) cells upon E2 treatment. 3) E6-AP and ERα complex in N2a. 4) The learning and memory gene for prostaglandin E receptor 4, PTGER4, is an E6AP-dependent target gene that is downregulated in the presence of E6AP or estrogen.

Conclusions: We have identified a memory and learning gene that is regulated by E6AP and E2-dependent: PTGER4. This is evidence that PTGER4 may be altered in ASD, leading to learning and memory symptoms. PTGER4 allows phosphorylation of glycogen synthase kinase 3 (GSK3). GSK3 has a large role in apoptosis and has been implicated in neuropsychiatric disorders such as Alzheimer's disease and bipolar disorder. Given that GSK3 is amyloidogenic and ASD patients exhibit increased beta amyloid deposition, increased E6AP leading to decreased PTGER4 may lead to decreased inhibitory phosphorylation of GSK3. In a case study, the GSK3 inhibitor ketamine actually improved an adult ASD patient's symptoms, supporting this theory. Further experiments will be necessary to confirm these promising findings.

116 **167.116** Comparative Expression Analysis of Autism-Associated Cadherin Superfamily Members

J. A. Frei, G. J. Blatt and ***Y. C. Lin****, Hussman Institute for Autism, Baltimore, MD*

Background:

The cadherin superfamily is a group of cell adhesion molecules containing more than one hundred proteins, including classical cadherins type I and II, protocadherins, and atypical cadherins. N-cadherin functions throughout development of nervous system including neurite outgrowth, axon guidance, synaptogenesis, spine morphogenesis and plasticity. Although there is only little known about the function of other cadherins they have been strongly implicated in autism. A genome wide association study identified the classical cadherin type II CDH8 and CDH11, the protocadherin PCDH9 and the atypical cadherin FAT1 as candidate risk genes. This suggests that cadherin signaling pathways could be disrupted and may display increased vulnerability in autism.

Objectives:

As a first step toward understanding the central role of cadherins in the etiology of autism, we focused on CDH8, CDH11, PCDH9 and FAT1 and investigated their expression patterns in specific brain areas, cell types and their subcellular localization during development. This comparative expression analysis could provide novel insights into common and distinct functions of these cadherins in neural circuit formation. We further determined the expression of these cadherins in human postmortem brain tissues of control and autism individuals to evaluate whether cadherin levels are commonly altered in autism.

Methods:

Western blot analyses was performed to evaluate the protein expression of CDH8, CDH11, PCDH9 and FAT1 in the developing mouse brain of embryonic day 14, postnatal day 0, P7, P14 and P21 and adult as well as in different brain areas. To analyze the cellular localization, enrichment of cadherins in synaptic plasma membrane and postsynaptic densities was analyzed. Additionally, primary neurons from different brain regions were cultured for 14 days *in vitro* and co-stained for cadherins and neuronal marker MAP2 or synaptic markers PSD95, Synapsin1 and GAT1.

Results:

Temporal expression analysis in the developing mouse brain revealed increased expression of CDH8, CDH11, PCDH9 and FAT1 at P7 and P14 with an additional peak of FAT1 expression at E14. Analysis of specific brain areas showed that CDH8, CDH11 and PCDH9 were prominently expressed in the cortex, hippocampus and thalamus/striatum whereas FAT1 expression was restricted to the cerebellum. Additionally, CDH8, CDH11 and FAT1 localized to MAP2-positive dendrites and were enriched in synaptic plasma membrane and post-synaptic density. Moreover, CDH8 and CDH11 were associated with excitatory and inhibitory synaptic markers. In addition, CDH8 expression was elevated in CDH11-kockout brains, indicating at least partially redundant functions of those type II classical cadherins. Preliminary results of CDH8, CDH11 and PCDH9 expression in postmortem cingulate cortices of control and autism individuals suggest an altered expression profile of cadherins in autism brains.

Conclusions:

Our results revealed similar overall expression profiles among CDH8, CDH11 and PCDH9, with a distinct expression pattern for FAT1. The temporal expression and the subcellular localization of cadherins were consistent with the proposed functions in synaptogenesis. Taken together, the present study highlights that cadherins of different subfamilies are expressed in a developmental time window and in brain areas implicated as vulnerable in autism, thus strengthening the hypothesis of a central role of cadherins in this neurodevelopmental condition.

117 **167.117** Differential Methylation of Metabolic Mitochondrial Pathways in a South African Autism Cohort

S. Stathopoulos[1], *A. Nell*[1], *R. Gaujoux*[2] *and C. O'Ryan*[1], *(1)Molecular and Cell Biology, University of Cape Town, Cape Town, South Africa,* *(2)Cytoreason, Tel Aviv, Israel*

Background:

Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterised by great phenotypic heterogeneity and overlapping co-morbidities. The genetic architecture of ASD is complex, with 100's of risk genes cumulatively contributing to the aetiology of ASD. Increasingly, recent findings support a role for epigenetic mechanisms in ASD, with DNA methylation being associated with the disorder.

Objectives:

We investigate whole-genome methylation patterns in a cohort of South African children. Differentially methylated genes are analysed to identify biologically relevant pathways. We correlate differential methylation from the epigenome-wide methylation assay with quantitative methylation and qPCR assays of candidate differentially methylated genes in both the discovery and replication cohorts.

Methods:

South African boys with ASD and boys with typical developmental profile (6 - 11 years old) were recruited. All participants were assessed using the Autism Diagnostic Observation Schedule-2, ADOS-2. DNA and RNA were extracted from study participants using buccal cells. We performed a whole-genome DNA methylation screen using Illumina 450K Human Methylation Array. Differentially methylated loci associated with ASD were assessed using a pathway-analysis approach. We validate our top differentially methylated gene from the whole epigenome assay, the stomatin-like protein 2 (STOML2) gene, using a quantitative pyrosequencing assay for DNA methylation, as well as a qPCR approach to quantify mRNA.

Results:

We identified over 900 differentially methylated genes (p-value ≤ 0.05) associated with ASD. Pathway analysis revealed canonical Metabolic, Mitochondrial and Autophagy pathways as being significantly enriched in our cohort. We correlate differential methylation patterns of STOML2 from the epigenome-wide assay, with a quantitate methylation measure, DNA pyrosequencing, as well RNA expression levels. The quantitative data supports a role for differential methylation in perturbating mitochondrial pathways in ASD individuals.

Conclusions:

This study is the first to investigate whole-epigenome profiles of DNA methylation in a South African cohort of children with ASD. We find that methylation patterns differ significantly between ASD and typically developing children at a large number of genes which converge on mitochondrial dysfuntion. We validate differential methylation and transcription levels of our top gene, STOML2, which is central to mitochondrial stress and the accumulation of reactive oxygen species. Our results suport a central role for mitochondrail function in ASD aetiology. As there are a number of pre-existing therapeutic options already in use for mitochondrial dysfunction, our results have important implications for re-examining exsiting therapeutic treatment of ASD symptomology.

118 **167.118** Elevation of a Putative Bacterial Metabolite in a Pediatric ASD Population

B. Needham[1], S. Mazmanian[1], M. Conrad[2], ***S. Rao***[3] *and S. Campbell[2], (1)Division of Biology & Biological Engineering, California Institute of Technology, Pasadena, CA, (2)Axial Biotherapeutics, Inc., Boston, MA, (3)Axial Biotherapeutics, Boston, MA*

Background:

It was previously shown that changes in the gut microbiome (dysbiosis) and increased intestinal permeability (IP) are present in the "maternal immune activation" (MIA) mouse model of autism spectrum disorder (ASD), a model that recapitulates key features of the autism phenotype, including increased anxiety, stereotypic behaviors, and decreased vocalizations and social behaviors. In addition, elevated levels of the putative bacterial metabolite 4-ethylphenylsulfate (4-EPS) were found by untargeted serum metabolomics in this model vs. controls, and this elevation was thought to be driven by dysbiosis and/or increased IP. Oral treatment with *Bacteroides fragilis***,** a human commensal gut bacterial species, resulted in restoration of gut microbial profiles, decreased IP, and markedly reduced serum concentrations of 4-EPS. Several tryptophan metabolites were also altered in the MIA model, and their levels were normalized by *B. fragilis* treatment. Remarkably, this treatment was also observed to increase vocalization, reduce anxiety-like features and correct stereotyped behaviors. Finally, causality between 4-EPS and anxiety-like behaviors was established by parenterally administering 4-EPS to naïve mice and demonstrating that such treatment resulted in the development of an anxiety phenotype similar to that observed in the MIA model.

Objectives:

The objectives of the current study was to extend the preclinical results by determining whether elevations in serum 4-EPS can also be found in children diagnosed with ASD.

Methods:

- A targeted analysis of 4-EPS and several other putative biomarkers was performed on a cohort of 50 subjects and controls via ultra-performance liquid chromatography-tandem mass spectrometry.
- A non-targeted analysis encompassing ~1,000 analytes was performed on 129 children aged 3-12yo diagnosed with ASD and 101 age matched controls (cohorts from the "Childhood Autism Risks from Genetics and the Environment" study ongoing at the Univ. of California Davis)

Results:

In the targeted analysis in 50 pediatric subjects, elevated serum 4-EPS concentrations were found in the ASD children vs. controls. This finding was replicated in the non-targeted serum metabolomics study involving 230 children, wherein the mean concentration of 4-EPS was found to be elevated by ~6-fold in the ASD vs. control children. Several tryptophan metabolites were also altered, including indolelactate, which was one of the metabolites most strongly associated with ASD in the non-targeted analysis.

Conclusions:

4-EPS concentrations, as well as several other microbial products, were found to be elevated in children with ASD vs. healthy controls in replicate analyses. The impact of this elevation on behavior and the impact of treatment with *B. fragilis* will be the subject of subsequent studies.

119 **167.119** Estimation and Comparison of Serum and Salivary Immunoglobulin G4 Levels in Children with Autism Spectrum Disorders:

A Case Control Study from South India

B. S. S. Kalal[1,2], *S. S. Bhat*[3], *V. KM*[4], *A. Kakunje*[5], *S. KS*[6], *R. PD*[2], *J. Chandra*[7], *V. S. Bhat*[8] *and N. I*[3], *(1)Department of Biochemistry, Yenepoya University, Mangaluru, India, (2)Yenepoya Research Centre, Yenepoya University, Mangaluru, India, (3)Department of Paedodontics, Yenepoya Dental College, Yenepoya University, Mangaluru, India, (4)Department of Oral Medicine & Radiology, Yenepoya Dental College, Yenepoya University, Mangaluru, India, (5)Department of Psychiatry, Yenepoya Medical College, Yenepoya University, Mangaluru, India, (6)Department of Pediatrics, Yenepoya Medical College, Yenepoya University, Mangaluru, India, (7)Department of Oral and maxillofacial Surgery, Yenepoya Dental College, Yenepoya University, Mangaluru, India, (8)Department of Prosthodontics, Yenepoya Dental College, Yenepoya University, Mangaluru, India*

Background: Autism spectrum disorders (ASD) are heterogeneous group of neurodevelopmental disorders with complex etiologies. Accumulating evidence suggests the role of deregulated immune components and mediators that may play role in the pathophysiology of autism. Some of the previous reports have suggested the abnormal immunoglobulin (Ig) levels in the circulation of individuals with ASD.
Objectives: To estimate and compare the serum and salivary immunoglobulin G4 (IgG4) levels in children with autism and typically developing control children (TD) from South India.

Methods: Case-control study. Children of special schools and those visiting hospitals in Mangaluru and neighbouring districts of Karnataka and Kerala were recruited. We collected blood and saliva from children with ASD (*n*=55), and age-matched typically developing (TD) controls (*n*=60). Childhood Autism Rating Scale (CARS) used to identify ASD children. Samples were assayed in duplicate using the commercial enzyme-linked immunosorbent assay (ELISA) kit (Human IgG4 Ready-Set-Go Kit, eBioscience, San Diego, CA, USA; #88-50590).

Results: The mean ages of autistic children were 10.7 year (SD± 4.2) and healthy children 11.2 year (SD± 2.7). The CARS assessment of children with ASD showed that 60% were under severe autism while 40% of the cases were mild to moderate autism. Routine laboratory tests showed no significant difference among two groups. Children with ASD had significantly higher levels of serum and salivary IgG4 (44.80 ±20.76 and 0.89 ±0.69 mg/dL) as compared to the TD (34.90 ± 20.19; *p*=0.021 and 0.56 ± 0.38 mg/dL; *p*= 0.024). Both serum and salivary IgG4 levels were positively correlated in ASD (R= 0.3729: *p*= 0.005), TD (R= 0.4644; *p*=0.0003).

Conclusions: Children with ASD have significantly higher levels of serum and salivary IgG4 compared TD controls, suggesting an underlying defect in immune function and can be used as diagnostic marker. The levels of serum and salivary IgG4 levels show significant correlation suggesting that saliva can be used for diagnostic platforms and as non-invasive assessment tools for health monitoring.

120 **167.120** Functional Alteration in Gating Behavior of IP3R Channel Mediating Calcium Signaling As Common Biomarker in Autism Spectrum Disorder

J. Gargus[1,2], *R. L. Nguyen*[3], *D. Ferguson*[3], *Y. Medvedeva*[4], *I. Parker*[5], *G. Schmunk*[3] *and S. Reiter-Akhavan*[3], *(1)University of California, Irvine, Irvine, CA, (2)The Center for Autism Research & Translation, Irvine, CA, (3)Physiology & Biophysics, University of California, Irvine, Irvine, CA, (4)Neurology, University of California, Irvine, Irvine, CA, (5)Neurobiology & Behavior, University of California, Irvine, Irvine, CA*

Background: Current clinical measures used in diagnosing Autism Spectrum Disorder (ASD) have been adapted to screen core characteristics that range widely in severity. However, even at its most refined, ASD remains a group of developmental disorders that is defined by behavioral qualities, not by its pathogenesis. Studies on the genetic architecture of ASD and related neurological disorders have brought light to the central role of calcium channelopathies and its effects on calcium signaling pathways rationally implicated in diverse aspects of ASD pathogenesis.
Objectives: We propose that depressed function in IP3R mediated calcium release channels in the ER may be a reliable diagnostic biological marker for monogenic and 'sporadic' forms of ASD.

Methods: Functional components of calcium signaling were dissected in ASD and a super-resolution STORM system was used to obtain molecular-resolution optical patch clamp analysis on monogenic ASD models. Fibroblasts derived from skin biopsies of healthy, unaffected inviduals, and patients with rare monogenic forms or 'sporadic' autism were cultured and monitored for agonist-evoked calcium signals using a high throughput FLIPR assay. Human induced pluripotent stem cells (hiPSCs) were generated from primary fibroblasts using the Thermo-Fisher Sendai virus protocol. hiPSCs were differentiated into neuronal progenitors, and measured with UV-activated caged iP3.

Results: Local IP3-mediated calcium signaling was decreased in fibroblasts derived from patients with monogenic forms of ASD when compared to those derived from healthy, control patients. Likewise, IP3-mediated calcium signaling was repeatedly decreased in fibroblasts derived from patients with monogenic or 'sporadic' forms of ASD when compared to healthy, control patients. iPSC- derived neuronal precursors from patient fibroblasts also share this signaling defect.

Conclusions: Our results strongly implicate deregulated calcium signaling in the pathogenesis of ASD and supports iP3-mediated calcium signaling as a diagnostic biological marker for ASD. Furthermore, a high-throughput FLIPR assay may be used as a highly reproducible diagnostic that is able to capture differences in IP3-mediated calcium signaling.

121 **167.121** Functional Recording of Neuronal Network Activity in Cortical Neurons Differentiated from Human Pluripotent Stem Revealed Mutation Dependent Patterns of Abnormalities in SHANK3 Haploinsufficiency Associated ASD Patients

L. Chatrousse[1], *C. Boissart*[2], *T. Bourgeron*[3,4], *M. Peschanski*[2], *R. Delorme*[5,6] *and A. Benchoua*[2], *(1)CECS/ISTEM/AFM, Corbeil-Essones, France, (2)CECS/I-Stem/AFM, Corbeil-Essones, France, (3)Human Genetics and Cognitive Functions, Institut Pasteur, Paris, France, (4)University Denis Diderot Paris 7, Paris, France, (5)AP-HP, Robert-Debré Hospital, Child and adolescent Psychiatry unit, Paris, France, (6)Pasteur Institute, Human Genetic and cognitive function, Paris, France*

Background: Human induced pluripotent stem cells (hiPSC), obtained by reprogramming of somatic cells of individuals with ASD, provide a promising route for *in vitro* modeling of the pathology by combining relevance, robustness and high availability of the biological resource, and offering a unique opportunity for powerful drug discovery approaches. One of these approaches relies upon using live cell imaging to study developing cortical networks differentiated from control or ASD iPSC in order to characterize functional abnormalities associated with the emergence of the symptoms. This will help understanding the impact of different genetic mutations on neuronal function and discover new, personalized pharmacological treatments.
Objectives: As a proof of principle we choose to model ASD associated with SHANK3 gene haploinsufficiency, also known as Phelan-McDermid syndrome, and compared the neuronal network activity of SHANK3-/+ neurons with controls in the context of different SHANK3 mutations.

Methods: We derived neuronal stem cells (NSC) from hiPSC of 4 controls and 5 ASD individuals bearing different heterozygotous mutations in SHANK3 gene. Each NSC line was differentiated into cortical neurons for up to 60 days. Neuronal phenotypes were analyzed using immunocytochemistry (beta-III Tubulin as a neuronal marker coupled with GABA and Glutamatergic markers) on days 14 and 28. Neuronal network activity was quantified using a fluorescent calcium probe Fluo4-AM from day 32 to 60. Calcium imagines were recorded during 3 min using the automated imaging system ImageXpress micro (Molecular Devices) and analyzed using FluoroSnap Software (Tapan Patel, University of Pennsylvania).

Results: This revealed that synchronized firing started in hiPSC derived neurons from day 50 where almost all the sampled cells participated in the synchronized firing. We observed synchronized firing defects in all SHANK3 +/- neuronal networks but we demonstrated that the type of defect differed with the type of mutation, suggesting that these defects are dependent of the type of isoforms spared by the mutation. Being totally amenable to automation, this read-out will be used to test the therapeutic potential of several pharmacologic compounds, more particularly, their ability to restore normal firing in SHANK3-/+ neuronal networks.

Conclusions: This approach may provide a pathway to an efficient stratification of ASD patients and a better personalization of their treatment.

122 **167.122** High Serum Vitamin B12 in Children, Adolescents and Adults with Neurodevelopmental Disorders.

S. Hope[1], *T. Nærland*[2], *L. Mørkrid*[3], *A. Høyland*[4], *T. Torske*[5], *E. A. Malt*[6], *T. G. Abrahamsen*[7], *M. Nerhus*[8], *K. Wedervang-Resell*[9], *J. Johannessen*[10], *V. Lonning*[9], *I. Agartz*[11], *N. Stenberg*[12] *and O. A. Andreassen*[13], *(1)Oslo University Hospital, Oslo, Norway, (2)National Center of Competence for Rare Disorders and Disabilities, Oslo University Hospital, Oslo, Norway, (3)Department of Clinical Medicine, University of Oslo, Oslo, Norway, (4)NTNU, Trondheim, NORWAY, (5)Vestre Viken, Drammen, Norway, (6)Division of medicine, Oslo University, Oslo, Norway, (7)Pediatry¨, Oslo University Hospital, Oslo, Norway, (8)K.G Jepsen Norment Norwegian Centre for Mental Disorders Research, Oslo University Hospital, Oslo, Norway, (9)CHild and adolescent mental health Research Unit, Oslo University Hospital, Oslo, Norway, (10)Autism Society Norway, Oslo, Norway, (11)Dep of Psychiatric Reseach, Diakonhjemmet Hospital, Oslo, Norway, (12)Child and adolescent mental health, Oslo University Hospital, Oslo, Norway, (13)NORMENT, KG Jebsen Centre for Psychosis Research, Institute of Clinical Medicine,, University og Oslo, Oslo, Norway*

Background: The disease mechanisms underlying Neurdodevelopmental Disorders (ND) imply both heriditable and environmental factors. Vitamin B12 is a factor which is essential for proper neurodevelopment, and serum levels are influenced by diet as well as by genetic variants. Lack of vitamin B12 during pregnancy and in childhood pertubs neurodevelopment and adequate vitamin B12 status is necessary for neurocognitive function in adults. The last years it has become clear that not only lack of vitamin B12 confers a health hazard, but that also too high serum levels have negative implications. Vitamin B12 is solemnly present in animal products and a high plasma level is a common finding in a western country as Norway were diets are rich in meat. Elevated serum levels of vitamin B12 associate with poor outcome and mortality of diseases, as cancer, liver and kidney failure. Importantly, it was recently reported that elevated serum levels in pregnant women increased the risk of autism in the child.

Objectives: We hypothesized that high vitamin B12 would be frequent in patients with ND and that their mean vitamin B12 levels would be equal as in healthy controls (HC). We also hypothesized that vitamin B12 levels would be equal as in schizophrenia, a clinical group that shares some genetic and sociodemographic characteristics with autistic patients, and were previous studies indicate adequate vitamin B12 status.

Methods: Patients with ND conferred to specialist services were asked to participate. Altogether 217 children, adolescents and adults with a diagnose of pervasive ND, specific NDs or intellectual disability were included. Their vitamin B12 serum levels were compared with 498 HC and 414 schizophrenia patients. In addition, 117.000 primary care patients from a catchment area were used as reference population. Levels in ND were also compared with a clinical control group consisting of 414 schizophrenia patients that had been conferred to specialist health services. We controlled the results for possible confounders. In Norway, available vitamin B12 supplements also contain folic acid, and thus we controlled for levels of folic acid as a proxy for supplement intake. We also controlled for indicators of general nutrition, liver disease, kidney function and inflammation.

Results:

19% of the patients with ND had elevated levels (above the current reference range of 650 mmol/l) of vitamin B12 and mean vitamin B12 levels (age and gender adjusted) were higher than among HC (p=0.004) and among schizophrenia patients (p=0.0003). We controlled the results for differences in age, gender, levels of folic acid, hemoglobin, creatinine, Alanine transaminase and leukocyte count. Serum vitamin B12 was still significantly higher in ND than in HC (p=0.015). Vitamin B12 was not associated with scores on the Social Responsiveness Scale, but was higher in patients who had experienced a loss of previous abilities (p<0.05).

Conclusions: Patients with ND have higher serum vitamin B12 than HC and schizophrenia patients. This result is supported by a previous finding of high levels in pregnancy increasing the risk of autism and warrants further research for possible underlying mechanisms.

123 **167.123** Identifying Autism Risk Genes Essential for Proliferation and Differentiation Using Genome-Wide CRISPR Screens

S. Shohat *and S. Shifman, The Hebrew University of Jerusalem, Jerusalem, Israel*

Background:

Recent advancements in sequencing technologies led to the discovery of many genes associated with autism spectrum disorders (ASD). Many of those genes are involved in chromatin regulation and synaptic functions. While a great deal of research has focused on the role of synaptic genes in ASD, less is known about how disruption of chromatin regulators can lead to ASD. Our hypothesis is that those chromatin genes are associated with ASD because they regulate proliferation and neuronal differentiation during development.

Objectives:

Our aim is to perform a genome-wide screen for genes essential for neuronal proliferation and differentiation and to test their connection with ASD.

Methods:

We have established a system which allows for a genome wide detection of genes essential for proliferation and neurogenesis. Using a CRISPR pooled library, we generated a population of mouse embryonic stem cells (mESCs) with a different guide RNA targeting almost every gene in the mouse genome (~20,000 genes). We proliferated the cells for two weeks and sequenced the guide RNAs to measure their frequency. The mESCs also contains GFP inserted into the Sox1 locus, and can be used to identify and isolate neural stem and progenitor cells.

Results:

We screened across the genome for genes affecting embryonic stem cells proliferation and survival. We found 1348 genes that were negatively selected (essential genes), and 32 genes that were positively selected. The essential genes are highly enriched for genes implicated in ASD, other neurodevelopmental disorders, and microcephaly. Moreover, the genes negatively selected in the screen are significantly enriched with genes intolerant to mutations in the human population. Among the essential genes are some high confidence ASD genes such as POGZ, CHD8 and SETD5.

Conclusions:

The study demonstrates the ability to trace the involvement of all genes in the genome in proliferation and differentiation and to subsequently decipher the functional role of ASD genes. We showed that some ASD genes affect proliferation of embryonic stem cell even before differentiation. Our ongoing screens during neuronal differentiation will shed further light on the function of chromatin regulators and their connections with abnormal brain growth observed in ASD.

124 **167.124** Neural Precursor Cells (NPCs) from 16p11.2 Deletion Patients Exhibit Enhanced Proliferation, and Alterations in FGF Mitogenic Signaling

R. J. Connacher[1]*, M. Williams*[2]*, S. Prem*[2]*, M. Mehta*[3]*, P. G. Matteson*[3]*, J. H. Millonig*[3] *and E. DiCicco-Bloom*[2]*, (1)Rutgers University- New Jersey Medical School, Piscataway, NJ, (2)Rutgers Robert Wood Johnson Medical School, Piscataway, NJ, (3)Center for Advanced Biotechnology and Medicine, Rutgers Robert Wood Johnson Medical School, Piscataway, NJ*

Background:
Autism spectrum disorder (ASD) genetic etiology is complex and heterogeneous. Within ASD, ~1% contain a copy number variation (CNV) within the 16p11.2 chromosomal region, exhibiting varying phenotypes. This CNV affects one copy of 27 genes, including MAPK3 encoding for ERK-1. Extracellular factors signal through ERK to stimulate proliferation and growth while alterations in ERK-1 impact brain development, as observed in 16p11.2 deletion (16p) mice that exhibit ERK dysregulation. Humans with 16p often have macrocephaly, suggesting developmental growth phenotypes due to this deletion.
Objectives:
We investigated induced pluripotent stem cell (iPSC) derived neural precursor cells (NPCs) from 3 16p individuals (2:1; M:F) compared to 3 age matched controls. 16p individuals were diagnosed with ASD to various degree, as well as comorbid macrocephaly and cognitive impairment. We hypothesized there is a proliferation phenotype in 16p NPC and altered ERK signaling.

Methods:
iPSCs were induced into NPCs which expressed markers Sox2, Pax6, and Nestin, and differentiated into neurons and glial subtypes. All proliferation and signaling assays utilized NPCs from passages 3-8 of 1-3 clones per individual cultured in control media +/- fibroblast growth factor (FGF). Experiments were conducted in 24-well plates or 35mm dishes and harvested after 2 days unless otherwise specified. DNA synthesis was assayed by measuring tritiated thymidine 3[H] incorporation following a 2hr pulse. NPCs cell counts were performed at 2, 4 and 6 days using hemocytometer. Signaling proteins levels from two male 16p compared to 3 controls were visualized by western blot.

Results:
CNV 16p patient NPCs exhibited 2-fold greater DNA synthesis than controls at 2 days. Exposure to extracellular factor FGF, a well-known neurogenic regulator and stimulator of ERK, elicited increased DNA synthesis in both 16p and unaffected NPCs. Interestingly, the magnitude of the FGF-induced stimulation of DNA synthesis was blunted in 16p NPCs. While cell counts were not different between groups at 2 days, there were 2-fold increases in 16p NPC numbers by day 6, reflective of earlier increases in DNA synthesis. Preliminary analysis of total ERK-1 protein in 16p NPCs revealed a 30% reduction, while P-ERK protein normalized to total ERK revealed a non-significant increase compared to control. Interestingly, mitogenic signals downstream of ERK, including Cyclin D1 and P-S6, were increased by 30 and 80%, respectively in 16p NPCs, suggesting differential activation of ERK-1 pathway.

Conclusions:
Using iPSC technologies, we observe that 16p NPCs exhibit greater DNA synthesis and proliferation, as well as alterations in signaling compared to unaffected controls. 16p NPCs may also exhibit a blunted response to FGF, though further studies are warranted. The increased proliferation and activation of mitotic regulators, cyclins and P-S6, may provide a mechanism that contributes to the macrocephaly observed in these two male 16p patients. These studies suggest that analyses of ASD NPCs may provide insights into developmental dysregulation that contributes to these disorders, as well as define underlying mechanisms that may ultimately be targeted to address these complex disorders.

125 **167.125** Platelet Studies to Unravel Defective Pathways in Neurodevelopmental Disorders

M. Padmakumar[1]*, E. Turro*[2]*, C. Thys*[1]*, C. Van Geet*[1]*, J. Jaeken*[1] *and K. Freson*[1]*, (1)KU Leuven, Leuven, Belgium, (2)University of Cambridge, Cambridge, United Kingdom*

Background: Next generation sequencing has opened new horizons for hitherto unexplained rare diseases. But with the discovery of novel candidate genes, it is becoming increasingly difficult to pin-point the cellular pathways modified by these genes, especially for neurodevelopmental disorders that are very heterogenous and typically lack patient-derived cell models. Platelets are easily accessible cells and share molecular players that regulate granules, receptors, calcium-dependent activation and cell junctions with neurons. The serotonin pathway, frequently studied in Autism Spectrum Disorder (ASD) also plays an important role in platelet-based hemostasis, as serotonin is stored in the platelet dense granules and is released upon activation. We have used platelets to study ASD and other developmental disorders to gain insights in underlying pathophysiological mechanisms (Bijl et al, Molecular Autism, 2015 and Goubau et al, Dev Med Child Neurol, 2014).
Objectives: We here present ‘platelets as model cell to study neuropathology’ with the description of a patient with a severe neurodevelopmental disorder caused by recessive variants in *SLC18A2* that codes for the vesicular monoamine transporter 2 (VMAT2) protein. VMAT2 is expected to transport dopamine, serotonin and other monoamines from the cell cytosol into synaptic granules. Its exact biological role in granules is still largely unexplored.

Methods: Our patient was included in the National Institute for Health Research (NIHR) BioResource - Rare Disease study using whole genome sequencing (WGS) for diagnosis of unexplained inherited disorders. Platelet granules were evaluated using functional assays and electron microscopy (EM) and a sensitive ELISA was conducted to measure serotonin levels in platelet extracts

Results: Our patient from consanguineous parents presented with severe psychomotor developmental delay, hypotonia, mental retardation, uncontrolled movements, gastrointestinal problems, and died at the age of 5.5 years due to pulmonary complications. Metabolic testing, brain MRI, ECG and cerebrospinal fluid analysis were normal. Though the patient had no hemostatic dysfunction, platelet functional tests were performed. This showed reduced aggregation responses to epinephrine and ADP and a mildly abnormal ATP secretion after ADP stimulation indicative of a dense granule secretion defect. Platelet EM analysis further revealed reduced numbers of dense granules with abnormal content and the presence of immature membrane complexes. WGS identified a novel homozygous variant c.946C>G in *SLC18A2* that results in p.P316A in VMAT2. Both parents were heterozygous carriers. VMAT2 is highly expressed in platelets compared to other blood cell types but its role in dense granules was not studied. ELISA measurements of serotonin levels in platelet extracts showed almost undetectable levels for the patient while the parents have comparable levels to platelets from unrelated healthy controls. This, together with the EM observation indicates a defect in VMAT2 function in the patient, abolishing the serotonin transport into platelet dense granules

Conclusions: This is the first report of defective platelet dense granule morphology, function and content in a patient with a mutation in VMAT2. It shows that defective monoamine transport in neurons can be studied using mirrored defective serotonin transport in platelets and stresses the possibility of using platelet studies to gain insight into the pathophysiology of neurological disorders

126 **167.126** Urinary Metabolomic Profile in Autism Spectrum Disorder: A Comparison between Patients, Siblings and Healthy Controls.

M. Siracusano[1], *A. Noto*[2], *L. Barberini*[2], *A. Riccioni*[3], *L. Mazzone*[3], *A. Benvenuto*[3], *P. Curatolo*[3], *V. Fanos*[2] *and C. Fattuoni*[2], *(1)Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy, (2)University of Cagliari, Italy, Cagliari, Italy, (3)Systems Medicine, Division of Child Psychiatry, University of Rome Tor Vergata, Rome, Italy*

Background: Despite the progress in understanding the neurobiology of Autism Spectrum Disorder (ASD), the causes remain still unknown. A complex relationship between genetic, epigenetic and environmental factors contributes to ASD etiopathogenesis and it is responsible of the clinical heterogeneity. Metabolomics explores the molecular complexity of ASD and the relationships among phenotypes related to external agents. As an emerging tool of network medicine, metabolomics provides a direct functional read-out of the phenotype by the detection, identification, and quantification of metabolites in biological fluids in order to recognize metabolic alteration between comparative samples. Recent evidences show a different urinary metabolomic profile between ASD children and their unaffected siblings. More in details high level of mammalian-microbial cometabolites, alteration in nicotinic-acid metabolism and mitochondrial dysfunction and a dysregulation of antioxidant status and amino acid metabolism have been observed in ASD individuals.

Objectives: to identify urinary metabolic pathways involved in the etiopathogenesis of ASD in 3 different samples: ASD children, siblings and control group (typical development). To describe a specific urinary metabolomic profile related to the clinical phenotype (intelligence quotient, functioning, core symptoms, disruptive behaviours, medical comorbidity such as sleep and gastrointestinal problems).

Methods: we enrolled 105 children, (age range 18 months–11 years): 38 ASD, 35 unaffected siblings, 32 typical developing children without familiarity for ASD. Morning urine samples were collected for all participants. Urinary metabolites were analysed and quantified by Gas chromatography–mass spectrometry (GC-MS). Standardized neuropsychological assessment was performed for ASD children and their affected siblings.

Results: Our preliminary results on 45 children (26 ASD and 20 unaffected siblings) show two distinct urinary metabolomics profiles in the ASD population compared to their unaffected siblings (OPLS-DA R_2 0.5, Q_2 0.02, with a valid permutation test=0.049). The loading plot analysis reveals the different clusterization among the two groups (Figure 1). The main metabolic findings in ASD children include high concentrations of mammalian-microbial metabolites (lyxose, xylose, glucose, arabitol, sorbitol, threitol, fucose, p-cresol) and an alteration of tryptophan pathway (kynurenic acid, xanturenic acid, quinic acid, ribonic acid) (Figure 2). The metabolites most notably changed were compared with information obtained by Human Metabolome Database.

Conclusions: High level of mammalian-microbial metabolites, suggesting gastrointestinal (GI) dysbiosis, can be related to the GI symptoms described in autistic children. In particular, the high urinary level of p-cresol, can be due to proliferation of gut bacteria, constipation and increased oral exploration of objects. Low concentrations of kynurenic acid are associated with dysregulation of the tryptophan pathway, increased oxidative stress, excitatory/inhibitory imbalance.Our preliminary findings suggest a potential role of gastrointestinal dysbiosis, perturbation of antioxidant status, in the etiopathogenesis of ASD comorbidity such as gastrointestinal disorders, epilepsy, sleep disorders.

168 - Sensory, Motor, and Repetitive Behaviors and Interests
5:30 PM - 7:00 PM - Hall Grote Zaal

127 **168.127** A Multi-Disciplinary Exposure Therapy Approach to Treating Auditory Sensory over-Responsiveness

T. Carson[1], *C. Gayle*[2], *L. Guerrero*[3] *and C. Mathews*[2], *(1)Occupational Therapy, University of Florida, Gainesville, FL, (2)Psychiatry, University of Florida, Gainesville, FL, (3)School Psychology, University of Florida, Gainesville, FL*

Background: Auditory hyper-reactivity is estimated to affect up to 66% of children with autism spectrum disorders (ASD) and has been linked to both child and family mental health factors such as higher levels of stress and anxiety. Although hyper-reactivity to auditory stimuli is a significant problem for these children and their families, there are currently no evidence based treatments available to treat this problem in ASD. Exposure and response prevention (E/RP) is highly effective form of treatment for reducing escape/avoidance behaviors associated with obsessive and compulsive disorders, anxiety and phobias. It has also been shown to be effective for reducing OCD behaviors in children with concurrent ASD suggesting that children with ASD may also respond well to this type of treatment approach being applied to sensory hyper-reactivity behaviors.

Objectives: The present study is a clinical pilot to determine the feasibility of implementing a modified E/RP approach for reducing auditory sensory over-responsive behaviors in children with ASD.

Methods: A modified E/RP protocol was provided at the University of Florida Center for Translational Science Clinical Research Center to patients (n = 5) with high functioning ASD ages 5-17 with strong aversions to specific sounds. In addition to autism diagnostic assessments, participants also completed cognitive testing and caregivers provided reports for adaptive behavior scales and sensory processing. Exposure therapy was provided to each participant for up to 12 weeks. Prior to beginning exposures, patients and caregivers were provided psychoeducation on how to identify levels of anxiety and arousal level as well as how to enact self-regulation strategies. Exposure hierarchies were designed to address specific auditory aversions. Parent and patient reports were collected weekly before, during and after treatment regarding the participants' behavioral responses and levels of anxiety experienced when exposed to these sounds. Participant performance on self-reported distress scales, caregiver reports and behavioral observations are compared within subjects across three phases: baseline (no treatment;4 weeks), treatment (12 weeks) and follow-up (home programs; 4 weeks).

Results: Preliminary results suggest good feasibility and that patients with high functioning ASD respond to a modified E/RP protocol as evidenced by decreased avoidance/escape behaviors and decreased self-reported levels of discomfort/anxiety to auditory stimuli that were initially reported to be intolerable.

Conclusions: A modified E/RP approach can be useful for reducing avoidance behaviors and anxiety associated with auditory hyper-reactivity in patients with high functioning ASD. This study supports the idea that auditory hyper-reactivity, in some patients, may be the result of a conditioned response and thus, an E/RP based approach may be effective for such patients. Further studies are warranted to further evaluate treatment efficacy, generalization/maintenance of treatment outcomes, patient-treatment matching as well as follow through with home programs. The results from these studies can serve to: (a) improve children's abilities to tolerate every day sounds and to engage in activities of daily living and (b) improve evidence-based approaches to sensory processing difficulties in ASD. This work represents the first step in evaluating the feasibility and efficacy of applying E/RP treatment to reduce auditory hyper-reactivity in children with ASD.

128 **168.128** Abnormal Frontoparietal Network Connectivity Is Correlated with Motor Skill Ability in Children with Autism

N. F. Wymbs[1,2]*, M. B. Nebel*[1,3] *and S. H. Mostofsky*[1,3]*, (1)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (2)Neurology, Johns Hopkins School of Medicine, Baltimore, MD, (3)Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD*

Background: Children with autism spectrum disorder (ASD) frequently show abnormal motor signs early in development, and strong correspondence with social and communicative features of ASD render it a critical focus of study. Converging evidence has shown that children with ASD have marked impairment in the production of motor skills, termed dyspraxia. Neurobiological evidence of motor skill (praxis), taken from both healthy and impaired states, is by in large supported with the functional involvement of a dorsal frontoparietal (dFPN) cortical network. Although the dFPN abnormalities have been identified in ASD, there is little understanding of how dFPN connectivity affects praxis performance in children with ASD.

Objectives: Our aim was to test if dFPN connectivity is abnormal in children with ASD, and if dFPN connectivity is related to dyspraxia in children with ASD.

Methods: We acquired resting state functional magnetic resonance imaging (rsfMRI) scans from 162 children (81 ASD, 81 typically developing, TD) aged 8-12 years. Groups were balanced for age, socioeconomic status, handedness, and general ability index (GAI). Independent component analysis (ICA) was used to estimate functional connectivity. The dFPN was localized using spatial matching, with left-lateralized sources localized to premotor and parietal regions. Local maxima in the dFPN map were converted to ROIs, and implemented in a seed-based functional connectivity analysis with correction for sources of extraneous noise. We tested for brain-behavior relationships by including measures of gesture and imitation ability (Florida Apraxia Battery modified for children), motor coordination (movement assessment battery for children, MABC-2), social skills (social responsiveness scale, SRS), and ADOS as covariates of interest in the regression model (SPM12).

Results: ASD children were less accurate on gesture imitation than TD children ($p < 0.0001$). We observed a consistent increase in connectivity between right and left inferior parietal lobule (IPL) dFPN seeds and the default mode network (DMN) ($p < 0.05$, FWE). In ASD children, increased connectivity between left IPL and left somatosensory cortex and right precentral gyrus was correlated with gesture accuracy. Connectivity between left IPL and left dorsal premotor, somatosensory cortex, and right cerebellum was correlated with measures of gesture and manual dexterity performance (MABC-2). Further, connectivity between left IPL and premotor, parietal, insula, and cerebellum correlated with gesture and ADOS, while overlapping right prefrontal and premotor, and medial premotor regions correlated with SRS scores and gesture.

Conclusions: These results suggest that praxis deficit in ASD arises from reduced connectivity between the IPL and other within- and between-network regions. Reduction of left IPL connectivity may hinder imitation through reduced ability to carry out dexterous movement. The reduced asynchrony with DMN suggests that abnormal between-network connectivity may contribute to dyspraxia in children with ASD. Our findings further demonstrate the striking correspondence between brain connectivity related to motor skill, and overlapping connectivity related to ASD severity and social skills. These findings represent a step towards understanding the involvement of the dFPN in skilled behavior in ASD, with extension to abnormalities in core social and communicative behaviors.

129 **168.129** An Integrative Approach of Visual Functions in ASD

K. Kovarski[1]*, M. Latinus*[2]*, J. Malvy*[3]*, F. Bonnet-Brilhault*[4] *and M. Batty*[5]*, (1)UMR 930 INSERM, University of Tours, Tours, France, (2)UMR INSERM U930, Tours, France, (3)CHRU Tours, Tours, France, (4)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (5)Centre d'Etudes et de Recherches en Psychopathologie et Psychologie de la Santé, Université de Toulouse - Jean Jaurès, Toulouse Cedex 9, France*

Background:

Visual perception is atypical in children with ASD at many stages from oculomotor functions to cerebral processing. ASD children present more ophthalmological disturbances, faster saccades and atypical early brain responses to social and non-social stimuli. A number of studies have recently suggested that sensory processing might play a crucial role in social disturbances. However, few studies have investigated the relationship between impairements in fixation, saccades and the underlying brain responses recorded by EEG.

Objectives:

The current analysis aims at investigating whether impairments in high-level perception are the consequence of low-level sensory dysfunctions and to quantify their respective influence.

Methods:

After ophthalmological examination, thirteen children with ASD with normal vision completed several tasks conceived to investigate visual perception at different stages. Children were aged from 42 to 130 months (mean age ± standard deviation: 78.4 ± 29.2 months). Because several children presented an intellectual delay, all tasks were passive, and no explicit instruction was given to the participants. The tasks included the recording of visual evoked potentials to pattern reversal stimulation and to emotional faces. Moreover, two eye tracking tasks were designed to investigate i) fixation and ii) saccade metrics. For the ERPs studies, latency of the N170 and amplitudes of N75 and P1 for pattern-reversal stimulation and P1 and N170 for faces were measured in each child. For the oculomotor tasks, we focused on number of fixations and fixation duration in the fixation task, and the time to reach the target and the precision of the saccades in the prosaccade task. These parameters were entered in a principal component analysis.

Results:

The principal component analysis revealed that two components explained about 52% of the variability between the thirteen children. The first component was summarised mainly by the number of fixations, and the amplitudes of early visual evoked potentials (N75, P1 and N170) regardless of them being evoked by a social or non-social stimulation. The second component had larger weights on N170 amplitude and latency as well as saccade precisions. None of the components correlated with clinical scores such as ADOS or CARS. Future analyses will look at whether weighting the atypicalities found at each processing step influence the next step of processing at the individual level, therefore providing an individualised approach to bridge between clinical and research findings.

Conclusions:

These data highlights a strong link between oculomotor functions and visual evoked potentials in ASD, regardless of the stimuli being social or not. Moreover, the latency and amplitude of the N170 seems to depend on the ability of the child to reach the point of interest with accuracy, and fixate on it. This analysis strategy allows to determine the weights of low-level atypicalities on social difficulties. It further demonstrates the importance of controlling for sensory impairments (from ophthalmologic pathologies to oculomotor behaviour) in research looking at higher functions in ASD.

168.130 Are Restricted and Repetitive Behaviours Related to Executive Function Performance? a Correlational Meta-Analysis.

***R. K. Iversen**, Lancaster University, Lancaster, United Kingdom of Great Britain and Northern Ireland*

Background: A growing number of correlational studies have been undertaken to evaluate the proposed relationship between executive function (EF) skills and restricted and repetitive behaviours (RRBs) in young children (e.g. Tregay, 2009) and individuals with autistic spectrum disorder (ASD) (e.g. South et al., 2007). The EF theory is a strong contender for explaining RRBs across both populations, as it proposes that an inability to control behaviours does not facilitate the inhibition of RRBs. For example, this theory is capable of accounting for the age-related changes occurring in typical development around the age of four/five, when EF skills undergo a rapid development (e.g. Carlson, 2005) and RRBs decrease (e.g. Evans et al, 1997). Despite this, the evidence regarding the relationship between EF skills and RRB levels is mixed, as some studies have found associations with several EF components, such as set-shifting and inhibitory control (e.g. Lopez et al, 2005), whereas others have found that only set-shifting performance predicted RRBs (Van Eylen et al, 2014). The current meta-analysis will, therefore attempt to evaluate the relationship with a focus on set-shifting and inhibitory control measures, but also parental-reports. The parental-report measures will be included as a separate analysis, as although both types of tasks are commonly used to measure EF skills, Toplak et al (2013) found that they measured different levels of cognition, namely, cognitive abilities and goal pursuit achievement. There is now a need for a systematic attempt to evaluate the relationship across studies and between task batteries.

Objectives: This meta-analysis (following recommendations from Quintana, 2015) will allow us to examine the general EF hypothesis, but also identify whether the link between RRBs and EF skills is a general one, or if it is caused by one specific mechanism.

Methods: Following a comprehensive search in three databases, three random-effects analyses were run. The set-shifting analysis consisted of 20 studies (with 26 correlations) and a sample size of 869. The inhibitory control analysis comprised of 14 studies (with 17 correlations) and a sample size of 664. Finally, the parental-report analysis included 8 studies (with 12 correlations) and a sample size of 1362. Moderators such as age, diagnosis, EF task and type of RRB measure were investigated.

Results: The analyses found significant but moderate associations between RRBs and set-shifting performance (.27, 95% CI 0.17-0.41, $p< 0.0001$), inhibitory control performance (.20, 95% CI 0.02- 0.37, p 0.02) and scores on parental-report measures (.31, 95% CI 0.0736-0.5514, $p <0.001$). We found that for set-shifting tasks and parental-scores; the association remained stable with age, between diagnoses and across different types of EF and RRB measures. In contrast, the relationship between RRBs and inhibitory control performance was moderated by age and diagnosis.

Conclusions: This meta-analysis offers support for the EF hypothesis, and suggests that at least two cognitive mechanisms may underpin the high RRB levels in individuals with ASD, as well as in young children. The relationship between cognitive skills and behaviours may have clinical training implications so directions for future intervention research will be proposed.

131

168.131 Audiovisual Integration Abilities in ASD Using Music-Based Stimuli

***L. Silverman**[1], A. R. Canfield[2], N. Gebhard[3] and M. Schutz[4], (1)University of Rochester Medical Center, Rochester, NY, (2)Psychological Sciences, University of Connecticut, Storrs, CT, (3)Massachusetts General Hospital, Cambridge, MA, (4)McMaster University, Hamilton, ON, Canada*

Background: Individuals with autism spectrum disorder (ASD) have difficulty with audiovisual integration, which may contribute to some of the core symptoms of the disorder. However, the full extent of their sensory integration abilities is not yet well characterized. Studies using complex, language-based tasks have found that individuals with ASD do not use lip movements or hand gestures efficiently to improve speech perception. Conversely, research with simple non-social stimuli, such as auditory-beeps and visual-flashes generally suggests intact integration abilities. These findings are hard to compare because most language-based stimuli involve biological motion, while non-social studies tend to use computer-generated stimuli without natural human movements and artificial synthesized sounds. It is unclear whether individuals with autism

can integrate natural human, audiovisual information in the absence
Objectives:

The current study addresses this gap by examining integration of human, audiovisual information in the absence of language demands. This was achieved by utilizing a musical illusion documented by Schutz and Lipscomb (2007).

Methods: Participants were 24 adolescents with high-functioning ASD and 24 typically developing (TD) controls, matched on age, gender, and IQ. They watched videos of an internationally acclaimed musician performing short and long notes on the marimba (a percussion instrument similar to a xylophone). Prior research suggests that features of a musician's performance gestures (height and trajectory of hand movements) affect listeners' perception of note duration (longer gestures result in perception of longer sounding notes). This illusion is well documented in typical adults. The current experiment included three conditions: audio-visual, audio-alone, and video-alone. Participants were told that they would complete a computer game and some parts of the game had gestures, others had sounds, and other parts had both. They were informed that in the audiovisual condition, sometimes auditory and visual stimuli were mismatched. Participants were asked to judge the duration of each independently. Integration was determined based on participants' estimation of note duration and the presence of an audiovisual illusion.

Results:

We assessed the visual influence of gesture on perception of note duration in the two groups using a 2 (visual gesture length) X 2 (group) X 6 (note duration) repeated measures ANOVA. Notably, there was a significant influence of visual gesture length on note duration $F_{(1, 46)}$=22.00, $p < .0001$ (partial h^2 =.0454), as well as a lack of interaction between gesture length and group $F_{(1, 46)}$= .0004, p=.984. This indicates that individuals with ASD integrated auditory and visual information, and experienced the illusion no differently than the controls. In unimodal conditions there was a significant effect of group in the audio-only $F_{(1, 46)}$=9.781, p = .0003 (partial h^2 =.0791), and the video-only $F_{(1, 46)}$=8.988, p = .0044 (partial h^2 =.0642), with the ASD group providing shorter relative judgments, but no group X visual gesture nor group X pitch interaction.

Conclusions: The magnitude of the audiovisual illusion in the ASD group was comparable to the illusion experienced by controls. This suggests intact integration abilities in ASD for natural, human audiovisual information in the absence of language demands.

132

168.132 Audiovisual Speech Perception in Children with Autism Spectrum Disorders: An Eye Tracking Study

S. Feng[1], *Z. Ma*[2], *Y. Wu*[1], *T. Li*[3], *L. Chen*[1] *and L. Yi*[3], *(1)School of Psychological and Cognitive Sciences, Peking University, Beijing, China, (2)Emory University, Beijing, China, (3)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China*

Background: Children with autism spectrum disorders (ASD) show weaker audiovisual speech integration, such as a weaker McGurk effect (Bebko, Schroeder & Weiss, 2014) than typically developing (TD) children do. The reduced McGurk effect could be related to their atypical face processing pattern (Rice, Moriuchi, Jones & Klin, 2012) or their deficits in multisensory temporal processing (Stevenson et al., 2014).
Objectives: We examined whether the potential weaker McGurk effect of children with ASD was due to their reduced fixation time on the face or the mouth. We also investigated whether the children with ASD had a deficit in the audiovisual temporal processing for the audiovisual mismatched McGurk stimuli.

Methods: Forty-nine children with ASD and thirty-one TD children participated in the two experiments in this study. First, we investigated whether the ASD group showed similar McGurk effect as the TD group did. We designed two conditions: the one with the speakers' eyes open and the other one with the speakers' eyes closed. In both conditions, we presented the audiovisual matched stimuli and the audiovisual mismatched stimuli (McGurk stimuli). The participants reported what the speaker said. Meanwhile, we recorded participants' eye movements. Second, we explored the width of the two groups' temporal binding window (ASD vs TD) using the McGurk stimuli. Participants completed an audiovisual simultaneity judgement task with SOAs of 0, ±40, ±120, ±240, ±360, ±480, and ±680 ms (negative values indicate auditory stimulus appeared first).

Results: In Experiment 1, we found a Group-Condition interaction for the McGurk effect: the ASD group showed significantly less McGurk effect than the TD group did in the open-eye condition only; the two groups performed similarly in the closed-eye condition. The TD group showed weaker McGurk effect in the closed-eye than the open-eye conditions, while ASD group did not differ between these two conditions (Figure 1). The area of interest analysis for the eye movement of the McGurk trials revealed that the ASD group looked shorter at the mouth and the face than the TD group for the audiovisual mismatched stimuli in both conditions (Figure 2). Additional trial by trial generalized linear mixed modeling revealed that longer mouth-looking time or longer face-looking time in the ASD group predicted stronger McGurk effect. In Experiment 2, each participant's percentages of simultaneous responses were fit by psychometric functions. The audiovisual temporal binding windows for the ASD group were significantly wider than those of the TD group. However, we failed to discover any correlation between the width of the audiovisual temporal binding windows and the strength of the McGurk effect.

Conclusions: The present study provided direct evidence for the relation between the children with ASD's audiovisual speech perception and their atypical face processing. These findings will further our understanding of the underlying mechanisms for the abnormal audiovisual speech perception in ASD.

133

168.133 Autistic Individuals Are Slow in Updating Their Internal Representations and Predictions

M. Ahissar[1], *I. Lieder*[2] *and G. Vishne*[2], *(1)Hebrew Universiy, Jerusalem, Israel, (2)Hebrew University, Jerusalem, Israel*

Background:
In the last 15 years our lab studied dyslexia, asking what neural and cognitive mechanisms underlie their poorer performance in a broad range of simple serial discrimination tasks. We found that dyslexics' performance reflects impaired inference of stimuli statistics rather than a noisier sensory system. To assess dyslexics' sensitivity to context we studied a phenomenon termed "contraction bias" – the pulling of perception towards the "prior" – the mean of similar, previously encountered, stimuli. This pulling occurs shortly after stimulus presentation, and can be understood within a Bayesian framework of optimizing perception based on previous knowledge, given noisy sampling or memory. Dyslexics' contraction bias is smaller than controls', reflecting inefficient use of environmental statistics. Using behavioral, ERP and computational methods developed in our lab, we found that this inefficiency stems from faster decay of their implicit memory of previous stimuli.

Objectives:

We now asked whether the pattern of inference of high functioning autistic individuals, with no language difficulties, is similar to dyslexics'. Recent studies found reduced efficiency of statistical inference in Autism. However, Autistics' difficulties are quite different than those of dyslexics.

Methods:

We recruited a population of 58 adults, 28 autistic and 30 typically developing (TD) individuals, matched for age and reasoning skills, and replicated experiments of simple serial frequency discrimination, and paced finger tapping, which we previously administered to adult dyslexics.

Results:

Classical thresholds did not differ between the groups. However autistics' contraction bias was substantially smaller than that of TD participants. Analyzing the impact of previous trials on autistics' performance we found that they tend to under weigh recent trials. While both dyslexics and TD participants weigh recent trials more than earlier ones when implicitly calculating the mean of previous trials, autistic participants do not. However, their accumulation of stimuli statistics based on earlier trials is similar to that of TDs. This observations suggests that while they may accumulate adequate statistics in stable environments, they are less flexible in adjusting their representations, and hence predictions, to novel ones where statistics changes. To test this interpretation we administered a simple synchronize to metronome tapping task, where performance is determined only by very recent intervals. While dyslexics' performance was similar to TDs', autistics could not reliably synchronize to the external beats. Particularly challenging situations were those when metronome' beat changed and autistic participants were slower in adapting to new intervals, further supporting the slow-update interpretation.

Conclusions:

Autistics and dyslexics show inefficient statistical learning, but due to different underlying mechanisms. While dyslexics are fast adapters but show fast decay of their memory traces, autistics adapt slowly but show adequate retention. This difference is consistent with the broader behavioral profiles - dyslexics' fast adaptation but impoverished categorical representations, and autistics' slow adaptation but adequate categorical representations. A broad range of daily behavioral characteristics can also be explained as a consequence of these implicit learning patterns.

134 **168.134** Bilateral Patterns of Repetitive Movements in 6- to 12-Month-Old Infants As a Red Flag for Autism Spectrum Disorders

V. Costanzo[1]*, G. Purpura*[2]*, N. Chericoni*[1]*, F. Apicella*[1]*, M. L. Scattoni*[3] *and F. Muratori*[4]*, (1)IRCCS Fondazione Stella Maris, Calambrone (Pisa), Italy, (2)IRCCS Fondazione Stella Maris, Pisa, Italy, (3)Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy, (4)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*

Background: During the first year of life of an infant, repetitive movements represent a phase of typical motor development and they are considered a step towards voluntary purposeful movements. However, some types of repetitive movements and their higher frequency, from 12 months onwards, have been proved to distinguish infants with a Neurodevelopmental Disorders from infants with Typical Development (TD) . To distinguish between typical and atypical repetitive movements, the criteria that should be adopted are their frequency and the child's age : in fact, a higher rate of these movements beyond their physiological temporal window might reduce the infant's opportunity to develop more functional strategies of motor action. This is the case of Autism Spectrum Disorder (ASD), in which the persistence of repetitive and stereotyped movements during toddlerhood is considered, together with restricted interests and activities, one of the core symptoms.
Objectives: The purpose is to point out if a higher rate, duration and repertoire of repetitive movements could differentiate a) infants with ASD from infants with DD and TD aged between 6 and 12 months b) high-risk infants with ASD (HR-ASD), from high-risk infants without ASD (HR-nonASD), during the administration of the AOSI at 6 and 12 months of life.

Methods: We coded Repetitive Movements Episodes (RMEs), defined as a period of time characterized by a repetition of a movement for at least 2 times. We analyzed video-clips from retrospective homemade movies and from video-recordings of the AOSI administration, to compare the frequency and the duration of Repetitive Movement Episodes (RMEs) of a sample of 50 children equally distributed among the five groups (ASD, TD, DD, HR-ASD, HR-nonASD).

Results: Significantly higher total scores in RMEs with arms, hands, fingers and lower limbs were found to distinguish ASD infants from TD infants, with a satisfactory diagnostic efficiency (AUC>=80%). No significant difference was found between the distributions of unilateral RMEs between ASD and DD/TD. A similar difference was found between high-risk infants with ASD and without ASD. Results will be discussed in terms of the type of repetitive movements and of their implication for early diagnosis.

Conclusions: the results indicate that during the first year of life of life, an increased frequency of a particular repertoire of repetitive movements appears to be specific to ASD and could therefore be considered an early sign of the disorder.

135 **168.135** Brainstem Alterations in Young Children with Autism Spectrum Disorders: Comparison Among Automated Algorithms

P. Bosco[1]*, A. Giuliano*[1]*, J. Delafield-Butt*[2]*, F. Muratori*[3]*,* ***S. Calderoni***[3] *and A. Retico*[4]*, (1)National Institute for Nuclear Physics (INFN), Pisa, Italy, (2)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (3)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, (4)Pisa Division, National Institute for Nuclear Physics, Pisa, Italy*

Background:
Sensorimotor abnormalities have been consistently reported in ASD individuals as an early impairment that may precede the development of defining characteristics. Motor abilities depend on multiple interacting pathways including cortico-cortical, cortical-subcortical, and cortico-cerebellar connections that reach spinal motor neurons through the brainstem.

Structural MRI studies of ASD individuals have demonstrated the potential role of the brainstem in the pathophysiology of ASD. However, the findings in volume alterations in subjects with ASD with respect to matched controls are controversial both in adults and children cohorts with some early studies that did not detect any significant differences between the ASD and control samples. For this reason, it is important to investigate the contribution to variability of brainstem volume measurements performed with different automated methods.

Objectives: The inter-method reliability of automated algorithms for brainstem segmentation was investigated, focusing on the potential involvement of this structure in ASD. Indeed, inconsistencies highlighted in previous studies on brainstem in ASD, may in part be a result of poor agreement in the extraction of structural features with different methods.

Methods: Structural MRI was used to measure the volume and the shape of the brainstem in young children with ASD and matched controls. A sample of 38 male children and 38 female children with ASD and their age and intellective-quotient matched controls were considered. Volume and shape analysis were carried out through some largely-used neuroimaging analysis tools for brain structure segmentation (FSL-FIRST, FreeSurfer -FS-, Advanced Normalization Tools -ANTs-), and for shape analysis (SPHARM-MAT). The inter-method agreement was quantified in terms of Pearson correlations between pairs of volumes obtained by different methods, whereas the degree of overlap between segmented masks was quantified in terms of the Dice index. In addition, a statistical examination of brainstem volume was performed using the analysis of variance (ANOVA) test. A comparison between ASD and control subjects was performed both in the male and female groups separately and in the entire dataset using gender as covariate and considering subjects with or without by intellectual disability separately.

Results: Both in terms of the Pearson correlation and of the Dice index, FSL-FIRST showed poor agreement with the other segmentation methods, which, by contrasts, consistently showed Pearson correlations greater than 0.93 and average Dice indexes greater than 0.76 in comparison among each other. The shape analysis confirmed the discrepancies among different segmentation methods, with particular reference to the FSL-FIRST under- and over-segmentation problems in specific brainstem regions. The BS volume resulted significantly higher in ASD when compared to controls both in the entire sample and in male subgroup for ANTs, FS 5.3, and FS 6.0 computations. No statistically significant volume differences were obtained for females in BS total volume.

Conclusions: This study suggests that research on brainstem alterations should cross-validate findings across multiple methods. Nevertheless, we reliably detected an enlargement of brainstem volume in the whole sample and in the male cohort, which is particularly driven by the subgroup of subjects with intellectual disability.

136

168.136 Classifying Gender in Autism Spectrum Disorder Based on Restricted and Repetitive Behaviors and Interests

L. Antezana[1], *R. S. Factor*[1], *E. E. Condy*[2], *M. V. Strege*[2], *A. Scarpa*[3] *and J. A. Richey*[2], *(1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Virginia Tech, Blacksburg, VA, (3)Virginia Polytechnic Institute & State University, Blacksburg, VA*

Background: The female autism phenotype has been defined by differences in core autism spectrum disorder (ASD) symptomology related to reciprocal social communication and restricted and repetitive behaviors and interests (RRBI). Previous research on RRBI in ASD has found that affected boys have increased stereotyped and restricted behaviors compared to girls with ASD (Hiller, Young, & Weber, 2014; Mandy et al., 2012). Other domains of RRBI (i.e., self-injurious, compulsive, and insistence on sameness behaviors), which contribute to DSM-5 diagnosis, are less studied and have not been examined across gender. To date, no studies have examined gender differences using a comprehensive RRBI measure, which spans stereotyped, self-injurious, compulsive, insistence on sameness, and restricted behavior domains.

Objectives: To investigate whether symptoms of RRBI (i.e., stereotyped, self-injurious, ritualistic, compulsive, insistence on sameness, and restricted behavior), as measured by item-level data on the Repetitive Behavior Scale-Revised (RBS-R), can classify males versus females with ASD.

Methods: Participants included 615 youth with ASD (507 males; 82.4%), between 3 and 18 years of age (M=10.26, SD=4.20), who agreed to share data with the National Database for Autism Research (NDAR). A stepwise discriminant function analysis (DFA) was used to predict the degree RBS-R data could correctly classify gender in a large sample of individuals with ASD. Standardized canonical function coefficients (SCFC) from the DFA represent the contribution of each variable to the discrimination between groups, with greater SCFC indicating greater discrimination.

Results: DFA results suggest that RBS-R items significantly differentiate girls versus boys with ASD, Wilks' λ=0.89, χ^2=70.79, p<0.001. Of note, gender was classified based on a set of 8 items (see table 1). Interestingly, the items that differentiated boys from girls did not solely consist of higher stereotyped and restricted behavior in boys (as indicated by negative SCFC scores). Half of the items that differentiated gender were higher in females with ASD (as indicated by positive SCFC scores) and from the self-injurious, compulsive, and insistence on sameness domains. This set of RBS-R items had greater success in correctly classifying boys with ASD (67.90%) than in correctly classifying affected girls (61.00%).

Conclusions: This study extends findings of gender differences in RRBI for ASD, demonstrating that girls with ASD may demonstrate higher self-injurious, compulsive, and insistence on sameness behavior than affected boys. It is important for future research to disentangle whether these elevated rates of RRBI in girls with ASD are central to the female autism phenotype or an epiphenomenon of the high rates of co-occurring disorders (e.g., anxiety) noted in affected girls.

137

168.137 Closure and Symmetry Perception in Autism

N. S. Subri[1], *C. Dickinson*[2] *and E. Gowen*[3], *(1)The University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland, (2)Division of Pharmacy and Optometry, The University of Manchester, Manchester, United Kingdom, (3)Division of Neuroscience and Experimental Psychology, University of Manchester, Manchester, United Kingdom*

Background:

Closure describes a perceptual grouping cue, where a closed shape (e.g. a square) stands out more than an open shape (e.g. a single line), creating a 'pop-out' effect. Closure is believed to involve a global processing mechanism where feedforward information is integrated with feedback from visual areas responsible for shape processing. Previous work has shown that autistic adults have a reduced closure effect, suggesting reduced visual integration in this group (Jachim et al, 2015). However, it is unknown whether this is due to the short duration of stimulus presentation used in this study, as no group differences have been observed in studies measuring different aspects of visual integration that use longer durations (Kovács et al. 1999; Hadad et al. 2010). In addition, it is still unknown whether reduced closure may affect other aspects of perception in autism that also rely on global mechanisms such as symmetry perception. During symmetry perception, symmetrical shapes are processed faster than asymmetrical shapes. Given that both closure and symmetry perception involve global processing, we investigated how symmetry perception may be affected by reduced closure in autism.

Objectives:

Using two experiments, we investigated the effect of stimulus duration on closure (experiment 1) and how closure affects symmetry perception (experiment 2) in autistic and non-autistic adults.

Methods:

Two experiments were tested on autistics and matched non-autistic adults. Both experiments were based on a 2-IFC contour integration task, where participants had to detect a contour formed by Gabor elements, against a background of randomly oriented Gabors. In experiment 1, contour detection was compared between closed and open shapes at two durations: 150ms and 500ms. The closure effect was then calculated as the difference in performance between the two shapes, for each duration. In experiment 2, instead of detecting the contour, participants were asked to choose the most symmetric shape (symmetry detection task). Symmetry was varied by changing the angle of the sides of a square pattern, and performance was compared between closed and open shapes.

Results:

In experiment 1, we found a significant interaction of stimulusXgroup where the autistic group has less closure effect compared to the non-autistic group at both durations. This was similar across both durations with no three-way interaction with duration. For experiment 2, symmetry was significantly easier to detect with closed than the open shape for the non-autistic participants. However, symmetry detection was not significantly different between closed and open shapes in the autistic group.

Conclusions:

Experiment 1 showed that reduced closure in autistic group does not improve with longer durations, indicating a persistent alteration in the closure effect over time. In addition, Experiment 2 showed that closure seems to provide less benefit in symmetry detection in the autistic compared to non-autistic group, suggesting that the autistic group might be using different mechanisms to process both symmetry and closure. Overall, both findings depict atypical visual processing in autism, providing knowledge on how differences in visual perception may arise.

138 **168.138** Differences in Interoception and the Bodily Representation of Emotion in Autism and Typical Development

E. R. Palser[1], *E. Pellicano*[2], *A. Fotopoulou*[1] *and J. M. Kilner*[3], *(1)Clinical, Educational and Health Psychology, UCL, London, United Kingdom, (2)Macquarie University, Sydney, Australia, (3)Institute of Neurology, University College London, London, United Kingdom*

Background: Interoception is the detection of signals that relate to the physiological condition of the body, encompassing internal sensations such as those arising from the cardiac, respiratory and gastrointestinal systems, as well as external sensations such as temperature and pain (Ceuen et al., 2016; Craig, 2002; Sherrington, 1948). The perception of interoceptive signals has been considered of importance for understanding emotion since the seminal work of James and Lange (Lange & James, 1922), who suggested that emotion relies on the interpretation of physiological signals. It is now known that emotions are associated with discrete bodily maps of where they are experienced (Nummenmaaa et al., 2014), and these maps become more differentiated throughout child development (Hietanen et al., 2016). Difficulties in identifying and describing emotions are an integral part of autism (Griffin et al., 2015; Hill, Berthoz, & Frith, 2004).

Objectives: Here, we sought to investigate if there are differences in the bodily representation of emotion in children and adolescents with autism, compared to typical development and if so, do these differences relate to interoceptive processing.

Methods: Participants comprised 79 children and adolescents aged 6 to 19 years (mean=13.5, SD=3.0), of which 40 were reported to be typically developing, and 39 were reported to have an independent clinical diagnosis of ASD, verified by ADOS-2 administration. These groups were matched for chronological age and IQ. The Embody emotion coloring task (Nemmenmaa et al., 2014) was used to measure the bodily representation of seven emotions and interoceptive accuracy was gauged using the heartbeat tracking task (Schandry, 1981).

Results: We find significant differences in how emotions are embodied between typical development and autism ($t(77)=2.425$, $p=0.018$) and these group differences remain after controlling for age, gender and IQ. Further, interoceptive accuracy significantly explains more variance in the bodily representation of emotion, over and above group membership.

Conclusions: Autistic children and adolescents show significant differences in how they report the bodily sensations associated with emotions. These data suggest one possible cause of these differences is reduced interoceptive accuracy. Finally, the Embody emotion coloring task (Nemmenmaa et al., 2014) may offer a means of identifying difficulties in describing emotions that does not rely on the individual's ability to recognize that they have a difficulty, as is the case with traditional questionnaire measures.

139 **168.139** Disruption to Motor Intentions in Children with Autism: Evidence for Brainstem Timing Errors

J. Delafield-Butt[1], *K. Sobota*[2,3], *A. Anzulewicz*[4,5], *L. Millar*[2] *and P. Rowe*[6], *(1)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (2)Faculty of Engineering, University of Strathclyde, Glasgow, United Kingdom, (3)Harimata Sp.Z.o.o., Krakow, Poland, (4)Faculty of Humanities and Social Sciences, University of Strathclyde, Glasgow, United Kingdom, (5)Harimata Sp. z.o.o., Kraków, Poland, (6)Department of Biomedical Engineering, University of Strathclyde, Glasgow, United Kingdom*

Background:

Human movements are prospective. They must anticipate ahead of time their lawful consequences. In children with autism, evidence indicates a common disruption to movement may underpin its early pathogenesis (Trevarthen & Delafield-Butt, 2013). and may be a cardinal feature (Fournier et al., 2006). Yet, more work is required to better characterize this possible 'autism motor signature' and to probe its neurodevelopmental origins. In this study, we employed smart tablet computers with touch-sensitive screens and embedded inertial movement sensors to ecologically record the subsecond motor kinematics of movements made by children developing with and without autism.

Objectives:

(1) Characterise the subsecond motor kinematics of children with autism and those developing typically to identify autism-specific features. (2) Probe likely neurobiological origins of the motor disruption based on these variables.

Methods:

37 children 3-6 years old diagnosed with Childhood Autism and 45 age- gender-matched children developing typically were included. Children with sensory or motor impairment were excluded. iPad mini tablet computers employed two education games: *(1)* 'Sharing' where the main gameplay was to divide a piece of food and distribute it among four children; and *(2) Creativity* where gameplay was open, unstructured colouring of a toy or animal. Data were collected from the tablets' inertial sensors (tri-axial accelerometer, tri-axial gyroscope and magnetometer) and touch screen. Raw values and simple kinematic calculations produced 262 features. Previously we analysed these using machine learning

methods with a classification accuracy of 93% (Anzulewicz, Sobota & Delafield-Butt, 2016). Here, these features were extracted and analysed using standard statistical multivariate analyses to identify significant ones. Further, kinematic analyses of goal-directed gestures were analysed using standard biomechanical methods, and groups compared.

Results:

Features associated with impact force made at initial contact and forces put into the device during a gesture were significantly different between groups. Gesture kinematics were faster and larger across both games, with more distal use of space in children with autism. Children with autism made faster taps on the screen. Greater peak velocities with commensurate increases in acceleration and deceleration peaks and with significantly increased jerk amplitude were evident in goal-directed movements in the autism group.

Conclusions:

These data indicate under- and over-exertion of the motor impulse with velocity remaining high at a movement's conclusion. Acceleration-deceleration shifts with increased jerk amplitude appeared to oscillate at a fast, subsecond rate of ca. 13 Hz, corroborated by others (Cook et al., 2013). Greater impact forces confirm a greater velocity at movement termination, a finding in agreement with others' (Crippa et al., 2015). Disruption to sub-second control of intentional movements and timing their termination are two key features of the autism motor signature. A likely neuromotor origin of these is the brainstem inferior olivary pace-maker responsible for action timing. Disruption to basic action patterning will thwart motor intentions regularly, and may lead to distress, withdrawal, and the familiar simplification found in repetitive movement.

140 **168.140** Do Repetitive Behaviours and Restricted Interests Predict Later Cognitive Ability in Children with Autism Spectrum Disorder?

***V. Courchesne**[1], T. Savion-Lemieux[2], R. Bruno[2], T. Bennett[3], E. Duku[4], S. Georgiades[4], P. Mirenda[5], I. M. Smith[6], P. Szatmari[7], W. J. Ungar[8], T. Vaillancourt[9], J. Volden[10], C. Waddell[11], L. Zwaigenbaum[10], A. Thompson[4] and M. Elsabbagh[12], (1)McGill University, Montreal, QC, Canada, (2)Research Institute-McGill University Health Centre, Montreal, QC, Canada, (3)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (4)McMaster University, Hamilton, ON, Canada, (5)University of British Columbia, Vancouver, BC, Canada, (6)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (7)The Hospital for Sick Children, Toronto, ON, Canada, (8)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (9)University of Ottawa, Ottawa, ON, Canada, (10)University of Alberta, Edmonton, AB, Canada, (11)Simon Fraser University, Vancouver, BC, Canada, (12)McGill University, Montreal, PQ, Canada*

Background: Restricted and repetitive behaviors and interests(RRBIs) are one of the two domains of symptoms that constitute the diagnostic criteria of Autism Spectrum Disorder(ASD)(APA, 2013) and are therefore an important pillar for ASD diagnosis. The functional impact of RRBIs is source of debate in the literature. When studied as a single construct, RRBIs have shown to be negatively correlated to cognitive and adaptive functioning (e.g. Troyb et al. 2016). However, some argued that RRBI symptoms should be examined individually, rather than as a single homogenous construct, as they represent a vast array of heterogenous behaviours with possibly distinct underpinnings differentially affecting functioning across the lifespan (Lidstone et al. 2014). Support for this hypothesis comes from studies showing that when RRBIs are broken down into specific behaviours, some have been found to have an "adaptive" function and be associated to higher cognitive abilities(i.e. *stereotyped language,* Kim & Lord, 2010; *restricted interests*, Bishop et al., 2006; *rituals*, Militerni et al., 2002; *insistence on sameness*, Mooney et al., 2009). Nonetheless, there is still a paucity of research investigating individual RRBIs and their functional impact across development.
Objectives: Using data from a large longitudinal inception cohort of children with ASD, we explored whether the presence or absence of specific RRBIs, as reported by parents around the time of their child's diagnosis, could help predict non-verbal cognitive ability later in childhood.

Methods: Data were drawn from *Pathways in ASD*, a longitudinal study of 421 preschoolers diagnosed with ASD followed yearly across five Canadian provinces. Analyses included 206 children for whom the Autism Diagnostic Interview – Revised(ADI-R) was completed when they were 2-4 years (M=39.6 months; SD=8.6) and the Wechsler Intelligence Scales for Children – Fourth edition(WISC-IV) was completed when they were 8-9 years (M=104.7months; SD=2.5). Selected RRBI predictors of non-verbal cognitive ability (measured using the WISC-IV Perceptual Reasoning Index (PRI) standard score) included: stereotyped language (Q. 33), restricted interests (Q.68), rituals (Q.70), and insistence on sameness (Q.75), grouped as "absence" (score=0) or "presence" (scores of 1-3) of symptom as reported on the ADI-R. Student tests and linear regression models were performed to answer research question. Model validation was examined using adjusted R squared and homoscedasticity test of residuals variance.

Results: We found that the group of children for whom parents reported *rituals* (R^2=0.02 F=4.5, p=0.04) or *insistence on sameness* (R2=0.02 F=4.2, p=0.04) around the time of diagnosis had a tendency to have a slightly more elevated mean PRI standard score later in childhood as compared to the group of children for whom parents did not report these behaviors. No significant results emerged for the other two RRBIs (p>.05)

Conclusions: Our results support the notion that RRBIs should be considered as distinct behaviours that can differentially affect functioning across development. Further research is warranted using observational data and/or more dimensional measures capturing frequency of the behavior (rather than presence or absence) to better understand the differential impact of RRBIs on different spheres of functioning and across the lifespan to ultimately better inform RRBIs' targets in interventions.

141 **168.141** Emotional Contexts of Postural Control in Neurodevelopmental Disorders

***D. Green**, CHILD Research Institute, Jönköping University, Sweden*

Background:
Motor and social impairments are commonly reported to overlap in neurodevelopmental disorders. However, assessment of movement problems via standardised assessment requires an understanding of both implicit and explicit instruction e.g. 'stand on one foot as long as you can'. Standardised assessment is further complicated where anxiety may affect performance; evidenced by the literature with respect to balance and anxiety. There are few, if any studies, directly contrasting postural control between children with autism spectrum disorders (ASD) and those with developmental coordination disorder (DCD).

Objectives: This study will explore the potential relationship between emotional factors and balance in children with ASD and DCD and implications for assessment.

Methods: A scoping review profiling the motor impairments and emotional problems of children with ASD and DCD. Secondary data from an intervention study will contrast performance on tests of balance from the Movement Assessment Battery for Children (MABC) and compare associations between balance and emotional factors as measured by the Strengths and Difficulties Questionnaire (SDQ).

Results:

This paper will present data contrasting use of standardised measures of static and dynamic balance between children with ASD and those with DCD. Data on 48 children (median age 8 years; range 5 years-4 months to 10 years-8 months; 12 with ASD, 36 with DCD) were available. Findings reflect similarities in performance with a lack of distinction between these groups on standardised testing on both static and dynamic balance on the MABC (*p*>.05). Spearman correlations reflect an association between poor dynamic balance and emotional difficulties on the SDQ (*rho* =-.382, *p* = .016). No associations were found between emotional difficulties and other motor skills.

Conclusions:

The literature and preliminary findings support a potential relationship between emotional adjustment and motor skills, particularly balance. The results and interpretation will be considered with respect to administration of assessments, consequent interpretation of findings and implications for research and practice.

142 **168.142** Examining the Relationship between Sleep Patterns and Rrbs in Individuals with 16p11.2 Deletion with and without ASD

J. Straus[1]*, E. Hanson*[2] *and S. M. Attar*[3]*, (1)Developmental Medicine, Boston Children's Hospital, Boston, MA, (2)Boston Children's Hospital/Harvard Medical School, Boston, MA, (3)Boston Children's Hospital, Boston, MA*

Background:

Restrictive and Repetitive Behaviors (RRBs) can be extremely impairing for individuals and their families (Richler, Huerta, Bishop, & Lord, 2010). RRBs are necessary for a diagnosis of Autism Spectrum Disorder (ASD) and are also present in other disorders of development (Harrop et al., 2015). Previous research has shown gender differences in RRBs, with males reported to have greater numbers of these behaviors than females (Attar et al., submitted, 2017). In addition, past research has shown an increase in sleep difficulties in individuals with ASD (Cohen et al., 2014) as well as individuals with 16p11.2 deletion (Girirajan et al., 2010). Research has not yet been conducted to examine whether the presence of RRBs in individuals with 16p11.2 is related to sleep disturbance and, if so, if this is impacted by ASD and gender.

Objectives:

We hypothesized that sleep difficulties would be related to a higher presence of RRBs for children with 16p11.2 deletion with and without ASD.

Methods:

Data was used from the Simons Variation on Individuals Project on individuals with 16p11.2 deletion (N=117) with ASD (n=30) and without (n=87). Participants ranged from 1 year to 22 years old (*m*=8). Inclusion criteria included a completed Behavior and Sensory Interest Questionnaire (BSIQ, Hanson et al., 2016), which measures type and severity of 74 RRBs and the Pediatric Sleep Questionnaire (PSQ, Chervin, Hedger, Dillon & Pituch, 2000), which assesses disordered sleep patterns. Three items were used to measure sleep difficulty (SD) from the PSQ: difficulty falling asleep, waking up during the night, and difficulty falling asleep after waking up.

Results:

Of the 74 RRBs measured on BSIQ, five were found to be most prevalent in our sample and used in our preliminary analysis: delayed echolalia (35.67%), sensitivity to loud noises (58.92%), pushing face (35.14%), hitting caregivers or family members (70.27%), and difficulty with changes in school routine (41.62%).

RRBs were observed in 52 out of 59 (88.14%) of the male participants. Preliminary results suggest that there was a positive but not significant correlation between SD and presence of the five RRBs (*r* =.070, p = .357). When looking separately at individual RRBs and SD, two behaviors reached significance: pushing face (*r* =.353, p =.006) and hitting caregivers (*r* =.306, p =.018). Delayed echolalia, sensitivity to loud noises and difficulty with changes in school routine did not reach significance.

RRBs were observed in 46 out of 58 (79.31%) of the female participants. Preliminary results reveal that there was a positive but not significant correlation between SD and presence of the five RRBs (*r* =.094, p = .216). When looking separately at individual RRBs and SD, none reached significance.

Conclusions:

This preliminary data analysis supports the hypothesis that disordered sleep disturbances may be related to some common RRBs in male but not female individuals with 16p11.2 deletion with and without ASD. Further analysis will examine the relationship between sleep difficulties and severity as well as amount of a range of RRBs controlling for gender, IQ and diagnostic status.

143 **168.143** Exploring the Link between Sensory Reactivity, Anxiety and Related Mental Health Symptoms in Children with and without Autism

L. Roach[1] *and T. Tavassoli*[2]*, (1)University of Reading, Reading, United Kingdom, (2)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom*

Background:

Around 80% of individuals with autism spectrum disorder (ASD) report sensory reactivity symptoms. Sensory hyper-reactivity can be disturbing for daily life and has been suggested to be associated to anxiety. Specifically previous research has found there to be a link between sensory hyper-reactivity and anxiety in autistic children. Those with more severe sensory symptoms have also been found to have higher anxiety levels than those with less severe sensory symptoms. However, most studies have previously used questionnaire measures of sensory reactivity and focussed on anxiety only.

Objectives:

Thus this study set out to investigate the potential link between sensory reactivity, anxiety and related mental health symptoms using an observational tool.

Methods:

The study included 39 children with and without autism who were categorised according to their sensory reactivity; 16 children with sensory reactivity symptoms, and 23 without. We used a direct observation, the Sensory Processing Scale Assessment, to measure sensory reactivity, and the Behaviour Assessment System for Children (BASC) for measuring mental health symptoms, such as anxiety.

Results:

Children with sensory reactivity symptoms had significantly higher parent reported anxiety (p=.006), depression (p=.019), attention problems (p=.010), social skills (p=.019), withdrawal (p=.011) and adaptability (p=.020) compared to children without sensory reactivity symptoms. There were no significant differences in regards to aggression (p=.643), hyperactivity (p=.163), conduct problems (p=.246) and somatization (p=.456).

Conclusions:

Children with and without autism who have sensory reactive symptoms have significantly more mental health symptoms compared to children without sensory reactivity symptoms. This study used a direct observation to measure sensory reactivity, future research should include more direct measures of mental health symptoms as well. Identifying a link between sensory reactivity and mental health symptoms has implications for treatment approaches.

144 **168.144** Fine Motor Trajectories in Children with Fragile X Syndrome and Siblings of Children with Autism

E. A. Will *and J. E. Roberts, Psychology, University of South Carolina, Columbia, SC*

Background: Early motor delays and atypical motor movements are associated with autism related outcomes including increased autism symptomatology for children with fragile X syndrome (FXS; Roberts et al., 2016a) and expressive language delays in at-risk siblings of children with autism (ASIBs; LeBarton & Iverson, 2013). In addition, children with FXS and ASIBS demonstrate divergent fine motor skills from one another at 24 months old, indicating a differential motor profile in these groups at high risk for ASD (Roberts et al., 2016b). However, little is known regarding developmental trends in fine motor skills in children with FXS compared ASIBs and whether this is a potential area for early identification of autism in FXS.

Objectives: The purpose of the two studies presented was to 1) compare longitudinal developmental trajectories of fine motor skills in children with FXS contrasted to unaffected ASIBS, and 2) to compare these trajectories between children with FXS, children with FXS and comorbid autism (FXS+ASD), and ASIBs.

Methods: Study 1 compared longitudinal fine motor trajectories between a larger FXS group (N=128; mean chronological age (CA) at initial assessment=17.60 months) and the non-ASD ASIB group (N=34; *M* initial CA=11.48). Study 2 examined fine motor trajectories between the FXS (N=27; *M* initial CA=15.07), FXS+ASD (N=13; *M* initial CA=22.84), and the non-ASD ASIB (N=34) groups. Groups were assessed annually between 5 and 60 months old. Measures included the Mullen Scales of Early Learning (MSEL, 1995) for both studies, and for study 2, data from the Autism Diagnostic Observation Schedule-2 (ADOS-2, Lord et al., 2000) was drawn for clinical best estimates of comorbid ASD. The subset of FXS participants in study 2 (n=40) and all ASIBS were evaluated for a clinical best estimate of ASD. Approximately 33% (n=13) of the FXS group were diagnosed with comorbid ASD (FXS+ASD), and ASIBS were confirmed as not meeting criteria for ASD. Multilevel models were estimated to examine fine motor trajectories between groups.

Results:

Study 1: Results indicated that the FXS group had lower fine motor skills (b=1.49, p=.0026) at 9 months of age as well as a decelerating trend in fine motor skills over time compared to the ASIBs (b=.025; p<.001). The FXS and ASIB demonstrated increasingly divergent trends, with the greatest fine motor discrepancy at 60 months (b=14.43; p<.001).

Study 2: The fine motor skills of the FXS group were lower than the ASIBs (b=2.59, p=.0001) at 9 months of age, but were similar to the FXS +ASD group. The FXS and FXS+ASD groups became gradually more divergent from ASIBs over time. The FXS and FXS+ASD groups were marginally different at 24 months (*p=.059)*, and differed at each subsequent assessment, with the FXS+ASD group demonstrating lower rates fine motor skill acquisition over time.

Conclusions: Collectively, study findings indicate that fine motor skills are an area of marked delay for children with FXS, and in particular FXS+ASD, relative to ASIBs. These results also provide preliminary evidence that fine motor trajectories may serve as a potential early indicator of atypical development and autism risk in FXS.

145 **168.145** Gender Comparison of Repetitive Behavior Profiles Among Two Age Cohorts

M. G. Evans[1,2], ***A. B. Barber***[1], *S. Ryan*[3], *S. W. Eldred*[4] *and P. E. Reed*[1], *(1)Communicative Disorders, University of Alabama, Tuscaloosa, AL, (2)University of Alabama, Tuscaloosa, AL, (3)The University of Alabama, Tuscaloosa, AL, (4)Department of Psychology, University of Alabama, Tuscaloosa, AL*

Background:

ASD is identified more often in boys than girls, at a ratio of 4.5:1 (Christensen et al., 2016). Research suggests that a possible gender bias leads to under diagnosis of girls (Dworzynski et al., 2012), particularly for those with higher cognitive abilities (Frazier et al., 2014). More research is needed to better understand differences in core symptom presentation, including repetitive behavior profiles (Halladay et al., 2015). In general, boys tend to demonstrate more repetitive behaviors than girls (Szatmari et al., 2012) although the repertoire may be similar under age 5 (Harrop et al., 2015). Qualitative differences in repetitive behavior presentations have been suggested, which may be contingent on higher social proficiency, making repetitive behavior difficult to classify as diagnostically relevant in girls (Halladay et al., 2015; Hiller et al., 2015). Therefore, the female ASD phenotype should be reevaluated in order to improve diagnostic precision (Van Winjngaarden-Cremers et al., 2014).

Objectives:

The purpose of this study is to describe and compare repetitive behavior profiles and frequencies in two age cohorts of girls and boys with ASD measured by the Repetitive Behavior Scale-Revised (RBS-R; Bodfish et al., 2000).

Methods:

Participants included 214 children with ASD (42 girls; 172 boys) ranging from 16 months to 10 years of age (mean = 46.1 months). Participants were recruited from a university based ASD Clinic research database. Each participant met the following criteria: (1) a clinical diagnosis of ASD (2) 10 years of age or younger at the time of their evaluation; and (3) no co-morbid medical diagnosis that could attribute to repetitive behavior. Repetitive behaviors demonstrated by children in two age cohorts (1-3 years; 4-10 years) were compared using the RBS-R, a 43-item parent report measure which assesses frequency and repertoire of repetitive behaviors across 6 categories.

Results:

Preliminary analyses indicated that prior to 3 years of age, girls demonstrated a significantly higher overall number of repetitive behaviors (t = -1.66; p = .03) and significantly more ritualistic behaviors (t = -.12; p = .004) and sameness behaviors (t = -1.9; p = .002). A different profile emerged in older children indicating that girls demonstrated more stereotyped behaviors than boys (t = -2.2; p = .001). The younger cohort of girls (n = 23) demonstrated more stereotyped behaviors (62.7% of the total number of stereotypical behaviors assessed were endorsed), followed by restricted interests (58%), sameness (41%), compulsive (46%), ritualistic (36%) and self-injurious behavior (27%). This profile remained fairly consistent among the older cohort of girls (n = 19) with one exception. Ritualistic behaviors were endorsed more often than compulsive behaviors in the older female cohort. Both cohorts of boys demonstrated restricted behaviors most often, followed by stereotypical behaviors. Repetitive behavior profiles will be discussed relative to developmental level and social skills.

Conclusions:

In opposition to previous findings, results indicated that girls demonstrate more repetitive behaviors than boys, which may be reflective of methodological differences (parent report vs. direct observation). These findings contribute the understanding of the female ASD phenotype. Diagnostic implications will be suggested.

146

168.146 Generalised Time Processing Impairment in Autism Spectrum Disorders

C. M. Falter-Wagner[1], *S. Isaksson*[2], *S. Salomaeki*[2], *J. Tuominen*[2], *V. Arstila*[2] *and V. Noreika*[3], *(1)LMU Munich, Munich, Germany, (2)University of Turku, Turku, Finland, (3)University of Cambridge, Cambridge, United Kingdom*

Background: Individuals with ASD have been known to show a poor sense of time *“to a degree that is markedly discrepant with their level of intelligence”* (Wing, 1996: 89). Deviations in the processing of time do not currently form diagnostic criteria, but may affect every day behaviour and could feed into many diagnostic domains. In particular, efficient interaction and communication are reliant on accurate timing of durations and events. Hence, timing has received increasing attention in recent research (for a review see Allman & Falter, 2015). Yet, a lack of systematic studies testing different aspects of timing in the same sample of participants, prevents a conclusive assessment of whether there is a generalised time processing deficit in ASD and whether there is any relationship to diagnostic symptoms.

Objectives: The aim of this study was to test performance across time processing functions, scales and modalities in the same group of individuals.

Methods: 17 children diagnosed with ASD and 18 typically developing age- and IQ-matched controls carried out a set of motor and perceptual timing tasks: free tapping, simultaneity judgment, auditory duration discrimination, and verbal time estimation. In addition, parents of participants filled out a questionnaire assessing the sense and management of time.

Results: Children with ASD showed faster and more variable free tapping than controls. Auditory duration discrimination thresholds were higher in the ASD compared to the control group in a sub-second version of the task, while there were no group differences in a supra-second discrimination of intervals. Children with ASD showed more variable thresholds of simultaneity judgment, and they received lower parental scores for their sense and management of time. No group differences were observed in the verbal time estimation task in the minute-range. Importantly, we found an inter-correlation between timing functions in the ASD group only, pointing towards less differentiation and specification of timing functions in ASD. Finally, autistic symptom severity was associated with several timing measures.

Conclusions: The time processing deficit in ASD can be generalised to motor timing, perceptual timing, and temporal perspective, and it is associated with autistic symptom severity. An interrelation between timing functions suggests that, in contrast to control participants, individuals with ASD might apply a similar strategy irrespective of task demands and context.

168.147 Identifying the Origins of Postural Control Deficits in Autism Spectrum Disorders: Sensory Acuity Vs. Sensory Integration

M. Doumas[1], *R. Knox*[2], *C. Craig*[3] *and C. O'Brien*[2], *(1)School of Psychology, Queen's University Belfast, Belfast, United Kingdom, (2)Queen's University Belfast, Belfast, United Kingdom, (3)Manchester Metropolitan University, Manchester, United Kingdom*

Background: Individuals with Autism Spectrum Disorders (ASD) experience the world differently compared with neurotypical individuals. ASD is characterised by deficits in social interaction and communication, but also in sensory processing and motor control. One of the key aspects of movement affected by ASD is postural control. Postural control deficits in ASD are well established, however, the underlying mechanisms of these deficits are not well understood. Recent studies suggest that the increased postural instability observed in individuals with ASD is most evident when one or more of the sensory channels (visual, vestibular and proprioceptive) involved in this task is compromised. Thus, this impairment is likely to be either due to impaired acuity of information from these channels, due to impaired sensory integration processes, or both.

Objectives: The main objective of this study was to assess the contribution of sensory acuity and sensory integration to the postural control deficits of individuals with ASD. We hypothesized that these deficits will be due to sensory integration rather than sensory acuity.

Methods: Fifteen high functioning (IQ>80) young adults with ASD (2 female, age range 18-35 years) and 15 age- and gender-matched neurotypical adults participated in our study. They first performed an ankle joint-position matching task measuring proprioceptive acuity. Then, they performed a postural control task, without vision, thus involving only proprioceptive and vestibular information. Participants were asked to stand on a fixed surface (baseline, 2 minutes), immediately followed by standing on a sway referenced surface (adaptation, 3 minutes) which induced inaccurate proprioceptive information about body sway, and then again on a fixed surface (reintegration, 3 minutes).

Results: Participants with ASD and neurotypical controls were not different in absolute and variable error in the joint position-matching task. In the balance task, no group differences in AP (Anterior-Posterior) and ML (Medio-Lateral) path length were shown during baseline. Subsequently, when sway referencing was introduced AP and ML path length increased in both groups as expected. However, over the course of the 3 minutes of adaptation to this environment, neurotypical participants were able to reduce sway especially in the AP direction over time through adaptation. In contrast, participants with ASD did not exhibit this ability to adapt to the sway referenced environment by reducing sway over time, reflecting an inability to reweight proprioceptive and vestibular information during postural control. Finally, when the fixed surface was restored both groups were able to return to their baseline levels of sway at the same rate.

Conclusions: These results confirm our hypothesis that the postural control deficit observed in individuals with ASD is primarily due to central, sensory integration deficits rather than peripheral, sensory noise. Future research is needed to identify ways to moderate this deficit in order to improve motor skill performance and quality of life in children and adults with ASD.

148 **168.148** Individuals with ASD Imitate By Way of Mirroring More Than Their Typical Peers

Z. M. Dravis[1], *J. Diaz*[2], *V. Obsekov*[2], *E. S. Kim*[1], *A. Tiedemann*[3], *M. Cola*[1], *S. Uh*[1], *E. F. Ferguson*[2], *L. Adeoye*[4], *L. Bateman*[2], *S. Plate*[1], *A. Zoltowski*[5], *A. Pomykacz*[6], *K. Bassanello*[1], *J. Pandey*[1], *S. H. Mostofsky*[3], *R. T. Schultz*[1] *and A. de Marchena*[7], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research/CHOP, Philadelphia, PA, (3)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (4)The Center for Autism Research/CHOP, Phladelphia, PA, (5)Vanderbilt University, Nashville, TN, (6)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (7)University of the Sciences, Philadelphia, PA*

Background: When performing elicited imitation, one can either *mirror* (e.g., use the right hand when the model is using their left, as if looking in a mirror) or *transpose* (i.e., imitate using the same hand as the model; see **Figure**). Mirroring is generally thought to be easier than transposition, potentially because mirrored movements have more visual parallels to the model's movement, and potentially because transposition requires greater perspective taking. From a developmental perspective, typically developing children are more likely to spontaneously mirror, while adults are more likely to transpose. When prompted to mirror, typical children and adults' performance tends to improve, suggesting that mirroring benefits imitation accuracy, a finding that has not been consistently demonstrated in ASD. Studies of school-age children have demonstrated that in goal-directed imitation, those with and without ASD do not differ in their spontaneous tendency to mirror. It is unknown whether adolescents and adults with ASD make the same shift to favoring transposition during imitation shown by typically developing adults.
Objectives: To determine whether older children, adolescents, and adults with ASD transition to a primarily mirroring strategy during elicited imitation.

Methods: Verbally fluent, right-handed children, adolescents, and adults with ASD (*n*=29) and age- and IQ-matched typically developing controls (TDC; n=14, see **Table**) completed a brief praxis battery, administered by right-handed examiners. The battery consisted of 19 items for which participants completed specified actions either by imitating the examiner (*imitation* condition), or following a *non-imitation* prompt (i.e., following verbal instruction with or without a relevant prop). Participants were explicitly instructed that they could use whichever hand they wanted to complete the actions. Each item was later coded for whether the participant used their right or left hand. Because all participants and examiners were right-handed, use of the right hand during imitation can be taken to reflect transposition, whereas use of the left hand reflects a mirroring strategy.

Results: Participants across groups primarily or exclusively used their right hand during the non-imitation condition (see Table for details). During the imitation condition, the TDC group continued to overwhelmingly select their right hand, showing the expected preference for a transposition strategy. In contrast, participants with ASD often switched to using their left hand, suggesting a stronger inclination toward mirroring compared to those without ASD (independent-samples t-test, p=.004, d=1.57).

Conclusions: The present study shows that older children, adolescents, and adults with ASD spontaneously imitate by way of mirroring more than their typical peers (who almost entirely transpose), even when doing so requires them to use their non-dominant hand. This suggests that, even beyond early childhood, people with ASD may continue to rely on a developmentally earlier strategy for imitation. Mirroring may be beneficial because actions occur in a more familiar spatial field, thereby reducing working memory load. Future research can test these potential mechanisms, and can examine whether strategy selection (i.e., mirroring vs. transposition) relates to task performance. Understanding how older individuals with ASD spontaneously imitate may shed light on self-other mappings and automatic perspective taking in this population.

149 **168.149** Measuring Dyspraxia in Autism with a Brief Praxis Exam

V. Obsekov[1], *J. Diaz*[1], ***Z. M. Dravis***[2], *E. S. Kim*[2], *L. Adeoye*[3], *L. Bateman*[1], *A. Pomykacz*[4], *E. F. Ferguson*[1], *M. Cola*[2], *S. Uh*[2], *S. Plate*[2], *A. Zoltowski*[5], *K. Bassanello*[2], *A. Tiedemann*[6], *J. Pandey*[2], *S. H. Mostofsky*[6], *R. T. Schultz*[2] *and A. de Marchena*[7], *(1)The Center for Autism Research/CHOP, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)The Center for Autism Research/CHOP, Phladelphia, PA, (4)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (5)Vanderbilt University, Nashville, TN, (6)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (7)University of the Sciences, Philadelphia, PA*

Background:
Individuals with ASD are now known to exhibit a wide array of motor differences. Over the past decade-plus, deficits in *praxis* have been robustly demonstrated and replicated in ASD. Praxis refers to the ability to perform learned skills movements, such as using tools or producing familiar symbolic gestures. A widely used measure of praxis, the Florida Apraxia Battery, typically takes 20-30 minutes to administer, and up to twice as long to score, limiting the feasibility of including it in multi-dimensional studies of ASD.

Objectives:

To test whether well-established deficits in praxis could be demonstrated using a brief (5-minute) measure.

Methods:

Verbally fluent children and adults with ASD (n=34) and age- and IQ-matched typically developing controls (TDCs; n=17) completed a 5-minute praxis battery. The battery consisted of 19 items from the Florida Apraxia Battery, across four sections: (1) Gestures to Verbal Command, (2) Gestures with Tool Use, (3) Gestures to Imitation, and (4) Gestures to Meaningless Imitation. The first three sections contained the same five transitive actions: stirring a cup of hot chocolate, hammering a nail, painting a wall, writing with a pencil, and scooping ice cream. The last section contained five “meaningless”/nonsense actions, similar to short dance moves. Administrations were video recorded and later coded by two independent raters, naïve to participant diagnosis, for the presence of errors, including: spatial, temporal, content, and body-part-for-tool errors (see Figure 2). Intraclass correlation coefficients for total errors ranged from .82-.98, demonstrating excellent interrater reliability.

Results:

Participants with ASD made far more errors on the task (M=11.53, SD=6.01) than did controls (M=6.41, SD= 2.09), $p<.001$, $d=1.32$, a reliable effect with a large effect size. Although participants with ASD performed worse on each individual subtest (Figure 1), there was no interaction between group and subtest ($p=.29$, $\eta^2=.08$), suggesting that both groups responded to the four subtests similarly. A significant interaction between group and error type ($p=.01$, $\eta^2=.23$) revealed that participants with ASD were more likely to make spatial and temporal errors specifically, compared to controls (Figure 2). Individual differences analyses revealed that better praxis performance was associated with higher IQ in the TDC group ($r=.521$, p=.032), and with older age ($r=.374$, p=.029) and lower ADOS scores ($r=-.318$, p=.072) in the ASD group.

Conclusions:

These preliminary results demonstrate that known weaknesses in praxis performance in ASD can be replicated using a significantly shortened version of a praxis exam. Using this abbreviated battery, individuals with ASD made more errors across all four sections of the battery relative to those in the typically developing group. Additionally, individuals with ASD were more susceptible to certain error types than others, specifically spatial and temporal errors. These findings are largely consistent with studies using the full battery (e.g., Mostofsky et. al, 2006), suggesting that a shortened battery may have sufficient sensitivity to observe group differences in praxis performance. The ability to measure praxis efficiently will increase the feasibility of including it as part of larger batteries aimed at testing the relationship between praxis and hypothesized downstream skills (e.g., social communication).

150 **168.150** Intact Sensorimotor Adaptation in Autistic Adults

J. R. Oulton[1], *J. Causer*[1], *S. J. Hayes*[2] *and S. J. Bennett*[2], *(1)Research Institute for Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, United Kingdom, (2)Research Institute Sport and Exercise Sciences, Liverpool John Moores University, Liverpool, United Kingdom*

Background: Atypical sensorimotor integration in autism leads to altered action models (Mostofsky & Ewen, 2011). There is growing evidence illustrating how atypical sensorimotor integration underlies differences in sensorimotor behaviour (Cook, Blakemore, & Press, 2013; Marko et al., 2015), however the majority of research has been carried out with autistic individuals that have mild severity, or require support. Whereas, autistic individuals who are moderate/severe, or require substantial support are understudied.

Objectives: Examine the effect of experience on sensorimotor adaptation in adults diagnosed with moderate/severe autism spectrum disorders.

Methods: Forty autistic individuals diagnosed with moderate/severe autism spectrum disorders formed an *experimental group* (n = 22) and a *control group* (n = 18). The *experimental group* participated in trampolining sessions and accumulated an average of 144 hours (SD =26) of sensorimotor experience. The *control group,* who were matched for age, gender, verbal IQ, social responsiveness, sensory profile, and motor proficiency, had participated in community-based activities that did not have a sensorimotor basis. A non-invasive preferential viewing protocol (PVP) measured gaze behaviour while observing one of four point-light models (8 seconds duration) displaying *experimental stimuli:* specialist trampolining movements (BAGA award level 2 *seat drops* and 3 *twists*) or the *control stimuli: straight jumps* on a trampoline, and *gait*. Participants viewed these on a computer monitor, while eye gaze was measured using a desk mounted Tobii X2 eye-tracker. A PVP trial required participants to view a vertical split screen, with the same action (e.g., seat drop) presented in an upright (congruent) and inverted (incongruent) orientation. Participants viewed each of the stimuli presented as a block of four trials, trial order within a block counterbalanced to avoid sequence effects. In total, there was 4 blocks and 4 trials. Preferential attention was quantified using first-fixation-location (e.g., congruent) and first-fixation-duration (Jones, Carr, & Klin, 2008; Ryan, Hannula, & Cohen, 2007).

Results: Significant group x congruency interactions were revealed for first-fixation-location ($p = 0.001$) and first-fixation-duration ($p = 0.037$) when viewing *twists*. The *experimental group* orientated attention to the incongruent point-light action, but then fixated longer on the congruent action (congruent: M = 193.85ms; incongruent: M = 147.63ms). The *control group* orientated attention to the congruent point-light action, but then fixated longer on the incongruent action (incongruent: M = 177.22ms; congruent: M = 169.00ms). No significant (*ps* > 0.05) effects were revealed when viewing seat drops, straight jumps, and gait.

Conclusions: Sensorimotor training leads to functional adaptation in the underlying perception-action system, with faster motor response times during the perception of learned stimuli (Catmur et al., 2009), and the development of experience-dependent perception-action processing (Calvo-Merino, Glaser, Grèzes, Passingham, & Haggard, 2005; Casile & Giese, 2006). Consistent with these effects, here there were differences found in preferential attention (first-fixation-location) and evaluation (first-fixation-duration) of specialist learned action stimuli (i.e., *twists*) following trampolining sensorimotor experience compared to those that engaged in community-based activities. This indicates intact sensorimotor development and processing in autistic adults diagnosed with moderate/severe autism spectrum disorders.

151 **168.151** Individuals with ASD Meet Diagnostic Criteria for Co-Occurring Developmental Coordination Disorder

H. L. Miller[1], *P. M. Caçola*[2], *G. M. Sherrod*[3] *and N. L. Bugnariu*[1], *(1)University of North Texas Health Science Center, Fort Worth, TX, (2)Kinesiology, University of Texas at Arlington, Arlington, TX, (3)University of Alabama - Birmingham, Birmingham, AL*

Background: Autism Spectrum Disorder (ASD) and Developmental Coordination Disorder (DCD) are developmental disorders with distinct definitions and diagnostic criteria. DCD is characterized by poor motor proficiency despite age and opportunity for learning. ASD and DCD can now be diagnosed as co-occurring in the same individual (DSM-5; APA, 2013). Systematic assessment for DCD is uncommon in the ASD diagnostic process, despite shared sensorimotor symptoms, and so the rate of co-occurrence (ASD+DCD) remains unknown.

Objectives: We aimed to determine whether individuals with ASD meet DSM-5 diagnostic criteria for DCD, using a combination of parent-reports and standardized clinical tests. We compared motor profiles and impact of motor problems on daily living in ASD and DCD. We also compared social communication skills in both groups.

Methods: Thirty-seven individuals participated in this study, 27 diagnosed with ASD (Male = 21) and 10 diagnosed with DCD (Male = 9). We assessed all 4 criteria for a DCD diagnosis based on the DSM-5. All participants completed three assessments: The Movement Assessment Battery for Children – 2nd ed. (MABC-2) for motor profiles, the Developmental Coordination Disorder Questionnaire (DCD-Q) for impact of motor problems on daily living. Both assess criteria A and B of the DSM-5, respectively. We used the Social Communication Questionnaire (SCQ) to assess social communication skills. In addition, we asked about delays in early milestones (crawling and walking) for Criterion C, and ruled out all neurological impairments (Criterion D) in both groups.

Results: Independent t-tests indicated no significant differences ($p < 0.05$) between the groups on the MABC-2 total percentile, with all individuals fitting the cut-off score for DCD (ASD: 6.69±16.81; DCD: 1.62±2.68). However, individuals with ASD scored significantly higher than those with DCD on the DCD-Q, indicating a lower impact of their motor deficits on daily living for this population (ASD: 37.32±11.60; DCD: 28.9±5.38). As expected, individuals with ASD scored significantly higher than those diagnosed with DCD (ASD: 20.04±6.53; DCD: 6.60±5.23) on the SCQ. Results on the early motor milestones indicated that the majority of the individuals in both groups did not have delays, but most individuals with ASD were close to the cut-off for a delay in waking (walked close to 18 months).

Conclusions: We conclude that all individuals in our sample could potentially be diagnosed with DCD in addition to ASD. We recommend that the evaluation of potential DCD in individuals with ASD be performed systematically and thoroughly, so as to distinguish this co-occurring condition from sensorimotor symptoms associated with ASD. The implications of a DCD diagnosis on individuals with ASD. This will aid clinicians in making important choices about intervention, informed by the distinction between individuals with co-occurring ASD+DCD and individuals with ASD who display some motor differences but do not meet criteria for DCD.

152 **168.152** Motor Skills As Moderators of ASD Core Symptoms: Insights from the Artificial Networks Approach

F. Fulceri[1], *E. Grossi*[2], *A. Contaldo*[3], *A. Narzisi*[4], *S. Calderoni*[5], *F. Apicella*[4], *I. Parrini*[3], *R. Tancredi*[3] *and F. Muratori*[3,5], *(1)Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy, (2)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (3)IRCCS Stella Maris Foundation, Calambrone (Pisa), Italy, (4)IRCCS Fondazione Stella Maris, Calambrone (Pisa), Italy, (5)Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy*

Background:

In addition to the core symptoms, both fine and gross motor delays/disorders have been reported in children with Autism Spectrum Disorders (ASD). However, it is still unclear whether motor impairments are uniformly distributed across the entire ASD spectrum and whether they are related to DSM-5 specifiers (i.e. intelligence, language, comorbidity and associated conditions). In the light of the high heterogeneity in ASD it could be possible that “a single symptom approach analysis” do not provide comprehensive information. The strong inherent non-linearity of the relationships between clinical variables may account for the inability to grasp the core problem by the traditional analysis. Artificial neural networks (ANNs) are computational adaptive systems particularly adapting to solving non-linear problems. The goal of this data mining model is to discover hidden trends and associations among variables. Recently this approach has been successfully applied to the ASD field.

Objectives:

To investigate associations between motor skills and clinical/developmental features in preschoolers with ASD. We hypothesized that ANNs will be able to find hidden trends among the variables revealing the clinical profiles related to motor functioning in ASD.

Methods:

This study was carried out according to the standards for good ethical practice of the IRCCS Stella Maris Foundation and in accordance with the guidelines of the Declaration of Helsinki.

32 male with ASD (age range: 30-60 months; nonverbal IQ≥ 70) were recruited at the IRCCS Stella Maris Foundation, a tertiary care university hospital. Multidisciplinary comprehensive diagnostic evaluation was associated with a standardized assessment battery for motor skills, the Peabody Developmental Motor Scale- Second Edition (PDMS-2). The PDMS-2 consists of six motor subscales (Reflexes, Stationary, Locomotion, Object Manipulation, Grasping and Visual-Motor Integration) and three motor quotients (MQ) (Gross MQ, Fine MQ, Total MQ). According to PDMS-2, motor skills were classified into 7 categories: very superior, superior, above average, average, below average, poor and very poor.

Analyses were performed through the Auto Contractive Map system which is a fourth-generation unsupervised ANNs. Auto Contractive Map system ‘spatializes’ the correlation among variables (‘closeness’) providing a graph that identifies the relevant associations and organizes them into a coherent picture.

Results:

Preliminary linear correlation analysis revealed that motor impairment was associated with both cognitive skills and repetitive behaviors in children with ASD (Table 1). The ANNs analysis (Figure 1) showed that motor disorders were strongly related to low level of expressive language and high level of repetitive behaviors in preschoolers with ASD. In addition, the ANNs approach considered the entire spectrum of relationship among clinical variables, revealing hidden trends among motor, cognitive and social skills.

Conclusions:

The ANNs approach revealed motor skills as moderators of ASD core symptoms. This appears to be consistent with the growing literature suggesting that the systematic observation of motor development in ASD may improve the knowledge about clinical and neurobiological involvement as well as guide development of treatments.

153 **168.153** Multisensory Integration and Autistic Traits

S. A. Lauzon, *S. E. Schulz, Z. I. Cohen and R. A. Stevenson, Western University, London, ON, Canada*

Background: Sensory processing issues are one of the most common complaints in ASD. One area of sensory difficulties that has been the focus of intense research in recent years is multisensory integration, or the ability to bind auditory and visual information into a single, unified perception. One consistent finding has been that multisensory integration is an area of difficulty in ASD when the sensory information contains social or linguistic information (e.g., audiovisual speech), but results have been less clear with simple, non-sociolinguistic stimuli. This study aims to address this current area of ambiguity.

Objectives: Our objective for this study is to determine whether multisensory integration abilities are related to traits and symptomatology commonly associated with ASD, specifically during the processing of non-sociolinguistic sensory information.

Methods: Sixty-five undergraduate students completed a behavioural audiovisual detection task, and completed a battery of questionnaires assessing ASD-related traits and symptomatology. During the behavioural component of the study, participants were presented with auditory tones and visual sinusoidal gratings (Gabor patches) embedded in auditory and visual white noise, respectively. Stimuli were presented either separately (audio *or* visual), or simultaneously in combination (audiovisual). Eighty trials of each modality were presented, as well as 240 catch trials (1/2 of all trials), in which no tone or grating was presented. Participants were asked to press the space bar as soon as they perceived either a tone or a grating. Multisensory enhancement (ME) was measured by comparing accuracy rates during audiovisual trials to the accuracy rate predicted by the unisensory conditions assuming independent processing:

$pAV_{acc} = A_{acc} + V_{acc} - A_{acc} * V_{acc}$.

Participants then completed measures of autistic traits in general (Autism Quotient, Broad Autism Phenotype Questionnaire), social competency and communication (Social Responsiveness Scale, Multidimensional Scale of Social Competency), repetitive behaviours (Repetitive Behaviours Questionnaire), and sensory processing (Sensory Profile 2, Sensory Perception Quotient).

Results: Mean accuracies for auditory, visual, and audiovisual conditions are presented in Figure 1A. Measures of multisensory enhancement for individuals were found in the normal range, from -.12 (no enhancement) to .02 (enhancement). Importantly, correlations between ME and all measures of ASD-related traits and symptomatology were non-significant, and did not approach significance, with R-squared values ranging from 0.001-0.03. Scatterplots associated with each questionnaire can be seen in Figures 1B-H.

Conclusions: These results suggest that there is no relationship between ME of simple, non-sociolinguistic sensory information and autistic traits and symptomatology. While multisensory integration issues are well established with sociolinguistic stimuli, these data suggest that these issues may be restricted to social or linguistic information. These data align well with studies of multisensory integration in ASD using different paradigms. For example, processing of the temporal characteristics of multisensory stimuli are impacted in autism when social or linguistic information is present, but not simple, non-sociolinguistic information. Importantly, the lack of any relationship between ME and ASD traits spanned a range of symptoms, including repetitive behaviours, social communication, and sensory issues, suggesting multisensory integration may be associated with autism symptomatology only when sociolinguistic information is present.

154 **168.154** Oculomotor Functions in ASD

M. Latinus[1], *J. Malvy*[2], *M. Siwiaszczyk*[3], *K. Kovarski*[4], *F. Bonnet-Brilhault*[5] *and M. Batty*[6], *(1)UMR INSERM U930, Tours, France, (2)CHRU Tours, Tours, France, (3)Inserm U930 - Université François Rabelais de Tours, Tours, France, (4)UMR 930 INSERM, University of Tours, Tours, France, (5)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (6)Centre d'Etudes et de Recherches en Psychopathologie et Psychologie de la Santé, Université de Toulouse - Jean Jaurès, Toulouse Cedex 9, France*

Background: Atypical sensory information processing is today part of the diagnostic criteria of ASD. Several studies reported atypical visual exploration of both social and non-social stimulation in ASD with less precise and more heterogeneous saccade, which could be the manifestation of underlying difficulties in oculomotor control.

Objectives: We aimed at characterizing oculomotor functions in children with ASD.

Methods: We assessed a subset of oculomotor functions (saccade, fixation) in children with ASD and age-matched controls using paradigms of increasing complexity, while no instructions were provided. First, participants fixated a cartoon presented at the center of the screen. Second, participants were involved in a prosaccade gap paradigm. Finally, the children performed three visual search tasks: a feature search (e.g., color), and social/non-social visual-search task (e.g., a face among butterflies and vice-versa).

Results: Children with ASD showed shorter fixation duration and more microsaccades. In the prosaccade task, they were as accurate as control participants, yet faster to reach the target, an effect partially attributable to shorter saccadic response times. In the color search task, children with ASD performed less well than TD children, but were faster in reaching their closest position to the target. Finally, we compared visual search of complex stimuli (butterfly and faces), and found a significant interaction between group and stimulus type, showing that control children were more precise in searching for faces among butterflies, while ASD children performed similarly in the social and non-social visual search tasks. Once again, participants with ASD were generally faster in reaching the odd one out.

Conclusions: Children with ASD showed atypical, but not always impaired oculomotor behaviors. Atypical oculotomor behavior from enhanced motor functioning to impaired fixation abilities could hinder exploratory behavior of children with autism, leading to difficulties in complex situations, whether social or not.

155 **168.155** Odor Identification Skills in Adults with ASD Are Associated with Anatomical Abnormalities in the Tractography of Fronto-Occipital Fasciculi

V. Parma[1], *K. G. Stephenson*[2], *D. N. Top*[2], *J. S. Beck*[3], *N. C. Russell*[2], *A. W. Carr*[2], *L. Peacock*[3], *C. Ray*[2], *N. J. Goodrich-Hunsaker*[3] *and M. South*[4], *(1)William James Center for Research, ISPA - Instituto Universitário, Lisbon, Portugal, (2)Brigham Young University, Provo, UT, (3)Psychology, Brigham Young University, Provo, UT, (4)Psychology & Neuroscience, Brigham Young University, Provo, UT*

Background: Individuals diagnosed ASD exhibit abnormal chemosensory experiences from childhood into adulthood. Sensory function is likely linked to social communication function (Bennetto et al., 2007) and the manifestation of anxiety (South & Rodgers, 2017). However, there few studies of olfaction in adults with ASD and to date there are no published neuroimaging studies of olfactory processing in ASD.

Objectives: We investigated white matter tractography to determine point-wise quantifications of abnormal anatomical connections in olfactory areas in adults with ASD. We additionally examined correlations of tractography results alongside olfactory identification skills.

Methods: Thirty-four adults with ASD (13F) and 39 neurotypical controls (NT group, 19F) participated in the study. Tracts within inferior fronto-temporal areas, chosen *a priori*, were defined using automated fiber-tract quantification. High fractional anisotropy (FA) values indicate greater fiber density while mean diffusivity (MD) describes the rotationally-invariant magnitude of water diffusion within brain tissue. The odor identification task required participants to smell 16 odorous pens one at a time after having visualized four images representing the target odor and three distractors, then choosing the correct odor from the four possibilities.

Results: Bayesian models showed that individuals in the ASD group were nearly 3 times more likely to show reduced odor identification skills than NT controls. The tract profiles of infero fronto-occipital and longitudinal fasciculi show abnormalities in ASD especially in rostral sections of the tracts. Odor identification performance was significantly associated with FA values in frontal sections of tract profiles. Odor identification skills in ASD are binomially distributed, in line with other sensory-related experiences in ASD (Bogdashina, 2016).

Conclusions: Taken together, our findings describe for the first time the relationships between odor identification skills and their neural underpinnings in adults with ASD. Results suggest that olfactory perception and neuroimaging can provide non-invasive tools for ASD subgroup characterization. Further exploration of relationships between olfactory processing, social communication skills, and anxiety symptoms is warranted.

156 **168.156** Ophthalmologic Peculiarities in Children with Autism Spectrum Disorder

ABSTRACT WITHDRAWN

Background:
Impairments in the exploration and perception of social stimuli could at least partially result from undetected eye pathology in ASD. Although highly recommended, eye examination is not done systematically due to a lack of complaints. Moreover, this examination is difficult to realize in children with ASD.

Objectives:

The main purpose of this prospective study was to evaluate the prevalence of ophthalmological disorders in children presenting ASD and understand the influence of these disorders on autistic traits. Another important aim of the study was to developp a suitable clinical protocol to evaluate opthalmological pathologies in children with ASD, including children without langage or with mental retardation.

Methods:

An original procedure was born from the collaboration of ophthalmologic and child psychiatric departments to propose an ophthalmologic examination for each child included in a therapeutic follow-up protocol. Ophthalmologic assessment included a visual acuity test, a sensorimotor exam, a slit lamp examination and a cycloplegic refraction with an automated refractometer. Parents and children were familiarized to the examination thanks to an instruction book. A second examination was conducted when visual acuity could not be evaluated in the child psychiatry department, a place familiar to the child.

Results:

The strategy adopted to measure visual acuity allowed us to measure monocular visual acuity in 52% of the children with ASD after the first examination and was improved to 74% after the second examination. Ophthalmologic pathology was found in 32% of the participants, with 29% having significant refractive errors, 6.5% presenting strabismus and 3.2% demonstrating amblyopia. Children with ophthalmological disorders had significant lower verbal intelligence quotients and higher social impairment.

Conclusions:

The existence of undetected ophthalmologic pathology in ASD and its influence on autistic traits stressed the importance of early, systematic, and comprehensive examination by a pediatric ophthalmologist. It is of main importance to have a reliable diagnosis in order to prescribe spectacles to improve visual development, especially in children with neurodevelopmental issues. This examination procedure of children with ASD contributes to a comprehensive examination, including subjective and objective data, which is mandatory to obtain a reliable diagnosis. Besides, this would help to replicate these results in further prospective studies. Finally, taking into account ophthalmological parameters is a requisite before any research on visual functions in ASD.

157 **168.157** Parent Perspectives on DEEP Touch Pressure Sensory-Based Interventions for Chldren with ASD

***M. Pena**, Holland Bloorview Bloorview Kids Rehabilitation Hospital, Bloorview Research Institute, Canada, Toronto, ON, Canada*

Background: Deep touch pressure sensory-based interventions are recommended by occupational therapists to enable function and participation in children with autism spectrum disorder. There is a paucity of research however, on parents' perceptions of these interventions when administered within naturalistic settings
Objectives: To examine parents' perceptions of the value, uptake, and acceptability of deep touch pressure sensory-based interventions when used to target challenging behaviours in children with autism spectrum disorder.

Methods: Using a survey design, an online questionnaire was created. The questionnaire was sent to 399 families registered at the Province of Ontario Neurodevelopmental Disorders' database; 152 parents completed the study, yielding a response rate of 39%. Data were analyzed for frequency of responses and open-ended responses were reviewed and grouped by the researchers.

Results: The most frequently recommended interventions were trampoline (54.6%), massage (47.8%), and oral-motor tools (43.8%). Of the recommended interventions, the percentage of use was highest for massage (96.3%), followed by trampoline (89.2%), and joint compressions and brushing (89.2%). The majority of parents found the interventions helpful in addressing challenging behaviours and most viewed their use to be important (31.7%) or very important (43.1%). Main barriers included: interventions were not recommended to parents, parents found them difficult to use, and families did not have access to the recommended equipment. To increase the use of these interventions, parents wanted ongoing support from the occupational therapist and access to therapeutic equipment.

Conclusions: These interventions are valued and accepted by parents of children with autism spectrum disorder, but that there are barriers to their use. By gaining an understanding of, and addressing, these barriers occupational therapists may support improved uptake of these interventions.

158 **168.158** Perceptual Atypicalities in Autism Revealed By Pupillometry

***D. C. Burr**[1], P. Binda[2] and M. Turi[2], (1)Department of Neuroscience, Psychology, Pharmacology and Child Health, University of Florence, Florence, Italy, (2)Department of Translational Research on New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy*

Background:

It has long been known that perceptual processing is unusual in autism: they have superior performance on some tasks, such as the Embedded Figures Test and visual search tasks, and inferior performance on many complex tasks requiring a more holistic, global perception. Recently these differences have been well modelled within the *Bayesian* approach to perception, with the suggestion that autistic observers have reduced integration of sensory and predictive information. This study explores further the different styles of autistic perception with an objective measure that correlates well with autistic traits.

Objectives:

The aim of the study is to use an objective and non-invasive technique to characterize different perceptual styles correlated with autistic traits in the typical population.

Methods:

We measured modulation of pupil-size in 50 typical adult humans viewing a bistable-rotating cylinder, constructed so the brightness of the front surface changes with perceived direction of rotation. Subjects reported perceptual switches as they viewed the stimulus. We correlated the amount of pupil modulation in pupil size associated with the perceptual switch of the bistable stimulus with the autistic traits of participants, measured by the Autism-Spectrum Quotient AQ.

Results:

In some but not all participants, pupil diameter oscillated in phase with the ambiguous perception, more dilated when the black surface was in front. Importantly, the magnitude of oscillation predicts autistic traits of participants, assessed by the Autism-Spectrum Quotient AQ. Further experiments suggest that these results are driven by differences in perceptual styles: high AQ participants focus attention on the front surface of the rotating cylinder, while those with low AQ distribute attention to both surfaces in a more global, holistic style.

Conclusions:

This is the first evidence that pupillometry reliably tracks inter-individual differences in perceptual styles, quickly and objectively, without interfering with spontaneous perceptual strategies. The results confirm the relationship between high autistic traits and local perceptual-style, suggested by previous, less objective studies. This relationship will be discussed in terms of Bayesian models suggesting less use of predictive *priors* in autistic perception.

159 **168.159** Prospective Action Planning: Autistic Children Go Their Own Way

C. Becchio[1], *A. Cavallo*[2], *L. Romeo*[3], *C. Ansuini*[4], *J. Podda*[1], *E. Veneselli*[5], *F. Battaglia*[1] *and M. Pontil*[1], *(1)Italian Institute of Technology, Genova, Italy, (2)University of Turin, TORINO, Italy, (3)Università Politecnica delle Marche, Ancona, Italy, (4)C'MON Unit, Istituto Italiano di Tecnologia, Genoa, Italy, (5)Istituto G. Gaslini, Genova, Italy*

Background:

The simple act of picking up a water glass involves predictive control mechanism. People alter their manipulative behavior as a function of what they plan to do with the objects. Failure to develop this form of prospective motor control has been proposed to contribute to faults in higher mind functions of individuals with autism spectrum disorders (ASDs; Trevarthen and Delafield-Butt, 2013), however, no study to date has *quantified* the extent to movement parameters specify future action plans in ASD.

Objectives:

The present study combined kinematic analysis with machine learning techniques to determine whether and how movement parameters specify *self-action* and *other-action* plans in ASD and TD. The specification of action plans was analyzed at three levels: i) individual level, to investigate whether individuals with ASD show consistent motor patterns specifying self- and other-action plans; ii) within-group level: to determine whether specification of self- and other-action plans is similar across individuals with ASD; iii) between-group level: to determine whether specification of self- and other-action plans is similar across ASD and TD individuals.

Methods:

We used a sequential object manipulation task to test prospective motor control in children with ASD (n = 20) and IQ-matched typically developing (TD) children (n = 20). To quantify changes in behavior as a function of self-action plans, we first trained a support vector machine to classify grasping movements as a function of onward self-actions (place, pour, and pass). We next attempted to verify whether ASD and TD children altered their initial grasp in anticipation of co-actor’s forthcoming action by training the same classifier to distinguish grasps as a function of onward other-actions (pass-to place and pass-to pour).

Results:

Self-action plans. Specification of self-action plans detected at the individual level was similar across individuals with ASD. As shown by cross-classification, ASD and TD children activated similar motor plans in anticipation of forthcoming self-demands.

Other-action plans. Both ASD and TD children altered their grasp in anticipation of other-demands, showing consistent within-group patterns. However, a cross-group analysis in which a classifier was trained on one group and tested on the other, failed to achieve greater than chance performance, suggesting that specification of other-action plans varied across ASD and TD children.

Conclusions:

While motor parameters specify future action plans in both ASD and TD individuals, children with autism appear to have their own way to accommodate other-action plans. This may contribute to bilateral difficulties in reciprocal social interaction, reinforcing the view that the difficulties that autistic individuals experience in social cognition are rooted in atypical motor patterns.

160 **168.160** Quantification of Predictive Motor Impairments in Children with Autism Spectrum Disorder

S. W. Park[1,2], *A. Cardinaux*[2], *S. Ben-Ami*[3], *D. Guo*[1], *L. Denna*[2], *P. Sinha*[2] *and D. Sternad*[4], *(1)Northeastern University, Boston, MA, (2)Massachusetts Institute of Technology, Cambridge, MA, (3)Brain and cognitive science, Massachusetts Institute of Technology, Cambridge, MA, (4)Biology, Electrical & Computer Engineering, and Physics, Northeastern University, Boston, MA*

Background: Anecdotal reports and selected research results suggest that individuals with autism spectrum disorder (ASD) exhibit difficulties in motor coordination, particularly when interacting with dynamic objects, like catching a ball. A recent theoretical framework from our group suggests that the seemingly distinct manifestations of ASD in multiple domains may share a common core: an impaired ability to make predictions. Difficulties in language, social interactions, repetitive behaviors, and motor coordination may all result from the same underlying impairment, albeit at different time scales. This study examined motor predictive impairment through multiple tasks of catching and bouncing a ball, which involve predicting and intercepting a moving object.
Objectives: Motivated by the theory of predictive impairment in autism, our hypothesis is that individuals with ASD will show impaired motor coordination when interacting with moving objects, specifically when performing actions that involve prediction.

Methods: Four children with ASD (IQ-matched, divided into 2 age groups, 7-9 and 10-12 years) and 21 neurotypical (NT) children performed 5 ball interception tasks in a virtual environment that afforded controlled manipulation of the time window for prediction, while simplifying the coordination challenges for hand movement. Subjects either pressed a button to predict the time or location of a launched ball (low motor challenge), or they vertically moved a paddle to catch or bounce a ball to hit a target (higher motor challenge). Additionally, subjects performed naturalistic ball catching with two hands, where 3D kinematics of joint movements and muscle activity of arm, leg, and postural muscles were recorded to quantify endogenous predictive responses. A set of control tasks assessed more elementary motor abilities, such as postural sway, reaction time, and smoothness of hand movements.

Results: NT and ASD children successfully completed all tasks. However, ASD children performed with significantly higher errors in temporal and accuracy metrics. In virtual ball catching, when the challenge for predicting the ball's trajectory was increased by partial occlusion, ASD children's accuracy registered a disproportionately large decrease relative to NTs. Additionally, ASD children displayed lower accuracy when intercepting a ball to bounce it to a target. Importantly, in reaction times and smoothness, tested in control tests designed to closely relate to the experimental tasks, ASD children did not differ from NT children. Similarly, while NT children achieved significantly more safe ball catches during the naturalistic ball catching task, their performance in postural balance alone was not superior to ASD children. Preliminary EMG analysis suggests that when catching balls ASD children show less coordinated muscle activity than NT children in stabilizing trunk muscles.

Conclusions: Results from a sequence of prediction-based tasks reveal that despite considerable individual differences in skill, ASD children on average show impaired motor performance compared to NT children. These data are consistent with our hypothesis that the ability to predict may be an explanatory construct common across ASD individuals despite their phenotypic variation. Given its broader theoretical embedding, the results of this study have implications beyond motor skills towards a more encompassing understanding of autism.

161 **168.161** Quantitative Assessment of TIP-TOE Behavior in Autism Spectrum Disorder Subjects: A CROSS-Sectional Cohort Study

G. Valagussa[1,2]*, V. Balatti*[1]*, L. Trentin*[1,3]*, A. Signori*[3] *and E. Grossi*[1]*, (1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)School of Medicine and Surgery, University of Milan-Bicocca, Milano, Italy, (3)Department of Health Sciences (DISSAL), Section of Biostatistics, University of Genoa, Genoa, Italy*

Background:
About one fourth of individuals with autism stand, and/or walk, and/or run on their tiptoes. Studies about quantitative assessment of Tip-toe behavior (TTB) are scarce relating to walking and running and absent relating to standing. In a previous cohort study, using a qualitative assessment we described three mutually exclusive clinical functional classes of TTB of increasing severity: TTB only during running (TTB1), TTB only during walking and running (TTB2) and TTB during standing, walking and running (TTB3).

Objectives:
The aims of this cross-sectional study are: 1) to quantify TTB during both a static and a dynamic test in our ASD sample; 2) to compare the intensity of TTB in the three TTB clinical functional classes and in the NO-TTB group.

Methods:
Our study sample included 45 ASD subjects (mean age: 13,15 years – 4,63 SD; 40 males) diagnosed according to DSM V criteria and under observation at our Institute. The confirmation and the severity of autism was established through ADOS-2. A therapist assessed the presence/absence of TTB during standing, walking and running using direct observation and interview of the main caregiver living with the child through a structured assessment. According to this assessment, 25 ASD subjects resulted not TTB, 3 resulted in TTB class 1, 10 in TTB class 2 and 7 in TTB class 3. The intensity of TTB expression during static and dynamic tests was quantified as percentage of time spent on the tip toes and as the percentage of toe steps, respectively. Both tests were conducted using standardized video recordings reviewed independently by two expert therapists.

Results:
The overall ADOS calibrated severity score (CSS) of all the subjects was 7.56 (1.71 SD). The overall ADOS CCS was 6,92 (1,55 SD) in NO-TTB, 8,15 (1,73 SD) in TTB1+2 and 8,71 (1,38 SD) in TTB3 ($p = 0.02$). The TTB time percentage values of the NO-TTB group during the static quantitative test was 0.25% (0.37 SD), while the time percentage values of the TTB1+2 was 1,82% (2,82 SD) vs 32,34% (31,82 SD) in TTB3 (table 1). We found a significant difference between each of the 3 groups ($p < 0,02$). In the NO-TTB group, during the dynamic quantitative test, the mean percentage of the TTB steps was 0.66% (1.48 SD), while it was 7,91% (5,71 SD) in TTB1+2 vs 60,93% (28,29 SD) in TTB3 (table 1). We found a significant difference between each of the 3 groups ($p= 0.000$)(fig 1). Moreover, we found a significant correlation ($r = 0.702$) between the quantity of TTB in the static and the dynamic test. Finally, we also found a significant correlation between the severity of TTB during both the static and the dynamic tests and the ADOS-2 CSS ($r = 0.305$ and $r = 0.406$ respectively).

Conclusions:
We quantified TTB using a new structured static and dynamic assessment test in our ASD sample. We found significant difference between NO-TTB and the 2 TTB subgroups. The TTB quantity in the static test is correlated with TTB quantity in the dynamic test.

162 **168.162** TIP-TOE Behavior in Autism Spectrum Disorder: A Prospective Cohort Study

G. Valagussa[1]*, V. Balatti*[1]*, L. Trentin*[2] *and E. Grossi*[1]*, (1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)Autism Research Unit, Villa Santa Maria, Tavernerio, Italy*

Background:
According to the literature, about one fourth of individuals with ASD present with toe walking. In a previous study, we found that this behavior is present not only during walking but also while standing and running, and described three mutually exclusive clinical functional classes with a different degree of severity: TTB during running (TTB1), TTB during walking and running (TTB2) and TTB during standing, walking and running (TTB3). In another study we also found a positive relationship between the presence and severity of TTB and the Achilles's tendon shortening in ASD subjects. In this perspective, assessing and monitoring TTB in ASD subjects could become critical to identify ASD subjects at risk of developing muscle shortening. Moreover, to our knowledge in the literature systematic observations of the natural history of Tip-toe Behavior (TTB) in ASD children using standardized assessment are lacking.

Objectives: The aim of this prospective cohort study is to describe the natural history of TTB and NO-TTB ASD subjects at short-medium term.

Methods:

The prospective study included 72 consecutive subjects (62 males; mean age: 15,68 years – SD 3,85) present in our Institute. The inclusion criteria were: an ASD diagnosis according to the DSM V criteria, a diagnosis confirmation based on the ADOS–2. The exclusion criteria were: presence of co-morbid diagnoses that would have an impact on gait. The assessment of presence/absence of TTB during standing, walking and running was done through direct observation and a structured interview of the main caregiver living with the child. We repeated the same evaluation 12 to 44 During months (mean: 29,88 months – SD 8,86; median: 34,5 months) after the first observation.

Results:

During the first TTB assessment 49 subjects resulted Non-TTB (68,1%) and 23 resulted TTB. In TTB group, 4 subjects were TTB1, 9 subjects were TTB2 and 10 subjects were TTB3. At follow up 7 out of 23 TTB subjects (30%) changed the severity class, 5 decreasing and 2 increasing severity (table 1). No one shifted to NO-TTB group. In NO-TTB group 8 subjects (16%) shifted to TTB group (5 in TTB 1 class, 2 in TTB 2 class and 1 in TTB class 3. The ADOS calibrated severity score of the converters was not different from non-converters (7,5 – 1,4 SD versus 7,56 – 1,74 SD).

Conclusions:

TTB behavior can change over time in ASD subjects. In an average time of two years about one third of TTB subjects change their severity class and 16% of Non-TTB subjects become TTB. This finding underlies the importance of close monitoring of TTB with standardized protocols.

163 **168.163** Quantitative Measures of Motor Function in Children with Duplications of 15q11.3-13.1 (Dup15q Syndrome) and Typically Developing (TD) Children.

***R. R. Wilson**[1], A. H. Dickinson[2], C. Hyde[3], S. Rallapalli[1], K. Dahlerbruch[1], C. Rocha[1] and S. Jeste[2], (1)UCLA Medical Center, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Semel Institute, UCLA Medical Center, Los Angeles, CA*

Background: Motor skills are critical for the development of more complex social behaviors and overall cognitive development (Iverson, 2010; Karasik et al, 2012). Impairments in motor skills, specifically in gait, are prevalent in children with Autism Spectrum Disorders (ASD) and represent an important area for intervention to improve functional outcomes. Due to limitations in available standardized assessments, motor impairments in individuals with ASD are poorly quantified and understood. Impairments in gait are quantifiable and translatable measures of motor skills that provide insight into overall motor development and are directly related to social communication skills. In this study we utilize the Protokinetics Zeno Walkway to quantify kinematic variables of gait in children with Dup15q Syndrome, the most common copy number variant associated with ASD, and highly penetrant for motor delays (DiStefano et al, 2016). Preclinical models of Dup15q syndromes have specific gait impairments. We also compare gait variables to social communication skills using the Social Responsiveness Scale (SRS) (Constantino et al, 2012).
Objectives: To compare quantitative measures of gait, including stride width, cadence (steps/minute), and gait variability index (GVI), in children with Dup15q Syndrome and Typically Developing (TD) children and to evaluate the relationship between measures of gait and social communication.

Methods: Participants included 28 children with Dup15q Syndrome ages 3-15 years (Mean, 8 years). TD data included TD siblings and normative gait data. Children completed four trials of walking. Multiple kinematic variables of gait were extracted with specific focus on mean cadence, stride width, and GVI. Differences between group gait variables in Dup15q syndrome and TD were compared using Mann-Whitney U tests. Correlations were used to determine the relationship between cadence and step width to total T Scores on the preschool and school aged SRS.

Results: **See table 1 for detailed statistical analysis and results.** Significant differences were seen in stride width and GVI but not in cadence between groups. Expected markers of developmental maturity of motor function, such as reduction in cadence, step width, and GVI were not seen in children with Dup15q syndrome. Increased step width was positively correlated with increased preschool and school aged SRS scores (R= 0.38). When looking only at school aged SRS there was greater association with step width (R= 0.57). Cadence was negatively correlated with SRS scores (R= -0.002).

Conclusions: Gait patterns in Dup15q syndrome were strikingly similar to gait patterns reported in the Dup15q mouse model, specifically in increased stride width and decreased cadence which likely represent lack of stability, reduced strength, and overall motor dysfunction (Figure 1). Children with Dup15q syndrome show persistent abnormalities and delayed neuromotor maturation of gait. Children with greater motor dysfunction characterized by increased stride width and decreased cadence showed greater impairments in social communication. These findings not only establish feasibility of these motor measures, but they also emphasize their potential value as translational biomarkers in Dup15q syndrome**.** Use of this quantitative measure of motor function can aid in identifying biomarkers of clinical stratification, treatment targets, and meaningful outcome measures of clinical trials in ASD.

164 **168.164** Reduced Left Cradling Bias and Cerebral Lateralization in Children with ASD

***R. Davis**[1], B. Todd[2] and G. Forrester[3], (1)Birkbeck College, London University, London, United Kingdom, (2)City University, london, United Kingdom, (3)Birkbeck, University of London, London, United Kingdom*

Background: Previous studies have indicated a maternal preference to holding infants on the left side of their body. The physical positioning is thought to facilitate the processing of social-emotional stimuli by establishing a direct route to the right hemisphere. Reduced cortical lateralization has been associated with ASD and whilst disruption to left cerebral lateralization for fine motor dominance is associated with

weaker language acquisition in young children, the ramification of disruption of right cerebral lateralization associated with social-emotional processing has yet to be explored within the scope of cognitive development.
Objectives: To examine right cerebral lateralization of processing social stimuli through the left cradling bias in children with ASD and typically developing controls.

Methods: 60 4-6-year old children with ASD were compared with 80 control children in a cradling task consisting of three different holding conditions; participants cradled a lifelike human baby doll or a control object of an equivalent weight and dimension either with or without symbolic facial features. Handedness was also assessed across three motor tasks interspersed with each cradling trial.

Results: The control group demonstrated a significant left side preference when holding the human doll. Whilst a left side bias was not demonstrated when the group cradled the control object without social features, the addition of rudimentary facial features was sufficient to elicit a left holding bias. Conversely, no preference for left cradling was evident in the ASD group for any doll type and no significant difference was identified between the holding preference of social and non-social objects. Furthermore, stronger hand dominance was positively correlated with a left cradling bias overall.

Conclusions: We identified the absence of a left cradling bias as a possible indicator of atypical cerebral lateralization in children with ASD. Findings support the possibility that socialisation influences cerebral lateralization for processing social-emotional stimuli in typical development, whereas children with ASD did not distinguish between social and non-social stimuli.

165 **168.165** Relating Sensory Hypersensitivity and Autistic Traits in Typically-Developed Adults

S. E. Schulz *and R. A. Stevenson, Western University, London, ON, Canada*

Background:
Restricted interests and repetitive behaviours (RRBs) are a core diagnostic symptom of Autism Spectrum Disorder (ASD) and tremendously impact an individual's day-to-day life, yet the underlying factors of RRBs are not fully understood. Recent work suggests that sensory issues related to ASD, specifically sensory sensitivities, contribute to RRBs. While these studies have provided evidence for a relationship between RRBs and hypersensitivity in individuals with ASD, these studies have mostly utilized parent report measures which conflate sensory reactivity with sensory sensitivity.

Objectives:

1. Pilot a novel behavioural paradigm to empirically measure sensory sensitivity.
2. Determine the relationship between sensory sensitivity and autistic traits, specifically repetitive behaviours.
3. Compare relationships between RRBs and sensory sensitivity as measured through empirical, behavioural methods versus questionnaire data.

Methods:
Participants consisted of 110 university students who completed questionnaires reporting on sensory processing (Sensory Profile-2; SP-2), and RRBs (Repetitive Behaviours Questionnaire-2; RBQ-2). Behavioural measures of visual sensitivity involved a detection task from which sensory thresholds were determined. Participants were instructed to indicate when a Gabour patch was present in background noise. The Gabour patch was presented at 8 different contrasts ranging from 0.025 to 0.5 which were randomly presented ten times each. There were also 80 null trails for a total of 160 trials. A two-step analysis was employed. First, correlational analyses were conducted to identify relationships between sensitivities and RRBs using the various measurement methods. Second, hierarchical regressions were conducted to examine the unique contributions of sensory sensitivities while controlling for demographic variables.

Results:
Correlations confirmed a negative relationship between RRBs and visual thresholds (r^2=-0.275, p=0.008). There was also a strong positive relationship between RRBs and the Sensory Sensitivity Quadrant of the SP2 (r=0.340, p=0.001). Importantly, there was no relationship found between the two measures of sensory sensitivity (r=-0.049, p=0.645). In fact, a hierarchical regression revealed that both the behavioural measure of sensory sensitivities as well as the SP-2 "sensory sensitivity" measure significantly predicted RRBs (r=0.435, p<0.001), but each of them explained different portions of the variance in the RBQ (pr=-0.275, p=0.009; and pr=0.351, p=0.001, respectively).

Conclusions:
The relationship between the questionnaire data from the SP-2 and the RBQ confirm previous results that RRBs increase with increased sensitivity. There was also evidence for a relationship between empirically-measured visual thresholds and the RBQ. Lower visual thresholds imply higher levels of sensory sensitivity, suggesting, again, that as sensitivity increases, RRBs increase as well. However, surprisingly, there was no relationship between the two so-called measures of sensory sensitivity. Results from the hierarchical regression suggest that these two metrics measure distinct constructs and account for different aspects of RRBs. We hypothesize that the behavioural tasks measure sensory *sensitivity*, questionnaire data actually measure sensory *reactivity,* as parent reports are intrinsically dependant on parents observing the behavioural response that a child has to a sensory stimulus. These data also highlight the need to distinguish between sensory sensitivity and reactivity in the literature.

166 **168.166** Relationships between Sensory Atypicalities, Repetitive Behaviours, Anxiety and Intolerance of Uncertainty

M. Glod[1]*, D. M. Riby*[2]*, E. Honey*[3] *and J. Rodgers*[1]*, (1)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Department of Psychology, Durham University, Durham, United Kingdom, (3)Northumberland, Tyne & Wear NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom*

Background: Unusual sensory responses are common in autism spectrum disorder (ASD) and a subcategory of atypical sensory behaviours has been included in the restricted, repetitive patterns of behaviour, interests, or activities diagnostic criterion (APA, 2013). Not only has a high degree of co-occurrence between sensory atypicalities and repetitive behaviours been reported in a number of studies (for the review see Glod et al., 2015), but interestingly, repetitive behaviours and sensory atypicalities have been linked to anxiety (Green et al., 2011; Lidstone at al., 2014;

Wigham et al., 2015) and intolerance of uncertainty (Wigham et al., 2015) in ASD. The associations, however, are still not well understood and the degree of co-occurrence of these features is still not fully explored.

Objectives: The aim of this study was to examine the relationships between sensory atypicalities, repetitive behaviours, anxiety and intolerance of uncertainty in autistic children to better understand the complexity of the disorder and its pathogenesis.

Methods: Parents of 17 autistic children, aged between 4 and 9 years, were recruited. Parents were asked to complete the Sensory Profile to provide information about their children's sensory experiences, the Social Responsiveness Scale to assess a degree of social impairment, the Spence Children's Anxiety Scale/Preschool Anxiety Scale and assess anxiety symptoms, the Repetitive Behaviour Questionnaire to evaluate the severity or frequency of repetitive behaviours that the children were engaging in and the uncertainty subscale of the Anxiety Scale for Children-ASD to measure children's level of intolerance of uncertainty.

Results: Serial mediation analysis was performed using PROCESS (Hayes, 2012). The model was based on previous computational work (Wigham et al., 2015): direct paths from both sensory hyporesponsiveness and sensory hyperresponsiveness to both repetitive sensory/motor behaviours and insistence on sameness and an indirect path through intolerance of uncertainty and anxiety were tested. The significant total and direct effects were found: from sensory hyporesponsiveness to repetitive sensory/motor behaviours (β=-.12, *p*=.003 and β=-.14, *p*=.018 respectively) and insistence on sameness behaviours (β=-.17, *p*<001 and β=-.19, *p*=.007); and from sensory hyperresponsiveness to repetitive sensory/motor behaviours (β=-.13, *p*=.002 and β=-.11, *p*=.031) as well as to insistence on sameness (β=-.17, *p*=.001 and β=-.13, *p*=.040). Moreover, significant indirect effects through anxiety (β=-.09, LL=-.21, UL=-.00) and intolerance of uncertainty and anxiety (β=.19, LL=.02, UL=.46) from sensory hyporesponsiveness to insistence on sameness behaviours were found.

Conclusions: Significant direct relationships were found between sensory features and repetitive behaviours. Yet, all the paths between sensory processing abnormalities and repetitive behaviours were partially mediated by at least one of the mediation variables (intolerance of uncertainty or anxiety). Significant indirect relationship between sensory hyporesponsiveness and insistence on sameness behaviours was mediated via anxiety, and intolerance of uncertainty and anxiety. The important mediating role of anxiety and intolerance of uncertainty between sensory atypicalities and repetitive behaviours in ASD needs to be taken into account in sensory processing and repetitive behaviours treatment programmes for young children with ASD.

167 **168.167** Representational Gestures Provide a Direct Link between Motor Behavior and Social Communication Deficits in ASD

A. Bagdasarov[1], Z. M. Dravis[2], E. S. Kim[2], L. Adeoye[3], V. Obsekov[4], J. Diaz[4], B. B. Maddox[5], E. F. Ferguson[4], A. A. Pallathra[6], L. Bateman[4], A. Pomykacz[7], A. Tiedemann[8], E. S. Brodkin[9], J. Pandey[2], J. Parish-Morris[2], S. H. Mostofsky[8], R. T. Schultz[2] and ***A. de Marchena**[4,10]*, *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)The Center for Autism Research/CHOP, Phladelphia, PA, (4)The Center for Autism Research/CHOP, Philadelphia, PA, (5)University of Pennsylvania, Philadelphia, PA, (6)Department of Psychiatry, Catholic University of America, Washington, DC, (7)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (8)Center for Neurodevelopmental and Imaging Research, Kennedy Krieger Institute, Baltimore, MD, (9)Department of Psychiatry, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, (10)University of the Sciences, Philadelphia, PA*

Background:

Atypical motor behavior is widespread in ASD; individuals with ASD often display impairments in coordination, postural control, imitation, and praxis/pantomime performance. Praxis is the ability to perform learned skilled movements, and praxis weaknesses in ASD are associated with social-communication deficits (Dowell, Mahone, and Mostofsky, 2009). To date, research has only *indirectly* established a relationship between praxis performance and nonverbal communication, e.g., by correlating praxis and ADOS scores (Dziuk et al., 2007), leaving the question of mechanisms open. Here we propose a *direct* link between impoverished praxis skill and social-communication skills, via the performance of spontaneously produced co-speech hand gestures. Specifically, we predicted that participants with worse praxis scores would be less likely to use *representational* gestures ("descriptives" on the ADOS), in which speakers represent visuospatial information, such as shape or movement, with their hands.

Objectives:

To test the hypothesis that impoverished praxis skill is associated with decreased spontaneous production of representational gestures.

Methods:

Verbally fluent adults with ASD (n=12) and typically developing controls (TDC; n=21) were group-matched on age, gender, and full-scale IQ (see Table). Praxis was assessed using an abbreviated version of the Florida Apraxia Battery, consisting of 19 items, including gesture to command, gesture to imitation, and gesture with tool use, which were coded for a range of errors. To assess spontaneous production of co-speech gestures, participants completed a five-trial referential communication task, in which they described abstract three-dimensional figures to a trained confederate. The task was designed to allow for back-and-forth conversational interaction in a controlled setting. All hand gestures produced during the task were coded for: (1) frequency (gestures per minute), (2) type (representational, interactive, deictic, beat, or other; see Table), and (3) confidence (rater's confidence in the gesture's meaning).

Results:

Participants with ASD made marginally more errors on the praxis task compared to controls, with a robust effect size (*p*=.063, *d*=.893). On the referential communication task, participants with ASD and TDC gestured at a similar overall rate (*p*=.151; *d*=.529), but participants with ASD were less likely to use *representational* gestures specifically (*p*=.007, *d*=1.67), and coders were marginally less confident about what their gestures meant (*p*=.07, *d*=1.12). Looking at gestures broadly, praxis error rate and co-speech gesture rate were not correlated (*r*=-.029, *p*=.874). However, participants who produced more praxis errors were less likely to select *representational* gestures specifically (*r*=-.649, *p*=<.001), a finding that held in the ASD group alone (*r*=-.642, *p*=.045), but not in the TDC group (*r*=-.279, *p*=.247, see Figure). Participants who made more praxis errors also produced gestures with lower confidence ratings (*r*=-.477, *p*=.009).

Conclusions:

Adults with ASD who show greater deficits on a structured praxis exam are less likely to spontaneously produce representational gestures during conversation. Like praxis, representational gestures depend on access to underlying internal actions models, thus individuals with impoverished mental representations may evidence difficulty drawing on these representations both to perform skilled movements (i.e., praxis), and to perform communicative co-speech gestures. These findings demonstrate preliminary support for a *direct* link between motor skills impairments and communication skills in ASD.

168 **168.168** Sensory Abnormalities and Earlier P3a in Adults with Autism Spectrum Disorder

Y. L. Chien[1], *M. H. Hsieh*[1] *and S. S. F. Gau*[2], *(1)Department of Psychiatry, National Taiwan University Hospital, Taipei, Taiwan, (2)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan*

Background:

Perceptual disturbance is among the essential features of autism spectrum disorder (ASD) with hyper- or hyporeactivity in the same individual across different sensory modalities. Despite some data in children with ASD, little is known about the sensory profile of adults with ASD. Most of current studies assess sensory symptoms by self-report or parent-report questionnaire, rather than an objective method. Although some studies used event-related potentials (ERP) to demonstrate the sensory abnormality in children with ASD, whether the ERP abnormalities persist into adulthood remains inconclusive.

Objectives:

This study investigated perceptual disturbances in young adults with ASD by self-report on sensory measure as well as ERPs, including P50, Mismatch Negativity (MMN), and P3a.

Methods:

Thirty-seven participants, aged 15 to 30, with a clinical diagnosis of either high-functioning autism or Asperger's disorder and 35 typically developing controls (TD), aged 15 to 27, were assessed with ERPs and completed the self-administered questionnaires of the Chinese versions of the Adolescent/Adult Sensory Profile, Social Responsiveness Scale, and Autism Questionnaire. Three kinds of ERPs, P50, MMN, and P3a component using frequency and duration paradigms, were compared between the ASD and TD groups. The clinical correlates of ERPs parameters were also examined.

Results:

Compared to TD, young adults with ASD showed greater sensory symptoms on subscales of low registration, sensory sensitivity, and sensory avoidance, but less sensation seeking. Regarding the parameters of ERPs, young adults with ASD displayed shorter dP3a peak latency but similar amplitude on P50, MMN and P3a. Notably, there were different correlation patterns between the ASD and TD groups on sensory profiles, autistic symptoms and ERP parameters. The patterns of clinical correlates for ERP responses differed between the ASD and TD groups. Both P3a paradigms showed correlations with several ASD-related symptoms, such as social awareness deficits and stereotyped behaviors, as well as sensory symptoms such as sensory avoiding.

Conclusions:

Our findings of sensory symptoms and P3a latency deviations in ASD and their associations with clinical symptoms provide evidence to support perceptual disturbance in young adults with ASD and the clinical correlates of ERP responses. Pre-attentive sensory gating and novelty detection seem not different from TD in adulthood. These findings need further validation.

169 **168.169** Sensory Attenuation in Autism Spectrum Conditions

J. J. Finnemann[1] *and P. C. Fletcher*[2], *(1)Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (2)Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background:

The last years have seen a growing interest in using approaches within the predictive processing framework (Dayan et al., 1995; Rao & Ballard, 1999) to investigate differences in the cognitive, perceptual and neural processes in autism spectrum conditions (Pellicano & Burr, 2012; Sinha et al., 2014; Lawson et al., 2014; Van de Cruys, 2014).

At the core of models of prediction lies the notion of the brain as an 'optimal inference machine' which tries to model the external world with the purpose of minimising prediction errors (= the difference between the expectation of the experience and the experience itself).

Self-generated actions are thought to be accompanied by an efference copy of the motor command and as such generally result in smaller prediction errors than externally generated sensory input. There is evidence that predicted sensory input (such as from self-generated actions) is attenuated in order to make unpredicted sensory information more salient (Bays & Wolpert, 2007).

Objectives:

We were interested in investigating sensory predictive processes during self-generated movements in autism spectrum conditions.

Methods:

A well-established 'force matching' task (Shergill et al., 2003) was performed by 26 control and 23 ASC participants. During the experiment a force (varying between 0.5N and 2.75N) was applied to the participants' index finger via a lever and participants were are asked to match the force by pressing directly on the lever with their other index finger ('finger condition') or by adjusting a slider which controlled the torque motor and lever ('slider condition').

As the 'finger condition' models the sensory attenuation occurring during self-generated movements, it is expected that participants will overcompensate and apply a larger force than the reference force whereas limited experience with the 'slider condition' should produce more accurate matching results.

Participants also filled in self-report measures of autistic (AQ, Baron-Cohen et al., 2001) and schizotypal traits (PDI, Peters, 1999).

Results:

Regression lines were calculated for both the 'finger' and 'slider' condition.

Both group experienced sensory attenuation ($p<0.000$) as measured by a difference in slope and intercept between the 'finger' vs. 'slider' condition but there was no difference between the groups in the magnitude of overestimation ($p=0.805$).

Higher scores on the PDI were linked to smaller intercepts in the 'finger condition' in the control subjects only ($p=0.012$) whereas there was a trend in the ASC group relating higher scores on the AQ to larger intercepts in the 'finger condition' ($p=0.067$).

Conclusions:

Our experiment does not support the suggestion of autism as a generalised 'disorder or prediction' (Sinha et al., 2014) as attenuation of predicted sensory input seems to be preserved.

However while we replicated earlier findings of reduced sensory prediction in individuals with higher schizotypal traits in the control group (Teufel et al., 2010) the same did not hold for the ASC participants. This could be either due to the fact that the PDI is not measuring the same latent trait in the ASC group or because variance in sensory prediction is not mediated by the same factors in individuals with autism.

170 **168.170** Sensory Processing of Individuals with Autism Spectrum Disorder and an Intellectual Disability: A Systematic Review.

M. Werkman[1], *S. A. Reijneveld*[2], *S. Begeer*[3], *I. A. van Berckelaer-Onnes*[4], *Y. Dijkxhoorn*[5] *and J. A. Landsman*[6], *(1)UMCG, Groningen, Netherlands, (2)Health Sciences, UMCG, Groningen, Netherlands, (3)VU University Amsterdam, Amsterdam, Netherlands, (4)Faculty of Social Sciences, Clinical Child and Adolescent Studies, Leiden University, Leiden, Netherlands, (5)Leiden University, Leiden, Netherlands, (6)University Medical Centre Groningen - Applied Health Research, Groningen, Netherlands*

Background:

Autism Spectrum Disorders (ASD) and Intellectual Disabilities (ID) both coincide with atypical sensory processing. The severity of one of these disorders could have an impact on the other disorder regarding a number of outcomes. Little is known about the impact the combination of both conditions has on sensory processing. To date, we do not know to what extent the sensory processing of individuals with both ASD and ID differ from individuals with ASD or ID alone and what the impact will be on daily functioning.

Objectives:

The aims of this systematic review are 1) to investigate how individuals with both ASD and ID differ from individuals with ASD or ID alone in their sensory processing, and 2) to examine whether and how sensory processing problems are related to outcomes linked to sensory processing problems for individuals with ASD and/or ID.

Methods:

We searched three different databases: PubMed, PsycINFO, and Education Resources Information Center (ERIC), regarding papers published after 2010. For each database, a specific search strategy was developed. Search terms included key words and synonyms for the concepts: autism, intellectual disability, and sensory processing. We also searched in Online First, a website on which articles are presented that have not been published yet but will be published soon in peer-reviewed journals. Identified studies were first screened for eligibility for possible inclusion based on title and abstract. The next step was full text reading of the selected articles, systematic data-extraction and testing on quality of research. To answer the research questions, the outcomes of the three groups under study were compared: 1) ASD&ID, 2) ASD alone, and 3) ID alone.

Results:

The search yielded 800 studies which in particular covered descriptions of different sensory processing profiles for individuals with autism and outcomes such as stereotyped and repetitive behavior. Evidence on the sensory processing of the group of individuals with ASD and ID was very limited. We will be able to present full findings at the conference, regarding both research questions. For aim 1, an overview of the current state of knowledge of the sensory processing for each group will be given. If possible, a specification into different categories will be made. For aim 2, studies about the relationship between sensory processing problems and outcomes linked to sensory processing problems for individuals with ASD and/or ID will be shown.

Conclusions:

We will give an overview of the current state of evidence on the sensory processing of individuals with ASD and/or ID. We will also have insight into background and severity of sensory processing problems and differences between groups. Also, we will have gained insight into the outcomes linked to sensory processing problems for all three research groups. This review shows that evidence on the research group of individuals with ASD and ID is particularly limited. Study findings will help in gaining a better understanding of the sensory processing of individuals with ASD and/or ID, and may direct future research.

171 **168.171** Sensory Stress in Primary Schools: Not Just a Problem for Autistic Children

D. R. Simmons*, S. Bell and N. Stack, School of Psychology, University of Glasgow, Glasgow, United Kingdom*

Background: It is well-known, and now enshrined in diagnostic criteria, that unusual sensory experiences are problematic for children with Autism Spectrum Disorder (ASD). A vexed question, however, is whether autistic children should be protected by adjusting the environment, potentially requiring segregation from their neurotypical peers. Much previous research into the sensory experiences of children with ASD has relied heavily on parent/teacher-report measures and may have underestimated the difficulties experienced by neurotypical children (Simmons, Robertson & Brown, 2016). In this study we focused on two UK primary schools (equivalent to Grade Schools in the USA), one specializing in children with Additional Support Needs (ASNs), like ASD, and another with a largely neurotypical population. Objective measurement of sensory stressors using the "sensory audit" technique (Robertson & Simmons, 2012) were combined with focus groups and interviews with the pupils to establish the impact of sensory stress in the school environment.

Objectives: To combine objective environmental data with self-report data from pupils to assess the impact of sensory stress in primary schools on both autistic and neurotypical children.

Methods: The sensory audit technique involves acquiring data on potential visual, auditory and olfactory sensory stressors. Data were obtained using cameras, light meters, sound level meters, recording devices and trained human inspectors. In addition 45 children (17 in the ASN school and 28 in the mainstream school) took part in "sensory workshops" during which they were asked questions about sensory stress both in general and at their school. Additional data collected included parent-reported autistic trait levels (using the Children's AQ; Auyeung et al, 2008) and parent-reported sensory reactivity using the parents' version of the Glasgow Sensory Questionnaire (Robertson & Simmons, 2013). Transcripts of the focus groups/interviews were analysed using Thematic Analysis (Braun & Clarke, 2006).

Results: Preliminary analysis has revealed that most children, whether autistic or neurotypical, reported issues related to sensory stress.

Particular examples included distraction and discomfort caused by strong sunlight streaming through Venetian blinds, difficulties tolerating noise in the busy school canteen at lunchtime, and unpleasant smells from toilets and changing rooms. Curiously, younger (typical) children (4-8 years old) preferred busy, colourful classrooms ("Because it looks like a party room!") although older children (9-11 years old) preferred a less stimulating visual environment ("I like how it's tidy"). Future correlational analysis between objective measurements obtained during the sensory audit and the subjective reports from the children will further clarify the details of these sensory preferences and dislikes.

Conclusions: These data underline that sensory stress is problematic for both autistic and neurotypical children in school environments. Given the clear data from parent/teacher-reports that there are differences in sensory reactivity between autistic and neurotypical children it could be that methods for coping with sensory stress amongst neurotypical children are more effective, although potentially becoming internalized and manifesting differently as, for example, anxiety (Robertson & Simmons, 2015). Clearly, careful consideration should be given to the sensory environment in all schools, with a particular focus on the provision of quieter, less intense spaces for the most sensitive children.

172 **168.172** Spontaneous Oculomotor Movement and Stereotyped and Rigid Behaviors: Results from the ABC-CT Feasibility Study

S. Hasselmo[1]*, F. Shic*[2]*, S. J. Webb*[3]*, C. Sugar*[4]*, G. Hellemann*[5]*, D. Senturk*[5]*, M. Murias*[6]*, R. Bernier*[3]*, G. Dawson*[7]*, S. Faja*[8]*, S. Jeste*[4]*, C. A. Nelson*[8]*, K. Chawarska*[1]*, J. McPartland*[1] *and A. Naples*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)University of California, Los Angeles, Los Angeles, CA, (5)UCLA, Los Angeles, CA, (6)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (7)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (8)Boston Children's Hospital, Boston, MA*

Background: Individual variability in oculomotor movements such as blinks and saccades has been noted between individuals with autism spectrum disorder (ASD) and typically developing peers (TD) and can reflect variability in underlying biological systems. Characteristics of blinks and saccades, such as frequency and regularity, may be linked to processes and behaviors relevant to ASD, including motor stereotypies, cognitive rigidity, and attentional processing. However, there is scant research linking variability in spontaneous eye-movements and clinically meaningful individual differences. Examining the relationships among these traits and individual variation in the properties of blinks and saccades may contribute to understanding of oculomotor features in ASD and cognitive processing more generally. Features that are strongly differentiated by group or degree of stereotyped and rigid behaviors may serve as potential stratification biomarkers.

Objectives: This study examines relationships among oculomotor characteristics, such as spontaneous blink rate and saccadic rhythmicity, and stereotyped and rigid behaviors in children with ASD and their TD peers.

Methods: Remote eye-tracking data were collected from 51 participants (ASD: n=25, 20 male; TD: n=26, 17 male; ages 4-11, mean age = 7.17) using an SR Eyelink 1000+ while participants freely viewed static images. Blink rate was calculated as the average number of blinks per second across all stimuli. Rhythmicity of eye movements was examined in the frequency domain; power spectra were generated from 250ms segments of data and amplitude was extracted for frequencies between 4 and 10 Hz based on prior studies of saccadic rhythmicity. Stereotypy and rigidity were measured using the stereotypy subscore of the ADOS-2, the frequency of restricted behavior subscale of the Autism Impact Measure (AIM), and the Behavior Assessment System for Children (BASC-3) adaptability and attentional control subscales.

Results: One-way ANOVA indicated a statistically significant difference in blink rate between diagnostic groups ($F(1,49)=6.097$, $p=0.017$), such that individuals with ASD blinked more than TD controls. However, no main effects of stereotypy or rigidity were seen in multiple regression models examining the effect of diagnosis, behavioral measures, and their interactions on blink rate. Saccadic rhythmicity was associated with frequency of restricted behavior as measured by the AIM, such that, among individuals with ASD, those with more regular eye movements scored higher on the AIM ($\beta=45.57$, $p=.034$). No independent effect of restricted behavior on saccadic rhythmicity was seen across diagnostic groups. A one-way ANOVA showed a significant difference in the power of the 4-10Hz frequency component between diagnostic groups ($F(1,49)=25.67$, $p<0.01$) suggesting that individuals with ASD exhibited a higher frequency of saccadic eye movements.

Conclusions: Preliminary analyses suggest that blink rate and frequency dynamics of spontaneous eye movements differ in children with ASD and their TD peers. Among children with ASD, saccadic rhythmicity exhibited a stronger frequency component from 4-10 Hz, which was further modulated by the degree of restricted behavior they display. Further research linking these measures to other measures of cognitive processes and to stereotyped behaviors may extend understanding of ways spontaneous eye-movements underlie stereotypical movement and rigidity of cognition and behavior in ASD.

173 **168.173** Statistical Learning of Dynamic Contingencies in Autism Spectrum Conditions

O. Parsons[1] *and S. Baron-Cohen*[2]*, (1)University of Cambridge, Cambridgeshire, United Kingdom of Great Britain and Northern Ireland, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background: The capacity to implicitly process statistical regularities in one's environment is a core aspect of perception and cognition. Prior experiences of environmental regularities are used in conjunction with incoming sensory information to arrive at the perceived interpretation of the external environment.

There have been suggestions that there may be impairments in the ability to build these 'priors' in autism. Despite this, studies looking at implicit learning have failed to find significant differences between people with autism and the typical population. However, it is important to note that these studies predominantly focus on implicit learning under deterministic and stable conditions.

Objectives: We set out to assess i) whether differences in implicit learning occur in individuals with autism when underlying regularities are probabilistic rather than deterministic and ii) whether individuals with autism show differences in their ability to update these priors when the underlying regularities change.

Methods: We used a probabilistic serial reaction time task in which participants were asked to use key presses to respond to a visual target which appeared on the screen in one of four possible locations.

During the task, trial outcomes were determined by a probabilistic Markov chain. This was designed so that for each 2-back context, there was a probable and improbable target location for the subsequent trial. Acquiring implicit knowledge of the underlying structure of the trial sequence leads to reduced response times during probable trials when compared to improbable trials.

The participants (15 with a diagnosis of autism and 20 controls) were asked to complete a primary phase of 8 blocks (of 120 trials each) before moving on to a secondary phase of 8 blocks in which probable and improbable locations were reversed for all contexts.

Results: Individual differences in implicit acquisition of the underlying sequence in the task were assessed by comparing response times for probable and improbable trial types. To assess differences in the ability to adapt to changes in the underlying predictive structure, we calculated gain scores for performance in the second session relative to the first session.

We conducted a Bayesian Independent T-Test on the gain scores between the autism group (ASC) and the control group (CTR). The CTR group had higher gain scores on average than the ASC group (M = 0.67 and -1.21 respectively), with a Bayes factor of 19.90 in favor of the alternative hypothesis suggesting that there is strong evidence in support of a group difference.

We then used a computational model to assess how perceptual expectations are influenced by using different lengths of temporal window when calculating the level of uncertainty (Entropy) in the task environment.

Conclusions: Under stable probabilistic conditions, the ASC group showed increased rates of implicit learning relative to the CTR group. However, when the underlying probabilistic structure changed the ASC group were slower to update these expectations.

We discuss how data from computational models can be used to infer how attending to statistical regularities across different time scales might lead to the observed group differences in the behavioral data.

174 **168.174** Stereotypies in Autism: The Construction of a Large VIDEO Catalogue from a Cohort Study

E. Caminada[1], *F. Vanzulli*[1], *B. Vescovo*[1], *E. Alfiedi*[2] *and E. Grossi*[1], *(1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)Autism Research Unit, Villa Santa Maria, Tavernerio, Italy*

Background:

Stereotypies, despite their high frequency and strong diagnostic significance within autism, have not yet been fully elucidated due to their broad spectrum of presentation and pattern complexity. Standardized video-recordings can help to depict the complex pattern of stereotypies commonly observed in autism, thus allowing for a better definition of major phenotypes.

Objectives:

The aim of this study is to analyze stereotypies patterns observed in a sample of children and adolescents residing at our Institute and subsequently classify them by means of video-recordings.

Methods:

20 expert caregiver wearing a body cam recorded specific stereotypic behavior in a natural context during the everyday activities of 67 autistic subjects for 3 months of close follow-up. After a few minutes of recording, the possibility to interrupt their behavior by intervening physically to divert attention was registered.

A team consisting of a senior child neuro-psychiatrist and a senior psychologist reviewed all the video recordings (1868) selecting 780 of them as the most meaningful to summarize the whole spectrum in each individual in the given time window. Each video was classified according to components (motor, sensorial, vocal, intellective), complexity (2 classes, simple and complex), body parts involved (n=18) and sensory channels involved (hearing, sight, proprioception, taste, pain, smell).

Results:

The vast majority (87%) of the780 patterns occurred several times generally (73%) in a state of tranquility.

In more than half of cases (53.4%), the interruption required intervening physically, but a poor correlation was found between the pattern type and possibility to interrupt the behavior by way of verbal or physical intervention (r= -0.08/+0.08).

The individual stereotypies spectrum ranged from 1 to 33 different patterns (average= 11.6; S.D= 6.82). The most frequent pattern was represented by the combination of simple motor and sensorial components (accounting for 23% of the total number) followed by simple motor and simple sensorial (9% and 8% respectively). The other 47 patterns with combinations from 1 to 4 components accounted for the remaining 60%.

In the 569 patterns containing motor components, whole body and arms movements constituted the most frequent body parts involved (41% e 38% respectively) followed by mouth and hands (10% and 9.8% respectively).

In the 531 patterns containing sensorial components, the most frequent channel involved was tactile (50%) followed by proprioceptive(34%) and acoustic (19.5%).

Most of the 127 stereotypies with vocal components were constituted by simple vocalizations, 85.8% and only 14.2% by phonemes or words.

Conclusions:

This study represents a first attempt to systematically document the patterns of expression of stereotyped behavior in a cohort of autistic subjects closely followed by professional educators.

Open access to this video bank and to the clinical data will be allowed to interested researchers , with the aim of improving the comprehension of this complex phenomenon and its correlation with clinical and demographic features.

175 **168.175** Stop Making Noise! Auditory Sensitivity in Adults with Autism Spectrum Disorder: Physiological Habituation and Subjective Detection Threshold.

M. W. Kuiper[1], *L. Verhoeven*[2] *and H. M. Geurts*[3], *(1)University of Amsterdam and Dr. Leo Kannerhuis, Doorwerth, Netherlands, (2)Dr Leo Kannerhuis, Doorwerth, Netherlands, (3)University of Amsterdam, Amsterdam, Netherlands*

Background: One of the most commonly reported sensory sensitivities in ASD is sensitivity to sounds (e.g., Haesen et al., 2011). However, possible underlying mechanisms are still unknown. Some suggest that habituation might play a role, while others postulate that altered sensory detection thresholds might be an explanatory mechanism. So far, studies on auditory habituation show mixed results and focused mainly on ASD children (e.g., for review see Lydon et al., 2014). Altered sensory detection thresholds have been shown in ASD children (e.g., Tavasolli et al., 2015). Research on auditory detection thresholds in ASD adults is, however, limited.

Objectives: We examined whether ASD adults habituate slower and have lower auditory detection thresholds compared to typically developing (TD) adults. We also examined whether habituation and detection threshold are related to self-reported auditory sensitivities.

Methods: We included 33 ASD and 31 TD adults (25-45 years; IQ>70). Habituation is defined the number of trials until on two consecutive trials no skin conductance response (SCR; >0.03 uS; Boucsein et al., 2012) was given to a simple tone (1000Hz) and a Dutch ambulance siren. Detection threshold is measured by decreasing the volume of a simple tone until participants report not to hear the tone anymore. This is repeated until participants reach the same threshold twice. The self-reported auditory sensitivity is measured with the adolescent adult sensory profile (AASP).

Results: A MANOVA analysis revealed that the groups (N=24 each) did not differ on predefined habituation for both tone (*p*=.96; *Cohen's d*=.02) and siren (*p*=.92; *Cohen's d*=.03). There was also no significant Pearson correlation between habituation and self-reported auditory sensitivity (N=48; *r*=.02; *p*=.90). The groups also did not differ on auditory detection thresholds (N_{ASD}=33; N_{TD}=31; *p*=.20; *Cohen's d*=.32). There was, however, a significant correlation between detection thresholds and self-reported auditory sensitivity (N=64; *r*=.29; *p*=.02). Moreover, exploratory repeated measures analyses revealed that when habituation was defined as decreasing SCR amplitudes (Boucsein et al., 2012) that ASD adults had a significantly slower decline in SCR amplitude compared to ASD adults (*p*=.04; *Cohen's d*=0.64). Regarding the siren, no significant differences were found.

Conclusions: At first sight, no large differences between ASD and TD adults were observed on habituation and auditory detection threshold, but a higher auditory detection threshold did seem to be related to more self-reported auditory sensitivity. At second sight, concluding that no differences emerge between the groups might be premature as our exploratory analyses revealed that the intensity of the physiological response to auditory stimuli might remain heightened in ASD. Hence, it seems to depend on how habituation is operationalized whether or not one can conclude that ASD adults habituate slower than TD adults.

176 **168.176** The Relationship between Motor Performance and the Broad Autism Phenotype When Performing Movements of Varying Complexity

***I. Naiman**[1], B. M. Stoesz[2], J. M. Montgomery[3] and C. M. Glazebrook[4], (1)University of Toronto, Toronto, ON, Canada, (2)Psychology, University of Manitoba, Winnipeg, MB, Canada, (3)Psychology, University of Manitoba, Winnipeg, MB, CANADA, (4)University of Manitoba, Winnipeg, MB, CANADA*

Background: For effective social communication, we must proficiently interpret and use body language, which illustrates the link between social and motor behaviour. The proficiency of these skills progress based on an individual's experiences and interactions.
Objectives: The purpose of this study was to investigate the relationship between motor behaviour and self-reported social communication skills of individuals without a diagnosed psychological or physical condition using the Broad Autism Phenotype Questionnaire (BAPQ).

Methods: Twenty-four individuals without autism spectrum disorder were recruited. Each participant completed the BAPQ (measuring rigidity, aloofness, and pragmatic language) and a motor task. During the motor task, participants were asked to *look at*, make a *button-press*, or *point* to one of two pictures of animals that appeared with an 18° visual angle on the left and right sides of a computer monitor (CNE, Gainesville, FL; resolution 1920x1080 pixels, refresh rate = 60Hz). The target image was indicated by either an auditory (sound of the animal) or a visual (matching picture located central on the screen) cue. The dependent variables were mean and standard deviation of the reaction time (RT) and movement time (MT) of the saccade and hand movements. Gaze behaviour was sampled using the Eyelink1000plus eye-tracker (SR Research Ltd., Ottawa, ON) at 500Hz. Hand movements were recorded using custom built micro-switches that acted as home switches/buttons. A series of simple regression analyses were used within participants to examine the relationship between motor performance in the six conditions (2 sensory modalities by 3 motor tasks) and the BAPQ subscale scores.

Results: Overall, the analysis for motor planning demonstrated that the look conditions were the most challenging (i.e. longest RTs) for participants, and the auditory look condition was significantly more challenging than the visual look condition. The following results are presented by the three BAPQ subscales: (1) Rigidity was positively correlated with saccade RT during the auditory look condition (R^2=0.398), suggesting that individuals with higher rigidity experienced increased cognitive stress during this challenging task affecting their efficiency to create and carry out a motor plan. (2) Aloof behaviour was positively correlated with the variability of saccade RT during the auditory point condition (R^2=0.167), suggesting that more aloof individuals are less practiced in this type of multisensory (social communication) action. (3) Pragmatic language was negatively correlated with mean hand RT during the auditory point (R^2=0.311), the visual button-press (R^2=0.283), and the visual point (R^2=0.398) conditions, and negatively correlated with mean saccade MT during the visual button-press (R^2=0.277) and visual point (R^2=0.179) conditions. The latter findings suggest that individuals with higher pragmatic language scores (i.e. those less confidence in social verbal skills) attend better to visual information during eye-hand coordinated tasks.

Conclusions: The present study demonstrates explicit relationships between self-report social communication skills and motor performance. Specifically, auditory tasks were more difficult for rigid and aloof individuals and visual tasks were easier for individuals with higher pragmatic language scores (i.e. less confidence in pragmatic language skills). Results from these studies may inform new therapies targeting eye-hand coordination performance using auditory stimuli.

177 **168.177** The Relationship between Sensory over-Responsivity, Emotion Dysregulation Symptoms, and Psychophysiological Arousal to Sensory Stimuli in Youth with ASD

***J. E. Yeargin**[1], S. A. Green[2], T. Zbozinek[3], M. Dapretto[2], M. Craske[3] and S. Y. Bookheimer[2], (1)Brain Mapping Center, UCLA, Los Angeles, CA, (2)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (3)UCLA, Los Angeles, CA*

Background: Sensory over-responsivity (SOR) in youth with Autism Spectrum Disorder (ASD) is related to significant impairment in functioning, including greater emotional and behavioral symptoms (Ben-Sasson et al., 2009). Emotion dysregulation, the inability to effectively modulate emotions in response to an emotional experience, is a common area of difficulty found in ASD (Samson et al. 2014), but is rarely examined directly in relation to SOR. Emotion dysregulation also co-occurs with other negative outcomes including increased anxiety, depression, and poorer social functioning (Mazefsky et al., 2015) as well as observable maladaptive behaviors such as deliberate self-harm, tantrums, physical altercations with others, and general increases in irritability, nervousness, and worry (Quek et al., 2012; Lerner et al., 2012). It is possible that when individuals with ASD are exposed to aversive environmental stimuli, the need to modulate incoming sensory information disrupts adaptive emotional processing resulting in increased emotion dyrsregulation (Mazefsky et al., 2015). There is evidence that children with ASD show one of two patterns of psychophysiological arousal in response to sensory stimuli: either high arousal and slow habituation or low arousal and high habituation (Schoen et al., 2008). However, it is unclear whether and how these patterns may relate to SOR and/or to emotional arousal more generally. Thus, we sought to examine the relative contributions of SOR and emotion dysregulation to physiological responses to sensory stimuli.

Objectives: To examine the relationship between emotion dysregulation, sensory over-responsivity, and physiological arousal in youth with ASD.

Methods: Participants were 37 children and adolescents with ASD, aged 8-17 years. Participants completed a psychophysiological assessment measuring skin conductance response (SCR) across 6 15-sec blocks of mildly aversive, simultaneous auditory and tactile stimuli (white noise and a scratchy sponge). Sensory over-responsivity (SOR) was measured using a composite score from parent reports on the tactile and auditory sensory sensitivity items of the Short Sensory Profile (Dunn, 1999) and Sensory Over-Responsivity Inventory (Schoen et al., 2008). Emotion dysregulation was measured using parent report on the Emotion Dysregulation Index (EDI; Samson et al., 2014) of the Child Behavior Checklist (CBCL).

Results: A repeated-measures ANOVA with the 6 blocks of SCR response as within-subjects factors and SOR and ED as between-subject factors showed a main effect of SCR decreasing over time ($p<.001$). There was a significant SCR*SOR interaction ($p<.05$) such that SCR decreased less over time for youth with high (more severe) SOR. There was also a main effect of ED ($p<.05$) such that youth with high (more severe) ED had higher SCR arousal across all 6 blocks.

Conclusions: Results demonstrate that both SOR and emotion dysregulation play a role in physiological response to sensory stimuli in youth with ASD. Emotion dysregulation may be more directly related to high overall arousal, whereas SOR may be related to decreased habituation to sensory stimuli (consistent with Green et al., 2015, where the same pattern was observed with amygdala response to sensory stimuli). Results will be discussed in terms of implications for including emotion regulation strategies in intervention for SOR.

178

168.178 The Relationship of Sensory Overresponsivity to Amplitude Discrimination

***E. P. McKernan**, J. Kopec, E. A. Kaplan, E. L. Koelmel and N. Russo, Psychology, Syracuse University, Syracuse, NY*

Background: Up to 95% of parents have reported differences in sensory processing for their child with ASD (Rogers & Ozonoff, 2005). An estimated 56 to 70% of youth with ASD meet criteria for sensory overresponsivity, defined as severe negative responses to sensory stimuli (Baranek et al., 2006; Ben-Sasson et al., 2007). Previous studies have suggested that hyperresponsivity is due to failure to habituate (Green et al., 2015). Use of vibrotactile methods can provide an objective, quantitative measure of tactile processing and adaptation.

Objectives: This study aims to relate performance on three amplitude discrimination tasks, two without adaptation and one with an adapting stimulus, to sensory overresponsivity in a group of typically developing (TD) children and children with ASD.

Methods: 42 children (21 TD, 21 ASD) matched on age and IQ completed a vibrotactile testing battery. For all three amplitude discrimination tasks, stimuli were delivered on two fingers of the left hand, with one of the stimuli having a higher amplitude. Participants were asked to determine which of the two stimuli had the higher amplitude. In the adaptation condition, each trial was preceded by an adapting stimulus delivered to a single site before the comparison stimulus, thus leveraging the effect of habituation. Parents of children completed the Sensory Profile (Dunn, 1999), which was used to measure sensory overresponsivity. Differences in amplitude discrimination task performance were investigated. A regression analysis was performed to determine whether sensory overresponsivity predicted task performance.

Results: There was a significant difference between amplitude discrimination with and without adaptation for TD children, but not for ASD children. Children with ASD had significantly greater sensory overresponsivity than did TD children. Sensory overresponsivity predicted performance on amplitude discrimination without adaptation for TD children, but did not significantly predict performance on any of the amplitude discrimination tasks for children with ASD.

Conclusions: Amplitude discrimination performance worsened with single-site adaptation for TD children, but not for ASD children, replicating previous research in this area. Children with ASD had higher sensory overresponsivity than did TD children; however, the restricted range of these values for children with ASD likely reduced the ability to predict amplitude discrimination performance. The performance of TD children with higher sensory overresponsivity appears to be less affected by the presence of an adapting stimulus, similar to that of children with ASD. These results may suggest that the level of sensory overresponsivity has a differential impact on adaptation.

168.179 Types of Restricted Interests and Preoccupations: Are There Differences across Sex?

*K. Nowell[1] and **C. Jorgenson**[2], (1)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO, (2)Special Education, University of Missouri, Columbia, MO*

Background:

It is unclear if females are less likely to be diagnosed with autism spectrum disorder (ASD) because of a protective, female effect or the result of a unique female autism phenotype that current diagnostic tools and criteria do not detect (Van Wijngaarden-Cremers et al., 2014). With regard to restricted, repetitive behaviors (RRBs), parents and clinicians anecdotally report differences between males and females (Jamison et al., 2017). However, research findings are inconsistent (e.g., Van Wijngaarden-Cremers). Research suggests that there are differences in total number of RRBs, but this depends on the particular measure used and differences may only be apparent at the symptom level (e.g., Frazier et al., 2014). Given the inconsistent research results, researchers have proposed that difficulties in detection of RRBs is a result of females having more socially appropriate and difficult to detect RRBs (Halladay et al., 2015).

Objectives:

The aim of the current study was to investigate whether differences in *types* of restricted, circumscribed interests or preoccupations are associated with sex (i.e., male vs female), particularly restricted, circumscribed interests and preoccupations (CIs).

Methods:

Multivariate analyses were completed for the entire Simons Simple Collection (SSC; *N*=2648) to replicate previous findings (see Frazier et al., 2014). Qualitative data were collected from a local sub-sample of caregivers at a North American, SSC site (*N*=186). Qualitative phenomenological investigations are suitable when interested in a discovery-oriented approach of how individuals construct meaning of an experience (Creswell et al., 2007). In this particular case, qualitative methodology is appropriate to gain an in-depth understanding of how caregivers perceive and describe CIs. Responses describing restricted interests and unusual preoccupations on the *Autism Diagnostic Interview – Revised* (ADI-R) (i.e., questions 67 and 68) were transcribed and categorized using qualitative methodology. Categories were sorted by sex (females=30) and proportions of individuals with CIs in each category were calculated. Additional analyses will be completed to test for significant differences in obtained proportions and to investigate how differences in CI across gender might be associated with other phenotypic measures.

Results:

Multivariate analysis from the entire SSC was significant $F(10,2648)$, $p < .00$, partial $\eta^2 = .40$) with significant differences evident at the RBS-R Restricted Interest subscale level ($p < .00$) and ADI-R Encompassing preoccupation/circumscribed interest subscale level ($p < .00$). Males had more symptoms (i.e., higher scores) in both instances. Analysis of qualitative data found similar proportions of males and females with intense interests in television/movies; animals; and, food. Males were proportionally more likely to have CIs in categories such as factual information (13% vs 0%, respectively). Females had more CIs in several categories including arts and crafts (16.7% vs 5.77%),

Conclusions:

Preliminary analysis indicates that there are differences in the types of CIs described by parents that appear to be associated with sex. As suggested in previous research, it is plausible that females demonstrate socially acceptable restricted interests. Further, parent completed measures may not be capture socially acceptable circumscribed interests. Alternatively, there may be real differences between males and females in the number of restricted interests.

180 **168.180** Typical and Atypical Visuo-Spatial Information Processing in Korean Children with Autism Spectrum Disorder

M. K. Kwon[1] *and H. Song*[2]*, (1)Division of General Studies, Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of (South), (2)Seoul Woman's University, Seoul, Korea, Republic of (South)*

Background: Individuals with Autism spectrum disorder (ASD) are known to show atypical sensory processing. According to the complexity-specific hypothesis, adults with ASD are particularly impaired with complex (also called second-order or texture-defined) information, whereas their sensitivity to simple (also called first-order or luminance-defined) information is either intact (Bertone et al., 2003) or even superior (Bertone et al., 2005). A recent study (Rivest et al., 2013) found that ASD children also show atypical brain activity in response to complex gratings but this atypical processing was not observed at the behavioral level in the same test session.

Objectives: The present study examined 1) whether atypical processing of complex visual information at the behavioral level is a defining feature of ASD children at individual level as well as group level and 2) whether this processing has a strong relationship with processing speed, one of the general cognitive skills.

Methods: Participants were 28 Korean children - 14 ASD (13 boys; mean age = 8.41 year; SD= 1.70) and 14 TD children (12 boys; 8.14 year; SD = 1.46) matched by chronological age and overall IQ (ASD mean IQ = 90.14; SD= 14.33; TD mean = 97.07; SD = 10.99). Children's overall IQ was assessed using K-WISC-IV and its sub-component, processing speed, was used to examine the relationship between processing speed and costs of the complexity. Children's processing of simple and complex visual information was assessed using a shorter version - 24 trials in total - of Bertone et al.'s (2005) grating task. In this task, either a set of simple and complex static gratings was presented on a computer monitor either horizontally or vertically. Children were asked to report the orientation of each grating set by pressing one of the right or top arrow keys and their accuracy and reaction times were recorded by a computer. Additionally, unlike previous studies, we directly quantified costs of the complexity by computing differences in reaction times and accuracy between simple and complex conditions.

Results: Mean accuracy and reaction times did not differ across ASD and TD children in either simple or complex condition (ps > 0. 23). However, costs of the complexity in reaction times, not in accuracy, were greater in the ASD group than in the TD group ($F(1,31) = 9.699$, $p= .004$). This high cost was also observed at the individual level - 11 of 14 ASD children showed complex cost scores above the mean of the TD group, resulting in a good level of differentiation between ASD and TD (ROC-AUC: 0.801, 95% CI = 0.628-0.974). Spearman correlation analyses showed that within the ASD group none of the overall IQ and processing speed scores have a strong association with complexity cost scores (ps > .105).

Conclusions: Our findings support the complexity-specific hypothesis in ASD children. High costs in processing complex visual information in ASD children are not simply explained by slow processing speed and could serve as a defining feature of ASD at both group and individual levels.

181 **168.181** Understanding the Beliefs and Experiences of Practitioners Who Have Worked in Multi-Sensory Environments with Children on the Autism Spectrum

K. L. Unwin*, G. Powell and C. R. Jones, Wales Autism Research Centre, Cardiff University, Cardiff, United Kingdom*

Background: Multi-Sensory Environments (MSEs; also called sensory or Snoezelen rooms) are present in most special needs schools across the UK, and are widely used with individuals on the autism spectrum. MSEs typically contain a variety of equipment that changes the sensory environment for educational or therapeutic benefit. Despite the wide use of MSEs, their effect and overall efficacy has been under-researched, with previous investigations presenting mixed findings.

Objectives: To understand the possible effects and overall efficacy of using MSEs with children with ASD by asking school-based practitioners in the UK about their beliefs and experiences.

Methods: Data collection is ongoing, here we present data from forty-nine school-based practitioners (43 female, aged 24-60 years, M=38.6) who were predominantly (n=27) teachers or teaching assistants. Each practitioner completed a 28 item online survey about their use of MSEs with autistic children in schools. Items were based on our previous qualitative findings. The practitioners were asked how strongly they agreed or disagreed with each statement on a five-point Likert scale, with percentage agreement calculated.

Results: Practitioners believed that there were multiple benefits to MSE use with autistic children including, reducing anxiety (96%), creating or increasing positive mood (90%), and decreasing challenging behaviours (90%). A large majority of practitioners (90%) believed that benefits were possible because the MSE was motivating and allowed the child to control their sensory environment. 86% of practitioners believed that the MSE could bring benefits not achievable through other school activities. However, 51% stated that MSE use did not always bring benefits. All practitioners agreed that the method of MSE use should be determined by the pupil's needs, suggesting that MSE use should not be used as a 'one-size-fits-all' activity.

Conclusions: Practitioners believed that MSEs were useful for autistic children, producing a range of positive outcomes. They believed these positive outcomes were possible because of the properties of MSEs (e.g. motivating), suggesting that MSEs may hold a unique function within schools. However, although positive outcomes were possible within the MSE, practitioners also reported that children's experiences and their subsequent behaviours varied. The data suggest further investigation is needed to establish the circumstances in which MSE use brings benefit to autistic children. Consequently, a follow-up study directly observing the behaviour of autistic children in a purpose-built MSE at the Wales Autism Research Centre, Cardiff University is in progress.

182 **168.182** Upper-Limb Movement Kinematics and Motor Proficiency Are Associated with the Severity of Autism Spectrum Disorder

*S. Busti Ceccarelli[1], S. Grazioli[1,2], A. Cesareo[3], G. M. Marzocchi[2], M. Molteni[1], M. Nobile[1] and **A. Crippa**[1,2], (1)Scientific Institute, IRCCS Eugenio Medea, Bosisio Parini, Italy, (2)Department of Psychology, University of Milano-Bicocca, Milano, Italy, (3)Dipartimento di Elettronica, Informazione e Bioingegneria, Politecnico di Milano, Milano, Italy*

Background: Although the core features of Autism Spectrum Disorder (ASD) are social impairment, communication abnormalities, and restricted and repetitive behaviors, fine and gross motor disturbances can present alongside core characteristics of the disorder and can have a significant impact on quality of life and social development (Lai et al., 2014). Quantitative methods, such as kinematic analysis, can describe precisely the spatial and temporal dimensions of the motor impairments associated with ASD, potentially identifying a well-defined motor phenotype within the spectrum.

Objectives: To investigate whether a group of school-aged, high functioning children with ASD would show abnormalities in kinematics of a simple reach-to-drop task. On the basis of our previous findings in a sample of preschool children with ASD (Forti et al., 2011, Crippa et al., 2015), we hypothesized that children with ASD would differ from typical developing peers in terms of the basic kinematics related to the second part of the movement, in which the participant transported the ball from a support to the target hole. In addition, to investigate whether, in our sample of individuals with ASD, kinematics abnormalities are linked with core clinical symptom severity, we correlated performance on this task and on other standardized motor measures with severity scores of ASD.

Methods: Fifteen children with ASD and twenty typically developing children (TD) aged between 6 and 12, matched by gender, age, and perceptual reasoning were enrolled. Three-dimensional kinematic data were collected by a motion-capture system based on eight infrared cameras during a simple reach-to-drop task. In addition, we assessed motor proficiency using the Movement Assessment Battery for Children—2 (MABC 2; Henderson et al., 2007), the Beery-Buktenica Developmental Test of Visual-Motor Integration (VMI; Beery and Beery, 2010) and an abbreviated battery of test from NEPSY-II (Korkman et al., 2007). The severity of ASD spectrum symptoms was measured with Social Responsiveness Scale (SRS; Constantino, 2002).

Results: Children with ASD showed lower peak of deceleration in the second part of movement ($p<0.05$), and scored significantly lower in MABC 2 and NEPSY-II (all $p<0.05$). The degree of clinical symptom severity was positively correlated with difficulties in balance, tapping, and with anomalous upper-limb kinematics all $p<0.05$).

Conclusions: These preliminary findings extend earlier investigations of our group (Forti et al., 2011; Crippa et al., 2015), depicting kinematics abnormalities also in children with ASD of school age. These peculiarities and other impairments in the motor domain are significantly associated with core clinical symptom severity of ASD.

183 **168.183** Which Motor Stereotypy Subtypes Are Most Indicative of an Autism Spectrum Disorder in Early Childhood?

***A. K. McCullough**[1,2], S. Lopez-Pintado[3] and S. Goldman[4], (1)Neurology, Columbia University Medical Center, New York, NY, (2)Teachers College, Columbia University, New York, NY, (3)Biostatistics, Columbia Universty - Mailman school of Public Health, New York, NY, (4)Department of Neurology, Division of Child Neurology, Columbia University Irving Medical Center, New York, NY*

Background:

Motor stereotypies, defined as repetitive, patterned, purposeless behaviors, are one of the hallmark behaviors in children with a diagnosis of autism spectrum disorders (ASD). However, these hyperkinetic movements are also reported in selected populations of children with non-autistic neurodevelopmental disorders, and during infancy in typically developing children. To date, the majority of studies focusing on stereotypies have used parent-reported questionnaires, which offer insufficient details for targeted discriminative analyses of restrictive and repetitive motor behaviors.

Objectives:

Therefore, the purpose of this study was to use a reliable motor stereotypy video coding system (Goldman, 2008) to identify and score each motor stereotypy in children with ASD and children with non-ASD developmental disorders (NASDD) in order to 1) examine which stereotypy subtypes reveal the most salient characteristics of restrictive and repetitive motor behavior in early childhood, and 2) determine which stereotypy subtypes best distinguish children with ASD from NASDD children.

Methods:

Motor stereotypies were coded individually from the first 15 minutes of 30-minute standardized video-recorded play sessions. A cohort of N=277 preschool children with a neurodevelopmental disorder [F: 24.5%(68); age: 4.6(1.2) years], with and without a comorbid diagnosis of ASD [ASD: 47%(129)], was recruited through a multi-site study focusing on neuropsychological and psychiatric assessments. For each video, the following topographical descriptors were used to generate eight mutually exclusive stereotypy subtypes: face, head/trunk, arm/leg, hand/finger, hand/finger with object, gait, self-directed, and visual.

Data were analyzed in MATLAB R2016b, and descriptive statistics were calculated as Mean (SD), and Frequencies [%(n)]. Among children with stereotypies, frequencies of stereotypy subtypes were entered into a principal components analysis (PCA) with a varimax rotation. PCA stereotypy subtypes with loadings ≥0.40 were used to interpret components. Then, using the entire cohort, associations between an ASD diagnosis and the presence of select motor stereotypy subtypes, as determined by the PCA, were tested using logistic regression (LR) and the odds ratios (OR) were calculated. Finally, the Receiver Operating Characteristic Area Under the Curve (AUC) was evaluated. All models were run with an a priori significance level of $p<0.05$.

Results:

All children [*n*=122, ASD: 72%(88)] with stereotypy frequencies >1 were included in the PCA. Results showed that three components explained 76.6% of the variance, and could best be described by the following motor stereotypy subtypes: (1) self-directed, (2) limb (arm, leg, foot, and hand stereotypies combined), and (3) object-oriented. LR showed that, in the full cohort, the presence of limb (OR: 6.9) and object-oriented (OR: 3.01) stereotypies were significantly associated with an ASD diagnosis, while self-directed stereotypies were not (OR: 1.4). The LR model AUC was 0.75, with a sensitivity and specificity of 86% and 58%, respectively.

Conclusions:

A subset of motor stereotypies (self-directed, limb, and object-oriented) appear to be the most salient motor stereotypy subtypes at preschool in both children with and without ASD. Only the limb and object-oriented subtypes, however, appeared to sufficiently identify children with an ASD diagnosis. These results are particularly relevant to clinical assessments of autism in young children, as they may help to strengthen a diagnosis.

184 **168.184** "My Sensory Experiences": Everyday Sensory Preferences and Challenges Revealed By Young People on the Spectrum Using a Picture-Based Interview Tool

J. Ashburner[1] *and N. Bobir*[2]*, (1)Autism Queensland, The University of Queensland, Sunnybank, Australia, (2)Research and Business Development, Autism Queensland, Sunnybank, Australia*

Background: Information about the sensory responses of people on the spectrum is commonly gathered through parent/caregiver or teacher questionnaires. The perspective of the person on the spectrum is less commonly considered. As sensory sensitivities can contribute to distress and challenging behaviours, it is important that they are understood and accommodated.

Objectives: This project aimed to (a) evaluate the clinical utility of *My Sensory Experiences*, a tool which utilises photographic representations of every-day sensory experiences, combined with open-ended questions to assist individuals on the spectrum in describing their sensory experiences, and (b) analyse the nature of everyday sensory experiences that are frequently preferred or that present challenges.

Methods: Three cycles of participatory action research guided the development of *My Sensory Experiences*. Participants included 44 individuals on the spectrum (aged 8-49 years), 33 parents, and 5 occupational therapists. During the first two cycles, semi-structured interviews were conducted with 5 occupational therapists and 11 parents. In the final cycle, 21 children and 12 adults on the spectrum, and 21 parents completed surveys with closed- and open-ended questions. The feedback was analysed using (a) descriptive statistics, and (b) content analysis of the transcribed interviews and open-ended survey questions. The frequency with which items were identified as bothersome or calming, was also analysed using descriptive statistics.

Results: "My Sensory Experiences" uses photographs depicting sensory input in everyday contexts such as shopping centres, classrooms, and hairdressers, including everyday experiences that individuals often find challenging, calming or that they seek out. The tool includes child/adolescent and adult versions, and a family observation form. Although the tool can be completed independently by people on the spectrum and their families, administration through an interview provides a more in-depth, personalised perspective on the person's sensory preferences. The tool is intended to augment rather than replace standardised norm-referenced sensory processing assessments. In terms of clinical utility, the interview format and visual cues enabled people on the spectrum to express their preferences, and develop greater self-awareness of their sensory preferences, so that they were better able to self-advocate and develop their own strategies. The visual cues were reported to capture the full range of sensory experiences that are often liked or disliked. Occupational therapists appreciated the richness of the information gathered and its relevance to the person's life. Parents gained new insights into their child's sensory preferences. Analysis of the everyday sensory experiences that were frequently identified as challenging included unpredictable or uncontrollable sensations such as sirens, people talking or flickering lights. Sensations that are predictable and controllable such as repetitive patterns or sounds were often reported to be calming. Many people described difficulties filtering sensory information such as following someone talking in a noisy environment.

Conclusions: *My Sensory Experiences* effectively captures the voice of people on the spectrum. Analysis of items that are commonly preferred or that present challenges can inform the design of everyday environments to better accommodate the sensory needs of people on the spectrum.

185 **169.185** Affective Salience Influences Looking Preference for Social Elements during Interactive Play Scenes in Young Children with Autism

L. Ruta[1]*, G. Tartarisco*[1]*, I. Dubey*[2]*, F. Fama'*[3]*, L. Spadaro*[3]*, C. Carrozza*[1]*, E. Leonardi*[3]*, F. Marino*[1]*, P. C. Torre*[4]*, S. Baieli*[4]*, R. Scifo*[4]*, G. Pioggia*[1] *and B. Chakrabarti*[2]*, (1)Institute of Applied Sciences and Intelligent Systems, "Eduardo Caianiello" (ScienceApp) – National Research Council of Italy (CNR), Messina, Italy, (2)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (3)Institute of Applied Sciences and Intelligent Systems, National Research Council of Italy (CNR), Messina, Italy, (4)Centre for Autism Spectrum Disorders, Child Psychiatry Unit, Acireale Hospital, Provincial Health Service (ASP), Catania, Italy*

Background:

In typically developing children, social elements within natural scenes substantially bias allocation of attention (Chevallier et al., 2012). Furthermore, affective salience and positive affect act as additional cues to drive attention and engagement within complex scenes (Pool 2016). Reduced preference for social stimuli has been reported in autism and related to social learning impairment (Dawson 2012; Chita-Tegmark 2016).

Eye-tracking studies using dynamic social stimuli, indicated that children with autism specifically fail to attend to social cues in more naturalistic conditions (Chawarska et al., 2012; Chevallier et al., 2015). However, none of these studies have systematically manipulated the level of emotional salience of social cues, and tested its impact on the looking patterns for natural interaction scenes.

Objectives:

To test, using an eye-tracking experiment, whether a) children with and without autism attend equivalently to videos of naturalistic interactive play; b) affective salience and positive affect are able to modulate attention to social-related elements of interactive play scenes equivalently in children with and without autism.

Methods:

Fifty-eight male children (19 children with autism (ASD) and 29 typically developing children (TD)), aged 35-75 months were enrolled in the study.

The experiment consisted of 6 trials (3 different trials, each repeated in a neutral and an affectively salient condition) of a child and an adult interacting with objects (fish game, blocks and toy train) in a naturalistic play interaction, presented on a computer screen. Each trial lasted 25 seconds and was presented in a random order. Gaze patterns were recorded with a SMI iView XTM RED dark-pupil 120Hz eye-tracking system (Sensomotoric Instruments, 2005) and exported using SMI BeGaze 2.4 software. Statistical analyses were conducted using R (http://www.r-project.org/). A linear mixed effects model (package: lme4) was applied to explore the effect of group and condition (neutral vs salient) to predict looking time (dwell time) in the regions of interest (adult and child face, activity area, background).

Results:

A main effect of group (Wald χ^2=10.02, p=.002 ; Wald χ^2=4.5, p=.03; Wald χ^2=3.5, p =.06) and condition (Wald χ^2=6.7, p=.01; Wald χ^2=4.6, p=.03; Wald χ^2=6.04 , p=.01) was observed on the looking time to the adult face in all the trials, with the ASD children looking significantly less than the TD children at the adult face and the salient condition significantly enhancing the looking time to the adult face in both ASD and TD children. No group by condition interaction was found (Wald χ^2=0.11, p=.74; Wald χ^2=0.4, p=.54; Wald χ^2=0.5, p=.5).

Conclusions:

We found a significant group difference in the amount of time spent attending to the social elements of the scene, with the ASD children attending less than the TD children to the adult face. Furthermore a significant effect of affective salience was noted, with an increase of time spent attending to the faces in both the ASD and TD children during the salient condition.

This study provides preliminary evidence of a substantial influence of affective salience in visual orientation and exploration of social-related elements in naturalistic play interaction scenes in young children with autism.

186 **169.186** Affective State and Decision Making in Autism Spectrum Disorder: Evidence from the Ultimatum Game

A. Acosta Ortiz[1]*, S. B. Gaigg*[2] *and S. Reimers*[2]*, (1)City University London, London, United Kingdom, (2)City, University of London, London, United Kingdom*

Background:

Classical economic models regards decision-making as an exclusively cognitive process, however Bechara et al., (1997) and Camerer (2003) show that emotions and their associated physiological process influence decision making. This was demonstrated by Sanfey et al., (2003) and Van't Wout et al., (2006), in the context of the Ultimatum game (UG; Güth et al, 1982), in which a proposer can decide how to split a given amount of money (£10) between themselves and a responder who can either accept or reject the offered amount. If s/he accepts, the money is paid out as proposed; if s/he rejects neither participant receives any amount. Both Sanfey et al., (2003) and Van't Wout et al., (2006) reported an association between high skin conductance and rejection of unfair offers, suggesting that emotional processes influence people's decisions. Social-cognitive processes are also thought to play a role, such as considerations of fairness and the intentions of proposers. The difficulties ASD demonstrate in social cognition and in processing emotional related information (Johnson et al, 2006; Maras, Gaigg, & Bowler, 2012) would lead to the prediction that the decisions ASD make in the UG would be less contingent on emotional responses to offers and be less influenced by whether offers stem from an intentional agent (human) or non-intentional machine (computer).

Objectives: To test the above prediction by examining the physiological responses to human vs. computer generated offers in ASD and comparison participants on a multitrial version of the UG that require a standard accept/reject response to offers that varied in fairness.

Methods: 36 ASD and 36 age and ability matched comparison adults completed 24 UG, half time receiving offers from people and the other half pseudo-randomly generated by a PC. In each condition, twelve trials were fair (£5 vs £5) and twelve unfair (£9 vs £1; £8 vs £2; £7 vs £3). Offers were presented in a random order and skin conductance and heart rate recorded. After offer presentation, in the form of a short video-clip or animation, which showed either a real person or the computer generating an offer, participants were prompted to accept or reject. Not time limit was imposed and feedback was given at the end, yet participants knew that all decisions would be paid out at 10% of their value at the end of the experiment

Results: Unfair offers proposed by humans were more frequently rejected than unfair offers proposed by the computers. Similarly, GSR responses to unfair compared to fair offers were greater in the human than the computer condition $F(1,65) = 5.911$, $p = .018$, $\eta^2 = .083$ .No differences between ASD and comparison participants was observed

Conclusions: The results confirmed observations by Sanfey et al., (2003) and van't Wout et al., (2006), which show that emotional and social-cognitive factors are involved in rejection of unfair offers in the UG. The predicted difference for the ASD was not supported, suggesting that difficulties in emotional and social-cognition might not confer a disadvantage in the context of social-economic decision making.

187 **169.187** Altered Responses to Social Chemosignals in Autism Spectrum Disorder

Y. Shapira[1]*, O. Perl*[2]*, A. Ravia*[2]*, D. Amir*[2]*, A. Eisen*[2]*, V. Bezalel;*[2]*, L. Rozenkrantz*[2]*, E. Mishor*[2]*, L. Pinchover*[2]*, T. Soroka*[2]*, D. Honigstein*[2] *and N. Sobel*[2]*, (1)Weizmann Institute of Science, Rehovot , Israel, (2)Weizmann Institute of Science, Rehovot, Israel*

Background:

Social chemosignals are volatiles secreted by one individual to affect the behavioral, physiological, brain activity and hormonal state of other individuals. A Growing body of evidence implies that social chemosignals likely play a major role in human social interaction, mostly without conscious awareness.

Objectives: Because Autism spectrum disorder (ASD) is characterized by impaired social communication, often attributed to misreading of emotional cues, we hypothesized that misreading of emotional cues in ASD partially reflects altered social chemosignaling.

Methods:

In a series of experiments we investigated this hypothesis by comparing the physiological and behavioral responses of typically developed (TD) adults and cognitively able adults with ASD to the subliminal presentation of social chemosignals. In the first two experiments, we tested the effects of *smell of fear* (actual body-odor collected from first-time tandem skydivers). We tested the physiological responses to the *smell of fear* in both TD (n =20) and ASD (n=20) participants, and in a second experiment we tested how TD (n =20) and ASD (n=20) participants respond behaviorally to the *smell of fear*. Then, we tested the impact of two different isolated putative social chemosignals. The first is a commonly studied putative social chemosignal, 4,16-androstadien-3-one (AND). we measured the impact of AND on physiological measures using a widely applied assay for human chemosignaling (TD, n =23, ASD, n = 17). The other chemosignal tested is a novel putative compound, hexadecanal (HEX), a molecule that promotes social buffering in rodents. Given that HEX is also present in human skin, we measured the impact of HEX on the acoustic startle response, a brainstem aversive reflex that occurs after a startling event such as a loud noise (TD, n =17, ASD, n = 17).

Results:

The undetected *smell of fear* increased physiological arousal in TD yet did not affect arousal in ASD ($F_{1,34}$ = 12.8, p = 0.001). In addition, the undetected *smell of fear* reduced explicit and implicit measures of trust in TD, but acted opposite in ASD ($F_{1,37}$ = 10.1, p < 0.003). The putative chemosignal AND drove increased arousal in TD yet decreased arousal in ASD ($F_{1,37}$ = 8.0, p = 0.007). Finally, the putative chemosignal HEX significantly reduced startle in TD but not in ASD ($F_{1,30}$ = 7.7, p < 0.01).

Conclusions: Experiments with subliminal presentation of a natural stimulus (*smell of fear*) and two different synthetic putative social chemosignals (AND and HEX) converged to imply altered autonomic and behavioral responses to social chemosignals in ASD. I speculate that altered response to chemosignals may be involved in part of the symptoms of ASD. This speculation suggests novel paths of research, diagnosis, and treatment.

188 **169.188** Analysis of Teacher-Student Interactions within Classroom Activities: Implications for Effective Instructional Practices

N. Sparapani[1]*, L. Towers*[1]*, J. Traser*[1]*, J. Suhrheinrich*[2]*, S. R. Rieth*[2,3] *and A. C. Stahmer*[4]*, (1)School of Education, University of California, Davis, Davis, CA, (2)San Diego State University, San Diego, CA, (3)Child and Adolescent Services Research Center, San Diego, CA, (4)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: High quality interactions between teachers and students are associated with accelerated academic development (Burchinal et al., 2008), more student participation (Ponitz et al., 2009), and communication and language development (Walsh, 2002). During high quality interactions, teachers encourage children to contribute, generating ideas and questions that further the interaction while supporting the learning process by shaping and expanding on the children's contributions. Teachers' use of responsive language, which follows the child's lead, is delivered with positive affect, and is sensitive and respectful, is a key marker of interaction quality (Landry et al., 2006; Kim & Mahoney, 2004; Lawrence et al., 2015). Little research has examined teachers' use of responsive language and its impact on learning and development within educational settings for students with ASD.

Objectives: This study utilized video observations to examine the relations between teachers' responsive language and students' initiations within a sample of school-age children with ASD.

Methods: Participants included (*n* = 123) preschool–3rd grade students with ASD and their teachers across 66 schools and 16 districts enrolled in a longitudinal study evaluating the efficacy of classroom-based Pivotal Response Training (PI Stahmer). At study entry, ASD diagnoses were confirmed using the ADOS-2, and IQ was estimated using the *Differential Abilities Scales-II* (DAS-II; Elliott, 2007). Video-recorded classroom observations of students and their teachers were collected across a two-year period. The current study utilized video observations from the beginning of the school year, measuring the frequency of teacher responsive language and students' communication initiations across three categories, commenting, asking questions, and seeking clarification. Trained research assistants coded the teacher and student dimensions within classroom activities using Noldus Observer® Video-Pro Software (XT 14). Inter-rater agreement between the coders using percent agreement and Cohen's Kappa coefficients indicated overall good reliability, with coefficients ranging between 80–97% in agreement (Kappa = 0.72) across behaviors within each dimension.

Results: Lag sequential analysis was used to examine the frequency of student initiations following and preceding teachers' responsive language. Preliminary analyses including 30 students (M_{age} = 7.09, *SD* = 1.84) and 21 teachers indicated that on average students initiated communication 2.5 times following teachers' responsive language within a 10-second tolerance window (56% on-topic commenting; 30% seeking clarification; 12% asking content-related questions). Teachers responded 5.2 times on average (45% of the time) to students' communicative initiations across the observation. Furthermore, quality ratings (1–3) assigned to each activity as a measure of overall responsiveness were associated with a higher frequency of student on-topic commenting (*r* = .54, *p* < .01) and asking on-topic questions (*r* = .47, *p* < .01) after controlling for NVIQ (*M* = 85.09; *SD* = 13.49).

Conclusions: These data provide preliminary conceptualization and operationalization of key student and teacher interaction dimensions, providing insight into patterns of interaction between students with ASD and their teachers within classroom activities. Findings suggest that teachers' use of responsive language is associated with a higher frequency of student on-topic initiations. These data may have important implications for understanding the quality of instructional practices for students with ASD within educational settings.

189 **169.189** Anxiety and Social Initiation in Young Children with Autism Spectrum Disorder

R. A. Bowler*, E. A. Bisi and B. J. Wilson, Seattle Pacific University, Seattle, WA*

Background: Previous research indicates that children with autism (ASD) are less likely to initiate social interactions (Rivard et al., 2016) which may result in decreased opportunities for effective social development (Schietecatee et al., 2012). Many children with ASD also experience co-occurring anxiety, with recent studies reporting comorbidity rates as high as 40% (Kerns et al., 2016). Moreover, previous literature suggests that anxiety is associated with several social communication impairments (Taylor & Gotham, 2016), but the relation between anxiety and social initiation in school-aged children with ASD is not clear (Swain, Scarpa, White, & Laugeson, 2015).

Objectives: The purpose of this study was to examine the role of anxiety on social initiation behaviors in children with ASD compared to their TD peers. Anxiety was hypothesized to moderate the relation between developmental status and social initiation behaviors, such that children with autism and high anxiety would have the lowest level of social initiation behaviors compared to the TD sample.

Methods: Our sample included 110 children (ages 3:0 to 6:11), 71 (49 % female) TD children and 45 children with ASD (20% female). Video recordings of an 8-minute parent-child free-play task were coded using an adapted version of the Modified-Classroom Observation Schedule to Measure Intentional Communication (M-COSMIC; Clifford et al., 2010), from which percentages of child social initiations were obtained. Child anxiety ratings were collected using the Parent-Form Anxiety subscale of the Behavioral Assessment System for Children—Second Edition (BASC-2; Reynolds & Kamphaus, 2004).

Results: A moderated multiple regression analysis was conducted using the PROCESS macro for SPSS (Hayes, 2013). Child age, gender, and verbal ability were controlled for in the analysis. Findings included a significant main effect for developmental status on social initiation (B = -.225, CI_{95} [-.423, -.026], p = .027), which supported our hypothesis that children with ASD would initiate less than TD children. There was a nonsignificant main effect for anxiety on social initiation (B = .001, CI_{95} [-.002, .003], p = .558), contrary to our hypothesis that lower levels of anxiety would yield higher levels of social initiation. Finally, the interaction between developmental status and anxiety on initiation was nonsignificant (B = .002, p = .393), but trending in an unexpected direction. While the TD group demonstrated the highest levels of social initiation overall, children with ASD and high levels of anxiety demonstrated the highest levels of social initiation for the ASD group. Results suggest that the variables in our model accounted for 38% of the variance in initiations.

Conclusions: Consistent with previous research, children with autism initiated fewer social interactions with their parents than TD children (Humphrey & Symes, 2011; Rivard et al., 2016), but children with ASD in our study did not have higher levels of anxiety. Although nonsignificant, results suggest the frequency of social initiations in children with ASD tended to increase with higher child anxiety. Future research should investigate the function of anxiety in the social interactions of children with ASD, as moderate levels of anxiety may potentially be adaptive in young children with ASD.

190 **169.190** The Role of Theory of Mind on the Stress Intensity of Parents of Young Children with Autism

***R. A. Bowler**, T. Estrada, A. J. Lee, T. M. Rutter, B. Van Vleet and B. J. Wilson, Seattle Pacific University, Seattle, WA*

Background: A substantial amount of research indicates that parents of children with ASD experience higher levels of stress than parents of typically developing (TD) children (Rao & Beidel, 2009). In addition, research suggests that children with ASD have deficits in theory of mind (ToM), the ability to attribute mental states to others and oneself (Baron-Cohen, Leslie, Frith, 1985; Colle, Baron-Cohen, & Hill, 2007). Limited research suggests that increased parental stress may predict lower child ToM abilities, but this association has yet to be explored in children with ASD (Guajardo, Snyder, & Petersen, 2008).

Objectives: Understanding the factors that may contribute to parental stress is crucial in both treatment outcomes and family functioning. We hypothesized that a child's ToM ability would moderate the association between developmental status and the intensity of parental stress, such that parents of children with ASD and lower ToM skills would report the most intense stress.

Methods: Participants were 101 children (ages 3:0 to 6:11) and their parents. Sixty-one children were typically developing (38% female) and 40 children had a diagnosis of autism spectrum disorder (25% female). Children's theory of mind was assessed using a battery of tasks comprised of a diverse beliefs task, an unexpected contents false belief task and a changed location false belief task. Intensity of parenting stress was reported by parents on the Parenting Daily Hassles Scale (Crnic & Greenberg, 1990). Children's verbal abilities were measured using the verbal comprehension and naming vocabulary subtests of the Differential Ability Scales II (DAS-II; Elliot, 2007).

Results: A moderation analysis using the SPSS macro PROCESS (Hayes, 2013) evaluated whether the association between developmental status and intensity of parental stress is moderated by child ToM abilities. Controlled variables included children's language abilities and age. Results indicated the main effect of status on parental stress intensity (B = -1.509, CI_{95} [-12.386, 9.368], p = .783) and the main effect of ToM skills on parental stress intensity were not significant (B = -.956, CI_{95} [-4.673, 2.761], p = .611). The contribution of the interaction between status and ToM was significant, $\Delta R2$ = .04, F(1, 95) = 4.012, p = .048. Specifically, at higher levels of ToM ability in children with ASD, parental stress intensity is higher (ToM = 3: B = 16.516, CI_{95} [5.248, 27.784], p = .005; ToM = 2: B = 10.501, CI_{95} [3.217, 17.798], p = .005). When ASD children had low levels of ToM ability, parental stress intensity did not differ compared to parents of TD children.

Conclusions: The current study found that parents of children with ASD and higher ToM abilities experienced the highest intensity of stress, in contrast with our hypothesis and limited past research. The findings suggest that, although children with ASD and higher ToM abilities may appear more similar to their TD peers, their parents may be experiencing more intense stress than parents of TD children. More research is needed to better understand the experience of stress in parents with children with ASD.

191 **169.191** Atypical Scanning Patterns of Static Social Scenes in ASD: Results from the ABC-CT Feasibility Study

***E. Barney**[1], F. Shic[1], A. Naples[2], S. J. Webb[3], M. Murias[4], C. Sugar[5], J. Dziura[6], C. Brandt[6], R. Bernier[3], G. Dawson[7], S. Jeste[5], C. A. Nelson[8] and J. McPartland[2], (1)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (5)University of California, Los Angeles, Los Angeles, CA, (6)Yale University, New Haven, CT, (7)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (8)Boston Children's Hospital, Boston, MA*

Background: Previous eye-tracking research has shown that children with ASD spend less time looking at faces and eyes than their typically developing (TD) peers (Hanley et al., 2013; Riby & Hancock, 2008, 2009; Sasson et al., 2007). When faces are shown in the context of complex social situations, these diagnosis group differences may be larger (Hanley et al., 2013; Speer et al., 2007).

Objectives: To examine face preference (%Face) of children with and without ASD when looking at static social photographs presented during eye tracking. These results were reviewed in conjunction with the preference for looking on screen at all (%Valid). Exploratory analyses were conducted to assess face preference differences across trials (to examine scene qualities that amplify group differences) and over time within trials (to investigate how long stimuli need to be shown for differences to be detected).

Methods: Eye-tracking data was collected from 51 children (N_{ASD} = 25, N_{TD} = 26) aged 4-11 using a 500 Hz EyeLink 1000 Plus. Forty-seven (N_{ASD} = 23, N_{TD} = 24; $\mathrm{M}_{\mathrm{Age}}$ = 7.3 ± 2.2 years) remained after quality exclusions (trials: <50% onscreen looking or >2.5 degrees of calibration error; participants: <2 of 6 valid trials). Each static social image (from the EU-AIMS LEAP task battery) was presented for 20 seconds.

Results: Linear mixed models controlling for image and full scale IQ were used to examine group differences on %Valid and %Face. For %Valid, we observed a main effect of group (ASD<TD; p<.01, d=1.6). Exploratory time bin analyses (5s bins) revealed a main effect of time (%Valid decreasing over time; p<.001) and a group*time interaction (p<.01): ASD and TD groups had similar %Valid in the first five seconds, but between-group differences increased over time (6-10s: p<.05, 11-15s: p=.001, 16-20s: p<.001). For %Face, a group effect was observed in the expected direction (ASD<TD; p<.001, d=0.91). Exploratory analyses including a group*image interaction showed the ASD group looked less at faces than TD participants for all images except an image of a single person coloring (all other images involved multiple people). Further analyses examined how long images needed to be shown to observe between group differences. A group effect appeared for all presentation times examined, ranging from 0-10s (p<.001, d=0.82) to 0-1s (p<.01, d=.77), indicating pervasive differences in face looking. The strongest effect size was seen for 0-5s (p<.001, d=1.02), matching up to the time when no between-group differences in %Valid were observed.

Conclusions: Eye-tracking results from static social images revealed consistent and large differences in face preference between children with and without ASD. An exploratory content analysis suggested increased social complexity may increase group differences. An exploratory time analysis revealed face-looking differences as early as the first second of presentation, indicating that shorter trials may be sufficient for between group differentiation. Finally, the correspondence of the largest face-looking effect size in the first five seconds to a period where no between-group differences existed in overall looking potentially highlights the separability of social attention differences specific to ASD from general attention differences.

192 **169.192** Autism Spectrum, Risk Behavior, and Law Involvement: Contrbutions of Theory of Mind and Executive Function

ABSTRACT WITHDRAWN

Background:
Are young adults with autism spectrum disorder (ASD) overrepresented in the criminal justice system? Research is inconclusive. However, examining the relation of risk behaviors and law involvement to the core features of ASD may be a more useful than examining prevalence per se (Woodbury-Smith, 2014).

Objectives:

We sought to explore pathways by which individuals with ASD may be at risk for criminal justice involvement: a direct path in which ASD increases the likelihood of risky and unlawful behaviors, or an indirect path in which persons with ASD may react poorly to the social demands of interactions with law enforcement around lesser offenses, e.g., traffic violations, to escalate the situation. In this exploratory study, we tested cognitive and social-cognitive functions associated with ASD, but that also vary in the general population, to explore their relation to risk behavior among college-aged males, both neurotypical and with ASD.

Methods:

Participants were 40 college aged males, 12 with ASD. Measures included both self-report and direct observations. We combined correlated scores from the AQ and SRS-2 (Baron-Cohen, Hoekstra, Knickmeyer, & Wheelwight, 2006; Constantino, 2012) to create an autism index. We assessed theory of mind and executive function using report, Basic Empathy Scale (Joliffe & Farrington, 2006) and BRIEF-A (Roth, Isquith, & Gioia, 2013), and behavior, Flanker (Eriksen & Eriksen, 1974), Go/NoGo (Filmore, 2006), Wisconsin Card Sort (Grant & Berg, 1948), Reading the Mind in the Eyes (Baron-Cohen, et al. 2001), and Mentalistic Interpretation (Channon & Crawford, 2010). Risk behaviors, assessed by self-report, included general risk proneness (de Haan et al., 2011), antisocial behavior (Cho, Martin, Conger, & Widaman, 2010), and risk behavior and involvement with the law (arrest, probation, incarceration; MSALT, http://www.rcgd.isr.umich.edu/msalt/researchers.htm).

Results:

Concurrent predictions were tested across the entire sample, yielding several key results. Impulsivity as indicated by Flanker reaction time (r = -.46, p < .01) and a high autism index (partial r = .35, p < .05) predicted criminal justice involvement, but elevated autism index scores were not associated with any risk behaviors per se. In fact, a low autism index and poor executive function (self-report; Go-No Go inhibition errors) predicted proneness to risk (adjusted r-square = .39, p < .001). Race (white) and impulsivity (Flanker RT) predicted antisocial behavior (adjusted r-square = .15, p < .05). Impulsivity (Flanker and Go/No-Go RT) and race (white) predicted unsafe/unlawful risk behavior (adjusted r-square = .16, p = .05).

Conclusions:

We found that the ASD index predicted law involvement, but not risk behaviors. Executive function, but not theory of mind, contributed to risk. We believe these results are consistent with an indirect pathways hypothesis. Because of failure to regulate social behavior in ways that might keep minor transgressions or altercations from becoming more serious, aspects of ASD such as compromised executive function may place these individuals at risk for a cascade of negative events that result in justice involvement. Results are limited by sample size and age, and will be discussed in the context of preliminary follow-up data from college-aged males diagnosed with ADHD.

193 **169.193** Autism, Mentalising and the Effect of Social Presence

***E. J. Morgan**, D. J. Carroll and M. Freeth, Psychology Department, University of Sheffield, Sheffield, United Kingdom*

Background:
Recent research has shown that neurotypical participants perform significantly better on explicit mentalising tasks when a real person is present, but that participants with autism do not show the same social facilitation effect (Chevallier et al., 2014). In an earlier study we studied explicit and implicit mentalising in neurotypical adults. Our findings showed that implicit mentalising was highly sensitive to a social presence, with significantly improved accuracy when a task was completed in the presence of real people. Participants with autism have been shown to display pervasive deficits in implicit mentalising ability (Senju et al., 2009; Schuwerk et al., 2016), however, no previous studies have tested the effect of a social presence on implicit mentalising in adults with autism.

Objectives:

The aim of the current study was to investigate the effect of a social presence on explicit and implicit mentalising ability in adults with an autism spectrum condition.

Methods:

We used a non-verbal second-order theory of mind task to study explicit and implicit mentalising in adults with autism (n=18, m= 40.83, SD= 15.89), and age, gender and non-verbal IQ matched neurotypical controls (n=18, m= 41.66, SD= 15.49). The task was completed in two conditions: A 'live' condition where the task was acted out in real time in front of the participant, and a 'recorded' condition where the participant was shown recorded videos of the same task.

Results:

A Mixed-Model ANOVA on data from the implicit task revealed a main effect of condition ($F(1,35) = 6.967$, $p=.012$, partial $\eta^2= .170$), as participants were significantly more accurate at the implicit task when it was completed in the live compared to the recorded condition. There was no interaction between condition and group, indicating that neurotypical participants and autistic participants showed the same improvement and performed comparably on each task. By comparison, a Mixed-Model ANOVA on data from the explicit task found that participants in both groups were as accurate in both the live and recorded conditions as there was no main effect of condition, no main effect of group and no interaction between condition and group.

Conclusions:

Our findings showed that implicit mentalising was highly sensitive to a social presence, with significantly improved accuracy when completed in the live condition. This suggests that individuals may implicitly mentalise within real life environments when faced with powerful social cues, but that this is less apparent when in environments without the potential for a social interaction. In contrast to previous research, our results showed no difference in mentalising ability between the neurotypical and autistic participants, suggesting that implicit mentalising deficits are not as pervasive as previously assumed and that adults with autism also demonstrate a social facilitation effect.

194 **169.194** Caregiver Viewing Patterns during Infant-Caregiver Dyadic Interactions

A. Kreuzman[1,2,3]*, S. Glazer*[1,4]*, S. Shultz*[5]*, A. Klin*[5] *and W. Jones*[5]*, (1)Marcus Autism Center, Atlanta, GA, (2)Children's Healthcare of Atlanta, Atlanta, GA, (3)Emory University Department of Pediatrics, Atlanta, GA, (4)MD Anderson Cancer Center, University of Texas, Houston, TX, (5)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: The first six months of life constitute a uniquely important period of growth and development for human infants, during which normative social development in typically developing (TD) infants is scaffolded and facilitated by highly contingent and mutually-reinforcing interaction with caregivers. In order to create and sustain high degrees of contingency, caregivers and infants must be closely attuned to one another's behavior on a moment-by-moment timescale. Caregivers, for example, must allocate their visual resources to maximize perception of developmentally important infant cues, such as smiling or the initiation of eye contact, in order to optimally respond to these signals and thereby elicit further signaling. In doing so, caregivers promote future opportunities for learning via continued social interaction. Infants later diagnosed with autism spectrum disorder (ASD), however, show a reduction in shared smiles and mutual eye gaze, behaviors that would otherwise serve as important signals to caregivers (Stallworthy et al., 2016; Ozonoff et al., 2009). These differences in infant signaling may then alter or disrupt social contingency in the infant-caregiver dyad, in turn influencing caregiver behavior. This study seeks to investigate whether subtle differences in the behavior of infants later diagnosed with ASD are reflected in changes in caregiver viewing patterns.

Objectives: To examine and quantify caregivers' visual scanning of infant faces during dyadic interactions with TD infants and infants with ASD.

Methods: Eye-tracking data were collected from caregivers and their 2- to 6-month-old infants during three 30-second interactions via closed-circuit live video feed. Diagnostic evaluations at 24 and 36 months were used to separate participants into two groups: caregivers whose infants received an ASD diagnosis at outcome (n=6), and those whose infants were TD and had no family history of ASD (n=6) (Table 1). Caregiver eye-tracking fixation locations were coded relative to four mutually exclusive regions of interest (ROIs): eyes, mouth, nose/body, and background.

Results: To compare caregiver fixation patterns across groups, we performed a repeated-measures ANOVA with diagnosis as a between-subjects factor and ROI as a within-subjects factor. We observed a significant main effect of ROI ($p<0.001$), with caregivers fixating more on their infant's eyes than mouths, and more on infant's mouths than bodies (all p's<.05). The diagnosis by ROI interaction trended towards significance ($p=0.096$). Exploratory independent-samples t-tests revealed a trend towards increased mouth-looking in caregivers of TD infants compared to caregivers of infants with ASD (p=0.067) (Figure 1).

Conclusions: Preliminary analyses provide the first exploration of caregiver viewing patterns during infant-caregiver dyadic interactions, revealing that caregivers spend more time fixating on their infant's eyes, followed by mouth, and body. Immediate next steps include increasing the sample size to further investigate the observed trend towards increased mouth-looking in caregivers of TD infants. Additionally, longitudinal analyses of infant affect, facial cues, and vocalizations will be completed to identify specific infant signals that influence moment-by-moment shifting of caregiver visual attention. These analyses have important implications for understanding how early disruptions to interactive contingency within the infant-caregiver dyad may impact subsequent development in infants with ASD.

195 **169.195** Changes in Social Referencing in Response to Pivotal Response Treatment in ASD: A Preliminary Eye Tracking Study

M. Kim[1]*, C. Foster*[2]*, Q. Wang*[3]*, C. A. Wall*[4]*, B. Li*[5]*, E. Barney*[6]*, Y. A. Ahn*[7]*, L. L. Booth*[8]*, M. Lyons*[3]*, C. A. Paisley*[9]*, C. C. Kautz*[8]*, F. Shic*[6] *and P. E. Ventola*[10]*, (1)Seattle Children's Research Institute, Seattle, WA, (2)Binghamton University, Binghamton, NY, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Department of Psychology, University of South Carolina, Columbia, SC, (5)Computer Science and Engineering, University of Washington, Seattle, WA, (6)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (7)University of Miami, Miami, FL, (8)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (9)The University of Alabama, Tuscaloosa, AL, (10)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Social referencing behavior is exhibited less in children with ASD than those with typical development (TD; Dawson et al., 2004). Pivotal Response Training (PRT) addresses this by targeting social motivation and social use of language. In an ongoing study, we used eye tracking paradigms designed to capture intervention outcomes. Here we report preliminary results from a Social Referencing paradigm that examines the monitoring of nonverbal information.

Objectives: To explore PRT treatment effects by comparing eye tracking data at Baseline and Endpoint (16 weeks later) between PRT and Waitlist

Control (WLC) groups and examine the utility of eye tracking in capturing phenotypic changes moderated by PRT.

Methods: 4-to-8 year olds with ASD randomized to either PRT (*n*=16) or Waitlist Control (WLC, *n*=13) watched videos of an actor involved in an escalation of stressful activities (e.g. stacking a tower) that comes to a resolution (e.g. tower falls down). A linear mixed model, controlling for age, was used to examine eye tracking variables of valid onscreen looking time (ValidLooking%) and looking percentages to actor/scene regions (Face%, Activity%, Eyes%, and Mouth%) throughout the different stages of the activity (Escalation and Resolution). Participants re-watched the videos at 8-week Midpoint (PRT *n*=14, WLCl *n*=9) and 16-week Endpoint (PRT *n*=12, WLC *n*=9). Relationships between changes in clinical variables and eye tracking variables were examined using Pearson's correlations.

Results: Between-group differences were only detected for Mouth% at Endpoint during the Resolution (*p*=.048), with lower mouth looking in the PRT group (*M*=10.1, *SD*=1.10) than WLC (*M*=6.60, *SD*=1.00). Within the PRT group, there was a negative correlation between time point changes in Face% during the Resolution and time point changes in SRS T-scores in Autistic Mannerism (*r*(10)=-.725, *p*=.018), suggesting face looking increases were associated with reduced severity in autism mannerisms. However time point changes in Face% during Resolution was also negatively correlated with time point changes in behavioral coding of reciprocal turns in conversations (*r*(12)=-.657, *p*=.020), suggesting that increased face monitoring during Resolution was not a prerequisite for improving social reciprocity.

Conclusions: Preliminary results suggest that PRT is associated with Endpoint outcomes of decreased attention to the mouth compared to WLC. Previous studies have suggested that mouth scanning can supplement communicative cues, especially in uncertain situations (Klin et al., 2002). However when the situation is easier to understand, attention to the mouth may be less necessary (Norbury et al., 2009). By treatment Endpoint, PRT participants may have developed efficient processing skills and begun to rely less on mouth scanning. Caution is warranted, however, as correlational results suggest heterogeneity within the PRT group in treatment and eye tracking results. Furthermore, improvements in PRT targets may not be adequately captured by time point increases in looking at actor/scene regions of the Social Referencing paradigm. Future analyses will examine the complicated and nuanced relationships between eye tracking data and behavioral coding of PRT intervention goals.

196

169.196 Comparing Intensity Ratings of Emotions in Music and Faces By Adolescents with Autism Spectrum Disorder

***H. Dahary**[1], S. Sivathasan[2] and E. M. Quintin[2], (1)McGill University, Montreal, QC, Canada, (2)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: Individuals with autism spectrum disorder (ASD) often demonstrate difficulty in processing basic emotions in faces particularly with specific negative emotions, including sadness (Boraston et al., 2007) and fear (Humphreys et al., 2007). However, little research has compared emotion processing of faces to that of other modalities. Music is a powerful emotional vehicle (Juslin & Sloboda, 2001), an area in which individuals with ASD often show great interest and skills (Heaton, 2009), and is thus an alternative (and potentially preferred) domain for measuring emotion processing. Further, studies on emotion recognition with low-functioning adolescents are virtually non-existent which limits the applicability of findings to individuals with varying cognitive abilities.

Objectives: The purpose of this research is two-fold: 1) To directly compare intensity ratings of music-evoked and facial expressions of emotions, and 2) to extend the applicability of findings to children with varying levels of cognitive functioning.

Methods: Twenty-three participants aged 12 to 16 with ASD and low to high WISC-V Verbal IQ (50-111) completed three emotion recognition (ER) tasks: A Music ER task and two Facial ER tasks (1.Face Only ER task, 2.Combined ER task). Across the three tasks, the participants identified and rated the intensity of emotions (i.e., happy, sad, or fearful) in music excerpts (Music ER task) and in faces (Facial ER tasks). The Face Only ER task presented each face without the accompaniment of music, while the Combined ER task presented each face simultaneous to music that evoked the same emotion presented on the face. Each ER task included 18 trials (6 trials per emotion) of 4 seconds in length and took about 2-3 minutes to complete.

Results: Participants with lower cognitive ability (VCI: ≤80; n=12) rated emotions more intensely than those with higher cognitive ability (VCI: >80; n=11) across Music and Facial ER tasks (*p* < .01). However, cognitive ability did not have a significant effect on intensity ratings of specific emotions and intensity ratings of emotions within any of the three ER tasks (p < .05). Across participants, a main effect of emotion revealed that happy and fearful were rated more intensely than sad (*p* < .01). A marginal main effect of task showed that participants rated emotions more intensely in the Combined ER tasks than in the Music ER task (*p* = .07). A two-way interaction between task and emotion was also found such that in the Music ER task, fearful and sad were rated more intensely than happy, but in the Combined ER task, the reverse was found (*p* < .05).

Conclusions: Adolescents with ASD with lower cognitive ability appear to be more sensitive to emotions presented in faces and music than adolescents with ASD with higher cognitive ability. Higher intensity ratings for arousing emotional stimuli (happy and fearful) may support previous accounts of atypical development or connectivity of limbic brain areas including the amygdala (Baron-Cohen, 2000). Findings provide important implications for using targeted music interventions that capitalize on disorder-specific strengths (musical ability) to teach emotion processing skills to individuals with ASD.

197

169.197 Comparing the Communication Profiles of Children with Autism Spectrum Disorder & with Multisensory Impairments

***M. Nunez**, A. San Jose Caceres and E. Loth, Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Communication is severely affected both in young children with Multisensory Impairments/deafblindness (MSI) and children with ASD (Autism Spectrum Disorders). This can lead to apparent similarities in the surface behaviour that, however, may have very different causes, relations with other developmental processes and implications for developmental outcomes

Objectives: This exploratory study aimed to compare the early communication and other behavioural profiles of young children with MSI and children with ASD in order to identify specific markers/associations of behaviours that can help to distinguish the communication characteristics of each group and inform practice

Methods: Fifteen young children (aged 2 -6 years) and their families took part in our study. All children had either an ASD diagnosis or a MSI diagnosis only as a prerequisite for their inclusion in this study. Children were assessed with a set of observational tools, including parental reports (e.g., Rowland's Communication and Matrix, a tool for special needs populations) and direct observations of child/parent interactions in a semi-structured free-play situation

Results:

Results showed both quantitative and qualitative differences in the *communication behaviour* of the two groups. Children with ASD were at a higher level of communication than MSI children in terms of the percentages of skills credited in the Communication Matrix (e.g. at level VI, 94% in the ASD group as compared to 21% in the MSI group). Differences in favour of the ASD group, however, were mainly for skills categorised with the Obtain function (ASD, 78% vs MSI 31%) A microanalysis of the parent/child interactions showed *qualitative differences* between the two groups in three aspects; the typicality of the developmental path to Joint Attention (JA), the structure of the interactions and the quality of the engagement. JA episodes are not frequent in any group but are more "typical" in the MSI group. Initiation of attention bids by the children are rare in both groups but the responses to attention bids by the mothers and their engagement in the communication event was easier and clearer in the MSI group. Repetition of actions is common in both groups but the repetition of shared actions is more frequent in the MSI group. The strategies used by the mothers to get the child's attention and her/his engagement in the interactions are adapted to each child but also have some common differences between the two groups.The two groups also differed in their repetitive behaviours scores (much higher in the ASD group). They did not differ, however, in their sensory profiles where both rated in the "atypical" range

Conclusions: These findings indicate that, despite the enormous heterogeneity within each group and their different levels of development, there are core differences between the two groups in their communication profiles. These differences can be identified in the *typicality, structure* and *function* of the parent/child communication. Other behaviours that can affect communication, such as the prevalence of repetitive behaviours, proved to be a good way to discriminate between the two groups too

198 **169.198** Construct Validity of Eye-Tracking Indices of Active Engagement in School-Aged Children with ASD

L. A. Edwards[1]*, L. Morgan*[1]*, M. Siller*[1]*, A. Wrencher*[2]*, J. M. Moriuchi*[3]*, A. Klin*[1] *and W. Jones*[1]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (2)Andrew Young School of Policy Studies, Georgia State University, Atlanta, GA, (3)Department of Psychiatry, Rush University Medical Center, Chicago, IL*

Background: Autism Spectrum Disorder (ASD) is associated with a heterogeneous phenotype marked by social interaction difficulties as well as restricted and repetitive behaviors. Evidence-based treatments targeting core social difficulties in ASD are limited to behavioral or educational methods, and show wide variability in effectiveness and post-intervention outcomes. A major obstacle in the development of more effective, individualized, developmentally-appropriate ASD interventions is the absence of validated clinical outcome measures that objectively quantify treatment effects. From educational theory, the construct of 'active engagement' describes how children attend to and participate in learning opportunities. Active engagement is the means by which the content of educational interactions is accessed, and is one of the best predictors of successful learning for children with disabilities (Iovannone et al., 2003). Assays for rapidly and reliably quantifying active engagement are thus crucial for improving educational interventions for ASD. Eye-tracking-based measures of social visual engagement—the way children look at and attend to social information in their surrounding environment—are strong candidates for monitoring active engagement, pinpointing precise opportunities for intervention, and assessing response to treatment in ASD.

Objectives: This study aims to assess the validity of eye-tracking-based, quantitative assays of social visual engagement as measures of active engagement to be used in educational interventions aimed at addressing social difficulties in school-aged children with ASD.

Methods: Eye-tracking data were collected from a large and heterogeneous sample of children with ASD (mean age=10.08 years, n=159), as well as from an age-matched comparison sample of typically developing children (TD, mean age=9.50 years, n=43), during free viewing of naturalistic videos of social interaction. Data were quantified in terms of overall engagement (percent total fixation) and engagement with social information (percent fixation to people's eyes, mouths, or bodies), and assessed for specificity and sensitivity to ASD severity, and test-retest reliability.

Results: Sensitivity and specificity to ASD social impairment severity were determined using regression analyses of ADOS social affect (SA) and restricted and repetitive behavior (RRB) scores (respectively), on eye-tracking indices of active engagement, controlling for age and cognitive level. Results indicate significant associations between ADOS SA and overall engagement (b=-8.82, p=0.003), and ADOS SA and social engagement (b=-12.47, p=0.002), as well as a significant association between ADOS RRB and overall engagement (b=-3.31, p=0.005), but no association between ADOS RRB and social engagement (p=0.152). Preliminary analyses of test-retest reliability for ASD and TD are promising: overall engagement, ICC>0.8, $p<0.001$; social engagement, ICC>0.6, $p<0.001$.

Conclusions: Eye-tracking measures of social visual engagement show promise as reliable, specific, and sensitive quantitative biomarkers of active engagement and social abilities in ASD. Higher overall engagement is associated with higher social affect and lower restricted and repetitive behavior, and higher engagement with social information is associated with higher social affect, but is not related to restricted and repetitive behaviors. Future analyses will explore convergent validity of these measures with clinician-administered assessments of child engagement, as well as comparative validation of eye-tracking measures of moment-by-moment perceived stimulus salience for objective, quantitative monitoring of active engagement, treatment response, and social development.

199 **169.199** Divergent Patterns of Time-Varying Visual Attention to Social Stimuli in Toddlers with Autism Spectrum Disorder and Williams Syndrome

A. L. Ford[1]*, S. K. Markert*[2]*, J. A. Olmstead*[3]*, M. D. Lense*[4]*, A. Klin*[3]*, S. Shultz*[3] *and W. Jones*[3]*, (1)Marcus Autism Center, Atlanta, GA, (2)Department of Pediatrics, Marcus Autism Center, Children's Healthcare of Atlanta & Emory School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (4)Vanderbilt University Medical Center, Nashville, TN*

Background:

When looking at the world, a child faces an array of almost unlimited visual information, yet at each moment in time she can look at just one thing. Remarkably, typically developing (TD) toddlers, when watching video scenes of social interaction, exhibit patterns of time-varying visual attention that are tightly synchronized with one another. The majority of TD toddlers look at the same stimuli at the same moments in time: they orient towards caregiver faces, affective cues, and gestures in a tightly time-locked fashion that scaffolds their social learning. In autism spectrum disorder (ASD), however, research suggests that these patterns of time-varying visual attention may be disrupted, potentially driving a developmental cascade towards atypical experiences of and interactions with the social world. In comparison, time-varying visual attention in young children with Williams syndrome (WS), a neurodevelopmental genetic disorder with a behavioral phenotype characterized by hypersociability, is relatively unstudied. Quantifying moment-by-moment patterns of visual scanning in these groups situated at the extremes of the spectrum of sociability has the potential to reveal how and when toddlers attribute meaning to signals in their environments and the resulting impact on developing socio-cognition.

Objectives:

To map patterns of time-varying visual attention in toddler cohorts with distinct diagnoses of social impairment (ASD, WS) in order to study how early deviations from typical developmental patterns of attention may scaffold later manifestations of both hypo and hyper-social behavior.

Methods:

Participants were 24-to-45-month-old children with ASD (n=30) chronological-age and sex-matched to cohorts of children with WS (n = 9), and typical development (n=30). Diagnoses were made by licensed clinicians blind to experimental eye-tracking data, with genetic testing to confirm the WS deletion. Eye-tracking data were collected as children viewed video clips of toddlers engaged in a variety of naturalistic social interactions. Time-varying kernel density estimation quantified dynamic visual scanning.

Results:

Visual attention in TD controls was synchronized (looking at the same location at the same time) 41.9% of the time (with statistically significant synchronization defined by comparison with results expected by chance, $p<0.05$). When TD viewing patterns were synchronized, the visual scanning of ASD and WS children differed significantly ($p<0.05$) from TD controls for 15.03% and 4.52% of viewing time, respectively. Moreover, there was little overlap between the WS and ASD groups in when these moments of divergence occurred (Figure 2), suggesting that WS and ASD children diverge from TD viewing patterns in unique ways. Further study will focus on identifying scene-specific stimuli that are uniquely captivating to viewers with ASD relative to WS and TD viewers.

Conclusions:

Findings reveal disorder-specific patterns of divergence in dynamic visual scanning in toddlers with ASD. Patterns of dynamic visual scanning were more atypical amongst ASD compared to WS viewers, with visual scanning of ASD viewers diverging from that of TD viewers nearly 3 times as often as for viewers with WS. These analyses offer insight into how atypical allocation of attentional resources in toddlerhood may contribute to the emergence of the social phenotype of ASD.

169.200 Educator Practices and Perspectives on Social and Emotional Skills Teaching in UK Autism Education

*S. Mantinioti[1], **E. Ainger**[1], A. M. Alcorn[1] and E. Pellicano[2], (1)Centre for Research in Autism and Education, University College London, London, United Kingdom, (2)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom*

Background: Difficulties with social skills and with recognising and managing emotions can impact autistic individuals across almost all areas of their lives. It is widely agreed that autism education must go beyond academics, to also develop children's social, emotional and communicative skills (e.g. Helps, Newson-Davis & Callias, 1999). Nevertheless, educators may receive insufficient support to incorporate these skills into the curriculum and help learners apply them *outside* the classroom. Morrier, Hess & Heflin (2011) found that US teachers received some 'teaching strategies' training for autistic students, but that programmes often were not evidence-based, and only a few addressed social and emotional skills. The current picture of social and emotional skills teaching in UK autism education is unclear, making it difficult to identify needs and potential improvements in this area.

Objectives: To understand UK educators' current practices for, and attitudes towards, teaching social and emotional skills to autistic students.

Methods: Fifteen autism education staff (including teachers, teaching assistants, subject specialists, and speech and language therapists) took part in individual semi-structured interviews lasting 40-60 minutes. Five additional staff members took part in a focus group. Participants represented a range of mainstream, special, and independent UK schools. Interviews asked about existing social and emotional skills teaching practices, in the broader context of educator aspirations for their students, how aspirations are communicated to families, and the use of autism-specific programmes and supports in their settings. Interviews and focus groups were transcribed verbatim and analysed thematically.

Results: Five themes and multiple interlinked subthemes were developed from the data (see Figure 1). Across the areas discussed (current practice, aspirations, etc.) educators consistently placed high importance on teaching social and emotional skills. They highlighted that **every child is different** and therefore each child may need different strategies and supports to develop these skills. A widely shared goal was to help children work towards **leading independent lives**, through communication and self-regulation of their emotions. With this in mind, educators stressed that such skills need to be **generalizable** to the community and home, as well as school. Staff were understood to play a huge role in successful teaching; they shared **effective ways of working** including consistency across contexts and shared ideas within school teams. Despite the perceived importance of children developing these skills, participants felt ill-equipped to teach them due to a lack of training and guidance. Participants disagreed on the ideal **balance between social and academic teaching**. Overall, participants were either not including social and emotional skills in their teaching, or had developed personal strategies to teach these skills.

Conclusions: There was a notable gap between UK educators' views and aspirations regarding social and emotional skills, and what they felt equipped to teach their autistic students. Participants reported a lack of training and guidance to address these skills in the classroom *at all*, let alone with evidence-based strategies. This indicates a clear area in which autism education in the UK may be strengthened better reflect "best practices", by improving the support and professional development available to teachers.

201

169.201 Observing Interactions between Teaching Staff and Autistic Children: Who Communicates, How Often, and Why? a Cross-Cultural Comparison between UK and Serbia

***E. Ainger**[1], Y. Shek[2], A. M. Alcorn[1] and E. Pellicano[3], (1)Centre for Research in Autism and Education, University College London, London, United Kingdom, (2)Centre for Research in Autism and Education, UCL, London, United Kingdom, (3)Centre for Research in Autism and Education (CRAE), UCL Institute of Education, University College London, London, United Kingdom*

Background: Interactions with school staff are a central opportunity for autistic children to develop and practice social and communicative skills, and to develop trusting, reciprocal relationships. There is remarkably little research examining the nature of adult-child interactions in the classroom, particularly for children who have intellectual disability, are preverbal or have emerging language skills, or may communicate

idiosyncratically. The potential effects of culture on the nature, frequency, and purpose of adult-child communications is also essentially unknown. For many countries including Serbia, there is little existing research on autistic children in the classroom.
Objectives: To describe and compare child-adult interactions during observations of structured and unstructured activities in UK and Serbian special education settings.

Methods: 16 autistic children (aged 5-11 years; 2 female) from three UK special schools were observed during at least two structured and two unstructured classroom activities, equalling 80 minutes of interaction per child over multiple days (~22 hours total). Observations of seven additional children are ongoing in Serbia. Researchers recorded adult-child interactions every two minutes for a 20-minute activity period, recording who initiated, using what modality and for what purpose. Researchers noted if any supports were used during the interaction, the response from the communicative partner, and any reciprocal interactions (Figure 1). Researchers subsequently recorded a qualitative narrative of the entire activity. Some adults observed were classroom teachers, while others were teaching assistants or subject specialists. Standardised measures of autism severity (CARS-2 ST) were completed for each child (Table 1).

Results: Data analysis is ongoing. We observed 1,238 interactions (per child, M=29.4 child-initiated, SD=24.49; M=47.9 adult-initiated, SD=17.70). 40% of these were child-initiated. While adult initiations most frequently had social or instructional purposes, most child initiations were commenting and requesting. Children and adults frequently responded to one another's initiations (children 87%; adults 82%). Surprisingly, additional supports such as PECS were used less than 20% of the time. Adults responded more to children categorised on the CARS-2 ST as having 'mild to no symptoms of autism' (90% of the time) in comparison to 'mild-moderate' (83% of the time) or 'severe' (75% of the time). Child mood also appeared to influence interactions, with fewer adult initiations observed when adults had rated children as having a negative mood during an observed activity, versus a positive or neutral mood. Child mood did not appear to affect adults' responses to the child, and therefore may be due to child bids being more frequent when they are anxious. Additional cross-cultural analyses will be conducted following Serbian data collection.

Conclusions: Child-adult interaction observations revealed that adults initiate interactions more frequently than do autistic children, and that initiation varies with children's mood. The rate of child-initiated interaction in this sample is surprisingly high, more than double that of previous research with comparable participants and settings. This discrepancy may reflect subsequent positive developments in early intervention and autism practice. Yet, very few additional communicative supports were used during interactions within any of the schools, despite literature recommending such supports as best practice in autism education.

202 **169.202** Estimating Social Communication Functioning (ACSF:SC) from ADOS-2 Data: Development of an Algorithm

S. J. Gentles[1], *B. Di Rezze*[1], *P. Rosenbaum*[2], *E. Duku*[1], *L. Zwaigenbaum*[3], *M. J. C. Hidecker*[4] *and S. Georgiades*[1], *(1)McMaster University, Hamilton, ON, Canada, (2)CanChild Centre, McMaster University, Hamilton, ON, Canada, (3)University of Alberta, Edmonton, AB, Canada, (4)Communication Disorders, University of Wyoming, Laramie, WY*

Background: Innovative algorithmic tools have exciting potential for extracting novel information from commonly used measures used in ASD, such as the item-level ADOS-2 data that are abundantly available in existing datasets, vastly increasing the utility of such datasets for research purposes. The Autism Classification System of Functioning: Social Communication (ACSF:SC) allows parents and professionals to categorize the social communication functioning of children aged 3-5 years into one of five meaningfully distinct levels. Grounded on WHO's International Classification of Functioning, Disability, and Health (ICF) framework, the ACSF:SC differs from traditional measures, including severity metrics, by assessing abilities rather than deficits. At IMFAR 2016, we presented pilot results regarding the feasibility of developing and validating an algorithm to generate estimates of social communication functioning (descriptive ACSF:SC levels) from existing ADOS data, including (a) results of a modified Delphi process to identify ADOS items most relevant to the social communication construct used in the ACSF:SC, and (b) a preliminary decision tree algorithm predicting ACSF:SC from a limited data sample comprising paired SRS-2 social communication subscale and ACSF:SC assessments.
Objectives: We now present the initial decision tree algorithm developed from analysis of prospectively collected paired ADOS-2 and ACSF:SC data from multiple diagnostic clinics in Ontario, Canada.

Methods: Classification and Regression Tree (CART) analysis is being used to develop and validate the ADOS-to-ACSF:SC algorithm. CART requires paired data (i.e., contemporaneous ADOS-2 assessment and ACSF:SC level in the same child). A required sample size of n=300 was estimated from pilot work. Data will be split on response items within A and B groupings of the ADOS-2 when developing the algorithm. CART interim and final analyses are being run using IBM SPSS Statistics per the pilot work.

Results: In work to date, we have gained the necessary ethics approvals and site agreements, and begun recruitment and data collection from partners at 6 diagnostic clinics from varying regions across Ontario. Generating ACSF:SC tool adoption and enthusiasm was important for this recruitment. At the time of writing (approximately 3 months into data collection), paired data from 29 cases have been collected. This number of cases was insufficient to conduct interim analysis to reliably identify ADOS-2 items that are predictive of ACSF:SC level. Data collection will continue, and a CART analysis and decision tree based on the latest data will be presented in the poster.

Conclusions: An ADOS-to-ACSF:SC algorithm would increase the utility of available ADOS-2 data by providing a means to conduct secondary analysis to characterize the social communication functioning of children within historic datasets. For example, such estimates derived from previously collected data could facilitate examination of longitudinal trajectories of social communication functioning in ASD; work is currently ongoing to extend the age range of the ACSF:SC beyond age 3-5 years. This methodology has value as a template for developing additional algorithmic means for deriving ICF-based ratings of functioning in ASD (not limited to social communication) and creating longitudinal perspectives from previously collected, routinely available data generated by commonly used instruments—extending opportunities for secondary data analysis.

203 **169.203** Exploring Theory-of-Mind in Children, Adolescents and Adults with Autism Spectrum Conditions in a Large European Cohort

H. L. Hayward[1], *K. L. Ashwood*[2], *F. Happé*[3], *R. Holt*[4], *S. Baron-Cohen*[5], *E. Loth*[6], *M. C. Lai*[7], *D. V. Crawley*[6], *D. G. Murphy*[8], *A. San Jose Caceres*[6] *and J. Ahmad*[6], *(1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, King's College London, London, United Kingdom, (2)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Social, Genetic and Developmental Psychiatry Centre,* *Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)University of Cambridge, Cambridge, United Kingdom, (5)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (6)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)Centre for Addiction & Mental Health, University of Toronto, Toronto, ON, Canada, (8)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:
'Theory of Mind' (ToM) hypothesis is a prominent account of social-communicative impairments in ASC; the ability to ascribe mental states to others/self to predict behaviours (Baron-Cohen, et al., 2000). Studies report many adolescents/adults with ASC pass 'first-order' tasks, yet struggle in social situations (Klin, 2000). This has led to the distinction between 'first order' *ToM* abilities (e.g. 'false belief' measured in a continuous manner by the "Sandbox" task (Begeer et al., 2012)), and perhaps more pervasive impairments in *spontaneous* usage (Klin, 2000; Volkmar et al., 2004). One paradigm that taps spontaneous attribution of mental status is the 'animated shapes' task that elicits a (verbal)ToM response more akin to the "social demands" inherent in real-life.

Objectives:

To investigate *false belief* and *spontaneous* ToM usage in a mixed sex cohort of males and females with ASD across different ages and IQ. Associations between ToM and social-communicative abilities will also be examined

Methods:

Participants with ASCs (N=363) and age-matched typically developing (TD) participants (N=262) recruited as part of EU-AIMS Longitudinal European Autism Project (LEAP). A battery of cognitive tasks included the Frith-Happe Triangles animations 'Animated Shapes' task (Abell et al 2000; Castelli et al., 2002) and the continuous false belief 'Sandbox' task to assess theory of mind. The 'Triangles' task were audio-recorded/transcribed /analysed for "accuracy" (I.e. correct inference of underlying scenarios) and "psychological state descriptions" (i.e. use of mental state terms) using a scoring system developed by the authors, based on Castelli (2000). 100% of the narratives were scored by two raters at each LEAP site, inter-rater reliability was above 91% across.

IQ assessed using the WASI, autism symptomatology using the (parent-report) Social Responsiveness Scale (SRS-2), adaptive functioning using the Vineland (VABS-III).

2 (group) x 2(sex) x 3 (age group: child, adolescent, adult) between-subject ANOVAs were used.

Results:

Both tasks revealed moderate correlations in both groups (ASC: $r = .25$, $p = .01$;TD: $r = .14$, $p = .05$).

The "Sandbox" task found a significant effect of group ($F(1,516)=8.403$, $p<.05$, $d= 0.24$) with the ASC group performing significantly worse (i.e. greater egocentric bias) than TDs.

No group differences found on the 'Triangles' task. Significant effect of sex($F(1,609)=6.938$, $p<.05$, $d=0.28$)(females<males) and age($F(3,609)=33.349$, $p<.001$)(children<adolescents<adults) found, effects do not hold with diagnosis.

The 'triangles' task was moderately correlated with ASD symptomatology in both groups (TD; $r =-.31$, $p < .01$, ASC; $r =-.21$, $p < .01$). 'Sandbox' task correlated with ASC symptomatology in the ASC group only($r =-.16$, $p < .01$).

In the ASC group, the 'triangles' task was correlated with adaptive behaviour ($r =-.14$, $p = .05$) in males, and adolescents (social domain, $r =-.23$, $p = .05$). TD group; the 'triangles' task correlated with Communication($r =-.20$, $p = .05$).

The continuous FB task correlated with adaptive behaviour in the ASC group, (daily living($r =.22$, $p = .01$.;communication($r=.15$, $p=.05$);social($r=.30$, $p=.01$)) in males. In the TD males, it correlated with all domains of adaptive behaviour.

Conclusions: We report group differences in *prompted* ToM usage, though find no group deficits in *spontaneous* ToM usage in individuals with ASC.

204 **169.204** Exploring the Underlying Mechanisms of Spontaneous and Voluntary Facial Expressions

D. A. Trevisan[1], *G. Iarocci*[2] *and E. Birmingham*[1], *(1)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada, (2)Simon Fraser University, Burnaby, BC, Canada*

Background:
Facial expressions can be the physiological outcome of an internal emotional state (i.e., spontaneous productions), or consciously controlled displays used for social communication purposes (i.e., voluntary displays; Gordon et al., 2014). Previous research has shown that individuals with ASD are less spontaneously expressive (McIntosh et al., 2006) contributing to 'flat affect', and are more likely to produce confusing or inaccurate facial expressions (Brewer et al., 2016) impairing social interaction quality.

Objectives:

The goal of this study is to determine whether *reduced* spontaneous expression and *inaccurate* voluntary expression have distinct underlying mechanisms. The prediction is that reduced spontaneous expression will be better explained by alexithymia than ASD traits because interoceptive difficulties (poor awareness of one's internal affective cues) will impair proprioceptive processes (i.e., automatic facial muscle movements). In contrast, inaccurate voluntary expression will be better explained by ASD traits than alexithymia because voluntary nonverbal expression represents the core social communication difficulties characteristic of ASD.

Methods:

This study examined ASD traits and alexithymia using the Autism Spectrum Quotient (AQ) and the Toronto Alexithymia Scalef (TAS-20) in a sample of neurotypical undergraduates to predict variance in spontaneous and voluntary expressions. Spontaneous expressions were assessed in response to participants telling emotional stories about their lives, or from watching emotional video clips. Voluntary expressions were assessed by asking participants to pose various emotional facial expressions. Facial expressions were analyzed using iMotions software.

Results:

Spontaneous expression was calculated as the total amount of emotional expression detected while telling a negative story, or while watching the movie clips. A hierarchical multiple regression with quantity of negative expression entered as the dependent variable was conducted with AQ entered into the first step, and TAS-20 entered into the second step. The model approached significance in step 1, F Change$(2,39) = 3.84$, $p = .057$, accounting for 9.0% of the variance (R^2 Change = .090). Upon entering TAS-20 into the regression in step 2, the model was significant, *F* Change(2,39) = 14.11, *p* < .001, adding 24.7% explained variance (R^2 Change = .247).

Voluntary expression accuracy was calculated dichotomously based on whether the target emotion was judged by iMotions as being the dominant emotion. A hierarchical multiple regression with expression accuracy entered as the dependent variable was conducted with TAS-20 entered into the regression in step 1 and AQ entered in step 2. The model approached significance with TAS-20 entered into the model in step 1, *F* Change(2,37) = 2.164, *p* = .150, and accounted for 5.7% of the variance (R^2 Change = .057). Upon entering AQ into the regression in step 2, the model became significant, *F* Change(2,37) = 6.38, *p* = .016, adding 14.5% explained variance (R^2 Change = .145).

Conclusions:

As predicted, alexithymia is more strongly related to spontaneous expression of emotion than ASD traits, whereas ASD traits are more strongly related to voluntary expression. Research is needed to replicate this study in individuals with ASD to determine whether “flat affect” is a symptom of alexithymia, and “confusing expression” is a symptom of ASD.

205 **169.205** Gaze Patterns during Parent-Child Versus Clinician-Child Interactions

E. Ajodan[1], *B. Silver*[2], *M. R. Silverman*[1], *A. Southerland*[3], *K. Chanda*[3], *E. A. Stubbs*[3], *C. Lord*[4], *J. Rehg*[3], *A. Rozga*[3] *and R. M. Jones*[2], *(1)Sackler Institute for Developmental Psychobiology, New York, NY, (2)Weill Cornell Medicine, New York, NY, (3)Georgia Institute of Technology, Atlanta, GA, (4)University of California Los Angeles, Los Angeles, CA*

Background: Atypical eye contact during social interactions is a hallmark of autism spectrum disorder (ASD). Prior literature suggests that social communication behavior varies in children with ASD depending on whether they are interacting with a familiar or unfamiliar person. It is unknown if young children with ASD will vary their gaze pattern depending on whether they are interacting with a clinician or their caregiver.
Objectives: We examined the frequency and duration of direct gaze in young children with ASD when engaging with their caregiver versus a clinician during a semi-structured play interaction.

Methods: 18 more verbally able children diagnosed with ASD (mean 40 months;25-59 months, mean VIQ= 80; mean NVIQ= 87) completed a modified version of the Brief Observation of Social Communication Change (BOSCC), while seated at a table. Children first completed the BOSCC with a clinician, and then completed the same procedures with their caregiver. The adult sat across from the child and wore a pair of Pivothead Kudo glasses that had an outward facing camera embedded between the eyes, so that the videocamera readily captured the child’s face and shifts in eye gaze to the adult. Video data was manually coded at the frame level using Mangold Interact for the child’s direct gaze to the adult. Repeated Measures ANOVAs determined differences in the duration and frequency of direct gaze across the two conditions (unfamiliar clinician versus caregiver). Age, verbal IQ and autism symptom severity (ADOS CSS) were included as covariates to determine whether child characteristics influenced gaze patterns.

Results: The frequency and duration of gaze were not significantly different during play interactions with a caregiver versus an unfamiliar clinician (p’s >0.2). Of note, there were no differences between caregivers and clinicians in how well they captured the child’s gaze with the Pivothead glasses, suggesting the lack of condition effects were not explained by sampling differences. There were no significant interaction effects with age, VIQ or ADOS severity scores (p’s > 0.1). A pilot sample of two children completed the procedures twice across three months, before and after their caregivers completed a 12-week behavior training program at the clinic and there were also no significant differences in gaze frequency or duration across condition (p=0.5) or time point (p=0.6) and no interaction (p=0.3).

Conclusions: Surprisingly, there were no differences in gaze patterns in young children with ASD when interacting with their caregiver compared to an unfamiliar clinician. This data represents a subset of participants as data collection is ongoing, thus a larger sample size may illuminate more subtle differences in gaze behavior across the two conditions. Determining whether familiarity can facilitate gaze patterns in young children with ASD may ultimately be a critical first step for designing treatment strategies that address social communication difficulties.

206 **169.206** Good Social Skills Despite Poor Theory of Mind: Exploring Compensation in Autism Spectrum Disorder

L. Livingston[1], *E. Colvert*[1], *P. Bolton*[2] *and F. Happé*[1], *(1)Social, Genetic and Developmental Psychiatry Centre, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Department of Child & Adolescent Psychiatry, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: It is proposed that some individuals with Autism Spectrum Disorder (ASD) can ‘compensate’ for their underlying difficulties (e.g., in theory of mind; ToM), thus demonstrating relatively few behavioural symptoms, despite continued core cognitive deficits. More broadly, the phenomenon of compensation may have the potential to explain heterogeneity in outcome, the female autism phenotype, and late diagnosis. The mechanisms underpinning compensation, however, are largely unexplored, as is its potential impact on mental health.
Objectives: This study aimed to estimate compensation patterns in adolescents with ASD, by contrasting overt social behaviour with ToM task performance, in order to compare the characteristics of ‘Low’ and ‘High’ Compensators.

Methods: 136 autistic adolescents, from the ongoing Social Relationships Study, completed a range of cognitive tasks, the Autistic Diagnostic Observation Schedule (ADOS), and a self-report anxiety questionnaire. Participants were assigned compensation group status; High Compensators demonstrated good ADOS scores despite poor ToM performance, while Low Compensators demonstrated similarly poor ToM, accompanied by poor ADOS scores.

Results: High Compensators demonstrated better IQ and executive function (EF), but greater self-reported anxiety, compared to Low Compensators. Such differences were not found when comparing individuals who had good ToM performance with good versus poor ADOS scores. Other core autistic characteristics (weak central coherence, non-social symptoms) did not differentiate the High and Low Compensators.

Conclusions: IQ, EF and anxiety appear to be implicated in the processes by which certain autistic individuals can compensate for their underlying ToM difficulties. This tendency to compensate does not appear to reflect the severity of ‘hit’ for ASD *per se,* suggesting that well compensated individuals are not experiencing a milder form of ASD. The construct of compensation in ASD has a number of implications for research and clinical practice. The findings have informed a novel theoretical framework for understanding compensation in ASD and other neurodevelopmental disorders.

207 **169.207** How Children with Autism Spectrum Disorder Recognize Facial Expressions Displayed By a Rear-Projection Humanoid Robot

*F. Askari[1], H. Feng[2], **A. Gutierrez**[3], T. Sweeny[4] and M. Mahoor[2], (1)Electrical and Computer Engineering, University of Denver, Denevr, CO, (2)University of Denver, Denver, CO, (3)University of Miami, Miami, FL, (4)Psychology, University of Denver, denver, CO*

Background:

Children with Autism Spectrum Disorder (ASD) experience reduced ability to perceive crucial nonverbal communication cues such as eye gaze, gestures, and facial expressions. Recent studies suggest that social robots can be used as effective tools to improve communication and social skills in children with ASD. One explanation has been put forward by several studies that children with ASD feel more contented and motivated in systemized and predictable environment, like interacting with robots.

Objectives:

There have been few research studies evaluating how children with ASD perceive facial expression in humanoid robots but no research evaluating facial expression perception on a rear-projected (aka animation-based) facially-expressive humanoid robot, which provide more life-like expressions. This study evaluates how children with high functioning autism (HFA) differ from their typically developing (TD) peers in recognition of facial expressions demonstrated by a life-like rear-projected humanoid robot, which is more adjustable and flexible in terms of displaying facial expressions for further studies.

Methods:

Seven HFA and seven TD children and adolescents aged 7-16 participated in this study. The study uses Ryan, a rear-projection, life-like humanoid robot. Six basic emotional facial expressions (happy, sad, angry, disgust, surprised and fear) with four different intensities (25%, 50%, 75% and 100% in ascending order) were shown on Ryan's face. Participants were asked to choose the expression they perceived among seven options (six basic emotions and none). Responses were recorded by a research assistant. Results were analyzed to obtain the accuracy of facial expression recognition in ASD and TD children on humanoid robot face.

Results: We evaluated the intensity of expression in which participants required to reach the peak accuracy. They were best for happy and angry expressions in which the peak accuracy of 100% was reached with at least 50% of expression intensity. The same peak accuracy was reached for surprised and sad expressions in the intensity of 75% and 100%, respectively. But fear and disgust recognition accuracy never reached above 75%, even in the maximum intensity. The experiment is still in progress for TD children. Results will be compared to a TD sample and implication for intervention and clinical work will be discussed.

Conclusions:

Overall, these results show that children with ASD recognize negative expressions such as fear and disgust with a slightly lower accuracy than other expressions. On the other hand, during the test, children showed engagement and excitement toward the robot. Besides, most of the expressions were sufficiently recognizable for children in higher intensities, which means, Ryan, a rear projected life-like robot could be able to successfully communicate with children in terms of facial expression, though more investigations and improvements should be done. These results serve as a basis to advance the promising field of socially assistive robotics for autism therapy.

208 **169.208** Individual Differences in Distinct Aspects of Executive Function Predict Theory of Mind in School-Aged Children with ASD

***M. R. Altschuler**[1], R. Gilbert[2], A. Vaidyanathan[3], S. Kala[4], M. Warshawsky[5], D. P. Carroll[6] and S. Faja[2], (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Boston Children's Hospital, Boston, MA, (3)The Banyan Academy of Leadership in Mental Health, Mugappair west, Chennai, India, (4)Dartmouth College, Hanover, NH, (5)Tufts University, Medford, MA, (6)Autism Spectrum Center, Boston Children's Hospital, Boston, MA*

Background: Executive function (EF) and theory of mind (ToM) are often difficult for children with ASD. Previous research has consistently documented theory of mind (ToM) delays in preschoolers with ASD, but investigations examining ToM in school-aged children with ASD and average IQ have produced mixed results. Moreover, research is limited on whether distinct aspects of EF predict different types of ToM in ASD, above and beyond the influence of age and IQ.

Objectives: To examine the relation between individual differences in EF and ToM in school-aged children with ASD and average IQ using large batteries of ToM and EF measures.

Methods: Sixty-four children with ASD between the ages of 7-11 years participated. All children had an ASD diagnosis (ADOS-2, ADI-R, DSM-5) and WASI-2 Full Scale IQ of 80 or higher. The ToM battery included tasks measuring: (1) emotion recognition (TOM Test-Level 1), (2) first-order false belief (Location Change and Unexpected-Contexts False Belief Videos [TOM Videos], and TOM Test-Level 2), (3) second-order false belief (TOM Test-Level 3), and (4) spontaneous social attribution abilities (Social Attribution Task [SAT]). For the TOM Test (Muris et al., 1999) and TOM Videos, children viewed pictures and videos with pre-recorded questions. For the SAT (Klin, 2000), children viewed animated geometrical figures enacting a social scene and answered open-ended questions, which were coded into six index scores representing different aspects of spontaneous social attribution: Pertinence, Salience, Cognition, Affect, Person, and Problem-Solving. The EF battery included tasks measuring: (1) interference suppression (Attention Network Task [ANT] and Stroop task), (2) behavioral inhibition of a dominant response (Change task), and (3) working memory (Backward Digit Span).

Results: A bigger reaction time (RT) difference on the ANT task (more mistakes for the incongruent versus congruent flanker condition) related to lower TOM Videos scores, when controlling for age and VIQ ($\beta = -.31$, $p = .01$). A bigger RT difference on the Stroop task (more mistakes for the incongruent versus congruent condition) related to lower SAT Salience scores, when controlling for age and IQ ($\beta = -.39$, $p < .01$). Decreased verbal working memory on the digit span related to lower TOM Test-level 2 performance, when controlling for age and VIQ ($\beta = .26$, $p = .04$).

Conclusions: Above and beyond the influence of age and verbal IQ, individual differences in EF predicted ToM in school-aged children with ASD. First, children with ASD with decreased interference suppression for incongruent flankers had worse first-order false-belief performance. Second, children with ASD with decreased interference suppression of incongruent color-word pairs had a decreased ability to make salient social attributions about animated geometrical figures enacting a social scene. Finally, children with ASD with decreased working memory had worse first-order false belief performance. Overall, our results indicate that for school-aged children with ASD, interference suppression predicts both spontaneous ToM and first-order false belief, while verbal working memory predicts first-order false belief. Results suggest a clinically relevant link between individual differences in specific aspects of EF and social cognition in ASD.

209 **169.209** Individuals with and without ASD Describe “Funny” Videos in Similar Ways

E. F. Ferguson[1], *L. Bateman*[1], *M. Cola*[2], *Z. M. Dravis*[2], *S. Uh*[2], *S. Plate*[2], *N. Minyanou*[2], *A. Pomykacz*[3], *K. Bassanello*[2], *A. Zoltowski*[4], *J. D. Herrington*[5], *K. Bartley*[5], *E. S. Kim*[2], *A. de Marchena*[6], *J. Pandey*[2], *R. T. Schultz*[2] *and J. Parish-Morris*[2], *(1)The Center for Autism Research/CHOP, Philadelphia, PA, (2)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (3)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (4)Vanderbilt University, Nashville, TN, (5)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)University of the Sciences, Philadelphia, PA*

Background: Humor is key to positive social interactions, but very little is known about humor in individuals with Autism Spectrum Disorder (ASD). Prior research suggests that individuals with ASD are more likely to select straightforward endings to jokes, which require more abstract thought than stories (Emerich et al., 2003), and are less likely to take mental states into account when describing cartoons (Samson & Hegenloh, 2009). This study is the first to explore verbal descriptions of two funny videos; one that is simple slapstick and one that is more socially complex and includes contrasting emotions. We hypothesized that participants with ASD and typical development (TD) would produce more positively-valenced descriptions of the slapstick video, and that the ASD group would use fewer cognitive words when describing the socially complex video.
Objectives: Compare verbal descriptions of two funny videos in individuals with and without ASD.

Methods: Fifty-eight individuals (ASD=37, 12f; TD=21, 14f) watched and then described two short videos that showed: 1) a baby laughing at a dog chasing bubbles (Fig.1a), and 2) a father giving his baby a lemon wedge to taste for the first time (Fig.1b). Groups did not differ on mean age (15y) or IQ (M=106), but did differ on sex ratio (this limitation will be addressed by May, 2018). Verbal descriptions of each video were orthographically transcribed and processed using the *qdap* package (R) and Linguistic Inquiry and Word Count software (Tausczik & Pennebaker, 2010). Our primary dependent variables were the polarity of each video description (dimensional valence from negative to positive), and proportion of total words that referred to cognitive processes.

Results: The average duration of each video description (~18s) and number of words produced per video (~30) did not differ by group. Linear mixed effects models tested effects of diagnosis (ASD/TD), video (Bubbles/Lemon), and diagnosis*video on polarity and cognitive words. As predicted, ASD and TD participants produced more positively polarized descriptions of the Bubbles video than the Lemon video, $F(1, 112)=51.81$, $p<.001$. The Lemon video elicited words such as “disgusted”, suggesting that participants in both groups were sensitive to the baby’s emotional state. The Lemon video also elicited a higher proportion of words about cognitive processes in both groups, $F(1, 112)=20.42$, $p<.001$. This confirmed our assessment that it is imbued with more social-cognitive complexity than the Bubbles video, but the lack of interaction with diagnostic group was contrary to our expectation that the ASD group would talk comparatively less about cognitive processes.

Conclusions: Our findings contrast with prior literature, suggesting possible next steps in the goal of understanding humor in ASD. To capture response patterns more fully, we will use coded facial expressions (e.g., smiling, grimacing) to predict video descriptions. We are increasing our sample size to explore developmental change, and equalizing sex ratios to examine sex differences. Audible laughter is an area of relative social strength for individuals with ASD (Hudenko & Magenheimer, 2011), and humor research thus has important implications for promoting positive peer outcomes in social skills interventions.

210 **169.210** Lower Lifetime ASD Symptom Severity Predicts Increase in Separation Anxiety with Age in Adolescents with ASD

S. L. Sommer[1], *C. E. Simson*[1], *L. A. Santore*[1] *and M. D. Lerner*[2], *(1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY*

Background:

Separation Anxiety (SA) has a distinct presentation in youth with autism spectrum disorder (ASD; White et al., 2014). SA symptoms reliably decline in typically developing (TD) populations throughout childhood (Copeland et al., 2014; Allen et al., 2010). However, previous research in adolescents suggests the opposite pattern in ASD, wherein greater age predicted *greater* self-reported SA symptoms (Sommer et al., 2016). This presentation may reflect difficulty transitioning social support from parents to peers, as seen in TD populations (Lieberman et al., 1999). Additionally, in ASD populations, past research has shown ASD symptoms predict atypical presentations of anxiety (Kerns et al., 2014). However, whether this relationship between symptom severity and anxiety accounts for the typical trajectory of SA in ASD over time remains unknown.

Objectives:

This study examined the relationship between age and SA symptoms as a function of ASD symptom severity in adolescents with ASD. It was hypothesized that greater age would predict increased SA, and that this effect would be moderated by ASD symptom severity, such that individuals with more severe ASD symptoms would report a stronger relationship between age and SA.

Methods:

56 youth (M_{age}= 12.168, SD_{age}= 2.897, 41 male) with ADOS-2 confirmed (Lord et al., 2012) ASD completed a measure of self-reported anxiety (MASC-2; March, 2012). Parents completed a lifetime measure of ASD symptoms (SCQ; Rutter et al., 2003).

Results:

Age predicted *greater* SA ($b = 1.388$, $p = 0.02$). This relationship was moderated by ASD symptoms ($b = -0.28$, $p = 0.0098$), such that it was evident *only* among those with *fewer* symptoms ($b = 2.83$, $p < 0.001$). Probing of the SCQ subscales revealed this effect was driven by the reciprocal social interaction domain ($b= -0.42$, $p = 0.018$). No other SCQ subscale moderated the relation between age and anxiety for any other anxiety subscale (all $p > 0.07$)

Conclusions:

Results suggest, contrary to the robust normative decrease in SA seen in TD populations, ASD adolescents may struggle to separate from their parents with age. This effect was augmented by parent-reported SCQ scores, specifically in the reciprocal social interactions domain, but was only significant for youth with *lower* scores, or perceived *better* social interaction skills. Adolescents with confirmed ASD diagnoses but fewer parent-reported social deficits may reflect the phenomenon of social camouflage (Head et al., 2014), in which – typically beginning in adolescence (Lai et al., 2016) – individuals with ASD learn to mask their symptoms and mimic normative behaviors of peers. It may be that doing this exerts a cost on the individual with ASD – specifically in terms of their ability to shift to normative reliance on peers for social support and separate from their parents. This is consistent with findings that youth with ASD and anxiety often exhibit greater parent-reported communication skills (Kerns et al., 2015). Thus, the moderating effect here may represent a mechanism by which this occurs. These findings further highlight the importance of understanding the heterogeneity of phenotypic expressions of SA in adolescents with ASD.

211 **169.211** Effect of Excitatory rTMS Applied to the Posterior STS in Adults with ASD

A. Saitovitch[1]*, J. C. Lamy*[2]*, E. Rechtman*[3]*, A. Vinçon-Leite*[4]*, T. Popa*[5]*, N. Chabane*[6]*, A. Philippe*[7]*, F. Bonnet-Brilhault*[8]*, G. Martinez*[9]*, R. Gobbo*[10]*, A. Cavalcanti Ferreira*[10]*, H. Lemaitre*[11]*, D. Grevent*[12]*, R. Calmon*[12]*, S. Meunier*[2]*, F. Brunelle*[7]*, N. Boddaert*[13] *and M. Zilbovicius*[12]*, (1)INSERM, Paris, France, (2)Inserm U 1127, CNRS UMR 7225, Sorbonne Universités, UPMC Univ Paris 06, ICM, CENIR, Paris, France, (3)INSERM U1000, Institut Imagine, Paris, France, (4)INSERM U1000, Paris, France, (5)Inserm U 1127, CNRS UMR 7225, Sorbonne Universités, UPMC Univ Paris 06, ICM, CENIR, Inserm U 1127, CNRS UMR 7225, Sorbonne Universités, UPMC Univ Paris 06, ICM, CENIR, Paris, France, (6)CHUV, Lausanne, Switzerland, (7)Necker Hospital, Paris, France, (8)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (9)Hôpital Sainte Anne, Paris, France, (10)Inserm U1000, institut Imagine, UNICAMP, Paris, France, (11)Inserm U1000, institut Imagine, Université Paris Sud, Paris, France, (12)Inserm U1000, institut Imagine, Paris, France, (13)Hospital Necker, Paris, France*

Background:

The superior temporal sulcus (STS) is known to be implicated in processing social information. Previous brain imaging studies have suggested that abnormalities within the STS would be related to social impairments in autism. In addition, eye-tracking studies have shown abnormalities in gaze behavior while viewing social stimuli in participants with ASD, mainly characterized by a lack of preference for socially relevant stimuli. In a recent study with healthy volunteers, we have shown that it is possible to change gaze pattern by transitory inhibition of the neural activity of the STS using repetitive transcranial magnetic stimulation (rTMS). Indeed, inhibition of the right STS reduced fixations to the eyes of characters during visualization of social movies, as measured with eye-tracking (Saitovitch et al. 2016).

Objectives:

In this study performed in adults with ASD, we investigated changes induced by rTMS stimulation of the right STS in gaze behavior using a paradigm of visual preference displaying biological and geometric motion simultaneously.

Methods:

Forteen adults with ASD (mean age = 21.7 ± 2.9) participated in the study. ASD diagnosis was based on DSM IV-R and ADI-R criteria. All subjects underwent a structural MRI for a precise localization of the stimulation target for each individual. Subjects underwent both sham stimulation and excitatory rTMS delivered over the right posterior STS (mean Talairach coordinates: 50 -53 15). The rTMS stimulation was delivered following protocol described by Huang et al., 2005. Stimulation was delivered in 2sec trains every 10sec, a total of 190sec (600 pulses), with an intensity of 90% of the active motor threshold. Gaze parameters were measured with a Tobii-120 eye-tracker during passive visualization of a 1min movie preference paradigm displaying biological and geometric motion simultaneously. Eye-tracking measures were performed at three time-points: at baseline, after sham (placebo) and after TMS and we measured percentage of viewing time to biological motion and geometric motion scenes for all participants. Data was processed with Tobii-Studio® software and analyzed at the group level and at the individual level.

Results:

At the group level, no significant changes in gaze behavior were observed after stimulation of the STS. Qualitative analysis of data indicates strong heterogeneity in the response. Therefore, individual analysis of data has allowed to identify three different groups within participants: 4 subjects respond to the stimulation by increasing the viewing time to the biological motion scenes; 5 subjects respond to the stimulation by reducing the visual duration of the geometric motion scenes and 2 participants presented no changes in gaze pattern.

Conclusions:

This study shows the feasibility of a TMS protocol in participants with ASD. Preliminary results show that, in line with the heterogeneity observed in ASD, response to the TMS varies among individuals.

212 **169.212** Overlap in Parent and Teacher Reports of Externalizing and Problem Behaviors in School-Age Children with Autism Spectrum Disorder

M. Reid[1]*, A. A. Pallathra*[2]*, M. K. Alvord*[3] *and B. Rich*[1]*, (1)Catholic University of America, Washington, DC, (2)Department of Psychiatry, Catholic University of America, Washington, DC, (3)Alvord, Baker & Associates. LLC, Rockville, MD*

Background: Parent and teacher report measures are essential to assessing domains of functioning in different settings for school-age children with autism spectrum disorder (ASD). Investigating the relationship between parent and teacher observations offers a better understanding of impairing symptomatology potentially overlooked in school settings. Evidence from parent report measures suggests children with ASD are significantly more impaired than typically developing peers on all subscales of the Behavior Assessment System for Children, Second Edition (BASC-2; Reynolds & Kamphaus, 2004) with the exception of aggression, anxiety, and internalizing behaviors (Mahan & Matson, 2011). BASC-2 teacher rating scales have also indicated that children with ASD display significantly greater impairment than their typically developing peers on most of the clinical subscales (Hass, Brown, Brady & Johnson, 2012). However, evaluating the relationship between parent and teacher rated BASC-2 scores is warranted in order to assess inter-rater reliability, especially in relation to externalizing symptoms.

Objectives: To assess agreement between parent and teacher reports of children's adaptive and problem behaviors in the home and school settings.

Methods: 23 participants with ASD between the ages of 7 and 12 (*M* = 10.06 years, *SD* = 1.61), were enrolled in a study of the Resilience Builder Program®, a 14-week, manualized, group intervention for children with social competence deficits (RBP; Alvord, Zucker, & Grados, 2011) at a large, private practice. Prior to treatment, parents and teachers completed the BASC-2 to evaluate children's adaptive and problem behaviors in community and home settings. Bivariate correlations between all BASC-2 parent and teacher rated subscales were analyzed using SPSS, after which Bonferroni's correction was applied.

Results: There were statistically significant positive correlations between parent and teacher ratings of primarily externalizing behaviors including aggression ($r = .65$, $p = .001$) and externalizing problems ($r = .64$, $p = .001$). There was a lack of significant correlations between all other BASC-2 parent and teacher rated subscale scores, including measures of anxiety, depression, and overall internalizing problems.

Conclusions: The results suggest a strong agreement between parent and teacher assessment of externalizing behaviors, but a disconnect between parent and teacher's abilities to report similar levels of internalizing behaviors. Significant agreement on behavioral functioning may reflect the fact that this is easier to observe and therefore characterize. Interestingly, it also suggests that despite differences in the environment in which children are being assessed (i.e., home vs. school), youth with ASD are perhaps displaying comparable levels of behavioral difficulties. In contrast, the disagreement between parents and teachers on affective functioning may reflect the difficulty in observing these internalized deficits, or it is possible that children are exhibiting varying degrees of these problems depending on the setting. Data from the current study suggest that more targeted, objective measures may be needed to assess internalizing deficits that occur in the home vs. school settings. Finally, the results may also suggest that communication between parents and teachers is critical to ensure comprehensive awareness of mood related deficits, which may differ in presentation based on setting.

213 **169.213** Patterns of Visual Exploration of Complex Social Scenes Are Increasingly Deviant over Time in Preschoolers with ASD: A Longitudinal Eye-Tracking Study

N. Kojovic[1]*, M. Franchini*[2]*, Z. Daniela*[3]*, H. F. Sperdin*[4] *and M. Schaer*[5]*, (1)Developmental Imaging and Psychopathology Lab, UNIGE, Geneva, Switzerland, (2)Dalhousie University / IWK Health Centre, Halifax, NS, Canada, (3)Medical Image processing Laboratory, University of Geneva, Geneva, Switzerland, (4)Developmental Imaging and Psychopathology (DIP) Lab, Office Médico-Pédagogique, Department of Psychiatry, University of Geneva School of Medicine, Geneva, Switzerland, (5)Developmental Imaging and Psychopathology Lab, University of Geneva, Geneva, Switzerland*

Background: Numerous studies using eye tracking have highlighted atypical visual exploration patterns in individuals with ASD, e.g. less focus on eyes and faces compared to typically developing (TD) individuals. Little is known about the mechanisms driving the emergence of these atypical patterns and their change with age.

Objectives: We developed a method that defines age-appropriate dynamic "norms" of visual exploration of complex social scenes. This method allows definition of characteristic gaze behavior for both groups, and quantification of its change with age (i.e. change in group focus precision), thus discriminating normal and atypical developmental processes. It allows to, without any a priori, measure for each child with ASD the deviance in his gaze pattern from the "norm", based on a gaze of TD children.

Methods: A 3-minute cartoon was displayed on a Tobii eye-tracker device for 16 ASD males (aged 3.5±0.3) and 17 TD males (aged 3.3±0.3) and same procedure was repeated a year later. A measure of dispersion of gaze data was calculated for each frame of the video, in both groups. For each frame of the video we created "normative" gaze pattern distribution by employing kernel density distribution estimation on the raw gaze data of TD individuals. We then calculated the *Proximity index-PI* for each patient, and averaged these values for the duration of the video. Higher values indicate the visual exploration of the individual is being more similar to the one of TD subjects. The PI was further correlated with clinical behavioral data and a measure of the complexity of social plot (number of interacting characters).

Results: While TD gaze behavior showed increasing focus with age (less dispersion, $p < 0.0000$ $h^2= -0.47$), ASD children showed a more dispersed gaze pattern a year later ($p < 0.0001$, $h^2= -0.04$). We found positive correlation between the change in PI and change in measures of cognition ($R^2 = 0.57$, $p = 0.008$). In a group of males with ASD, higher PI characterized scene sequences with less social content (one character alone), while in sequences with two or three characters interacting this index was lower ($p = 0.004$).

Conclusions: Our results show that this data-driven method can be used to characterize change in visual exploration in typical and atypical development. In one year TD preschoolers showed increased attunement in visual exploration of complex social scenes. The opposite was observed in our group of males with ASD. This finding highlights the importance of intense early intervention to help preventing the derailment

214 **169.214** Pupil Dilation to Emotional Faces in Relation to Social Anxiety and Autistic Traits in Adolescents with Social Anxiety Disorder

J. L. Kleberg[1]*, T. Falck-Ytter*[2]*, S. Bolte*[3]*, E. Serlachius*[4,5]*, J. Högström*[4,6] *and M. Nordh*[4,6]*, (1)Uppsala University, Uppsala, Sweden, (2)Karolinska Institutet & Uppsala University, Uppsala, Sweden, (3)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (4)Department of Clinical Neuroscience, Karolinska Institutet, Solna, Sweden, (5)Stockholm Health Care Services, Stockholm County Council, Stockholm, Sweden, Stockholm, Sweden, (6)Stockholm Health Care Services, Stockholm County Council, Stockholm, Sweden*

Background:

Social anxiety and autistic traits are overlapping but distinguishable symptom dimensions, both in individuals with psychiatric conditions and in the general population. In social anxiety disorder (SAD), autistic traits may predict treatment response. Autistic traits may also be related to individual variation in attentional processes implicated in the development and maintenance of SAD. Both SAD and autism have been associated with atypical autonomic nervous system (ANS) arousal to emotional faces, although the literature is inconsistent. It is not known whether individual differences in autistic traits modulate ANS arousal to emotional faces in SAD. In the present study, we measured phasic pupil dilation, an index of ANS arousal that is modulated by the sympathetic and parasympathetic branches of the ANS.

Objectives:

To examine pupil responses in individuals with SAD as a function of autistic traits, controlling for self-rated level of social anxiety.

Methods:

Participants were treatment-seeking adolescents with a diagnosis of Social Anxiety Disorder (SAD; $N = 23$; 3 Male; Mean age = 15 years; $SD = 1$). Participants viewed images of 10 happy and 10 angry faces presented for 4 seconds while pupil size was recorded at a sample rate of 120 hertz. Stimuli were matched for luminance and low-level visual characteristics. Pupil response was defined as relative change in pupil size from baseline (1 second preceding the stimuli). Samples where the gaze was within the face were included in the analysis. Autistic traits were measured dimensionally with the Social Responsiveness Scale (SRS)[1]. Social anxiety was measured dimensionally using the Social Phobia and Anxiety Inventory – Child version (SPAI-C)[2]. We analyzed data using a linear mixed effects model (LME) with random intercepts for individual and trial, and fixed effects for emotion, autistic traits, and social anxiety level.

Results:

Significant effects were found for emotion (larger pupil responses to angry vs happy faces; $F = 14.66$; $p = .0002$), and autistic traits (higher level of autistic traits predicted smaller pupil responses; $F = 7.24$ $p = .008$), but not for social anxiety level, ($F = 2.31$; $p = .12$).

Conclusions:

Pupil dilation to emotional faces in individuals with SAD may be modulated by autistic traits. Our results suggest that this effect is independent of social anxiety level. This can inform theories about the overlap between autism and social anxiety.

215 **169.215** Racial Disparities in an Inpatient Sample of Youth with ASD: Nonverbal IQ, Problem Behaviors, Verbal Ability, and Social Functioning

H. Nichols[1], *S. Dababnah*[1], *C. A. Mazefsky*[2], *B. Troen*[3], *R. Mahajan*[3] *and J. Vizzoli*[4], *(1)University of Maryland, Baltimore, Baltimore, MD, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Sheppard Pratt Health System, Towson, MD, (4)University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Research in atypically developing Black youth has found significant disparities in symptoms/behavioral profiles. However, there is limited research examining symptom profile differences between Black youth with ASD and youth with ASD from other racial groups. Furthermore, results have been inconsistent across the few studies that have looked at symptom profile differences by race and none of these studies have examined the inpatient population of youth with ASD.

Objectives: The current study evaluated differences between Black inpatient youth with ASD and inpatient youth with ASD from other racial groups, regarding: demographic & health-related characteristics; problem behaviors; communication; and, social functioning.

Methods: Participants were recruited as part of the Autism Inpatient Collection – a multi-site study enrolling youth diagnosed with ASD between the ages of 4 and 20 from six specialized inpatient psychiatry units in the US. Research-reliable Autism Diagnostic Observation Schedule (ADOS) testers administered the ADOS to confirm ASD diagnosis. Nonverbal IQ was assessed using the Leiter-3. Problem behaviors were measured using the Aberrant Behavior Checklist – Community; communication using the Vineland-II; and, social functioning using the ADOS-2 social affect summary score. Data were analyzed with chi-square difference tests, one-way ANOVAs, and basic descriptive statistical procedures using Stata.

Results: Of the 605 youth in the sample, the majority were male (78%) and the mean age was 13.1 years ($SD = 3.4$). Approximately 81% of youth were White, 9% were Black, and 10% identified as another race and/or multiple races. Black youth were admitted to psychiatric hospitals significantly more often over their lifetime than White youth ($p = .021$). Black youth were more likely to be non-verbal or minimally verbal (72%), compared to White youth (49%) and youth who identified as another race (52%; $p = .006$).

Black youth had significantly lower mean nonverbal IQ scores ($M = 61.0$, $SD = 24.7$) in comparison to White youth ($M = 73.6$, $SD = 28.7$; $p = .026$). Black youth with ASD had significantly lower written communication scores ($F(2, 485) = 3.66$, $p = .026$) in comparison to youth who identified as White or another race, but there was no difference between groups in parent-reported receptive and expressive communication skills. Black youth had significantly greater impairment regarding social functioning, compared to White youth ($F(2, 567) = 3.98$, $p = .019$).

Conclusions: This study highlighted significant racial disparities in psychiatric inpatient care among youth with ASD. Black psychiatric inpatient youth with ASD had overall lower functioning than inpatients of other races, as evidenced by lower nonverbal IQs and a higher proportion who are minimally verbal, as well as more impaired social functioning. The results pertaining to nonverbal IQ are consistent with previous research in other settings. However, few other differences in specific skill deficits or problem behaviors emerged between Black and non-Black inpatients. Given that all participants had marked problem behaviors that necessitated inpatient hospitalization, future research should investigate this association in a broader sample.

216 **169.216** Recognition of Music-Evoked Emotions Among Adolescents with Autism Spectrum Disorder: Examining the Effect of Musical Excerpt Duration and Relationship with Cognitive Skills.

T. Fernandes[1], *H. Dahary*[2], *S. Sivathasan*[1] *and E. M. Quintin*[1], *(1)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (2)McGill University, Montreal, QC, Canada*

Background: Individuals with autism spectrum disorders (ASD) show impairments recognizing emotions conveyed in facial expressions and speech, but can recognize music-evoked emotions comparably to individuals with typical development, suggesting a strength within the musical domain. Music is a dynamic stimuli, which can convey different emotions over the course of minutes and even seconds. Yet, the potential confound of length of exposure to a melody on music-evoked emotion recognition has not been investigated within the context of ASD. We investigate this issue considering cognitive skills and ASD symptomology.

Objectives: We examined the effects of 1) stimuli (musical excerpt) exposure duration, 2) cognitive skills (verbal and visual spatial), and 3) ASD symptomology on the performance (accuracy and reaction time) of adolescents with ASD on music-evoked emotions recognition tasks.

Methods: Twenty-one participants with ASD (mean age = 14.14 years) completed two music-evoked emotions tasks of varying durations. The long music task (LMT) consisted of 15 excerpts with a mean duration of 37 seconds while the short music task (SMT) comprised of 18 excerpts with a duration of 4 seconds. In both tasks, the participants were asked to identify the emotion that best describes the music (happy, sad, or fearful). Participants completed the Verbal Comprehension Index (VCI) and Visual Spatial Index (VSI) of the WISC-V and their teachers completed the Social Responsiveness Scale (SRS-2). Participants were divided into groups based on a median split of Low and High WISC-V scores (VCI : 80; VSI : 95).

Results: An examination of emotion recognition accuracy revealed ceiling effects for the LMT (M=94%, SD=10%) and SMT (M=92%, SD=10%). A repeated-measures ANOVA with response time as an outcome variable, task and emotions as within subject repeated factors, and VCI group as a between subject factor revealed significant main effects of task (p <.01) and emotions (p = .03). Participants were faster in identifying emotions in the SMT compared to the LMT and in identifying happy vs. fearful music-evoked emotions. A significant interaction effect between task and group (p = .01) revealed that the Low VCI group was slower at identifying emotions in the LMT but were comparable to the High VCI group in the SMT. The same pattern of results was found with VSI group as a between subject factor. ASD symptomology did not have an effect on response times.

Conclusions: Results indicate that adolescents with ASD can accurately recognize music-evoked emotions irrespective of musical excerpt exposure duration. However, their speed at identifying emotions was differentially impacted by exposure duration and cognitive skills. These findings suggest that emotion processing and decision making among individuals with ASD and difficulty with verbal and visual-spatial skills may be facilitated by shorter exposure to emotions and potentially to other types of stimuli, which warrants further research.

217 **169.217** Seeing Eye to Eye? Discrepancies in Perceived Social Skill Competency and Motivation Among Adolescents with ASD and Their Parents

A. Osuna, *T. W. Vernon, A. R. Miller and J. A. Ko, University of California Santa Barbara, Santa Barbara, CA*

Background: Adolescents with autism spectrum disorder (ASD) may have limited insight regarding the quality of their interactions and perceived level of social competency (Lerner et al. 2012). As a result, they may over-estimate their level of social success and quality of relationships compared to third party observers, such as their parents. This trend may partially explain the reluctance that some individuals with ASD have to engage in social skill improvement efforts, as they already view themselves as socially competent with an established social network. Understanding this discrepancy may shed light onto the underlying vulnerabilities in social insight that could provide guidance towards removing barriers to treatment utilization and inform methods for promoting more accurate social perception.

Objectives: To examine differences in pre-intervention scores and resulting treatment gains on parent and adolescent socialization measures in the context of an RCT for the START intervention model.

Methods: A total of 35 adolescents, aged 12 to 17 (mean age: 13.46) with ASD participated in the 20-week Social Tools And Rules for Teens (START) Intervention Model. Individuals had an IQ over 70 and a confirmed diagnosis of ASD. Each family completed two socialization measures with corresponding parent and adolescent-report versions– the Social Skills Improvement System Rating Scale (SSIS-RS) and the Social Motivation & Competencies Scale (SMCS). The SSIS is a commonly-used measure of social skills, including communication, cooperation, assertion, responsibility, empathy, engagement, and self-control (Gresham & Elliott, 2008). The SMCS, developed for the purpose of this study, contains items pertaining to comfort in social interaction, conversation skill use, empathy, friendships, appropriate behavior, social contact, and social interest. SSIS-RS and SMCS data were collected before and after intervention. Pre-intervention scores and change scores were examined using paired sample t-tests.

Results: Prior to intervention, adolescents endorsed significantly higher levels of social skills proficiency based on self-report SSIS-RS total scores compared to corresponding parent-reported SSIS Scores, t(34) = 4.087, $p <.001$. They also endorsed significantly higher levels of social motivation and competencies based on self-report SMCS raw scores compared to corresponding parent-reported SMCS Raw Scores, t(34) = 8.568, $p <.001$. There was no significant differences in the pre-to post intervention change scores between groups.

Conclusions: The findings highlight noteworthy discrepancies regarding the adolescents' social skills, motivation, and competencies. These incongruences may be influenced by the adolescents' lack of awareness in self-perceived social competency (Morin, 2011) or possibly suggest that parents tend to be more critical raters of their own child's social competencies.. Furthermore, while there were increases in scores in reported social skill after treatment, the change scores were not significantly different from one another, suggesting that both parties perceived a comparable magnitude of change despite perceiving different baseline levels of social competence.

218 **169.218** Sequential Associations between Supported Joint Engagement and Parent Talk in Children with ASD and Typical Development

K. Bottema-Beutel[1], *B. P. Lloyd*[2], *L. R. Watson*[3] *and P. Yoder*[2], *(1)Lynch School of Education, Boston College, Chestnut Hill, MA, (2)Department of Special Education, Vanderbilt University, Nashville, TN, (3)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: Previous research indicates that caregiver talk that is tailored to the child's attentional focus (*follow-in utterances)* elicits child play, and more so for children with ASD than TD children (Bottema-Beutel et al., 2017). Further, *follow-in directives*, a subset of follow-in utterances, has been shown to be especially elicitative of high-level play in both children with ASD and TD children, as compared to follow-in comments. It is yet to be explored if particular types of caregiver talk elicit caregiver-child joint engagement. An important form of caregiver-child engagement is *supported joint engagement* (SJE), in which the caregiver influences the child's play, but the child does not visually reference the adult. SJE is a robust predictor of language development in TD children and children with ASD (Adamson et al., 2009).

Objectives: This project examines different combinations of SJE and caregiver talk sequences to explore temporal relationships between these constructs. Follow-in utterances, and especially follow-in directives, may be particularly suited to eliciting SJE in comparison to other types of caregiver talk. Further, SJE may elicit follow-in utterances, and potentially more so in dyads that include a child with ASD as compared to a TD child.

Methods: We compared sequential associations (SAs) between different types of caregiver talk and joint engagement sequences, and between children with ASD and typical development (TD). SAs quantify the extent to which one behavior is likely to follow another behavior, while controlling for each behavior's base rates (Yoder & Symons, 2010). SAs were calculated from a coded play session for each child. Mixed-effects models were used to determine effects of group and sequence on mean SAs.

Fifty children with ASD and 48 children with TD participated. Groups were matched on mental age (~13.5 months). Caregiver-child dyads engaged with toys during a 15-min, video recorded free-play procedure. Coding schemes for joint engagement and caregiver talk were applied to these videos, using a 5-s partial interval sampling method.

Results: Follow-in utterances were more likely to elicit SJE than utterances related to the caregiver's focus of attention (p =.05), and this association did not differ by group. Further, follow-in directives were more likely to elicit SJE than follow-in comments (p < .05), but this association did not differ by group. Finally, SJE was more likely to elicit follow-in utterances in the ASD group as compared to the TD group (p <

.05).

Conclusions: Providing talk that (a) is related to what the child is doing, and (b) provides suggestions about what the child might do with the toys (i.e., follow-in directives), elicits SJE to a greater extent than other forms of caregiver talk. Additionally, caregivers of children with ASD appear particularly attuned to providing talk at moments when their child is highly engaged, which may correspond to moments when the child is likely to be processing such talk (Bottema-Beutel et al., 2014). These findings can be used to improve intervention practices for children with ASD that seek to maximize joint engagement as a means to support development (e.g., Kasari et al., 2006/2008).

219 **169.219** Sex Differences in Social Cognition, Executive Functioning and Restricted and Repetitive Behaviours across Development in ASD

R. C. Leung[1,2]*, V. M. Vogan*[1,2]*, V. Yuk*[2,3] *and M. J. Taylor*[2,3]*, (1)Hospital for Sick Children, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)The Hospital for Sick Children, Toronto, ON, Canada*

Background: One characteristic of Autism Spectrum Disorder (ASD) is a male preponderance, with a 4:1 male to female ratio frequently cited in current literature. However, recent research has indicated that this ratio may be influenced by biases towards males in terms of symptom presentation, diagnostic criteria and intellectual functioning. Relative to males with ASD, females with ASD have been shown to demonstrate increased social behaviour, greater language ability and reduced repetitive behaviours. These findings indicate that the current diagnostic criteria for ASD may not be sensitive for ASD in females and may be biased in favour of more disruptive and stereotypical behaviour. Thus, investigating differences in the presentation between males and females with ASD may lead to a better understanding and characterization of the female ASD phenotype, which in turn, has important clinical implications in terms of diagnosis and treatment.

Objectives: The present study characterized sex differences in everyday executive functioning, social cognition and restricted and repetitive behaviours across three age cohorts, children, adolescents and young adults, with ASD.

Methods: We recruited 187 children and adolescents with ASD (N=96, M=10.54+2.3 years, IQ=100.9+15.4; females only: N=14, M=11.07+2.2 years, IQ=99.3+15.4), typically developing children and adolescents (N=91, M=11.02+2.5 years, IQ=113.4+12.2; females only: N=23, M=10.39+2.2 years, IQ=114.0+14.7) and 16 adults with ASD (mean = 27.9+4.6; IQ = 112.4+19.7; 8 females). Informants filled out measures of executive functioning, social cognition and repetitive behaviour, as assessed by the Behavior Rating Inventory of Executive Function (BRIEF; Parent/Relative/Other Form), Social Responsiveness Scale (SRS; Parent Rating Scale), and Repetitive Behaviour Scale – Revised (RBS-R), respectively.

Results: To investigate overall group effects on executive functions, social responsiveness and repetitive behaviours, MANCOVAs were conducted with all BRIEF, SRS and z-scored RBS-R subscales, controlling for IQ. Informants rated males and females with ASD as having greater difficulty in executive functioning, social responsiveness and repetitive behaviours relative to their typically developing peers. Preliminary analyses further indicated that female children and adolescents with ASD had more difficulty with the ability to interpret social cues (p = 0.03) and stereotypical behaviours or highly restricted interests (p = 0.006).

Conclusions: Difficulty with the ability to interpret social cues carries profound implications in terms of the ability to successfully engage in social interactions. Our preliminary results suggest that impairment in social cognition, specifically the interpretation of social cues and stereotypical behaviours or highly restricted interests, is particularly heightened in female children and adolescents with ASD, relative to their male counterparts. Thus, females with ASD may exhibit greater impairment in social cognition to meet diagnostic criteria for ASD, particularly in terms of cognitive-interpretive aspects of reciprocal social behaviour. Furthermore, these differences are present in early childhood. Data analyses are ongoing to further explore sex differences in executive functioning, social skills and repetitive behaviours in children, adolescents and adults with and without ASD.

220 **169.220** Sibling Concordance for Viewing Social Dynamic Scenes in Children with ASD and Typical Development

A. Vinçon-Leite[1]*, E. Rechtman*[2]*, E. A. Douard*[3]*, A. Philippe*[4]*, N. Chabane*[5]*, N. Boddaert*[6]*, A. Saitovitch*[7] *and M. Zilbovicius*[8]*, (1)INSERM U1000, Paris, France, (2)INSERM U1000, Institut Imagine, Paris, France, (3)Research Center of UHC Sainte-Justine, Montreal, QC, Canada, (4)Necker Hospital, Paris, France, (5)CHUV, Lausanne, Switzerland, (6)Hospital Necker, Paris, France, (7)INSERM, Paris, France, (8)Inserm U1000, institut Imagine, Paris, France*

Background: Very recent findings in monozygotic and dizygotic twins toddlers show a concordance in the viewing of social scenes. This concordance is observed for levels of preferential attention and for time spent in the social stimuli (Constantino et al, 2017). Results of this study point to a high concordance in monozygotic twins, a lower concordance in dizygotic and non-concordance for non-siblings in the time spent looking at eyes or mouth, suggesting a strong genetic component influencing this type of behaviour.

Objectives: The objective of the present study was to measure such concordance in a non-twin but brotherhood sample using a paradigm of visual preference displaying at the same time biological and geometric motion.

Methods:

Twenty-eight siblings from 13 brotherhoods participated in the study: 4 brotherhoods of children with autism spectrum disorders (ASD) of which 1 brotherhood contain 3 siblings (so a total of 9 children with ASD) and 9 brotherhoods of typically developed (TD) children of which 1 brotherhood contain 3 siblings (so a total of 19 TD children) and thirty non-sibling children. Age characteristics are as follows: in the brotherhood group (mean=11.9, sd=5.7, range=2.7-25 years) and in the non- sibling group (mean= 9.9, sd = 3.2, range = 4.7- 17.4 years). ASD diagnosis was based on DSM IV-R and ADI-R criteria. Tobii T120 eye-tracker was used to measure looking behavior in a preferential viewing paradigm. Participants were presented with a movie consisting of dynamic geometric images (DGI) and dynamic social images (DSI) displayed simultaneously on the screen and percentage of time spent looking at DGI and DSI was measured for all participants.

Results: We found a significant positive correlation between the percentage of time spent looking at DSI in paired sibling (r =0.72; p=0.002), regardless of the diagnosis. This correlation was not observed among the singleton children, randomly paired.

Conclusions: These results highlight that visual engagement to biological motion could be viewed as a neurodevelopmental endophenotype of variation in social information gathering strategies, not only for autism but also for the typically developing population**.**

221 **169.221** Sleep, Cognition, and Autism Spectrum Disorder

A. Lausberg[1], *N. J. Minshew*[2] *and S. Eack*[1], *(1)University of Pittsburgh School of Social Work, Pittsburgh, PA, (2)University of Pittsburgh, Pittsburgh, PA*

Background: Problems with sleep are common in children with autism spectrum disorder (ASD). Family-reported sleep quality issues have become a growing concern in this population, but the specific areas of sleep that cause the most difficulties are understudied. Further evidence indicates that sleep disturbances significantly impact information processing, but little is known about the impact of sleep dysfunction on cognition in ASD. Objectives: The objective of this study was to examine the specific areas of sleep that are the most problematic in children with autism versus their typically developing peers, and the association between sleep and cognitive impairments in children with ASD.

Methods: The sample consisted of children with autism (n = 62) whose diagnosis was confirmed using the Autism Diagnostic Observation Schedule and the Autism Diagnostic Interview-Revised, and a demographically-matched typically-developing control group (n = 29). Parents or legal guardians completed the Child Sleep Habits Questionnaire, a well-validated measure of sleep quality and disturbance, and participants were assessed with a comprehensive battery of field standard neuropsychological and social-cognitive tests. General linear models and moderated multiple regression were used to examine group differences in domains of sleep quality, as well as the association between sleep quality and cognitive functioning within and across study groups.

Results: Children with autism were reported to have significantly more overall sleep problems as compared with their typically developing peers (t = 3.60, p = .0005), especially in sleep onset delay (t = 2.51, p = .014), sleep duration (t = 2.37, p = .0201), sleep anxiety (t = 3.56, p = .0006), and daytime sleepiness (t = 2.70, p = .0083). Furthermore, it was observed that greater sleep anxiety was related to poorer theory of mind performance (r = -0.27, p = .0142), and similar trend level effects were noted for total sleep problems and sleep-disordered breathing (all p < .090). Conversely sleep quality was not related to measures of neuropsychological impairment.

Conclusions: These results highlight the difficulties children with autism have in sleep onset delay, sleep duration, sleep anxiety, and daytime sleepiness, and also suggest that these challenges may be associated with core social-cognitive impairments in theory of mind. New treatment options that target the unique sleep challenges of children with ASD are needed, and may ultimately support improved social-cognitive functioning in this population.

222

169.222 Social Cognition in Adults with Autism Spectrum Conditions: Validation of the Edinburgh Social Cognition Test (ESCoT)

A. Baksh[1], *S. Abrahams*[1], *S. Baron-Cohen*[2], *C. Allison*[2], *P. Smith*[3], *S. E. MacPherson*[4] *and* ***B. Auyeung***[1,2], *(1)University of Edinburgh, Edinburgh, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (3)University of Cambridge, Cambridge, United Kingdom, (4)Department of Psychology, Human Cognitive Neuroscience, Edinburgh, United Kingdom*

Background:

Current tests of social cognition have limited use in clinical settings, do not assess the different aspects of social cognition within the same test and performance on these tests has shown associations with other cognitive abilities such as intelligence. We developed a new test called the Edinburgh Social Cognition Test (ESCoT) to address these limitations. The ESCoT uses animated interactions to assess cognitive and affective ToM and inter- and intra-personal understanding of social norms.

Objectives:

There were three main objectives of this study. First, we sought to investigate convergent validity of the ESCoT against established tests of social cognition. Second, we compared adults with Autism Spectrum Conditions (ASC) and neurotypical controls (NC) on the ESCoT and established tests of social cognition. Finally, we evaluated the psychometric properties of the ESCoT and compared these to traditional social cognition tests by examining the influence of intelligence, ASC traits, empathy and systemizing traits on performance.

Methods:

To support the development of the ESCoT as a clinical tool of social cognition, we derived cut-off scores from a neurotypical population (n=236) and sought to validate the ESCoT in a sample of nineteen adults aged 19-66 (12 males) with a diagnosis of Asperger's Syndrome or High-Functioning Autism according to established DSM-IV. These individuals were recruited from charities and support groups in Edinburgh, UK and from the Cambridge Autism Research Database (CARD), UK. A comparison group of thirty-eight NC (23 males) aged 19-67 years were recruited using online advertisement and through a research volunteer panel in Edinburgh.

The ESCoT was administered alongside established tests; Reading the Mind in the Eyes, Reading the Mind in Films and the Social Norms Questionnaire. Participants also completed the Autism Spectrum Quotient (AQ), the Empathy Quotient (EQ), the Systemizing Quotient (SQ) and the Wechsler Abbreviated Scale of Intelligence.

Results:

Performance on the subtests of the ESCoT and ESCoT total scores correlated with performance on traditional social cognition tests, demonstrating convergent validity. Adults with ASC performed poorer than NC on all measures of social cognition. Unlike the ESCoT, performance on the established tests was predicted by verbal comprehension. A ROC curve analysis demonstrated that the ESCoT was more effective than existing tests at differentiating adults with ASC from NC. Furthermore, a total of 42.11% of ASC adults were impaired on the ESCoT compared to 5.50% of NC adults.

Conclusions:

The results from this study demonstrate that the ESCoT is a valid and sensitive measure of social cognition, it shows better diagnostic accuracy than established tests and it may be a useful test to assess social cognition in clinical settings.

169.223 Social Impairments Emerge in Infancy and Persist into Childhood in Fragile X Syndrome

J. E. Roberts[1], *A. L. Hogan*[2], *H. Crawford*[3,4], *A. Fairchild*[2], *B. Tonnsen*[5], *A. M. Brewe*[2], *S. L. O'Connor*[2], *C. Pappas*[6] *and D. Roberts*[7], *(1)Psychology, University of South Carolina, Columbia, SC, (2)Department of Psychology, University of South Carolina, Columbia, SC, (3)Faculty of Health and Life Sciences, Coventry University, Coventry, United Kingdom, (4)Cerebra Centre for Neurodevelopmental Disorders, University of Birmingham, Birmingham, United Kingdom, (5)Psychological Sciences, Purdue University, West Lafayette, IN, (6)University of North Carolina Charlotte, Charlotte, NC, (7)GA State University, Atlanta, GA*

Background: Fragile X syndrome (FXS) is the leading genetic cause of autism spectrum disorder (ASD) symptoms, with approximately 60% of individuals with FXS meeting diagnostic criteria for ASD (Lee, Martin, Berry-Kravis, & Losh, 2016). Social-communicative impairments in FXS are characterized in part by reduced and/or atypical social approach behaviors when interacting with unfamiliar adults. However, no studies to date have examined social approach behaviors longitudinally in young children with FXS, so the emergence and trajectories of atypical social approach in FXS are unknown.

Objectives: This study aimed to characterize the trajectory of social approach behaviors across infancy and early childhood in FXS and typical development (TD).

Methods:

The Social Approach Scale (SAS; Roberts et al., 2007) was used to longitudinally measure approach behaviors in children ranging from 4 to 72 months of age (FXS $n = 66$; TD $n = 59$). In total, 290 observations were included (FXS $n = 153$; TD $n = 137$). Physical Movement, Facial Expression, and Eye Contact were rated in the first minute (Rating 1 = R1) and last hour (Rating 2 = R2) of social interaction during a research assessment. Hierarchical generalized linear models (HGLMs) were employed to examine R1 and R2 scores on all three scales, with chronological age nested within participants. To assess whether children with FXS were more likely to "warm up" to examiners over the course of an assessment, the proportion of participants in each group that was rated better at R2 than R1 was compared using Chi-square analyses.

Results:

For Physical Movement, Facial Expression, and Eye Contact, the FXS group was less likely to exhibit normal approach behaviors at both R1 and R2 (bs > ± 1.49, ps < .05) with both the FXS and TD groups demonstrating reduced social approach with age at R1 (bs > ± .02, ps < .05) but not R2 (bs < ± .01, ps > .10) (Figure 1). Age by group interactions were non-significant (bs < ± .02, ps > .25). Similar proportions of participants in both groups exhibited improved Physical Movement ($X^2(1) = 0.17$, $p = .68$) over the course of the assessment, but that the FXS group had a larger proportion of participants exhibit a "warm-up" effect on Facial Expression ($X^2(1) = 5.22$, $p < .05$), and Eye Contact ($X^2(1) = 14.47$, $p < .001$).

Conclusions: As young children with FXS and TD children age, they are less likely to exhibit normal approach behaviors upon initial introduction to a stranger, with atypical approach behaviors more likely in the FXS group. Interestingly, age did not impact ratings at the end of the assessment, suggesting that approach behaviors once the child is familiar with an adult do not change with age. The lack of an age by group interaction suggests that atypical social approach is evident at infancy and persists across early childhood in those with FXS. Children with FXS were more likely to exhibit a "warm-up" effect for Facial Expression and Eye Contact over the course of the assessment.

224 **169.224** Social Information Processing and Victimization in Children with Autism Spectrum Disorders

M. Hooper[1]*, A. Porthukaran*[2]*, J. H. Schroeder*[3,4] *and J. M. Bebko*[3]*, (1)York University, Toronto, ON, CANADA, (2)Psychology, York University, Toronto, ON, Canada, (3)York University, Toronto, ON, Canada, (4)Durham District School Board, Oshawa, ON, Canada*

Background: Peer relationships in childhood and adolescence play a critical role in healthy development (Cairns & Cairns, 1994; Rubin, Bukowski, Parker, & Damon, 1998). Children with difficulties in social competence show a wide range of problems in development, including an increased risk of experiencing victimization through bullying (Schroeder, 2013). Researchers have also demonstrated that there are differences in how children process social information and that these differences can impact and are impacted by, children's experiences with aggression, both as a perpetrator and as a victim.

Objectives: The aim of this study was to examine victimization and social-information processing in children and adolescents with autism spectrum disorders relative to those with typical development. More specifically, it was posited that early social-information processing difficulties in those with ASD impact their ability to generate adaptive solutions to social problems, which increases their likelihood of becoming targets of bullying. This study uses eye-tracking technology to examine the association among variables of victimization. This study is also one of the few to explore multiple types of victimization across multiple raters.

Methods: Twenty-three children with ASD (83% male), and 24 in the TD comparison group (79% male) were matched based on age, IQ and PIQ as assessed by a brief measure of intelligence (WASI; Wechsler, 2011). Both the *Promoting Relationships and Eliminating Violence Network Assessment Tool-Parent and Child Versions* (PREVNet tool; PREVNet Assessment Working Group, 2008) were used to gather child and parent reports of victimization. Participants were shown videos filmed from a first-person perspective of children in various scenes depicting potential bullying and eye-tracking software was used to monitor gaze patterns. The children with ASD were then asked what their response would be in each of the scenes, and responses were categorized as passive, assertive or aggressive.

Results: Parent-reported victimization rates for children with ASD were higher than for typically developing children ($p = 0.001$), with approximately 70% of parents (ASD group) reporting some type of victimization within the past month.. The ASD group also had significantly fewer assertive responses to social scenes depicting bullying scenarios than the TD group ($p = 0.006$). Finally, children with ASD spent less time looking at faces during these social scenes than TD children ($p = 0.03$). For some videos, the amount of time looking at faces was negatively correlated with victimization rates ($r = -0.57$, $p = 0.01$) and passive responses ($r = -0.46$), and positively correlated with assertive responses ($r = 0.56$, $p = 0.02$).

Conclusions: The way in which children process their environment is associated with their everyday interactions. The results of this study can help us to understand the difficulties that children with ASD experience with bullying and victimization. Practically, this research can inform interventionists with specific information regarding areas to target when working on bullying prevention with children affected by ASD.

225 **169.225** Social Rhythmic Entrainment to Child-Directed Singing: The Role of Predictability

M. D. Lense[1]*, L. A. Edwards*[2] *and W. Jones*[2]*, (1)Vanderbilt University Medical Center, Nashville, TN, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: Social communication makes use of predictable, rhythmic behaviors and typically developing (TD) individuals are sensitive to the timing of these behaviors beginning in infancy. In contrast, impairments in the timing of social coordination and reduced sensitivity to rhythmic social behaviors are widely reported in individuals with autism spectrum disorder (ASD). In the current study, we used child-directed singing, a universal form of rhythmic social behavior, to examine how rhythm scaffolds social attention in TD toddlers. Given the critical importance of looking at the eyes of others for understanding social information, we examined how attention to the eyes of a caregiver is modulated by the rhythmic structure of the interaction.

Objectives: Examine sensitivity to social rhythmic information in TD toddlers.

Methods: Sixteen TD toddlers (24 months) watched videos of actresses engaging them with child-directed singing while eye-tracking data were collected. The stimuli videos included natural rhythmic versions of the songs as well as experimentally manipulated, arrhythmic versions. For the rhythmic versions, we used original video recordings of the singing. For the arrhythmic versions, the rhythmic structure of the original videos was disrupted by pseudo-randomly jittering the interval timing between beats of the song. Two levels of jitter were used (moderate: 30%; severe: 50%) to create stimuli that varied in degree of rhythmic predictability. Beats of the singing were determined through vowel onsets and offsets of beat-aligned syllables. The original versions of the singing (coefficient of variation (CV) = 9.5%) were less variable than the 30% jitter versions (CV = 27%), which were less variable than the 50% jitter versions (CV = 43%). We measured whether changes in looking to the eyes of the singer were time-locked to the beats by constructing crosscorrelograms and comparing observed eye-looking with rates of eye-looking expected by chance using permutation testing.

Results: Rhythmic social behaviors in child-directed singing significantly increase attention to the singer's eyes in TD toddlers. When viewing the original, natural rhythmic condition, toddlers' looking to the eyes was significantly time-locked to the beat, with eye-looking increasing by 15.8% above mean levels (p<0.05). This time-locked eye-looking was substantially greater for the original versions of the singing than for the experimentally-manipulated arrhythmic versions. There was only a 9.0% increase in eye-looking at the beat for the 30% jittered version (p<0.05) and a non-significant 3.9% increase for the 50% version (see Figure). The overall proportion of time fixating on the eyes was not significantly different across conditions (p=0.72).
