100 - Welcome and INSAR President Address
8:30 AM - 9:00 AM - Grote Zaal

8:30 Welcome and INSAR President Address.

Oral Session -
Invited, Keynote Speakers, Awards
101 - Keynote Address - Geraldine Dawson, PhD
9:00 AM - 10:00 AM - Grote Zaal

Geraldine Dawson is Professor in the Departments of Psychiatry and Behavioral Sciences, Pediatrics, and Psychology & Neuroscience at Duke University. She is Past-President of the International Society for Autism Research and a member of the Interagency Autism Coordinating Committee. She is Director of the Duke Center for Autism and Brain Development, an interdisciplinary autism research and treatment center, and Chair of the Faculty Governance Committee for the Duke Institute for Brain Sciences. Dawson has published extensively on early detection, brain function, and treatment of autism. With Sally Rogers, she developed the Early Start Denver Model, a comprehensive early behavioral intervention for young children with autism. Her awards include a Lifetime Achievement Award from the Association for Psychological Science and the NIH Top 20 Advances in Autism Research Award in 2007, 2008, 2009, 2010, 2012, 2013, 2014, 2015, 2016, and 2017. TIME magazine recognized her work as a top 10 medical breakthrough of 2012. She completed a Ph.D. in Developmental/Child Clinical Psychology from University of Washington and clinical internship at UCLA.

9:00 Paradigm Shifts in Approaches to the Early Detection and Treatment of Autism

***G. Dawson**, Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Over the past few decades, scientists have discovered how early brain development differs in infants and young children with autism, which has helped explain both the challenges and the strengths and abilities that are associated with autism. Furthermore, research has demonstrated the potential of early behavioral intervention to positively influence the trajectory of both behavioral and brain development in children with autism. As our understanding of the biological basis of autism increases, new treatments designed to enhance neuroplasticity and improve outcomes are currently being developed and tested. Clinical trials evaluating these new treatments are incorporating brain-based measures and quantitative, digital assessments of behavioral outcomes. Such digital approaches to behavioral assessment are transforming how we detect and understand autism and improving our ability to assess the efficacy of novel treatments.

Panel Session
Brain Function (fMRI, fcMRI, MRS, EEG, ERP, MEG)
102 - Translational Electrophysiological Predictors of Individualized Treatment Response in School-Age and Adolescent Individuals with ASD
10:30 AM - 12:30 PM - Grote Zaal

Panel Chair: Tessa Clarkson, *Stony Brook University, Stony Brook, NY*

Discussant: Shafali Jeste, *University of California, Los Angeles, Los Angeles, CA*

A variety of empirically-supported treatments for individuals with autism spectrum disorders (ASD) exist, however given the vast heterogeneity and comorbidity in ASD (Simonoff et al., 2008), predicting an individual's likelihood to respond to treatment remains challenging. Subjective-report and behavioral measures capture a broad-range of symptoms collapsed within a single measure, which are not ideal for understanding within- and between-person variability in discrete constructs that might best predict treatment response. In contrast, electroencephalography (EEG) provides unique insights into the neural mechanisms of discrete constructs in ASD such as threat sensitivity in anxiety (Meyers et al., 2013), approach-withdrawal behaviors (Sutton & Davidson, 1997), incidental face-memory (Key et al., 2013), and suppression of interfering information (Faja et al., 2016). This specificity makes EEG measures ideal predictors/outcome measures of construct-specific treatment response. The coordination of these presentations aims to outline "who will respond to which treatment" by discussing the development and application of specific EEG measures that either suggest an individual has a propensity to improve or experience an attenuation in social skills and anxiety after targeted intervention. The goal of this panel is evaluate different EEG measures for their use in determining the best course of treatment for a particular individual with ASD.

10:30 **102.001** Developing ERP Biomarkers of Social Cognition: The Journey from Task Design to Treatment Outcome Measures

***A. Key**[1], B. A. Corbett[2] and D. Jones[3], (1)Vanderbilt Kennedy Center; Dept. of Hearing and Speech Sciences, Dept, of Psychiatry and Biological Science, Vanderbilt University Medical Center, Nashville, TN, (2)Psychiatry and Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN*

Background: Successful development of effective treatments targeting social cognition in children with autism spectrum disorder (ASD) depends in part on the availability of objective outcome measures. Multidimensional approaches combining traditional behavioral assessments with psychophysiological measures yield more detailed information about treatment effects than standardized tests alone.
Objectives: The purpose of this series of studies was to develop and validate the nonverbal measure of social interest (incidental face memory) as a brain-based marker of social cognition suitable for use as a treatment outcome measure in children with autism.

Methods: Brain responses associated with spontaneous face perception and memory were evaluated using visual event-related potentials (ERPs)

in a pre-post design in four groups of children with ASD (age 7-16 years, total n=90), including three treatment cohorts (peer-implemented social skills program). Additional data from typical controls (age 7-46, total n=37) and children with Prader-Willi syndrome (PWS; age 7-16 years, n=28) who demonstrate social deficits overlapping with ASD were used to further validate the proposed ERPs as a measure of social interest. All subjects viewed a series of color photographs depicting unfamiliar smiling young adults or house facades. One image of each type was randomly selected and repeated throughout the test session while the rest were shown only once. Social interest was quantified as the increased parietal ERP amplitude (300-600 ms) to repeated faces vs. those seen once. Behavioral measures of social cognition included NEPSY Memory for Faces test, caregiver reports (Social Communication Questionnaire, Social Responsiveness Scale, Child Behavior Checklist), and coded observations of playground behaviors with peers.

Results: All participants demonstrated perceptual discrimination of faces vs. houses as reflected in the larger N170 responses to the former. Increased parietal ERP responses to the repeated faces indicative of incidental memory traces were present in typical controls and in children with PWS with more typical social functioning, but not in children with ASD prior to treatment or in children with PWS with greater ASD-related symptomatology. Following the social skills intervention, children with ASD in the treatment group demonstrated increased ERP amplitudes to repeated faces compared to the baseline assessment, while the waitlist control group showed no change. This pattern of results was replicated in each of the three treatment cohorts. The ERP index of social interest did not correlate with IQ or ADOS severity scores, but showed associations with behavioral measures of social skills and behavior.

Conclusions: ERP-based measure of social cognition obtained in the incidental memory paradigm is a promising treatment outcome measure. It fits the biomarker definition as an objective and reproducible measure of neural activity differentiating typical and atypical social information processing. The replicated evidence of its sensitivity to treatment effects, good test-retest stability in the control groups, correlations with behavioral endpoints, and reduced susceptibility to the placebo effects due to the passive nature of the task further support its value as a treatment outcome measure.

10:55 **102.002** Does Baseline Frontal Alpha Asymmetry Moderate the Effect of the PEERS® Intervention in Adolescents and Young Adults with ASD?

H. K. Schiltz[1], *A. J. McVey*[1], *A. D. Haendel*[2], *A. Barrington*[3], *B. Dolan*[4], *K. Willar*[5], *S. Pleiss*[6], *A. Carson*[7], *F. Mata-Greve*[8], *C. Caiozzo*[9] *and A. V. Van Hecke*[10], *(1)Marquette University, Milwaukee, WI, (2)Speech-Language Pathology, Concordia University Wisconsin, Mequon, WI, (3)Biomedical Engineering, Marquette University, Milwaukee, WI, (4)Medical College of Wisconsin, Milwaukee, WI, (5)Children's Hospital Colorado, Aurora, CO, (6)Great Lakes Neurobehavioral Center, Edina, MN, (7)Baylor College of Medicine, Houston, TX, (8)Marquette University, Shorewood, WI, (9)Psychiatry and Behavioral Sciences, Children's Hospital of Philadelphia, Philadelphia, PA, (10)Psychology, Marquette University, Milwaukee, WI*

Background: Challenges in social relationships are at the core of ASD. Previous research suggests that social skills interventions are beneficial (Miller, Vernon, Wu, & Russo, 2014), although they are not one-size-fits-all; variability exists in the degree of change even for studies demonstrating mean-level improvements. The heterogeneity in ASD, in terms of behavior and neurobiology (e.g., Sutton et al., 2005), likely contributes to the differences in intervention outcome. Thus, this necessitates further investigation of the question: for whom are particular interventions most beneficial (Lerner, White, & McPartland, 2012)?

Objectives: The current study examined whether patterns of neurological activity, as indexed by frontal alpha asymmetry, might impact outcomes of the PEERS® intervention. Alpha asymmetry has previously been related to motivational systems involving tendencies for withdrawal (rightward) and approach (leftward) patterns of behavior (Sutton & Davidson, 1997).

Methods: One-hundred and one adolescents and young adults with ASD participated in this randomized controlled trial (RCT) of PEERS® and PEERS® for Young Adults. Diagnoses of ASD were confirmed using the ADOS-G (Lord et al., 2002). The KBIT-2 (Kaufman & Kaufman, 2004) was used to assess IQ; participants had an IQ of 70 or higher. Measures were taken at pre- and post-intervention for the experimental group (EXP), and occurred approximately 14 or 16 weeks apart for the waitlist control group (WL) for teens and young adults, respectively, followed by participation in PEERS®. Measures included caregiver-report on the *Social Responsiveness Scale* (SRS: Constantino, 2005) and a 3-minute resting state EEG paradigm, from which frontal alpha asymmetry was calculated with larger asymmetry values reflective of more leftward dominant alpha activity.

Results: A multiple linear regression was employed to test the effect of Pre-SRS scores, Group (WL as the reference group), frontal alpha asymmetry, and the interaction between asymmetry and Group on Post-SRS scores $F(4,96)=47.23$, $p < 0.001$. Results indicated a significant effect of Pre-SRS scores $b=0.83$, $p < 0.001$ and Group $b=-19.73$, $p < 0.001$ and a significant interaction between Group and Asymmetry $b = 18.68$, $p = 0.05$. This interaction was probed by regressing Post-SRS on Pre-SRS and plotting the residuals against alpha asymmetry. Examination of the plot revealed a positive slope in the EXP group and a negative slope in the WL group. Thus, in the EXP group, those with more negative residuals and, thus, a lower-than-predicted SRS score at post-intervention, had more negative asymmetry scores indicative of a more rightward dominant frontal alpha activity before intervention.

Conclusions: These findings suggest that the impact of the PEERS® intervention may be moderated by frontal alpha asymmetry. Those with the greatest improvement seem to be participants with a more rightward asymmetry before intervention. Thus, participants with a neurobiological profile suggestive of withdrawal seem to receive the most benefit from the intervention, even when controlling for initial levels of social functioning. Considering the practice of approach-related behaviors involved in PEERS®, perhaps those with a tendency towards withdrawal have the most room for improvement in this domain that can be further compounded with the acquisition of social skills.

11:20 **102.003** Discrete Electrophysiological Indices of Anxiety Differentially Predict Anxiety Symptom Reduction Following Group Social Skills Interventions

T. Clarkson[1], *E. Kang*[1], *C. M. Keifer*[1], *T. Rosen*[1] *and M. D. Lerner*[2], *(1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY*

Background: While anxiety symptom reduction is a frequent target for common autism spectrum disorder (ASD) treatments such as Group social skills interventions (GSSIs; McMahon et al., 2013), individual differences in baseline anxiety can make it difficult to predict such response. Parent and child reports of anxiety symptoms are often highly discrepant and likely measure different anxiety constructs (White et al., 2015). Additionally, there are two established electroencephalography (EEG) indices that measure different manifestations of anxiety; 1) the error-related negativity

(ERN), an EEG response to the commission of errors, which reflects endogenous threat sensitivity (Meyer, 2013), and 2) resting-state EEG frontal hemispheric asymmetry (HA) within the alpha frequency band, wherein left- and right-dominant patterns of HA relates to observable-approach motivation and withdrawal/anxiety, respectively (Coan & Allen, 2004; Thibodeau, Jorgensen, & Kim, 2006). However, whether these EEG indices of anxiety relate to discrete subjective reports of anxiety symptom reduction in GSSIs among youth with ASD has yet to be determined.
Objectives: We aim to measure the ERN and HA in ASD youth to predict anxiety symptom reduction in response to GSSI.

Methods: Fifty-three youth (M_{age}=11.60, SD_{age}=2.96; 38 male) with IQ≥70 (M_{IQ}=103.49, SD_{IQ}=15.40) and ADOS-2-confirmed ASD diagnosis participated in a 10-week GSSI. Pre-post anxiety symptoms were measured via self- and parent-report (MASC-2; March et al., 1997). Baseline ERN responses to the Flanker Task (Eriksen & Eriksen, 1974) were measured, such that more negative ERNs indicated greater threat sensitivity (Figure 1A). Baseline frontal alpha-band (7.5-12.5 Hz) power during eyes-open rest was measured, such that positive HA scores indicated greater relative left frontal alpha power (Figure 1B). ANCOVA-of-change models controlling for baseline anxiety symptoms were used to examine both neural measures' ability to predict GSSI response.

Results: ERN amplitudes predicted changes in *self-reported* total anxiety symptoms (Figure 2A), generalized anxiety, social anxiety (including humiliation and rejections), and performance anxiety symptoms (all B>0.39, p<0.04), such that larger ERN amplitudes predicted *greater* improvements, but *smaller* ERN predicted *attenuated* improvements. In contrast, HA predicted changes in *parent-reported* total anxiety (Figure 2D), generalized anxiety, social anxiety (including humiliation and rejections), and *self-reported* tense and restlessness symptoms (all B>0.31, p<0.05), such that more right-dominant HA predicted *greater* improvements, but more left-dominant HA predicted *attenuated* improvements.

Conclusions: These results suggest that the ERN specifically predicted *subjective* anxiety symptom changes, which further validates its use in measuring internally oriented threat sensitivity as an anxiety construct in ASD. In contrast, HA predicted *parent-observable* anxiety symptom changes, consistent with previous work suggesting it relates to overt approach-withdrawal behavior (Coan & Allen, 2004) and parent-reported treatment response (Burnette et al., 2011). Thus, results suggest that individuals with ASD that exhibit a smaller ERN or left-dominant HA may experience attenuated improvement of anxiety symptoms after GSSI, and utilizing these neural indices may be especially useful in social skills treatment planning for youth with ASD and comorbid anxiety.

11:45 **102.004** Event-Related Potentials Linked to Executive Function Predict Intervention Response and Later Social-Emotional Function Among Children with ASD

R. Gilbert[1], A. Vaidyanathan[2], D. Hyatt[3], T. Clarkson[4], G. Greco[5], D. P. Carroll[6] and ***S. Faja****[1], (1)Boston Children's Hospital, Boston, MA, (2)The Banyan Academy of Leadership in Mental Health, Mugappair west, Chennai, India, (3)Medicine, University of Illinois Chicago, Chicago, IL, (4)Psychology, Temple University, Philadelphia, PA, (5)University of Washington, Seattle, WA, (6)Autism Spectrum Center, Boston Children's Hospital, Boston, MA*

Background: Executive function (EF) underlies the ability to strategically approach novel and complex problems. By mid-childhood, it is comprised of inhibition, set-shifting, and working memory. Understanding individual differences in EF and its underlying neural profile is critical because subsequent social function and anxiety are predicted by EF in children without ASD. The N2 event-related potential (ERP) is thought to measure monitoring of conflicting information, enabling inhibition of extraneous information. We have shown that children with ASD have less efficient neural response (i.e., larger overall N2 amplitudes) than children without ASD and larger relative amplitude for more challenging trials related to EF behavior (Faja et al., 2016). The predictive utility of this neural EF signature for changes in social functioning and anxiety in ASD is relatively unexplored.
Objectives: To examine individual differences in ERPs as a predictor of later social function and anxiety. To examine whether ERPs predict social and anxiety changes related to an intervention that targets EF, metacognition, and emotion regulation.

Methods: As part of a clinical trial of EF intervention, 71 children (7 female) with ASD aged 7-11 years with full-scale IQ of M=106 (range: 80-135) participated; 49 provided adequate ERP data at baseline. Thirty-five were randomly assigned to an EF training program and 33 to a waitlist (3 were lost to attrition). Parents responded to the CBCL about emotional and behavioral challenges and the SSIS regarding social functioning. Electrophysiological recordings were collected to examine the N2 during a Flanker task. Mean amplitude was computed for each condition (congruent/incongruent). Regression models controlling for baseline social functioning and anxiety symptoms were used to examine whether baseline N2 predicted changes over a 3-month intervention period.

Results: Regardless of training assignment, baseline N2 amplitudes predicted social function on the SSIS at post-test controlling for baseline social function, such that more inefficient (larger) neural responses to incongruent flankers relative to congruent predicted *smaller increases* in social function (β = -.21, p=.045). Similarly, CBCL Anxiety at post-testing relative to baseline was predicted by overall N2 amplitude (β = -.24, p=.045), such that more efficient amplitudes predicted *lower* levels of anxiety. Within the intervention group alone, SSIS social change was no longer significant, but CBCL Anxiety was predicted by overall N2 amplitude at baseline (β = -.33, p=.06). That is, children who had smaller initial N2 amplitudes had a greater reduction in anxiety symptoms after treatment. Data from 5 subjects who are currently in progress will be included for final analyses.

Conclusions: Efficient neural response to extraneous stimuli may be an important predictor of individual differences in social skills growth and anxiety symptom reduction among children with ASD. In particular, overall social function and anxiety symptom improvements appear related to more efficient interference suppression. Moreover, more efficient interference suppression, as measured by the N2, predicted greater anxiety reduction among children in the EF training group. Thus, the N2 may provide a biomarker for predicting best responders to targeted intervention.

Panel Session
Interventions - Non-pharmacologic - School-Age, Adolescent, Adult
103 - Reaching Children Where They Are: The Promise and Challenge of School-Based Intervention for Autism
10:30 AM - 12:30 PM - Willem Burger Zaal

Panel Chair: Lauren Kenworthy, *Children's National Health System, Washington, DC*

Discussant: Aubyn Stahmer, *Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Schools are the primary service provider for children with ASD over five. They are accessible to more children than the clinic and offer greater opportunities for generalization of treatment effects. Yet there is a lack of evidence-based intervention in schools related to difficulties with adoption and implementation of treatments that were developed in research settings (Weisz et al, 2005). Effective school-based interventions are developed within the systems in which they will be delivered, with stakeholder involvement, appropriate training, and fidelity monitoring. They acknowledge the time and financial constraints driving schools, and provide low-intensity treatments where appropriate, and adaptive methodologies that allow rapid tailoring of treatments (Wood et al, 2015). Moderated by an expert in the translation of evidence-based autism research to the community (Stahmer), this panel will share knowledge gleaned from experience working in schools, as well as empirical evidence for specific school-based interventions. Data will be presented on: Positive outcomes following novel executive function interventions in elementary (Anthony) and middle-school classrooms (Strang); Application of innovative SMART methodology and the adaptive interventions it enables (Sturm); and a survey of school professionals about their knowledge of evidence-based interventions and how they select interventions to implement (Kenworthy).

10:30 **103.001** Improving the Executive Functioning of Adolescents with ASD through School-Based Intervention: The on Target for Life Curriculum

J. F. Strang[1], *L. Anthony*[2], *C. E. Pugliese*[3], *L. Cannon*[4], *M. A. Werner*[5], *S. Seese*[3], *M. F. Skapek*[6] *and L. Kenworthy*[3], *(1)Center for Autism Spectrum Disorders, Children's National Health System, Washington, DC, (2)University of Colorado, Denver, Aurora, CO, (3)Children's National Health System, Washington, DC, (4)Ivymount School, Rockville, MD, (5)Program Development and Training, Ivymount School, Rockville, MD, (6)Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Executive function (EF) challenges increase as youth with ASD enter the teen years, and executive dysfunction is related to long-term adaptive outcomes. The On Target for Life (OTL) school-based curriculum is the upward age-extension of the empirically supported Unstuck and On Target curriculum.

Objectives: OTL is a Cognitive Behavioral Therapy intervention employing a neurodiversity framework, drawing on specific learning strengths in autism, such as the particular ability to get “stuck” on key details, in this case self-regulatory EF scripts (e.g., “stuck on a detail”, “big picture”, “flexible thinking”, etc.) OTL was developed through a community-based participatory process, engaging key stakeholders (autistic youth and their parents, teachers and administrators) in the objectives and design of the curriculum.

Methods: A randomized comparative trial (n=33) was conducted in 9 public middle schools (five schools receiving OTL and four schools receiving the school version of PEERS, an empirically supported social skills intervention). Intervention “dosages” were matched across the two treatments, and curricula were administered by school staff. The fidelity of intervention delivery was measured twice through in vivo observations. Masked (i.e., blinded to treatment condition) pre-post assessments were conducted with youth and their families, including classroom observations in the students’ English classes conducted at the beginning and end of the school year and a masked in vivo behavioral assessment measure of flexibility and planning skills in a one-on-one interactive context (Executive Function Challenge Task; EFCT). Youth and parents also completed a standardized pre- and post-battery: Behavioral Rating Inventory of Executive Function II (BRIEF II; parent and self report); Social Responsiveness Scale II (SRS II); and the Tower of London DX (TOL DX), a measure of a high-order planning skills. A newly developed autism-specific anxiety measure (Scahill et al., 2016) was completed by the parents.

Results: Pre-post paired sample t-tests indicated significant improvement for both intervention groups in social functioning as measured by masked classroom observations of social functioning, standardized parent report (SRS II), and autism-specific anxiety symptoms (all p’s < 0.05). Both groups also showed increased convergence between standardized parent and youth self-report of everyday behavioral functioning (BRIEF II; $p=.035$), considered a marker of increased self-awareness in the youth. The OTL group, but not the comparison intervention group, made significant gains (p’s < 0.05) on classroom observations of executive functioning, the EFCT, as well as on the average of key indices of the TOL DX.

Conclusions: Both treatments were associated with greater convergence between parent and youth report of a young person’s functioning, suggesting improved insight/self-awareness in the youth. Similarly, both interventions were associated with improvements in the youth’s social functioning and anxiety; OTL-related gains in social skills are in accordance with previous evidence linking EF intervention and improved socialization. OTL was uniquely associated with improvements in flexibility and planning skills measured with treatment blind tools across multiple modalities, including observed classroom behaviors, suggesting that CBT-informed EF treatment with repeated exposure to/practice with self-regulatory scripts may have a generalized effect on EF-related behaviors across real-world settings.

10:55 **103.002** What Matters?: An Examination of Implementation Factors in the Effectiveness of Two Tier 2 School-Based Interventions

L. Anthony[1], *A. Verbalis*[2], *C. E. Pugliese*[2], *K. Hardy*[2], *J. F. Strang*[2], *B. J. Anthony*[1], *A. B. Ratto*[2], *S. Seese*[2], *J. Safer*[3], *A. C. Armour*[2], *M. Troxel*[1], *Y. Myrick*[2], *D. Limon*[2] *and L. Kenworthy*[2], *(1)University of Colorado, Denver, Aurora, CO, (2)Children's National Health System, Washington, DC, (3)Georgetown University, Washington, DC*

Background:

The intervention research field for children with neurodevelopmental disorders is increasingly moving beyond efficacy towards effectiveness, dissemination, and implementation trials. As this shift occurs, we must continually examine which implementation factors do – and do not - influence outcomes in order to consider the likelihood of broad dissemination and implementation.

Objectives:

This study presents the exploratory analyses of the effects of possible implementation factors on classroom-based outcomes from a comparative effectiveness research (CER) trial, factors that may be used for hypothesis generation for future studies.

Methods:

The CER trial compared two Tier 2 interventions for students with ASD or ADHD, Unstuck and On Target (UOT) and Contingency Behavior Management (CBM), in 21 Title I (low-income) elementary schools in three districts. Both interventions targeted executive functioning skills in the classroom. The primary outcome for these analyses are change in pre-post academic classroom observations on the following behaviors: demonstrates social reciprocity, follows rules, transitions appropriately, gets stuck, displays negativity, and participates in class (total raw scores ranging from 0 (worst) to 6 (best)). Family income ranged from $8,796-400,000. There were fewer than 30% White Non-Hispanic/Latino students in the study and only about 51% of the families spoke only English at home.

Results:

Diagnosis was an important moderator for this outcome, with ADHD students making significant treatment gains in both interventions, while ASD students only showed a positive effect in UOT. The following implementation factors did not have a significant impact on effectiveness (whether separated by intervention, diagnosis or when combined): Treatment fidelity, number of intervention sessions completed, profession of the school-based interventionist, and amount of knowledge that the parent gained.

Some important acceptability factors were significant, though. Students reported that they enjoyed UOT more than CBM (t=2.018,df=128,p=.046), though there was no significant relationship between how much they enjoyed the group and how much they improved within intervention group. Parents also reported that they felt that UOT helped their child more (t=2.767,df=117,p=.007), they were more satisfied with UOT (t=3.015,df=116,p=.003) and are more likely to use UOT techniques in the future (t=2.055,df=90,p=.043). Improvements measured by masked classroom observations were significantly correlated with parents' report of how much they felt the interventions helped their child (r=.267,p=.005,N=109) and how satisfied they were with the intervention (r=.336,p<.001,N=108). Qualitative analyses of student and parent responses will also be presented.

Conclusions:

The lack of relationship between most standard implementation factors, such as fidelity, training of interventionist, and completion of the intervention, and outcome is unexpected and difficult to explain. First, it is possible that the participating schools delivered both interventions with exceptional skill, though the fidelity and completion rates ranged considerably. It may also be that these implementation factors do not matter as much in Tier 2 (middle intensity, group-based) as in Tier 3 (High-intensity, individualized, and more frequently studied) interventions designed to be delivered in schools to students experiencing disparities. Finally, it could be that providing *any* explicit training of EF skills can have positive effects for these at-risk students.

11:20 **103.003** Acceptability and Feasibility of a Pilot SMART Design in a School Setting

A. Sturm[1]*, A. J. Schlink*[2]*, S. Y. Shire*[3]*, W. I. Shih*[4]*, D. Almirall*[5] *and C. Kasari*[4]*, (1)UCLA, Los Angeles, CA, (2)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (3)University of Oregon, Eugene, OR, (4)University of California, Los Angeles, Los Angeles, CA, (5)University of Michigan, Ann Arbor, MI*

Background:

School-aged children with ASD require interventions that are evidence-based and adaptable if there are indications of slow-response to treatment. Adaptive interventions (AI) are sequences of individually-tailored interventions over time that can address this need. Yet, more work is needed to determine the acceptability and feasibility of AIs employing empirically-supported interventions in schools.

Objectives:

The present study aimed to evaluate the acceptability and feasibility of an AI in a school setting by assessing (1) the acceptability of AI changes to school staff (i.e., teachers and aides) delivering the component interventions and (2) the fidelity of AI components delivered by school staff.

Methods:

The 18-week AI was composed of initial randomization to Remaking Recess (RR; delivered by playground aide), or RR plus Classroom Supports (CS; delivered by teacher), both environmental modification interventions. After 8 weeks, the environmental modifications were then augmented with Parent-Assisted Home Intervention (Parent) or Peer- mediated School Intervention (Peer) delivered by research staff. Twenty-four children ages 5 to 10 (M=7.2, 74% male, 67% Hispanic/Latino, 87% free or reduced meals) from 18 classrooms and five schools participated. Outcome measures included researcher-rated CS (teacher; N=22) and RR (aide; N=18) fidelity, teacher-rated treatment expectations (N=17), aide-rated treatment acceptability (N=18), and structured aide (N=17) and teacher (N=17) diaries assessing implementation issues.

Results:

Nearly all teachers surveyed held positive opinions regarding the potential for adaptive change in (82%), or intensification of (100%), student's treatment and 100% endorsed that they were likely to agree to potential changes in intervention. Surveyed after intervention, 83% of aides held positive opinions about changes made to their student's treatment. When no change in treatment was indicated, aides who felt negatively about lack of change (0.7%) would have preferred to add the intervention that their student had not received (Peer/Parent).

Aides (RR) and teachers (CS) found the respective intervention strategies to be natural and relatively simple. While most aides felt confident (82%) and comfortable (94%) in their delivery of RR strategies, teachers felt less so with CS (confident: 60%; comfortable 66%). However, fidelity at the end of treatment varied widely (RR, aides: 0-100%, *M*=58%; CS, teachers: 22-67%, *M*=37%). Aides and teachers reported the most difficulty finding time to implement the respective strategies, most often during Phase 2 when 76% of aides and 53% of teachers endorsed this to be at least "somewhat true". Several aides (29%) and teachers (33%) reported that strategy implementation required substantial work. This was reflected in qualitative feedback from some aides who reported that they would have liked more time to review the RR strategies, and that they struggled with juggling strategy implementation and their other responsibilities on the playground.

Conclusions:

The present study found that AIs are acceptable to school staff, however adjustments are required to ensure feasibility of school staff implemented intervention components. In planning for a fully-powered AI, variability in degree of successful strategy implementation suggests that researchers must provide sufficient individualized support to quickly ensure a high level of school staff comfort with intervention strategies and their flexible and accurate use.

11:45 **103.004** How Do We Disseminate?: What School Staff and Parents Need to Implement Evidence Based Interventions in Public Schools

L. Kenworthy[1]*, M. D. Powers*[2]*, A. Verbalis*[1]*, M. Troxel*[3]*, L. Anthony*[3] *and Y. Myrick*[1]*, (1)Children's National Health System, Washington, DC, (2)Children's National Health System, Rockville, MD, (3)University of Colorado, Denver, Aurora, CO*

Background: Public schools are the primary service provider for children with ASD over three, and unlike clinic settings, they are accessible for all children. School staff encounter significant obstacles to the adoption and implementation of evidence based (EB) autism treatments, however, including: a lack of cost/time-effective lower intensity interventions; ineffective training methods; and limited emphasis on the scientific evidence for various treatments (Wood et al., 2015; Stahmer et al., 2015; Stormont et al., 2011). Children without intellectual disability are the fastest growing segment of the burgeoning school-aged ASD population (CDC, 2014) and are often placed in mainstream educational classrooms, where they can succeed at basic academic skills, but struggle to access the educational curriculum related to social and executive function deficits (APA, 2013). There is a developing EB for lower-intensity, or Tier 2, school-based social and executive function interventions for these children (Kasari et al., 2016; Kenworthy, Anthony et al., 2014).

Objectives: Survey educational stakeholders across the nation regarding their: commitment to using EB interventions, knowledge of the EB for the interventions they use, and current and preferred methods for learning about interventions. Also, survey parents regarding their interest in school-based services.

Methods: Participants were English speakers/readers, >18 years old, with internet access and were either school staff/officials or parents of children in 3rd – 5th grade with ADHD or ASD. Recruitment was through advertising on online platforms, including Facebook "Boosted Posts" and nationally-read education publications. The educator survey focused specifically on Tier 2 educational interventions, defined in the survey as small group or classroom strategies targeting the 10-20% of students who need more intensive support than Tier 1 (=universal strategies), but less support than is provided in intensive, individualized Tier 3 interventions. Definitions were also provided in the survey for EB practices and executive function.

Results: Survey respondents reflected a nation-wide sample (223 zip codes). 76.3% of the 227 school-staff respondents reported a school policy of using EB practices. Yet, when asked to list the EB social skills and executive function interventions they use, they reported few interventions, and, identified many interventions as being EB that have no peer-reviewed published evidence of efficacy (Figure 1, details to be presented). School personnel report a discrepancy between how they get information about EB interventions and how they would like to get information (Figure 2), indicating that they rely heavily on personal research, but would like more mentoring and outside training (e.g., workshops, conferences). 85.6% of the 125 parent survey respondents want to devote substantial time (mean= 32(±58) hours/school-year) to school-based trainings to help them support school-based interventions for their children.

Conclusions: School personnel want to use EB interventions but do not have accurate information on the EB for the programs they use. They would like more professional training and hands-on mentoring, which aligns with research indicating long-term on-site training improves implementation. Parents want to partner with schools to support interventions. Future research should investigate the dissemination of EB Tier 2 interventions with self-sustaining school-based training models for teachers and parents.

Panel Session
Adult Outcome: Medical, Cognitive, Behavioral

104 - Tapping the Talent: Strategies to Address the International Employment Problem in Autism

10:30 AM - 12:30 PM - Willem Burger Hal

Panel Chair: Alycia Halladay, *Autism Science Foundation, New York, NY*

Discussant: Anne Roux, *A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

About half of individuals with autism spectrum disorder (ASD) around the world are un- or under-employed, making ASD among the least effectively- or consistently-employed group worldwide. Unfortunately, there is very little known about factors affecting employment in people with ASD, as well as effective interventions and services to prepare and maintain employment for people with autism. Last year, in order to translate scientific knowledge into actionable policy in this area, INSAR awarded researchers from the Autism Science Foundation, Stony Brook University (US), Curtin University (Australia) and the Karolinska Institute (Sweden) support to develop an international policy brief around employment targeting the specific needs of those with ASD. This panel will present the scientific studies and community partnerships to inform this policy brief. They included: 1. a scoping review of the literature on employment organized in the framework of the ICF, 2. results of direct interactions and collaboration with various community stakeholders to inform suggested policy, 3. a survey filled out by individuals with ASD, and 4. a parallel survey completed by other relevant stakeholders, both internationally, which assessed needs, challenges and opportunities for employment. Finally, a discussant will then integrate the specific policy recommendations that arose from these activities.

10:30 **104.001** Factors Impacting Employment for People with Autism Spectrum Disorder: A Scoping Review

M. T. Scott[1], *B. T. Milbourn*[2], *M. Falkmer*[3], *S. Bolte*[4], *A. Halladay*[5], *M. D. Lerner*[6], *J. L. Taylor*[7] *and S. J. Girdler*[2], *(1)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (2)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (3)Curtin University, Bentley, Australia, (4)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (5)Autism Science Foundation, New York, NY, (6)Psychology, Stony Brook University, Stony Brook, NY, (7)Vanderbilt Kennedy Center, Nashville, TN*

Background:

Adults with Autism Spectrum Disorder (ASD) demonstrate not only difficulties, but possess unique strengths and abilities which can be harnessed in the work environment often performing well in jobs requiring systematic information processing, precision and repetition. However, despite increasing recognition of the potential contribution that individuals with ASD can make in the workplace, they continue to experience challenges in finding and maintaining employment. Given that employment research in ASD is progressing there is a need to synthesize research to enable an understanding of those factors impacting employment, and a description of the targets and effectiveness of various intervention approaches. This scoping review examined the extent and range of literature relating to the employment of individuals with ASD.

Objectives:

The primary objectives of this review were to: 1) comprehensively review employment literature relating to ASD and employment; 2) explore measures used in evaluating employment outcomes; 3) identify the strengths and abilities of individuals with ASD in the workplace; 4) classify and link ASD employment interventions to the International Classification of Functioning, Disability and Health (ICF) Core Sets for ASD; and 5) summarise the targets and outcomes of employment interventions.

Methods:

Database searches of Medline, CINAHL, PsychINFO, Scopus, ERIC, Web of Science and EMBASE were conducted. Studies describing adults with ASD in competitive, supported or sheltered employment, the role of vocational support, or the evaluation of employment interventions were included. Data were extracted in relation to author, year of publication, country, design, participants, outcome measures and nature stage of employment. Quality of the evidence was assessed. Content analysis of results identified the strengths and abilities of employees with ASD in the workplace. Lastly, meaningful concepts relating to the evaluation of employment interventions were extracted and linked to International Classification of Functioning, Disability and Health (ICF) Core Sets for ASD.

Results:

The search identified 3,701 references, of which 117 were include for review. Methodological quality of the articles ranged from limited to strong. Of the 117 articles, only 14 explored the strengths and abilities of individuals with ASD in the workplace including attention to detail, high quality of work, strong sense of morality and precise technical abilities. Thirty-two studies evaluated employment interventions for adults with ASD, primarily focusing on modifying autism-related characteristics such as social interaction, communication skills and executive functioning for improved performance in acquiring a job. While environmental factors such as technology, employer and co-worker support and job coaches were utilised in facilitating work participation, these were never the focus of interventions.

Conclusions: The ICF Core Sets for ASD enabled a holistic review of the employment literature relating to individuals with ASD. While employment interventions targeting intrinsic personal factors of adults with ASD are beneficial in improving work-related outcomes, there has been limited consideration of the role that environmental factors may play in the workplace. This review highlighted the need for the development of more holistic approaches, which consider the influence of both personal and environmental factors in improving the employment outcomes of people with ASD.

10:55 **104.002** An International Survey on Barriers & Access to Employment: Perspectives of Adults with ASD

M. D. Lerner[1], *C. M. Esposito*[2], *A. H. Gerber*[3], *B. T. Milbourn*[4], *M. H. Black*[4], *S. Bolte*[5], *S. Mahdi*[6], *A. Halladay*[7] *and S. J. Girdler*[4], *(1)Psychology, Stony Brook University, Stony Brook, NY, (2)Stony Brook University, Staten Island, NY, (3)Stony Brook University, Stony Brook, NY, (4)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (5)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (6)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Karolinska Institute Center of Neurodevelopmental Disorders, Stockholm, Sweden, (7)Autism Science Foundation, New York, NY*

Background: Across the globe, adults with autism spectrum disorder (ASD) are among the most underemployed populations (Carter et al. 2012). For instance, in the United States, 33% of adults with ASD are currently employed, while in Australia – where considerably more support services are available – that number remains only 42% (Standifer, 2011; Australian Bureau of Statistics, 2010; United Nations, 2007). A number of factors including stigma, lack of information and training, and insufficient supports have been identified by researchers as impacting the process of finding and keeping a job among those with ASD (Scott et al. 2015; Chen et al. 2015; Muller et al. 2003). However, little research has sought to understand the perspectives *of individuals with ASD* on the factors that influence their ability to obtain and maintain a job. Given the wide range of services, supports, and norms across countries, the establishment of common goals regarding employment require an international perspective.

Objectives: This study aimed to assess the self-reported factors contributing to employment among adults with ASD across three different countries: the United States, Australia, and Sweden.

Methods: Using items derived from a previous mixed-methods study designed to identify common factors regarding employment in ASD, a standardized survey instrument was deployed (and translated) in the three target countries. Fifty-one, 28, and 37 adults with ASD completed the survey online in the United States, Australia, and Sweden, respectively. An examination of distribution of responses was conducted. Data from additional participants will be included in the final presentation.

Results: There was international consensus that work experience and vocational training are important to helping individuals with ASD to obtain a job (>89% rating across countries). However, only 68% (stable across countries) of participants indicated that educating staff about ASD prior to the individual being hired was important to obtaining a job. 100% of participants across countries indicated that focusing on individuals' strengths in the workplace was important for maintaining a job. However, only 50 – 75% of participants across countries indicated that increased or modified pay rates would be valuable for maintaining a job.

Conclusions: This survey – the first to ask individuals with ASD across nations their perspective on obtaining and maintaining employment – highlights key areas of international consensus regarding getting and keeping a job. Hands-on work experience was considered extremely important for obtaining a job, while educating staff at the new place of employment was considered less so. In terms of maintaining a job, every participant indicated that focusing on their strength was essential, while comparatively fewer wished for greater pay. These results highlight the unique goals and priorities of individuals with ASD as they enter – and try to remain – in the workplace around the world.

11:20 **104.003** Seeking and Maintaining Employment Among Adults with ASD: Clinician, Family and Employer Views in Australia, Sweden and the USA

S. Bolte[1], *S. Mahdi*[2,3], *C. M. Esposito*[4], *M. Falkmer*[5], *M. H. Black*[6], *M. D. Lerner*[7], *S. J. Girdler*[6] *and A. Halladay*[8], *(1)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (2)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Karolinska Institute Center of Neurodevelopmental Disorders, Stockholm, Sweden, (3)Center for Psychiatry Research, Stockholm, Sweden, (4)Stony Brook University, Staten Island, NY, (5)Curtin University, Bentley, Australia, (6)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (7)Psychology, Stony Brook University, Stony Brook, NY, (8)Rutgers University, Piscataway, NJ*

Background: Employment rates for adults with disabilities are low, including those for autism spectrum disorder (ASD). Research on facilitators and barriers for seeking and maintaining jobs is limited in ASD, particularly from a multi-informant and cross-cultural perspective.

Objectives: The aim of this study was to collect views on factors potentially promoting or hampering access to jobs and long-term employment in the eyes of family members, clinicians, care providers, researchers and employers across Australia, Sweden and the USA.

Methods: Based on previous research a standardized online survey was developed, translated and further adapted to each country's setting based on national clinical and practical experience, and requirements. The survey contained three parts: informed consent, socio-demographic background information and 65 to 70 Likert-scaled items of seeking and maintaining employment, taking about 25 minutes to complete. As of October 2017, a total of 134 family members, 73 professionals (clinicians, service providers and researchers) and 6 employers had completed the survey, 113 from the USA, 53 from Australia and 47 from Sweden.

Results: Across countries and informants there was more convergence than divergence regarding views on facilitators and barriers of findings and maintaining employment. Especially, there was a robust consensus on the relevance of matching skills and job demands in ASD, as well as the decisive role of one responsible manager at the workplace being approachable to assist in avoiding and solving conflicts. Informants also agreed of the necessity to destigmatize ASD, to stress ASD-related strengths, and whenever possible to adapt the workplace environment to need and skills of individuals with ASD.

Conclusions: Our findings demonstrate a broad consensus across stakeholders in high income countries concerning factors promoting and hampering employment of adults with ASD. The survey results provide many options to derive recommendations for private and public employers, policy makers, interest organizations, and individuals on the spectrum to achieve higher employment rates in autism.

11:45 **104.004** A Cross-Cultural Perspective of the Views of Stakeholders on the Employment of Individuals with ASD

S. J. Girdler[1], *M. Falkmer*[2], *M. T. Scott*[3], *M. D. Lerner*[4], *C. M. Esposito*[5], *A. H. Gerber*[6], *B. T. Milbourn*[1], *M. H. Black*[1], *S. Mahdi*[7], *A. Halladay*[8] *and S. Bolte*[9], *(1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (2)Curtin University, Bentley, Australia, (3)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (4)Psychology, Stony Brook University, Stony Brook, NY, (5)Stony Brook University, Staten Island, NY, (6)Stony Brook University, Stony Brook, NY, (7)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Karolinska Institute Center of Neurodevelopmental Disorders, Stockholm, Sweden, (8)Autism Science Foundation, New York, NY, (9)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Background: The right to employment for all is enshrined in Article 23 of the Universal Declaration of Human Rights; however, for many people living with Autism spectrum disorder (ASD) this right is yet to be realised. While there is a clear need to improve employment outcomes, developing appropriate services depends not only on systematic empirical measurement, but on an in-depth understanding of the perspectives of key stakeholders.

Objectives: This study aimed to elicit an in-depth understanding of the perspectives of stakeholders, including adults with ASD, their families, clinicians and service providers and employers, on the processes associated with employment across Australia, Sweden and the United States.

Methods: Focus groups and interviews were held across countries, guided by questions reflecting the process of employment from job preparation through to maintaining a job, the contribution of people with ASD to the workplace, and the meaning of employment for people with ASD. As of October 2017 three community forums have been held in Australia, in partnership with the Autism Association of Western Australia, including 24 people with ASD and family advocates, and 14 Service providers. Additional findings from the perspective of employers and Sweden and the United States will be included in the final presentation.

Results: Across forums discussions in relation to preparing for employment focused on job-match, social communication, preparing for interviews and building independence in other major life areas. Considerations of gaining and maintaining employment were employer and co-worker's knowledge of ASD, support from mentors, the social demands of the workplace, and understanding of job requirements. People with ASD were described as having attributes of value in the workplace including focus, loyalty, honesty, reliability, directness, creativity and impartiality. The meaning of employment for people with ASD included increased independence, specifically financial, improving mental health and quality of life, and reducing parental stress.

Conclusions: Findings point to the importance of adopting a holistic view of employment and the need for interventions to focus on aspects beyond individuals with ASD themselves to factors in the environment, including workplace relationships, available supports and the attitudes of employers and co-workers towards ASD. Discussions highlighted that people with ASD commonly possess attributes highly valued in the work environments. As is recognised globally that employment is key in improving outcomes for all, findings from this study highlight that employment is key to improving outcomes in other major life areas for adults with ASD.

Panel Session
Genetics

105 - Next Steps in Autism Genetics: Leveraging Genetic Variation to Understand Risk Mechanisms and Phenotypes

10:30 AM - 12:30 PM - Jurriaanse Zaal

Panel Chair: Stephan Sanders, *Psychiatry, University of California San Francisco, San Francisco, CA*

Discussant: Stephan Sanders, *Psychiatry, University of California San Francisco, San Francisco, CA*

Large-scale genomic analyses have identified genetic variants with a causal relationship to autism. These variants provide a starting point from which we can explore the etiological mechanisms between genotype and phenotype, including the neurological mechanisms, developmental changes, and cell types involved in autism. This panel describes several approaches to developing this genetic foundation and leveraging it to understand autism biology and phenotype. Parallel genetic approaches and consistent gene discovery methods in autism and developmental delay help distinguish genes shared between these disorders from those with more specific roles. Integrating new autism data into this gene discovery approach, alongside population-level allele frequencies, refines and expands the autism gene list. Whole genome sequencing data allows us to also investigate the role of rare noncoding variation in autism, potentially increasing the resolution to detect specific cell types, brain regions, and developmental stages involved in autism risk. Finally, integrating whole genome sequencing with RNA expression data in the developing human brain provides a complementary approach to identify the critical processes and genomic regions involved in brain development and assess how these intersect with known ASD risk factors such as disruptive variation, expression changes, and sex differences.

10:30 **105.001** Genotype-Phenotype Relationships: Exploration of Shared and Distinct Genetic Risk for ASD and ID

L. Klei[1]*, S. De Rubeis*[2]*, S. Sanders*[3]*, X. Xu*[4]*, B. K. Sheppard*[5]*, C. Betancur*[6]*, M. State*[3]*, E. Cook*[7]*, J. Buxbaum*[8]*, K. Roeder*[9] *and B. Devlin*[10]*, (1)University of Pittsburgh, Pittsburgh, PA, (2)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Psychiatry, University of California San Francisco, San Francisco, CA, (4)Icahn School of Medicine at Mount Sinai, New York, NY, (5)Johns Hopkins School of Public Health, Baltimore, MD, (6)Sorbonne Universite, Paris, France, (7)University of Illinos at Chicago, Chicago, IL, (8)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (9)Carnegie Mellon University, Pittsburgh, PA, (10)Univ of Pittsburgh School of Medicine, Pittburgh, PA*

Background: Whole-exome sequencing has identified dozens of genes affecting risk for autism spectrum disorder (ASD) and even more for severe developmental disorder (SDD). SDD typically involves intellectual disability (ID), which is often comorbid with ASD.
Objectives: Because these discoveries intersect for some genes and not others, we hypothesized that the joint study of data from ASD and SDD subjects could reveal the patterns of genetic overlap and etiology of these disorders.

Methods: We assessed rare *de novo* variants identified via exome sequencing of 4,109 ASD trios from the Autism Sequencing Consortium (ASC) and 4,293 SDD trios from the Deciphering Developmental Disorders (DDD) Study. We applied the same statistical algorithm, TADA (Transmission And *De novo* Association), to both datasets to identify likely risk genes in each disorder based on identical criteria.

Results: We find substantially greater clustering of probably damaging mutations in specific genes in SDD than ASD subjects, consistent with there being a greater role for polygenic risk in ASD than SDD. We identify 33 and 149 genes associated with risk for ASD and SDD, respectively (FDR < 0.05), with 17 falling in both gene sets. Meta-analysis of the two datasets yields additional significant genes, while also producing evidence for genetic heterogeneity: disruption of some genes confers risk predominantly for one disorder whereas disruption of others affects risk for both. Genes implicated in SDD alone or in risk for SDD and ASD have an impact on the IQ of ASD subjects, whereas mutations in genes conferring predominantly ASD risk tend to have smaller impact.

Conclusions: Our analyses identify genes that appear to have a more direct role in ASD traits and others with greater impact on general neurodevelopment. The gene sets we identify should be useful for understanding early developmental similarities and differences that lead to ASD with and without ID.

10:55 **105.002** Improving Genetic Association Approaches for Risk Gene Discovery in ASD

B. K. Sheppard[1]*, J. Wang*[2]*, M. Peng*[2]*, J. Y. An*[1]*, M. State*[1]*, B. Devlin*[3]*, K. Roeder*[2] *and S. Sanders*[1]*, (1)Psychiatry, University of California San Francisco, San Francisco, CA, (2)Carnegie Mellon University, Pittsburgh, PA, (3)Univ of Pittsburgh School of Medicine, Pittburgh, PA*

Background: Sequencing studies of autism spectrum disorder (ASD) have successfully identified dozens of risk genes, particularly through loss of function (LoF) *de novo* mutations (DNMs). However, it has been estimated that hundreds of genes contribute to the genetic architecture of ASD. Recent work by the Daly lab has shown that using Exome Aggregation Consortium (ExAC) allele frequencies can help distinguish risk from non-risk variants (Kosmicki et al. 2017). Here we assess the impact of this on gene discovery.
Objectives: Our study aims to adapt existing gene discovery methods to incorporate ExAC allele frequency data. Additionally, we will present a new ASD gene list based on this methodology after incorporating additional samples.

Methods: We used the Transmission and De Novo Association (TADA) method to identify ASD risk genes using LoF and probably damaging missense (Mis3) DNMs in whole exome sequencing (WES) data on 4,109 ASD probands. TADA is a hierarchical Bayesian model that incorporates information from various functional categories by parameterizing each category by its average relative risk derived from estimates of genome-wide burden and hypothesized number of risk genes. Burden estimates were obtained using a subset of 1,911 probands and their unaffected siblings. TADA was used to identify gene lists passing false discovery rate (FDR) at 10% for: 1) the full set of high confidence LoF and Mis3 DNMs and 2) a subset of DNMs after filtering mutations present in the ExAC database. These two gene lists were then compared using the GeNets Metanetwork protein-protein interaction algorithm. We will also incorporate data from targeted sequencing of 250 putative ASD risk genes in 14,208 samples from 5,357 ASD families, incorporating additional priors based on allele frequency observed in ExAC and gene-based conservation scores.

Results: Using the full set of mutations, genome-wide burden estimates for LoF and Mis3 DNMs were 1.99 (average RR = 20.74) and 1.08 (average RR = 2.64), respectively. Multiple testing correction yielded 57 genes with FDR q-value < 0.10. After filtering DNMs present in the ExAC database, approximately 9% of LoF and 29% of Mis3 mutations were removed, increasing the LoF burden estimate to 3.16 (average RR = 44.18) and the Mis3 burden estimate to 1.11 (average RR = 3.11). This resulted in 55 genes with FDR q-value < 0.10. Fourteen genes identified by the previous analysis slipped below the detection threshold, while 12 new genes from this list were raised above this threshold. Despite minimal change in the number of associated genes, network analysis revealed improvement in overall functional connectivity for the new gene list (network p-value = 0.002) compared to the list identified in the first analysis (network p-value = 0.09).

Conclusions: As hypothesized, filtering ExAC variants from our DNM list resulted in higher estimates of genome-wide burden when compared to unaffected siblings. This yielded a refined list of ASD risk genes, which was similar in size, but overall more functionally connected based on network analysis. Incorporation of additional priors to the model and new samples are expected to further improve quality of ASD gene lists.

11:20 **105.003** Whole-Genome Sequencing to Detect Rare Noncoding Variants in Autism Spectrum Disorder

J. Y. An[1], *D. M. Werling*[2], *H. Brand*[3,4,5], *M. R. Stone*[3], *S. Dong*[6], *R. L. Collins*[3,4,7], *K. Roeder*[8], *M. State*[1], *B. Devlin*[9], *M. E. Talkowski*[3,4,5,10] *and S. Sanders*[1], *(1)Psychiatry, University of California San Francisco, San Francisco, CA, (2)Psychiatry, UCSF, San Francisco, CA, (3)Center for Genomic Medicine and Department of Neurology, Massachusetts General Hospital, Boston, MA, (4)Department of Neurology, Harvard Medical School, Boston, MA, (5)Program in Medical and Population Genetics and Stanley Center for Psychiatric Research, Broad Institute, Boston, MA, (6)University of California San Francisco, San Francisco, CA, (7)Program in Bioinformatics and Integrative Genomics, Division of Medical Sciences, Harvard Medical School, Boston, MA, (8)Carnegie Mellon University, Pittsburgh, PA, (9)Univ of Pittsburgh School of Medicine, Pittburgh, PA, (10)Departments of Pathology and Psychiatry, Massachusetts General Hospital, Boston, MA*

Background: Genomic studies in autism spectrum disorder (ASD) have largely focused on high impact *de novo* mutations that disrupt protein-coding sequence. Given the size of the noncoding genome and its regulatory role in gene function, it is likely that rare, noncoding variation could be an important component of the genetic architecture of ASD. Characterization of noncoding mutations could also provide insights into the cell types and critical developmental stages involved in ASD. After correcting for multiple comparisons we observed no clear enrichment for noncoding risk in 519 families. Other groups have described nominally significant association at DNase sites, UTRs, and Promoters.
Objectives: To assess whether existing hypotheses regarding noncoding risk in ASD replicate in new datasets and to perform an unbiased analysis corrected for multiple comparisons across the combined dataset.

Methods: Whole genome sequencing (WGS) of an additional 1,024 individuals from 256 quartets (256 cases, unaffected sibling controls, and both parents) were compared alongside the existing WGS data for 2,076 individuals in 519 families. *De novo* SNVs, indels, and structural variants (SVs) were identified using 12 variant discovery algorithms; cross-site validation exceeded 93% for all variant classes. Variants were annotated using an extensive series of noncoding functional annotations at the level of nucleotides, genes, and regulatory regions, resulting in 51,801 combinations of annotation categories. ASD association within each category was assessed using a binomial test to compare variant counts in cases and controls in a Category-Wide Association Study (CWAS). To account for multiple testing, correlations of p-values were assessed between the 51,801 categories from 20,000 sets of simulated variants. Eigenvalue decomposition estimated that 4,123 effective tests explained 99% of the variation.

Results: We did not observe replication of prior hypotheses for noncoding variation in the new samples. Combining these samples with existing data, no annotation category was significant after correcting for 4,123 tests in the CWAS. As before, the lowest p-values were observed in coding regions, including missense variation and SVs not detected by previous technologies. Similarly, no category of rare inherited variants demonstrated parental transmission bias or ASD association.

Conclusions: Our results suggest that there is no clear category of rare noncoding variation with equivalent impact on ASD risk as large SVs or protein-disrupting mutations. Furthermore, given the lack of replication of previous hypotheses, we conclude that identifying noncoding disease associations and quantifying this risk will require a statistically rigorous approach that includes stringent multiple testing correction for this multitude of plausible hypotheses. Analogous to genome-wide association studies of common variation, this approach is likely to identify sound and replicable noncoding associations, but will require substantially larger sample sizes, likely in excess of 5,000 cases.

11:45 **105.004** Functional Impact of ASD-Associated Genetic Risk Variants in Human Cortical Development

D. M. Werling[1], *S. Pochareddy*[2], *J. Choi*[2], *J. Y. An*[3], *C. Dastmalchi*[3], *M. Li*[2], *M. State*[3], *K. Roeder*[4], *B. Devlin*[5], *N. Sestan*[6] *and S. Sanders*[3], *(1)Psychiatry, UCSF, San Francisco, CA, (2)Yale University, New Haven, CT, (3)Psychiatry, University of California San Francisco, San Francisco, CA, (4)Carnegie Mellon University, Pittsburgh, PA, (5)Univ of Pittsburgh School of Medicine, Pittburgh, PA, (6)Yale School of Medicine, New Haven, CT*

Background: Establishing clear links between genetic variation and gene function is a critical step toward translating genetic association into a mechanistic understanding of the etiology of autism spectrum disorder (ASD). Variants identified by genome-wide association studies (GWAS) and whole-genome sequencing (WGS) are frequently noncoding, but do not clearly implicate a specific gene or the manner in which the gene is impacted. Expression quantitative trait loci (eQTLs) can help clarify these questions by demonstrating functional impact on the expression of specific genes. Though ASD risk genes are strongly expressed during prenatal development, available eQTL discovery data sets are based largely on data from adult brains.
Objectives: To test adult brain eQTLs for intersection with ASD biology and to validate and extend these findings in the human cortex across brain development. Then, to apply these functional data to determine the developmental gene regulatory targets of noncoding ASD risk variants from recent WGS and GWAS data.

Methods: We tested gene targets of the eQTL SNPs identified in adult brain from the Common Mind Consortium (CMC) for enrichment with gene sets implicated in ASD. We also generated WGS and RNA-sequencing (RNA-seq) data from post-mortem dorsolateral prefrontal cortex (DLPFC) samples from 200 individuals aged 6 post-conception weeks (PCW) through 22 years. Gene-level transcript counts have been identified across the dataset. We are in the process of identifying high-quality common and rare single nucleotide variants and indels, allowing eQTLs to be identified using Matrix eQTL. We will identify eQTLs in mid-fetal (13-24 PCW) and adolescent (12-20 years) brains, along with a combined analysis. As with adult eQTLs, we will test for enrichment in ASD-related gene sets. Finally, we will use all of these eQTL sets to assess help identify and interpret variants in GWAS and WGS data from ASD samples.

Results: We find that CMC eQTL gene targets are enriched for CHD8 binding targets (adjusted p=4.1e-31) and an astrocyte-associated, ASD brain-up-regulated co-expression module (adj. p=0.003), but depleted for FMRP targets (adj. p=5.1e-13), genes with higher expression in the female brain (adj. p=0.03), and ASD-associated risk genes (adj. p=0.04). Our DLPFC expression data also confirmed published findings that age is the most significant biological driver of expression differences sample-wide, suggesting that fetal eQTLs are likely to differ substantially from those identified in adult brains.

Conclusions: eQTLs offer an opportunity to identify genomic regions that play important regulatory functions in the human brain and that are also sensitive to genetic variation. The enrichment for CHD8 binding sites and depletion for FMRP targets suggest that eQTLs in adult brain are capturing an important, but complicated, dimension in ASD biology. Replication of the observation that developmental stage is the most important component in determining cortical gene expression suggests that there are likely to be considerable differences between fetal and adult eQTLs. We therefore anticipate fetal eQTLs providing important and novel insights into the role of ASD genes in cortical development and illuminating genomic regions likely to contain noncoding ASD risk factors in GWAS and WGS data.

Epidemiology
106 - Prenatal Nutrition and Risk for Autism Spectrum Disorders: Major Findings and Emerging Evidence across Four Cohorts
10:30 AM - 12:30 PM - Arcadis Zaal

Panel Chair: Renee Gardner, *Karolinska Institutet, Stockholm, Sweden*

Discussant: Cheryl Walker, *University of California, Sacramento, CA*

Maternal nutrition during pregnancy influences the neurodevelopment of the fetus, as is strikingly apparent in the case of folate deficiencies and increased risk for neural tube defects. Given the crucial role that many micronutrients play in the development and functioning of the central nervous system, it is plausible that maternal nutrition during pregnancy may also influence offspring risk of developing autism spectrum disorders (ASD). Numerous studies have now been conducted examining a variety of aspects of maternal nutrition in pregnancy and risk of ASD. The aim of this panel is to present key findings from four cohorts representing a diversity of epidemiological study designs, source populations, and geographic regions. Data will be presented regarding offspring risk of ASD in relation to pre-conceptual and prenatal micronutrient supplementation, maternal BMI, weight gain during pregnancy, prenatal vitamin D exposure, and prenatal polyunsaturated fatty acid exposure.

10:30 **106.001** Prenatal Nutrition and Risk of Child ASD: Findings and Updates from the Stockholm Youth Cohort

B. K. Lee[1], *C. Dalman*[2], *H. Karlsson*[3], *E. A. DeVilbiss*[4], *D. Rai*[5], *C. J. Newschaffer*[6], *J. McGrath*[7], *D. Eyles*[8] *and C. Magnusson*[9], *(1)Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (2)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden, (3)Department of Neuroscience, Karolinska Institutet, Stockholm, Sweden, (4)Drexel University, Philadelphia, PA, (5)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom, (6)AJ Drexel Autism Institute, Philadelphia, PA, (7)Queensland Brain Institute, University of Queensland, Brisbane, Australia, (8)Queensland Brain Institute, University of Queensland, St Lucia, Australia, (9)Karolinska Institutet, Stockholm, Sweden*

Background:

Early life nutrition is critical for proper neurodevelopment. Whether this paradigm extends to risk of autism spectrum disorders (ASD) is not established.

Objectives:

Our goals were to assess whether prenatal nutritional factors, including 1) maternal body mass index (BMI) and gestational weight gain (GWG); 2) nutritional supplementation, and 3) gestational vitamin D were associated with risk of ASD in a population-based electronic register and biomarker study taking place in Sweden.

Methods:

The Stockholm Youth Cohort is a total population register-based study consisting of all individuals born from 1984 onwards and resident in Stockholm County, Sweden for ≥4 years. ASD and intellectual disability (ID) diagnoses were extracted from electronic health and services registers using a validated approach covering all pathways to care in Stockholm County. Maternal sera and neonatal dried blood samples were available for a subsample of births. Data on maternal BMI at first antenatal visit, GWG, and nutritional supplementation were extracted from registers. Concentrations of total 25-hydroxyvitamin D (25[OH]D) were assessed from maternal and neonatal samples using a highly sensitive liquid chromatography tandem mass spectrometry method. The associations of prenatal nutritional factors and ASD, ASD without co-occurring ID, and ASD with ID were analyzed in logistic regression models adjusting for a large number of covariates, and odds ratios (ORs) and 95% confidence intervals (CI) were estimated. Sibling-matched samples of ASD cases and their unaffected siblings were analyzed to address potential familial genetic or environmental confounding.

Results:

We found in a sample of 333,057 individuals that maternal overweight/obesity and either insufficient or excessive GWG was associated with increased risk of child ASD. However, in sibling analyses, the relationship between elevated maternal BMI and ASD was not apparent, suggesting that maternal BMI may be a proxy for other risk factors. In a sample of 273,107 individuals, maternal multivitamin use with or without additional iron or folic acid was associated with lower odds of ASD with ID, when compared to mothers who did not use multivitamins, iron, and folic acid (OR: 0.69, 95% CI: 0.57-0.84).

In an analysis of 1,230 ASD cases and 1,500 controls. 25[OH]D deficiency (< 25 nmol/L serum equivalent) was associated with 1.35 times higher odds of ASD (95% CI: 1.04-1.75) as compared with 25[OH]D sufficiency (≥ 50 nmol/L serum equivalent). ORs were similar for associations of 25[OH]D deficiency with ASD without ID (1.36, 95% CI: 1.10-1.82) and ASD with ID (1.30, 95% CI: 0.87-1.96), although the latter was not statistically significant. Sibling-matched control analyses suggested these associations were not due to familial confounding. Maternal sera analysis is ongoing and results will be presented.

Conclusions:

In epidemiological studies based in the Stockholm Youth Cohort, we found that diverse prenatal nutritional factors may be associated with later risk of child ASD.

10:55 **106.002** Gestational Nutrition and Autism in the Charge Case-Control Study, with New Findings for Neonatal Vitamin D

R. J. Schmidt[1,2], *Q. Niu*[3], *D. Eyles*[4], *R. L. Hansen*[3] *and A. M. Iosif*[1], *(1)Public Health Sciences, University of California Davis, Davis, CA, (2)MIND Institute, University of California, Davis, Sacramento, CA, (3)University of California Davis, Davis, CA, (4)Queensland Brain Institute, University of Queensland, St Lucia, Australia*

Background:

Gestational nutrition has critical influences on neurodevelopment and evidence is building for a role in autism etiology; this includes associations with folate, iron, and potentially vitamin D.

Objectives:

To review findings from the population-based CHARGE (Childhood Autism Risks from Genetics and Environment) case-control study on gestational nutrients in relation to autism spectrum disorders (ASD) in the child, discuss potential mechanisms, and present new findings on neonatal vitamin D.

Methods:

Children with clinically-confirmed diagnoses of ASD, developmental delay (DD), or typical development (TD) were included. We collected through structured telephone interviews maternal intake of supplements for the three months before pregnancy, each month of pregnancy, and during breastfeeding. We then calculated total average values of selected nutrients for each month. Total 25-hydroxyvitamin (25OHD) was measured using sensitive isotope dilution LC-MS/MS in archived newborn screening dried blood spots.

Results:

Maternal folic acid near conception was associated with decreased ASD, especially in those genetically susceptible to inefficient metabolism. Iron intake also was associated with decreased ASD especially in combination with conditions associated with functional iron insufficiency. Newborn 25OHD was associated with significantly reduced ASD only in females (OR_{adj}=0.66; 95% CI: 0.48, 0.91, P_{intxn}=0.01). 25OHD was significantly associated with reduced DD (OR=0.84, 95%CI: 0.73, 0.97), cognitive and adaptive function prior to but not after adjustment for factors that contributed to vitamin D status (OR_{DD_adj}=0.91, 95%CI: 0.78, 1.06). Significant interaction by race/ethnicity was observed (p=0.02), with an association between 25OHD and DD only in non-Hispanic white children (OR_{adj}=0.76; 95% CI: 0.61, 0.95).

Conclusions:

Evidence for a role of nutrition in ASD etiology is similar to that observed for other neurodevelopmental conditions. Maternal folic acid, iron, and vitamin D could potentially reduce ASD in certain genetically and environmentally susceptible subgroups. Further investigation of nutritional contributions and mechanisms are needed to identify targeted ASD prevention strategies.

11:20 **106.003** Maternal Folic Acid and Multivitamin Supplementation and Risk of Autism Spectrum Disorders Among an Israeli Birth Cohort

***S. Sandin**, Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background:

The role of maternal folic acid and multivitamin supplement use before and during pregnancy and the risk of Autism Spectrum Disorders (ASD) in offspring is unclear.

Objectives:

To examine the associations between maternal folic acid and multivitamin supplement use before and during pregnancy and the risk of ASD in offspring.

Methods:

Design: A case-cohort of 45,300 Israeli children born 2003 – 2007, followed-up from birth to January 26th, 2015 for the risk of ASD. The cases comprised of all children diagnosed with ASD by an Israeli health provider and controls comprised of a random sample of 33% of all live born children in Israel 2003 to 2007.

Exposures: Maternal vitamin supplements were classified for folic acid (B9), multivitamin supplements (ATC A11 vitamins: A, B C and D), and any combination thereof, exposed in the intervals before and during pregnancy.

Main outcome(s) and Measure(s): The association between maternal vitamin supplementation and the risk of ASD in the children was quantified with relative risks (RR) and their 95% confidence intervals (CI) fitting Cox regression models and adjusting for year of birth, parental psychiatric history, Socioeconomic status, maternal and paternal age and parity. Extensive sensitivity analyses were performed to test the robustness of the results.

Results:

Maternal folic acid and/or multivitamin supplement exposure ***before*** pregnancy was statistically significantly (P<.01) associated with a lower likelihood of ASD in the offspring compared to no exposure before pregnancy, RR=0.39 (95% CI: 0.30-0.50). Maternal folic acid and/or multivitamin supplement exposure ***during*** pregnancy was statistically significantly (P<.01) associated with a lower likelihood of ASD in offspring compared to no exposure during pregnancy, RR=0.27 (95% CI: 0.22-0.33). Corresponding RR's was estimated; for maternal folic acid ***before*** pregnancy at RR=0.56 (95% CI: 0.42-0.74); ***during*** pregnancy at RR=0.32 (95% CI: 0.26-0.41) and for multivitamin supplements ***before*** pregnancy at RR=0.36 (95% CI: 0.24-0.52) and ***during*** pregnancy at RR=0.35 (95% CI: 0.28-0.44). The results remained statistically significant across sensitivity analyses.

Conclusions: Maternal intake of folic acid and multivitamin supplements before, and during pregnancy are associated with a reduced risk of ASD in the offspring, compared to offspring of mothers without such intake.

11:45 **106.004** Prenatal Polyunsaturated Fatty Acid Levels in Association with Autism Spectrum Disorder

***K. Lyall**[1], G. C. Windham[2], N. Snyder[1], J. Carver[3] and C. J. Newschaffer[4], (1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)Environmental Health Investigations Branch, California Department of Public Health, Richmond, CA, (3)Sequoia Foundation, La Jolla, CA, (4)AJ Drexel Autism Institute, Philadelphia, PA*

Background: Polyunsaturated fatty acids (PUFAs) are critical to neurodevelopment. Though emerging work has identified associations between certain prenatal nutrients and reported supplements in association with autism spectrum disorder (ASD), and suggested altered levels of PUFAs in individuals already diagnosed with ASD, no prior study has examined the association between measured levels of prenatal PUFAs and ASD in order to determine potential etiologic involvement of these fats.

Objectives: To determine whether levels of PUFAs, measured in stored mid-pregnancy serum samples, differ in mothers who go on to have a child with ASD as compared to those who have an unaffected child.

Methods: This population-based statewide case-control study includes approximately 500 cases and 500 general population (GP) controls, matched on sex and month and year of birth (2011-2013). Cases of ASD were identified from the California Department of Developmental Services (DDS), and GP controls were randomly selected within strata of matching factors from birth certificate files after excluding DDS clients. Prenatal serum samples were drawn from the California Biobank Program, and levels of specific omega 3 and omega 6 PUFAs were measured using liquid chromatography-mass spectrometry/high resolution mass spectrometry (LC-MS/HRMS). Conditional logistic regression analyses, accounting for matching factors and adjusted for potential confounders, were used to examine the association between PUFAs (as individual fatty acids and as classes) and ASD.

Results: In preliminary analyses, mean levels of PUFAs did not significantly differ. In adjusted analyses examining associations with extremes of the distribution, there was a suggestion of an increase in odds of ASD for individuals in the lowest 5th percentile of linoleic acid levels (OR=1.57, 95% CI 0.90-2.76), relative to those with mid-distribution levels. Reductions of approximately 20% in odds of ASD for those in the highest 5th percentile of total PUFAs and total omega 6, were also observed, though these associations also did not reach statistical significance (OR=0.83, 95% CI 0.44, 1.56, respectively). Analyses will be updated as final samples are processed. Additional analyses will also investigate potential non-linear relationships between these fats and ASD using cubic splines, as well as associations with PUFAs measured in neonatal bloodspots in a subset of 400 cases and controls. Secondary analyses will examine the odds of ASD with and without comorbid intellectual disability (ID), relative to GP controls.

Conclusions: Preliminary findings from this large population-based case control study did not reveal significant associations between prenatal PUFA levels and ASD. However, associations similar in direction and magnitude for extremes of total PUFA, as well as linoleic acid specifically, are generally consistent with our previous results based on reported maternal diet, suggesting potential influences of very high and very low levels of these fats. Given the critical role of PUFAs in fetal brain development, and their influence on mechanisms with evidence for involvement in ASD etiology (inflammation and oxidative stress), further exploration of these potential associations is needed. Findings here will be updated using the full study group, exploring more complex exposure distribution relationships, and considering additional outcome subtypes.

Poster Session
107 - Animal Models
11:30 AM - 1:30 PM - Hall Grote Zaal

1 **107.001** A Novel Vasopressin V1a Antagonist Restores Social Behavior in the Mouse Cntnap2 KO Model of Autism

C. Grundschober[1], *A. Genet*[2], *M. Saxe*[2], *P. Schnider*[3] *and B. Biemans*[1], *(1)Neuroscience Discovery, Roche Pharma Research and Early Development, Roche Innovation Center Basel, F. Hoffmann-La Roche, Basel, Switzerland, (2)Neuroscience Discovery, Roche Pharma Research and Early Development, Roche Innovation Center Basel, Basel, Switzerland, (3)Medicinal Chemistry, Roche Pharma Research and Early Development, Roche Innovation Center Basel, Basel, Switzerland*

Background: The neuropeptide vasopressin is mainly produced in the lateral hypothalamus and plays an important role in regulating aggressive and social behavior by activating the V1a vasopressin receptor. A missense mutation in the human contactin-associated protein-like 2 (*CNTNAP2*) gene has been identified in an Amish family, leading to cortical dysplasia–focal epilepsy (CDFE) syndrome. Out of the 9 originally reported cases, 6 have autism. *CNTNAP2* is a cell adhesion molecule, important for AMPA receptor trafficking, development of dendritic arborization, and stabilization of dendritic spines. *Cntnap2* knockout mice (*Cntnap2* KO) demonstrate reduced social behavior and increased repetitive behavior (grooming).

Objectives: Investigate the effect of central V1a receptor blockade on the phenotype of the mouse *Cntnap2* KO model of autism.

Methods: *Cntnap2* KO mice were treated daily during 3 weeks with a novel brain penetrant V1a receptor-specific small molecule antagonist, starting at postnatal day 40. Social behavior and self-grooming was assessed during a direct social interaction test at P48. Self-grooming was measured again in a single setting at P52, and locomotor activity was assessed at P62.

Results: At postnatal day 48, chronic treatment with our V1a receptor-specific small molecule antagonist completely reversed the impairment in social behavior seen in *Cntnap2 KO* at 15 and 30 mg/kg i.p., which are doses predicted to block 77 to 88% of brain V1a receptors. The exaggerated grooming was also reduced at the highest dose tested (60 mg/kg i.p). None of the tested doses affected locomotor activity at P62.

Conclusions: Our data show that sub-chronic inhibition of vasopressin V1a receptors restores normal social behavior in *Cntnap2* KO mice. The effect on repetitive behavior is only apparent at the highest tested dose, suggesting that grooming is either less sensitive to V1a inhibition or not directly mediated by V1a activation. Further experiments will be needed to clarify this finding.

These results suggest that V1a antagonists have the potential to improve social interaction in autism, a core symptom for which there is currently no drug treatment.

2 **107.002** Defensive Response to Whisker Stimulation and Reduced Somatosensory Cortex Activation in the Engrailed-2 Mouse Model of Autism

G. Chelini, L. Cimino, A. Grigoli, M. Gadler, S. Miorelli, S. Casarosa, G. Provenzano and ***Y. Bozzi****, University of Trento, Trento, Italy*

Background:
Increased responsiveness to somatosensory stimuli is a common symptom in autism spectrum disorders (ASDs), which often leads to defensive behaviors in response to tactile stimulation. Recent studies performed in mouse models of ASDs confirm these findings. As an example, *Fmr1* knock-out (KO) mice (a model of syndromic autism) present a marked adaptation deficit of somatosensory cortex neurons in response to repetitive whisker stimulation, which is not observed in wild-type (WT) controls.

Objectives:

Here we evaluated the behavioral response to whisker stimulation in *Engrailed-2* (*En2*) KO mice, another model of ASDs characterized by a significatly reduced expression of *Fmr1*.

Methods:

Ten WT and 10 En2 KO mice of both sexes were assessed for whisker-guided, somatosensory functions using the sensory maze exploration and whisker nuisance test. The two tests were performed in sequence on the same groups of animals. At the end of the whisker nuisance test, brains were dissected and processed for c-Fos immunohistochemistry as a marker of neuronal activity.

Results:

When tested in the sensory maze, adult *En2* KO mice spent a comparable whisker-guided exploration time as their WT controls, thus indicating that whisker-mediated exploratory behavior is preserved in these mutants. Conversely, *En2* KO mice showed aggressive and active avoidance responses to repeated whisker stimulation in the whisker nuisance test, which instead resulted innocuous to WT controls. Quantitative analysis of c-Fos immunohistochemistry showed that in *En2* KO mice, avoidance behavior to whisker stimulation was paralleled by a significantly lower number of c-Fos positive neurons in layer IV of the primary somatosensory cortex, as compared to WT controls.

Conclusions:

These results suggest that tactile defensiveness is accompanied by a reduced activation of somatosensory cortical circuits in *En2* KO mice. Thus, impaired signal processing in the somatosensory cortex seems to be a common feature in different mouse models of ASDs, and might be a cause of tactile defensiveness in ASDs.

3

107.003 Effects of Riluzole and Gabapentin on Learning, Anxiety and Social Behaviors in Autism-like Rat Model

S. Karakoç Demirkaya[1]*, C. Orak*[2]*, F. Şirinyıldız*[2]*, G. Taşlı Yeşilçayır*[2]*, G. Cesur*[2] *and R. O. Ek*[2]*, (1)Child and Adolescent Psychiatry, Adnan Menderes University School of Medicine, Aydın, Turkey, (2)Physiology, Adnan Menderes University School of Medicine, Aydın, Turkey*

Background: Autism spectrum disorder (ASD), is a neurodevelopmental disorder, characterized by difficulties in social interaction and communication and as well as repetitive and ritualistic behaviors. Despite the burden of the ASD on individual, family and community is high, no specific causes and optimal treatment modalities have not been identified yet. Dysfunction in the glutamatergic and GABAergic systems contributing the neurobiology of ASD have recently been proposed.

Objectives: We aimed to investigate effects of the riluzole, an antiglutamate agent, and gabapentin which increases GABAergic transmission, on learning, anxiety and social behaviors in autism-like rat model.

Methods: On the 12.5th gestational day, valproic acid was applied parenterally to the female *Wistar Albino* rats, except for the autism-negative control group, to create autism-like model (ALM). Newborn male rat pups (n=40) divided into 5 equal groups; negative control, ALM-nontreated (sham control), ALM+ riluzole treated, ALM + gabapentin treated, and ALM + combination of gabapentin & riluzole treated (n=8). Riluzole (10 mg/kg/day p.o) and gabapentin (300 mg/kg/day p.o.) were administered via orogastric gavage in the 3rd postnatal week for 2 weeks. Behavioral tests, Morris water maze (MWM), open field test (OFT) and three-chambered social approach test (TSAT) were applied in the 6th postnatal week.

Results: Both sociability and social preference indices with strangers in TSAT were lower in the ALM rats than the negative groups ($p<0.01$) indicating that the model was well fitted. Among the drug groups, combined treated rats showed the highest sociability index and social preference index ($p<0.01$). In the OFT, riluzole treated group had spent more rearing behaviors and spent less time in the outer squares (periphery) ($p<0.05$). Gabapentin treated rats showed the least rearing and grooming behaviors in the OFT. In the MWM test, the percent of the time spent in the previously learned platform was the highest in the riluzole only group ($p<0.05$) and this learning was the worst in the gabapentin treated rats ($p>0{,}05$).

Conclusions: All these results suggest that riluzole, an antiglutamatergic agent, seems to have some possible positive effects on social interaction, anxiety level and spatial learning in an autism-like rat model. If gabapentin is used alone, limitedly play a positive role on social behavior whereas a negative role in learning. However gabapentin may attenuate the social behaviors in combined treatment. Gabapentin may also decrease exploratory motions as well as anxiety levels. Further molecular and biochemical studies are needed to reveal the underlying etiological and therapeutic mechanisms of these neurotransmitter modulators.

107.004 From Genetic Modification to Seizure-Induced Hyperactivity; Insights from SYNGAP1 Zebrafish Models of ASD

S. H. Sumathipala*, R. A. Kozol and J. E. Dallman, Biology, University of Miami, Coral Gables, FL*

Background: Autism Spectrum Disorders (ASD) are a collection of inherited neuro-developmental disorders characterized by social and cognitive impairments, communication deficits, and repetitive behaviors. With the increasing prevalence of ASD, insights from genetics and gene-environmental interaction studies are helping to explain unique symptoms found in different individuals. Significantly high number of ASD cases are reported from gene variations associated with synaptic proteins such as *shank3*, *cntnap2*, *nrxn* and *nlgn*3, which play important roles in synapse formation, modification, and maintenance. Alterations associated with the synapses may result in disrupted synaptic function, thereby causing neuro-developmental and behavioral phenotypes linked with ASD.

This study focuses on Synaptic Ras-GTPase Activating Protein 1 (*SYNGAP1*), a gene encoding the post-synaptic protein *syngap1,* known to cause intellectual disability (ID) and Autism in humans. *syngap1* is a component of the post synaptic density of glutamatergic synapses and plays an important role in receptor trafficking and synaptic strengthening allied with learning and memory. In our lab, we have generated a stable *syngap1ab* zebrafish models of Autism using CRISPR/Cas 9 genome editing. High conservation of *syngap1* between humans and zebrafish make it a favorable model to study the mechanisms underlying neuro-developmental and behavioral phenotypes associated with ASD.

Objectives: Using *syngap1* zebrafish models of ASD our aims are, (i) To identify and quantify comparable ASD-related behaviors and, (ii) To delineate the molecular mechanisms underlying those behaviors in zebrafish larvae to gain insight to symptom etiology in humans with *SYNGAP1* variants.

Methods: s*yngap1* models of ASD were generated using the CRISPR/ Cas 9 genome editing method by injecting *SYNGAP1A and SYNGAP1B* gene specific guide RNA, and Cas 9 nuclease into zebrafish embryos at one cell stage. Resulting embryos were reared, screened for the *SYNGAP1* gene mutations, and were used in the subsequent behavioral assays. To study the light-induced hyperactivity and epilepsy, a visual-motor response assay was carried out using *syngap1* and wild-type (WT) larvae from 4, 5 and 6 days post fertilization (*dpf*). The activity of each zebrafish larva was recorded in terms of their center point movement using the Noldus- DanioVision^{TM} high throughput tracking software. Larvae were exposed to 30 minutes of alternating light-dark cycles for a duration of 4 hours. Cumulative duration of movement for each larva was recorded and analyzed over time.

Results: Our preliminary data suggest that there are significantly higher levels of activity associated with the *syngap1ab* mutants compared to the WT larvae, during both light and dark periods. These observations are comparable with the intractable seizures associated with *SYNGAP1* variants in humans. Moreover, larvae with *syngap1ab* $^{-,-/+,-}$ genetic composition had the highest activity levels compared to the *syngap1ab*$^{-,-/-,-}$ and *syngap1ab* $^{+,+/+,+}$ (WT) combinations recapitulating the similar phenotype in human *syngap1* $^{+,-}$ mutations.

Conclusions: Given our preliminary data, *syngap1* zebrafish models of ASD can potentially be used to address the behavioral phenotypes and understand the underlying molecular mechanisms linked to ASD. Identifying these machinery will be useful in the future to develop therapeutic strategies.

5 **107.005** Interneuron-Specific Knockout of Semaphorin 3F Results in Increased Inflammation, Oxidative Stress and Autism-like Behavior.

R. Jagadapillai[1]*, Z. Li*[2]*, E. Gozal*[3] *and G. Barnes*[4]*, (1)Departments of Pediatrics, PRI, University of Louisville, Louisville, KY, (2)Neurology, Vanderbilt University, Nashville, TN, (3)Pediatrics, PRI, University of Louisville, Louisville, KY, (4)University of Louisville School of Medicine, Louisville, KY*

Background:
The neuropathology of all neural circuits in ASD is dependent on changes in functional connectivity via the excitation/inhibition (E/I) ratio that impact routine neurotransmission, synaptic plasticity, and network function. We were the first to publish an extensive investigation of an animal model of autism and epilepsy (Barnes et al., 2009). The semaphorin/neuropilin gene family, an ASD associated set of genes, are guidance cues that control processes and cell motility in a wide variety of tissues. In the developing brain, these cues control interneuron migration/cell numbers, regulate neurite outgrowth (axon/dendrite), and control both GABA/excitatory synaptogenesis. Several groups, including our own, have noted behavioral phenotypes consistent with autism in both the semaphorin 3F (Sema 3F) and neuropilin 2 (NRP2) knockout mice. Similar to NRP2 KO mice, the interneuron specific but not excitatory neuron specific knockout of Sema 3F had decreased Parv+ and NPY+ interneurons and increased epileptogenesis with decreased social behaviors and increased repetitive behaviors compared to wild type littermates.

Objectives: We aimed to determine whether semaphorin 3F KO mice also presented with brain inflammation and oxidative stress that could be associated with ASD-like behavior.

Methods: DLX5/6 Cre Sema 3F Knockout mice and controls were tested for social novelty using the three chamber social interaction test. Markers of neuroinflammation (Iba1 for microiglia, and iNOS) and of oxidative stress (DHE for superoxide, 4-HNE for lipid peroxidation and 3-nitrotyrosine for protein nitrosylation) were assessed by immunostaining in three areas of DLX5/6 Cre Sema 3F Knockout mice and control brains.

Results: The significant increase in immunoreactivity of Iba1, a microglial marker, and of oxidative stress markers (DHE, 4HNE, iNOS, and 3-nitrotyrosine) in hippocampus, cortex and amygdala brain regions suggest increased inflammation and oxidation products within both the glia and neurons of the interneuron- specific Sema 3F KO mouse.

Conclusions: Thus, although this is a single ASD associated gene KO mouse, these data strongly suggest that genetic mouse models of autism with markers of inflammation will be an excellent tool to investigate the role of genomics, environmental factors influencing the immune system, clinical endophenotypes, and metabolic conditions. Most importantly, these models and others can define molecular mechanisms influencing the interactions among organ systems contributing to ASD brain dysfunction.

6 **107.006** Maternal Infection By Group B Streptococcus Induces Sex-Specific Maternofetal Inflammatory Signaling Leading to Postnatal ASD-like Behaviors in Males

M. J. Allard[1]*, A. Giraud*[2]*, M. Segura*[3] *and G. Sebire*[1,4]*, (1)Pediatrics, McGill University, Montreal, QC, Canada, (2)Pediatrics and Neonatal Intensive Care Unit, Saint-Etienne University Hospital, Saint-Etienne, France, (3)Pathology and Microbiology, Universite de Montreal, St-Hyacinthe, QC, Canada, (4)Pediatrics, Universite de Sherbrooke, Sherbrooke, QC, Canada*

Background: Placental infection and/or inflammation (chorioamnionitis) is a common complication associated with adverse outcomes including premature birth and brain injuries leading to neurodevelopmental disabilities such as autism spectrum disorder (ASD). Chorioamnionitis is a polymicrobial infection most often due to ascending genital pathogens. Group B *Streptococcus* (GBS) is a gram-positive bacterium colonizing the urogenital tract of 20-30% of pregnant women. GBS is isolated in 15% of chorioamnionitis, *i.e.* twice as often as the gram-negative bacterium *Escherichia coli* (Tita & Andrews, *Clin Perinatol*, 2010). Chorioamnionitis is characterized by the release of neurotoxic inflammatory mediators affecting placental synthesis of neurotrophic factors, and potentially disrupting neuroglial fiber tracts in the developing brain. Dysregulation of specific proinflammatory cytokines, including interleukin (IL)-1β, tumor necrosis factor (TNF)-α and IL-6, in maternofetal tissues have been associated with higher risks of having a child with ASD. We previously developed a rat model of end-gestational GBS infection that induces histological chorioamnionitis, characterized by an increased density of neutrophil cells in placentas associated with male *versus* female fetuses. Following natural birth, male – but not female – offspring *in utero*-exposed to GBS presented ASD-like behavioral impairments (Allard et al., *Autism Research*, 2016). We hypothesized that a differential activation of proinflammatory mediators and cells according to the fetal sex is responsible for sex-specific neurobehavioral outcomes in GBS-exposed offspring.

Objectives: Mapping out the expression profiles of cytokines and innate immune cells within GBS-infected placentas, and comparing this immune profile between male and female tissues.

Methods: Lewis dams were injected intraperitoneally on gestational day 19 with β-hemolytic serotype Ia GBS (10^8 CFU) or saline (control; CTL). Caesarean-sections were performed at 24 h, 48 h and 72 h post-injection to collect maternofetal tissues (placentas, maternal and fetal blood, fetal brains), and to investigate sex-specific maternofetal immune activation and prenatal brain injuries (GBS: n = 18, CTL: n = 14). Proinflammatory cytokines IL-1β, TNF-α and IL-6 were studied by ELISA and immunohistochemistry.

Results: At 24 h, no difference in titers of IL-1β, TNF-α and IL-6 in maternal sera was detected between experimental conditions. At 48 h, increased titers of IL-1β, but not TNF-α and IL-6, were detected in GBS-exposed maternal sera and GBS-exposed male placentas compared to control tissues. At 72 h, increased titers of IL-1β, TNF-α and IL-6 were detected maternal sera, male placentas, and male fetuses' sera *versus* CTL tissues. At 72 h, increased levels of IL-1β, TNF-α and IL-6 were detected in GBS-exposed male *versus* GBS-exposed female placentas. The correlation between maternofetal inflammatory responses and fetal forebrain injuries will be characterized by ongoing studies.

Conclusions: These results suggest that IL-1β might be implicated in the induction of the male-specific forebrain injuries, and subsequent ASD-like behaviors observed in this rat model. Innovative insights into the mechanistic underpinning the pathophysiology of pathogen-induced placental injuries are needed to develop appropriate novel therapeutic interventions.

107.007 Microbial Signatures Associated with Gastrointestinal Function in a SERT Ala56 Knock-in Mouse Model

R. A. Luna[1]*, A. Venkatachalam*[1]*, N. Israelyan*[2]*, J. Runge*[1]*, M. Balderas*[1]*, R. Blakely*[3]*, J. Veenstra-Vander Weele*[4] *and K. G. Margolis*[5]*, (1)Baylor College of Medicine, Houston, TX, (2)Columbia University, New York, NY, (3)Vanderbilt University, Nashville, TN, (4)Psychiatry, New York State Psychiatric Institute / Columbia University, New York, NY, (5)Pediatrics, Columbia University Medical Center, New York, NY*

Background: The gut-microbiome-brain (GMB) axis plays a pivotal role in the manifestation of gastrointestinal (GI) and behavioral symptoms. The crosstalk between the enteric and central nervous systems is heavily influenced by the serotonin transporter (SERT), and specific enteric microbiota have been shown to modulate enteric serotonin (5-HT) production. The SERT Ala56 knock-in mouse model displays gastrointestinal (GI), brain, and behavioral phenotypes similar to those observed in autism spectrum disorder (ASD), and administration of a 5-HT$_4$ agonist, prucalopride has reversed the GI manifestations.
Objectives: 1) Characterize the enteric microbiome in a SERT Ala56 knock-in mouse model. 2) Determine whether treatment with prucalopride corrects gut dysbiosis. 3) Identify key organisms that are associated with changes in GI function.

Methods: Dams were given either prucalopride or vehicle (normal saline) throughout pregnancy and breastfeeding (E1-P21). Drug administration was stopped after 3 weeks to rule out acute drug effects. Five fecal pellets were collected from 9 male progeny per group (WT, SERTAla56+/-prucalopride) at 6-7 weeks of age. Bacterial DNA was extracted from fecal pellets, and next-generation sequencing targeting the V4 region of the 16S rRNA gene was performed on the Illumina MiSeq. With a minimum of 15,000 reads per sample, sequences were quality filtered, clustered into operational taxonomic units (OTUs), and taxonomic assignments were made. GI motility studies were done to measure in vivo total GI transit and colonic motility and in vitro colonic peristalsis. Integrative analysis of GI function and the microbiome was performed to identify factors influenced by microbial species.

Results: The microbial profile of the SERT Ala56 knock-in mice compared to wild type (WT) mice included increases in *Prevotella sp.* and *Lactobacillus sp.* and decreases in *Bacteroides sp.* and *Odoribacter sp*. Prucalopride treatment of SERT Ala56 mice during neurodevelopment, which prevented abnormalities in ENS anatomy and GI function, also caused microbial shifts that closely resembled WT mice. Integrative analysis also revealed a specific OTU, potentially identified as *Clostridium clariflavum*, that was found in increased abundance in mice that had the greatest improvements in total GI motility and the frequency of peristalsis.

Conclusions: Identification of a distinct microbial signature in the SERT Ala56 knock-in model, with parallel changes in GI improvements following prucalopride treatment, further solidifies an interaction between motility and the microbiome. This reversible mouse model effectively illustrates the interconnectivity of GI function and the enteric microbiome, with 5-HT playing a critical role. Future studies will include evaluation of behavior and CNS function.

107.008 Modifications in Cytoskeletal and Astrocytic Proteins Content in Prefrontal Cortex, Hippocampus and Cerebellum of the Murine Model of Autism C58/J Strain

I. Barón-Mendoza[1] *and A. González-Arenas*[2]*, (1)Instituto de Investigaciones Biomédicas, National Autonomous University of Mexico, Ciudad de México, Mexico, (2)National Autonomous University of Mexico, Ciudad de México, Mexico*

Background:
Autism Spectrum Disorder (ASD) is presented with a global prevalence of 1/160. ASD have been recognized as a complex brain disorder with high heritability. Two common characteristics are presented in this disorder: impairment of social interaction and communication, and restricted and repetitive behaviours.

Alterations in neuritogenesis, elongation of axons and dendrites, and greater spine densities in ASD patients, particularly found in brain structures associated to memory, learning and motor processes as prefrontal cortex, hippocampus and cerebellum, besides a reported synaptic gene dysfunction, suggest connectional changes and disturbances in plasticity in the autistic brain. The cytoskeleton has a pivotal role in regulating the structure and dynamics of dendrites, spines and axon outgrowth. Also it is essential for synaptic connections stabilization and remodelling. Hence, some modifications of cytoskeletal and astrocyte components could be involved at molecular level in the mentioned alterations.

Objectives:

The objective of this research was to analyse changes in the content of cytoskeletal proteins β-actin and actin-binding-proteins cofilin and synaptopodin; α-tubulin and microtubules-associated proteins MAP2A and Tau, and astrocyte secreted protein thrombospondin-1 (TSP-1) in prefrontal cortex, hippocampus and cerebellum of an autistic animal model corresponding to the C58/J mice strain.

Methods: Prefrontal cortex, hippocampus and cerebellum from C58/J and C57 BL/6 (wild type) mice were dissected. Samples were processed for Western Blot technique.

Results: α-tubulin content showed no change in prefrontal cortex, neither hippocampus nor cerebellum between both strains. However microtubule-associated proteins as MAP2A and Tau presented clear differences. We observed six Tau isoforms with molecular weights between 20-100 kDa in prefrontal cortex, hippocampus and cerebellum of wild type mice strain (C57BL/6). Four Tau isoforms completely disappear in autistic brain areas, 80 and 60 kDa isoforms were detected in both strains. The 80 kDa Tau isoform content in prefrontal cortex, hippocampus and cerebellum of autistic mice (C58/J) was not different compared to the WT strain (C57 BL/6), but the 60 kDa isoform and its phosphorylated form showed a decrease in the autistic prefrontal cortex and hippocampus compared to the WT regions. Furthermore the MAP2A protein content was lower only in prefrontal cortex of autistic mice compared to WT strain. The content of β-actin was uniform in the studied brain areas between WT and autistic mice. Instead, the content of phosphorylated actin-binding protein cofilin showed a decrease in the autistic prefrontal cortex and an increase in autistic cerebellum. Besides, synaptopodin content, another actin-binding protein enriched in dendritic spines neck, was diminished only in hippocampus of autistic mice. Finally, the protein content of astrocyte-secreted protein thrombospondin-1 showed a decrease in prefrontal cortex and hippocampus of autistic mice, although the GFAP protein content was not different between both strains.

Conclusions:

Our work showed important brain structure-dependent changes in protein content of 60 kDa Tau/phospho-Tau isoform, MAP2A, phosphorylated-cofilin and synaptopodin, as well as differences in the astrocyte-secreted protein thrombospondin-1 content in prefrontal cortex, hippocampus and cerebellum of autistic animals (C58/J) compared to wild type mice (C57 BL/6). These differences in autistic mice brain could be associated with disturbances in neuronal cytoskeleton dynamics.

9 **107.009** Obesity and Weight Gain during Pregnancy Associate Independently with Behavior of Infant Rhesus Monkeys (Macaca mulatta)

C. K. Walker[1]*, C. A. VandeVoort*[2,3]*, C. S. Li*[4]*, C. L. Chaffin*[5] *and J. P. Capitanio*[6,7]*, (1)University of California, Sacramento, CA, (2)Reproductive Medicine, UC Davis California National Primate Research Center, Davis, CA, (3)Obstetrics & Gynecology, University of California, Davis, Sacramento, CA, (4)Division of Biostatistics, Department of Public Health Sciences, University of California, Davis, CA, (5)Obstetrics, Gynecology and Reproductive Sciences, University of Maryland School of Medicine, Baltimore, MD, (6)Neuroscience and Behavior, California National Primate Research Center, Davis, CA, (7)Psychology, University of California, Davis, Davis, CA*

Background: Growing evidence identifies maternal adiposity as a potentially-modifiable risk factor for adverse neurobehavioral development including autism spectrum disorder (ASD) and attention deficit / hyperactivity syndrome (ADHD).

Objectives: We explored relationships between maternal obesity, gestational weight gain (GWG) and neurobehavioral impairment in the indoor colony of rhesus (*Macaca mulatta*) monkeys at the California National Primate Research Center (CNPRC).

Methods: This retrospective cohort analysis examined whether maternal prepregnancy obesity and gestational weight gain were associated with behavioral outcomes in 172 rhesus macaque infants at the California National Primate Research Center. The rhesus macaque model is highly relevant to the study of gestational obesity, fetal programming and neurobehavioral outcomes with strong generalizability to humans. Dams conceived indoors, had uncomplicated pregnancies, delivered vaginally and reared infants indoors. Measures of maternal adiposity included prepregnancy Body Condition Score (BCS), a subjective semi-quantitative anatomic assessment that reliably identifies obese monkeys, and GWG measured as steepness of weight change over the interval from the last weight prior to pregnancy to the first weight after birth of the infant. Infants underwent standardized bio-behavioral analysis (BBA) at 90-120 days of age between March 2001 and May 2015. Outcomes were a series of measurements recorded in a standardized 25-hour program designed to characterize behavioral and physiological responsiveness.

Results:: Our exploration of rhesus macaque maternal adiposity measures revealed a pattern of greater behavioral disturbance during the BBA testing for infants of dams that had higher prepregnancy adiposity and / or that gained excess weight. Importantly, these effects were not evident immediately upon relocation to the testing area when all animals responded similarly to the separation and relocation. Rather, the pattern for the infants of obese mothers reflected poor adaptability, as indicated by a number of results from the later assessments, during which infants exhibited enhanced holding-cage Emotionality, substantial disturbance during the human intruder test, and completion of fewer problems and less interest in novel stimuli during the test for visual recognition memory compared with control infants. They also had significantly lower cortisol levels in response to dexamethasone suppression, indicating that the cortisol feedback loop in these animals was more sensitive to negative regulation by glucocorticoids.

Conclusions: These results amplify growing public health concerns implicating maternal adiposity in impaired fetal neurobehavioral programming. Further, this study highlights the translational potential of the nonhuman primate model for the study of developmental programming in humans. Children with ASD and ADHD often exhibit similar variation in temperament traits, including decreased adaptability, increased activity level and unusual approach behaviors. The nonhuman primate cohorts identified in this study would be excellent models for elucidation of fetal programming mechanisms that link maternal obesity and high GWG with adverse offspring behaviors often identified in individuals with ASD and / or ADHD.

10 **107.010** Pogz Mutation Leads to Abnormal Behavior and Transcription Dysregulation in the Brain

R. Suliman *and S. Shifman, The Hebrew University of Jerusalem, Jerusalem, Israel*

Background:

De-novo loss-of-function mutations in POGZ (Pogo Transposable Element with ZNF domain) were identified in multiple individuals with developmental delay, half of them with a diagnosis of autism spectrum disorder (ASD). POGZ consistently interacts with the three isotypes of HP1 and therefore may play a key role in transcription regulation. As of today, the molecular, cellular and neuronal mechanisms through which POGZ is associated with ASD remain incompletely understood.

Objectives:

Our overall aim was to delineate the function of POGZ in the normal brain and in ASD. In particular, we inquired how rare genetic insults in this gene influence networks of genes leading to ASD.

Methods:

Our approach to study the function of POGZ was based on Pogz-deficient mice. We used a conventional knockout mice with a whole body heterozygous mutation in Pogz gene (Pogz KO$^{+/-}$), and conditional knockout mice that harbor a homozygous Pogz knockout restricted to the brain (Pogz cKO$^{-/-}$). To characterize the anatomical and behavioural phenotypes we used several staining methods and a battery of behavioural assays relevant to ASD. To explore how POGZ modulates gene expression in the brain and identify its transcriptional targets we used RNA-Seq and dual-luciferase reporter assay.

Results:

Pogz deficient mice showed a significant growth delay relative to their WT littermates. Behaviourally, these mice exhibited reduced anxiety, deficits in learning and memory and impaired sociability. Similar to what was reported in humans, the KO mice were “overly friendly”. To identify defects in neural development that may explain the behavioral phenotypes, we first studied brain anatomy, including the structure of the cortex, but found that Pogz-deficient mice displayed no detectable defects. However, adult neurogenesis was significantly decreased in the hippocampus because of reduced neuronal survival. Gene expression profiling of the hippocampus identified a large number of dysregulated genes. The majority of differentially expressed genes with fold change above 1.5 or above 2 were upregulated (67%, P = 0.026; 93%, P = 0.00098, respectively) and enriched for genes involved in axon guidance, and regulation of locomotion. Since POGZ was found to be an integral part of the HP1 protein complexes, and given the gene expression results, we hypothesized that POGZ plays a key role in transcription repression. Indeed, dual-luciferase reporter assay showed that POGZ acts as a negative regulator of transcription through its interaction with HP1 proteins.

Conclusions:

Our study shows that Pogz deficiency in mice is sufficient to cause ASD-related behaviours, similar to those found in human individuals with *de-novo* mutations in POGZ. The behavioral abnormalities and growth delay may result from lower survival of newly born neurons and transcriptional dysregulation in mature neurons caused by POGZ deficiency.

11 **107.011** Resveratrol Prevents Molecular Aspects in Sensory Areas of Rats Prenatally Exposed to Valproic Acid

M. F. Dutra[1,2,3]*, J. Santos-Terra*[2,3,4]*, I. Deckmann*[2,3,4]*, G. B. Schwingel*[2,3,4]*, G. Della Flora Nunes*[2,3,5]*, M. M. Hirsch*[2,3,4]*, G. Bauer-Negrini*[2,3,4]*, C. Hedin-Pereira*[6]*, V. Bambini-Junior*[2,3,7]*, R. Riesgo*[2,3,8] *and C. Gottfried*[2,3,4]*, (1)Federal University of Rio Grande do Sul, Porto legre, Brazil, (2)Translational Research Group in Autism Spectrum Disorder (GETTEA), Porto alegre, Brazil, (3)National Institute of Science and Technology on Neuroimmunomodulation-INCT- NIM, Porto alegre, Brazil, (4)Department of Biochemistry, Federal University of Rio Grande do Sul, Porto alegre, Brazil, (5)SUNY at Buffalo, Buffalo, NY, (6)Institute of Biophysics Carlos Chagas Filho, Rio de Janeiro, Brazil, (7)School of Pharmacology and Biomedical Sciences, University of Central Lancashire, Preston, United Kingdom, (8)Clinical Hospital of Porto Alegre, Porto alegre, Brazil*

Background: Autism Spectrum Disorder (ASD) characterized by impairments in communication and social interaction in addition to repetitive or stereotyped behaviors. Another extremely important aspect for ASD are the sensory alterations present in more than 90% of the individuals with ASD like hyper-responsiveness to non-harmful stimuli (visual, tactile and auditory) and hypo-responsiveness to harmful stimuli, which implies a great loss in life quality. Although etiology is unknown, both genetic and environmental risk factors have been associated with the development of ASD, including the use of valproic acid (VPA) during pregnancy. Based on these observations, an animal model of autism by prenatal exposure to VPA was developed and validated by the reproducibility of behavioral, molecular and morphological changes observed in ASD individuals. It also includes alterations in redox, immune and inflammatory systems. We previously showed that a prenatal subchronic treatment of pregnant rats with the antioxidant and anti-inflammatory compound resveratrol (RSV), was able to preven important sensorial deficits induced by VPA in male offspring rats.

Objectives: The aim of the study was to perform a quantitative and organizational analysis of the effects of RSV and VPA on parvalbumin-positive GABAergic interneurons in sensory processing related regions – Primary Somatosensory Area and Amygdala Region.

Methods: Mating was undertaken overnight and confirmed in the following morning by the presence of spermatozoa in vaginal smears. Females received a single intraperitoneal injection of 600 mg/kg VPA or physiological saline on Embryonic day 12.5 (E12.5). For the RSV treatment females received daily subcutaneous injections of 3.6 mg/kg of RSV solution or the correspondent volume of DMSO from E6.5-E18.5. Experimental groups: Control, RSV, VPA and RSV+VPA. At 30 days-old, male rats were perfused with PF 4%, followed by brain dissection. The tissue was sliced in cryostat at -20ºC. Specific regions of *interest were* defined *using* Paxinos atlas. Immunofluorescence labelling: DAPI, Anti-NeuN and Anti-Parvalbumin (PV). The images were obtained by confocal microscopy and processed in ImageJ software with Cell Counter plug-in. Statistical analysis realized in GraphPad Prism 5 software, using one-way ANOVA test followed by Bonferroni's poshoc and considering $p<0.05$ as significant.

Results: In Primary Somatosensory Area, VPA group exhibitedlaminar disorganization, associated to changes in PV^+-neurons positioning, increasing in layer IV-V and decreasing in layer II-III. The prenatal administration of RSV not only promoted cortical reorganization at laminar and columnar level, but also prevented all alterations in layer II-III and IV-V induced by VPA. Moreover, considering total layers, no changes were observed in the amounts and density of PV^+-neurons, suggesting a possible alteration in the migration of these interneurons between the cortical layers. In Amygdala Region, only the density of PV+-neurons were significant reduced in VPA group and RSV was able to prevent this alteration.

Conclusions: These data demonstrates for the first time not only alterations at a cellular level with expressive consequences in the excitatory/inhibitory balance, but also the neuroprotective effect of RSV. Further studies will focus on the mechanisms involved in the RSV-preventive effects.

12 **107.012** Role for Striatal Glutaminergic Signaling in Decreased Risk Assessment in Autism Mouse Models

E. Elliott[1]*, S. Shifman*[2]*, E. Reuveni*[3]*,* ***O. Oron***[3] *and S. Shohat*[2]*, (1)Bar Ilan University, safed, Israel, (2)The Hebrew University of Jerusalem, Jerusalem, Israel, (3)Bar Ilan University, Safed, Israel*

Background:

The genetic etiology of Autism Spectrum Disorder (ASD) is composed of hundreds of genes, and it is expected that these genes affect common molecular mechanisms responsible for ASD-related behavior. In addition to the core autism phenotypes, individuals diagnosed with ASD often display anxiety and impulsivity However, the molecular drivers of these behaviors are unknown.

Objectives:

Using multiple genetic mouse models of ASD, we aimed to determine the relationship between anxiety and impulsivity, and to determine the molecular mechanisms responsible for these behaviors.

Methods:

We performed locomotion, anxiety-related and risk-assessment (RA) behavioral and molecular experimentation on four mouse models of ASD: Shank3 KO, CNTNAP2 KO, Chr16p11.2del, and BTBR mice. We performed Open Field (OF), Dark Light (DL), and Elevated Plus Maze (EPM). We extracted RNA from the striatum of all four mouse models, and their controls, and performed whole throughput RNA sequencing (RNA-seq) on all samples. We then performed Weighted Gene Coexpression Network Analysis (WGCNA) on the RNA-seq data, and correlated co-expressed genes to the behavior of the knockout animals. We further analyzed the WGCNA data to locate hubs of gene products that could be used as potential therapeutic targets. Finally, we performed *in-vivo* pharmacological intervention to target these hubs, and affect behavior in the mic models.

Results:

In behavioral experiments, the CNTNAP2 KO, Shank3 KO and Chr16del models displayed reduced anxiety-like behavior, which correlates with reduced risk-assessing behavior in the EPM and DL test. In the OF, all four mouse models expressed locomotion deficits. The WGCNA analysis of the striatal transcriptome revealed one distinct module of co-expressed genes that had a significant correlation with the risk-assessment behavior both in the EPM and DL, and subsequent PPI analysis of this genetic module revealed a cluster of hubs dominated by Glur4 and Glur5 glutamate receptors. Western blot analysis performed on the synaptosomes of the Shank3 KO mouse model's striatum revealed a significantly reduction of Glur4. We therefore acutely injected the AMPA and Kainate antagonist NBQX into the striatum of C57 and Shank3 KO animals via cannulas. The C57 mice expressed reduced Anxiety-like and risk assessment behavior both in the EPM and DL, while no changes were observed in the OF. Interestingly, the Shank3 KO mice treated with NBQX showed additional decrease in anxiety-like and RA behavior in the EPM, and reduced RA behavior in the DL test and no changes in the OF. These results validate our bioinformatic analysis.

Conclusions:

Our study has determined that there is significantly decreased risk assessment in multiple autism mouse models. Furthermore, the molecular and pharmacological data implicate striatal glutaminergic-signalling as a potential molecular driver of decreased risk assessment. These results suggest a mechanism driving increased impulsivity and decreased awareness of risk in individuals diagnosed with ASD.

13 **107.013** Role of a Circadian-Relevant Gene, NR1D1, in the Brain Development: Possible Involvement in the Pathophysiology of Autism Spectrum Disorders

K. I. Nagata[1], *M. Mizuno*[2], *M. Goto*[3], *H. Tabata*[2] *and T. Yamagata*[3], *(1)Institute for Developmental Research, Aichi Human Service Center, Kasugai, Japan, (2)Institute for Developmental Research, Aichi Human Service Center, Kasugai, Kasugai, Japan, (3)Jichi Medical University, Shimotsuke, Japan*

Background: In our previous study, we screened autism spectrum disorder (ASD) patients with and without sleep disorders for mutations in the coding regions of circadian-relevant genes, and detected mutations in several clock genes including *NR1D1*. Here, we further screened ASD patients for *NR1D1* mutations and identified three novel mutations including a *de novo* heterozygous c.1499G>A (p.R500H).
Objectives: We analyzed the role of Nr1d1 in the development of mouse cerebral cortex.

Methods: We examined the pathophysiological significance of Nr1d1 by the acute knockdown or mutant expression in mouse brain with *in utero* electroporation.

Results: Acute knockdown of mouse Nr1d1 with *in utero* electroporation caused abnormal positioning of cortical neurons during corticogenesis. This aberrant phenotype was rescued by wild type Nr1d1 but not by the c.1499G>A mutant. Time-lapse imaging revealed characteristic abnormal migration phenotypes of Nr1d1-deficient cortical neurons. When Nr1d1 was knocked down, axon extension and dendritic arbor formation of cortical neurons were also suppressed while proliferation of neuronal progenitors and stem cells at the ventricular zone was not affected. Taken together, Nr1d1 was found to play a pivotal role in corticogenesis via regulation of excitatory neuron migration and synaptic network formation.

Conclusions: The results suggest that functional defects in NR1D1 may relate to ASD etiology and pathophysiology.

14 **107.014** The Effects of Maternal High Fat Diet on BTBR and B6 Offspring on Reversal Learning in the Water T-Maze.

K. K. Chadman[1] *and S. Ye*[2], *(1)New York State Institute for Basic Research, Staten Island, NY, (2)Center for Developmental Neuroscience, CUNY College of Staten Island, Staten Island, NY*

Background:

The etiology for most cases of autism spectrum disorder (ASD) is unknown at this time. There is strong evidence for the genetic role in ASD but environmental factors also have a modifying role. One potential environmental factor is the maternal diet during fetal development. Obesity before and during prenatal development increases the vulnerability of affective disorders including schizophrenia and ASD. Prenatal maternal obesity has been shown to be a risk factor for ASD and other developmental disabilities (Krakowiak et al. *Pediatrics* 2012;129;e1121).

Objectives:

The objective of these experiments was to determine if a maternal high fat diet affected reversal learning in C57BL/6J and BTBR T+ ^{tf} Itpr/J (BTBR) offspring.

Methods:

Female C57BL/6J and BTBR mice were placed on either a high fat diet (60 kcal% fat D12492, Research Diets Inc, NJ) or a control diet (45 kcal% fat D12451, Research Diets Inc, NJ) for 2 weeks and then mated. The dams and pups remained on the diet through weaning and then were placed on regular mouse chow. One male and female pup per litter were tested as adults in the water T-maze and reversal test. Training trials for acquisition began with 10 trials per day for 3-days and were followed by reversal training (where the escape platform was moved to the opposite arm) for 2 days of 10 trials. The first arm entered was noted for each trial.

Results: All of the mice learned at the same rate suggesting that acquisition learning was not affected by the high fat diet or mouse strain. However, there were differences among the groups of mice during reversal learning. The BTBR mice prenatally exposed to the high fat diet learned the reversed arm more slowly compared to the BTBR pups from the dams on the control diet, as shown by the increased number of errors during reversal training. The C57BL/6J offspring were not affected by the maternal diet during reversal training as there were no differences in the number of errors between the high fat diet offspring and the control diet offspring.

Conclusions:

The results from the water T-maze reversal trials indicate that the C57BL/6J offspring demonstrated no changes in learning when exposed to the high fat diet during gestation. The offspring from the mouse model of ASD exposed to the maternal high fat diet showed no impairments in acquiring the water T-maze task, but were impaired in reversal learning. This suggests that the mouse model of ASD is more susceptible to environmental stressors affecting reversal learning, one of the core symptoms of ASD.

15 **107.015** The Study of the Relationship between the Copy Number Variants of HUWE1 Gene and Autism Spectrum Disorder

***J. Xie**, The ministry of science and education, Chengdu Third People's Hospital, chengdu, China*

Background:

Autism spectrum disorder (ASD) is a kind of generalized neurodevelopmental disorder. Except the environment factors, the genetic causes also have a vital role in ASD.Although numerous ASD genes have been discovered during the last two decades, for many of them the molecular mechanism via which they contribute to the ASD phenotype remains unknown. In our study, we found that the ASD patients have the elevated copy number of *HUWE1* gene suggesting that the increased gene dosage of *HUWE1* was associated with ASD. In addition, the animal model experiment showed that over-expression HUWE1 could increase the expression of Lef1, ccnd1 and c-myc, which suggested that HUWE1 could regulate the development of the nervous system through the Wnt pathway. Taken together, Our study provides the potential of HUWE1 copy number variants in occurrence of ASD via HUWE1-mediated Wnt signaling.

Objectives:

This study focused on whether the copy number variants of *HUWE1* gene is associated with autism spectrum disorder (ASD).

Methods:

We investigated the copy number of *HUWE1* gene of 67 ASD patients and 74 normal controls by RT-PCR. Zebrafish embryos were injected with synthesis RNA of HECT structure domain with 4 gradients (50ng/ul,40 ng/ul,30ng/ul, 20ng/ul). RT-PCR was used to detected the different expression of Lef1, ccnd1 and c-myc of zebrafish embryos in experimental group and control group.

Results:

We detected the 6 (6/67) persons with elevated copy number of *HUWE1* gene in the patients and all the controls with the normal copy number ($X^2 = 6.921$, $P < 0.05$). The result of RNA injected zebrafish embryos was that the development of the nervous system of 123 cases (56%) were affected in the experimental group and 10 cases (12%) had the abnormal development of the nervous system in the control group ($X^2 = 48.128$, $P < 0.01$). The expression of Lef1, ccnd1 and c-myc in RNA injected zebrafish embryos was significantly higher than the control ($p<0.05$).

Conclusions:

The increased of the copy number of *HUWE1* gene may be a pathogenic factor in ASD.The over-expression of HUWE1 could affect the development of the nervous system of zebrafish embryos by increasing the expression of the relative proteins of wnt pathway. The findings strongly support that the copy number variants of *HUWE1* gene has the potential to be a novel detecting target in the etiological diagnosis of ASD.

16 **107.016** Towards Preclinical Validation of Arbaclofen (R-baclofen) Treatment for 16p11.2 Deletion Syndrome

***A. H. Luo Clayton**[1], B. B. Gundersen[1], W. T. O'Brien[2], T. Abel[3], T. Tsukahara[4], S. R. Datta[4], M. D. Schaffler[5], M. Schultz[5], J. C. Crawley[5], S. Martin Lorenzo[6], V. Nalesso[6] and Y. Herault[6], (1)Simons Foundation, New York, NY, (2)University of Pennsylvania, Philadelphia, PA, (3)University of Iowa, Iowa City, IA, (4)Harvard Medical School, Boston, MA, (5)University of California, Sacramento, CA, (6)Institut de Genetique et de Biologie Moleculaire et Cellulaire (CERBM GIE), Illkirch, France*

Background: Human chromosome 16p11.2 microdeletion is one of the most common copy number variants that confers risk for autism spectrum disorder and other related neurodevelopmental disorders. Animal studies suggest that 16p11.2 deletion may share pathophysiology with Fragile X syndrome (Tian et al., 2015). Data from previous clinical trials suggest that the GABA-B receptor agonist, arbaclofen, may improve symptomatology in some individuals with Fragile X syndrome and idiopathic autism, although the trials themselves did not find statistical significance on their primary endpoints. Taken together, these data raise the intriguing possibility that arbaclofen may be beneficial for 16p11.2 deletion syndrome. Indeed, a recent mouse study supports this possibility (Stoppel et al., 2017). However, the justification for pursuing arbaclofen as a rational therapy for 16p11.2 deletion must be supported by robust preclinical evidence. Concerted efforts to validate early scientific findings may be crucial in addressing the recent paucity of success in translational research (Arrowsmith, 2011).

Objectives: To rigorously determine the robustness and reproducibility of arbaclofen's normalizing effects on behavior in 16p11.2 deletion mouse models.

Methods: Four academic labs and one Contract Research Organization are working as a consortium to rigorously assess the behavioral effects of chronic arbaclofen treatment in mouse models of 16p11.2 deletion. Three different mouse models of 16p11.2 deletion on three different background strains and their wildtype controls were treated for at least 12 days with one of three doses of arbaclofen in their drinking water (0.25, 0.5, 1.0 mg/ml). Using harmonized protocols, mice were tested on Open Field activity, Novel Object Recognition, Object Location Memory, Contextual Fear Conditioning and Accelerating Rotarod. Open Field activity was additionally analyzed using 3D imaging and a novel, machine-learning based algorithm that parcellates behavior to sub-second resolution (Wiltschko et al., 2015). Individual performance on these tasks will be correlated with individual home-cage monitoring measures, as well as high-performance liquid chromatography-tandem mass spectroscopy (HPLC-MS/MS) analysis of arbaclofen levels in each brain.

Results: Approximately 180 of the 360 expected animals have been tested behaviorally and for brain penetration levels of arbaclofen. Data collection is ongoing and will be completed in 2018. In the spirit of data transparency, study results will be broadly disseminated regardless of whether they support or refute the initial hypotheses.

Conclusions: Our consortium offers an example of how to develop and execute a rigorous test of preclinical efficacy of a potential pharmacological therapy for a genetic syndrome that predisposes to autism and related disorders.

108 - Communication and Language
11:30 AM - 1:30 PM - Hall Grote Zaal

17 **108.017** A Longitudinal, Multi-Method Analysis of Pragmatic Language in ASD and Related Neurodevelopmental Disorders

***M. Lee**[1], G. E. Martin[2], A. Goodkind[1], N. Maltman[1], L. Bush[3], K. Bicknell[1] and M. Losh[4], (1)Northwestern University, Evanston, IL, (2)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (3)Northwestern Feinberg School of Medicine, Chicago, IL, (4)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Pragmatic (i.e., social) language impairments are universally observed in ASD. Qualitatively similar pragmatic language impairments have also been observed in fragile X syndrome (FXS), the most common inherited cause of intellectual disability and the monogenic disorder most frequently associated with ASD. Careful characterization of pragmatic language in both groups has important implications for understanding the role of *FMR1* (the gene that causes FXS) in autism symptomatology, and potential targeted interventions. An important question concerns how pragmatic skills, and underlying abilities, in each group present across different contexts and over development. Using both detailed hand coding and computational linguistic analyses, this longitudinal study aims to comprehensively characterize pragmatic language development across four different language contexts in males with idiopathic ASD (ASD-O), FXS with and without co-morbid ASD (FXS-ASD, FXS-O), Down syndrome (DS) and typical development (TD).
Objectives: 1) Compare pragmatic language profiles and trajectories of pragmatic development in ASD-O and related disorders across multiple language contexts varying in social demand. 2) Assess the utility of computational linguistic tools for identifying ASD-related language impairments.

Methods: This longitudinal study assessed school age males with ASD-O (n=43), FXS-ASD (n=57), FXS-O (n=13), DS (n=22) and younger TD males (n=24) at up to three time points annually. Participants completed a comprehensive battery assessing cognition, structural language, and theory of mind. Pragmatic assessments included 1) parent questionnaire (Children's Communication Checklist-2nd Edition), 2) a standardized measure (CASL-Pragmatic Judgment Subscale), 3) hand-coding of a structured narrative task, and 4) ratings of conversational behaviors during the Autism Diagnostic Observation Schedule using the Pragmatic Rating Scale-School Age (Landa, 2011). Computational linguistic analyses were applied to narrative and conversational samples using vector semantics to measure coherence and reciprocity.

Results: Males with ASD-O showed deficits in pragmatic language across all contexts that were stable across time points (ps < .05). Within the conversational context, males with FXS-ASD also demonstrated a similar quantity and quality of pragmatic language difficulties to males with ASD-O. Notably, both ASD groups showed significantly greater impairment in the conversational context relative to the structured narrative (p = .004). Computational measures differentiated clinical groups during conversation (ps < .03), and were related to ratings of pragmatic competence in both ASD groups (rs > .4). Assessment context drew on different skills across groups, with standardized measures and narrative quality more strongly related to mental age and structural language (rs > .35), whereas conversational difficulties were not significantly correlated with mental age or structural language in the ASD groups (rs < .27).

Conclusions: Groups showed unique profiles of strengths and weaknesses across different language contexts, with the ASD groups showing greatest difficulties in less structured conversation. Computational approaches appear sensitive to language differences observed in ASD, and may guide the development of efficient, quantitative, objective measures of social communication. Observed overlap both in severity and quality of pragmatic violations in males with ASD-O and FXS-ASD across development suggests specific shared pragmatic skills that may relate to variation in the *FMR1* gene.

18

108.018 A Mixed Models Approach to Analyzing Large Cohorts of Natural Conversational Data from Individuals with ASD

M. Cola[1]*, E. F. Ferguson*[2]*, L. Bateman*[2]*, S. Uh*[1]*, S. Plate*[1]*, Z. M. Dravis*[1]*, A. Pomykacz*[3]*, K. Bassanello*[1]*, A. Zoltowski*[4]*, J. D. Herrington*[5]*, K. Bartley*[5]*, E. S. Kim*[1]*, A. de Marchena*[6]*, J. Pandey*[1]*, R. T. Schultz*[1] *and J. Parish-Morris*[1]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research/CHOP, Philadelphia, PA, (3)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (4)Vanderbilt University, Nashville, TN, (5)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)University of the Sciences, Philadelphia, PA*

Background: Natural, unstructured conversation represents a significant challenge for individuals with autism spectrum disorder (ASD), but relatively little is known about how speech and language unfold in an uncontrolled context; less yet is known about the myriad interacting factors that likely influence dynamic conversation in ASD, such as age, sex, and cognitive ability. Until recently, most studies lacked sufficient power to assess all of these contributors in a single cohort. Here, we report on a growing corpus of natural conversations between individuals with and without ASD and naïve confederates. This corpus will ultimately provide the field with a multi-faceted view of conversational interactions in typical development (TD) and in individuals with ASD, and lay the foundation for new metrics to assess social interaction that allow us to track change across ages, sexes, and ability levels.
Objectives: Use mixed effects models to assess the contributions of diagnostic status, age, IQ, and sex to speech/language features produced during naturalistic conversations with naïve confederates.

Methods: Sixty-nine individuals aged 5-59 years with ASD (N=48, 15 female, mean age=14.93y, mean IQ = 96) and TD (N=21, 15 female, mean age=21.89y, mean IQ=107) participated in a naturalistic ~5 minute "get to know you" conversation with one of 13 undergraduate confederates (10 female). Language was transcribed and time-aligned using XTrans (LDC). Average speaking rate, words per minute, word length, response latency, and turn length were calculated. LIWC was used to calculate social category words (Tausczik & Pennebaker, 2010). The contributions of diagnostic status (ASD, TD), chronological age, sex (M, F), and full-scale IQ to speech and language features were assessed using linear mixed effects models, with confederate ID included as a random effect to account for individual variability in naïve interlocutors.

Results: Linear mixed models revealed that participants spoke faster as they got older (t=3.52, p<.001). Older participants produced more words (t=5.39, p<.001), as did individuals with higher IQ estimates (t=3.05, p=.003). Participants with ASD used slightly longer words than TD participants (t=2.12, p=.04). Older participants had longer response latencies (t=2.30, p=.02), produced more overlapping speech (t=2.40, p=.03), and took longer turns (t=4.54, p<.001). Participants with higher IQ estimates also took longer turns (t=3.48, p<.001). Social topics were discussed more often by older participants (t=2.42, p=.02) and by female participants (t=2.40, p=.02).

Conclusions: A multi-faceted understanding of natural conversational interactions in ASD will inform the next generation of highly granular intervention response metrics. We anticipate adding an additional 20 participants to this cohort by May, 2018, as well as including additional speech/language metrics and an analysis of confederate speech.

19

108.019 A Systematic Review of Communication Interventions for Minimally Verbal Children with Autism Spectrum Disorder

A. Brignell[1]*, K. V. Chenausky*[2]*, H. Song*[3] *and A. T. Morgan*[4]*, (1)Audiology and Speech Pathology, University of Melbourne, Carlton, Australia, (2)Neurology, Beth Israel Deaconess Medical Center, Boston, MA, (3)Centre of Public Health Sciences, University of Iceland, Reykjavik, Iceland, (4)Murdoch Children's Research Institute and University of Melbourne, Melbourne, Australia*

Background: Language difficulties commonly co-occur with autism spectrum disorders (ASD) and it is estimated 25-30% of children with ASD fail to develop functional language, or are minimally verbal. The ability to communicate effectively is an essential life skill and difficulties communicating can have a range of adverse sequelae including poorer academic achievement, behaviour difficulties and reduced quality of life. Historically, most studies have investigated communication interventions for verbal children with ASD. We cannot assume the same interventions will work for minimally verbal children. To date, there has been no systematic review to determine the most effective intervention for minimally verbal children.

Objectives: To evaluate the effectiveness of communication interventions for children with ASD who are minimally verbal.

Methods: Fourteen databases were searched to identify relevant studies. Inclusion criteria were: children with ASD < 12 years of age who were minimally verbal (less than 30 functional words/unable to use speech alone to communicate); diagnosed using standard diagnostic assessments and/or criteria (e.g. Diagnostic Statistical Manual for Mental Disorders or International Classification of Diseases) and cognitive level > 12 months. Interventions included randomised controlled trials (RCTs) that used communication-focused interventions and aimed to improve spoken communication or non-verbal communication. Primary outcomes were spoken communication (e.g. direct assessments, parent-completed tools, language samples) and non-verbal communication/augmentative communication (e.g. number of key word signs, number of initiations on an augmentative communication device). Risk of bias of included studies was assessed along with the overall quality of the body of evidence.

Results: Of 5233 studies identified, nine were randomised trials that focused on communication interventions for children with ASD who were minimally verbal. Seven of these compared 2 different interventions but only 2 studies with 153 participants compared an intervention to a control group and thereby met inclusion criteria. One study investigated a Picture Exchange Communication System (PECS) intervention administered by school teachers and the other a parent-mediated Focused Playtime Intervention (FPI). Age at baseline ranged from 4 to 11 years. Outcomes were standardised language scores and the PECS study also included frequency of initiations, speech and PECS use. Children enrolled in the PECS intervention were significantly more likely to use verbal initiations and PECS symbols immediately after intervention, however gains were not maintained 10 months later. PECS did not improve frequency of speech or language ability. There was no significant treatment effect for the FPI on expressive language, however, baseline expressive language (<11.3 months age equivalent) moderated a significant medium-large treatment effect. Both studies had high or unclear risk of bias in at least 4/7 risk of bias categories. The overall quality of the evidence was rated poor.

Conclusions: Across all outcomes, data are insufficient to show whether communication interventions (specifically, PECS and FPI) are effective in increasing verbal and non-verbal communication in minimally verbal children with ASD. Future studies that compare two treatments and include a control group will allow us to better understand treatment effects in the context of spontaneous maturation and will allow further comparison of different treatments and investigation of moderators.

20

108.020 Active Listening Strategy Differences Associated with Autism during a Referential Communication Task

J. Beriont[1], *M. Conca*[2], *A. de Marchena*[3], *A. Bagdasarov*[4], *Z. M. Dravis*[5], *L. Bateman*[6], *E. F. Ferguson*[6], *B. B. Maddox*[7], *A. A. Pallathra*[8], *N. Minyanou*[5], *A. Pomykacz*[9], *K. Bartley*[10], *E. S. Brodkin*[11], *J. Pandey*[5], *J. Parish-Morris*[5], *R. T. Schultz*[5] *and E. S. Kim*[5], *(1)Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, (2)Center for Autism Research, Philadelphia, PA, (3)University of the Sciences, Philadelphia, PA, (4)Child Study Center, Yale University School of Medicine, New Haven, CT, (5)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (6)The Center for Autism Research/CHOP, Philadelphia, PA, (7)University of Pennsylvania, Philadelphia, PA, (8)Department of Psychiatry, Catholic University of America, Washington, DC, (9)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (10)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (11)Department of Psychiatry, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA*

Background: An active listener's comments and questions can guide a speaker to provide more useful information. Active listening behaviors are important pragmatic language skills—a behavioral domain of concern in autism—with specific deficits observed in conversational repair, contingent response, and requesting information, among others (reviewed in Simmons, Paul, & Volkmar, 2014; Tager-Flusberg et al, 2005).

Objectives: The present study compares the types of comments and questions adults with ASD and typically developing controls (TDC) use to actively manage the information provided by interlocutors, while playing a listening role, in a goal-oriented dyadic referential communication paradigm.

Methods: Adults with ASD (n=12) and age-, gender-, and IQ-matched controls with typical development (TDC; n=13) completed a collaborative, dyadic referential communication task designed to elicit spontaneous back-and-forth conversation in a controlled setting. Each participant viewed a computer touchscreen displaying a blank 2x4 grid, as well as eight abstract figures scattered throughout the screen. A confederate sat opposite the participant, viewing the same eight figures in a particular arrangement within the 2x4 grid. Participant-confederate pairs were tasked with communicating so that the participant (primarily in a listening role) could move and arrange his or her figures to match the arrangement on the confederate's (primarily in a speaking role) screen. Dyads collaborated to arrange a single set of eight figures into 5 immediately consecutive, unique target arrangements (trials). Speech was transcribed, and participants' utterances were classified as managing discourse (DM), requesting clarification (RC), a non-DM non-request (NR), or as serving a combination of these. Requests for clarification were further subcategorized into 6 mutually exclusive types. These ranged from highly informative, such as requesting confirmation of the identity of the figure currently under discussion, using novel descriptors (confirmation of new, or CN, e.g., "The one that's like a barbell?"); to extremely vague, such as open-ended requests for elaboration (E, e.g., "Say more?").

Results: Listeners in both groups spoke more during the first (p<.01) than during subsequent trials. Given that minimal amounts of each type of listener utterances occurred after the first trial, further analyses focus only on the first trial. There were main effects of diagnosis (p<.005) and utterance type (p<.001), and a marginal interaction effect between the two (p=.057), driven by more non-requests (p=.036) and discourse management utterances (p=.024) by the ASD than TDC group. Non-request and discourse management frequency correlated directly with ADOS calibrated severity score (CSS; r=.44, r=.60, respectively). Listeners in both groups varied the types of requests for clarification they produced (p<.01), with TDCs requesting confirmation of novel terms more frequently than participants with ASD (p=.050; see figure), a behavior which correlated inversely with ADOS CSS (r=-.47).

Conclusions: Adult listeners in both groups actively listened by producing comments and questions to manage the information they received from an interlocutor, during a dyadic referential communication task. Use of discourse management and non-request utterances was associated with greater ASD severity, while arguably the most actively informative form of feedback to the speaker—introduction of novel or alternative descriptors—was related with lower ASD symptom severity.

21 **108.021** An Investigation into Executive Function Differences between Autistic and Non-Autistic Monolinguals and Multilinguals

S. Crockford[1]*, A. Remington*[2] *and L. Kenny*[3]*, (1)University of Cambridge, Cambridge, United Kingdom, (2)UCL Centre for Research in Autism and Education, London, United Kingdom, (3)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland*

Background: There has been extensive research to show that multilinguals (those who speak more than one language) enjoy cognitive benefits, such as improved executive function, as a result of their fluency in more than one language (Bialystok, 2010). In contrast, autistic individuals have been documented as having poorer executive function abilities than their neurotypical peers (Hill, 2004). However, relatively little is known about how being multilingual may influence these abilities, The large prevalence of multilingual speakers worldwide and the assumption that autism is a universal condition (i.e. Baxter et al, 2015), would suggest that a large number of multilingual autistic individuals are currently being ignored in research. In addition, families are often advised against raising autistic children as multilinguals, although there is no evidence to support the notion that multilingualism is detrimental to autistic individuals (Jegatheesan et al, 2010; Kremer-Sadlik et al, 2005). This study therefore hopes to highlight that multilingualism is present, and not detrimental to those on the autistic spectrum.

Objectives: This study aimed to examine whether there were differences in executive function performance between autistic multilingual adolescents, autistic monolingual adolescents, and their neurotypical multilingual and monolingual peers.

Methods:The study involved 66 participants, aged 12 to 19, who were administered flanker and set-shifting tasks as part of a battery of executive function measures (NIH Examiner battery, Kramer et al, 2014) and a questionnaire regarding their level of multilingualism. The data from the questionnaire allowed for the creation of four groups of participants, monolingual autistics (N = 18), multilingual autistics (N = 8), monolingual neurotypicals (N = 17) and multilingual neurotypicals (N = 23). Groups were cognitively matched based on their performance on a measure of verbal and non verbal intelligence (from the WASI II, Weshler, 2011) Ethical approval was received from the UCL Institute of Education Ethics Committee.

Results: Mean differences analysis on the two tasks of executive function revealed that on the set-shifting measure, multilingual neurotypical peers performed significantly better than monolingual autistic adolescents ($p = 0.009$). However, there we no significant differences between the other groups of participants. On the other executive function measure, a flanker task, no significant differences were found. Finally, two regression models measuring the effect of multilingualism and autism on the two executive function scores showed a small, but significant positive effect for set-shifting ($r^2 = 0.113$, $p = 0.023$) but not for the flanker task ($r^2 = 0.088$, $p = 0.055$), though this was approaching significance.

Conclusions: The findings from this study support the notion the multilingualism is not detrimental to autism. They also extend further to suggest there may be some relationship between multilingualism and mental flexibility for both autistic and non-autistic individuals. Further research into this relationship will highlight the full extent of multilingual cognitive benefits autistic individuals may or may not receive, in comparison with their neurotypical peers. Finally, it is hoped that these findings will help inform the choices parents and professionals make when raising and educating a multilingual autistic child.

22 **108.022** Assuming Ability: Synthesis of Methods Capturing First Person Perspectives of Children and Youth with Disabilities

R. Tesfaye[1]*, A. Yusuf*[2]*, V. Courchesne*[3]*, T. Savion-Lemieux*[4]*, I. Singh*[5]*, K. Shikako-Thomas*[6]*, P. Szatmari*[7] *and M. Elsabbagh*[8]*, (1)Neuroscience, McGill University, Montreal, QC, Canada, (2)Psychiatry, McGill University, Montreal, QC, Canada, (3)McGill University, Montreal, QC, Canada, (4)Research Institute-McGill University Health Centre, Montreal, QC, Canada, (5)Department of Psychiatry, Oxford University, Oxford, United Kingdom, (6)School of Physical and Occupational Therapy, McGill University, Montreal, QC, Canada, (7)Centre for Addiction and Mental Health, Toronto, ON, Canada, (8)McGill University, Montreal, PQ, Canada*

Background: The United Nations Convention for the Rights of the Child states children have the right to express their own views in all matters that affect them. A large majority of research regarding children with autism has not focused on their first person perspectives. The appropriate capture of first person perspectives of youth with disabilities improves research quality and informs practice, while empowering youth participants themselves. Due to the diversity of communication and cognitive abilities in autism, different methods need to be employed to ensure inclusion. However, existing studies provide limited insight into what methods and approaches are best suited to eliciting their voices. Methods already applied with other disability groups may be suitable for youth with autism.

Objectives: Our main objective was to conduct a synthesis of research methodologies previously used to obtain the first person perspective of youth with various disabilities. Another objective was to present the synthesis results to a group of parents who have children with ASD. This stakeholder validation was used to build on the methods identified in literature. Insights from this review will be used to inform a new study entitled *ASD Voices*, which aims to capture the lived experiences of youth as they transition from adolescents to adulthood.

Methods: Searches for our scoping review were conducted on the *PubMed, Academic Search Complete, and Web of Science* databases (Aug 2017) for relevant articles within the past 15 years. Empirical articles meeting the inclusion criteria: 1) communicating the lived experience of youth with disabilities, from a first person perspective 2) at least one child 18 years of age or under; 3) no single case studies, were included. Thematic analysis was used to extract themes from our stakeholder validation comprised of a group of four parents.

Results: 284 articles met the inclusion criteria. We identified six distinct primary methods (questionnaires, interviews, group discussion, narratives, diaries and art) expressed through four communication modalities (language, writing, images, and augmentative and alternative communication(AAC)). The most common method of communication was a verbal semi-structured interview. 63 studies included some youth with communication/language impairments. Six themes, including eleven sub-themes, were identified from our stakeholder validation.

Conclusions: Based on our findings, we present a novel methodological framework to capture the perspectives of youth with various communication and cognitive abilities, while highlighting family, youth and expert contributions. Our synthesis is line with previous research, underlining the underrepresentation of youth with cognitive and communication impairments. The authors conclude that existing methods applied with various disability groups can be adapted for a range of youth with ASD. A stakeholder consultation with parents confirmed barriers that may be encountered during this type of participant engagement and also provided concrete recommendations on how to best conduct first person research with youth with autism. Future research should consider increasing transparency with methodological struggles to inform other studies. Using these findings, we will now tailor methodologies and implement them for feedback with stakeholder youth in our next pilot phase of *ASD Voices*, to test the efficacy of our results.

23

108.023 Atypical Influence of Visible Speech in Children with ASD

J. Irwin[1,2]*, T. Avery*[1]*, J. Turcios*[1]*, B. Cook*[3]*, L. Brancazio*[1,2]*, J. McPartland*[4] *and N. Landi*[1,5]*, (1)LEARN Center, Haskins Laboratories, New Haven, CT, (2)Psychology, Southern Connecticut State University, New Haven, CT, (3)Communication Disorders, Southern Connecticut State University, New Haven, CT, (4)Child Study Center, Yale University School of Medicine, New Haven, CT, (5)Psychology, University of Connecticut, Storrs, CT*

Background: In face-to-face conversation, when a speaker talks, the outcome of their speech *and* seen (visual). In some recent research, children with an autism spectrum disorder (ASD) have been reported to be less sensitive to the visible consequences of speech, even when gazing at the speaker's face. However, the underlying mechanisms of deficits in audiovisual speech perception are still unknown.

Objectives: We employed a novel visual phonemic restoration paradigm to assess neural signatures (using event related potentials; ERPs) of audiovisual processing in typically developing children and in children with ASD.

Methods: Participants were 30 monolingual American English-speaking children (15 children with ASD= 12 males and 3 females and 15 neurotypical children = 5 males and 10 females; age range 6.40 to 14.20, mean age = 10.28 years, SD = 1.98 years). Two types of stimuli were alternately presented with video of a speaker saying the consonant-vowel syllable /ba/, while EEG was continuously recorded; 1) an auditory consonant-vowel syllable /ba/ or 2) a syllable in which the auditory cues for the consonant was substantially weakened, creating a stimulus which is more like /a/. In this paradigm, a visual /ba/ should cause the auditory /a/ to be perceived as /ba/ (a visual phonemic restoration) and cause an attenuated ERP discrimination response (measured with the mismatch negativity; MMN).

Results: Typically developing (TD) children exhibited an attenuated discrimination response (MMN) for as predicted, demonstrating a visible influence of seen on heard speech, however, children with ASD showed a large discrimination response, suggesting reduced influence of visual speech, this was evidenced as an interaction between group and the size of the MMN effect ($F(1, 29) = 5.862$, $p = 0.022$, $\eta^2 = 0.132$).

Conclusions: Typically developing children exhibited an attenuated response, demonstrating a visible influence of seen on heard speech. In contrast, children with ASD showed a large /ba/, /a/ discrimination response suggesting reduced influence of visual speech. These findings may implicate impaired integration of auditory and visual speech signals in ASD.

24

108.024 Categories of Word Comprehension in Toddlers with ASD or Typical Development: An Extension of Beckage, Smith, and Hills (2011)

S. Kover[1]*, D. A. Fein*[2] *and* ***L. R. Naigles***[2]*, (1)University of Washington, Seattle, WA, (2)Psychological Sciences, University of Connecticut, Storrs, CT*

Background:

In concert with social and environmental influences, vocabulary development and outcomes hinge on the contents of a child's lexicon—what has already been learned influences what is learned next (Perry & Samuelson, 2011; Samuelson & Smith, 1999; Stokes, 2010). In particular, semantic relatedness of children's lexicons predicts learning, with delayed learners showing less relatedness among words (Beckage, Smith, & Hills, 2010). In typical development, a lure-of-the-associates model suggests that new words will be semantically related to previously acquired words (Hills et al., 2010). Beckage et al. (2011) proposed that, in contrast to that pattern, delayed learners preferentially acquire "oddballs": words not semantically related to known words. We extend this hypothesis to ASD, in comparison to typically developing (TD) children matched on receptive vocabulary.

Objectives:

We characterize the semantic relatedness of vocabulary items acquired by children with ASD or TD with two questions: (1) Despite similar vocabulary size, do toddlers with ASD or TD acquire words with different category patterns? and (2) Are toddlers with ASD more likely than TD toddlers to understand "oddballs" (i.e., words isolated within categories)?

Methods:

Toddlers with ASD (n=26; M age=32 months) and TD toddlers (n=26; M age=19 months) were matched pairwise on parent-reported receptive vocabulary (MacArthur-Bates Communicative Development Inventories [CDI]-Words&Gestures) within a margin of 10 words: M=111, SD=72/75, respectively. Groups did not differ on number of words understood, p=.991.

Words understood were tallied according to the 18 CDI categories (e.g., Clothing, Furniture) and calculated as proportions of children's receptive vocabularies. Extending Beckage et al., oddballs were identified as isolated words understood within a category in which at least one word was understood: 1-2 words understood were oddballs; more than 2 words within a category were considered associative. For each category, we tested: (1) group differences in counts and proportions of words understood and (2) group differences in proportions of children whose words in a given category were oddballs.

Results:

(1) Relative to TD toddlers, toddlers with ASD understood fewer pronouns, $t(50)=2.21$, p=.031. Using proportions, toddlers with ASD produced more sound effects, but lower proportions of time (e.g., *day*), description (e.g., *big*), and pronoun words, $ts(50)>2.0$, $ps<.050$. See Figure 1.

(2) The proportion of children with oddball words differed between groups for two categories. Fewer children with ASD (2 of 24) than TD (10 of 24) had oddball clothing words, p=.017. More children with ASD (7 of 22) than TD (1 of 23) had oddball description words, p=.022. See Figure 2.

Conclusions:

The findings point to many similarities, but also some differences in the relatedness of words in the lexicons of children with ASD and TD. Further semantic differences may emerge over developmental time: young children with ASD show typical semantic processing (Ellis Weismer et al., 2016; Rescorla, 2013), yet semantics is an area of weakness later in childhood (Ellawadi et al., 2016; Norbury et al., 2010). The current study has implications for theories of lexical acquisition in ASD, including whether words with certain functions (e.g., adjectives), rather than semantic properties, are vulnerable to delay.

25

108.025 Childhood Apraxia of Speech in Minimally Verbal Children with ASD

K. V. Chenausky[1,2]*, H. Tager-Flusberg*[3] *and G. Schlaug*[4]*, (1)Neurology, Beth Israel Deaconess Medical Center, Boston, MA, (2)Department of Neurology, Harvard Medical School, Boston, MA, (3)Psychological and Brain Sciences, Boston University, Boston, MA, (4)Beth Israel Deaconess Medical Center, Boston, MA*

Background:

Approximately 25% of children with autism spectrum disorder (ASD) remain minimally verbal (MV) past age 5 (Kasari etal. 2013). Many factors likely combine to limit spoken language acquisition in these children. One of them is hypothesized to be Childhood Apraxia of Speech (CAS; Shriberg et al. 2011a), a disorder of movement planning that results in imprecise, inconsistent, and unintelligible speech (ASHA 2007). CAS is estimated to affect approximately 1-2 children per thousand (Shriberg et al. 1997), but recent evidence suggests that it is over-represented in certain populations (Shriberg et al. 2011b, Fedorenko et al. 2015). Two main challenges confront researchers assessing the speech of children with MV ASD for signs of CAS: (1) These children produce very little speech, and (2) Consensus on the signs defining CAS is evolving (ASHA 2007).

Objectives:

We sought to estimate the prevalence of CAS in a group of 38 children with MV ASD. If CAS occurs at the same rate in children with MV ASD as in the general population, at most 1-2 would be expected to meet criteria for CAS.

Methods:

Video of 38 participants in a study comparing two spoken-language treatments (7 female, aged 3;5-10;8) was examined for signs of CAS. Treatment study inclusion criteria were: diagnosis of ASD, expressive vocabulary ≤20 words, no productive syntax, and the ability to repeat ≥2 phonemes. To address the first challenge, video of the participants after 25 treatment sessions was used. Each child produced the words “baby”, “cookie”, “daddy”, “mommy”, and “puppy” five times each. Signs of CAS were noted on each attempt, using the operational definitions from Iuzzini-Seigel et al. (2015). Children met criteria for CAS if they showed ≥5 signs from the list on any word. To address the second challenge, an exploratory factor analysis was performed to determine whether the factors underlying the observed signs of CAS grouped into three categories (ASHA 2017) or two (Shriberg et al. 2017).

Results:

37 of 38 children met criteria for CAS. Observed variables loaded onto two factors (“segmental” and “prosody”), consistent with the taxonomic domains in Shriberg et al. (2017).

Conclusions:

Preliminary results suggest that CAS is highly over-represented in MV ASD. However, these initial findings must be interpreted with caution because the inclusion criteria for the treatment study may have inadvertently selected for children with CAS, omitting (a) children with ASD who cannot consistently phonate on request, and (b) low-, but not minimally-verbal, children with ASD. Accordingly, we are in the process of replicating the study in a larger group of 78 MV and low-verbal children and teens with ASD (aged 4;4-19;6), using video from administration of the Kaufman Speech Praxis Test (Kaufman, 1994). Figures documenting reliable identification of signs of CAS in both groups by two independent judges, prevalence estimates for the replication group, and the results of a confirmatory factor analysis on the replication group will be presented along with the initial findings. Results will be interpreted in the context of phenotyping studies and treatment design for children with MV ASD.

26 **108.026** Behavioral Predictors of Improved Speech Output in Minimally Verbal Children with Autism

K. V. Chenausky[1], *A. Norton*[1], *H. Tager-Flusberg*[2] *and G. Schlaug*[3], *(1)Neurology, Beth Israel Deaconess Medical Center, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA, (3)Beth Israel Deaconess Medical Center, Boston, MA*

Background: Approximately 25% of children with autism spectrum disorder (ASD) remain minimally verbal (MV) past age 5 (Kasari etal. 2013). Less language is associated with challenging behaviors and poorer long-term outcomes (Venter et al. 1992, Howlin et al. 2004), but maladaptive behaviors decrease and long-term outcomes improve when children learn to communicate more successfully (Buschbacher et al. 2003). Thus, efforts to identify the factors predicting improvement in spoken language are increasingly important as we develop more effective treatments for these children.

Objectives: We wished to understand what factors predict the amount of improvement in % Syllables Approximately Correct after 25 sessions of an intonation-based spoken-language therapy in 38 children with MV ASD.

Methods: Participants were 38 children receiving one of two spoken-language treatments (7 female, aged 3;5-10;8). Treatments were Auditory Motor Mapping Training (AMMT), a novel intonation-based intervention; and Speech Repetition Treatment (SRT), a non-intonation-based control intervention. Inclusion criteria were: diagnosis of ASD, expressive vocabulary ≤20 words, no productive syntax, and the ability to repeat ≥2 phonemes. Seven predictor variables were chosen based on the literature: Sex; chronological age; and baseline measures of expressive language, phonetic inventory, autism severity, and nonverbal IQ. First, bivariate correlations were performed to eliminate predictors not significantly correlated with the outcome variable. Then, regression models were fit to assess the effect of the remaining predictors. Both complete case and multiple-imputation analyses were employed because of missing predictor data. Finally, because some children in each group improved, subgroup analyses were performed to investigate whether predictors differed according to treatment group and improvement status.

Results: Over the course of 25 treatment sessions, AMMT participants (n = 27) improved by a mean of 17.8% Syllables Approximately Correct (SD 18.8), while SRT participants (n = 11) improved by a mean of 0.5% Syllables Approximately Correct (SD 12.0). Bivariate correlations eliminated all predictors save autism severity (ADOS score) and phonetic inventory (the number of phonemes a child could correctly repeat). Together, the two variables accounted for 50-60% of the variance in change in % Syllables Approximately Correct. Across groups and analyses, every additional phoneme a child could repeat at Baseline resulted in a 1.4-2% increase in the amount of improvement after 25 therapy sessions. A one-point increase in ADOS score resulted in a 2-3% decrease in the amount of improvement. Complete-case analyses resulted in lower standard errors than multiple-imputation analyses, despite the smaller number of participants (24 complete cases out of 38 participants total). Phonetic inventory significantly predicted improvement only in children who received AMMT.

Conclusions: ADOS score emerged as a significant predictor when SRT participants were included. These results are consistent with previous findings that children with MV ASD benefit more, on average, from intonation-based therapies and suggest that intonation may be more efficient at enabling these children to harness their speech production abilities to learn new phonetic patterns. The fact that age did not significantly predict improvement is optimistic, in that it means that older children may still show some improvement in spoken language.

27 **108.027** Challenges to the Development of Core Vocabulary for Arabic Symbol-Based AAC

M. Habash[1] *and F. Alnemary*[2], *(1)Irada Autism Services Palestine, Gaza, Palestinian Territory, (2)UCLA, Los Angeles, CA*

Background: There has been enormous research towards the determination of core vocabulary for non-verbal and minimally verbal people using augmentative and alternative communication (AAC) systems in English and other Latin languages; however, there is limited literature about this in Arabic. This is partly due to the grammatical and lexical complexity of the Arabic language. This has created issues to attempts to create an Arabic symbol-based AAC.
Objectives: The aim of this study was to develop a core vocabulary list for a symbol-based Arabic AAC suitable for nonverbal children with mild to moderate autism.

Methods: a participatory study focused on the collection of naturally occurring Arabic vocabulary from 80 neurotypical children, aged from 3 to 10 years from 4 Arabic speaking countries. Parents and children are engaged through the use of an online tool developed for reporting. The tools allows submission of words and offers an option to submit recordings of conversations with parents consent.

Results: this is an ongoing study. Results are expected in March 2018

Conclusions: conclusions will be included once study is completed.

28 **108.028** Characterization of Cross-Genre Writing Ability in Children with Autism Spectrum Disorders

__E. Hilvert__[1], D. Davidson[2] and I. Misiunaite[3], (1)Loyola University, Chicago, IL, (2)Psychology, Loyola University Chicago, Chicago, IL, (3)Loyola University Chicago, Chicago, IL

Background: With an increase in the prevalence of technology, effective writing is not only critical for academic success, but it is also essential for obtaining a high-skill, high-wage job and maintaining daily social interactions. Unfortunately, it is estimated that writing may be one of the most significant academic problems for children with Autism Spectrum Disorders (ASD), with as many as 60% of children having a learning disability in writing (Mayes & Calhoun, 2006). Despite evidence from standardized assessments that writing is generally challenging for children with ASD, little is known about how children with ASD write in different genres. In neurotypical (NT) development, children begin to make important inter-genre distinctions around the age of 9. Typically, children master genre structure earlier in narrative writing compared to expository writing, but use more complex syntax and vocabulary earlier in expository essays (Berman, 2008). More research is needed to understand whether children with ASD are also developing these important distinctions between text genres. Additionally, the mechanisms that influence writing development in children with ASD are still unclear.
Objectives: The objectives of this study were (1) to comprehensively characterize the cross-genre (i.e., narrative, expository) writing development of children with ASD; and (2) to better understand how heterogeneity in handwriting, language ability, and cognitive processing contribute to the writing ability of children with ASD.

Methods: Eighteen children with ASD (M_{age}= 11;02) participated in the present study. All children had an IQ > 70 and were native English speakers (see Table 1). Children completed two writing tasks on the computer: one personal narrative and one expository essay. Writing performance was assessed in terms of productivity, lexical diversity, syntactic complexity, use of evaluative devices (i.e., hallmark feature of narratives, including character's internal states, hedges, intensifiers), and genre structure. Measures of handwriting, language, theory of mind (ToM), and executive functioning were also administered.

Results: We found that children with ASD wrote expository essays that were more syntactically complex in terms of the frequency of noun phrases compared to their personal narratives. However, there was also a trend towards children with ASD using better structure and more evaluative devices when writing their personal narratives, but writing longer expository essays. No other differences between the text genres were found (see Table 2). After controlling for variation in non-verbal IQ, we found that ToM ability was related to syntactic and semantic complexity across text genres. Additionally, greater executive functioning ability was related to the use of more complex syntax and better text structure. Surprisingly, chronological age, language ability, and handwriting fluency were not related to writing performance in either genre.

Conclusions: These findings provide evidence that children with ASD make some distinctions in text style when writing in different genres. Additionally, we found that ToM and executive functioning were significant mechanisms for various aspects of writing development in children with ASD. These results have important implications for the development of effective writing curriculum and interventions for children with ASD.

29 **108.029** The Relationship between Person Reference and Mental State Language in Preschoolers with ASD

__M. Barokova__[1] and H. Tager-Flusberg[2], (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA

Background:
Although past research has provided mixed evidence of the nature and extent of personal pronoun difficulty in autism, children with autism's preference for proper names when referring to themselves and others along with their experience of a deficient sense of self stand out across studies (e.g., Lee at al., 1994; Tager-Flusberg, 1994; Shield et al., 2015).

Increase in personal pronoun use after the second year has long been used as a reflection of the emerging sense of self in typical development (e.g., Lewis & Ramsay, 2004). Furthermore, mental state language use in autism reflects Theory of Mind (Capps et al., 2000), which is also related to sense of self. Yet, no study has specifically examined the relationship between mental state language as an appropriate context to differentiate between self and others and personal pronoun use as a reflection of sense of self in autism.

Objectives:

We aimed to examine how children with autism refer to themselves and others: using fixed (common nouns and names) vs. shifting (personal pronouns) reference terms, and how this changes across time. Furthermore, we wanted to evaluate the relationship between children's person reference and their use of mental state language.

Methods:

Natural language samples from mother-child interactions were collected from children with autism (N = 50) at two (**T1:** *M*=27.13 months), three (**T2:** *M*=39.63), and four (**T3:** *M*=51.68) years of age. Their autism diagnosis was confirmed with the administration of the ADOS at each time point. Other key measures of the children's development included the Mullen, ESCS, and Vineland. We used the Linguistic Inquiry and Word Count software (LIWC, Pennebaker et al., 2007) to analyze the transcripts of the mother-child interactions by extracting rates (% of total number of words) of the children's use of personal pronouns (1st and 2nd person singular) and of mental state terms using an established word list (Bartsch & Wellman, 1995).

Results:

At each age, children used significantly more personal pronouns (*M1*=1.46; *M2*=4.99; *M3*=6.68) than common nouns and names to refer to themselves and others (*M1*=.63; *M2*=1.37; *M3*=1.27; **T1:** *Z*=-2.17, *p*<.05; **T2:** *Z*=-4.64, *p*<.05; **T3:** *Z*=-5.61, *p*<.05) (Figure 1). Children's use of mental state language was significantly correlated with their use of personal pronouns at all time points even after controlling for general language ability (Table 1).

Conclusions:

Contrary to past research, the children with ASD in our study exhibited no preference for common nouns and names over personal pronouns. This surprising finding could be attributed to the use of natural language sampling rather than pronoun elicitation tasks potentially posing different social and cognitive demands. The children's use of mental state language was related to their use of personal pronouns providing support for the notion that talking about mental states might provide the appropriate context for children to differentiate between themselves and others. These findings demonstrate a new approach to the study of selfhood in autism focusing on the characteristics of speech.

30 **108.030** Choosing a Definition of "Minimally Verbal": Characteristics of Minimally Verbal Children with ASD in the Autism Genetic Resource Exchange

C. DiStefano[1]*, Z. T. Tucker*[2] *and S. Jeste*[3]*, (1)University of California Los Angeles, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)University of California, Los Angeles, Los Angeles, CA*

Background:

Approximately 30% of children with autism spectrum disorder (ASD) remain minimally verbal (MV) despite intervention, using only single words or fixed phrases in familiar contexts (Tager-Flusberg & Kasari, 2013). There is inconsistency in the measures used to make a research determination of MV status. A previous study using the Simons Simplex Collection (SSC) found that the MV sample composition varied depending on the measures chosen and found substantial variability in cognitive skills in all MV groups (Hus et al., 2016). Given that SCC excludes children with a nonverbal (NV) mental-age below 18 months, many MV children were likely excluded from that sample. The current study builds on the contributions of Hus et al. (2016) by examining characteristics of MV children in the Autism Genetic Resource Exchange (AGRE) dataset. The AGRE dataset provides a representative MV sample, as it has no mental-age cutoff.

Objectives:

(1) Evaluate rates of MV in the AGRE dataset based on different assessment definitions. (2) Compare MV sample characteristics based on different definitions.

Methods:

Participants included individuals 5-18 years old in the AGRE database with scores for all relevant assessments (N=1478; Male N=1153). We testing the following definitions of MV: Autism Diagnostic Interview – Revised (ADI-R) "single/no words"; Autism Diagnostic Observation Schedule (ADOS) Module-1 (further split into "some words"/"few words"); and Vineland Adaptive Behavior Scale (VABS) expressive language (EL) age below 24 months or below 18 months.

Results:

See table 1 for detailed results. The ADOS Module-1 definition resulted in the largest proportion of participants classified as MV (27%). Including only children who scored "few words" reduced the proportion to 20%, similar to the proportion identified using ADI-R score and VABS EL below 24 months. VABS EL below 18 months resulted in the smallest proportion of participants identified as MV (13%). 72% of participants who received ADOS Module-1 were identified as MV based on ADI-R; this increased to 87% when restricted to participants who received an ADOS rating of "few words". Participants with VABS EL below 18 months had the lowest cognitive and adaptive behavior scores. All groups showed substantial variability in cognitive scores with notably higher non-verbal IQ scores compared to verbal.

Conclusions:

Three of the definitions (ADI-R "single/no words", ADOS "few words", VABS EL below 24 months) had high overlap and consistent sample characteristics. Including all ADOS Module-1 participants yielded a larger MV group, indicating that some participants used less language during the ADOS administration than in their daily activities as reported by parents. Reducing the VABS cutoff to 18 months resulted in a much smaller MV group with notably lower cognitive scores, indicating that this group likely represents a subgroup of the MV population with greater overall intellectual impairment. All MV groups showed variability in cognitive scores, with many participants achieving non-verbal IQ scores in the normal range. This study highlights the importance of selecting a MV definition based on the study goals, as well as carefully assessing participants and reporting sample composition, as there is substantial variability within the MV group regardless of definition used.

31 **108.031** Cognitive Orientation and Linguistic Diversity in the Narratives and Retellings of Children with ASD Vs. Controls

J. Boorse[1]*, L. Bateman*[2]*, E. F. Ferguson*[2]*, M. Cola*[3]*, S. Uh*[3]*, S. Plate*[3]*, Z. M. Dravis*[3]*, A. Pomykacz*[4]*, K. Bassanello*[3]*, A. Zoltowski*[5]*, J. D. Herrington*[6]*, K. Bartley*[6]*, E. S. Kim*[3]*, A. de Marchena*[7]*, J. Pandey*[3]*, R. T. Schultz*[3] *and J. Parish-Morris*[3]*, (1)University of Pennsylvania, Philadelphia, PA, (2)The Center for Autism Research/CHOP, Philadelphia, PA, (3)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (4)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (5)Vanderbilt University, Nashville, TN, (6)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (7)University of the Sciences, Philadelphia, PA*

Background: Narrative storytelling can be challenging for individuals with autism spectrum disorder (ASD) because it is essentially a social-communicative task. To successfully tell a story from pictures, one must be able to take the perspective of characters and communicate their appearances, actions, motives and emotions to another person. Prior research shows that individuals with ASD use fewer mental state terms than typical controls or children with Down syndrome (Tager-Flusberg, 1992), and tell less cohesive stories than children without ASD (King et al., 2014). In addition, many children with ASD have verbal working memory deficits (Williams, Goldstein, & Minshew, 2006), making it easier to describe a story from pictures than to retell the same story from memory.

Objectives: Use a computational approach to assess cartoon story narrations in participants with ASD and matched typical controls (TD), and compare retellings by group.

Methods: Thirty-three school-aged children with ASD (N=17, 3 girls) or typical development (N=16, 9 girls) participated in the present study. Groups did not differ significantly on age (11y) or IQ (105; 2 missing from the ASD group) but there were more girls in the TD group (imbalance will be corrected by May, 2018). Audio recordings of the Cartoon task of the Autism Diagnostic Observation Schedule-2nd Edition (Fig.1) were orthographically transcribed. Four variables were assessed: duration of narratives, proportion of nouns produced relative to total words (concrete orientation), proportion of words about cognitive processes (cognitive orientation), and Shannon entropy (a measure of linguistic diversity; low diversity captures predictable speech that may be repetitive or otherwise restricted in range).

Results: Linear mixed effects models with participant ID as a random effect revealed that children in both groups produced equally long initial narratives (TD M=39s, ASD M=35s, *t*=-.79, *p*=.44). The ASD group demonstrated greater concrete orientation, as evidenced by proportionately more nouns (*t*=2.61, *p*=.01), and diminished cognitive orientation, as evidenced by fewer words about the inner processes of characters, than the TD group (*t*=-2.18, *p*=.07; Fig.1). In addition, participants with ASD produced narratives that were less linguistically diverse than participants in the TD group (*t*=-1.66, *p*=.107; Fig.2). In the retelling (without a picture), children with ASD produced narratives that were significantly shorter than their own first telling (-29%; M=25s; *t*=-3.40, *p*=.004), while children in the TD group produced retellings that only trended toward being shorter (-15%; M=33s; *t*=-1.78, *p*=.10). Retellings in both groups indicated similar concrete orientation (*p*s=n.s.). However, the ASD group continued to demonstrate diminished cognitive orientation (*t*=-2.33, *p*=.03) and reduced linguistic diversity (*t*=-2.15, *p*=.04; Fig.2) as compared to the TD group.

Conclusions: Our results replicate and extend prior research showing that children with ASD produce and remember narratives differently than typically developing children. In a short cartoon narrative and retelling, we found consistent indicators of diminished cognitive orientation and linguistic diversity in the ASD group, as well as evidence of working memory deficits. The next steps in this research are to double our sample size (transcription underway) and explore whether cognitive orientation during narratives relates to ASD symptomology.

32

108.032 Comprehension of Interrogative Sentences in Autism Spectrum Disorder

E. Vila Borrellas[1]*, J. Rosselló Ximenes*[1] *and W. Hinzen*[2,3,4]*, (1)General Linguistics, University of Barcelona, Barcelona, Spain, (2)Department of Translation and Language Sciences, Universitat Pompeu Fabra, Barcelona, Spain, (3)FIDMAG Germanes Hospitalaries. Research Foundation Benito Menni Hospital, Sant Boi de Llobregat, Spain, (4)Catalan Institute for Advanced Studies and Research (ICREA), Barcelona, Spain*

Background: Individuals with Autism Spectrum Disorder (ASD) have difficulties to initiate and follow a conversation and respect turn-taking. Despite the importance of asking and answering questions for social interaction, how ASD individuals comprehend the language structures involved in them has been understudied. Prosody on the other hand has a role in shaping questions to the point that there are languages such as Spanish where *yes/no* questions differ from declaratives only prosodically. As for wh questions, ASD children understand them much later than typically developing (TD) children (Goodwin et al., 2012), They are also more difficult to answer than *yes/no* ones (Oi, 2010; Oi and Tanaka, 2011). The difficulty in answering *wh* questions in ASD should be clarified since the assessment of the understanding of false-belief (Sally-Anne task) and other explicit Theory of Mind (ToM) experiments is usually made through *wh* questions.

Objectives: Study the comprehension of different types of questions in ASD and establish the role of visual support and ToM on it.

Methods: In this study, we examined the comprehension of *wh* and *yes/no* questions through visual and non-visual tasks, with and without false-belief content. We selected 16 high-functioning ASD children from 7 to 12 years old (mean = 10.03 years old). All of them were Spanish-Catalan bilingual with Spanish dominance. They were individually matched by verbal mental age with a group of children in the same age range (mean= 9.79 years old).

Results: No significant differences were found between the TD and the ASD group. The ASD and the TD have greater difficulties to answer *wh* rather than *yes/no* questions. In addition, both groups performed better in Non-ToM than ToM tasks and in those with visual support.

Conclusions: High-functioning ASD children did not show significant difficulties to understand interrogative sentences compared to their neurotypical peers. ASD and TD showed a greater level of understanding *yes/no* rather than *wh* questions. Moreover, both groups show that visual support helps to a better question comprehension. Questions involved in ToM tasks are not only more demanding to comprehend for ASD but also for typically developing children.

33

108.033 Comprehension of Word Order in the General Population of Mandarin-Exposed Preschool Children with Autism Spectrum Disorders: Evidence from Intermodal Preferential Looking

Y. E. Su[1] *and L. R. Naigles*[2]*, (1)Childa Language Lab, School of Foreign Languages, Central South University, Changsha, Hunan, China, (2)Psychological Sciences, University of Connecticut, Storrs, CT*

Background:
Recent comprehension studies have revealed grammatical strengths in children with autism spectrum disorders (ASD), often when they achieve similar vocabulary levels as those of successfully comprehending (but younger) typically developing (TD) children. For example, 3-year-old English speakers with ASD were able to process basic Subject-Verb-Object (SVO) word order similarly to vocabulary-matched 25-month-old TD children (Swensen et al., 2007); 4-5-year-old high-functioning Mandarin-speaking children with autism also used SVO word order in sentence comprehension (Zhou et al., 2017). However, no studies have investigated whether the general population of Mandarin-exposed preschool children with ASD demonstrates similar grammatical strengths.

Objectives:

Using Intermodal Preferential Looking (Naigles & Tovar, 2012), this study assessed the processing of SVO word order in a general group of Mandarin-exposed preschool children with ASD.

Methods:

Participants included 39 Mandarin-exposed children with ASD (MA=61.28 months (SD=14.84); *M*(vocabulary)=382.29 words (SD=238.73) and 29 TD children (MA=35.07 months (SD=.92); *M*(vocabulary)=713.47 words (SD=90.89). The TD children were recruited to be significantly younger (p<.001) with the goal of matching the ASD group in vocabulary; however, TD vocabularies were significantly larger than ASD (p<.001). Children listened to simple reversible SVO sentences paired with two visual scenes, only one of which matched the sentence, e.g., distinguishing between 'the bird pushing the horse' and 'the horse pushing the bird'.

Results:

Three different measures of looking behavior while viewing the videos indicated that both groups demonstrated comprehension of SVO order (all tests 1-tailed). **With the percent looking to match measure**, group effects emerged when the test trials were divided into first-half vs. second-half [F(1,66) = 5.42, p < .05]. Children looked significantly longer to the match during the test relative to control trials for the 1st half (TD) or 2nd half (ASD) of the test trials (ps < .05). **With the latency of first look measure**, the effect of scene was significant, F(1, 66) = 9.70, p < .01. Both the TD and the ASD groups looked faster to the match than the nonmatch. **With the number of switches measure**, there were significant effects of trial, F (1, 66) = 40.64, p < .001, and group, F (1,66) = 4.99, p < .05. The number of switches of attention decreased significantly between the control and test trials for both groups (ps < .001).

Conclusions:

Mandarin-exposed preschool children with ASD demonstrated similar sensitivity to SVO word order as younger TD children, even though the expressive vocabulary levels of the ASD group were dramatically delayed. Thus regardless of their verbal language skills, grammatical knowledge may be available in the general population of children with ASD. Similar to the comprehension pattern with wh-questions in English-speakers with ASD (Goodwin et al., 2015), the 2nd half of the trials was a more reliable indicator of children with ASD's comprehension. This may suggest that Mandarin-exposed children with ASD need to hear full rather than fragmentary SVO structures (i.e., without omitted nouns) to master SVO word order, i.e., certain types of input information may be more facilitative than others in the acquisition process of children with ASD.

34 **108.034** Cross-Modal Generalization of Vocabulary in Children with Autism Spectrum Disorder

P. L. Su[1] *and S. Camarata*[2]*, (1)Hearing and Speech Sciences, Vanderbilt University, Nashville, TN, (2)Hearing & Speech Sciences; Psychiatry & Behavioral Sciences, Vanderbilt University Medical Center, Nashville, TN*

Background: Vocabulary is a foundation for many aspects of language and is an important predictor of reading comprehension and later academic success (Dickinson, McCabe, Anastasopoulos, Peisner-Feinberg, & Poe, 2003). Though previous research suggests that children with autism demonstrate deficits in vocabulary in both the receptive and expressive modalities very early in their development (Ellis Weismer, Lord, & Esler, 2010; Luyster & Lord, 2009), the nature of vocabulary deficits involved in this process remains unclear. Researchers have suggested that compared to typically-developing children, children with ASD may acquire partial knowledge of a learned language form and encounter more difficulties generalizing across settings and modalities(Wynn & Smith, 2003). This study aims to investigate receptive and expressive word acquisition and cross-modality generalization in children with ASD.

Objectives: 1) To examine potential differences in word acquisition across receptive and expressive modality in children with ASD; 2) To examine whether children with ASD demonstrate expressive to receptive or receptive to expressive cross-modal generalization of word learning following a combined storybook and play vocabulary intervention.

Methods: A single-subject, multiple-probe design (Wolery, Gast & Hammond, 2010) was implemented to compare vocabulary learned within receptive or expressive vocabulary intervention conditions. Twelve children with ASD between 36 and 90 months were recruited and taught unfamiliar vocabulary in a combined storybook and play intervention (see Table 1 for participants' cognitive, language, and vocabulary ability). For each child, by random assignment, half of the target words were trained expressively and the other half were trained receptively. Probe sessions occurred both before, during, and after each phase of intervention to compare target words learned in the receptive and expressive modality and to probe the extent of cross-modal generalization.

Results: Children learned target words in both receptive and expressive conditions, as evidenced by an average of 80% accuracy across three trials at the end of each intervention. In receptive modality, participants learned target vocabulary to criterion in an average of 10 sessions. In expressive modality, participants learned target vocabulary in 12 sessions on average. Visual analysis of the immediate post-intervention probe condition showed that participants showed considerably greater success generalizing from expressive to receptive modalities. In cross-modal probes, participants identified 79% of the words taught expressively and 46% of the words taught receptively (see Figure 1 & 2 for sample data of successful and unsuccessful cross-modal generalization).

Conclusions: Unlike typically-developing children who are able to generalize vocabulary learned across both receptive and expressive modalities, children with autism in this study were more likely to cross-modal generalize from the expressive to the receptive modality than the opposite direction. Findings from this study provide clinical implication about teaching vocabulary in this population. Specifically, findings showed that vocabulary forms taught receptively will not reliably generalize to the expressive modality. Children with autism may benefit from an intervention focusing primarily on expressive vocabulary which may lead to growth in both the expressive and receptive modalities.

35 **108.035** Cross-Population Comparison of Expressive Language Profiles in Mandarin-Exposed Children with ASD, MR, and LD

Q. Xie[1] *and Y. E. Su*[2]*, (1)School of Foreign Languages, Central South University, Changsha, Hunan, China, (2)Childa Language Lab, School of Foreign Languages, Central South University, Changsha, Hunan, China*

Background:

Cross-population comparison of language development is beneficial to reveal the similarities and differences between children with autism spectrum disorders (ASD) and those with other language impairments. Studies in western children with ASD have yielded evidence for their core linguistic abilities in lexical and grammatical development, in contrast to the more impaired pragmatic abilities (Ellis Weismer et al., 2011; Geurts & Embrechts, 2008; Tager-Flusberg et al., 1990). Cross-population studies in children with ASD speaking typologically different languages (as a comparison with other language delayed groups) are needed to unveil the unique and universal language profiles in children with ASD across countries.

Objectives:

To compare expressive language profiles including lexical, grammatical and pragmatic skills among children with ASD, children with mental retardation and children with language disorder, via the Putonghua Communicative Development Inventory: Words and Sentences (PCDI-Toddler

Form).

Methods:

Parents of 114 preschool children with language impairments participated in this study, including 41 children with ASD (the ASD group), 41 children with mental retardation (the MR group), and 32 children with language disorder (the LD group). These three groups of children were matched on age (ASD: 47.80±13.82 months, MR: 48.95±16.81 months, LD: 41.84±13.45 months, F（2,110） = 2.28, p>.05) as well as the total vocabulary production score via the PCDI lexical checklist (ASD: 225.20±233.78, MR: 221.71±270.21, LD:279.13±313.14, F(2,111) =.49, p>.05). However, the ASD group had significantly higher scores on the Autism Behavior Checklist than the other two groups (ASD:83.07±21.67, MR:39.00±16.21, LD:32.45±13.95, F（2,100） =72.322, p<.001). Children's lexical, grammatical and pragmatic levels were compared through the completed PCDI-Toddler Form.

Results:

(1) While matched on the total vocabulary production level, these three groups were comparable in the five lexical subcategories: nouns, verbs, pronouns, quantifiers and question words (Fs(2,111)=.27-2.15, *ps*>.05). (2) In the grammatical aspect, three groups of children did not differ on most items of "words and sentences", "combining" (Xs^2=.30-5.22, *ps*>.05), MLU and grammatical complexity (Fs(2,111)=.10 and .59, *ps*>.05). But further pairwise Chi-square test revealed that the ASD group used fewer perfective/experiential aspect markers "le" or "guo" than the LD group (17.1% vs. 37.5%, X^2=3.90， *p*<.05). (3) Three groups were equivalent on most of the pragmatic items in the subscale of "how to use words "(Xs^2=1.04-5.90, *ps*>.05). Pairwise chi-square tests revealed that though the MR and LD groups did not differ in their pragmatic skills, the ASD group displayed a relatively weaker command on "describing past events/people" (17.1%) than the MR group (37.5%) and the LD group (37.5%), X^2=4.27 and 3.90, *ps* <.05.

Conclusions:

In general, Mandarin-exposed children with ASD exhibited similar levels of lexical and grammatical abilities as the MR group and the LD group. Consistent with Ellis Weimer et al. (2011), this is further evidence for the dimensional account that different populations of children with language delays demonstrated core linguistic abilities. However, Mandarin-exposed children with ASD's deficits in the use of perfective/experiential marker and the description of past events/people may reflect their special difficulties in expressing past events, both grammatically and pragmatically (Eigsti, et al., 2007; Jyotishi et al., 2017).

36 **108.036** Current Profiles and Early Predictors of Reading Skills in School-Age Children with Autism Spectrum Disorders

ABSTRACT WITHDRAWN

Background:

The number of studies exploring reading skills of children with autism spectrum disorders (ASD) has grown in recent years. A lot of this research has focused on the mismatch between stronger word reading (decoding) and weaker reading comprehension observed in some children with ASD, with the term "hyperlexia" sometimes being used to describe an extreme version of this profile. However, other studies have noted a very considerable heterogeneity in reading capacity between children with ASD.

Objectives:

To study reading profiles and early predictors of reading in a cohort of school-age children. At age 2.5 years the cohort underwent an autism assessment following identification in a population-based screening. At age 8 years, we used a subgrouping procedure based on individual children's scores on standardized tests of word reading and reading comprehension to determine the prevalence of different reading profiles. The identified subgroups were then compared both concurrently and retrospectively on a range of linguistic, cognitive and social skills data.

Methods:

A total of 53 Swedish speaking school-age children with ASD were followed up using a broad test battery tapping aspects of reading, print knowledge, oral language comprehension, oral language production, nonverbal IQ and severity of autistic presentation. Oral phonological processing was also assessed since this is considered a key correlate of word reading development.

Intake-data at age 2.5y included ADOS, adaptive social and communicative functioning and oral language comprehension and production.

Results:

Approximately half of the sample (n = 25) performed generally poor in reading, meaning that they scored below the normal range on both word reading and reading comprehension tests. In contrast, a sizable minority (n =18) were skilled readers performing above cut off. A final subgroup (n = 10) presented with the hyperlexic profile of normal-to-strong word reading, but poor reading comprehension. The generally poor subgroup was found to score poorly on most assessments, as well as showing a more severe autistic presentation than skilled readers. Group differences between skilled and hyperlexic readers were more selective: whereas the subgroups did not differ on autistic severity, phonological processing, print knowledge or nonverbal IQ, the hyperlexic subgroup scored poorly on tests of oral language comprehension.

When intake data were considered, no differences were seen between the subgroups in social skills or autistic severity. Importantly, however, already at this age it was possible to identify oral language comprehension difficulties in the subgroups that five years latter presented as generally poor or hyperlexic readers.

Conclusions:

The results of this unique population-based study of children with ASD confirm a high degree of heterogeneity in reading skills in ASD. Yet, the patterns appeared to be predictable and align well with established findings in general reading research: that word reading is backed up by phonological skills, whereas reading comprehension builds on a foundation of language comprehension.

37 **108.037** Development of the Critical Communication Skills Assessment

S. Bissell[1] *and J. McCleery*[2]*, (1)University of Birmingham, Birmingham, United Kingdom of Great Britain and Northern Ireland, (2)The Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background:

The first step in the Picture Exchange Communication System (PECS) training program (Bondy & Frost, 1994; Frost & Bondy, 2002) is to assess ability to follow nine critical communication skills according to checklist criteria. The nine critical communication skills are: 1) requesting reinforcers, 2) requesting help, 3) requesting a break, 4) accepting items, 5) rejecting items, 6) responding to wait, 7) responding to directions, 8) following a visual schedule and 9) transitioning between activities. Skills 1-5 relate to expressive communication and skills 6-9 relate to receptive communication.

Objectives:

The aim of this study was to pilot and validate an assessment protocol of the nine critical communication skills for use in intellectual disability (ID) and autism spectrum disorder (ASD) populations.

Methods:

The Critical Communication Skills (CCS) assessment was developed based on a model employed in a school for children with ASD. The refined CCS assessment protocol is composed of 38 items that allow for both spontaneous and prompted demonstration of the nine critical communication skills. Ten of the items are also administered by the parent/caregiver to determine whether communicative ability varies according to social demands. Each item is scored on a 0-2 scale, with 0 indicating a communication error or incorrect response and 2 indicating a correct response. The assessment is administered in a naturalistic environment utilising the child's own toys and activities as reinforcers and preferred items. Excluding time needed to brief the parent/caregiver on administration strategy, the CCS assessment takes approximately 30-40 minutes to administer.

To determine inter-rater reliability and concurrent validity, scores were compared between two raters, and expressive and receptive communication scores obtained on the CCS assessment were compared to expressive and receptive language raw scores on the Vineland Adaptive Behavior Scales (VABS-2; Sparrow, Cicchetti, & Bala, 2005).

Results:

The CCS assessment was piloted with 20 children aged 2-15 years (*M* age = 7.65; *SD* = 4.32), with a confirmed diagnosis of a genetic syndrome. Most children in the study (*n* = 15) were diagnosed with Kleefstra syndrome, a disorder characterised by language delay and ASD symptomatology.

Inter-rater reliability ranged from good to excellent across items (weighted Cohen's κ = 0.63-1.00; *M* = .85), and a strong correlation was found between the CCS and VABS-2 for expressive communication ($r_{s\,=}$ .666, *p* = .001), but not for receptive communication ($r_{s\,=}$ .358, *p* = .060).

Conclusions:

The CCS assessment is a valuable tool to measure critical communication abilities in ID and ASD populations, particularly expressive communication skills. This measure is now being used to examine the relationship between communication abilities, difficult behaviours, ASD symptomatology, age and level of ability in a cohort of young children with tuberous sclerosis complex. However, the CCS assessment also shows promise as a measure of critical expressive communication skills pre- and post- intervention in randomised controlled trials, and its use within both academic and clinical contexts will be discussed.

38 **108.038** Discriminating Autism Spectrum Disorder and Specific Language Impairment on Acuity of Musical Imagery

***P. F. Heaton**, Psychology, Goldsmiths College, University of London, London, United Kingdom*

Background: Deficits in auditory short-term memory have been linked with impairments in music perception in children with Specific Language Impairment (SLI). Autism Spectrum Disorder (ASD), when co-morbid with language impairment (ALI), is also characterized by auditory short-term memory impairments, although music perception has yet to be systematically investigated in this group.

Objectives: The objective of this research is to investigate the relationship between music perception and auditory short-term memory in individuals with ASD and co-morbid language impairments.

Methods: Children and adolescents with SLI (n=14), ALI (n=14) and typically developing (TD) controls (n=14), matched for chronological age (M = 14.06, S.D = 0.97) and musical experience, completed tests of pitch and temporal acuity within Voluntary Musical Imagery and short-term auditory memory, using the digit span test.

Results: Results revealed significantly lower digit span scores in the SLI and ALI groups than in TD controls, although this was only associated with poor performance on the visual musical imagery task for the SLI group. The ALI participants performed as well as TD controls on the tempo conditions of the musical task and better than TD controls on the pitch condition. For both ALI and TD groups, performance on the musical imagery task was positively associated with levels of musical experience.

Conclusions: This research demonstrates that despite language impairments, individuals with ASD show strengths in music perception skills.

39 **108.039** Do Play Contexts Impact Language Production in Preschool Children with Autism Spectrum Disorder?

***A. Binns**[1], D. Casenhiser[2], S. Shanker[3,4] and J. Oram Cardy[5], (1)Western University of Ontario, London, ON, Canada, (2)Audiology & Speech Pathology, University of Tennessee Health Science Center, Knoxville, TN, (3)The MEHRIT Centre, Peteborough, ON, Canada, (4)York University, Toronto, ON, Canada, (5)Western University, London, ON, Canada*

Background: Children's language environments affect their language production during early stages of language development, and beyond. Language contexts also impact language assessment (i.e., language sampling) and influence how clinicians approach intervention. One essential environmental factor to consider for young children is the play context or toys available in the environment. Research on typically developing toddlers revealed symbolic play contexts that involved interaction with blocks and cars promoted more frequent and complex language than play contexts with gross motor toys. However, when the symbolic toys context was altered to include dolls and house toys, children used more labels than in the gross motor context but the frequency and complexity of language was not significantly altered, Additionally, preschool children spoke more frequently and used more diverse language during free-play with a parent than when engaged in a structured task (i.e., puzzle completion). Currently there is little research examining the impact of play contexts on the language production of preschool children with Autism Spectrum Disorder (ASD). Given the social communication deficits and sensory challenges children with ASD often encounter, it is possible that the most beneficial play contexts for yielding a language sample in children with ASD would not be the same as for typically developing children.

Objectives: To explore the impact of three different play contexts (symbolic, tactile, and gross motor) on the communication of preschool children with ASD.

Methods: Forty-nine children with ASD aged 25-57 months were videotaped during natural play interactions with a parent. Five minutes each of play with three sets of toys (symbolic, tactile, gross motor) were used to examine children's communication. Data used in this study were part of a larger RCT, however, only pre-treatment, parent-child play interactions were examined here. Videos were transcribed in CHILDES CHAT format and the main function of each child utterance was coded for language function (Casenhiser et. al, 2015). CLAN analyses of the transcripts extracted the frequency of each function code, total number of utterances, mean length of utterance (MLU), total word types, total word tokens, type-token ration (TTR), and number of verbs/utterance.

Results: There were no significant differences across the three contexts in most aspects of children's language productions, including their use of comments, protesting, questions, verbs/utterance, or diversity of language functions. However, children produced significantly fewer word types ($p<0.5$) and fewer utterances in the tactile play context than the other two contexts ($p<0.001$). In addition, children produced more affirming utterances during symbolic and tactile than gross motor play ($p<0.5$), and more directing utterances during gross motor play than during symbolic or tactile play ($p<0.5$).

Conclusions: Play contexts seem to impact some aspects of language production differently and not others, in preschool children with ASD. Children with ASD appear to use language differently than their typically developing peers across different play contexts, and might benefit from using a variety of play contexts (e.g. symbolic and gross motor) during language assessment or intervention.

40 **108.040** Early Predictors of Later Language Abilities in High-Risk Infant Siblings of Children with Autism

V. Yuk[1,2], *S. E. Bryson*[3], *I. M. Smith*[5] *and J. A. Brian*[6], *(1)The Hospital for Sick Children, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)Dalhousie University, Halifax, NS, Canada, (4)University of Alberta, Edmonton, AB, Canada, (5)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (6)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Younger siblings of children with autism spectrum disorder (ASD) are at increased risk of developing ASD themselves; those who do not have ASD often show related language and communication delays. Impairments in language are often preceded by deficits in nonverbal communication, such as gesture use and pretend play, which suggests that they may be pre-linguistic indicators of later language outcomes. Indeed, both gestures and play have been shown to predict later language in young children with and without ASD, but less work has examined this relationship in high-risk siblings, even though they, like children with ASD, exhibit poorer gestures and play compared to low-risk children.

Objectives: To determine whether gestures and play at 18 months predict language proficiency at 36 months in high-risk siblings with and without ASD, and in low-risk controls.

Methods: Our sample included 105 high-risk siblings diagnosed with ASD at age 36 months, 313 high-risk siblings not diagnosed with ASD (non-ASD), and 164 low-risk controls, drawn from the Canadian Infant Sibling study. At 18 months, gestures and play were assessed using the ADOS-Generic (ADOS-G), Module 1, and at 36 months, language abilities were measured using the Mullen Scales of Early Learning (MSEL). A multi-group structural equation modeling (SEM) approach was used, as it allowed us to capture shared variance between similar variables. Our model involved three latent variables representing our constructs of interest: "gestures", which comprised "Pointing" and "Gestures" from the ADOS-G; "play", which included "Functional Play with Objects" and "Imagination/Creativity" from the ADOS-G; and "later language", which included Receptive and Expressive Language scales of the MSEL. Estimated parameters included the regression of later language on gestures and play, and the correlation between the latter two.

Results: SEM revealed that the relationship between gestures, play, and later language differed between groups. In controls, gestures ($\beta=-0.342$, $p=0.005$), but not play ($\beta=-0.110$, $p=0.305$) predicted later language, and gestures were not correlated with play ($r=0.162$, $p=0.269$). For non-ASD high-risk siblings, gestures ($\beta=-0.486$, $p=0.001$), but not play ($\beta=-0.041$, $p=0.758$), predicted later language, but the two were significantly correlated ($r=0.573$, $p<0.001$). In the ASD group, neither gestures ($\beta=-1.937$, $p=0.151$) nor play ($\beta=1.309$, $p=0.331$) predicted later language, but this apparent lack of significance could be explained by high collinearity ($r=0.952$, $p<0.001$). In fact, when gestures and play are combined into one latent variable, it significantly predicts later language ($\beta=-1.104$, $p<0.001$).

Conclusions: This study provides evidence that gestures significantly predict later language in high-risk siblings not diagnosed with ASD. Play did not predict language outcome in our sample, although other aspects of play not captured here may yield different results. Our findings complement previous work by demonstrating that not only do specific measures of gestures predict later language, but so does the underlying construct representing gesture use. This study emphasizes the importance of attending to early indicators of language, especially gestures, in high-risk siblings, as they may help identify children who could benefit from early language interventions.

41 **108.041** Emotional and Social Development in Vocalizations in Korean-Speaking Toddlers with Autism Spectrum Disorder and Those with Developmental Delay

S. W. Cho[1], ***K. S. Lee***[2] *and H. J. Yoo*[3], *(1)Sogang University, Seoul, Korea, The Republic of, (2)Rehabilitation, Hanshin University, Seoul, Korea, Republic of (South), (3)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, The Republic of*

Background:

Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder that may impair social interaction and communication. Many infants with ASD lack vocalization during the first year of life, and may have impaired communication during future development. Vocal behaviors play a key role in developing language and speech from six to twelve months after birth, infants develop critical vocal behaviors including canonical babbling and variegated babbling as they fully develop nonverbal communication skills using gestures and vocalizations

Objectives:

This study examines the development of socializing and emotional expressions through vocalizations and joint attention behaviors in Koreanspeaking children with Autism Spectrum Disorder (ASD) compared with those with developmental delay (DD).

Methods:

Video samples were collected from 28 toddlers with ASD and 18 age-matched toddlers with DD and vocalizations were each coded in detail for the purpose of this retrospective research. In addition to some statistical analysis, Computerized Language Analysis (CLAN) was done for obtaining the final results.

Results:

Although they produced a higher number of vocalizations than the DD group, the ASD group did not engage in emotional or social interactions with their caretakers as the DD group did. The children with ASD used more atypical vocalizations and socially unengaged vocalizations than the children with DD did. Joint attention using vocalizations in the ASD group, in particular, was largely dyadic, with triadic types occurring at a significantly lower frequency than those in the DD group.

Conclusions:

Results from this study indicate the importance of assessing early vocalizations in toddlers with ASD, suggesting that some common symptoms of ASD, such as lack of typical, emotional and social functions in early vocalizations, could be used to develop screening and intervention programs related to ASD.

42

108.042 Engaging the Play Partner in Pretence: Verbal and Non-Verbal Signalling between Children with ASD and Their Parents

L. Stirling[1]*, S. Douglas*[1]*, C. Dissanayake*[2] *and S. Conte*[1]*, (1)School of Languages & Linguistics, The University of Melbourne, Parkville, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background:

It is well accepted that pretend play is critical for children's development, and also that sophisticated communicative abilities are essential for collaborative pretend play to proceed successfully, as the players must negotiate the transformed meanings that constitute the pretence. This involves each play partner gaining the other's acceptance of the potential intended pretend play elements they wish to include. Research on the degree to which children with ASD are able to engage in shared or negotiated pretence in interactive contexts in the form of collaborative social pretend play is ongoing, but has generally not focused on the conversational interaction which accompanies the play. This project compares social pretend play sessions between adult/child pairs from an ASD and typically developing (TD) group, focusing on verbal and non-verbal communicative strategies used by both adult and child to engage the play partner in the developing pretend scenario.

Objectives:

This study is part of an on-going project which investigates the ways in which high-functioning children with ASD interact and communicate with their play partners during pretend play. We propose that studying engagement in pretence from a discourse analytic perspective may allow us to build more adequate theories around pretence deficits in ASD, and we hypothesise that communicative interactions involved in collaborative pretend play between children with ASD and their play partners will be found to be atypical in the sequential organisation of their verbal and/or non-verbal signalling.

Methods:

Video data from 20 high-functioning children with ASD and 20 TD children, age range approximately 4-8 years old and matched on Verbal Mental Age, had been collected for a previous research project. We used a detailed discourse analytic approach to re-examine a 10-minute free play session from these data. In particular, the sessions were coded for the number of attempts to engage the play partner verbally or non-verbally in the play – "solicitations" – and for whether these attempts were successfully taken up by the partner in order to progress the play.

Results:

Results from a pilot study of 10 children in this corpus show only small differences in the types of signalling produced by the children. However we found that adults in the ASD dyads produced approximately 50% more "solicitations" than adults in the TD dyads and that these were less likely to be taken up by the children. Adults used more non-verbal signalling with ASD children and their attempts to engage ASD children were more likely to succeed when they aligned with the child's plot developments and when they involved non-verbal signalling rather than purely verbal communication. Analysis of the full data set is on-going.

Conclusions:

An earlier study of this data set using behavioural coding of the play had showed no significant differences in symbolic pretend play behaviour between the groups except for small frequency differences in object substitution. However a discourse analytic approach allows us to identify some differences, which have implications for potential intervention. This study illustrates a complex interaction between differences in children's contributions and differences in parental style.

43

108.043 Examining How Varying Levels of Verbal and Visual-Spatial Skills Relate to Emotional and Cognitive Aspects of Music Perception

E. M. Quintin[1]*, S. Sivathasan*[1] *and H. Dahary*[2]*, (1)Educational & Counselling Psychology, McGill University, Montreal, QC, Canada, (2)McGill University, Montreal, QC, Canada*

Background: There is growing evidence that music perception is a strength for people with autism spectrum disorder (ASD; Boso et al., 2009; Heaton, 2008). Music represents a unique domain in which to assess both cognitive and emotional processing, and it has been shown that people with ASD recognize music-evoked emotions (Quintin et al., 2011; Stephenson, Quintin, et al., 2015), as well as show enhanced pitch discrimination (Bonnel et al., 2003, 2010), musical memory (Stanutz et al., 2014), and melodic perception (Heaton, 2003). Previous research has also demonstrated that level of intellectual functioning is related to perception of musical structure (Quintin et al., 2012) and music-evoked emotion (Quintin et al., 2011), however direct comparisons between cognitive and emotional processing of music, including individuals with varying levels of intellectual functioning, have yet to be established.

Objectives: The aim of this research is to assess the impact of variations in intellectual functioning within the autism spectrum on perception of cognitive and emotional aspects of music perception.

Methods: Twenty-three adolescents with ASD ages 12-16 years old with varying levels of cognitive functioning (Wechsler Intelligence Scale for Children [WISC-V]: Verbal Comprehension [VCI] range: 50-111; Visual-Spatial [VSI] range: 61-144) completed two musical emotion recognition tasks in which they identified happy, sad, and fearful emotions in long excerpts (mean duration of 37 seconds) and short excerpts (mean duration of 4 seconds). Participants also completed a musical working memory and rhythm perception task.

Results: Participants were grouped into low and high VCI and VSI groups using median splits of the index scores (VCI = 80; VSI = 95). Overall, across emotion recognition tasks, results showed that performance accuracy (*M* = 92%) was not influenced by participants' level of intellectual functioning (VCI and VSI). However, participants in the low VCI group rated music-evoked excerpts as more intense than those in the high VCI group. Participants in the low VCI group were also slower at identifying emotions in the long excerpts compared to those in the high VCI group, but there were no differences between groups in response time for the short excerpts. Additionally, VCI marginally predicted performance accuracy only on the musical working memory task (*M* = 81%) but not the rhythms perception task (*M* = 64%), which were significantly influenced by participants' level of visual-spatial skills.

Conclusions: Overall, results suggest that adolescents with ASD are able to recognize music-evoked emotions, irrespective of level of intellectual functioning, though their ratings of intensity and response times may be impacted by their level of verbal cognitive skills. Furthermore, individuals with varying levels of verbal comprehension were able to process cognitive aspects of music perception (i.e., musical working memory and rhythm perception), however accuracy was more greatly influenced by visual-spatial skills. Findings lend support toward the use of targeted, strengths-based music interventions adapted to varying cognitive skills within the spectrum.

44 **108.044** Examining Unique Predictors of Language Growth in Infants at High and Low Risk for Autism Spectrum Disorder

C. C. Dick[1], *S. R. Edmunds*[2], *T. DesChamps*[1], *L. V. Ibanez*[3], *E. A. Karp*[1] *and W. L. Stone*[1], *(1)Psychology, University of Washington, Seattle, WA, (2)University of Washington, Seattle, WA, (3)UW READi Lab, Seattle, WA*

Background: Language ability is a powerful predictor of outcome for individuals with ASD (Anderson et al., 2013; Venter et al., 1992), highlighting the importance of understanding how early language emerges. Previous studies exploring predictors of language development in ASD often examined one predictor in isolation, preventing the identification of predictors that contribute most to language outcome. To address this, recent work examined several predictors within a single model, identifying three that uniquely account for language growth in preschool-aged children with ASD: intentional communication (IC), response to joint attention (RJA), and parent verbal responsiveness (PVR; Yoder et al., 2015). The current study evaluates these value-added predictors of language growth in infants at high risk (HR) and low risk (LR) for ASD to capture the developmental period in which language is rapidly developing.
Objectives: (1) To examine expressive language (EL) and receptive language (RL) growth trajectories for HR and LR infants. (2) To examine the unique contribution of predictors (IC, RJA, and PVR) on EL and RL growth trajectories.

Methods: Data were collected at 12, 15 and 18 months as part of a prospective, longitudinal, multi-site study of HR (n=45) and LR (n=32) infant siblings. IC and RJA were measured using the Early Social Communication Scales (Mundy et al., 2003). PVR was coded from videos of parent-child free play (data coding ongoing). EL and RL were measured using the MacArthur-Bates Communicative Development Inventory (MCDI; Fenson et al., 2007). Hierarchical linear modeling was used to examine the contributions of risk group and hypothesized predictors at 12-months on EL and RL growth between 12-18 months.

Results: Preliminary analyses tested growth in EL and RL over time for HR and LR infants with time modeled as infant age. For EL, growth was best modeled by fixed-intercept, random quadratic time, b=1.09, p<.001. There was a significant quadratic time by group interaction, b=-.83, p=.027, suggesting that LR infants' growth in EL accelerated more quickly than that of HR infants. For RL, the best fitting growth model included a random intercept and random linear slope, b=14.49, p<.001. Although RL increased on average across age, LR infants showed consistently higher RL compared to HR infants across time as indicated by a main effect of risk group, b=-29.67, p=.005, and a lack of linear time by group interaction. IC and RJA were not predictive of level or change in EL or RL. Upon completion of PVR video coding, analyses will examine PVR in relation to these trajectories.

Conclusions: Risk group differentially predicted trajectories for both EL and RL. Preliminary analyses indicate that some hypothesized 12-month behavioral predictors (i.e., IC and RJA) did not account for these differences in growth, potentially because joint attention, an important aspect of both constructs, may still be emerging at 12 months (Ibanez et al., 2013; Mundy et al., 2007). Further analyses will examine the contribution of PVR, and whether changes in IC and RJA as they emerge predict language growth.

45 **108.045** Factors Affecting Gestural Development in Children with Autism

H. Ying[1], *M. K. Y. Wong*[2], *W. Y. Lam*[2], *C. H. E. Cheng*[2] *and W. C. So*[3], *(1)The Chinese University of Hong Kong, HONG KONG, China, (2)The Chinese University of Hong Kong, Hong Kong, Hong Kong, (3)Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background:
Gestures are spontaneous hand movements produced during communication. They convey ideas and thoughts. Previous studies have reported a delay in gestural development in children with autism, in comparison to their typically developing peers (e.g., Luyster et al., 2007; So, et al., 2015b).

Objectives:

Little is known about the individual variations in gestural use among children with autism and underlying factors affecting gestural use. Understanding these issues can provide us insights into the spectrum of gestural communication skills, and more importantly, help us to design tailor-made intervention programs for individual children with autism.

Methods:

Twenty-nine Cantonese-speaking children aged 4 to 7 years participated in this study. All of them were diagnosed with ASD or autistic disorder. We assessed their severity of autistic symptoms (by the Social Communication Questionnaire, SCQ) and visual memory skills (by Beery Visual Perception sub-test, VM) since they were found to be correlated to gestural use (So, et al., 2016; So, Wong, & Lam, 2016). Higher scores in SCQ represent more sever communication and social skill symptoms while higher scores in VM represent better visual memory. Gestural communication skills were assessed in the recognition task, followed by the production task. Twenty pantomime gestures (e.g., DRIVE) and markers (e.g., GREETING) commonly used in daily life were tested in the assessments (So et al., 2016). In the gestural recognition task, children were asked to point to the corresponding meaning of these gestures demonstrated by a human model. In the gestural production task, children were asked to produce these gestures, one at a time, when prompted by the human experimenter (e.g., “What is the gesture for eating?”). Gestural production was evaluated by four parameters (use of hands, hand-shapes, placement, direction of movement). Any inaccuracy in one of the parameters would lead to erroneous production of that gesture.

Results:

There were individual variations in gestural recognition and production. Two separate multilevel logistic regression analyses were conducted for gestural recognition and production task performance, with participants and gesture items as the random effects and chronological age and scores of SCQ and VM were the fixed effects in each analysis. We found that SCQ negatively predicted gestural production, and VM positively predicted gestural recognition and production. The effect of age was not statistically significant in both analyses. Results indicated that children with better visual memory recognized and produced gestures better than those with poorer visual memory (Figure 1 right panels), suggesting that visual memory is substantially involved in gestural learning. Those with mild autistic symptoms gestured more accurately than those with more severe symptoms (Figure 1 left panels). This is probably because children with more severe autistic symptoms may not be able to use nonverbal means, including gestures, to communicate with others.

Conclusions:

Our findings suggested that we should take autistic symptoms and visual memory into consideration when designing gestural intervention programs that can cater different needs of children with autism. For example, more training sessions should be provided for those with poorer visual memory and more severe autistic symptoms.

46 **108.046** Gender Differences in Narrative Language in 10-Year-Olds with Autism Spectrum Disorder

O. Conlon[1]*, J. Volden*[1]*, I. M. Smith*[2]*, P. Szatmari*[3]*, P. Mirenda*[4]*, T. Vaillancourt*[5]*, C. Waddell*[6]*, L. Zwaigenbaum*[1]*, S. Georgiades*[7]*, T. Bennett*[8]*, E. Duku*[7]*, M. Elsabbagh*[9] *and W. J. Ungar*[10]*, (1)University of Alberta, Edmonton, AB, Canada, (2)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (3)Centre for Addiction and Mental Health, Toronto, ON, Canada, (4)University of British Columbia, Vancouver, BC, Canada, (5)University of Ottawa, Ottawa, ON, Canada, (6)Simon Fraser University, Vancouver, BC, Canada, (7)McMaster University, Hamilton, ON, Canada, (8)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (9)McGill University, Montreal, PQ, Canada, (10)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada*

Background: Autism spectrum disorder (ASD), characterized by deficits in social communication (SC), is found in 4:1 M:F ratio. This ratio has sparked questions about whether girls present a more subtle symptom profile. Because competence in SC requires synchronous application of social, cognitive and linguistic skill, it is particularly vulnerable to subtle differences in functioning making appropriately sensitive assessment tools imperative. Narrative analysis provides one way to examine SC. Conlon et al. (2015) examined narrative performance of 8-year-old boys and girls with ASD, matched on age, NVIQ (WISC4 Perceptual Reasoning Index, boys M=94.00: girls M=94.08) and language. Girls produced narratives containing more of the salient story elements (Ideas SS) than boys on the Expression Reception and Recall of Narrative Instrument (ERRNI) (Bishop, 2004). Follow-up detailed transcript analysis revealed that girls made fewer pragmatic errors and enhanced their stories (e.g., added emotional terms) more than boys.

Objectives: The current study examines the narratives of the same participants at age 10, to determine if gender differences persist.

Methods: Participants were 12 10-year old boys and 12 girls who had participated in Conlon et al. (2015). The ERRNI was administered. Current NVIQ and core language scores were not available, but Vineland Adaptive Behavior Scales-2, Communication SS were stable from age 8 to age 10 (ANOVA IV: Age, DV: VABS Comm SS, Boys F(1,10) = 0.637, p = 0.451, Girls: F(1,10) = 0.001, p = 0.977), as were ERRNI MLUw scores, a rough index of syntax (ANOVA IV: Age, DV: MLU, Boys: F(1,10) = 0.135, p = 0.725, Girls: F(1,10) = 2.50, p = 0.145). A coder, blinded to gender, analyzed the narrative transcripts for syntactic complexity, story macrostructure, pragmatic difficulties and semantic enhancement (e.g., mental state words) using a system modelled on Norbury, et.al. (2014). Preliminary results from four boys and four girls are presented.

Results: ANOVAs (IV: gender, DVs: ERRNI subscale SS) revealed significant gender differences on the Ideas SS, [F(1,22) =5.32 p=0.03, *d*=0.71], such that girls (M=85.29, SD=13.87) included more salient story elements than boys (M=75.41, SD=12.57). Significant differences were also found on the detailed transcript analysis; girls (M=0.28, SD=0.22) made fewer pragmatic errors (boys M=0.76, SD=0.21; F(1,6) = 9.72, p=0.02, *d*=2.23), semantically enhanced their narratives more (girls M=0.39, SD=0.07; boys M=0.09, SD=0.07; F(1,6) = 35.53, p=0.001, *d*=4.29), and used more complex syntax (girls M=0.33, SD=0.15; boys M=0.08, SD=0.04; F(1,6) = 10.72, p = 0.02, *d*=2.28). Girls also (M=0.33, SD=0.20) made fewer errors in sentence formulation (boys; M=0.73, SD=0.18; F(1,6) = 8.70, p=0.03, *d*=2.10).

Conclusions: ERRNI Ideas scores were significantly better in girls than boys, replicating the findings of Conlon et al (2015). Preliminary findings from detailed analysis on a subset (4 boys, 4 girls) indicate persistent gender differences in pragmatic errors and semantic enhancements, as previously found, and additional difficulties in syntax and sentence formulation in boys. Overall, the ERRNI captures broad but subtle SC differences between boys and girls with ASD. Detailed transcript analysis may help in understanding differences in SC in boys and girls with ASD.

47 **108.047** Indexing Social Focus in the Natural Conversations of Individuals with and without ASD

S. Uh[1]*, L. Bateman*[2]*, E. F. Ferguson*[2]*, M. Cola*[1]*, S. Plate*[1]*, Z. M. Dravis*[1]*, A. Pomykacz*[3]*, K. Bassanello*[1]*, A. Zoltowski*[4]*, J. D. Herrington*[5]*, K. Bartley*[5]*, E. S. Kim*[1]*, A. de Marchena*[6]*, J. Pandey*[1]*, R. T. Schultz*[1] *and J. Parish-Morris*[1]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)The Center for Autism Research/CHOP, Philadelphia, PA, (3)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (4)Vanderbilt University, Nashville, TN, (5)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)University of the Sciences, Philadelphia, PA*

Background: Language is a window into people’s inner worlds. Analyzing words produced during the course of a natural conversation can shed light on a person’s thoughts, feelings, personality traits, and interests (Tausczik & Pennebaker, 2010). In this study, we tested the extent to which social focus is evident in language, by exploring personal pronoun use in individuals with social communication challenges (autism spectrum disorder; ASD) and matched individuals that are typically developing (TD). We hypothesized that individuals with less social focus would use fewer personal pronouns during natural conversation with a naïve confederate, and individuals with more social focus would use more personal pronouns. Our natural conversation task was designed to be an ecologically valid analogue for everyday experiences of meeting new people and establishing relationships; an essential challenge for individuals with ASD and a frequent target for intervention.

Objectives: Use natural language to index social focus: Compare rates of all pronouns, personal pronouns, "I", "you", and "we" produced by individuals with ASD and typically developing control participants. Determine whether linguistic markers of social focus are validated by expert clinical ratings of social communication impairment: Correlate rates of personal pronoun use with autism symptoms in the ASD group.

Methods: Fifty-six participants aged 5-36 with ASD (N=38, 12 female) or typical development (N=18, 12 female) engaged in a ~5 minute unstructured "get to know you" conversation with one of 13 randomly assigned undergraduate confederates (10 female). Participants in the ASD and TD groups did not differ significantly on age (mean=14y) or IQ (106, all IQs>75), but did differ on sex ratio (*p*=.02). This limitation (uneven sex ratios by group) will be addressed before May, 2018 through increased sample sizes. Linear mixed effects regression models included diagnosis as a fixed effect and confederate ID as a random effect to account for individual differences among confederates.

Results: The ASD and TD groups did not differ on overall pronoun use (including words like "it" and "that"), but the ASD group produced significantly lower rates of personal pronouns than the TD group (*t*=2.29, *p*=.03, Fig.1). The ASD group produced less "we" than the TD group (*t*=2.11, *p*=.04), but groups did not differ significantly on rates of "I" or "you". In participants with ASD and ADOS evaluations (N=37), personal pronoun use correlated significantly with ADOS social affect calibrated severity scores (*r*=-.36, *p*=.03, Fig.2), but not with repetitive behaviors/restricted interests subscores (*r*=-.15, *p*=.38).

Conclusions: We found that short, naturalistic conversations with a naïve interlocutor provide an index of social focus that correlates with expert clinical ratings of social impairment. Specifically, we found that personal pronoun use is diminished in individuals with ASD relative to typical controls, and individuals with more autism symptoms produce fewer personal pronouns than individuals with fewer autism symptoms. This result holds promise as a potential metric for tracking social intervention effectiveness, via natural conversations that reveal the extent of an individual's social focus from week-to-week or even day-to-day.

48 **108.048** Integrative Nonverbal Communication in Children with ASD during Conversation and Free PLAY

***S. Tal**, I. Gordon, S. Fridenson-Hayo and O. Golan, Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel*

Background:

Nonverbal communication (NVC) has long been recognized as a core deficit in Autism Spectrum Disorder (ASD). NVC is multi-channel by nature, and conveys meaning via a finely-tuned, integrative presentation of facial expressions, gaze, vocal expressions, and gestures. NVC is context-bound by nature, and influenced by the social situation in terms of activity type and identity of the interaction partner. Integrative NVC deficit is currently a mandatory diagnostic criterion for ASD in the DSM-5. However, integrative NVC has rarely been empirically studied, and existing studies have not evaluated more than two NVC channel combinations. In addition, most studies focused on infants and toddlers, with little attention given to NVC in school-aged children.

Objectives:

To compare integrative NVC in children with ASD to that of Typically Developing (TD) school-aged children, during two contexts: positive conversation and joint free play. It was predicted that, compared to children with TD, children with ASD will exhibit reduced integrative NVC abilities, and would rely more on intense single channel NVC expressions.

Methods:

Thirty-nine children (1 girl) with ASD (clinically diagnosed, and verified using ADOS2), aged 5-10 years, with no intellectual impairment, and 31 typically developing (TD) controls (1 girl), matched on gender and cognitive abilities, were video-recorded with their mothers during a free-play, and during a conversation. Videos were micro-coded for display of single channel NVC behaviors: facial expressions (low vs. high intensity expressions), vocal expressions (low vs. high intensity expressions), gesturing (gesture production vs. no production) and gaze (directed to/away from mother's face). Integrative NVC variables were computed, and represented co-occurring NVC single channel behaviors. Parental reports regarding children's autism symptomatology were collected with the SRS-2.

Results:

During conversation, compared to their TD peers, children with ASD showed reduced integrative use of NVC, and intensified vocal and facial expressions. Reduced NVC on a single channel during conversation was only found for gesturing. Gesturing during conversation was also negatively correlated with SRS-2 social-communication scores, over and above group.

During joint free-play, compared to their TD peers, children with ASD showed more intensified vocal expressions and directed more gaze to their mothers' faces. These single channel group differences were found only when integrative NVC was examined, which suggests that children with ASD also exhibit integrative NVC deficits within a joint free play interaction with their mothers.

Conclusions:

The findings provide evidence for an integrative NVC deficit among children with ASD. In our elementary school-aged sample, Integrative NVC was found to be more indicative of NVC deficits of children with ASD, than single-channel NVC behaviors. Contextual differences were interpreted in terms of compensatory attempts during conversation (resulting in intensified facial and vocal expressions), and developmental delay during free-play (demonstrated through extensive gaze to mother's face) of children with ASD. These findings validate the NVC deficits of individuals with ASD, which have mostly been described clinically. Findings highlight the importance of NVC integration, and the role of various contexts when diagnosing children with ASD, and when designing appropriate interventions.

49 **108.049** Investigating Pragmatic Communication Abilities in Minimally Verbal Children and Adolescents with Autism Spectrum Disorder

***C. G. La Valle**[1], D. Plesa-Skwerer[2] and H. Tager-Flusberg[2], (1)Department of Psychological and Brain Sciences, Boston University, Boston, MA, (2)Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Individuals with ASD demonstrate difficulties with pragmatic communication or an incongruence between situational demands and the communication employed (Tager-Flusberg et al., 2005; Volden et al., 2009). The pragmatic communication abilities of minimally verbal (MV) individuals with ASD and how these abilities change with age, has not been studied in-depth, although these individuals comprise 30% of the ASD population (Tager-Flusberg & Kasari, 2013). This research is relevant for assisting in the design of developmentally appropriate interventions to improve social communication in MV individuals with ASD.

Objectives: To compare the pragmatic communication abilities of MV children and adolescents with ASD.

Methods: Thirteen MV children with ASD (MV-C; 10 males; age range:6-11 years) and 13 MV adolescents with ASD (MV-A; 12 males; age range:12-18 years) were administered the ADOS (*n*=24 Module 1; *n*=2 Module 2). Transcripts of the ADOS sessions were coded for pragmatic functions building on a coding scheme developed by Tager-Flusberg & Anderson, 1991. Intelligible utterances were coded for contingency and function and adjusted for session length. Contingency was assessed in terms of adjacency (follows or doesn't follow prior adult utterance) and topic relevancy (contextually appropriate or inappropriate) and the utterances were coded for function. Function was assessed in terms of requests, agreement, disagreement, "yes" and "no" responses, scripted recitation (e.g., repeating fragments from various media) and perseverative speech (repetition of a word/phrase when inappropriate). Structural language was assessed in terms of rate/minute of intelligible utterances, different words used, and mean length of utterance in words (MLUw).

Results: MV-C had a lower rate of adjacent ($t(24)=2.537$, $p<.05$) and contingent utterances ($t(24)=2.669$, $p<.05$) compared to MV-A, but the groups didn't differ in nonadjacent utterances ($p>.05$), indicating that MV-A are responding in a more "topically related" way that builds upon the previous utterance elicited by the adult, compared to MV-C. When assessing function, MV-C had fewer requests ($t(24)=2.677$, $p<.05$), responses indicating agreement ($t(24)=2.649$, $p<.05$), disagreement ($t(24)=2.633$, $p<.05$), and "yes" and "no" responses ($t(24)=3.066$, $p<.05$) compared to MV-A, but they did not differ in scripted recitation or perseverative speech (*ps* >.05), suggesting that MV-A are utilizing a wider range of responses to maintain engagement with the examiner compared to MV-C. When assessing structural language, MV-C had fewer intelligible utterances ($t(24)=2.876$, $p<.05$) compared to MV-A; however the groups didn't differ in their rate/minute of different words used or MLUw (*ps* >.05; see Figure 1). Although, the groups didn't differ in the use of structural language, significant differences emerged when evaluating pragmatic communication.

Conclusions: Findings highlight developmental differences between MV-C and MV-A in their ability to engage in social exchanges, including conversations, as suggested by increasing contingency and a wider range of pragmatic functions demonstrated during the interactive ADOS sessions. Findings underscore the potential for improvement in pragmatic communication even among MV individuals with ASD, which should be a primary focus of language intervention. Clinical implications of the study findings suggest the utilization of speech and language therapy to support communicative development.

108.050 Is Cross-Situational Word Learning Impaired in Children with Autism Spectrum Disorder?

C. Hartley[1]*, L. A. Bird*[2] *and P. Monaghan*[1]*, (1)Lancaster University, Lancaster, United Kingdom, (2)Lancaster University, Lancaster, United Kingdom of Great Britain and Northern Ireland*

Background:

Word learning is of crucial importance to language acquisition. The challenge of mapping sound-to-meaning is often characterised by referential ambiguity; there might be multiple potential referents for a newly-heard word. In the absence of ostensive cues, typically developing (TD) children can infer the meanings of new words from cross-situational statistics alone. By contrast, many children with autism spectrum disorder (ASD) experience impaired language acquisition and word learning. Here we explore whether children with delayed linguistic development have specific difficulty tracking word-referent co-occurrences.

Objectives:

The objective of this study was to examine the ability of children with ASD (and concomitant language delay) to identify, retain, and generalise the meanings of unfamiliar words from cross-situational statistics.

Methods:

Participants were 15 children with ASD (*M* age: 8.78 years) and 20 TD children (*M* age: 6 years) with similar receptive vocabulary age equivalents (ASD *M*: 5.7 years; TD *M*: 6.5 years). Populations differed on non-verbal IQ (TD *M*: 101.7; ASD *M*: 83.73; $t = 3.99$, $p < .001$). Using a touch-screen tablet, participants were presented with pairs of unfamiliar objects and were instructed to identify the referent of a novel word. These exposures were intentionally ambiguous (i.e. there was no cue to which object was the correct referent), but cross-trial statistics enabled children to disambiguate correct word-object pairings. Participants learned six new word-object relationships over 48 trials, divided into two blocks. After a 5-miute delay, children completed 24 test trials assessing label retention and generalisation to differently-coloured exemplars.

Results:

Performance on learning and test trials was analysed via generalised linear mixed effects models. Learning was significantly more accurate in Block 2 (ASD: 71.7%; TD: 74%) than Block 1 (ASD: 64.4%; TD: 68.5%; $Z=2.93$, $p=.003$), and populations did not differ. Both populations demonstrated similar accuracy on retention (ASD: 64.4%; TD: 65%) and generalisation test trials (ASD: 64.5%; TD: 67.5%) that significantly exceeded chance (all *ps* < .001). For children with ASD, both learning and test trial accuracy were predicted by receptive vocabulary ($Z = 3.78$-4.5, $p < .001$) and chronological age ($Z = 3.09$-3.4, $p = .002$-$.001$). For TD children, both learning and test trial accuracy were predicted by non-verbal IQ ($Z = 2.01$-3.12, $p = .04$-$.002$) and chronological age ($Z = 2.32$-2.35, $p = .02$).

Conclusions:

In comparison to TD controls matched on receptive vocabulary, the accuracy of cross-situational word learning in linguistically-delayed children with ASD is unimpaired. Both groups were able to identify, retain, and generalise novel word meanings from statistical associations alone. Thus, delayed language development in ASD may not be attributable to specific difficulties tracking word-referent co-occurrences. However, ASD may impact the mechanisms that scaffold this ability. Performance was predicted by receptive vocabulary in children with ASD and non-verbal IQ in TD children, suggesting that cross-situational word learning may be influenced by language-specific mechanisms in the former population and domain-general mechanisms in the latter. We recommend that follow-up analyses examine potential differences in reaction times and explore whether test trial accuracy can be enhanced by attentional cues during learning.

51

108.051 Is Repetitive Speech a Marker of Development or Impairment?: Correlates of Unconventional Language Use

M. Maeda[1]*, C. Lord*[2] *and R. J. Luyster*[1]*, (1)Communication Sciences and Disorders, Emerson College, Boston, MA, (2)University of California Los Angeles, Los Angeles, CA*

Background: Children with ASD often use unconventional language, including echolalia, neologisms, idiosyncratic phrasing, and pedantic/formal speech. However, there is a tension in clinical realms: is unconventional language best characterized as functional language or as problematic, repetitive behavior? Speech-language therapy generally emphasizes the communicative value of unconventional language, treating it as a developmental achievement (Charlop, 1983; Tarplee and Barrow, 1999). In contrast, behavioral approaches tend to focus on reducing unconventional language, interpreting it as a problem behavior (Lanovaz & Sladeczek, 2012; Neely, Gerow, Rispoli, Lang, & Pullen, 2016). Despite this marked divide, there is a relative dearth of empirical evidence associating unconventional language with language, cognitive, adaptive, or behavioral characteristics.

Objectives: The objective was to address whether unconventional language is associated with higher or lower scores across measures of language, cognition, adaptive functioning and repetitive behaviors.

Methods: Children were selected from a larger sample (Anderson, Liang, & Lord, 2014; Lord et al., 2006). Sixteen children with high levels of unconventional language at ages 2 and/or 3 (based on the Autism Diagnostic Observation Schedule, ADOS) were identified. Each child was individually matched on gender/nonverbal ratio IQ to a child with no evidence of unconventional language on the ADOS. This resulted in an overall sample of 32 children: 16 with high levels of unconventional language (HiUL), and 16 with low levels of unconventional language (LoUL).

Results: The HiUL group had higher ratio verbal IQ than the LoUL group, $t(30)=4.13$, $p<.001$. Similarly, HiUL had higher standard scores for the Vineland Communication [$t(30)=4.05$, $p<.001$)] and Socialization domains [$t(30)=2.49$, $p<.05$], though no group differences were noted in Vineland Daily Living Skills or Adaptive Behavior Composite. On the ADOS, HiUL had *lower* social affect algorithm scores – indicating lesser impairment – than LoUL [$t(30)=2.42$, $p<.05$]. There was no significant difference in the restricted and repetitive behavior algorithm scores. On the Repetitive Behavior Scale-Revised (RBS-R), the HiUL group had a *lower* mean score (M=21.80, SD=15.89) than the LoUL group (M=11.67, SD=8.74), though the difference was not significant.

However, we note a potential bias in the ADOS, whereby children could be scored as having low levels of unconventional language because of minimal expressive language overall. Therefore, a second round of matches was generated (HiUL: n=6; LoUL: n=6), including only children who showed established single word speech on the ADOS. Table 1 indicates a consistent pattern of results: HiUL showed higher average skills. Mann Whitney tests were significant ($p<.05$) for the Vineland Communication and Socialization domain scores and Adaptive Behavior Composite.

Conclusions: These findings indicates that -- compared to LoUL peers -- children with high levels of unconventional language in their toddler/preschool years have higher communication skills and lower levels of social impairment. This has important clinical implications: these preliminary findings support the position that unconventional language is associated with developmental progress and should not be discouraged in therapeutic settings. Additional analyses will address associations between early unconventional language and adolescent outcomes.

52 **108.052** Is the Sky Blue?: Question Asking in Children with ASD

A. Netburn[1], J. Georgeson[1], S. Arunachalam[2] and ***R. J. Luyster**[1]*, *(1)Communication Sciences and Disorders, Emerson College, Boston, MA, (2)Boston University, Boston, MA*

Background: As they grow, children use language in a number of different ways. A substantial amount of research in typically developing children delineates the importance of *question-asking* for linguistic, cognitive and social development. In autism spectrum disorder (ASD), language development is often impaired or delayed. Although there are a few intervention studies detailing procedures to teach, or train children with autism to correctly use questions, there is a dearth of research exploring everyday question-asking in children with autism. Better understanding naturalistic question-asking in children with ASD would provide clues about opportunities for everyday learning across language, cognitive and social domains.

Objectives: The aim of this research is to investigate the frequency, content, and development of question-asking in young children with ASD.

Methods: This study contains preliminary data from a two-part online survey. Part I included demographics and questions about daily activities. Participants were then instructed to spend time observing their child's language. Approximately one day later, they were sent an email with a link to Part II, which focused on question-asking. Recruitment is ongoing, but to date, reports have been collected from caregivers with children under 6 years of age; 55 caregivers had a child with ASD (8 female), and 22 had a child with typical development (TD, 5 female). Children were categorized by their caregivers according to expressive language level, including (a) those who spoke at the single word level (9 ASD; 4 TD), (b) those who spoke in 2-3 word phrases (28 ASD; 11 TD), and (c) those who spoke in sentences of 4 or more words (18 ASD; 7 TD).

Results: Comparisons across diagnostic groups were conducted according to caregiver-reported language level. Because of the small cell sizes for the TD sample, non-parametric tests were used. Preliminary analyses suggest that the proportion of utterances that are questions did not differ across diagnostic groups (within expressive language levels; see Figure 1a). However, for children using phrase-level speech, the children with ASD used significantly fewer questions per day than the TD ($p=.001$; see Figure 1b and c), and a similar pattern was observed for the children using sentence level speech (though it was not significant, $p=.05$; see Figure 1b and e).

Qualitative review of the data suggests some other important points. First: many more children with ASD (even those who are speaking in phrases or sentences) are reported by their caregivers to ask fewer than 10 questions per day (see Figure 1c and e). Moreover, caregivers of children with ASD report less frequent usage of *what, where, when, why* and *how* questions than caregivers of TD children, whereas groups are remarkably similar in their rates of *yes/no* questions (see Figure 1d and f).

Conclusions: These results suggest that typically developing children and children with ASD approach the developmental process of question-asking considerably differently. By asking fewer questions overall and by favoring dichotomous *yes/no* forms over more open-ended *what, where, when, why* and *how* questions, children with ASD may create fewer and less rich opportunities to learn from their world.

53 **108.053** Joint Attention Skills Concurrently Predict Receptive Vocabulary in Minimally and Low Verbal Youth with ASD

***M. G. Pecukonis**, D. Plesa-Skwerer and H. Tager-Flusberg, Psychological and Brain Sciences, Boston University, Boston, MA*

Background: While 30% of individuals with ASD are classified as minimally or low verbal, little is known about the correlates of language ability in this population (Tager-Flusberg & Kasari, 2013). It has been argued that joint attention (JA) skills, which are often impaired in ASD (Mundy, Sigman,

Ungerer, & Sherman, 1986), are a precursor to language development (Tager-Flusberg, Paul, & Lord, 2005). However, several studies that have found a relation between language and JA skills in ASD have not differentiated between responding and initiating JA (e.g., Bean & Egisti, 2012). Furthermore, many of these studies have been conducted with young and/or verbally fluent samples (e.g., Dawson et al., 2004). Thus, there is a need to explore the relation between specific types of JA skills and language in older, minimally and low verbal youth with ASD.
Objectives: To investigate the relation between joint attention (JA) skills and concurrent receptive vocabulary in minimally and low verbal youth with ASD.

Methods: 59 minimally and low verbal youth with ASD (41M, 18F), ages 5.33 to 20.92 years, participated in this study (Table 1). Raw scores from the Initiating Joint Attention (IJA), Responding Joint Attention (RJA), Pointing, and Showing items of the Autism Diagnostic Observation Schedule-2 (ADOS-2; Lord et al., 2012) or the Adapted ADOS (A-ADOS; Hus & Lord, in preparation) were collected. Youth also completed the Peabody Picture Vocabulary Test-4 (PPVT-4; Dunn & Dunn, 2007), a standardized measure of receptive vocabulary. Non-verbal IQ (NVIQ) was measured using the Leiter International Performance Scale-3 (Roid, Miller, Pomplun, & Koch, 2013).

Results: Age was not significantly correlated with JA or PPVT-4 scores (*p*s > .1). NVIQ however was significantly correlated with RJA and PPVT-4 scores (r_s=-.273, *p*=.037; r_s=.364, *p*=.005, respectively). When controlling for age, NVIQ, and gender, RJA, Pointing, and Showing scores were significantly correlated with PPVT-4 scores (r_s=-.278, *p*=.038; r_s=-.315, *p*=.018; r_s=-.337, *p*=.01, respectively), while IJA scores were not significantly correlated with PPVT-4 scores (r_s=-.212, *p*=.116) (Figure 1).

Conclusions: The findings demonstrate that better RJA, Pointing, and Showing, but not IJA, skills are related to higher receptive vocabulary in minimally and low verbal youth with ASD. The results may be explained by the scoring guidelines for these ADOS items. The RJA item includes response to both gaze and gesture (i.e. pointing and showing), while the IJA item includes initiation of gaze only. Importantly, the Pointing and Showing items include initiation of these gestures. Therefore, deficits in JA skills, particularly the response to and initiation of explicit pointing and showing gestures, may explain why some youth with ASD fail to acquire receptive language. Gaze may have less of an influence on acquisition of receptive language in these older youth with ASD. Future studies should examine the relation between language and objective measures of gesture versus gaze skill. The findings also highlight the importance of targeting non-verbal communication skills, particularly explicit gesture behaviors, in interventions to improve language outcomes throughout development.

54 **108.054** Language Discrepancy and Aggressive Behaviors in Individuals with Autism Spectrum Disorder

H. V. Medeiros[1], *E. Hanson*[2] *and P. Hickey*[1,3], *(1)Developmental Medicine, Boston Children's Hospital, Boston, MA, (2)Boston Children's Hospital/Harvard Medical School, Boston, MA, (3)Psychology, Tufts University, Boston, MA*

Background: Individuals with Autism Spectrum Disorder often display deficits in language, with receptive skills frequently more developed than expressive **(**Tager-Flusberg & Kjelgaard, 2001). Aggression is also prevalent, with 1 in 4 individuals exhibiting these behaviors (Hill et al., 2014). Previous studies identified a relationship between language and aggression (Estrem, 2010) but have not examined the impact of a discrepancy in receptive and expressive skills on aggression.
Objectives: The current study used language and aggression scores to see if data replicated previous studies. This study first assessed for discrepancy between receptive and expressive language ability, and then assessed the correlation between the amount of discrepancy, direction of discrepancy, and possible relation to physical aggression levels.

Methods: Data on individuals with ASD (n = 713) aged 1.9 to 22.7 years was used from the Simons Simplex Collection and the Boston Autism Consortium. Diagnosis was verified using The Autism Diagnostic Observation Schedule and Autism Diagnostic Interview-Revised (ADI-R). The Vineland Adaptive Behavior Scales were used to measure receptive and expressive language skills. Aggression was measured by ADI-R items 81, 82, and 83: “aggression towards caregivers/family” and “towards non-caregivers/non-family” and “self-injurious behavior” on a 0-3 scale (0=not present). The ADI-R was used to evaluate participant’s age of onset of aggressive symptoms and the current presence or absence of aggression. We calculated a mean value for behaviors by averaging the current aggression scores (CAS).

Results: Results suggest that a majority of our cohort (65%) exhibited language delay and (70%) aggressive behaviors. 84% of the sample had discrepancies between their receptive and expressive language skills, with 8.5% being a statistically significant discrepancy and 6.5 % having significantly higher receptive language (HRL). There was a significant relationship between CAS and HRL (p=.011), with larger discrepancy related to higher (more severe) aggression. There was also a significant relationship between HRL and aggression towards caregivers/family (p=.034) as well as aggression towards self (p=.036). Results were not significant for non-caregiver/non-family members (p=.259).

Conclusions: Preliminary results suggest a significant relationship between HRL and CAS within the family, as well as for self-injurious behavior, whereas there was not a significant relationship between HRL and CAS for non-family members. The current study highlights the importance of examining receptive and expressive skills as separate variables within the context of current aggressive behaviors. Future directions include analyzing the sample of children who displayed higher expressive than receptive language skills within the context of aggression (2% displayed statistically significant higher expressive language skills).

55 **108.055** Linguistic Markers in the Narratives of Children on the Autism Spectrum

K. F. Schroeder[1,2], *M. García*[1,2], *J. Rosselló Ximenes*[1,2] *and W. Hinzen*[2,3], *(1)General Linguistics, University of Barcelona, Barcelona, Spain, (2)Grammar and Cognition Lab, Barcelona, Spain, (3)Catalan Institute for Advanced Studies and Research (ICREA), Barcelona, Spain*

Background: Narratives are ecological means to elicit speech in clinical populations- both to assess formal aspects of language as well as how language construes a shared reality of agents and events. While narrative skills are assessed in diagnostic measures such as the Autism Diagnostic Observational Schedule (ADOS), the language which builds these narratives rarely receives analysis. Previous literature on narratives in autism spectrum conditions (ASC) have shown that referential anomalies distinguish children with ASC from clinical groups like ADHD or typically-developing peers [1, 2] and may relate to ASC symptom severity [3]. However, this previous work has not looked at reference fully systematically.
Objectives: In the present study, we catalogue referential constructions and errors though a linguistic lens and explore the relation between qualitative deficits in narratives and specific grammatical profiles.
Methods: Fifteen children with high-functioning ASC (mean age: 8.6, range: 7-12 years) and fifteen typically-developing controls who were

individually matched on verbal-IQ and chronological age participated in the storybook narration task of the ADOS. Narratives were transcribed and annotated for various grammatical constructions across nominal, verbal, and clausal domains. Narratives were further rated for story completeness and errors were catalogued.

Results: Our results showed that our ASC population didn't differ from controls on errors (all $p \geq .325$). However, we found significant differences in the way in which the narratives were built- primarily with regard to a reduction of anaphoric devices ($p = .003$) and relative clauses ($p = .011$) in the ASC group. The proportional reduction of anaphora correlated to lower overall story completeness and quality across groups (r=.514; p =.004).

Conclusions: These results show that even at the high-functioning end of the spectrum and controlling for verbal IQ, linguistic markers based on fine-grained grammatical measures can detect ASC against typically developing controls.

56 **108.056** Listening in Your Shoes: Can Children with Autism Take the Perspective of Others When Interpreting Language?

K. Abbot-Smith[1], *D. M. Williams*[2] *and D. Matthews*[3], *(1)University of Kent, Canterbury, United Kingdom of Great Britain and Northern Ireland, (2)University of Kent, Canterbury, United Kingdom, (3)School of Psychology, University of Sheffield, Sheffield, United Kingdom*

Background: Individuals with Autism Spectrum Disorder (ASD) frequently fail to interpret the intent of a speaker's utterance, apparently because they have difficulty determining the crucial aspects of common ground, which they share with the speaker. Only two studies (both with adults with ASD) have previously investigated this experimentally (Begeer et al., 2010; Sanstieban et al., 2015). Both manipulated level one visual common ground (whether the speaker can see a particular object). Both found that the participants with ASD were unimpaired relative to typical controls. However, visual perspective-taking may not align in development with social perspective-taking, which is understanding the interlocutor-specific experiences shared with the conversation partner.

Objectives: To determine whether social versus visual perspective-taking have differential effects on the ability of children with ASD to interpret requests.

Methods: We compared 24 eight- to eleven-year-olds with ASD with 23 typically-developing eight- to eleven-year-olds. Groups were matched on non-verbal IQ, receptive language, chronological age and gender. Children interpreted requests (e.g. 'Can I have that ball?') in contexts which would be ambiguous (i.e. because the child can see two balls) if perspective-taking was not utilized. There were three within-subjects conditions: Social perspective-taking, Level 1 Visual Perspective-taking (VPL1) and Level 2 Visual Perspective-taking. There were three trials per condition. For each the requester wore dark sunglasses and did not point. In the VPL1 condition one of the two objects was hidden from the viewpoint of the requester (E1). The correct choice was the object that the requester could see. In the Social Condition, the child was told that E2 had bought toys that E1 had not yet seen. E2 passed one of these (e.g. a pink ball) over to E1, who played with / discussed this with the child. Then E1 left the room and E2 showed the child another object of the same type (e.g. a yellow ball) and played with /discussed this with the child. When E1 returned to the room, both the child and E1 could see two balls as E1 excitedly verbalized the request. The correct choice was the object that was new for E1 (here: yellow ball).

Results: Overall the group with ASD performed significantly worse than the typically-developing control ($p = .032$, $\eta_p^2 = .073$). Their performance was not found to relate to affect recognition. There was also a main effect for condition ($p = .033$, $\eta_p^2 = .097$). Children with ASD found the Social Condition significantly harder than the VPL1 Condition (p <.01). Nonetheless, Social and VPL1 conditions were strongly inter-correlated for children with ASD ($r = .73$, $p < .001$), even when non-verbal IQ, receptive language and age were partialled out ($r = .73$, $p < .001$).

Conclusions: Children with ASD find it more difficult to use social than to use VPL1 to interpret language. VPL1 may be a more basic form of social perspective-taking (Harris, 1992) since the two are related. A large proportion of intellectually high-functioning children with ASD may have difficulty interpreting language if instructions or discourse require social perspective-taking

57 **108.057** Property Extension in ASD: Categorically but Not Perceptually Restricted

V. Tecoulesco *and L. R. Naigles, Psychological Sciences, University of Connecticut, Storrs, CT*

Background: Difficulties with how words are represented, organized, and accessed have been observed in individuals with Autism Spectrum Disorder (ASD). Category formation and generalization abilities are also often atypical in ASD, with school age children and adolescents frequently performing inconsistently on categorical induction tasks. For example, they often restrict properties assigned to specific instances of a named category, to the taught instance itself rather than extending to new instances of that named category (Kelley et al., 2006). What is still unclear is whether their category restrictions apply to all new instances vs. just instances that differ visually/perceptually from what was taught.

Objectives: The current study compares TD children and children with ASD during their early school years on their extension of stated properties to new instances when these instances were (a) identical except for the pose, (b) from the same category but different perceptually, and (c) perceptually similar but from a different category.

Methods: Typically developing (TD) children (N=29, MA =5.55 years (0.33), 5 girls) and children with ASD (N=16, MA= 6.35 years (0.59), 2 girls) participated. The children's Test for Auditory Comprehension of Language (TACL-3) vocabulary raw scores were similar (M(TD)=36.66(4.78), M(ASD)=32.31(5.47) although the TD group was more advanced (t(43)=2.81,p = 0.008). Pictures of eight natural kinds, both animate and inanimate, were presented. Children were asked to predict whether a known property of one member of a named category would be applicable to another member of the same category. For example: "This white rabbit eats grass. Does this brown rabbit/white squirrel/white-rabbit-in-different-pose/cat also eat grass?" The four test pictures included a target (same natural kind but different color or form), perceptually similar but not the same category, same natural kind with slight modifications in pose, and a distractor.

Results: Most TD children and children with ASD successfully extended the attribute to the slightly modified item of the same natural kind at above chance levels (TD=93%; ASD=88%); however, the TD group performed more consistently than the ASD group (M(TD)=7.24(1.15); M(ASD)=5.88(1.59); t(43)=3.32, p=0.002). With the critical target item, the TD group endorsed the category extension significantly more often than the ASD group: M(TD)=4.72(1.51), M(ASD)=3.56(1.86) (t(43) =2.27 p=0.028). Many in the TD group performed above chance unlike most in the ASD group (TD=59%, ASD=25%). These group differences held when TACL vocabulary scores were entered as a covariate (Fs >4.76, ps<0.035). Finally, for the physically similar but not of the same natural kind stimuli, there were no observed differences between the groups t(43)=-1.773, p=0.09, who both endorsed the physical similarity foil at levels significantly below chance.

Conclusions: Both the TD and ASD groups successfully extended the property to instances that only varied in pose from the taught instance; hence, property extension is not completely restricted in children with ASD. However, when property extension involved perceptual differences within a named category, the children with ASD performed at chance, unlike the TD children. Thus, extension on the basis of categories seems to be a major challenge for children with ASD.

58 **108.058** Relating Neural Response Consistency to Complex Speech Sounds and Concurrent Language Ability in School Age Children

V. Tecoulesco[1]*, K. Stevens*[2]*, D. A. Fein*[1]*, E. Skoe*[3] *and L. R. Naigles*[1]*, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)University of Connecticut, Storrs, CT, (3)Speech Language Hearing Sciences, University of Connecticut, Storrs, CT*

Background: Investigations into the neurological basis of atypical language development in autism spectrum disorders (ASD) have largely focused on cortical indices. Atypical language-relevant neural networks, however, may also arise from unreliable sensory representations. Auditory brainstem responses (ABR), auditory evoked potentials that reflect neural activity in the auditory nerve and brainstem, have been linked to reading ability in the general population and in dyslexia (Banai et al.,2009). In addition, abnormal neural conduction time, as revealed by prolonged ABR latencies, has been found in the ASD central auditory system. ABR responses recorded in childhood have recently been linked to more advanced language development displayed several years earlier, in late toddlerhood.
Objectives: The purpose of the current study is to investigate the extent to which instabilities in early stages of central auditory processing can account for differences in language development in ASD by examining the relationship between neural response consistency to complex speech sounds and current language ability.

Methods: Typically developing (TD) children (N=8, MA=11.25 years (1.9), 2 girls) and children with ASD (N=8, MA=12.5 years (3.59), 1 girl) participated. All testing was performed in the children's homes using a portable EEG system, including a screening for normal hearing thresholds, and ABR recordings to a "da" stimulus (10.9/sec, 6000 trials) presented at 80 dB SPL. Consistency was determined by correlating the first 3000 responses with the last 3000 responses. Current language ability was measured using four subtests of the Clinical Evaluation of Language Fundamentals 5 (CELF-5); Word Classes, Formulated Sentences, Repeated Sentences, and Following Directions. Nonverbal cognition was measured using the Differential Ability Scales (DAS).

Results: No significant group differences were found for ABR consistency. The TD group scored significantly higher than the ASD group on all four CELF 5 subtest standard scores (*Fs* > 12.67, *ps* < .003) raw scores (*Fs* > 5.23, *ps* < 0.038) and age equivalents (Fs > 5.79, ps < 0.03). These group differences held (ps < 0.006, ps < 0.04, ps < 0.049) when digit span from the DAS was entered as a covariate. Significant correlations were found for ABR response consistency and three CELF-5 subtest standard scores (Word Classes, Formulated Sentences, and Repeated Sentences), for the ASD group only (*rs* > 0.797, *ps* < 0.018). Formulated Sentences raw scores and age equivalents also correlated significantly with ABR responses (*rs* > 0.757, *ps* < 0.03).

Conclusions:

In children with ASD, /da/ ABR consistency has a significant relationship to concurrent language, such that greater neural fidelity in representing auditory input is associated with more advanced language abilities. Both knowledge of how words relate to each other as well as the ability to remember and formulate grammatically correct sentences are positively correlated with how consistently sensory input was being processed early in the auditory pathway, suggesting that some origins of language delays and impairments in ASD may lie in inconsistent auditory processing. The absence of similar relationships in the TD group could be an artifact of the limited variability of both language measures and ABR responses in this group.

59 **108.059** Linking Auditory Processing and Lexical Representation Via Phonological Discrimination

V. Tecoulesco[1]*, E. Skoe*[2] *and L. R. Naigles*[1]*, (1)Psychological Sciences, University of Connecticut, Storrs, CT, (2)Speech Language Hearing Sciences, University of Connecticut, Storrs, CT*

Background: Auditory Brainstem Responses (ABRs) are auditory evoked potentials recorded on the scalp that reveal the earliest stages of auditory processing. Prolonged conduction time to click-evoked ABRs as well as differences to speech-evoked ABRs have been found in children with autism spectrum disorders (ASD). The Auditory Stability Hypothesis of Language Development, proposes that inconsistent neural processing of sound negatively impacts the ability to form a stable representation of the auditory world, thus disturbing higher-level functions, such as language, that depend on that sensory signal. Unstable neural responses to sound may be characteristic of reading-impaired populations, and recent evidence suggest that other language-impaired individuals, including those with ASD, may likewise have unstable neural responses to sound, suggesting that stability of auditory processing may support language development in both typical and atypical populations.
Objectives: The purpose of this project is to study the connections between auditory processing and language learning using a phonological discrimination task, which by hypothesis links early auditory processing and macro-level language competency. The overarching goal is to understand the role of consistency of sound processing in early word learning by looking at its effect on phonological discrimination.

Methods: Sixteen children participated in the study, eight typically developing (TD) (two girls) with a mean age of 11.25 (1.9) years and eight diagnosed with ASD (one girl) with a mean age of 12.5 (3.59) years. All participants were first screened for normal hearing thresholds. ABRs were recorded in response to a "da" stimulus (10.9/sec, 6000 trials) presented at 80 dB SPL. To assess phonological discrimination, pairs of bisyllabic CVC-CVC (consonant-vowel-consonant) novel words that differed by only one phonemic unit (biskar vs. bisdar) or were identical (selzim vs. selzim) were presented, and the child was asked if they were the same or different. Current language ability was measured using four subtests of the

Clinical Evaluation of Language Fundamentals 5 (CELF-5); Word Classes, Formulated Sentences, Repeated Sentences, and Following Directions.

Results: The TD group performed significantly more accurately on phonological discrimination than the ASD group (*t*(14)= 2.84, *p*= 0.023). Neural response consistency was positively correlated with phonological discrimination ability in the ASD group (*r*=0.825, *p*= 0.014) but not in the TD group (*r*= 0.213, ns). Bivariate correlations including both groups found that children with better phonological discrimination also had higher standard scores on all CELF 5 subtests (*rs*> 0.747, *ps* < 0.001). The relationship between neural response consistency and language ability (Formulated Sentences and Word Classes) was mediated by phonological discrimination, as indicated by a Sobel test (*z's*>2.28, *ps* <0.02).

Conclusions: Phonological discrimination appears to mediate the relationship between neural response consistency to speech sounds and current language ability. Neural consistency may engender firmer phonological representations that encourage word-learning as well as more advanced language development. As group differences were not observed between TD and ASD this may indicate that similar processes are at work in both typical and atypical populations. Greater heterogeneity within the ASD sample may account for more pronounced relationships between phonological discrimination and neural responses.

60 **108.060** Measuring the Broad Autism Phenotype in Parents of Children with Autism

K. Nayar[1], *N. Maltman*[2], *S. P. Patel*[2], *L. Bush*[3], *S. Crawford*[4], *G. E. Martin*[5] *and M. Losh*[6], *(1)Feinberg School of Medicine, Department of Psychiatry and Behavioral Sciences, Northwestern University, Evanston, IL, (2)Northwestern University, Evanston, IL, (3)Northwestern Feinberg School of Medicine, Chicago, IL, (4)Communication Sciences and Disorders, Northwestern University, Chicago, IL, (5)Communication Sciences and Disorders, St. John's University, Staten Island, NY, (6)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: The broad autism phenotype (BAP) refers to a constellation of subclinical personality and language features in unaffected relatives of individuals with autism spectrum disorder (ASD), thought to index genetic liability to ASD, and therefore informative for understanding ASD etiology. Whereas gold standard diagnostic tools exist for evaluating ASD, methods for characterizing the BAP are less consistent, including direct assessment measures that have the benefit of objective independent ratings based on concrete behavioral examples, as well as questionnaires that rely on self- or informant-reports and are therefore more efficient but susceptible to rater bias. Indeed discrepancies between self- and informant-reports have been observed, pointing to a strong need to evaluate different measures of the BAP to determine the most accurate methods for characterizing this important construct.

Objectives: This study compared rates of the BAP using gold standard direct assessment measures, and questionnaire data in mothers and fathers of individuals with ASD. We examined interrelationships among measures, and within-family correlations of clinical-behavioral features across measures that could provide insights into those measures most sensitive to biologically meaningful clinical features.

Methods: One hundred eighty four parents of individuals with ASD were assessed for personality and language features of the BAP using three different methods: 1) the Modified Personality Assessment Scale Revised (MPAS-R; Tyrer, 1988), a direct assessment interview, 2) the Broad Autism Phenotype Questionnaire (BAPQ; Hurley et al., 2007), and 3) the Pragmatic Rating Scale (PRS; Landa, 1992), which was used to assess pragmatic language during semi-naturalistic conversations. BAP status was established based on established cut-offs (Hurley et al., 2007; Losh et al., 2008). Within family associations in clinical-behavioral symptoms were examined with child variables from the ADOS, ADI-R, and the Pragmatic Rating Scale-School Age (PRS-SA).

Results: The self and informant ratings of the direct assessment MPAS-R classified 48% and 49% of the sample as BAP+, respectively. The self and informant ratings of the BAPQ classified 15% and 19% of the sample as BAP+, respectively. The BAPQ captured only 25% (self) and 20% (informant) of those classified by the MPAS as BAP+. The PRS classified 22% of the sample as BAP+ on the pragmatic language trait only. The BAPQ classified only 23% (self) and 20% (informant) of these individuals as “positive” for the pragmatic language feature of the BAP. Parent-child correlations revealed negative associations between the BAP (as measured by direct assessment on the MPAS-R) and child ADI-R social and verbal communication scores (*ps*<.05). Similarly, the pragmatic language domain on the BAPQ was negatively associated with child’s overall ASD symptom severity (*p*<.03).

Conclusions: Findings suggest that questionnaires may markedly under-classify the BAP, relative to objective, direct assessment measures of personality and pragmatic language. Parent-child correlations were also most robustly observed with direct assessment measurement of the BAP. Theoretical and methodological considerations for future studies of quantitative traits in ASD and in family members will be discussed.

61 **108.061** Mechanisms of Voice Control in Autism Spectrum Disorder: A Family Study

S. P. Patel[1], *J. H. Kim*[2], *C. R. Larson*[2] *and M. Losh*[1], *(1)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)Northwestern University, Evanston, IL*

Background: Impairments in prosody (e.g., intonation, rate), have been noted since the earliest descriptions of social communication impairments in autism spectrum disorder (ASD; Kanner, 1948). Additionally, subtle differences in prosody have been identified in a subset of parents of individuals with ASD with the broad autism phenotype (BAP; Losh et al., 2012). Existing investigations of prosody in ASD have focused primarily on perceptual judgments and global acoustic measures (e.g., fundamental frequency), which are beneficial in characterizing prosodic profiles within this population; however, these studies have failed to investigate the feedforward and feedback control mechanisms, which support planning, production, self-monitoring, and self-correction of speech (Guenther, Tourville, & Bohland, 2015), that may underlie prosodic atypicalities in ASD.

Objectives: This study investigated potential breakdowns in sensorimotor monitoring and correction of prosody in individuals with ASD and their parents.

Methods: A pitch-altered voice auditory feedback paradigm in which participants vocalized and received real-time auditory feedback of their voice was implemented (Burnett et al., 1998). Participants included individuals with ASD (n=20), their parents (n=20), and respective controls (n=20 proband controls; n=23 parent controls). In the first task (“vowel”), participants vocalized “ah” for five seconds, while five randomly-timed pitch alterations occurred. Simultaneously, event-related potentials (ERPs) to pitch alterations were recorded using a 32-electrode electroencephalography (EEG) system. In the second task (“speech”), participants asked the question “You know Nina?” and one pitch alteration occurred on the third syllable. Vocal responses from both tasks were examined in relation to prosodic abilities assessed by the *Profiling Elements of Speech Prosody-Communication* assessment (Peppé & McCann, 2003).

Results: The ASD group had larger responses to pitch-altered voice auditory feedback in the vowel task compared to controls (*p*=.03). Increased vocal response magnitudes during vowel production in both ASD and their controls, were associated with poorer expressive prosodic abilities (*p*s < .05). The ASD parent group did not differ from parent controls in vocal response magnitude during the vowel task, but preliminary ERP results demonstrated smaller N1 amplitudes in fronto-central electrodes in ASD parents (*p* =.09). Both ASD and ASD parent groups demonstrated reduced vocal responses in the speech task compared to respective control groups (*p*s <.02). Differences in the parent groups were driven by parents with the BAP (*p* < .02).

Conclusions: In the ASD group, larger vocal responses to pitch-altered voice auditory feedback during vowel production but attenuated responses during speech, suggest difficulty incorporating auditory feedback cues into vocal control mechanisms. ASD parents, specifically those with the BAP, also demonstrated attenuated responses during speech, suggesting that response magnitudes to pitch-altered voice auditory feedback during speech may index genetic liability to ASD. ERP results from ASD parents during vowel production may indicate attenuated abilities in detecting mismatches between intended and actual sensory consequences. Correlational analyses provide additional support for the relationship between vocal responses to pitch-altered auditory feedback and prosodic production. Ongoing analyses investigate differences in response magnitude between vowel and speech tasks to determine if individuals with ASD and their parents demonstrate task-dependent responses similar to controls (Chen et al., 2006).

62 **108.062** Multimodal Communicative Patterns in Toddlers with Autism Spectrum Disorders and Toddlers with Other Developmental Disorders: A Deeper Look.

*E. Murillo[1], **L. Boada**[2] and M. Parellada[3], (1)Psicología Básica, UAM. Universidad Autonoma de Madrid, Madrid, Spain, (2)Hospital Universitario Gregorio Marañón. Child and Adolescent Psychiatry. IISGM. CIBERSAM, Madrid, Spain, (3)Fundación Investigación Biomedica Gregorio Marañon, Madrid, Spain*

Background:

Typically developing children produce multimodal communicative behaviors from the early stages of language development. The coordination of elements such as gestures, vocalizations and use of gaze has an important predictive value in the development of later language skills. For example, the coordinated use of gestures and vocalizations at 12 months is an important predictor of lexical development three months later (Murillo & Belinchón, 2012; Wu and Gros-Louis, 2014).

Many studies have shown that children with Autism Spectrum Disorder (ASD) have difficulties in the use of gestures with a communicative purpose and in the integration of multimodal information. For instance, prospective studies of high-risk children subsequently diagnosed with ASD indicate differences in the use of gestures and vocalizations at one year of age (eg, Parladé and Iverson, 2015). However, there is also some contradictory evidence. Some studies with adults and adolescents with ASD found no differences in the frequency of gestures production neither in its temporal coordination with speech compared to those with typical development. It seems, therefore, that the synchrony of communicative resources constituting multimodal communicative behaviors can be specifically affected in children with ASD at very early stages of development.

Our hypothesis is that children with ASD will produce not only less communicative behaviors, but specifically less multimodal communicative behaviors than children with other language or developmental disorders.

Objectives:

To explore the production of multimodal communicative behaviors as a specific marker of ASD.

Methods:

Participants: 6 children (4 boys, 2 girls) aged between 23 and 40 months assessed at a University Hospital due to social and communicative development concerns. Three of the participants had an ASD diagnosis, and the other three had a language or developmental disorders. Both groups were matched by age.

The ADOS was administered individually by a clinician with the appropriate clinical and research training and reliability for the administration of the instrument and the session was recorded for later analysis. We analyzed 180 minutes of behavior through the module 1 of the ADOS-G using ELAN software by the Max Planck Institute for Psycholinguistics.

We registered and coded all the communicative behaviors (a total of 668) during the ADOS-G administration session. Coding system included different categories for gestures, vocalizations and social use of gaze. The coders were blind to children's ages and diagnosis.

Results:

As expected, children ASD showed a lower frequency of communicative behaviors than children with a non-ASD diagnosis (U=0; z=-1,964; p=0,050). They produced less vocalizations (U=0; z=-1,964; *p*=0,050) **and less multimodal behaviors, combinations of gestures and vocalizations than children in the non-ASD group (U=0; z=-1,964;** *p*=0,050). However, considering the communicative behaviors produced in proportional terms, we did not find difference between groups in the frequency of gestures without vocal accompaniment (U=3; z= -0,655; *p*=0,513).

Conclusions:

Our preliminary data suggest that besides the decreased communicative acts, children with ASD have specific difficulties integrating the communicative elements into multimodal communicative behaviors but not in the frequency of gestures usewhen they are compared to other developmental disabilities.

63 **108.063** The Role of Augmented Language Input on the Expressive Language Growth of Young Children with Autism Spectrum Disorder (ASD)

***K. Sterrett**[1], C. Kasari[2], R. Landa[3] and A. P. Kaiser[4], (1)University of California Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (4)Special Education, Vanderbilt University, Nashville, TN*

Background: The development of language in children with autism spectrum disorder (ASD) is a potent predictor of positive social outcomes (Anderson et al., 2009). Yet despite intensive early intervention approximately 30% of children fail to develop functional language by the time they enter school (NRC, 2001). One promising intervention is the use of speech generating devices (SGD), which have shown treatment effects when used in isolation (Van Der Meer & Rispoli, 2010) or in conjunction with a behavioral treatment (Kasari et al., 2014). There are a number of

hypotheses as to the mechanism by which SGD lead to language growth such as the consistency of the language produced by SGD and the pairing of the language with a visual. There is little empirical evidence supporting these hypotheses (Blischak, Lombardino & Dyson, 2003).
Objectives: To test the moderating effect of the language input produced by SGD versus verbal language input from an adult on the expressive language growth of children with ASD during an intervention trial.

Methods: Thirty-one children were included with a mean age of 6.44 years (SD=1.23). All children received a 24-week behavioral intervention (JASPER+EMT) with an SGD used by the interventionist to model language (see Kasari et al., 2014 for intervention overview). The dependent variables were the number of spontaneous comments, word roots and requests measured using the Natural Language Sample. The independent variables were the proportion of children's responses to adult language (verbal and/or SGD models). A response was defined as the child producing contingent language within five seconds of adult's verbal or SGD language models.

Bi-variate correlations were run between the outcomes, children's response to models, Leiter age equivalency and ADOS severity scores. Next, linear regression models were run for each dependent variable at exit with the proportion of responses to SGD and verbal models at entry entered as independent variables controlling for cognitive ability and entry scores on the dependent variables.

Results: The percentage of responses to language input produced by the SGD was correlated with the number of different word roots ($r=.57$; $p<.01$) and spontaneous requests ($r=.47$; $p<.05$) at entry. None of the outcomes were correlated with the proportion of responses to verbal models.

The regression equations for spontaneous comments and number of different word roots were significant, $F(4, 17) = 5.28$, $p< .01$ and $F(4, 17) = 14.67$, $p< .01$.

Proportion of response to SGD models at entry (but not verbal models) was predictive of the number of spontaneous comments and different word roots at exit after controlling for entry scores and cognitive ability, $t(21) = 2.96$, $p < .01$ and $t(21) = 2.85$, $p = .01$ respectively.

Conclusions: These data suggest that children process augmented language models differently than adult verbal models. It could be that those children with higher receptive language or cognitive abilities are able to benefit from the input from the devices (Sevcik, 2006). A direction for future research will be to test the role of these potential moderators with a larger sample of children.

64 **108.064** Multipurpose Handheld Devices and Communication in Individuals with Autism Spectrum Disorder: A Meta-Analysis

ABSTRACT WITHDRAWN

Background: The development in technology has permitted the use of tablets for communication and social interactions. Tablet-based speech-generating devices (SGDs) have specific features that led to the frequent use of these devices in the AAC field, such as flexibility, availability, social acceptability, cost-efficiency, portability, and high quality. Recent systematic reviews show some common patterns about the effectiveness of utilizing tablet-based SGDs to enhance social-communication skills in individuals with autism spectrum disorder (ASD). However, the majority of systematic reviews used behavior-change indices (e.g., percentage of nonoverlap data–PND), that may provide unreliable results. Further, most meta-analyses did not mention whether tablet-based SGDs are considered an evidence-based practice (EBP).
Objectives: We aim to answer the following research questions: What is the magnitude of effectiveness of tablet-based SGDs by using rigorous nonoverlap method (i.e., nonoverlap all pairs-NAP) combined with with confidence interval (CI)? What is the level of evidence of utilizing tablets as SGDs by individuals with ASD?

Methods: Electronic databases, ancestral, and hand search were conducted to located relative studies. The studies were included based on the following criteria: (a) the study must utilize single-case experimental design (SCED) that demonstrate functional relation; (b) at least one participant with a diagnosis of ASD must be included in the study; (c) the independent variable had to be handheld multipurpose devices with AAC apps; (d) social-communication skills (e.g., requesting, labeling, answering and asking questions) had to be the main dependent variable; and (e) the study had to be published in English in a peer-reviewed journal. The studies were coded based on participants' characteristics, experimental design, setting, intervention, teaching methods, target behavioral outcome(s), quality of the single-subject research based on the quality indicators suggested by Horner et al. (2005), and effect size of treatment(s).

Results: The systematic review identified a total of 29 studies that applied tablet-based SGDs as a single treatment or as a treatment package in 81 individuals with ASD. The average NAP value for the tablet-based SGD was higher (*M* = 0. 90) with narrow estimated intervals (CI95% = 0.84, 0.94) compared to picture communication system (PCS) and manual sign (MS), which indicated more reliable and trustworthy effect size. Based on evaluating the quality of each study, all 29 were considered acceptable quality by the quality indicators established by Horner et al. (2005).

Conclusions: Overall, this review shows that using tablets as dedicated SGDs to teach social-communication skills met all the standards, suggested by Horner et al. (2005), to be considered EBP. Further, tablet-based SGDs display medium effects in improving different social-communication skills in individuals with ASD. The results of the review help guide future research in several directions to close the gap in the literature. Future studies should investigate whether tablet-based SGDs are best suited for infants, toddlers, and adults with ASD with a wide range of autism severity. Finally, future research is recommended to examine the stakeholders' perspectives about the effectiveness and the acceptability of tablet-based SGDs.

65 **108.065** Neurobehavioural Outcomes of a Music Intervention for Autism - a Randomized Controlled Trial

M. Sharda[1]*, C. Tuerk*[1]*, R. Chowdhury*[2]*, K. Jamey*[1]*, N. Foster*[1]*, M. Tan*[3]*, A. Nadig*[4] *and K. L. Hyde*[1]*, (1)International Laboratory of Brain, Music and Sound Research (BRAMS), University of Montreal, Montreal, QC, Canada, (2)Psychology, International Laboratory of Brain, Music and Sound Research (BRAMS), University of Montreal, Montreal, QC, Canada, (3)Abaton Integrative Medicine, Oakville, ON, Canada, (4)School of Communication Sciences and Disorders, McGill University, Montreal, QC, Canada*

Background: Music is an intrinsically rewarding stimulus that can enhance social-communication and sensorimotor abilities by engaging multiple brain networks. Previous studies of music-based interventions for children with autism spectrum disorder (ASD) have suggested positive outcomes (Geretsegger et al, 2015). Preliminary neuroimaging findings have shown that children with ASD have preserved functional connectivity during song-listening (Sharda et al, 2015). However, neurobiological mechanisms underlying specific benefits of music-based therapies for ASD remain unknown. Here, we evaluate the neurobehavioural effects of a music-based intervention compared to a non-music behavioural intervention for school-age children with ASD, using a randomized control trial (RCT).
Objectives: Our specific goal was to evaluate resting-state functional connectivity (RSFC) in children with ASD before and after 12 weeks of a music

or non-music intervention, particularly in fronto-temporal and salience brain networks implicated in social-communication and shown to be altered in ASD.

Methods: Fifty-one children with ASD (43 boys), 6-12 years old, participated in a single-blind, parallel-arm RCT of music therapy (ISRCTN26821793). Participants were randomly assigned to 12 weekly sessions of individual music (MT, n=26) or non-music (NM, n=25) therapy. Sessions in MT involved use of songs and rhythmic cues to improve turn-taking and reciprocal social interactions and communication skills. The NM sessions targeted similar skills but without the use of music. Groups did not differ on age, sex, IQ and socioeconomic status at baseline. Both behavioural (Children's Communication Checklist-2 composite score; CCC-2) and neuroimaging measures (T1; resting-state functional MRI) were obtained pre- and post-intervention. Here, we report preliminary neuroimaging results of 45 (MT=24, NM=21) participants with usable data. Seed-based RSFC maps with 4 apriori seeds were generated using an FSL-based pipeline for each participant. Seeds were anchored in language (left IFG) and salience (right fronto-insula) networks. Motion was corrected following guidelines in Power et al, 2012. Effects of MT vs. NM were evaluated by comparing the RSFC in each seed, pre- and post-intervention, using mixed-effects ANOVA. Results were considered significant when there was a group-by-time interaction at p<.05 (cluster-corrected using random field theory; RFT). RSFC at post-intervention was correlated with change in communication skills to study the link between the brain mechanisms underlying social-communication.

Results: Previously reported behavioural results (Figure1a) showed significant improvements in social-communication after 12 weeks of MT. We also found changes in RSFC pre- to post-intervention, in MT compared to NM, in networks seeded from left IFG (decrease in RSFC) and right fronto-insula (increase in RSFC; p<.001, RFT-corrected, Figure1b,c). Additionally, decreased RSFC in the left IFG network post-intervention was related to increases in CCC-2 score in MT participants who improved post-intervention (p=.04, Figure1d).

Conclusions: Children with ASD who underwent 12 weeks of music therapy had more typical RSFC in fronto-temporal brain regions compared to those who underwent a non-musical intervention. Changes in RSFC were further related to behavioural improvements in standardized measures of social communication suggesting neurobiologically-mediated improvements in social communication as a result of music intervention. These results provide neurobiological support for use of music as a therapeutic tool for children with ASD to improve social-communication.

66 **108.066** Perceptual Markers of Autism during Oral Narrative Production

ABSTRACT WITHDRAWN

Background:

Individuals with Autism Spectrum Disorder (ASD) have variable language abilities, ranging from severely impaired to above average. Verbal individuals with ASD frequently exhibit speech differences, including atypical or lack of prosody. These speech and/or vocal differences often result in difficulty conveying communicative information, such as affect, linguistic, and pragmatic information. It is not clear what the underlying mechanisms are that contribute most to the acoustic form of "speech atypicalities" among speakers with ASD compared to the speech of their Typically Developing (TD) peers. Regardless of the mechanisms (linguistic, motoric, temporal, prosodic) that contribute to the perception of speech "oddness", it is difficult to identify precisely what sounds "different" to the human ear.

Objectives:

The following research questions were addressed: 1) Are there distinct acoustic-perceptual speech and language differences as perceived by human listeners that distinguish children with ASD compared to TD peers?; 2) Do experienced and non-experienced judges acoustically rate oral narratives produced by children with ASD differently than those produced by TD peers?

Methods:

Oral narratives using the ENNI (2007) were collected on 31 children with ASD and 31 TD peers between the ages of 4-11 years matched for age, gender and receptive vocabulary. The 31 participants with ASD were formally diagnosed with ASD and had an IQ above 70. All acoustic samples were digitally recorded in a child-friendly sound-treated room. The "human listeners" included one group of 40 Speech Language Pathology (SLP) graduate students (trained listeners) and 40 randomly selected graduate students from different disciplines (untrained listeners) who were recruited across a university campus. All human listeners (judges) met inclusionary criteria: 1) normal hearing; 2) English as a native language; and 3) level of experience/contact time with individuals with communicative disabilities and/or ASD. The 40 SLP judges were engaged in coursework and clinical experiences working with individuals with communicative differences or disabilities and/or children with ASD. The 40 untrained judges earning degrees in different disciplines had little to no experience working with individuals with communicative disabilities and/or ASD. The judges applied a perceptual rating instrument that included 13 categories comprised of seven linguistic and six speech/acoustic variables. The judges rated each category using a three-point Likert scale.

Results:

There are distinct differences as perceived by human listeners that distinguish children with ASD as sounding "different" compared to TD peers. For the main effect diagnosis (ASD vs. TD), significant between group differences were found for four out of 13 variables: Story sequencing (p=0.008); Articulation (p=0.001); Fluency (p=0.005); and Rate (p=0.016). A trend, but nonsignificant differences at 0.05 were found for Topic organization (p=0.073) and Pitch (p=0.058). For the main effect judge (SLP vs. untrained listeners), significant within group interactions were found for three variables: Emotional language (ToM) (p=0.020); Articulation (p=0.002); and Rate (p=0.037). A trend was also found for Causal language (p=0.094). Inter-rater reliability was respectable at 0.73.

Conclusions:

Experienced and non-experienced judges rated the acoustic/speech aspects of connected speech as the most discriminating features that distinguished the connected speech among children with ASD compared to TD peers.

67 **108.067** Pragmatic Language Differences between Boys and Girls with Autism Spectrum Disorder: A Cross Cultural Comparison.

E. F. Dillon[1]*, R. Landa*[1]*, C. E. Wilson*[2]*, K. J. Greenslade*[3] *and E. Utter*[4]*, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Psychology, University of Dublin, Trinity College, Dublin, Ireland, (3)Communication Sciences and Disorders, University of New Hampshire, Durham, NH, (4)Kennedy Krieger Center, Center for Autism and Related Disorders, Baltimore, MD*

Background: Autism Spectrum Disorder (ASD) is a highly heterogeneous condition that traditionally has been defined by its maleness: both in describing the "extreme maleness" of its characteristics, and in the decidedly male ratio of diagnosis (Fombonne, 2007). However, the assumption of ASD as inherently male may overlook an alternative expression of ASD more common in, or specific to, women and girls. Some research suggests that girls with ASD may demonstrate a social advantage over boys, akin to that observed in typical development (Head, McGillivray, & Stokes, 2014).

Pragmatic, or social language, deficits have been observed across the autism spectrum, and sub-clinically, in family members of those with ASD (Landa et al., 1992). While pragmatic language differences are observed in healthy men and women, sex differences often have not been detected between mothers and fathers of children with ASD (Landa et al., 1992; Klusek, Losh & Martin, 2014). Little is known about potential sex differences in the pragmatic functioning of children with ASD.

Objectives: To explore gender differences in autism symptoms, focusing on pragmatics. To determine whether differences are consistent across cultures.

Methods: Fifty-three children with ASD (30 girls), aged 9-16 years (*M*= 11.86, *SD*= 1.60), were recruited from the United Kingdom and Ireland; 34 (9 girls), aged 8-12 years (*M*= 8.94, *SD*= 1.27) were recruited from the US. Samples were compared on *ADOS* items, and on pragmatic ability from examiner ratings of conversation samples using the *Pragmatic Rating Scale for School-Age* children (*PRS-SA*; Landa, unpublished).

Results: Recruitment and coding are ongoing; additional data will enhance existing sample (N=87) results, reported here. One-way between-subject ANCOVAs, controlling for nonverbal IQ, indicate similar sex differences in total *PRS-SA* scores, across the US and UK/Ireland samples. In the US sample, *PRS-SA* scores were significantly higher for males (M = 18.00, SD= 7.10, p = .01) than females (M = 9.44, SD = 4.30), indicating more pragmatic errors in males. Likewise in the UK/Ireland sample, (F (1, 49) = 3.57, p = .028), girls (M = 11.18, SE= 0.80) displayed significantly fewer pragmatic errors than boys (M = 13.79, SE = 0.84). Interestingly, nonverbal intelligence and pragmatic language errors were negatively related in boys, but not girls (Figure 1). In the UK/Ireland sample, girls (M = 15.33, SE = 1.32) displayed significantly lower *ADOS* total algorithm scores than boys (M = 22.82, SE= 1.55), (F (1, 49) = 12.88, p = .001), signaling fewer or less severe social-communication deficits and/or repetitive behaviors/restricted interests. Additionally, boys scored significantly higher (p < .05) on particular ADOS items (e.g., Excessive Interest, Compulsions, Conversation and Unusual Eye Contact).

Conclusions: Findings suggest similar sex differences on pragmatic errors in both cultures, with pragmatic ability possibly linked to nonverbal intelligence in boys with ASD. Also, sex differences on social-communication and repetitive behaviors/restricted interests are present on UK/Ireland sample *ADOS* scores. Implications for earlier identification and services for girls with ASD are discussed.

68 **108.068** Spatial Language Abilities of High Functioning Individuals with Autism

***A. Bochynska**, V. Vulchanov and M. Vulchanova, Norwegian University of Science and Technology, NTNU Trondheim, Trondheim, Norway*

Background: The cognitive and language profiles of individuals with Autism Spectrum Disorders (ASD) display both deficient and enhanced abilities within particular domains (Tager-Flusberg, Joseph & Folstein, 2001; Vulchanova, Talcott, & Vulchanov, 2014). Peaks can be observed in the areas of e.g. visual discrimination, Block Design and vocabulary size, whereas troughs are found in communication, pragmatics or egocentric transformations. Here we are interested in the peaks and troughs within the spatial domain. Even though spatial cognition has been widely studied in ASD (e.g. Caron et al, 2004; Edgin & Pennington, 2005; Shah & Frith, 1993; see Muth, Honekopp, & Falter, 2014 for meta-analysis on visuospatial skills), very little attention has been given to spatial language, i.e. descriptions of spatial relations between objects. Since the use of spatial language is based upon both linguistic and perceptual representations, it is particularly interesting in the context of autism and uneven cognitive profiles, and can provide new insights into the disorder characteristics as well as the interplay between language and cognition.
Objectives: The main aim of the current study was to investigate the use of spatial language and identify strengths and weaknesses of spatial verbal abilities in high functioning individuals with autism.

Methods: We have adapted a battery of three spatial language tests developed at the University of East Anglia (Markostamou, Coventry, Fox, & McInnes, 2015): Spatial Verbal Memory (immediate and delayed recall of verbal spatial information from egocentric and allocentric perspective), Spatial Naming Test (production of locative, directional and path prepositions), and Verbal Comprehension in Spatial Perspective Taking (spatial language comprehension in different frames of reference: absolute, egocentric, intrinsic and other-person). Twenty-five high functioning individuals with autism (HFA; 7 females) and 25 typically developing controls (TD; 11 females) participated in the study. The groups were matched on age (range: 9-27), Verbal and Perceptual IQ (Wechsler Intelligence Scales, WISC-IV and WAIS-V) and two linguistic components: grammatical comprehension and semantics (Test of Language Development, TOLD-I:4).

Results: In the Spatial Verbal Memory task, HFA individuals recalled significantly less spatial content from the egocentric, but not allocentric story, compared to TD group. In the Spatial Naming Test, HFA group differed significantly from the TD group in the production of proximity terms (by more frequently omitting the proximity terms, e.g. "to the left" instead of "far to the left", giving an alternative term, e.g. "first" instead of "nearest", or making a perspective error, e.g. "far in the front" instead of "far to the left") and source paths terms (by omitting source, e.g. "down" instead of "down off" or by semantic violations, e.g. "out of" instead of "away from"). Finally, in the Spatial Perspective Taking task HFA individuals showed longer response latencies in all, except the intrinsic frame of reference condition.

Conclusions: The results point to a selective fragility (see Landau & Zukowski, 2003) in the spatial language abilities of high functioning individuals with autism and uncover areas of strengths (e.g. intrinsic reference frames) and weaknesses (e.g. egocentric perspective, spatial memory source goals) in the profile.

69 **108.069** Statistical Learning and Autism-Related Social Communication Difficulties

***K. M. Parks**[1], L. Griffith[2], N. B. Noonan[2] and R. A. Stevenson[3], (1)The University of Western Ontario, London, ON, Canada, (2)Psychology, University of Western Ontario, London, ON, Canada, (3)Western University, London, ON, Canada*

Background: One of the defining characteristics of ASD is difficulties with social communication, including difficulties in the comprehension and the production of language. One contributor to learning these language skills is the ability to track statistical regularities and patterns that occur within languages specifically, and within the environment as a whole (statistical learning; SL). Likewise, difficulties with SL make it harder to learn patterns and regularities within the environment. Specifically, SL difficulties in ASD make it challenging to learn the inherent rules that govern language and social cues, and have thus been hypothesized to contribute to the language, speech, and social communication difficulties. Here, we explore this hypothesis by testing how difficulties in SL may help to explain the weak language, speech, and social communication patterns commonly observed in individuals with ASD.

Objectives:

- To test weather the ability to learn implicit statistics of the environment in both the auditory and visual domains relate to autistic traits associated with the broad autism phenotype.
- To examine specifically whether language comprehension and production are related to auditory and visual SL.
- To test whether other autism-related issues in socio-communication (e.g. social awareness, emotion regulation) are related to SL abilities.

Methods: We administered well-established measures of auditory and visual SL paradigms where individuals were presented with steams of syllables (auditory) and shapes (visual) during a learning phase that were embedded with statistical regularities unknown to the participants (N=24, data collection ongoing; mean age=19.50, *SD*=4.51). Following the learning phase, participants were tested on whether they learned these statistical regularities through completing pattern completion tasks. Participants receptive and expressive language skills were then tested using the Clinical Evaluation of Language Fundamentals (CELF-5), and completed clinically-reliable questionnaires examining autistic traits (Broad Autism Phenotype Questionnaire; BAPQ), social communication (Social Responsiveness Scale; SRS), and social competency (Multi-dimensional Scale of Social Competency; MSCS). We hypothesized that low levels of SL abilities would be associated with (a) higher levels of autistic traits, (b) decreased receptive and expressing language abilities, and (c) decreased social competency.

Results: Auditory SL was significantly correlated with receptive ($r_{(23)}$=.28, p<.05) and expressive ($r_{(23)}$=.32, p<.05) language comprehension. Further, visual SL was significantly correlated with multiple aspects of social communication related to ASD symptoms, including social communication ($r_{(23)}$=.45, *p*<.05), social cognition, ($r_{(23)}$=.42, *p*<.05), social awareness ($r_{(23)}$=.42), pragmatic language ability ($r_{(23)}$=.42, *p*<.05), social motivation (*r*(22)=.44, *p*<.05), and emotion regulation ($r_{(22)}$=.43, *p*<.05).

Conclusions: Our results demonstrate that auditory and visual SL are specifically related to a number of issues associated with ASD, including language abilities, social communication and competency, and autistic traits in general. These findings are in line with current theories of language development which suggest that SL tends to facilitate early language ability, and that lower-level SL difficulties in ASD may cascade into, or contribute to, the language and socio-communication issues canonically observed in ASD.

108.070 Structural Language/Nonverbal Ability Profiles in Children with ASD

S. Silleresi[1]*, P. Prévost*[2,3]*, R. Zebib*[1,3]*, F. Bonnet-Brilhault*[4]*, J. Malvy*[5] *and L. Tuller*[1,2]*, (1)Université François Rabelais de Tours, Tours, France, (2)UMR iBrain 1253, Inserm, University of Tours, Tours, France, (3)UMR Imagine & Brain Inserm 930, Tours, France, (4)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (5)CHRU Tours, Tours, France*

Background:

A diagnosis of ASD includes specification of any co-occurrence with language impairment and/or cognitive disabilities (APA, 2013). Regarding language impairment, studies on verbal children with autism have reported that approximately 50% manifest significant structural language impairment (ALI), while the rest display normal abilities (ALN) (e.g. Leyfer et al., 2008). Regarding cognitive disabilities, current large-scale studies have found that the mean rate in children with ASD is roughly 30% (CDC, 2014). However, few studies have explicitly explored the possible combinations of language (dis)ability and cognitive (dis)ability (Kjelgaard & Tager-Flusberg, 2001; Rapin et al., 2009; Joseph & Tager-Flusberg, 2002). There are two potential methodological stumbling blocks in this enterprise. One concerns how language is tested: language abilities have typically been assessed via receptive vocabulary tasks, which probably overestimate verbal abilities in this population (Mottron, 2004). The other concerns the evaluation of cognitive abilities in children with ASD, which have usually been reported as Full Scale IQ scores (FSIQ). However, a large body of literature has demonstrated that perception-based nonverbal tasks, Raven's Progressive Matrices (RPM) and the WISC-IV Perceptual Reasoning Index, better estimate cognitive level of children with ASD in comparison to FSIQ and other Wechsler indices (Courchesne et al., 2015; Mayes & Calhoun, 2008; Nader et al., 2016).

Objectives:

The aim of the present study was to explore the existence, nature and relative frequency of the profiles obtained by crossing both structural language and nonverbal abilities in children with ASD using more controlled evaluation of both of these properties.

Methods:

Forty verbal children with ASD (30 analyzed), aged 6-12 years (*M*=8.79, *SD*=18.76), were evaluated on formal language abilities via standardized language tasks and tasks targeting specific aspects of morphosyntax and phonology and on cognitive abilities via both RPM and WISC-IV/WPPSI-IV. The only inclusionary criterion was ability to produce utterances of at least three words, while no exclusionary criterion was applied for nonverbal abilities.

Results:

Results showed that both RPM and Wechsler nonverbal indices were strongly correlated with most structural language measures (Table 1). All four possible profiles consistently emerged, with both nonverbal measures: two "homogenous" profiles (ALN with normal NVIQ and ALI with low NVIQ) and two "discrepant" profiles (ALN with low NVIQ and ALI with normal NVIQ) (Fig 1), although their relative frequency was not equivalent. This was particularly striking given that, although no group differences were found between RPM and Wechsler indices (*p*=.742), some children showed a difference of 50 percentile points or more in favor of Wechsler scales (contra Nader et al., 2016).

Conclusions:

Our study provides evidence for the existence of all four structural language/nonverbal profiles in children with ASD. The relative infrequency of low NVIQ profiles among these verbal children, and especially the ALN/low NVIQ profile, may reflect population characteristics, although these children are typically excluded from studies on language in ASD. Understanding structural language/nonverbal ability profiles (and therefore appropriate treatment) can only be achieved through wide investigation across the entire spectrum, and thus not restricted to high-functioning children.

71 **108.071** Switching between Counterfactual Worlds and Reality in ASD: An ERP Study

J. S. Black[1]*, D. M. Williams*[2] *and H. Ferguson*[3]*, (1)School of Psychology, University of Kent, Canterbury, United Kingdom of Great Britain and Northern Ireland, (2)University of Kent, Canterbury, United Kingdom, (3)School of Psychology, University of Kent, Canterbury, United Kingdom*

Background: Research has previously found that children with Autism Spectrum Disorders (ASD) have difficulty reasoning counterfactually, and that this may contribute to deficits in Theory of Mind ability (Grant, Riggs & Boucher, 2004; Peterson & Bowler, 2000). Using an eye-tracking and reading paradigm, we have previously demonstrated that counterfactual understanding is undiminished in adults with ASD. However, these scenarios were limited to a single sentence, which may be too simplistic to fully test the limits of counterfactual comprehension in ASD. It has been suggested that people with ASD experience a local processing bias, and exhibit superior anomaly detection abilities during reading when the anomaly is incongruent with a local than global context (Au-Yeung et al, 2017). Furthermore, ASD is associated with difficulties in cognitive flexibility and attention switching. It is therefore possible that counterfactual information embedded within a longer context, or that requires switching between counterfactual/reality, may be problematic for people with ASD.

Objectives: We examined whether adults with ASD (compared to a sex, age, and IQ matched Typically Developing (TD) group) are able to accommodate counterfactual worlds over longer passages, or switch from counterfactual to real worlds. Ease of integration was indicated by recording event-related brain potentials (ERPs), specifically the N400 response, which is sensitive to anomaly detection during reading.

Methods: Participants read scenarios on a computer screen. The first sentence established the counterfactual context (e.g. "If it had been raining this morning, Susan would have rushed to get to work."), and was presented in full for self-paced reading. A second sentence described a consequence of this counterfactual event, and was presented word by word. Critically, this sentence included a noun that was either consistent or inconsistent with the preceding context, and either included a modal verb to indicate reference to the counterfactual world (e.g. "In the end, Susan would have arrived at work early/late") or switched back to the factual-world (e.g. "In the end, Susan arrived at work late/early"). Factual scenarios were used as a baseline measure of contextual integration (e.g. "Because…"). ERPs were recorded from 32 electrodes, time-locked to the onset of the critical word.

Results: Results showed that participants detected the contextual inconsistency in all context conditions (i.e. showed larger N400 for inconsistent than consistent words). Crucially, this pattern was manifest in both groups, suggesting comparable counterfactual language processing in TD adults and adults with ASD. Nevertheless, some subtle differences in the topography of the N400 effect emerged between groups; the effect was left lateralised in the ASD group but was balanced across hemisphere in the TD group.

Conclusions: Adults with ASD were able to rapidly accommodate a counterfactual context, showing that they successfully maintained access to this non-real world over a longer passage. Adults with ASD were also sensitive to contextual cues, which facilitated rapid switches back to the real world, suggesting that they maintain comparable access to reality as TD adults. These findings argue against general difficulties in global coherence and complex integration in ASD, and against a general impairment in cognitive flexibility.

72 **108.072** The Association between Narrative Language and Social Perception in Children with Autism Spectrum Disorder (ASD) and with Typical Development (TD)

L. Mäkinen[1]*, S. Loukusa*[1]*, S. Kuusikko-Gauffin*[2]*, I. Moilanen*[3]*, H. E. Ebeling*[4] *and S. Kunnari*[2]*, (1)Research Unit of Logopedics, University of Oulu, Oulu, Finland, (2)University of Oulu, Oulu, Finland, (3)Child Psychiatry, University of Oulu and Oulu University Hospital, Oulu, Finland, (4)Child Psychiatry, University of Oulu, Oulu, Finland*

Background:

Narration is essential for effective communication. Efficient narration and storytelling requires linguistic and social-cognitive skills, such as emotion recognition and understanding listener´s and story character´s minds. Children with autism spectrum disorder (ASD) have challenges in all above mentioned areas (Baixauli et al., 2016; Loukusa et al., 2014).

Objectives:

This study explores the associations between narrative language and social perception abilities in children with ASD and their typically developing (TD) peers. Even though narratives have been widely investigated, surprisingly little is known about the connections between narration and social perception. It could be assumed that narration requires social perception skills, since listener's needs in a given context should be acknowledged in order to produce a coherent and informative story.

Methods:

Sixteen high-functioning children with ASD (aged 5;1–10;7 years; mean age 7;7) and 16 children with TD (aged 5;2–10;0 years; mean age 7;5) participated in this study. Children with ASD were carefully diagnosed by child psychiatrists or child neurologists using ICD-10 criteria based on ADI-R, ADOS and other investigations by a multiprofessional team in Oulu University Hospital in Finland. The Edmonton Narrative Norms Instrument (ENNI, story A3), which is a picture-based story generation task, was used for narrative elicitation. Children's stories were analyzed for story grammar (SG), based on ENNI manual (Schneider, Dubé & Hayward, 2005). SG measures the informativeness and the hierarchical organization of the story. In addition, children's social perception abilities were evaluated with NEPSY-II subtests of Affect Recognition and Theory of Mind (ToM) (Korkman, Kirk & Kemp, 2008).

Results:

Children with ASD produced stories that contained less information measured by SG than did TD children. Moreover, compared to TD children, children with ASD had lower scores in both NEPSY-II subtests. In ASD group, we found a moderate positive association between SG and the Affect Recognition and non-significant association between SG and ToM. In TD children, there were no significant associations between SG and NEPSY-II subtests.

Conclusions:

Children with ASD showed difficulties in narration, emotion recognition and in ToM. Emotion recognition and SG seem to be associated in ASD. This is plausible, since, for example, characters' emotional reactions are measured in SG, which support the idea of interplay between emotional understanding and narrative practice in ASD. In this study we did not find association between SG and ToM. Picture-based storytelling, which concentrates mostly on the actions in stories may not be connected with ToM. The role of ToM in picture-based narration should be critically considered in future studies.

73

108.073 The Multiple Measure Approach to Diagnostics: Examining the Complexity and Stability of Autism Symptomatology

M. Roberts[1], *Y. S. Stern*[1] *and L. H. Hampton*[2], *(1)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)Northwestern University, Evanston, IL*

Background: Despite the US Preventive Services Task Force recommendation to avoid early autism screening if concerns have not been raised by a parent or clinician (Siu & USPSTF, 2016), there is sufficient evidence that early autism screenings are beneficial to not only ensure earlier access to diagnosis for children from diverse backgrounds (Veenstra-VanderWeele & McGuire, 2016), but to also facilitate access to early interventions that can provide long-term benefits (Dawson, 2016). Any one autism screening measure does not result in optimal sensitivity or specificity, but recent studies have demonstrated that by combining screening measures we may be able to add positive predictive value and reduce stress and unnecessary assessments for children who receive false positive screenings (Khowaja, Robins, & Adamson).

Objectives: What is the positive predictive value of two common autism screening measures (STAT, MCHAT) (1) alone? (2) when either results in a positive? And (3) when both result in a positive?

Methods: A total of 158 toddlers were screened for an autism diagnosis after parent referral to a developmental clinic. Participants were 23% female, 30.6 months (sd=4.4) old, and 63% were ultimately diagnosed with autism. The STAT (Stone et al., 2004) and MCHAT (Robins, Fein, & Barton,1999) were administered at referral, and the ADOS was given as part of a full diagnostic evaluation 3 weeks later. Both screening measures were used to assess positive and negative predictive value of adding a second screening measure for autism screenings.

Results: The STAT alone resulted in a positive predictive value of 0.81 (SE=0.04) and a negative predictive value of 0.87 (SE=0.07). The MCHAT alone resulted in a positive predictive value of 0.84 (SE=0.05) and a negative predictive value of 0.52 (SE=0.06). Combing the STAT and MCHAT during screening resulted in significantly better positive predictive value (0.91, SE=0.04) than considering either the STAT or MCHAT (PPV=0.78, SE=0.04; p=0.027). Additionally, considering either the STAT or the MCHAT resulted in a greater Negative predictive value (0.90, SE=0.05) than combining the two measures (0.54, SE=0.06; p=0.000).

Conclusions: Multiple screening measures should be considered to optimize autism diagnostics after referral based on concern. Additional measures may be necessary to increase the positive predictive value of multiple measures in autism screenings while also optimizing negative predictive value. Recommendations for practice and future research will be discussed. By the time these data are presented, we anticipate a sample of 200 participants.

74

108.074 Multiple Measures of Language Development in Autism: Understanding Language Ability and Usage across Contexts

L. H. Hampton[1] *and M. Roberts*[2], *(1)Northwestern University, Evanston, IL, (2)Communication Sciences and Disorders, Northwestern University, Evanston, IL*

Background: Toddlers with autism demonstrate highly variable language abilities (Kjelgaard & Tager-Flusberg, 2001), and as such it has been recommended that each language phase of early development in autism be assessed using multiple sources of information (Tager-Flusberg et al., 2010). Although automated measures of child vocalizations has been found to be stable and valid for predicting future spoken language outcomes (Woynaroski, Oller, Kaysili, & Yoder, 2016), these measures do not provide specific detail as to why a child is communication or whom the communication is directed. Additionally, many measures across development are not predictive of skills 5 years later in children with autism. However, early observations of non-verbal communicative acts are significantly associated with later language, social, and communication outcomes (Charman et al., 2005).

Objectives: Coupled with the current recommendations for assessment of expressive language benchmarks in early development of autism, we consider 4 primary measures of language: child vocalizations, non-verbal communication observed during a semi-structured observation, vocabulary as reported by parents, and pragmatics observed during a naturalistic language sample. (1) How do language measures relate to and diverge from one another in toddlers with autism? (2) What profiles of autism emerge across measures?

Methods: A total of 46 toddlers (mn=33, sd=6 months; 40% minority race; Mullen T-score mean=26.9, sd=8.7) with autism have been assessed for baseline characteristics and language abilities across contexts. Toddlers were recruited in the Chicagoland area and were included as part of a larger randomized control trial based on the following characteristics: a) between 18 and 36 months of age, b) live with their biological mother and she was willing to participate in the study, c) a confirmed diagnosis of autism, d) no other developmental or sensory impairment diagnosis including hearing impairment, uncorrected vision impairment, identified genetic disorder, or seizure disorder, and English as the primary language spoken at home. Children were assessed across multiple contexts. Parents reported the number of different words the child understood and said (MCDI, Fenson et al., 2007). Total child vocalizations was extracted from day-long recordings at home using LENA^{TM} technology (LENA Research Foundation).

Results: All measures of early language and communication were moderately and significantly correlated (r=0.34-0.75; p<0.00), except for the relationships between observed non-verbal communicative behaviors and all other measures of language and communication (r=0.03-0.23, p>0.1). Across participants, 4 profiles of toddlers emerge: high performing toddlers across all measures (8%), low performing toddlers across all measures (24%), toddlers who perform low across measures except demonstrate many different gestures (35%), and toddlers who present with mixed profiles (39%). These profiles illustrate the added benefit of including gestures and vocalizations in language measures.

Conclusions: Due to the discrepancy between non-verbal communication and verbal communication measures, it is critical to consider both forms of communication in early intervention research with this population, especially due to the known relationship between non-verbal communication (above other indicators) and long-term language outcomes in autism (Charman et al., 2005).

108.075 Biological Measurement in Toddlers with Autism: Auditory Brainstem Responses in Relation to Autism Symptomology

M. K. Jones[1], *Y. S. Stern*[1], *M. Roberts*[1] *and L. H. Hampton*[2], *(1)Communication Sciences and Disorders, Northwestern University, Evanston, IL, (2)Northwestern University, Evanston, IL*

Background: Neurological underpinnings of autism have long been sought out to shed light on heterogenic presentations of autism symptomology. Auditory brainstem responses (ABRs), a measurement of sound processing, have been considered a biological measurement that may aid in understanding the relationship between neurological mechanisms and autism symptomology. Previous research has reported atypical

ABRs in children with autism, characterized by longer wave V latencies. In addition, longer wave V latencies and less consistent ABRs are related to low language levels in children who did not have autism. However, little research has considered the relationship between ABRs and characteristics of autism, such as language levels and sensory processing challenges.

Objectives: The current study aims to characterize the relationship between ABRs and autism symptomology, specifically autism severity, language skills and sensory processing challenges. We extend the understanding of the relationship between ABRs and autism to include toddlers with autism. The study explores (1) the relationship between ABRs and language development in children with autism and (2) addresses whether differences between ABRs are associated with sensory processing challenges in children with autism.

Methods: ABRs were measured for 20 children (6 females) with autism (*M*=33.5 months, *SD*=4.82). Autism diagnoses were verified based on Autism Diagnostic Observation Schedule scores (*M*=20.85, *SD*= 4.55). ABRs were recorded in response to a click and /da/ stimulus. Wave V latencies and response consistency measures served as ABR outcome measures. The Preschool Language Scales-5 (M=65.6, SD=12.92) and Macarthur-Bates Communicative Development Inventories (M=47.55, SD=71.41) were primary measures of language development. Sensory processing profiles were characterized by summing of scores on two questions specific to sensory processing on the ADOS, yielding a group with greater sensory processing challenges (n=11) and a group with lower sensory processing challenges (n=9).

Results: More consistent responses were positively related to number of *Words Understood* and *Words Produced* on the MCDI. However, correlations between ABR measures and ADOS scores as well as measures of language development revealed no significant relationship (see Table 1). Children with greater sensory processing challenges showed numerically longer wave V latencies, when compared to those with lower sensory processing challenges, however no statistically significant relationships were found between these sensory groups for either the click wave V latency (*t*(19)=-1.04, *p*=.315) and /da/ wave V latency (*t*(19)=-1.01, *p*=.331). Additionally, on average children with greater sensory processing challenges showed less consistent responses, however this group difference did not reach significance (*t*(19)=.72, *p*=.480)**.**

Conclusions: The current study furthers the understanding of the relationship between ABRs and autism symptomology by including toddlers with autism. Previously reported atypical ABRs in older children with autism may be a reflection of the neurological impact that autism has on the sound encoding process over time. Atypical ABRs may not yet be apparent in toddlers with autism. Future research should include larger sample sizes as well as more nuanced behavioral measures of sensory processing. Longitudinal approaches should be considered when studying ABRs in children with ASD in order to explore the developmental relationship between ABRs and autism symptomology.

76

108.076 Towards a Cumulative Science of Prosody in ASD

R. Fusaroli[1]*, E. Weed*[1]*, A. Lambrechts*[2]*, D. M. Bowler*[3] *and S. B. Gaigg*[4]*, (1)Aarhus University, Aarhus, Denmark, (2)City, University of London, London, United Kingdom of Great Britain and Northern Ireland, (3)Autism Research Group, City, University of London, London, United Kingdom, (4)City, University of London, London, United Kingdom*

Background: Individuals with Autism Spectrum Disorder (ASD) tend to show distinctive, atypical acoustic patterns of speech. These behaviours affect social interactions and social development and represent a promising non-invasive marker for the clinical features of ASD. Fusaroli et al (2016) conducted a meta-analysis quantifying acoustic patterns in the speech of people with ASD across 34 articles. The study indicated fragmentary findings with little overlapping across studies in the investigated clinical and acoustic features, methods and findings.

Objectives: To overcome these challenges, we need to identify the barriers to data-sharing across research groups and highlight the potential of multi-study analysis across corpora (i.e. what is known as mega-analysis in genetic studies).

Methods: We updated the pool of studies under consideration (now 51 studies). We contacted all corresponding authors to inquire about shareability of the data and where possible requested participant level data. We performed a Bayesian multilevel mega-analysis combining participant-level and population-level data (when the former was not available), explicitly modeling age, gender and language of the participants, as well as relations between acoustic features.

Results: 30% of corresponding authors answered and 10% provided at least some of the requested data (some answers still pending). The mega-analysis identified: i) strong effects of age, and genderbeyond what approximate group-level matching accounted for; ii) strong interdependence between acoustic features, which needs to be accounted for, and iii) larger effect sizes than the previous meta-analysis. Interdependence is partly due to the common and inappropriate use of mean and standard deviation to describe long-tailed distributions of (within-subject) acoustic features. In addition, we identify key concerns: confidentiality and ethical concerns; lack of consent from co-authors; temporal and economic costs of retrieving the data.

Conclusions: Mega-analyses allow for more nuanced and powerful analyses than meta-analyses. However, they require more sophisticated statistical techniques and access to more detailed data than currently shared either within scientific articles or directly by their authors. We outline recommendations to reduce concerns in sharing data, avoid statistical confounds between acoustic features and provide examples to run analogous Bayesian mega-analyses.

77

108.077 Use of Communicative Gestures in School-Age Children and Adolescents with Nonverbal Autism

D. Slušná[1]*, W. Hinzen*[2]*, J. Rosselló Ximenes*[3]*, B. Salvado*[4] *and A. Rodríguez*[5]*, (1)Universitat Pompeu Fabra-CIBERER, Barcelona, Spain, (2)Catalan Institute for Advanced Studies and Research (ICREA), Barcelona, Spain, (3)General Linguistics, University of Barcelona, Barcelona, Spain, (4)COADI, BARCELONA, SPAIN, (5)COADI, Barcelona, Spain*

Background: Language is estimated not to develop in at least 25% of individuals on the autism spectrum, forming its most severe and understudied end. More studies of nonverbal cognition and communication in this population are urgently needed. A specific research desideratum is to profile nonverbal communicative gestures, some subtypes of which have been shown to be closely linked to language development in both typical and atypical populations.

Objectives: We aimed to shed light on language-gesture relationships by profiling production rates and types of nonverbal communicative gestures in this nonverbal population. Furthermore, we explored the interaction of gestural profiles with different measures of nonverbal cognition and receptive language.

Methods: 19 subjects were recruited from special schools in the Barcelona area. The examiner-child interaction during the ADOS was analysed and coded for gesture use. Standardized measures of nonverbal IQ (as measured by Leiter-R) and nonverbal symbolic cognition (as measured by the

ComFor) were also taken. Language status as a recruitment criterion was confirmed in production and comprehension assessed through diagnostic interviews (ADOS and ADI-R), teacher informants, and standardized language tests (Peabody Picture Vocabulary Test-III, and CELF-5 where possible).

Results: All subjects proved to be testable and had comprehension scores commensurate to production ones. Overall rate of production of communicative gestures was low as well, although in a study run in parallel, mean-rank distributions of gesture rates in typically developing pre-verbal infants between 9 and 22 months were interestingly not significantly different. Qualitative gesture profiling however showed the complete absence of declarative gestures including distal pointing. Even distal imperative pointing was scarce at group level, as were iconic gestures, which were produced with an imperative purpose in a strictly embodied context. The proportion of bimodal communicative acts (gesture + vocalization) was significantly lower than gesture-only acts. 79% of individuals scored ≤70 in nonverbal IQ. The remaining 21% of individuals above the cut-off for intellectual disability (ID) did not show different tendencies in any of the measures taken in comparison with the rest of the sample with ID. Neither language nor gesture scores correlated with levels of nonverbal symbolic cognition, which in turn were significantly correlated with nonverbal IQ.

Conclusions: This study provides evidence that in a population of both productively and receptively non-verbal school-age children and adolescents, nonverbal gestural communication changes fundamentally along with language, though this change is not seen quantitatively in communication rates. In particular, gesture types relating to certain restricted forms of referentiality were not present in this group, which would be predicted from independent evidence of their language-relatedness. Moreover, the same linguistic and gestural profile is seen in both high and low nonverbal IQ scores. These results inform debate on how verbal so-called 'nonverbal' communication is, and the debate on the role of language in autism at large.

78 **108.078** Using Early Words to Communicate Intentions- a Comparison of Toddlers with Autistic Spectrum Disorder and Toddlers with Typical Development

A. Oren[1], *A. Mimouni-Bloch*[2,3], *S. Goldberg*[2] *and E. Dromi*[4], *(1)Constantiner School of Education, Alona Oren, Tel Mond, Israel, (2)Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, (3)The Pediatric Neurology and Developmental Unit, Loewenstein Rehabilitation Hospital, Raanana, Israel, (4)Constantiner School of Education, Tel Aviv University, Tel Aviv, Israel*

Background:

About 70% of toddlers with Autism Spectrum Disorder (ASD) present delayed emergence of speech, a difficulty attributed to several factors, among them their core deficit in communication. Restrictions in the use of early words for various communicative intentions is among the earliest manifestations of ASD. The majority of toddlers with ASD eventually develop functional speech, hence, a close analysis of the function of early words and how they are used in context is highly desirable.

Objectives:

1. To study how toddlers with ASD use their early words to convey various communicative intentions
2. To compare the contexts in which Typically Developing (TD) toddlers and toddlers with ASD at similar lexical levels produce words.

Methods:

24 mother-toddler dyads participated in the study: In nine dyads, the toddlers had been diagnosed with ASD prior to the study; in fifteen dyads, the toddlers were typically developing. Toddlers in the two groups were matched by lexical levels at study entry. Each mother–toddler dyad was video-recorded three times, during naturalistic interaction. The first recording took place when toddlers reached a productive lexicon of 40-70 different words. Two additional recordings took place in intervals of two months. All verbal productions were classified into four main communicative intentions (Declarative, Requesting, Protesting and Non- Communicative speech). The frequency of each communicative intention was calculated in order to characterize within-group developmental changes (i.e., the developmental rate of each participant), as well as differences between the two groups.

Results:

1. Toddlers with ASD were delayed in the emergence of first words, compared to the TD toddlers (31.5 months and 17 months, respectively). In addition, a greater within-group variability was found in the ASD group.

2. In contrast to our assumption, in both groups, the most common communicative intention was Declarative: throughout the three visits, words were used to describe or comment, rather than to request items or activities. However, a statistically higher percentage of declaratives was found among toddlers with TD ($F(2,21)=7.41$, $p<0.01$). Both groups rarely used their words to protest or to object.

3. In both groups, the majority of productions was directed towards the communicative partner. However, toddlers with ASD used words for non-communicative purposes more often than TD toddlers ($F(2,21)=14.81, p<0.01$).

4. A statistically-significant higher frequency of approach- withdrawal, crying and self- stimulation was noted in the ASD group (i.e. for withdrawal: $F(1,22)=1.14$, $p<0.01$). In the TD group, a statistically significant higher frequency of showing and pointing was recorded ($F(1,22)=4.65$, $p<0.05$; $F(1,22)=8.39$, $p<0.01$, respectively).

Conclusions:

While TD toddlers begin to talk with an already-established knowledge of the main communicative functions of words, toddlers with ASD seem to have only partial understanding, and they improve as they expand their productive lexicon. The relative paucity of verbal requests and protests in both groups might be attributed to the unstructured setting. In the ASD group, non- verbal behaviours may have served as an alternative to requests or protests. These findings bear both theoretical importance and practical implications for early intervention for toddlers with ASD.

109 - International and Cross-Cultural Perspectives
11:30 AM - 1:30 PM - Hall Grote Zaal

79 **109.079** A Mixed Methods Investigation of Korean Americans' Autism Awareness and Attitudes

***H. S. Lee** and C. Kasari, University of California, Los Angeles, Los Angeles, CA*

Background: Korea's ASD prevalence is a staggering 1 in 38, but two-thirds of children with ASD in Korea have never received special education services (Kim et al., 2011). Korean parents avoid registering their children as disabled due to stigma (Kim & Kang, 2003), and view ASD as a hereditary disorder that threatens marriage prospects for relatives (Grinker et al., 2012).
As 76% of Korean Americans are Korean-born immigrants (U.S. Census Bureau, 2004), it is likely that many Korean Americans still hold Korean values and cannot access ASD information in English due to language barriers.

Misconceptions and stigma may discourage Korean American families of children with ASD from obtaining services. ASD knowledge and attitudes in the Korean American community need to be assessed.

Objectives: The goal of this study was to examine the relationships between age at immigration and 1) ASD knowledge and 2) attitudes in the Korean American community.

Methods: A survey was administered to 159 Korean adults at Korean community organizations in Los Angeles, CA. The survey consisted of adapted versions of the Autism Knowledge Survey (Tipton & Blacher, 2014) and open-ended questions assessing autism attitudes (Grinker et al., 2015). The survey was translated into Korean.

Participants' responses on the Autism Knowledge Survey, containing 14 statements about ASD, were scored based on correctness. Open-ended questions included: 1) What words or phrases do you think of when you think of autism? 2) What causes autism? The causes listed by participants were coded into categories. Interrater reliability calculated using Cohen's Kappa, was high (range=.72-.93).

Results: A multiple regression was conducted to investigate the relationship between age at immigration and autism knowledge, controlling for having a family member with ASD, gender, age, education level, and income (see Table1). Earlier age of immigration, having a family member with ASD, and being a female were associated with higher levels of ASD knowledge. The model explained 23.9% of the variance (R^2=.24, F(6, 122)=6.40, p<.001), with age at immigration by itself explaining 13.7%.

Four themes were identified through inductive coding of participants' perceived causes of autism: 1) biological, 2) parenting, 3) postnatal (includes parenting), and 4) unsure. A logistic regression was performed to examine the relationship between age at immigration and the likelihood of listing parenting as a cause, controlling for demographic variables (see Table2). The model was statistically significant ($\chi^2(6)$=16.92, p=.010). It explained 25.3% of the variance and correctly classified 84.7% of cases. Individuals who immigrated to the U.S. at an older age were more likely to list parenting as a cause (odds ratio=1.08, p=.017). Examples from the qualitative responses included "parents' drug addiction", "parents' lack of love", and "reckless behaviors".

Conclusions: Koreans who immigrated later in life tend to have lower levels of ASD knowledge and incorrectly believe that parenting causes ASD. More resources in Korean are needed to raise Korean Americans' ASD awareness. Mass media and educational seminars may be effective ways of disseminating ASD information. Awareness campaigns should consider individuals' acculturation levels and incorporate cultural adaptations in the design and implementation.

80 **109.080** A Randomized Controlled Trial of PEERS in Israel: Behavioral and Questionnaire-Based Outcomes

*[1]. **J. Rabin**, S. Israel Yaacov[1,2], I. Mor Snir[2] and O. Golan[1,2], (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat-Shmuel, Israel*

Background: Social communication impairments are a fundamental characteristic of autism spectrum disorder (ASD). Social skills training groups are the most common intervention for individuals with ASD and has been found to be an effective treatment mode. The Program for the Education and Enrichment of Relational Skills (PEERS; Laugeson & Frankel, 2010) is an evidence-based parent-assisted social skills training program for teens with ASD, which has been well validated in North America. PEERS has been adapted for clinical use in Israel, with promising results in adolescents, as well as elementary school aged children.
Objectives: The main aim of the current study was to conduct a randomized control trial (RCT) of the culturally adapted version of PEERS in Israel. Whereas previous evaluations of PEERS have mostly relied on questionnaires, this study employed a live role-play assessment of conversational skills as an ecologically valid outcome measure, in addition to parent, teacher, and self-report questionnaires.

Methods: Forty one participants (2 females) aged 12-18 (M= 14.04, S.D=1.71), who were diagnosed with ASD without an intellectual disability (diagnoses validated using the ADOS-2) were randomly assigned to an immediate treatment (IT, n=20) or to a delayed control treatment (DCT, n=21) group and were evaluated at three time points: pre and post intervention for both groups, and 16 weeks after treatment completion for the IT group. Behavioral assessment was conducted using the *interested* condition of the Contextual Assessment of Social Skills (CASS; Ratto et al., 2011). This semi-structured role-play comprises a three minute conversation with a confederate. Trained, independent, blind judges coded adolescents' conversational skills, including question asking, topic changing, vocal expressiveness, gestures, positive affect, kinesic arousal, social anxiety, quality of involvement, and quality of rapport. In addition, we assessed the intervention outcomes using various parent, teacher and self-report questionnaires: Social Skills Improvement System (Gresham & Elliott, 2008), Social Responsiveness Scale (Constantino & Gruber, 2012), Quality of Play Questionnaire (Laugeson & Frankel, 2010), Test of Adolescent Social Skills Knowledge (Laugeson & Frankel, 2010) and Empathy Quotient (Baron-Cohen & Wheelwright, 2004).

Results: In accordance with previous studies, compared to the DCT, significant intervention effects were found in the IT group. These included improved parent reported social skills and reduced autism symptomatology, and improvements on teacher reported communication skills, teen social knowledge, number of social encounters, and teen reported empathy. The analyses of the behavioral data revealed that following the intervention, compared to the DCT group, IT participants asked more questions and showed an improvement on the overall involvement subscale as well as on the total score of the CASS (see Figure 1). Most of these gains maintained on a 16 week follow up. Improvement on CASS involvement in conversation positively correlated with teens' gains on social skill knowledge and parent reported social and communication skills' improvement.

Conclusions: The current study validates the efficacy of the adapted PEERS program for adolescents' with ASD in Israel. The ecological validity of the impact PEERS has on adolescents' social skills had been corroborated by a behavioral outcome measure.

81 **109.081** Adapting the Who Caregiver Skills Training Programme for Implementation in Ethiopia

***B. T. Gebru**[1], F. G. Bayouh[2], M. Kinfe[2], M. Tesfaye[3], Z. Yenus[4], T. WHO CST Team[5], C. Servili[5], E. Salomone[6], L. Pacione[5], A. Fekadu[2,7], C. Hanlon[8] and R. A. Hoekstra[1], (1)Department of Psychology, King's College London, London, United Kingdom, (2)Department of Psychiatry, School of Medicine, College of Health Sciences, Addis Ababa University, Addis Ababa, Ethiopia, (3)Department of Psychiatry, St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, (4)Joy Center for children with autism, Addis Ababa, Ethiopia, (5)Department of Mental Health and Substance Abuse, World Health Organization, Geneva, Switzerland, (6)Department of Psychology, University of Turin, Turin, Italy, (7)Department of Psychological Medicine, Centre for Affective Disorders, Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom, (8)Addis Ababa University and King's College London, Addis Ababa, Ethiopia*

Background: The World Health Organization (WHO)'s Caregiver Skills Training Programme (CST) for caregivers of children with developmental disorders (DD) aims to teach caregivers strategies to help them support their child's development and learning. The programme consists of nine group sessions and three home visits and can be delivered by non-specialists to suit low-resource settings. Ethiopia has a shortage of trained health personnel and severe lack of service provision for children with DD and their families (Tekola et al., 2016); the CST may be able to address this unmet need.

Objectives: Explore the perspectives of caregivers, professionals and other stakeholders to inform adaptation of the WHO CST to the Ethiopian context and culture.

Methods: Four different types of consultations were conducted: i) Stakeholder meetings were held in April 2015; July 2015; August 2016 and August 2017 soliciting input from local psychiatrists, psychologists, Non-Governmental Organisation representatives, and parents of children with DD. The first two meetings focused on local training needs and programme delivery considerations; the third meeting included draft CST training materials, allowing for targeted feedback on programme delivery and content; the forth meeting focused on implementing the programme in rural settings; ii) in August 2016 all draft CST materials were reviewed in detail by the research team; iii) during a Training of Trainers workshop in May 2017 feedback on CST content, length and intensity was received from Ethiopian Master Trainees; iv) two Theory of Change (ToC) workshops (de Silva et al., 2014) were conducted with professionals in Addis Ababa and community stakeholders in rural Sodo to map out how to implement the CST in rural Ethiopia.

Results: The participants of all consultations agreed that the CST programme addresses an urgent need and is relevant to the Ethiopian context. For the programme to be effective, acceptable and feasible in Ethiopia, several recommendations were made: i) there is a need for greater emphasis on psychoeducation, stigma, parental feelings of guilt, and expectations of a cure; ii) in light of context-specific beliefs on parenthood, the training should more strongly highlight the role caregivers can play to support their child's development; iii) consider the wider family context (e.g. grandparents) who may be able to support the child but could also be a barrier to progress if they resist the training; iv) some materials were too complex for caregivers with limited education. The stakeholder meetings and the ToC workshop in Sodo also highlighted the need for a community-based approach: The CST programme needs to be embedded into wider community initiatives to raise awareness about DD and reduce stigma, and needs embedding in a broader care framework, including referral pathways to other health services (e.g. for comorbid physical problems). A Theory of Change map was constructed showing the underlying pathways and the prerequisites and interventions needed to allow the CST to achieve its impact.

Conclusions: The WHO CST programme addresses a need in Ethiopia, but socio-cultural and contextual adaptations are likely to increase its relevance and impact. An adapted CST is currently being piloted in Ethiopia.

82 **109.082** Are Autistic Students More Stigmatized Than Other Types of Neurodiverse College Students?

***K. Gillespie-Lynch**[1], N. Daou[2], R. Obeid[3], S. Khan[4], S. Reardon[5] and E. Goldknopf[6], (1)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY, (2)McNeese State University, Lake Charles, LA, (3)Psychology, The Graduate Center, City University of New York, New York, NY, (4)College of Staten Island, CUNY, Staten Island, NY, (5)NA, Burlington, VT, (6)University of California, Los Angeles, Los Angeles, CA*

Background: A growing body of research focuses on assessing attitudes towards autistic college students to identify factors that may contribute to autistic people being less likely than students with most other disabilities to enroll in college, despite often high cognitive potential (Gardiner & Iarocci, 2014; Matthews et., al 2015; Wei et al., 2013; White et al., 2016). Little remains known about the degree to which autism is stigmatized relative to other disorders. Feldman and Crandall (2007) analyzed stigma towards 40 disorders by having participants rate vignettes consisting of a diagnostic label, core characteristics, and common representations of each disorder (e.g., an autistic *child*). They found that autism was one of the *least* stigmatized disorders. Heightened perceived rarity, dangerousness, and personal responsibility were associated with greater stigma. Given that their approach to creating vignettes made it impossible to distinguish between stigma arising from core characteristics, labels, and/or commonly co-occurring characteristics, cross-disability research is needed to identify targets of anti-stigma intervention.

Objectives: We compared stigma towards college students with different disorders and examined factors that contribute to stigma towards autism in particular.

Methods: College students from the U.S. (Male = 193, Female = 233) and Lebanon (Male = 86, Female = 98) were randomly assigned to rate labels (e.g., "college student with autism") or unlabeled vignettes describing 10 disorders (autism, eating disorder, social anxiety, addiction to pain medication, psychopathy, schizophrenia, learning disability, depression, mania, and ADHD). Separate vignettes depicted a withdrawn and a severe form of autism. Students completed an adapted Social Distance Scale (stigma assessment: Bogardus, 1933), a social desirability scale, and rated perceived dangerousness, rarity, and personal responsibility for each disorder.

Results: Only p-values ≤ .001 were considered significant. A repeated-measures analysis with stigma as the dependent variable and condition (label vs. vignette), country, and gender as independent variables revealed main effects of condition (labels were less stigmatized than behaviors) and gender (women endorsed less stigma than men) and interactions between stigma and country and stigma and condition. Across cultures, psychopathy and schizophrenia were the most stigmatized (see Table 1). Stigma towards the label "autism" was relatively low while stigma towards behaviors associated with autism was moderate. The only cross-cultural difference in stigma was toward the label "pain medication addiction". Regressions were used to examine predictors of stigma towards autism; stigma towards the label "autism" was associated with being male, greater belief that autism is dangerous, lower quality contact with autistic people, and lower autism knowledge. Only lower quality contact with autism was associated with heightened stigma towards the autistic college student vignettes.

Conclusions: Findings suggest that autism is less stigmatized on college campuses than disorders like psychopathy and schizophrenia which may be perceived as dangerous. Indeed, stigma towards the label “autism” was associated with perceived dangerousness. Stigma was consistently related to quality of prior contact with autism, suggesting that interventions which put autistic students into high quality contact with peers are powerful tools for stigma reduction.

83 **109.083** ASD Prevalence Study across Europe: Cross Sectional Study Design in Six European Countries

M. Posada[1], *A. M. Vicente*[2], *D. Schendel*[3], *C. Rasga*[4], *C. Café*[5], *A. Boilson*[6], *G. Oliveira*[7], *J. Fuentes*[8], *M. L. Scattoni*[9], *M. Efrim-Budisteneau*[10], *R. Kawa*[11], *L. Poustka*[12], *J. Xenia Kafka*[13], *P. Garcia-Primo*[14] *and R. Canal-Bedia*[15], *(1)Carlos III Health Institute, Madrid, Spain, (2)Instituto Nacional Saude Doutor Ricardo Jorge, Lisbon, PORTUGAL, (3)Aarhus University, Aarhus, Denmark, (4)Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisbon, Portugal, (5)University of Coimbra, Coimbra, Portugal, (6)Dublin City University, Dublin 9, Ireland, (7)Centro Hospitalar e Universitário de Coimbra - CHUC, Coimbra, Portugal, (8)Policlinica Gipuzkoa, San Sebastian, Spain, (9)Research Coordination and Support Service, Istituto Superiore di Sanità, Rome, Italy, (10)'Victor Babes' National Institute of Pathology, Bucharest, Romania, (11)University of Warsaw, Warsaw, Poland, (12)Child and Adolescent Psychiatry and Psychotherapy, University Medical Center Goettingen, Goettingen, Germany, (13)Medical University of Vienna, Vienna, Austria, (14)Instituto de Salud Carlos III, Madrid, Spain, (15)University of Salamanca, Salamanca, Spain*

Background: Although ASD prevalence studies have been carried out worldwide, the lack of mechanisms to obtain consistent and reliable information about ASD trends across European countries has been an important obstacle for making policy decisions at both the European Union (EU) and individual national levels. The Autism Spectrum Disorder in the European Union (ASDEU – http://asdeu.eu) project is a multi-site European collaboration with several objectives including estimation of ASD prevalence and developing harmonized prevalence strategies. Objectives: The presentation will describe preliminary results of the harmonized multi-site field survey strategy aimed at children ages 7-9 years old. It will reflect upon lessons learned regarding the field survey methods and their practical implementation in real-world settings.

Methods: Eight ASDEU partners (Austria, Bulgaria, Ireland, Italy, Poland, Portugal, Romania, Spain) are conducting the prevalence field survey based on school screening methods in defined geographic catchment areas. In general, the field strategy first involves a “Teacher Nomination Form” (TNF) for teachers to nominate possible ASD cases in their classes, followed by completion of the SCQ by parents (of teacher-nominated children or all children in the classroom), followed by a clinical evaluation of nominated children using the ADOS-G and other tools; two countries only used the SCQ in the screening process. The presentation will focus on 6 countries (Spain, Portugal, Italy, Romania, Poland, Austria) with most progress to date. The six countries provided data from 9 different catchment areas; 4 countries used both the TNF and SCQ and 2 used the SCQ only. Each country implemented minor variations in the screening approach to comply with ethical committee or school approvals; to manage the relationship between researchers, teachers and school authorities; and to manage the timing of parental consent.

Results: Portugal, Poland, Austria and Romania screened children in both special needs and regular schools; in Spain and Italy special needs children are integrated into regular schools. Portugal, Italy, Austria and Romania randomly selected schools in their study catchment areas; Poland randomly selected schools in one study area and all schools in 3 areas; Spain included all schools in its study area. The number of selected schools ranged from 47-217 per country; the participation rate of schools across countries ranged from 49%-100%; 252-498 teachers per country contributed to the first screening phase of 5,951-13,335 students per country applying the TNF (Spain, Portugal, Poland and Romania) and 10,872 and 13,628 students from Austria and Italy, respectively, only using the SCQ. From 1.3% to 3.0% of children were TNF-nominated in Spain, Portugal, Poland, and Romania. The clinical assessment phase of nominated children is ongoing.

Conclusions: This is the first comprehensive European action to estimate ASD prevalence. Use of the TNF and SCQ as school-based screening tools suggests the TNF is feasible to administer, well received, and provides greater coverage of the target population with lower implementation costs than the SCQ. Analysis will compare prevalence estimates derived from the TNF versus SCQ screening tools and results will inform the development of future ASD prevalence strategies across EU countries.

84 **109.084** Autism Spectrum Disorder (ASD): Disease Conceptualization and Parental Roles in Puerto Rico

M. Chavarria, *Osteopathic Medicine/Anthropology, Michigan State University, East Lansing, MI*

Background:
Autism Spectrum Disorder (ASD) is a broad category encompassing a wide array of developmental delays, social-interactional differences, and sensory sensitivities. It is a diagnosis most frequently made during childhood and carries implications not only for the ASD child, but also for the broader community network raising and supporting them. Recent anthropological research has shed light on the complexities of autism conceptualization as both disease and expression of neurodiversity; along with parental conceptualization of autism as constructed around dominant biomedical and sociocultural paradigms. However, studies remain particularly scarce concerning the context of Latin America.

Objectives:

This study investigates how ASD parents in Puerto Rico conceptualize autism. The specific aims of this project are as follows: 1) to investigate how ASD parents frame and construct their conceptualization of autism as a disease and as a marker of identity, 2) to examine the dynamics of communication between ASD parents and treatment providers, noting in particular how each work together to navigate social-interactional and behavioral differences and/or challenges within the health care and educational setting, and 3) to examine how ASD parents advocate for their child and how they may stratagize to gain access to limited resources amidst a struggling socioeconomic and political environment.

Methods:

This study consists of preliminary dissertation ethnographic fieldwork conducted in May 2017 in Puerto Rico. Participant-observation was carried out at ASD-focused educational/therapeutic facilities and ASD-related community events. After obtaining written consent, 50 semi-structured interviews were conducted in either English or Spanish (dependent on subject's preference) with ASD parents and/or ASD community members, including extended family, treatment providers, and ASD organization members. Data analysis is in progress as interviews are coded for subject-specific and general thematic narratives.

Results:

Pervasive themes among the subject narratives concerned health/educational department management, inefficient government bureaucracy, and the current economic crisis faced by Puerto Rico. The ASD community of Puerto Rico struggles with the discontinuity of patient care, as the responsibility for the health and welfare of ASD children transfers from the Health Department (ages 0-3 years) to the Education Department (ages

3-21 years). There is little to no public institutional support or structure available for ASD children that age out of the system. ASD parents are placed in a role of advocate for their child to access medical and educational resources. Subject interviews demonstrated this role to be particularly challenging for individuals who lack financial or social resources to access legal aid or navigate the complex system of care on the island. Puerto Rico is currently experiencing dire economic struggle and mass exodus of the population to mainland USA. Subject interviews reveal how this has further marginalized the island's ASD community within this nation in crisis.

Conclusions:

Puerto Rican ASD parents and community members both construct and work within complex disease conceptualizations of autism. How ASD parents are thinking about autism influences how they approach navigating a difficult medical, educational, and legal system in order to gain access to limited resources for their ASD children.

85 **109.085** Autism Spectrum Disorder Symptoms' Perception: The Case of Andean-Ecuadorian Population

P. Buffle[1]*, M. G. Granero*[2] *and E. Gentaz*[3]*, (1)SMAS Laboratory, University of Geneva, Ge, Switzerland, (2)Universidad Nacional de Rosario, Rosario, Argentina, (3)Psycholgy, University of Geneva, Geneva, Switzerland*

Background: Adult identification of red flag behaviours in young children, as potential symptoms of developmental disorders, may increase the probability of seeking professional attention for early detection, which has been associated with better health outcomes. Perceptions of symptoms may vary according to different cultures, locations, and socio-economic factors. Hence, studies conducted in different countries are important in order to identify particularities that need to be taken into account during the diagnosis process.

Objectives: Autism Spectrum Disorder's detection is understudied in low and middle-income regions, such as Latin America. To our knowledge no studies related to ASD symptoms' perception have been undertaken in Ecuador or neighbouring countries. This study's aim is to analyse ASD behaviours that can be identified by general adult population as worrying symptoms that may lead them to seek for professional help.

Methods: We interviewed 54 subjects between 18 and 80 years old from different social classes and educational backgrounds, living in the Andean region of Ecuador. The questionnaire includes questions based on items extracted from screening and diagnosis tools, such as M-Chat and ADOS. Interviewers were asked to evaluate different behaviours present in children from 18 to 36 months as "normal", "strange" or "worrisome" (semi-structured questions). Participants were also asked to give a possible cause associated to such behaviours (open-ended questions). Answers to possible causes could be classified in six main categories: (1) personality/circumstantial causes ("his character", "is angry", "is too young"); (2) developmental causes (autism, language difficulty or "disorder"); (3) physical deficits (mostly referred as auditory or visual difficulties); (4) psychological causes (emotional impairment such as "trauma" or "stress"); (5) rearing/familiar causes.

Results: Preliminary results indicate that, most of the proposed behaviours are considered strange and worrisome. However, certain red flags such as the presence of unusual finger movements are considered normal by more than 50% of interviewers. Furthermore, explanations to these behaviours are not always associated to developmental concerns, but can also be perceived as a sensory and physical impairment, or as difficulties inherent to the child's personality that could improve with time.

Conclusions: Those findings suggest that adult perception of symptoms in Ecuadorian-Andean population could influence families' decision to ask for help and for a professional evaluation, which may increase the age of diagnosis. Being aware of these perceptions may also be informative during evaluation for ASD, as information from parents may not always correlate with the observation of a trained evaluator. Finally, as some of the red flags are being perceived as physical impairments, and some of the children presenting ASD symptoms may be addressed to practitioners in these fields, these findings highlight the importance of education on ASD identification among all health practitioners.

86 **109.086** Bilingualism in Autism: Language Learning Profiles and Social Experiences

B. G. Digard[1]*, S. Fletcher-Watson*[1]*, A. C. Stanfield*[2] *and A. Sorace*[3]*, (1)University of Edinburgh, Edinburgh, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom of Great Britain and Northern Ireland, (3)Department of Linguistics, University of Edinburgh, Edinburgh, United Kingdom*

Background: It is estimated that at least half the world's population is bilingual or lives in a bilingual environment, and theoretically, so does half the world's autistic population. This proportion may be reduced, due to the common belief among parents and practitioners that bilingualism may induce a cognitive overload for a child with autism. However, numbers may also be increased due to the many autistic people who adopt language-learning as a hobby.

Bilingualism impacts how our brain represents languages, but the influence of knowing several languages goes further, and changes the way people relate to others, and lead their lives. This is of particular interest in the case of autism, where social interaction presents many challenges. A better understanding of the overlap between the social variations of bilingualism and autism could unveil new ways to support the social experiences of autistic people.

Objectives: This research aims to understand the language learning and social experiences of autistic people who speak, one, two or more languages. We ask how people with autism become bilingual, and how this impacts their social life.

Methods: To address this question, we developed the Autism and Bilingualism Census (ABC), an online survey designed for monolingual, bilingual and multi-lingual adults with autism. The ABC consisted of:

1. General demographic questions;
2. Questions about social experiences including social life habits (such as the making and maintaining of friends, or the online and in-person engagement in social activities), and quality of life;
3. A language history section, to record how respondents had acquired and were using each of their languages.
4. Open-ended questions to gather qualitative data on the way language learning and knowledge had influenced respondents' lives.

Results: A total of 294 autistic adults took part in the ABC, including 86 monolingual English speakers, 98 bilinguals, 56 trilinguals, and 54 respondents knowing 4 languages or more. Respondents collectively reported knowledge of 55 spoken or signed languages. By combining the quantitative and qualitative assessments, respondent profiles emerged including: being raised bilingually; learning languages at school; learning languages later in life out of a passion for languages. We will report further quantitative and qualitative data comparing social life habits and quality of life between these groups. Early emergent themes drawn from section (iv) of the survey suggest that autistic people feel that bilingualism offers employment and educational opportunities, strengthens their ability to communicate with others, and teaches new ways of thinking.

Conclusions: This is the first study describing the language history and social experiences of a substantial sample of bilingual and multilingual autistic adults. It provides valuable insight into how autistic people can encounter a new language, learn it, and use successfully it in their daily life.

87 **109.087** Burden in Latin American Families of People with Autism Spectrum

C. S. de Paula[1,2], *A. Rattazzi*[3], *S. H. Cukier*[3], *G. R. Cunha*[4], *D. Bordini*[5], *D. Valdez*[6], *C. Montiel-Nava*[7], *G. Garrido*[8], *R. A. Garcia*[9], *A. Rosoli*[10] *and M. Irarrazaval*[11], *(1)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (2)Departament of Psychiatry, Federal University of São Paulo, São Paulo, Brazil, (3)PANAACEA, Buenos Aires, Argentina, (4)Departament of Psychiatry, Federal University of São Paulo - UNIFESP, São Paulo, Brazil, (5)Departament of Psychiatry, Federal University of São Paulo, Sao Paulo, Brazil, (6)Universidad de Buenos Aires-FLACSO, Buenos Aires, Argentina, (7)La Universidad del Zulia, Gainesville, GA, (8)Universidad de la República, Montevideo, Uruguay, (9)Universidad de Chile, Santiago, CHILE, (10)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (11)University of Chile, Santiago, Santiago, Chile*

Background: Studies conducted in developed countries indicate high burden to families of people with ASD, as well as high costs related to the disorder. However, few data are available about the lived experiences of families affected by ASD in the Latin America. To conduct international research collaborations related to ASD in Latin America, in 2015, researchers from Argentina, Brazil, Chile, Uruguay, Venezuela and Dominican Republic constituted the Latin American Autism Spectrum Network – REAL.

Objectives: To describe the stigma and financial impact of having a family member with ASD in six Latin American countries.

Methods: Study design: cross-sectional study. Sample: 2.953 parents/primary caregivers from six Latin American countries (convenience sample) – 1,243 from Brazil, 786 from Argentina, 375 from Uruguay, 291 from Chile, 147 from Dominican Republic and 111 from Venezuela. Instrument: Spanish/Portuguese version of the AS Caregiver Needs Survey (developed by Autism Speaks, Global Autism Public Health Initiative) with information about family demographics, affected individual characteristics, service encounters and parent/caregiver perceptions, including stigma and financial impact of ASD.

Results: More than 1/3 of the caregivers from all countries declared feeling powerless (overall 38.9%; ranging from 17.0% in Venezuela to 51.3% in Brazil) and discriminated (overall 34.4%, ranging from 17.0% in Venezuela to 38.3% in Uruguay) for having a child with ASD. A smaller proportion (14.6%) said that having a child with ASD imposes a negative impact over them (ranging from 5.7% in Venezuela to 16.8% in Brazil) and only 8.5% were worried that other people would know that they have a child with ASD (ranging from 6.0 in Uruguay to 10.7 in Chile).

Overall, 48.7% of the caregivers reported negative financial impact related to ASD, ranging from 42.8% in Argentina to 62.6% in Dominican Republic. Almost half of the participants (47.4%) declared that members of their family had to cut down working activities (ranging 43.9% in Brazil to 54.1% in Venezuela) and 35.5% had stop working (ranging from 27.9% in Dominican Republic to 39.6% in Venezuela).

Detailed description of data by country will be provided during the IMFAR.

Conclusions: A significant proportion of caregivers of individuals with ASD in Latin American have complaints related to stigma, mainly discrimination, with variation among countries. Perceived stigma is associated with decreased access to mental health care services, and delayed treatment may impact prognosis in these population. Further researches on the stigma of ASD in Latin American communities is necessary to clarify potential causes of stigma, address differences among countries and plan adequate interventions.

Additionally, having a child with ASD was associated with substantial financial burden with almost 50% of participants reporting some sort of burden in this field in most of the Latin America countries. Knowing that high costs should be affecting people with ASD throughout life, efficient use of health and educational resources is urgent, particularly in countries with limited resources as Latin America one

88 **109.088** Caregiver Health Related Quality of Life (HRQoL) and the Regularity of Family Routines in Families Raising Children with Autism Spectrum Disorder (ASD) in the Western Cape: A Descriptive Study

M. Harty, *University of Cape Town, Observatory, Cape Town, South Africa*

Background:

Literature states that the health-related quality of life (HRQoL) of caregivers may be impacted by caring for children with Autism Spectrum Disorder (ASD). Aspects of family life reported to be affected by the presence of a child with ASD include caregiver social, physical & mental health, and family routines. However, limited research exists which describes factors affecting well-being in families raising children with ASD in South Africa, a middle-income country. Available published literature indicates a direct and positive relationship between the regularity of family routines and families' satisfaction with their family quality of life for families of children with ASD living in South Africa. However, no studies have been conducted which describe the relationship between the regularity of family routines, and the health-related quality of life of caregivers who are raising a child with ASD in South Africa.

Objectives:

This study describes the HRQoL of caregivers raising children with ASD and the regularity of their family routines and explores the associations between these two variables.

Methods: A descriptive survey design was employed. Twenty-four parents of children with ASD participated in the online survey. The 36-Item Short Form Health survey (SF-36) was used to determine caregiver's HRQoL and the Family Routines Inventory (FRI) to determine the regularity of family routines. These surveys, together with a demographic survey were distributed to parents via SurveyMonkey, an online survey tool.

Results:

Sub-scale and total scale data for 21 participants were analysed using descriptive and correlational statistics. Data were normally distributed. Data obtained from the HRQoL measure indicates that caregivers of children with ASD experienced low levels of energy/vitality (M=48.57, SD=5.55), emotional well-being (*M*=57.33, *SD*=5.14) role limitations due to emotional health (*M*=57.14, *SD* =8.70), and social functioning (*M*=61.50, *SD*= 9.19). There was a significant correlation between social functioning and general health [$r = 0.484$, $n = 21$, $p = 0.026$]; and between emotional well-being and energy/vitality [$r = 0.738$, $n = 21$, $p = 0.000$]. Data obtained from the FRI measure indicate that, of all the routines explored in the FRI, bedtime (*M*=0.72, *SD*=0.014)), and leisure routines (*M*=0.75, *SD*=0.718) are implemented with the least regularity. Workday (*M*=1.65, *SD*=0.491), leaving and homecoming (*M*=1.65, *SD*= 0.246)), child focused routines (*M*= 1.492 *SD* = 0.542) and mealtime routines (*M*= 1.546, *SD*= 0.445) occurred with more regularity. There was no significant correlation between participant scores on the FRI and the SF-36 [$r = 0.195$, $n = 21$, $p = 0.199$].

Conclusions:

This data indicate that ASD impacts on caregivers' emotional well-being and social functioning, which are correlated with parents' perceptions of their general health and levels of energy/fatigue. When implementing routine-based interventions in the home, clinicians should focus on embedding goals in routines which happen regularly. Surveys such as the FRI can be used to assist clinicians and families to identify these routines.

89 **109.089** Developing a Group Intervention Programme to Enhance Communication Interaction for Parents of Young Children with Autism Spectrum Disorder.

M. Harty[1] *and A. Osman-Kagee*[2]*, (1)University of Cape Town, Observatory, Cape Town, South Africa, (2)Western Cape Department of Education, Cape Town, South Africa*

Background:

Group-based parent training is a cost-effective way of providing early intervention in resourced constrained settings, such as South Africa. Parent training literature from developed countries indicates that parent training improves sense of parenting competence and self-efficacy. However, limited parent training programs have been adapted for implementation in low-and-middle income (LAMI) countries, and even fewer have been developed and evaluated within LAMI contexts. This presentation describes the development and piloting of a group-based parent training program to facilitate the communication development of young children with ASD living in South Africa.

Objectives:

Four objectives will be discussed in this presentation:

1) To describe the content development of the program

2) To determine the program's social validity by soliciting feedback from professionals.

3) To pilot the program with a group of parents to determine the program's effect on parenting self-efficacy.

4) To determine the program's social acceptability by soliciting feedback from pilot participants.

Methods: The content of the training program was developed based on an extensive literature search for communication strategies which have a positive impact on child communication development and could be taught to parents. Four strategies were ultimately selected namely: environmental arrangement, contingent responding, modelling and expansion of language and creating opportunities to talk. To determine the social validity of the program an expert panel of 5 professionals (2 psychologists, 2 speech language pathologists, and an occupational therapist) were asked to evaluate the program. They were given access to the program manual, power point presentation materials and the video modelling material. Twenty-five parents completed the program. Pre-and post-test measures of parenting self-efficacy were collected using the Parenting Sense of Competence Scale (PSOC). They were asked to provide both qualitative and quantitative information about the social acceptability of the program.

Results:

Professionals were asked to rate the program on a 4-point Likert scale across 4 criteria (the relevance of the content, the comprehensiveness of the content, the relevance of the teaching tools, and the relevance of the delivery methods). Professionals rated all criteria either a 3 or 4, indicating they felt that the program content was appropriate and relevant. Pilot data indicate that parents' average PSOC efficacy score after training ($M = 37.26$, $SD = 4.27$) was significantly higher (indicating higher self-efficacy levels) than their average PSOC efficacy score before training ($M = 34.27$, $SD = 3.48$), with $t(24) = -3.26$, $p < .003$, $d = 1.33$. Eighteen parents (75%) reported they felt confident to use these strategies in play and daily routines. Twenty-one (84%) parents felt confident they could use at least 1 of the strategies at home with their child. Contingent responding was the strategy that parents reported they were most likely to use at home.

Conclusions:

The feedback from parents and professionals indicated that the program content was appropriate within the South African context. Data from the pilot study indicates that the program can improve parenting self-efficacy levels. Future research should determine if the COMPASS program positively impacts on the way in which parents interact with their child.

90 **109.090** The Effect of a Group-Based Training Program on the Parenting Self-Efficacy and Parent CHILD Interaction for Parents of Young Children with Autism Spectrum Disorder

ABSTRACT WITHDRAWN

Background:

A substantial body of evidence documenting the positive effects of group-based parent training in developed country contexts. Benefits include, but are not limited to, decrease in parental stress, increasing in parenting competence and increase in family well-being. However, relatively little research in low and middle-income countries like South Africa investigates the benefits of group-based training for parents of children with Autism Spectrum Disorder (ASD). The COMPASS parent training program is a group based training program which has been designed for implementation in the South African context. This training program aims to enhance parents' ability to support their child's communication development by teaching parents four language facilitation strategies (contingent responding, modelling, expansion of language and creating opportunities to talk).

Objectives:

This study investigated the effect of the COMPASS program on:

- Levels of parenting self-efficacy
- Parents communication interaction with their child.

Methods:

A pre-test post-test quasi experimental group design was employed. Parent's self-efficacy was measured using two parent self-report measures, namely the Parenting Sense of Competence Scale (PSOC) and the Parenting Self-Efficacy Measuring Instrument (P-SEMI). Parenting interactions were video recorded and analysed by blind assessors using the Parenting Interaction with Children Checklist Observations Linked to Outcomes (PICCOLO).

Results: Thirty-one parents with a mean age of 34 (*SD* 5.51) participated in the training program. Using an alpha level of .05, a dependent-samples *t* test was conducted to evaluate whether parents post training self-efficacy scores differed significantly from their pre-training scores. The data indicate that the parents average PSOC score after training ($M = 88.36$, $SD = 11.06$) was significantly higher (indicating higher self-efficacy levels) than their average PSOC score before training ($M = 85.00$, $SD = 13.78$), with $t(30) = 44.48$, $p < .000$, $d = 5.65$. Furthermore, parents average PSEMI score after training ($M = 117.87$, $SD = 27.23$) was significantly lower (indicating higher self-efficacy levels) than their average PSEMI score before training ($M = 129.10$, $SD = 34.15$), with $t(30) = 24.098$, $p < .000$, $d = 2.81$. The analysis of the parent interaction scores (pre and post-test PICCOLO data) is ongoing, however these data will be included in the presentation. Preliminary parent interaction results suggest that parents are able to incorporate the targeted communication strategies in their interactions with their child.

Conclusions: A group-based training program, such as COMPASS, improved the levels of parenting competence (specifically parenting self-efficacy) and increased parent use of the target communication strategies during parent-child interaction. Further research is needed to establish additional benefits of group based parent training for parents living in low and middle-income countries such as South Africa.

91 **109.091** Challenges and Priorities in Families of Children with Autistic Spectrum Disorders in Dominican Republic

A. Rosoli[1], *R. Mendoza*[2], *A. Rattazzi*[3], *C. Montiel-Nava*[4], *R. A. Garcia*[5], *G. Garrido*[6], *S. H. Cukier*[3], *D. Valdez*[7], *C. S. de Paula*[8] *and M. Irarrazaval*[9], *(1)Projects, Organizacion Estados Iberoamericanos, Santo Domingo, Dominican Republic, (2)CAID, Santo Domingo, Dominican Republic, (3)PANAACEA, Buenos Aires, Argentina, (4)Universidad Latina de Panama, Panama, Panama, (5)Universidad de Chile, Santiago, CHILE, (6)Universidad de la República, Montevideo, Uruguay, (7)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (8)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (9)University of Chile, Santiago, Santiago, Chile*

Background:

In developing countries, access and quality to basic services can be a barrier to the developmental of an autonomous life especially for people with Autism Spectrum Disorders (ASD). These limitations are the ones that deal families with challenges to overcome to guarantee the quality of life of their children with the condition. In Dominican Republic there is a lack of information about the challenges and priorities experienced by caregivers of people with ASD. The access to this information can guide to political decision in order to strength or develop priorities services.

Objectives:

To identify the challenges and priorities experienced by caregivers of people with Autism Spectrums Disorders in Dominican Republic.

Methods:

This research was part of a study carried out in Latin America, and was led by specialists of Argentina, Brasil, Chile, Dominican Republic, Venezuela and Uruguay. AS for collecting information they used SEAN Caregiver Needs Survey. To administer the survey they used a digital platform. The National Committee on Bioethics in Health in the Dominican Republic approved the research project.

Results:

In Dominican Republic 152 surveys were collected, of which only 147 were completed. The three most important challenges presented by the families were: difficulties in communication (49.7%), difficulties in social interaction (42.2%), and problems behaviors (40.8%). As per challenges they identified: daily life skills (40.1%); concerns about safety/ notion of danger (34%); diet/feeding/feeding difficulties(21.1%); repetitive behaviors/ restricted interests/ insistence that things remain the same (11.6%); sleep problems (10.2%); health problems(6.8%); sexuality (9.5%); and sensory themes(6.1%).

For the largest number of families surveyed, the most compelling challenges were to get children to receive adequate education (80.3%), followed by having access to good health services for people with ASD (62.6%) and to ensure that the basic rights for people with ASD were protected (56.5%). The family's highest priority was to achieve better education services (75.5%), better health services (48.3%), better social services and social assistance (40.8%), more rights for individuals with ASD (33.3%), and greater awareness in the community (28.6%).

Conclusions:

The most significant challenges in Dominican Republic are related to opportunities in the context of education, health services and rights guarantees. In responding to priorities, families are again emphasizing the importance of education, health and rights services and adding social services and community's awareness to the condition. These results indicate the need to continued research about this situation in this country to create and support the development of policies and programs that can positively impact in the ASD population. More investigations to expand the sample are necessary.

92 **109.092** Changes in Knowledge on the Early Signs of Autism Among Female Community Health Volunteers in Nepal

R. Shrestha[1], *J. Barbaro*[2] *and C. Dissanayake*[2], *(1)La Trobe University, Melbourne, AUSTRALIA, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background: Early identification and diagnosis of autism opens pathways to early intervention (EI) services, known to have positive developmental outcomes. Yet, children in low- and middle-income countries (LMICs) are diagnosed much later, missing the critical window for EI. A major barrier to early identification and diagnosis is a lack of knowledge of the early signs of autism amongst parents and professionals, coupled with a lack of early screening and surveillance programs and tools, as well as an inadequate number of trained health professionals. However, raising awareness in local communities through cost-effective training, and task shifting to community health workers, has been widely advocated to promote early identification of autism and other developmental problems in LMICs.

Objectives: Our objective was to evaluate knowledge regarding social attention and communication development and the early signs of autism among Female Health Community Volunteers (FCHVs), in a semi-urban community of Nepal, prior to and following training on Social Attention and Communication Surveillance (SACS). An evaluation of training on their day-to-day practice with families within their homes was undertaken.

Methods: 60 FCHVs (Mean age: 44.6 years; range 29.0-61.5), 82% having at least 6-years education and 73% with >10 years work experience, attended a workshop on typical and atypical social attention and communication development in young children, the early signs of autism, and the monitoring of key behaviours relevant to identification of autism in infants and toddlers. This was part of an implementation of SACS-Nepal into the daily practice of FCHVs in the Kirtipur Municipality. They completed a survey to assess their knowledge before and after the workshop. They also evaluated the training immediately after the workshop and 6 months after commencement of implementation of SACS-N. Change in FCHVs' confidence in monitoring and referring children at risk of autism was examined.

Results: The majority of participants were aware of social attention and communication development prior to training, with the exception of items: 'eye contact', 'gesture use', 'imitation', 'pretend play', and 'using words'; only 37% reported knowing the word "autism". Following training, they demonstrated significant improvement in their knowledge across all relevant behavioural items, including autism symptoms and its prevalence, diagnosis, and intervention. More than 96% reported greater confidence in monitoring and referring young children developing autism.

95% of FCHVs reported a positive impact of training on their work at 6 months, and rated the ease of implementation of SACS-N into their current practice; 73.3% agreed that parents were comfortable with the SACS-N being undertaken in their homes. Among those FCHVs who referred children for a developmental assessment, 98% reported that parents found it beneficial to participate in the SACS-N.

Conclusions: The findings indicate the effectiveness of training in improving FCHV's knowledge and confidence in monitoring and referring young children at risk of autism. These findings have important implications for lowering the age of diagnosis in low-resource settings by developing cost-effective services to monitor, identify and refer children at risk of autism early within the community as part of standard practice with families.

93 **109.093** Characteristics of Children Receiving an Initial Diagnosis of ASD in Jerusalem

J. Koller[1]*, T. P. Gumpel*[2]*, R. Shalev*[3] *and M. Begin*[4]*, (1)Seymour Fox School of Education, Hebrew University of Jerusalem, Jerusalem, Israel, (2)Seymour Fox School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel, (3)The Hebrew University of Jerusalem, Jerusalem, Israel, (4)Hadassah Medical center, Jerusalem, Israel*

Background: Early access to services and better prognosis depend on the early diagnosis of ASD (Zwaigenbaum et al, 2015). Studies have consistently shown discrepancies in age of diagnosis between children from varying SES, cultural and ethnic backgrounds (Daniels & Mandell, 2013; Durkin et al., 2017). Recent studies have examined some of these issues in Israel, finding significant divergences between age of diagnosis across religious and ethnic groups (Raz et al, 2015; Davidovitch et al., 2013). The data in these studies have come from large national databases and provide important perspective on national trends. This broad vantage point necessarily sacrifices a nuanced understanding of local trends. Jerusalem is comprised of three primary groups of residents: secular and modern religious Jews (SMRJ), ultra-Orthodox Jews, and Arabs. The mixed nature of the city provides a unique opportunity to examine the interaction between demographics and clinical characteristics of children receiving a diagnosis of ASD.

Objectives: To examine the interaction between the sociodemographic and clinical characteristics of children receiving an initial diagnosis of ASD in a public child development center in West Jerusalem. Specifically, to understand factors associated with greater severity of autism symptoms as measured by the ADOS total score.

Methods: Chart review of every child diagnosed with ASD at Leumit Healthcare Child Development Clinic in West Jerusalem from 2011-2016. Information extracted included: age of referral, age of diagnosis, symptom severity, ethnicity, age and educational levels of parents, and presence of siblings with an ASD diagnosis.

Results: Of the 126 children diagnosed with ASD between 2011-2016, 37 were SMRJ, 69 ultra-Orthodox and 20 Arabs. Most were males (79%) with a mean age of diagnosis of 56.6 months (SD:31.9, range:13-172). While the general trend included fewer children being referred for evaluations as their age increased, it is noteworthy that after the age of 6 no Arab children were seen for an evaluation. Even more noteworthy is that all Arab children diagnosed with ASD were non-verbal.

A linear regression to predict autism severity (as measured by ADOS total score) shows that the linear combination of gender, ethnicity, current age, and relatives with ASD successfully predicted ASD severity (adjusted R^2 = 19.7, F (5, 98) = 6.04, $p < .001$), with lower age at time of referral (β = -0.38, $p < .001$) and Arab ethnicity (β = 0.20, $p < .05$) predicting the dependent variable. In contrast with previous findings, no differences were found between SMRJ and ultra-Orthodox Jews.

Conclusions: This examination of a public child development center in Jerusalem indicates that Arab children are likely to be referred for an evaluation only if they were under the age of six and non-verbal. Arab ethnicity, independent of child's age, is associated with more severe ASD symptomatology. Additionally, all children diagnosed at earlier ages are likely to be more severely affected by ASD. These findings bear significance regarding public health policy relating to awareness, screening and referral for ASD evaluations in sectors of Israeli society.

94 **109.094** Chinese Children with Autism Spectrum Disorder Show a Preference for Dynamic Geometric Compared with Social Images Which Is Also Associated with Symptom Severity

J. Kou[1]*, J. Le*[1]*, M. Fu*[1]*, Y. Zhang*[1]*, B. Becker*[1]*, L. C. Lee*[2] *and K. M. Kendrick*[1]*, (1)Life Science and Technology, UESTC, Chengdu, China, (2)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background: Simple behavioral paradigms quantifying differential attention towards social vs non-social stimuli using eye-tracking measures may be potential markers for young children with autism spectrum disorder (ASD). One promising paradigm is where fixation on dynamic geometrical

images (DGI) is compared to dynamic social images (DSI) with ASD children showing greater interest in the geometric patterns[1]. However, other paradigms showing reduced attention towards biological as opposed to non-biological motion have also generated some positive findings[2]. It is also unclear the extent to which these measures are effective in Asian as well as Caucasian cultures.
Objectives: In this preliminary study on Chinese children diagnosed with ASD compared with age- and gender-matched typically developing (TD) children, we have investigated whether there is a similar bias attention towards DGI and away from biological motion, and if this is associated with symptom severity.

Methods: 40 children were recruited for the study. The ASD group consisted of 22 children diagnosed with autism (DSM-V) while the TD group consisted of 18 children (ASD mean±SD age = 4.47±2.05years; TD =4.18±0.45 years, t=.600, p=.552). All ASD children were assessed using the Autism Diagnostic Observation Schedule-2 (ADOS-2). Additionally, parents of children in each group completed the Social Responsivity Scale 2 (SRS-2), Caregiver Strain Questionnaire (CSQ), Social Communication Questionnaire (SCQ), and Repetitive Behavior Scale Revised (RBS-R). Data from 4 children were excluded due to parental interference, spending <50% time looking at the images or technical issues. A Tobii T120 Eye Tracker (Tobii, Stockholm, Sweden; www.tobii.com) was used to measure eye fixations during two paradigms: (1) a DGI vs DSI visual preference paradigm where 30 different pairs of videos were presented simultaneously side by side, each for 2 s. (2) a non-biological vs biological motion paradigm with pairs of videos with point-light displays depicting animate (cat or human) vs scrambled control inanimate images (cat or human control)(8, 10s trials).

Results: Fixation count and duration for DGI vs DSI stimuli in the two groups was analyzed using a one-way analysis of covariance (ANCOVA) in ASD and TD groups with age as a covariate. A significant difference was found for both fixation count [$F_{2,33}$=6.01 p=.02] and total duration [$F_{2,33}$=6.85, p=.013]. Post hoc analysis with Bonferroni correction showed that children in the ASD group had a significantly greater proportion of fixations (p<.020, Cohen's d=0.89) and total duration (p<.013, Cohen's d=0.96) on DGI than TD children. Pearson correlation showed that fixation number and total fixation duration to DGI in ASD subjects were significantly associated with the social affect (SA) score on ADOS-2 (r = 0.60, p=.007; r=0.57, p=.011). On the other hand, no significant difference was found between the ASD and TD groups in the biological motion paradigm.

Conclusions: Our results demonstrate that eye tracking measures showing greater attention towards DGI may be a sensitive marker for ASD and ASD symptom severity in Chinese subjects.

95 **109.095** Coping, Distress, and Well-Being in Latina Mothers of Children with Autism

E. J. Lang[1]*, K. Martinez*[2] *and A. R. Neal-Beevers*[3]*, (1)Child Development in Context at The University of Texas at Austin, Austin, TX, (2)Weill Cornell Medicine, White Plains, NY, (3)The University of Texas at Austin, Austin, TX*

Background:

Autism Spectrum Disorder (ASD) represents a continuum of disordered behavior and deficits that can affect communication, social, intellectual, and developmental progression (APA, 2017). ASD is a complex diagnosis that can present many challenges and lifestyle changes for the parents of affected individuals, (Karst & Van Hecke 2012). While many studies have explored the mental and emotional implications of ASD on mothers, the majority of these studies have investigated participants from predominantly white, middle-to-upper class populations. Latinos constitute one of the fastest growing demographic groups in the United States (Pew Research Center, 2014), yet little research has examined coping and well-being in Latina mothers of children with ASD (Magaña, et al., 2006).

Objectives:

This study examined (1) how Latina mothers cope with their child's ASD and (2) if child ASD symptoms and maternal coping strategies are associated with maternal distress and wellbeing.

Methods:

Participants included 32 mothers of children with ASD who identified as Hispanic or Latina (see Table 1 for demographics). Mother completed online survey measures, including a demographic questionnaire and the following assessments: the Brief COPE to measure how mothers cope with parenting a child with ASD (Carver 1997), the Abbreviated Multicultural Acculturation Scale (Zea, et al., 2003), the Center for Epidemiological Studies Depression Scale – Revised (Radloff, 1977), the Social Responsiveness Scale – 2 (Constantino, 2012), and the Satisfaction with Life Scale (Diener, et al., 1985). The following variables were examined: problem-focused coping skills (active coping, planning, positive reframing) and emotion-focused coping skills (denial, venting, and behavioral disengagement), religion coping skill, maternal depression, maternal well-being, maternal U.S acculturation, maternal Hispanic acculturation, child maladaptive behaviors, and child ASD symptom severity.

Results:

Pearson Product Moment correlations were calculated to examine the relations between coping strategies, maternal acculturation, child maladaptive behaviors, ASD symptom severity, and maternal depression, and well-being (Table 2). Maternal depression was significantly positively correlated with utilizing behavioral disengagement and denial coping strategies. Maternal stress was significantly positively correlated with both child maladaptive behavior symptoms and ASD symptom severity. Maternal well-being was significantly positively associated with using religion as a coping mechanism and marginally positively associated with having higher scores on the Latina subscale.

Conclusions:

The current study found significant correlations between emotion-focused problem solving and greater maternal depression. These findings concur with previous research, showing that emotion-focused coping is associated with more negative maternal emotions (Benson, 2010). Also consistent with previous research, we found that heightened ASD severity and maladaptive behavior symptoms were related to significantly increased parenting stress. Interestingly, using religion as a coping strategy was associated with higher well-being in our mothers. While evidence supporting the use of religion as an adaptive coping strategy has been mixed (Benson, 2010), these findings suggest that using religion to cope may be adaptive for Latina mothers of children with ASD.

96 **109.096** Cultural Differences in Cognitive Flexibility and Autism Traits; A Comparison between Malaysia and the United Kingdom

M. de Vries[1]*, S. Abu Bakar*[2] *and E. Sheppard*[3]*, (1)Univerity of Nottingham Malaysia Campus, Semenyih, Malaysia, (2)School of Psychology, University of Nottingham Malaysia Campus, Semenyih, Malaysia, (3)University of Nottingham, Nottingham, United Kingdom of Great Britain and Northern Ireland*

Background:

Individuals with an Autism Spectrum Disorder (ASD) are reported to have daily life difficulties in cognitive flexibility. However, when measuring cognitive flexibility with experimental or clinical tasks, findings are inconclusive. Individuals with ASD seem to perform worse than typically developing (TD) individuals on the Wisconsin Card Sorting Task (WCST). Switch task findings are less clear, but performance on a Gender-Emotion Switch Task appears to be related to repetitive and stereotyped behaviour in children with ASD. Remarkably, Malaysian university students report more flexibility problems compared to students from the United Kingdom (UK) on the Autism Spectrum Quotient (AQ; attention switching subscale). It is unclear whether the higher AQ scores reflect an actual difference in cognitive flexibility, or a cultural difference in how individuals from these two countries fill in questionnaires.

Objectives:

The aim is to study whether there is a difference between students from Malaysia and the UK in cognitive flexibility when measured with a diverse range of tasks, and whether this can be explained by differing levels of autistic traits.

Methods:

A digital version of the Wisconsin Card Sorting Task (WCST), the Gender-Emotion Switch Task, the AQ, the Social Responsiveness Scale (SRS), and the Cognitive Flexibility Index (CFI) are administered to 120 students (60 from Malaysia and 60 from the UK). We expect that individuals in the UK who report more cognitive flexibility problems on the questionnaires will perform worse on the tasks. However, we expect that this relation will not be as clear in Malaysia. Moreover, we expect that Malaysian participants will report being less flexible on the AQ, SRS and CFI compared to UK participants, but we expect similar task performance in both countries.

Results:

Currently 28 individuals completed the study in Malaysia. Data collection in the UK will take place from November 2017 onwards. In the Malaysian subsample there were no significant correlations between the questionnaires and the task performance after Bonferroni correction. However, the correlation between the Switch Task (switch costs in error rate), and the SRS repetitive behaviour scale showed a trend towards significance $r = -.38$, $p<.05$, indicating that higher switch costs are related to less repetitive behaviour.

Conclusions:

The current study aims to unravel whether higher reported cognitive flexibility deficits in Malaysia compared to the UK reflect a difference in cognitive flexibility, or in answering tendency. In a broader sense, the aim is to determine whether western developed questionnaires that screen for ASD are applicable in Malaysia. If individuals in Malaysia score higher on ASD screeners in general, it might be indicated to heighten the cut off score. However, if the higher scores reflect an actual deficit or problem, this should be taken seriously. The next step is to study whether the findings are also replicable in individuals with ASD in both countries.

97 **109.097** Delivery of the Early Start Denver Model in Inclusive Vs. Autism-Specific Classrooms in a Community Preschool Setting in Australia: Implementation and Child Outcomes

G. Vivanti[1]*, C. Dissanayake*[2]*, E. Duncan*[3]*, K. Capes*[3]*, J. Feary*[3]*, S. Upson*[3] *and K. Hudry*[4]*, (1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Victorian Autism Specific Early Learning and Care Center, La Trobe University, Melbourne, Australia, (4)Victorian Autism Specific Early Learning and Care Center, Olga Tennison Autism Research Centre, Melbourne, Australia*

Background: The Early Start Denver Model (ESDM) is an early intervention approach developed and empirically tested in the USA across several implementation formats, including 1:1 delivery at the child’s home and at specialized (i.e. autism specific) center-based programs. More research is needed to examine feasibility and effectiveness of ESDM in different cultural and implementation contexts, such as group-based delivery in inclusive (i.e., mainstream) classrooms in non-US countries.

Objectives: We examined the feasibility, acceptability and preliminary effectiveness of adapting the ESDM for delivery in inclusive childcare classrooms in a preschool setting in Melbourne, Australia.

Methods: We randomly assigned 29 preschoolers with ASD to receive ESDM in classrooms that included mostly children who were typically developing (Inclusive setting group) or only children with ASD (Specialized setting). The two groups were compared on a variety of measures at baseline, and after at least 9 months of intervention.

Results: Family uptake into and retention within the trial were very good. Staff in both settings demonstrated similar levels of treatment fidelity. Children in both settings showed equivalent improvements across measures of communication, social engagement, imitation, and adaptive behavior and autism symptoms. Among those in the Inclusive setting alone, children with higher baseline social attention, as measured through eye-tracking, had better social communication outcomes.

Conclusions: Adaptation of the ESDM for group-based delivery to young children with ASD in an inclusive setting appears to be feasible, acceptable, and not less effective than delivery within specialized classrooms.

98 **109.098** Early Identification of Autism Using Social Attention and Communication Surveillance in Tianjin, China (SACS-C)

C. Wang[1]*, C. Dissanayake*[2]*, J. Barbaro*[2]*, G. Liu*[3] *and J. Wang*[3]*, (1)Nankai University, Tianjin, China, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Child Health, Tianjin Women and Child Health Centre, Tianjin Shi, China*

Background: Advances in understanding the early autism phenotype means that earlier identification and diagnosis of Autism Spectrum Disorders (ASD) is now possible within the second year of life. However, this knowledge is largely based on studies undertaken in the Western world and published in English, with findings rarely impacting practices in non-English speaking nations. This situation is exacerbated in developing nations and low resource communities. The Tianjin Women and Children's Health Center sought a reliable and valid tool suitable for use by doctors in community hospitals, with high sensitivity and specificity, to detect ASD at younger ages within its community-based three level childcare network.

Objectives: Our objective was to translate evidence-based knowledge in developmental surveillance for ASD, by training early childhood medical professionals on Social Attention and Communication Surveillance - Chinese (SACS-C) in a pilot program in Tianjin, China.

Methods: Two-hundred and fifty two (252) medical professionals were trained to monitor early signs of ASD at 12-, 18- and 24-months of age as part of their routine developmental checks of babies. Sixty-two community hospitals in six urban districts in Tianjin participated in the study with 10,516 children monitored between 12 – 24 months of age: 3,178 at 12-months; 3,758 at 18-months; and 3,580 at 24- months (between May 2013 and October 2014). Children identified at risk of an ASD were referred to the Tianjin Women's and Children's Health Centre for further assessments and diagnosis.

Results: Eighty-nine (89) children were referred, and the referral rate was 0.85%; however, only 56 children (63% of referred families) attended the follow-up assessment session. Of these, 24 met the criteria for ASD (43% positive predictive value), 24 had a developmental and/or language delay (43%), and 8 were typically developing (14%). 50% (n=12) of those who had developmental and/or language delay were diagnosed with ASD at 3 years of age, resulting in a final Positive Predictive Value of 64%. Combining the number of children assessed who had a classification of an ASD, with 64% of those who were referred as "at risk" and not assessed, results in an estimated rate of 1:200 children with ASD in the sample monitored using SACS-C.

Conclusions: The findings indicate that it is possible to translate evidence-based practice from one cultural context to another. Developmental surveillance of social and communication behaviors, which differ according to the age at which the child is monitored, enables the accurate identification of children at risk for ASDs between 12- to 24-months. Clearly greater education about the early signs of ASD for all primary health-care professionals is needed to increase awareness of these conditions more widely and to highlight the importance of earlier diagnosis and intervention.

99 **109.099** Economic Burden of ASD

R. Linertova[1], *L. Garcia Perez*[1], *P. Serrano-Aguilar*[2], *V. Ramos-García*[1], *V. Lemmi*[3] *and M. Knapp*[4], *(1)Fundación Canaria de Investigación Sanitaria (FUNCANIS), Santa Cruz de Tenerife, Spain, (2)Servicio de Evaluación del Servicio Canario de la Salud (SESCS), Santa Cruz de Tenerife, Spain, (3)London School of Economics, London, United Kingdom, (4)PSSRU, LSE, London, United Kingdom*

Background: Getting a better understanding of costs associated with ASD can help decision makers weigh the relative merits of different ways to utilize, prioritize and allocate available resources. Costing information is also valuable for planning longer-term projections of the resources needed to support people with ASD under a range of alternative scenarios.

Objectives: To estimate current annual economic burden related to ASD in Europe.

Methods: A bottom-up approach was used to estimate the cost-of-illness in 12 European countries (Austria, Belgium, Bulgaria, Denmark, France, Ireland, Italy, Poland, Portugal, Romania, Spain and UK), collecting data directly from individuals with ASD and their families through a web-based survey. We used the "prevalence-based method" to estimate the current annual economic burden of ASD in each country from the societal perspective, i.e. including direct and indirect costs. Direct costs comprised education services, inpatient hospital services, residential respite care and other health and social care services. Indirect costs were based on lost productivity due to morbidity in persons with ASD and due to cessation or reduction of working time by the informal caregivers (parents or other).

Data on services utilization were gathered through an anonymous web-based questionnaire formed by 38 questions, translated from English to 11 languages and adapted according to the particular features of the healthcare and education system of each country. The survey was launched in most of the countries in February 2017 and it is still on-going.

Results: By September 2017 we collected 1,367 complete responses, mostly from Italy (276), Spain (257) and France (245). The mean age of individuals with ASD described by respondents was 16.2 years and 55% of them were male. Responders were mostly parents (61% of responses), although persons with ASD also responded in some cases (8%).

Among health and social services, the services mostly used were from psychiatrists (40% in Belgium, 36% in Poland), psychologists (37% in France, 32% in Spain), general practitioners (30-40% in all countries) and speech and occupational therapists (15-30% in all countries). Among special educational services, the most commonly used services were from educational psychologists (47% in Spain, 36% in Italy), classroom assistants (34% in Spain, 31% in France), specialist teachers (58% in Italy, 39% in Portugal) and speech and language therapists at school (34% in Portugal, 30% in Poland). All surveyed resources were assigned a unit cost in local currency and a total annual cost per patient will be estimated.

Only a small part of adult individuals with ASD were currently employed (paid or unpaid). Absences from work will be evaluated and together with production losses and informal costs of care provided by unpaid caregivers will form the indirect cost per patient. Finally, total annual cost per patient will be calculated, which will be combined with prevalence data in each country to obtain the ASD economic burden.

Conclusions: This cost-of-illness study provides valuable information on economic burden of ASD across Europe, based on individual data using the bottom-up approach.

100 **109.100** Examining Stigma Towards College Students with Withdrawn and Disruptive Autism: Does the Label "Autism" Confer a Protective Effect?

R. Obeid[1], *N. Daou*[2], *A. Cosenza*[3], *S. Khan*[4], *E. Goldknopf*[5] *and K. Gillespie-Lynch*[6], *(1)Psychology, The Graduate Center, City University of New York, New York, NY, (2)McNeese State University, Lake Charles, LA, (3)College of Staten Island, City University of New York, Staten Island, NY, (4)College of Staten Island, CUNY, Staten Island, NY, (5)University of California, Los Angeles, Los Angeles, CA, (6)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background:

Stigma towards autism remains apparent in college communities (Matthews et al., 2015). Perhaps to avoid stigma associated with the label "autism", only *one-third* of students identified as autistic in high school identify themselves as autistic in college (Newman et al., 2011). This choice may often be counterproductive as research suggests that college students are more accepting of peers who exhibit autistic behaviors when they are labeled as autistic (Brosnan & Mills, 2016; Matthews et al., 2015). However, prior research examining attitudes towards college students who exhibit autistic behaviors has focused on students who exhibit *mild* symptoms of autism and has confounded the label "autism" with a description of characteristics of autism and an indication that the autistic student is exceptionally intelligent. Potential benefits of the label "autism" are also likely to vary across cultural contexts (Obeid et al., 2015).

Objectives:

We examined if the label "autism":

- is less stigmatized than behaviors associated with autism among college students in the U.S. and Lebanon,
- confers protective benefits by reducing stigma towards symptoms of autism,
- is described differently than unlabeled symptoms when participants are asked to define the student's condition after reading a label, an unlabeled vignette, or a labeled vignette.

Methods:

College students from the U.S. and Lebanon were randomly assigned to evaluate the label "college student with autism," unlabeled vignettes describing college students with mild/withdrawn and severe/disruptive autism, or labeled vignettes by using an adapted version of the Social Distance Scale (assessing stigma; Bogardus, 1933) and by defining "the student's condition." Reliability of qualitative coding exceeded 95%. Only *p*-values ≤.001 were considered significant.

Results:

A repeated-measures analysis with stigma toward mild and severe autism as the dependent variables and group (label, vignette, or label plus vignette), country, and gender as independent variables revealed that stigma was higher for severe than mild symptoms of autism, highest among participants assigned to unlabeled vignettes, lower among participants assigned to labeled vignettes (a protective effect of the label), and lowest among participants assigned to the label autism (*ps* < .001). The attached table displays results from qualitative analyses comparing labels to vignettes in both the US and Lebanon. Participants in the US were more likely to name other disorders (such as ADHD or social anxiety) in the autism vignette condition relative to participants in Lebanon. Participants in both countries were less likely to identify autism in the vignette depicting a disruptive student with autism relative to the label.

Conclusions:

Consistent with research examining stigma more generally (Link et al. 1999), symptoms of autism are more stigmatized than the label "autism". In line with our prior research (Obeid et al., 2015), participants in the US were more likely to confuse autism with other disorders. Findings suggest that the behaviors of autism are stigmatized (particularly disruptive behaviors), and many people are unaware of what these behaviors consist of, suggesting that if more college students were educated about the different levels of severity of autism, they might become more accepting of their neurodiverse peers.

---

101 **109.101** Experiences of Autism Diagnosis: A Survey of 293 Parents in Saudi Arabia

F. Alnemary[1], *F. Alnemary*[2], *A. Al Saud*[3], *M. Zakaria*[3], *A. Alotaibi*[3] *and H. Al Dhalaan*[3,4], *(1)Taif University, Taif, Saudi Arabia, (2)UCLA, Los Angeles, CA, (3)Center for Autism Research, Riyadh, Saudi Arabia, (4)King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia*

Background: Investigations about parents parents' experiences attaining autism spectrum (ASD) diagnosis for their children in Saudi Arabia are scarce (Alnemary, et al., 2017).

Objectives: To examine parents' experiences attaining autism spectrum (ASD) diagnosis for their children in Saudi Arabia.

Methods: A convenience sample of 293 parents of children with ASD completed an online survey about their experiences and opinions attaining the ASD diagnosis for their children.

Results: The results revealed that the median age of the child when parents first noted atypicalities was 2.0 years. The median of the delays that parents experienced before they sought professionals help and to attain the diagnosis for their child were 0.3 years and 0.5 years, respectively. Just over one of third of parents were satisfied with the overall diagnostic process. Satisfaction was linked with higher perceived collaboration with professionals, higher perceived helpfulness of received information, higher perceived helpfulness of post-diagnosis support, lower household income, and shorter delay to attaining the diagnosis for those who live in a major city.

Conclusions: Findings provide a valuable picture of an important group of families affected by ASD in Saudi Arabia, pointing the need to increasing ASD awareness and mandating early identification in Saudi Arabia. National efforts for conducting research are needed to better understand and manage the access and use of diagnostic and ASD services in Saudi Arabia.

---

102 **109.102** Exploration of Diagnostic Validity of Autism Diagnostic Interview-Revised (ADI-R) in Korean Population.

M. Oh[1], *G. Bong*[2], *I. H. Cho*[3], *Y. S. Lee*[4], *M. S. Kim*[5], *H. J. Yoo*[6], *D. W. Han*[7] *and C. Y. Shin*[8], *(1)Psychiatry, Seoul National University Bundang Hospital, Sungnam, Korea, The Republic of, (2)Psychiatry, Seoul National University Bundang Hospital, Seungnam, Korea, Republic of (South), (3)Dr. Cho's Child & Adolescent Psychiatric Clinic, Seongnam, Korea, Republic of (South), (4)Department of Physiology, Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of (South), (5)Department Applied Chemistry, Kyung Hee University, Seoul, Korea, Republic of (South), (6)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, The Republic of, (7)Dept. of Stem Cell Biology, School of Medicine, Konkuk University, Seoul, Korea, Republic of (South), (8)Department of Neuroscience, School of Medicine, Konkuk University, Seoul, Korea, Republic of (South)*

Background: Autism Diagnostic Interview-Revised (ADI-R) is a semi-structured investigator-based interview, which has been characterized as one of the gold-standards in the assessment of children and adults with autism spectrum disorder (ASD). Research on the use of the ADI-R and its applicability for accurate identification of individuals with ASD among non-English speaking populations is significantly limited.

Objectives: The objectives of the current study is to examine the validity of the Korean version of ADI-R to determine its efficacy in identifying individuals with ASD aged 24 months to 34 years.

Methods: We used pooled data from an ASD genetic study, clinical trial of social skills training, research on the development of early screening instruments, and clinical record of Seoul National University Bundang Hospital, from 2008 to 2017. The subjects were composed of individuals with ASD, their unaffected siblings, children referred as developmental delay, and typically developing children volunteered in community. The ADI-R were administered and scored by professionals having research reliability for the instrument. ADOS (Autism Diagnostic Observation Schedule) was also completed for the subjects referred for diagnosis. Other measurements for ASD symptoms were also administrated, including Social Responsiveness Scale (SRS), Social Communication Questionnaire (SCQ) and Korean version of the Childhood Autism Rating Scale (K-CARS). We applied the cut-off scores for K-CARS (cutoff=24) and SCQ (cutoff=12 for 48 months and over, 10 for below 47 months) based on the validity studies performed in Korea (Kwon et al., 2017; Kim et al., 2015). Clinical best estimate diagnosis of ASD was confirmed by two board-certified psychiatrists based on DSM-IV-TR and DSM-5^{TM} criteria. We classified the clinical diagnosis into ASD (including pervasive developmental disorder and Asperger's syndrome) *versus* non-ASD in the validity analyses. Statistical analyses were used t-test and Cohen's kappa for comparison of two groups.

Results: Total 1,073 subjects (age 93.48 ± 62.42 months, male = 760, female = 313)participated. The sensitivity and specificity of ADI-R were 99.39% and 84.65%, respectively. Positive Predictive Value was 92.50 (between 84.21 to 95.31) and Negative Predictive Value was 98.64 (between 97.96 to 100) in all age group (below 48 months and 48 months and over) and language levels (with or without verbal language). In Individual items within diagnostic algorithms of ADI-R showed significant differences in scores for all algorithm items between ASD and non-ASD group in all age and language subgroups ($p<0.05$). The agreement between ADI-R and other measurements in diagnosing ASD was good to excellent level (Cohen's kappa of K-CARS, SCQ and SRS with ADI-R = 0.78, 0.66, 0.65, respectively).

Conclusions: This study examines the diagnostic validity of the Korean version of the ADI-R. The Korean version of ADI-R showed high levels of sensitivity, specificity, positive predictive value, and negative predictive value in all age groups and verbal language levels. This study suggests that ADI-R might be valuable diagnostic instrument for individuals with ASD, across countries with different languages, cultural backgrounds and levels of awareness for ASD.

103 **109.103** Francophone Students with Autistic Spectrum Conditions: What Do They Have to Say Regarding Their School Inclusion Experiences?

M. Aubineau[1,2]*, J. C. Kalubi*[3] *and T. Blicharska*[4]*, (1)Université de Toulouse, Toulouse, France, (2)Université Toulouse Jean Jaurès, Toulouse, France, (3)University of Sherbrooke (Canada), Longueuil, QC, Canada, (4)Psychology, University of Toulouse Jean Jaurès, Toulouse, France*

Background: In the last years, an increasing number of students diagnosed with high functioning autistic spectrum disorders (HFASD) was able to attend mainstream high schools in both France and Quebec. Despite international studies and governmental recommendations to involve directly youth with HFASD in research, their own perspective is rarely taken into account in francophone research settings.
Objectives: Grounded in an ecological approach where participants are acknowledged as experts and knowledge co producers, our work aims at understanding how Francophone youth with ASD cope with mainstream education in high schools.

Methods: 26 teenagers with HFASD (13-17) collaborated in this research, in France (n=17) and in Quebec (n=9). They took part in semi-structured interviews and completed two questionnaires: the *Friendship Qualities Scale* (FQS) and the *Self-Perception Profile for Adolescents* (SPPA).

Results: ***Questionnaire analysis.*** Cluster analysis identified three profiles for friendship representations, mainly distinguished regarding two dimensions: companionship and help/aid from the friend. Three dimensions (social acceptance, close friends and physical appearance) differentiate self-perception into a 4-group typology (SPPA). Moreover, social skills training support (individual or group sessions) are correlated positive with friendship and self representations. ***Thematic analysis.*** Managing school sensory aspects, perceived immature behaviors from their peers and tiredness resulting from to important workload are identified as the main obstacles for their wellbeing in high school. On the contrary, being included in an intensive or international academic program, being driven by a passion or a clear objective and having a friend in the school environment appear to be important enablers for inclusion success. In France, the benefits *vs* limits of the teaching assistant' presence in class (between 12 to 20 hours per week) needs to be examined more closely, regarding the specific challenges for self esteem and autonomy. Although strongly dependent of peers' representations, the autistic identity is generally well lived and accepted, especially outside of high school. Finally, health and school system organization differences between France and Quebec appear to have few impacts on adolescents' well-being but raise a number of questions regarding provision support access inequalities for families, considering the frequent use of private services in France.

Conclusions: When France and Quebec are currently releasing their new national plans for autism, transition from adolescence to adult life will constitute one of the major challenges for youth with HFASD in the next few years and has to be anticipated as soon as possible. This preparation would allow the adolescents to gain autonomy and practical skills to understand their needs and strengths and be able to speak for themselves in a professional environment. Finally, our work highlights the urge for Francophone research and society to move from a deficit-led approach to a neurodiversity paradigm, promoting empowerment of individuals and considering ASD as a valuable contribution to human diversity.

104 **109.104** Impact of the Early Start Denver Model on the Cognitive Level of Children with Autism Spectrum Disorder: First Results of the European French-Speaking Countries Study.

M. Geoffray[1]*, M. J. Oreve*[2]*, M. Speranza*[3]*, S. Marignier*[4]*, S. Bahrami*[3]*, I. Massat*[5]*, V. A. Delvenne*[6]*, N. Georgieff*[7]*, S. Grisi*[8]*, A. Zelmar*[9]*, G. Tenant*[10]*, L. Bouveret*[11]*, S. Carlier*[12]*, A. Denis*[4]*, S. Touzet*[13,14]*, C. Schröder*[15] *and S. Sonie*[16]*, (1)child and adolescent psychiatry, CH le Vinatier CNRS UMR 5229 UCB Lyon 1, Lyon, France, (2)CH Versailles, Paris, France, (3)CH Versailles, Versailles, France, (4)HCL, Lyon, France, (5)Service de Pedopsychiatrie , Hôpital Reine Fabiola, National Fund of Scientific Research, Université Libre de Bruxelles, ULB, Brussels, Belgium, (6)Head of child and adolescent department, Hôpital Universitaire des Enfants Reine Fabiola, Université Libre de Bruxelles, bruxelles, Belgium, (7)CH le Vinatier, BRon, France, (8)CH le Vinatier, bron, France, (9)Pôle IMER, HCL, HCL, France, (10)Vinatier, bron, France, (11)HCL, bron, France, (12)CH Bruxelles, Bruxelles, France, (13)EA 7524 - Health Services and Performance Research (HESPER), Universite Lyon I, Lyon, France, (14)Hospices Civils de Lyon, Lyon, France, (15)CHU Strasbourg, strasbourg, France, (16)TED DEPARTMENT, Saint Jean de Dieu, Lyon, France*

Background:
Early intervention for autism spectrum disorder (ASD) in the European French-speaking countries is heterogeneous and poorly evaluated to date. Early intervention units applying the Early Start Denver Model (ESDM) for toddlers and young children with ASD have been created in France and

Belgium to improve this situation. It is essential to evaluate this intervention for the political decision-making process regarding ASD interventions in European French-speaking countries.

Objectives:

We will evaluate the effectiveness of 12 hours per week ESDM intervention on the cognitive level of children with ASD, over a 2-year period.

Methods:

The study is a multicenter, randomized controlled trial using a two-stage Zelen design. Children aged 15-36 months, diagnosed with ASD and with a developmental quotient (DQ) of 30 or above on the Mullen Scale of Early Learning (MSEL) are included. The sample size required is 180 children (120 in the control and 60 in the intervention group). The experimental group is scheduled to receive 12 hours of ESDM per week by trained therapists; 10 hours per week in the centre and 2 hours in the toddlers' natural environment (alternatively by the therapist and the parent). The control group is receiving care available in the community. The primary outcome will be the change in cognitive level measured with the DQ of the MSEL scored at 2 years. Secondary outcomes will include changes in autism symptoms, behavioral adaptation, communicative and productive language level, sensory profile and parents' quality of life. The primary analysis will use the intention-to-treat principle.

Results:

The first descriptive results of the cohort showed a very heterogeneous population on the MSEL DQ, nonverbal and verbal DQ, autism severity and behavioral adaptation. The protocol study is well accepted by the families, few data are missing and we have rare study discontinuation. We have very rare non-consent for children randomized in intervention group.

Conclusions:

This multicenter, randomized controlled trial is feasible and well accepted by the families. It will add information about the effectiveness of ESDM intervention in European French-speaking countries over a 2-year period. A follow-up study will also predict how this intervention reduces autism severity and the effects on schooling 5 years after the initial inclusion.

105 **109.105** Implementation of Social Attention and Communication Surveillance in Gunma, Japan (SACS-J)

E. Kezuka[1] *and M. Okuno*[2]*, (1)Faculty of Literature, Gunma Prefectural Women's University, Gunma, Japan, (2)School of Nursing, Gunma Paz University, Gunma, Japan*

Background: Autism Spectrum Disorders (ASDs) emerge over the first two years of life, and early signs of ASDs are recognizable during this period. In Japan, over 90% of children have health check-ups at around 18 months and 36 months in compliance with the Maternal and Child Health Act. The 18-month check-up, in particular, is expected to play a role in early identification of developmental disorders, including ASDs. Public health centres provide the check-ups, and nurses are responsible for screening infants to identify developmental risk. The Japanese M-CHAT is utilized in some community health check-ups, but it’s still the case that old-fashioned questionnaires and/or behavior observation lists, which are not adequate for screening for ASDs, are commonly used at many health centres in Gunma.

Objectives: The goal in this study was to confirm the feasibility and effectiveness of Social Attention and Communication Surveillance (SACS) as a Level 1 screening tool within two health centres in Gunma, Japan.

Methods: The original SACS items were used and modified to adapt to the mass check-ups undertaken in Gunma. The number of items were reduced to enable implementation within 10 minutes. Fine and gross motor items were also added and some items adapted to take into account cultural differences. In Gunma, the SACS-J was first implemented in Tamamura (270 births/year) and then in Shibukawa (500 births/year). As there were slight differences in the age at which checkups were undertaken across the two settings (Tamamura: 15-, 20-, 27-, and 38-months; Shibukawa: 10-, 18-, 24-, and 36-months), the SACS-J items were appropriately modified to suit each age.

Results: In Tamamura, a total of 166 infants were monitored longitudinally (2012 – 2015; the first cohort born in 2011), and attended the 15- and 20-month check-ups. Infants were classified into 4 groups at 20 months, depending on their failure on more than 2 items at each age. 12 infants (7.2%) failed more than 2 items at both 15 and 20 months, and their low pass rates lasted through to 27 months. In this group, 4 infants were diagnosed with ASD (around 2%), and the other 8 infants comprised: 1 severe Developmental Delay, 1 ASD suspected, 1 ADHD suspected, and 5 infants who had caught up developmentally by 38 months. In Shibukawa, a total of 271 infants were monitored (2015 – 2017; the first cohort born in 2014), and attended the 18- and 24-months check-ups. 23 infants (8.5%) failed more than 2 items at both 18 and 24 months. 69.6% of these infants were considered to be at risk for ASD and 30.4% were not considered to be at risk by clinical psychologists.

Conclusions: Successive failure (at two ages) in SACS-J items indicates serious risk for ASD indicating that continuous developmental surveillance within the first 2 years of life is successful in identifying ASD in young children in two low resource community settings. The feasibility and effectiveness of implementing the SACS in a different cultural context was confirmed.

106 **109.106** Implementing Esdm in Africa - Is Caregiver Coaching Acceptable in South Africa and Which Joint Activity Routines Can We Target?

L. Franz[1,2,3]*, K. Ramseur*[1]*, J. Guler*[4]*, N. Shabalala*[3,5]*, N. Seris*[3,5]*, G. Dawson*[6] *and P. J. de Vries*[3]*, (1)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (2)Duke Global Health Institute, Duke University, Durham, NC, (3)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (4)Clinical Child Psychology Program, University of Kansas, Lawrence, KS, (5)Department of Psychology, University of Cape Town, Cape Town, South Africa, (6)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background:

A small but expanding evidence-base from low-and middle-income countries demonstrates that caregivers can be engaged to deliver early ASD intervention. In caregiver-mediated early ASD intervention, caregivers are taught strategies to embed learning in everyday activities with their child. To date, there are no published studies in sub-Saharan Africa regarding the acceptability of a caregiver coaching approach. In addition, limited African data exist about narratives of joint activity routines between young children with ASD and their caregivers.

Objectives:

In this formative study, we assessed the acceptability of a caregiver coaching approach and examined descriptions of joint activity routines.

Methods:

Focus groups and in-depth interviews were carried out with a lower socio-economic, multi-cultural group of 28 caregivers of young children with ASD in Cape Town, South Africa. In addition, four in-depth interviews with 6 caregivers of children with ASD who received two pilot sessions of parent coaching (1 in-clinic and 1 in-home) were conducted. Data were translated, transcribed, and coded using content analysis.

Results:

Caregivers who received pilot coaching sessions found the approach acceptable and noted that both they and their children had acquired skills as a result. For example, some caregivers noted they were able to use strategies to capture their child's attention, and reported that their children had gained personal independence/activities of daily living skills such as feeding themselves with a spoon or brushing their teeth. They described low-resourced home environments, with limited living space and access to child play materials. Caregivers reported regularly engaging in joint activity routines with their young children with ASD. Some but not all caregivers routinely joined in play with their child and intuitively incorporated learning opportunities into joint activity routines. Caregivers were aware of child affect and social cues. Multiple child play partners, particularly in sensory social routines, including grandparents, siblings, aunts, and uncles were reported by caregivers. Daily routines that occurred on a regular basis included meal and bath time. Some caregivers noted that their children were aware of steps of the routine and would participate, for example they would help lay the table and say the evening prayer before dinner time.

Conclusions:

Descriptions of joint activity routines and perception of the acceptability of a caregiver coaching approach in South Africa suggest that caregiver-mediated interventions may be feasible in low-resourced South African settings. The challenges of in-home implementation given limited resources, however, require careful consideration.

107

109.107 The Contextual and Policy Landscape for Caregiver-Mediated Early Intervention in South Africa

L. Franz[1,2,3]*, J. Guler*[4]*, K. Adewumi*[2]*, N. Seris*[3,5]*, N. Shabalala*[3,5]*, M. Viljoen*[3]*, G. Dawson*[6] *and P. J. de Vries*[3]*, (1)Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, (2)Duke Global Health Institute, Duke University, Durham, NC, (3)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (4)Clinical Child Psychology Program, University of Kansas, Lawrence, KS, (5)Department of Psychology, University of Cape Town, Cape Town, South Africa, (6)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC*

Background:

To ensure an intervention developed in one setting can be implemented in a new often dramatically different setting, a thorough understanding of the contextual landscape is essential. In South Africa, a middle-income country, marked by extreme economic and health disparities, little is known about the perspectives of caregivers of young children with ASD on contextual factors they deem important in early ASD intervention. Also, little is known about the perspectives of policymakers regarding which governmental/non-governmental sector and what type of provider would be most feasible and sustainable to deliver an early ASD intervention in South Africa.

Objectives:

Here we set out to investigate caregiver perspectives about contextual factors of importance to them, and policy-maker perspectives about policy and implementation of early interventions for ASD in South Africa.

Methods:

Focus groups and in-depth interviews were carried out with a lower socio-economic, multi-cultural group of 28 caregivers of young children with ASD in Cape Town, South Africa. In addition, eight in-depth interviews with District and Provincial leaders in the Departments of Health, Education, and Social Development and the Non-Profit sector in the Western Cape Province of South Africa were conducted. Data were transcribed and coded for emerging themes using content analysis.

Results:

Eight contextual factors including culture, language, location of treatment, cost of treatment, type of service provider, support, parenting practices, and stigma, emerged as important to caregivers of young children with ASD. Caregivers reported a preference for an affordable, in-home, individualized early ASD intervention, where they had an active voice in shaping treatment goals. Some caregivers were distrustful of community health workers. Challenges associated with ASD-related stigma were identified. Caregivers noted that they felt blamed for their child's behavior and that their children were often labeled as "naughty". ASD-related stigma was compounded when caregivers were immigrants or refugees. Policy stakeholders identified a national policy potentially relevant to early ASD intervention, reported the need for collaboration between sectors and highlighted the importance of integrating early ASD intervention into existing platforms of care. Provider capacity-building, increased ASD awareness and stigma reduction emerged as key areas of need. Community health workers, early childhood development workers and parents of children with ASD were identified by policy-makers as non-specialist workers who could deliver an early ASD intervention.

Conclusions:

Large-scale implementation of early ASD intervention in South Africa will likely require careful integration of parent/caregiver preferences with low-cost, sustainable funding approaches, in order to ensure a contextually-appropriate strategy within a collaborative multi-sectorial plan, preferably embedded into existing national policies.

108

109.108 Incidence of Comorbidities in Children with Neurodevelopmental Disorders in a University Teaching Hospital, Lagos, Nigeria

T. A. Fagbayi[1] *and J. Okpuzor*[2]*, (1)University of Lagos, Lagos, Nigeria, Lagos, Nigeria, (2)Cell Biology & Genetics, University of Lagos, Nigeria, Nigeria*

Background:

Comorbidities associated with neurodevelopmental disorders in children frequently complicate the course of diagnosis and treatment. These conditions may appear in form of medical, psychiatric or other neurodevelopmental problems occurring at different frequencies in different disorders. In recent times, the term 'comorbidity' has gained popularity in the field of neuro-paediatrics, with the increasing recognition that many conditions are rarely present in isolation.

Objectives: The present study aims to investigate the occurrence of comorbid conditions in children with neurodevelopmental disorders

Methods: Medical records of the neuro-peadiatric clinic were obtained from the health records department of the Lagos University Teaching Hospital (LUTH) and analyzed using statistical methods. Diagnoses of the disorders were done using the DSM criteria while the diagnostic codes were deciphered using the International Statistical Classification of Diseases & Related Health Problems (ICD).

Results: A total of 845 records were obtained with a male: female sex ratio of 1.3:1 (470 males and 375 females). An incidence of comorbid conditions were observed in 44% of the cases revealing cerebral palsy (CP), Down syndrome (DS), seizure disorder and Autism were the major neurodevelopmental disorders. Cerebral palsy presented with the highest frequency of comorbid conditions of 62.2% followed by autism (57.14%) and DS (55.3%) while seizure disorder had the least incidence of comorbidities (33 %). However, attention deficit hyperactivity disorder (ADHD) was the most prevalent comorbidity associated with autism, CP was the most prevalent in seizure disorder, while developmental delay and convulsions were the most common in DS and CP respectively. Convulsions, developmental delay, speech and language disorder and birth asphyxia were the most common comorbidities taking the four neurodevelopmental disorders taken together.

Conclusions: It is apparent that most neurodevelopmental disorders are closely phenotypically linked as have been strongly suggested that neurodevelopmental disorders lie on a spectrum. Understanding the pattern of the incidence of medical comorbidities would aid better-staged diagnosis and interventions, and also improved epidemiological profiling of the disorders.

109 **109.109** Knowledge and Awareness of Autism Amongst Somali Parents in the United Kingdom

A. M. Hussein[1], E. Pellicano[2] and ***L. Crane**[1]*, *(1)Centre for Research in Autism and Education, UCL Institute of Education, University College London, London, United Kingdom, (2)Macquarie University, Sydney, Australia*

Background: Despite rapid growth in autism research over the past few decades, little attention has been given to understanding autistic individuals in minority ethnic communities – placing them at serious risk of being under-recognised and under-served. The current study focuses on autism among the UK Somali community – one of the largest and most established communities in Europe, and one of the many immigrant groups affected by autism. While emerging work has examined UK-based Somali parents' experiences of accessing an autism diagnosis for their children, little is known about parents' knowledge and awareness of autism more broadly.

Objectives: The aim of the current, qualitative research was to examine knowledge and awareness of both typical and atypical development amongst UK-based Somali parents (of both autistic and non-autistic children); a minority group that has, until relatively recently, been neglected in autism research.

Methods: 32 parents (30 women, 2 men; from separate families) participated in this research, including 16 parents of autistic children (M age = 39.56 years) and 16 parents of non-autistic children (M age = 39.50 years). Parents were presented with seven vignettes, each of which described a child with typical or atypical development (including autism, attention deficit hyperactivity disorder, or global developmental delay). After reading each vignette, parents were asked to reflect on whether the behaviours described were similar to those of other children they knew; if not, they were asked whether they have a 'name' for these behaviours and to consider what might cause them. This was complemented by more general questions regarding how children develop as they grow older. Parents of autistic children were also asked to reflect on their own children's development.

Results: Interview data were analysed using thematic analysis. Four key themes were identified: (1) 'Somali people don't understand', reflecting a general lack of understanding of autism within the Somali community and the prejudice and discrimination that might ensue; (2) 'Differences between Somalia and the UK', reflecting how many parents felt autism did not exist in Somalia and the lack of provision available for autistic children in Somalia; (3) 'Strong reliance on faith', in enabling parents to understand and accept their children's diagnosis; and (4) 'Ways to support Somali families of autistic children in the UK', to promote awareness of autism and build capacity to better support families of children on the autism spectrum.

Conclusions: The parents of autistic children in this study highlighted the difficulties they experienced with understanding autism, as well as barriers in accessing help and support; some of which were unique to the Somali community, and some that were perceived to be more general across ethnic groups. Promoting acceptance of autism within the Somali community – in the UK and internationally – seems to be a key target for intervention efforts.

110 **109.110** Latino Caregivers' Facilitators and Recommendations for Accessing an ASD Diagnosis and Services in California

***F. Reinosa Segovia**[1]*, *N. Muldoon[2], L. Hughart[2], J. Goldblum[3], P. Luelmo[4] and C. Kasari[2], (1)UCLA, Hawthorne, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)UCLA, Westwood, CA, (4)Special Education, San Diego State University, San Diego, CA*

Background: Numerous barriers have been associated with the challenges involved in obtaining comprehensive early intervention for children with Autism Spectrum Disorder (ASD). Specifically, several studies have found that race, ethnicity, and socioeconomic status have been associated with a delay in the diagnosis of ASD and access to services (Liptak et al., 2008; Mandell et al., 2005; Parish et al., 2012). Latino children are typically diagnosed at a later age and receive poorer quality of health care compared to their white peers (Mandell et al., 2009; Magaña et al., 2013; Magaña et al., 2016; Parish et al., 2012). Furthermore, few studies have thoroughly examined the cultural relevance of ASD interventions to meet the needs of Latino children with ASD and their families. The present investigation examines how sociocultural factors influence Latino immigrant families' navigation efforts of California's Health Care System.

Objectives: This study's primary objective was to examine Latino Spanish-speaking caregivers' experiences that facilitated a prompt ASD diagnosis for their children, as well as caregivers' recommendations on how to navigate systems of care more efficiently.

Methods: Participants were 12 Latino caregivers for children with autism (m_{age} *(SD)* = 38.9 (5.2), n = 11 females). Two focus groups and three interviews were conducted across two sites in California. The aim was to collect information regarding caregivers' experiences in gaining access to an ASD diagnosis and services for their children. Eligible participants must have had a child between the ages of two and eight who had received a diagnosis of ASD within the last two years. All participants reported a low income or little access to resources at the time of recruitment. Interviews and focus groups were led by Spanish-speaker moderators, audio-recorded, and later transcribed into Spanish. Guided by the principles of thematic analysis, transcripts were open-coded to elicit major themes.

Results: Analyzed data revealed eight overarching themes concerning accessibility to an ASD diagnosis and obtaining ASD-specific services. These themes were grouped into two overarching domains: process facilitators and caregivers' recommendations. Four themes were identified for caregiver experiences after securing evaluations and services for their children: (a) caregiver proactivity, b) identification of ASD symptomology, c) caregiver support, and d) resource accessibility. Specifically, caregivers consistently noted advice and support from friends, service providers, medical providers, and other paraprofessionals that proved essential when searching for diagnoses and services. Qualitative data also revealed caregiver recommendations for successfully navigating healthcare systems and seeking an ASD diagnosis: obtaining knowledge regarding ASD symptomatology and services, standardizing more efficient ways to disseminate information, identifying ASD red flags in a timely manner, and accessing comprehensive evaluations and early intervention services.

Conclusions: Disparities persist in access and utilization of ASD quality care among families from low-SES and ethnic minority backgrounds. In this study, immigrant caregivers' provided several process facilitators and recommendations as a means to gain access to comprehensive evaluation services, and secure early intervention services for their children. Future research should attempt to incorporate these findings into evidence-based intervention programs that can be best disseminated and implemented in community settings.

111 **109.111** Linking Knowledge and Attitudes: Determining Neurotypical Knowledge about and Attitudes Towards Autism

M. Falkmer[1], *R. L. Kuzminski*[2], *J. Netto*[3], *J. Wilson*[3] *and T. Falkmer*[4], *(1)School of Occupational Therapy and Social Work, Curtin University, Perth, Western Australia, Australia, (2)School of Occupational THerapy and Social Work, Curtin University, Perth, Australia, (3)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (4)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia*

Background:

Following an on-line discussion with the autism community in Australia about areas of research they prioritise, the responses frequently reported experiences of being misunderstood and meeting numerous misconception about autism in society. These experiences may be a result of stigma. Stigma contains three key elements; knowledge issues (ignorance); attitudinal issues (prejudice), and behavioural issues (discrimination). Therefore, knowledge and attitudes may contribute to how autistic people are treated, and are important to identify. However, there is a paucity of studies exploring attitudes toward autism and existing studies have reported inconclusive results, often based on small sample sizes. In addition, no studies have been conducted in Australia.

Objectives:

This study and aimed to explore neurotypical knowledge about, and attitudes towards, autism and to identify factors that influenced these attitudes.

Methods:

Co-produced with an autistic researcher, a cross sectional on-line survey was distributed. One section of it explored attitudes using the existing Societal Attitudes Towards Autism (SATA) scale. A second section explored knowledge. It was developed in consultation with the wider autistic community and comprised of four different areas of knowledge. The survey was distributed to neurotypical adults throughout Australia. A total of 1,078 entries completed the SATA section and were used for analysis of attitudes. As 24 of these participants did not completed the knowledge section, 1,054 entries were considered for further statistical analysis. The sample represented the Australian population with the exception of a larger proportion with tertiary degrees and coming from metropolitan as opposed to regional parts of Australia (Table 1). Men were on average older than women (Men=43, SE=1 vs. Women=40, SE=0.5, p<.01).

Results:

The SATA scores were totalled for each participant, with high scores representing a positive attitude. Questions from the knowledge section of the questionnaire were grouped into areas, as shown in Table 2. Each area scores were summed. Following this, backwards entry multiple linear regression modelling were conducted, in order to determine the independent variables that were seen to influence the SATA scores. Overall, 81.3% of participants reported a strong positive attitude towards autism and 81.5% of participants had a high level of knowledge. Knowledge total scores (ranging from 21-65; mean 51.3) proved being positively related to the attitudes (SATA) in the model. Knowledge was then entered into a refined model (r^2 =.129) by its sections (Table 2), which included Section 1, Societal Views and Ideas (Standardised β=0.205, β 95% CI=0.268 - 0.510, p<.001), Section 2: What could it be Like to Have Autism (Standardised β=0.121, β 95% CI=0.109 – 0.346, p<.001), the dichotomous response to the question: "Do you know and have you spent time around someone with autism?" (Standardised β=0.115, β 95% CI=0.697 – 2.188, p<.001) and, finally, gender (Standardised β=0.071, β 95% CI=0.167 – 1.649, p=.016).

Conclusions: Knowing somebody with autism and being female had a positive impact on attitudes on top of the two knowledge sections whereas age, residential area or formal education had no impact; results that can inform targeted information interventions.

112 **109.112** Opinion and Satisfaction of Families Participating in the Different Stages of Universal ASD Screening in Spain

M. Magan Maganto[1], *Á. Bejarano*[2], *C. Fernandez Alvarez*[1], *A. Hernández Fabián*[3], *N. Flores*[1], *C. Dominguez Martin*[4], *M. A. Parrilla Escobar*[4], *M. Martinez Velarte*[5], *C. Jenaro*[1] *and R. Canal-Bedia*[1], *(1)University of Salamanca, Salamanca, Spain, (2)UNIVERSITY OF SALAMANCA, Salamanca, Spain, (3)Hospital Clínico Universitario de Salamanca, Salamanca, Spain, (4)Hospital Clínico Universitario de Valladolid, Valladolid, Spain, (5)Hospital Provincial de Zamora, Zamora, Spain*

Background:

Since 2005, Spain has been implementing an early Autism Spectrum Disorders (ASD) detection program in the public health services of Salamanca, Zamora and Valladolid with the M-CHAT (Robins et al., 2001) and from April 2014 with the revised version M-CHAT-R (Robins et al., 2014). This makes the program one of the longest running general population ASD screenings in the world. Nevertheless, the satisfaction of families participating in the screening procedures in Spain has not been reported. It is well known that early identification leads to access to better resources, and therefore, an improvement in the quality of life of the people with autism and their families; yet, there is scarce information regarding the opinion of the families implicated in the different early detection procedures.

Objectives:

The aim of this study is to describe and analyse the opinions of participating families in a universal ASD screening program taking into consideration the different stages in the process (from the moment that the caregivers complete the M-CHAT-R, and before and after the diagnosis is given).

Methods:

Three different forms were created to evaluate the satisfaction of the families collaborating in the ASD screening program. Copies of the first form were distributed to all the paediatricians participating with the study. These forms were randomly distributed amongst the families that signed the informed consent to participate in the study when attending the 18 months and/or 24 months Well-baby-Check-up-visit. The second form was given to the parents that came for diagnostic evaluation after a positive screen, but before the assessment was performed. Finally, the third form was given after receiving the diagnosis.

Results:

306 families responded the first form, and 24 the second and third forms. 90.5% of the parents who completed the first form assessed the global process as a positive/or/very positive experience, and 88.2% of families agreed that the public health system safeguards their child's health. 90.5% disagreed that answering the M-CHAT-R questionnaire was a waste of time, and approximately 90% of the parents consider including screening programs in the public health system as very important, also agreeing that it is useful to detect problems early in the children's communication and socialization development. On the second form, 75% evaluate this stage, as positive/or/very positive. However, there are mixed results concerning the waiting time between the phone call to attend the evaluation and the actual day of the assessment was too long, as 33.3% totally agree and 33.3% totally disagree. 100% of the families surveyed after the evaluation agree/or/totally agree in feeling glad about the information given about their child difficulties, prognostic, treatments, etc., during the assessment debrief.

Conclusions:

Most of the families highly valued the universal early detection system for communicative and social problems in their different stages, agreeing that implementation of the screening program is of great usefulness. Professionals and public health institutions should take into account these results, in order to provide and improve resources for children with ASD and their families.

113

109.113 Parent Ratings of Executive Function and Functional Communication in Children with ASD Exposed to One or Multiple Languages

G. Iarocci[1] *and S. M. Hutchison*[2]*, (1)Simon Fraser University, Burnaby, BC, Canada, (2)University of British Columbia, Vancouver, BC, Canada*

Background: Although exposure to a second language may have benefits for typically developing (TD) children, particularly in executive functioning (EF) (Bialystok, 2007), in children with ASD, the effects of exposure to a second language (L2) on EF and functional communication is unknown. Families and educators have relied on anecdotal evidence to make decisions about language learning, in some cases, limiting exposure to the language of education (typically English) despite lack of empirical evidence (Paradis, 2007). However, some parents have reported exposing their children with ASD to multiple languages and considered them able to achieve bilingualism (Bird, Lamond, & Holden, 2012). Bilingual children with ASD were found to be as proficient in English language production and vocabulary compared to monolingual children with ASD (Petersen, Marinova-Todd, & Mirenda, 2012).

Objectives: The aim of our study was to compare parent rated functional communication (FC) and executive function (EF) in youth 6-18 years with and without ASD exposed to a second language (L2) or only one language, as reported by their parents. Specifically, we wanted to examine whether any EF benefits from L2 exposure were apparent in children with ASD, as well as whether parent's ratings of FC differed across groups.

Methods: One-hundred and seventy-four youth between the ages of 6 -18 years (M= 12.04 years) were matched on age, IQ (WASI-II), maternal education, and were divided into four groups: ASD-L2 Exposure, TD-L2 Exposure, ASD-No L2 Exposure, and TD-No L2 Exposure. Each caregiver completed a demographic questionnaire and the BASC-2 rating forms that include EF and FC indices.

Results: An analysis of variance (ANOVA) was conducted between groups and the results indicated that although there was a significant difference in EF and FC in children with and without ASD, the children with ASD exposed to a second language were not significantly different from those with ASD who were exposed to only one language. Thus, second language exposure in the children with ASD was not associated with delay in EF and functional communication skills, rather, there was evidence of a reduced clinical impact in those with a second language exposure as indexed by a lower percentage of children whose FC and EF ratings fell within the clinical range.

Conclusions: The findings are consistent with previous evidence that exposure to a second language is not associated with an adverse impact on the communication and cognitive skills of children with ASD. Future research on clinical/functional rather than simply statistical differences between groups is needed to further elaborate on the potential benefits to EF in children with ASD exposed to a second language. Observational and qualitative methods may be particularly helpful in identifying any differences in language environments and EF and communication performance.

114

109.114 Parental Experiences in the Sultanate of Oman

P. Perepa*, University of Northampton, Northampton, United Kingdom of Great Britain and Northern Ireland*

Background:

Although we are aware that autism impacts children across the world, there is little research focusing on parental experiences from countries outside Europe and the English speaking world. This study focused particularly on the experiences of parents living in the Sultanate of Oman. As autism is not recognised as a separate condition in the country, this research shows the unique differences that these parents experience.

Objectives:

- To understand parental understanding of autism and its causes.
- To understand parental experiences of accessing services to support themselves and their children on the autism spectrum.

Methods:

The research used semi-structured interviews and focus groups. Altogether 24 interviews and focus groups were conducted with parents across the country. Both mothers and fathers were interviewed. Parents had children across a wide range of ages. All the interviews were conducted in

Arabic with an interpreter. The data was then analysed using thematic coding.

Results:

The results indicate that parents in the country have a wide range of perceptions with regards to characteristics of autism and its causes. While some parents attribute autism to fate and religious interpretations, others had a more scientific understanding of the condition. A number of difficulties in accessing services right from getting a diagnosis, to appropriate education and vocational options have been mentioned by the parents. They also mentioned about the lack of knowledge amongst professionals about the condition which made seeking support especially difficult for them. The research also found some unique barriers which are presented by the geography of the country where some communities live in small communities.

Conclusions:

This research reiterates some of the experiences and issues recorded in existing research on the topic from other parts of the world. It also highlights the need to develop services which address the cultural, social and economic realities of the country where the families live, and how the existing principles of good practice in autism may need to be adapted to meet these needs.

115

109.115 PILOT Experience of Promoting Adequate Conditions for Autism EARLY Detection from a National University in Salta (NORTHWEST ARGENTINA)

C. Ruiz-Danegger[1] *and E. Guantay*[2]*, (1)ICSOH-CONICET-UNSa / CISEN-UNSa, Universidad Nacional de Salta, Salta, Argentina, (2)Cátedra Biología. Medicina. UNT - Sede Salta, Universidad Nacional de Salta, Salta, Argentina*

Background: Salta is rich in cultural diversity (in its territory, more than ten native languages are used in addition to Spanish) and its social and economic reality generally imply numerous context challenges for development. It was observed that, due to some lack of official actions, the community of relatives of children with ASD and local professionals were concerned with doing early detection campaigns for autism, but without noticing certain inadequacies in the devices (since used instruments did not adapted neither that was considered necessary) and interpretations (in general the same notion of "early detection" was often somewhat indistinguishable in some practice near of “diagnosis”). There was no statistics on this issue at any level. Advanced this project, it emerged the need to broaden our view and to consider autism among other development challenges, as well as to emphasize in formative/educational aspects.
Objectives: As a strategy, to project and pilot a set of devices and practices towards the realization of early detection campaigns of autism and other development challenges according to provincial priorities of public health. Coherently with their academic mission in a challenging context, this university project emphasize both in connecting Salta’s people with the most advanced knowledge about this issue and doing training at all levels, as well as promote and empowering the local knowledge construction.

Methods: a) To analyze national and international background. b) To establish several interdisciplinary teams around key objectives and activities. c) To promote alliances and intra- and inter-institutional synergies with other professionals de Salta, community organizations, and public agencies (National Secretariat for University Policies and Secretariat of University Extension-UNSa, Ministry of Public Health, Statistics Division of the Province), as well as convening volunteers (among those who included people with ASD). d) Strategically, to conduct actions through continuous assessment, consultations on specific aspects to national and international experts, and request for evaluation and monitoring to UNICEF.

Results: a) To get some 'more refined' sense of need for early detection, using adequate instruments and to better distinguish the notion and scope of these actions, in general. b) Generate a device to raise awareness by “walk a mile in the shoes...” of various groups regarding the ASD, through the cinema. c) Develop local versions of the M-CHAT-R / F **in Spanish and Wichí** (one of the original indigenous languages) and pilot the Spanish version on the ground, as a preparation for to be validate. d) Create a suitable cascade training device for the interviewers who pilot such local version of M-CHAT-R/F on the ground, as well as design mixed teams with university volunteer students of Education, Nursing, and Medicine. e) Produce the first statistical data and estimations of Salta about this concerns. Data were collected by probabilistic sampling -elaborated by experts of the Salta Government, and being correlated with a corpus of context data relayed by the Permanent Household Survey. f) Elaboration of a plan of postgraduate courses related to this issues.

Conclusions: In their final form, this project seems adequate, replicable and sustainable in the time.

116

109.116 Quality of Life and Education of Adolescents and Adults with ASD in Argentina. Preliminary Analysis Based on an Online Survey

S. H. Cukier[1]*, N. Barrios*[2]*, J. P. Berman*[3]*, A. Rattazzi*[1]*, R. Geloso*[4]*, M. Gotelli*[5]*, F. Satorra*[6]*, K. Solcoff*[7]*, D. Valdez*[8] *and C. Ysrraelit*[5]*, (1)PANAACEA, Buenos Aires, Argentina, (2)Fleni, Capital Federal, ARGENTINA, (3)PANAACEA, Programa Argentino para Niños, Adolescentes y Adultos con Condiciones del Espectro Autista, Buenos Aires, Argentina, (4)Asociacion Asperger Argentina, Buenos Aires, Argentina, (5)Fundación Brincar por un Autismo Feliz, Buenos Aires, Argentina, (6)TGD Padres TEA, Buenos Aires, Argentina, (7)FLACSO. Facultad Latinoamericana de Ciencias Sociales., Buenos Aires, Argentina, (8)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina*

Background: In Argentina, services for adolescents and adults with ASD are sparse. Supports for education after primary school are only emerging. In 2016 RedEA (¨Autism Spectrum Network¨), an association of parent support groups and NGOs in Argentina, developed a survey to assess the current situation of adolescents and adults with ASD in relation to quality of life, services, education, employment and other variables.
Objectives: Provide a picture of the quality of life and challenges of adolescents and adults with ASD in Argentina related to the level of education attained, with the specific goal of thinking of ways to improve educational services and develop long-term policy solutions related to ASD in the region.

Methods: The Transition and Adulthood ASD Survey had been broadly disseminated via social networks of RedEA organizations in Argentina in 2016/2017. Caregivers of individuals over 13 and/or adults with ASD older than 18 completed it online. The survey solicited information about different variables including educational and Quality of Life issues. The educational background and main difficulties that individuals found to achieve their educational goals were analyzed and the association of these variables with current perceived quality of life.

Results:

534 surveys were completed. 31 % of people reported not being currently studying (15% of people reported working). Among those not currently studying, 64% reported that they haven't achieved their desired educational level.

The main obstacles to educational achievement described by individuals with ASD and their families were disagreement with teachers or institutions, difficulties to integrate, financial limitations, behavior problems, low cognitive level (services not being adapted to level). However, over half of those not currently studying have achieved the secondary level of education or higher. Almost half (46%) of the respondents expect to study at university and 17% already have. Variables related to emotional Quality of Life showed a strong association with the level of education achieved by adolescents and adults currently not studying.

Conclusions: This results together with current educational challenges reported by families affected by ASD in Argentina demonstrate the need for the identification of knowledge gaps, service needs, and inclusive education for these individuals and their families. It is also important in the development of culturally relevant strategies for raising awareness about adulthood and ASD, guiding the implementation of successful and improved ASD educational services and setting priorities for long-term national and regional public policy solutions in this age group

117

109.117 Semantic Fluency in Monolingual and Bilingual Children with ASD, ADHD, or Typical Development: Assessing the Role of Language and Executive Functioning Skills

S. Vanegas[1] *and S. Magaña*[2,3]*, (1)School of Social Work, Texas State University, San Marcos, TX, (2)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (3)University of Texas at Austin, Austin, TX*

Background: Little is known about how children with neurodevelopmental disorders learn and use two or more languages (Valicenti-McDermott et al., 2012). Although some advantages have been reported in executive functioning among typically developing bilingual children (Barac & Bialystok, 2012), it is unclear whether these findings will be similar among bilingual children with ASD or ADHD, considering that language can be an area of significant difficulty for these children (Kuijper et al., 2017). An important aspect of language development is the efficient and accurate retrieval of words, a concept often termed semantic or verbal fluency. To date, only one study has examined semantic fluency in bilingual children with ASD, finding that bilingual experience was associated with greater fluency when compared to monolingual experience among children with ASD (Gonzalez-Barrero & Nadig, 2016). However, it is unclear whether semantic fluency varies as a function of language experience (monolingual, bilingual) or diagnosis (ASD, ADHD, no diagnosis).

Objectives: The objective of the current study is to examine semantic fluency among children with ASD, ADHD or typically development and examine the contributions of language experience, language skills, and executive functioning skills.

Methods: Children between 6 and 14 years of age who communicated verbally and had consistent monolingual (English) or bilingual (English/Spanish) experience were recruited to participate. Children could have a diagnosis of ASD, ADHD, or no diagnosis of a neurodevelopmental disorder. Parents completed a language background questionnaire, documenting demographic characteristics, children's early language milestones, and language exposure. Parents also completed measures of clinical symptomatology through the Social Communication Questionnaire and the Conners-3. Children were assessed on nonverbal reasoning (Raven's Standard Progressive Matrices), overall language skills (Clinical Evaluation of Language Fundamentals – 4th version, CELF-4), and executive functioning skills (Behavior Rating Inventory of Executive Function).

Semantic fluency was assessed through the Word Association subtest of the CELF-4. This task requires participants to state as many items within 60 seconds for three semantic categories (animals, food, professions/clothing). Semantic fluency will be evaluated on total correct responses, number of switches between clusters, and the average cluster size. Bilingual children completed the CELF-4 and the Word Association subtest in English and Spanish.

Results: Data collection is ongoing, with an anticipated overall sample of 120 children. Data collected thus far includes a sample of 19 children with ASD (Monolingual n = 9; Bilingual n = 10). Preliminary analyses found no differences between monolingual and bilingual children with ASD on early language milestones, including age of 1st word (p = .878), short phrases (p = .243), and sentences (p = .091). Complete analyses will include comparisons across language (monolingual, bilingual) and diagnostic (ASD, ADHD, no diagnosis) groups on semantic fluency accuracy and retrieval strategies, including the role of language and executive functioning skills.

Conclusions: Overall, the results of this study will provide insight into the underlying processes of semantic fluency among children with neurodevelopmental disorders who have bilingual language experience. These results can inform educational and therapeutic strategies used in clinical and community settings to support children with diverse language experiences.

118

109.118 The Asdeu Multi-Site Survey of Services for Autistic Adults in Europe, Focusing on Customer Service Practices in Adult Services

D. Schendel[1]*, C. Warberg*[1]*, S. Cramer*[1]*, L. Poustka*[2,3]*, R. Diehm*[4]*, G. Iskrov*[5]*, R. Stefanov*[5]*, L. Bouvet*[6]*, B. Roge*[7]*, A. Staines*[8]*, M. R. Sweeney*[9]*, A. Background: The research base on ASD in adulthood is underdeveloped and there is very little knowledge regarding autistic adult services practices and delivery.
Objectives: To improve understanding of current services practices for autistic adults and opportunities for improvement as part of the Autism Spectrum Disorder in the European Union (ASDEU) project comprised of 20 partners in 14 European Union (EU) states. The presentation will describe ASDEU's anonymous survey designed to obtain information on services availability and user experiences related to autistic adult services in the EU, focusing on adult customer services practices.

Methods: Survey questions were based on published guidelines regarding services for autistic adults; separate versions were created for autistic adults, carers of autistic adults and professionals in adult services. The survey was translated into 11 languages and distributed by ASDEU partners via electronic media hosted by ASD organizations and in-country adult services facilities. The presentation will provide an overview of survey content and results, focusing on 'theme' questions on specific 'good' services practices that are repeated in different sections of the survey. The specific theme questions concerned services staff members' customer service competencies: level of ASD knowledge, knowledge of services availability for autistic adults, and providing information in ways autistic adults could understand. Analyses were performed on responses from all three respondent groups to theme questions in sections concerning adult services in general, and residential, employment, adult education, financial and social services areas, specifically.

Results: Currently, 945 respondents have completed the ongoing survey (358 autistic adults (65% female; 50% 18-35 years old), 297 carers of autistic adults (autistic adults described by carers: 27% female; 81% 18-35 years old), 290 professionals in adult services); > 85% of responders are from Denmark, Finland, France, Iceland, Italy and Spain; and 50-60% of responders are from communities of 1 million-20,000 inhabitants. Across all three respondent groups, all services areas, and all theme questions regarding customer service experiences in the past 2 years when applying for services, < 50% of respondents reported that they had experienced 'good practices': staff who seemed knowledgeable about ASD; seemed knowledgeable about services that were available for autistic adults; or provided information in understandable ways. Social services offices scored most favorably (35%-48% of adults or carers experienced these good practices) and financial services offices scored least favorably (9%-20% of adults or carers experienced these good practices); a financial service was the most frequent service applied for in the past 2 years by autistic adults (59%) and carers (74%). Carers tended to report a higher rate of experiencing these good practices in the last 2 years (30%-48%) compared to autistic adults (10%-40%).

Conclusions: The ASDEU adult services survey is best viewed as a detailed pilot study based on a large EU convenience sample. In these data, all three respondent groups consistently reported low rates of experience with basic measures of good customer service practices: knowledgeable and trained staff and understandable communication. Redressing these shortfalls may both improve customer service experiences and the efficiency of services delivery for autistic adults.

119 **109.119** Improving Access to Caregiver-Mediated Early Interventions: The Who Caregiver Skills Training for Families of Children with Developmental Disorders or Delays

ABSTRACT WITHDRAWN

Background: The majority of children with ASD and other developmental disorders live in low- and middle-income countries, where the treatment gap for these conditions is estimated to exceed 80%. The lack of skilled human resources, especially at the primary health care and community level, is recognized by the World Health Organization (WHO) as a major barrier to increasing service provision. The WHO mhGAP Intervention Guide provides guidance on developmental assessment and monitoring, and management of developmental disorders at primary health care level. The management plan includes offering caregiver-mediated early interventions, in light of the evidence of significant gains to children and families, but open-access, affordable caregiver-mediated programs that can be delivered by non-specialists in low-resource settings are not currently available.
Objectives: to develop a Caregiver Skills Training program for families of children with developmental disorders or delays (CST) meeting feasibility criteria for implementation at scale in low-resource settings.

Methods: A formative process was set up by WHO and partners, including: a) literature review, including analysis of implementation processes and components analysis using meta-regression techniques, and b) expert consultation. The expert consultation comprised of a meeting hosted by WHO and subsequent distance consultation with experts to define the intervention content and structure and capacity building strategies. Major issues discussed included target age group, inclusion/exclusion criteria for families receiving the intervention, number and length of sessions, strategies to reduce attrition, approaches to enable addressing individualized and heterogeneous needs of families and involvement of other family members.

Results: The literature review showed that caregiver-mediated interventions can be effectively delivered by non-specialists, and even low-intensity programs lead to improved child developmental and behavioral outcomes and improved family well-being. The moderation analysis showed that programs including behavior management techniques and instruction on the use of cognitive interventions to the caregivers had larger effect sizes. Caregiver skills training programs that used a combined delivery format of group and individual sessions had greater effect sizes in problem behavior reduction. A family-centered approach and stepped-care model were recommended, whereby the specific strengths and needs of families are assessed to ensure the program is relevant and referral to other available services is made whenever required. The need to allow for adaptation and flexibility to meet the realities of the local context and local health and educational systems was highlighted. The engagement of families and communities was considered paramount to make caregivers' attendance and participation to the program feasible. A modular organization, with 'core' sessions followed by additional optional sessions, as per specific needs and availability of resources, was proposed. Continuous support and supervision was discussed to be a critical element for effective implementation of CST by non-specialist providers.

Conclusions: Based on the evidence and experts' guidance, a package comprising intervention manuals, and adaptation, capacity building and Monitoring & Evaluation tools was developed and made available for field testing. The program aims to improve children's communication and adaptive behaviors and caregivers' wellbeing. The CST is currently being field tested in 30 countries from all regions, including high-income and low-and-middle-income countries.

120 **109.120** The Cultural Adaptation and Clinical Efficacy of the PEERS® Program in Israel

S. Israel Yaacov[1,2]*, N. Kanter*[3]*, I. Mor Snir*[2]*, E. A. Laugeson*[4] *and O. Golan*[1,2]*, (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat-Shmuel, Israel, (3)Clinical Child Psychology, Association for Children at Risk, Givat-Shmuel, Israel, (4)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA*

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental condition, characterized by social communication deficits and restricted, repetitive behavior patterns. Adolescence is a particularly troubling period for persons with ASD, with increased awareness of teens to the difficulties they encounter when interacting with peers, and their susceptibility to isolation, rejection and bullying. Learning to make and keep friends is especially difficult for teen with ASD. Thus, teaching the necessary skills may have significant life long impact for this group. In Israel, research supported social skills training has been available only for elementary school aged children within the educational settings (Bauminger, 2007). The Program for the Education and Enrichment of Relational Skills (PEERS®; Laugeson & Frankel, 2010) is a parent-mediated social-skills program for adolescents with ASD that has been well validated with and out of North-America.
Objectives: The current study had two objectives: (1) to culturally adapt PEERS® in Israel. (2) to clinically evaluate the efficacy of the adapted PEERS® protocol with Israeli adolescents with ASD and their parents in a clinical setting.

Methods: The PEERS® protocol has been translated to Hebrew and culturally adapted by a team of clinicians specialized in ASD. The adapted protocol was administered to sixty-one adolescents (7 girls), aged 10-16, and their parents, who attended social skills groups at the 'Bait Echad' clinical center for individuals with ASD. Questionnaires were filled out pre- and post-intervention. Parents reported on autism symtomatology (SRS-2) social skills (SSIS), and quality of socialization (QSQ). Teachers reported on autism symtomatology (SRS-2) and social skills (SSIS). Adolescents reported on social skills knowledge (TASSK), quality of socialization (QSQ), autism symtomatology (AQ), empathy (EQ), loneliness (UCLA), and social anxiety (SAS). Qualitative interviews were conducted with teens, parents, and clinicians who took part in the first two groups.

Results: Participants' and clinicians' feedback supported the applicability of PEERS® to adolescents with ASD in Israel. Cultural adaptations have been conducted around several themes, including choosing appropriate friends, appropriate use of humor, good sportsmanship, use of electronic communication, and the management of get-togethers. Questionnaire results show a significant improvement on adolescents' social skills knowledge ($p<.001$), and a greater frequency of social get togethers ($p<.001$). In addition, teens reported reduced feelings of loneliness ($p<.05$), enhanced empathy ($p<.05$), and reduced autism symptomatology ($p<.05$). Parents reported a significant reduction in autism symptomatology ($p<.01$), and both parents ($p<.01$) and teachers ($p<.05$) reported on improved social skills.

Conclusions: Results of this clinical trial support PEERS® as a promising evidence-based intervention for adolescents with ASD in Israel. A randomized controlled trial of the Israeli adaptation is currently undergoing. The significant effects of the intervention, conducted with a broader age range of participants, suggest PEERS® may also be applicable to a younger age group.

121

109.121 The Current State and Outlook of Autism in Mainland China

***Y. Fan**, South China Normal University Autism Research Center, Guangzhou, China*

Background:
In China, there are more than ten million (10,000,000) people on the autism spectrum as estimated by the prevalence of 1% in the whole population of one point three billion people. It is an extremely large population but little is known about their living conditions.

Objectives:

The present study provides a systematic review of 8 perspectives of the current situations of people with autism spectrum disorders (ASD) in mainland China, including prevalence, diagnosis, intervention, education, employment, family issues, research, and law.

Methods:

Literature Review

Results:

Results from a review of 26 epidemiological studies from 2000 to 2016 showed that the average prevalence rate was 0.30% ($SD = 0.32$). Diagnosis were mainly made by pediatricians using translated tools, such as DSM-5. However, there were very few of them certified to use ADOS, ADI-R or other established diagnosing and assessment instruments. With regard to intervention, there were around 2000 service providers in mainland. Among the 47 interviewed organizations, only 37% of intervention approaches they used were established and evidence-based. According to a survey of 1202 organizations, 92% of them provided rehabilitation and education service while only 8% of them provided employment service and adult care service. School-aged children with ASD had five options of education placements, including autism schools, special schools for children with mental retardation, and other three types of placements in mainstream schools. Our review also analyzed the financial burden of families with a child having ASD. Besides, number of publications in the field of autism were analyzed by year from 2000 to 2015. We found a consistent growing tendency which implied that autism was becoming a more and more popular research topic in China. Lastly, we have reviewed the development of laws related to individuals with ASD and its limitations.

Conclusions:

Based on the systematic review of the current state of individuals with ASD in China, suggestions of the future development in diagnosis, vocational education and support, and training professionals were proposed.

122

109.122 The Emergence of Autism Spectrum Disorder in Costa Rica

***D. Schelly** and A. Ohl, Clarkson University, Potsdam, NY*

Background:
In the U.S., the history of autism spectrum disorder can be traced to deinstitutionalization and the crisis of psychiatry that preceded the DSM-III in 1980. Parents of children with autism, some of them psychiatrists and psychologists, influenced the expansion of diagnostic criteria that would contribute to the autism "epidemic" of the 1990s (Eyal et al. 2010). But the history of autism does not end in the U.S.; as the category continues to be adopted globally, there is a collision between Western diagnostic criteria and local culture (Grinker 2007). The aftermath of this collision has been partially documented for autism, especially in India (e.g., Daley 2004) and South Korea (e.g., Grinker and Cho 2013), but nowhere has the lead

up to the adoption of the category been described, including the first diagnosed case and the eventual diffusion of autism in the new setting.

Objectives:

This paper considers the adoption of the diagnostic category of autism in Costa Rica, where cases were recruited in the early-2000s for a genetic study. What led to those first diagnosed cases? How do "networks of expertise" (Eyal et al. 2010) operate in relation to the category? How are the autism experts in Costa Rica tied to networks of expertise in the U.S. and abroad?

Methods:

The present research stems from a collaborative project with the Hospital Nacional de Niños (HNN), the diagnosing clinic for all children in Costa Rica. Interviews were conducted with the primary diagnosing physician—a developmental pediatrician—and other staff at the hospital, and medical files of early cases of autism were reviewed. Finally, all genetic studies on human populations in Costa Rica leading up to the autism study were complied, and connections among the 108 authors were mapped in a two-mode network diagram.

Results:

The network diagram reveals a dense interconnected network of 16 genetic studies, beginning in the early 1990s, involving collaboration between physicians, microbiologists, statisticians, and cytogeneticists in Costa Rica and researchers in the U.S., Canada, and several countries in Europe. A pharmaceutical company was the source of one bipolar study, but the remaining studies focused on Costa Rica because of its founder population. Almost by happenstance, a California author initiated the autism study after moving to an autism research center in New York and then hearing that the pediatrician, who had completed a residency in Boston, was inquiring about a possible autism case. The pediatrician was recruited for case recruitment, and after completing an ADOS course in the U.S., she eventually devoted time each week for diagnosing autism and began training other clinicians to consider the diagnosis.

Conclusions:

The importation of autism in Costa Rica was likely inevitable, but this study illustrates how network ties to research institutions with substantial financial resources can drive the diffusion of diagnostic practices and categories. In no way does the process appear exploitative or paternalistic; rather, both sides benefit from the collaborations, and medical practices in the U.S. are effectively transmitted to small countries with limited resources.

123 **109.123** The Standard and Practice of Assessing Response to Intervention for Children with Autism in Ethiopia

W. A. Zeleke[1,2] *and R. J. Charette*[3]*, (1)Counseling, Psychology and Special Education, Duquesne University, Pittsburgh, PA, (2)Duquesne University, Pittsburgh, PA, (3)Western Psychiatric Institute & Clinic, Pittsburgh, PA*

Background: Behavioral and educational intervention service for student with autism in Ethiopia is still primarily provided by the two parent owned autism centers. The primary goal of these center is to address the student's behavioral, developmental, social and academic needs, which is an intensive undertaking process that requires many hours each week of different instruction and therapies. In this process, it is crucial to assess intervention response on an individualized basis, especially in a country like Ethiopia where service is offered with limited resources and human power. However, the implementation of assessment to intervention response has received scant attention (Zeleke, Hughes, & Chiytio, 2017).

Objectives: The purpose of this study was to assess the standard and practice of intervention implementing plan for students with ASDs in Ethiopia.

Methods: Using mixed method, data was collected from 120 students with ASDs, 12 program coordinators, 32 teachers, and 12 parents. Survey questionnaires, direct observation, focus group discussions, and individual interviews were utilized to gather information on the standard and practice of (a) intervention selection, (b) identification of reasonable strength of intervention, (c)implementing the intervention, (d) assessing progress, and (e) applying decision rules to the resulting data.

Results: The preliminary results indicate that even though a substantial service provision practice that addresses student's behavioral, developmental, social, and academic needs observed, lack of documentation on intervention plan and implemented interventions were marked.

Conclusions: Implication on the role of plan implementation and how to assess response to intervention can be used to inform implementing an entitlement process in which services are integrated with assessment and a due process protection for students are discussed.

124 **109.124** Translation, Cultural Adaptation and Initial Testing of PEERS in the Netherlands

K. Greaves-Lord[1,2]*, S. Idris*[1]*, B. van Pelt*[1,2] *and G. Jagersma*[2]*, (1)Erasmus MC, Rotterdam, Netherlands, (2)Yulius, Dordrecht, Netherlands*

Background:

The PEERS intervention can be considered a well-established, evidence-based intervention in the USA. However, testing the efficacy of cultural adaptations of PEERS is still ongoing. So far, only Yoo et al. (2014) investigated the efficacy of PEERS outside the USA, and their study demonstrated promising findings regarding the Korean version of PEERS. More and more, the involvement of all stakeholders in the development and evaluation of interventions is acknowledged as crucial for the longer term implementation of interventions across settings. Therefore, in the current project, teens with ASD, their neurotypical peers, parents, teachers, clinicians as well as management staff were involved in the development and evaluation of the Dutch version of PEERS.

Objectives:

The current presentation covers the formative phase (1) and the preliminary adaptation test phase (2) of the cultural adaptation of evidence-based interventions, as adapted from Barrera and colleagues (M. Barrera & Castro, 2006; M. Barrera, Jr., Castro, Strycker, & Toobert, 2012), i.e. describing the process of adaptation of the PEERS program to the Dutch culture and care system (1), and presenting results from the preliminary adaptation test among 32 12-18 year old adolescents with ASD (2).

Methods:

In phase 1, a panel inventory on common vocabulary was conducted among 70 teenagers (and their teachers) from special and regular education aged 12-18 years old. This inventory concerned 14 key constructs from PEERS, e.g. areas of interests, locations for making friends, common peer groups and crowds inside and outside of school, activities with friends, commonly used ways for electronic communication, ways for handling disagreements, and common teasing comebacks. Also, 15 clinicians were involved in the translation and cultural adaptation process. The translation and cultural adaptation process was guided by the research team, and who included input and feedback from all stakeholders through an iterative feedback incorporation procedure. In phase 2, The parent-reported Social Responsiveness Scale (SRS) and the the Test of Adolescent Social Skills Knowledge (TASSK) were assessed pre- and post intervention to evaluate potential treatment outcome.

Results:

The most striking cultural adaptation - reflecting the standpoints of all stakeholders - concerned the strategies for handling rumors and gossip, which were suggested to be taught using a similar approach as the teasing comebacks, more in line with 'down-to-earth' Dutch standards. The preliminary testing of this adapted version indicated that the adolescents with ASD significantly improved their social knowledge (TASSK; t_{31} = -10.9, p<.01) and in parent-reported social responsiveness (SRS; t_{33} = 3.9, p<.01). In addition, subjective evaluations of teens with ASD, their parents and clinicians were positive.

Conclusions: Although these preliminary results are promising, larger scale controlled research is needed. Methodological and practical considerations in the design and implementation of a recently started randomized controlled trial will therefore be discussed.

125

109.125 Understanding Autism Spectrum Disorder in Context: A Comparison of Parent/Caregiver Perceptions of Functioning in a High-Income and Middle-Income Country

M. Viljoen[1], *S. Mahdi*[2], *S. Bolte*[3] *and P. J. de Vries*[1], *(1)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (2)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Karolinska Institute Center of Neurodevelopmental Disorders, Stockholm, Sweden, (3)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden*

Background: Autism Spectrum Disorders (ASD) are heterogenous and functional outcomes can be highly variable in different individuals. The World Health Organization International Classification of Functioning, Disability and Health (ICF) is widely-used to measure functioning. Core Sets for ASD were recently developed. The process included a qualitative preparatory study to explore parent/caregiver perceptions of functioning and environmental factors in five highly divergent countries (Canada, Sweden, India, Saudi Arabia and South Africa). However, the context in which individuals live strongly influences functional ability or disability and it is not known whether functional themes in these diverse environments would have been similar or different.

Objectives: The purpose of this study was therefore to examine the association between context and functional ability/disability in children with ASD by deliberately comparing and contrasting two of the most divergent countries who participated in the qualitative preparatory study. We aimed firstly to compare and contrast the *frequency* of functional items reported by parents/caregivers between a High Income Country (Sweden) and a Low/Middle Income Country (South Africa). We secondly set out to compare and contrast the *content* of the functional items reported by parents/caregivers in these two countries.

Methods: For the ICF core sets study focus group and individual semi-structured interview data from 35 participants were analyzed following ICF procedures to link themes to ICF-CY categories. In this secondary analysis we compared South African (22 participants) and Swedish data (13 participants). The identified ICF-CY categories were ranked and compared for similarities and dissimilarities in frequency of reporting and analyzed for similarities and dissimilarities in the content of the themes.

Results: Complete *frequency* agreement was seen in 4 categories - three 'Activities and Participation' (carrying out daily routines, dressing, complex interpersonal interactions), and one 'Environmental Factors' (immediate family). Dissimilarities were observed in one 'Environmental Factors' category (health professionals), 6 in 'Body Functions' (e.g. involuntary movement functions, gait patterns, basic cognitive functions, and mental functions of language) and 3 in 'Activities and Participation' (managing one's own behaviour, speaking, and undertaking a single task). Only four ICF-CY categories differed in *content* between South Africa and Sweden. Immediate family was reported as both a barrier and facilitator to functioning in South Africa and only as a facilitator in Sweden, attention was reported as a facilitator in Sweden and barrier in South Africa, and products and technology for personal use was reported as a facilitator in Sweden and barrier in South Africa. Interestingly, health professionals were mentioned as a barrier to function in Sweden and facilitator in South Africa.

Conclusions: In spite of the divergent nature of contexts, few differences were observed in parental perspectives about environmental factors relevant to functioning in ASD. Surprisingly, perceptions more frequently differered regarding body functions and activities & participation. The content of perceptions were, with a few exceptions, similar. Our results suggest that the interaction between context and functioning is more complex than we predicted. We recommend that more comparative studies on ASD and functioning should be conducted to gain a better understanding of ASD in different contexts.

126

109.126 Understanding "Autism Community Wealth" within the Latino Community in Los Angeles County: A Theoretical Framework

T. De los Santos[1], *I. Arriaga*[1], *A. Gulsrud*[1] *and D. Hayes-Bautista*[2], *(1)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (2)David Geffen School of Medicine at UCLA, Los Angeles, CA*

Background: It is well documented that Latino parents of children with autism spectrum disorder (ASD) in the United States face barriers to obtaining diagnoses and treatment for their children (Zuckerman et al., 2013). However, little is known about how Latino parents manage to overcome barriers to accessing autism services (Fryer 2008). This study uses Yosso's six-part Cultural Wealth Model, which includes six types of capital (i.e., familial, social, linguistic, resistance, aspirational, navigational), to conceptualize how Latino parents utilize cultural capital to overcome barriers and access autism-services for their children (Yosso, 2005).

Objectives:To identify community cultural capital used by low socioeconomic status (SES), Latino parents of children with ASD to access care for their children.

Methods:IRB approval was obtained to interview 21 self-identified English- and Spanish-speaking Latino parents of children with ASD and 3 key informants (community leaders). Criteria for study participation included residency in Los Angeles County, being of Latin American descent, of low SES, as defined by the U.S. Federal Poverty Guidelines, and a parent of a child between the ages of 2 and 10 years with a professional diagnosis of ASD. Key informants were eligible if they worked with low-income, Latino parents of children with autism. Focus groups were conducted utilizing open-ended prompts to elicit discussion. Focus groups were audio-recorded, transcribed verbatim, and independently coded for major conceptual models. Exploratory, qualitative analyses were conducted using a modified grounded theory approach. Six raters coded each transcript to ensure reliability. Data triangulation and methodology triangulation were employed to ensure validity and reliability of data interpretation.

Results:Latinos show the greatest wealth in the area of **(1)*Familial capital***, such that their *familias (kin)* provide significant emotional and informational support, particularly once they accepted the diagnosis. The strong kinship in the home, often expands into the community with professionals (e.g., teachers, doctors, etc.) and other parents, which then becomes their **(2)*Social capital***. Key informants report noting a kinship within these groups that helps parents stay informed and connect to more resources. Following the establishment of these relationships, they build a greater **(3)*Linguistic Capital*** within the realm of ASD as they become comfortable with the jargon. For monolingual Spanish-speaking parents, linguistic capital was depressed because of language barriers and resources were not usually offered in Spanish. Nonetheless, with the **(4) *Resistance capital*** they possessed, all parents indicated a stronger self-confidence that promoted their ability to advocate for their child and themselves. Consequently, in the face of biased practices they have the ability to counteract these comments. But of these capitals, their ***(5)Aspirational Capital***, which refers to their ability to maintain hopes and dreams for the future, motivates them the most to advocate for their children. Yet, this is limited by their concerns about their own future health.

Conclusions:Understanding how these parents use Community Wealth to navigate autism services for their children may facilitate the creation of novel and culturally sensitive educational and outreach strategies that may make early intervention diagnostic and interventions more accessible to low-income Latino communities.

127 **109.127** Uses of Semiotic Objects and Mediation in Early Triadic Interactions in Siblings of Children Diagnosed with Autistic Spectrum Disorder in the Province of Santa Fe, Argentina.

D. Valdez[1]*, J. Benassi*[2] *and C. Rodriguez*[3]*, (1)Universidad de Buenos Aires- FLACSO, Buenos Aires, Argentina, (2)FLACSO, Buenos Aires, Argentina, (3)UAM, Madrid, Spain*

Background: Latino children are diagnosed with ASD later in life, usually with more severe symptoms, compared with non-Latino children. Possible reasons for such disparities could be due to lower levels of parent education, lower socioeconomic status and limited knowledge of parents about autism spectrum disorder.(Montiel, Chacín et al. 2017) Our study proposes lines of research in the early development in search of risk indicators that allow to favor policies of early intervention in the context of our region. The learning of the conventional use of objects occurs in triadic units and through operations with signs. Thus, communicative interactions are fundamental in the semiotic processes involved in the child's entrance to the socially shared uses of objects. Taking into account that communication is one of the dimensions of development in which children with ASD present their main alterations, it is possible to think that the genesis of socially shared uses of objects also follows a particular course.

Objectives: Describe the development of triadic child-adult-object interactions in children from Santa Fe at risk of ASD, from 3 to 15 months of age

Methods: Understanding that the prospective longitudinal study with population at risk is recommended (eg. Zwaigmbaum et al., 2013); and considering that siblings of children diagnosed with ASD are at particular risk, a longitudinal, prospective case-based evolutionary design is performed. The sample is of the intentional type composed of 4 infants at risk of developing ASD, between 3 and 15 months of age, in accordance with the ages studied in the previous typical development research, in which this project is framed (Cárdenas, Rodríguez, & Palacios, 2014; Moreno-Núñez, Rodríguez & del Olmo, 2017).

Results: Through a pilot study, the preliminary categories of this research were reviewed, taken from our previous studies: rhythmic uses, non conventional, proto conventional, conventional, instrumental, symbolic and private / self-regulation of objects; as well as the production of gestures in contexts of triadic interaction. They analyze both the adult and the child, their communicative means, gestures, expressions, looks, language and uses of objects. The work emphasized the importance of considering the ostensible actions of the adult as a communicative tool, which favors the joint attention and action. Second, distant demonstrations of the uses of objects, structured in character, represent the most effective rhythmic-sound manifestations to attract the attention of the child, allowing their involvement in the pauses it generates. The mentioned data are analyzed with attention in the semiotic performances that the adult unfolds for the child with the selected object. Preliminary results indicate some variations, compared to previous studies in typical development, in triadic interactions, where the communicative intention is still the responsibility of the adult.

Conclusions: The findings indicate the need to continue investigating the early development of signs in the at-risk population. This allows to develop new instruments that contribute to the evaluation of alarm indicators, as well as to the development of early intervention tools consistent with the evaluation of the uses of objects in the light of a pragmatic semiotic approach.

128 **109.128** Who's Waiting for a School? a Systematic Database Search for Children with Autism Spectrum Disorder Waiting for Educational Services in the Western Cape Province of South Africa

S. Pillay[1]*, P. J. de Vries*[2] *and M. Duncan*[3]*, (1)Health Sciences, University of Cape Town, Cape Town, South Africa, (2)Centre for Autism Research in Africa, Division of Child & Adolescent Psychiatry, University of Cape Town, Cape Town, South Africa, (3)Occupational Therapy, University of Cape Town, Cape Town, South Africa*

Background:

Little is known about education for children with Autism Spectrum Disorder (ASD) in South Africa and in other low- and middle-income countries. We previously searched for all children with an ASD diagnosis in school in the Western Cape Province of South Africa. We identified only 940 children, representing a rate of less than 0.1%, significantly lower than the expected prevalence. The Western Cape Education Department (WCED) has a database for children waiting for school placement, but no previous analysis of this database has been undertaken. An understanding of this sample is important for identifying their needs in order to develop appropriate support and educational systems.

Objectives:

The objective of the study was to perform a systematic database search for children with ASD or suspected ASD waiting for educational services.

Methods:

The WCED Centralised Database for children with ASD waiting for educational services was first compiled in 2012. After appropriate ethical approvals, all relevant ASD-related data in the database and supporting referral documents were extracted on 27 June 2016. Variables of interest were demographic information, referral information, disability information and educational needs.

Results:

There were 744 children with ASD or suspected ASD waiting for educational services in the Western Cape Province. The male: female ratio was 5:1. Ninety percent were from South Africa, 6% from other countries (Angola, Burundi, Congo, Ethiopia, Libya, Malawi, Mali, Nigeria, Somalia, Zimbabwe and Bangladesh), and 4% did not specify country of origin.

A total of 17 different home languages were reported: English in the majority (52%), one of the 10 other official South African languages in 47%, and 1% non-South African languages.

The age range was between 1 and 17 years, with a median of 5 years. The majority of children waiting for services were in the 3-8 year age group. The legal school-going age for children in South Africa is 7 years. Forty five percent of children were waiting for formal school placement (aged 7 years and over) and 55% for Early Childhood Development (ECD) services (ages less than 7 years). Forty eight percent of the sample had been waiting for services for less than a year, 26% for more than a year, 19% for more than two years and 7% for more than three years.

Most referrals to the Centralised Database were made by medical practitioners from the state health sector. Ten percent of children had comorbid physical or mental health conditions, and a family history of ASD was reported in 4% of the sample. The majority of children (89%) referred were from urban areas, with only 11% from rural areas.

Interestingly, between 2012 and 2016, there was a 276% increase in the number of children waiting for educational services.

Conclusions:

The database investigation of children with ASD showed alarmingly high rates of children with ASD waiting for educational services in the Western Cape Province of South Africa. Findings support the need for urgent action to generate novel approaches for the identification, monitoring and education of all children with ASD in the country.

129 **110.129** Determinants of Response to Music Therapy in Autism: Insights from the Time-a Study

E. Grossi[1] *and C. Gold*[2], *(1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)GAMUT, Uni Research Health, Uni Research, Bergen, Norway*

Background:

Music therapy (MT) may facilitate skills in areas affected by autism spectrum disorder (ASD), such as social interaction and communication. The TIME-A study (Bieleninik et al. JAMA 2017) examined the effect of improvisational MT on generalized social communication skills of children with ASD and represents the largest randomized controlled trial of MT for ASD. In this assessor-blinded trial of 364 children aged 4-7 years across nine countries worldwide, those assigned improvisational MT, where trained music therapists sang or played music with each child, attuned and adapted to the child's focus of attention, to help children develop affect sharing and joint attention. The proportion of responders to MT, defined as having improved ADOS social affect score after 5 months, was 52%.

Objectives:

The availability of this large data set gives the possibility to assess the determinants of the response to MT by analyzing the baseline profile of 165 subjects randomized to improvisational MT. By using advanced machine learning systems, we are able to develop a semantic connectivity map of the factors associated with response to the therapy with the aim to derive possible new insights in interpretation of trial results.

Methods:

Data of the TIME-A study were re-analyzed with a special kind of unsupervised artificial neural network (Auto-CM). Auto-CM produces a semantic connectivity map in which the matrix of connections, visualized through a minimum spanning tree filter, takes into account nonlinear associations among variables and captures connection schemes among clusters. In this way, the patient state can be viewed as an hyperpoint in a "multimorbidity space" in which each dimension corresponds to a quantitative phenotype.

Results:

In the semantic map(fig.1), male gender was directly linked to response; age over 5 years and presence of mental retardation were linked with response through male gender followed by ADOS score above 14 and verbal ability. Concomitant treatments such as sensory-motor therapy, speech and language therapy, behavioral and educational interventions, as well as therapeutic leisure activities all pointed to the non-response node. A further reanalysis performed in the trial data set confirmed a completely different trend in response rate between the non-MT arm and MT arm. In the first subgroup the total number of hours in concomitant treatment was not correlated with difference in response rate (response rate in < 40 hours/month and > 80 hours/ month of concomitant treatment equal to 50% and to 54% respectively) while in the second group a marked difference in response rate was evident (response rate in < 40 hours/month and > 80 hours/ month of concomitant treatment equal to 66% and to 40% respectively).

Conclusions:

Response to MT depends on a complex interaction of variables. The prototypical responder to MT, as appears from TIME-A study data set, is a male child able to speak, with ADOS-SA over 14, age over 5, and mental retardation. Excess of concomitant treatments seems to interfere with response to improvisational MT.

130 **110.130** "I Wanna Play Too": Increasing Social Interactions of Preschool Children with Autism Spectrum Disorder through

Cooperative Outdoor Play

***S. M. Ziegler** and M. Morrier, Psychiatry and Behavioral Sciences, Emory University School of Medicine, Decatur, GA*

Background: Recent estimates from CDC's ADDM Network indicate that for 4-year-old children, the prevalence of ASD is 1 in 74. Thus, early educational settings have increased numbers of children with ASD attending. In these settings, daily outdoor recess is usually offered, allowing children to play in an unstructured manner. Such unstructured times, often lending children with ASD to spend the majority of recess isolated, socially disconnected, and engaging in non-functional behaviors, represent missed opportunities to teach needed peer-related social skills.
Objectives: This study examined if a structured, cooperative play recess curriculum with a focus on natural modelling and imitation: (a) increased the rate of proximity of children with ASD to peers with NTD, (b) increased the number of social bids from children with ASD to peers with NTD, and (c) increased the number of social bids from peers with NTD to children with ASD. Specific objectives included: (a) examining if the intervention increased social behaviors in children with ASD, and (b) examining factors related to the overall increases in social behaviors demonstrated by participating children as a whole.

Methods: Thirty-five preschool-aged children with and without ASD participated. A multiple baseline across classroom design was used to investigate the effect of the intervention on social communication behaviors, in one intervention and two generalization settings. The intervention consisted of child dyads singing randomly chosen movement songs in front of one another, in a larger group setting. Data was collected using a 120-s observe; 30-s record, partial interval system. A MANOVA was performed to determine the effects of study phase, ASD status, and age of child. Based on the results of the MANOVA, one-way ANOVA was conducted to determine how each variable played into the results obtained.

Results: Participants with ASD increased their social bids towards peers with NTD. Pre-K students generalized and maintained these increases in the free-play setting, whereas younger children did not generalize skills. Examination of factors related to increases showed significant differences based on child ASD status, child's age, and study condition. ANOVA results with age range as the between group factor indicated significant differences for rate of typical proximity, for rate of ASD proximity, for ASD receives, and for ASD gives. Study condition indicated significant main effects for rate of typical proximity and for rate of ASD proximity. Study condition was also significant for typical receives, and ASD receives. In terms of initiations of social bids to peers, only typical gives was significant for study condition.

Conclusions: Once the intervention was introduced, social interactions between children with ASD and their peers increased over baseline levels. These increases generalized and maintained for older, but not younger participants. The ASD status of the target child was investigated to determine which population of child, typical or ASD, made the most improvements. Results from this study support previous research on structuring peer interactions during unstructured times as a means to increase social bids between typical peers and peers with ASD, and extends the research downward in age to toddler and preschool-aged children.

131 **110.131** A Long-Term Follow-up of Participants Who Received Parent-Mediated Intervention for ASD in Toddlerhood: Stories from the First Cohort of the Social ABCs Pilot Study –Where Are They Now?

*J. A. Brian[1], **E. M. Dowds**[2], A. Solish[1], J. H. Leef[3], L. Senman[4], L. Zwaigenbaum[5] and S. E. Bryson[6], (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital-Autism Research Centre, Burlington, ON, Canada, (3)Department of Applied Psychology and Human Development, University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Autism, Bloorview Research Institute, Toronto, ON, Canada, (5)University of Alberta, Edmonton, AB, Canada, (6)Dalhousie University, Halifax, NS, Canada*

Background: The *Social ABCs* is a parent-mediated intervention (Brian et al., 2016) based on empirically supported Pivotal Response Treatment (PRT; Koegel & Koegel, 2006). The main targets of the *Social ABCs* are functional early (vocal/verbal) communication and positive affect sharing between child and caregiver for infants/toddlers who have suspected or diagnosed Autism Spectrum Disorder (ASD).
The *Social ABCs* was developed as a pilot study ten years ago to explore very early intervention in infants and toddlers showing early signs of ASD or related symptoms. The original participants included young toddlers between 12-30 months of age, across two sites (Halifax, NS and Toronto, ON). This abstract explores the long term developmental outcomes of the child participants from our pilot phase of the *Social ABCs*-Toronto cohort.

Objectives: Bolstered by evidence of positive (short-term) treatment outcomes, we sought to explore long-term developmental outcomes of early participants in the *Social ABCs*. We hope this can help us to understand how early intervention may interact with development and symptoms of ASD over time. Longitudinal exploration includes questions such as: "*What did social-communication look like in toddlerhood, before intervention, and what does social-communication look like now?", "Is response to treatment associated with current functioning?"*.

Methods: We have re-assessed six of the initial 11 participants from the Toronto site of the *Social ABCs* pilot within the context of our longitudinal infant sibling study (Zwaigenbaum et al., 2005). Analysis entails a mixed-methods approach. Through chart review, we examined each participant's performance on standardized measures of development, as well as ASD-related symptoms based on ADOS, ADI-R and parent interviews, from toddlerhood (mean age = 2 years) into middle childhood (mean age = 10 years). We will incorporate parents' informal anecdotal feedback and supplement this with qualitative interviews with parents at the long-term follow up assessment in order to explore themes relating to the perceived long-term impacts of the *Social ABCs* on the child and family.

Results: Data from the middle-childhood follow-up assessment revealed: (1) the children in the *Social ABCs* pilot group made considerable gains in standardized measures of cognitive, language, and social-communication development; (2) most of the participants did not go on to receive an ASD diagnosis; (3) parents in the pilot group spontaneously shared themes of positive feelings about the impact of the *Social ABCs* intervention on the child's social communication abilities over time; these reflections will be supplemented by formal interview data.

Conclusions: Significant gains were observed in the six pilot participants at a follow-up assessment in middle-childhood. Parents reported positive feelings about the *Social ABCs* and describe possible influences on their child's development and ASD symptoms. In order to further investigate the role of the *Social ABCs* on development over time, we will conduct formal interviews with this group of parents. Future work includes exploring the long-term development of a larger cohort of participants from our RCT.

132 **110.132** Integrating the Early Start Denver Model (ESDM) in ASD Preschools in Israel – Results of a Matched Controlled Study

***T. Gev**[1,2], Y. Sinai[1], G. Vivanti[3], I. Mor Snir[2] and O. Golan[1,2], (1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for*

Children at Risk, Givat-Shmuel, Israel, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA

Background:
The Early Start Denver Model was previously shown to be effective as an intensive home- and group based intervention (Dawson et al., 2010; Vivanti et al., 2014). However, there is currently no evidence for the effectiveness of the ESDM integration into existing community preschool-services. In Israel, this setting is the main provider of intervention services for young children with ASD. It is therefore important to assess the effectiveness of the ESDM when applied in this setting.

Objectives:

To conduct a controlled trial, comparing an implementation of the ESDM in ASD community preschools, to the eclectic program commonly applied in such preschools in Israel. The model has been adapted to the community preschool settings through: (1) translation of relevant training materials (2) A workshop on ESDM principles and teaching techniques conducted for preschool educational and clinical staff (3) weekly individual and group play activities conducted together by preschool aids and ESDM therapists.

Methods:

Fifty-eight children, aged 35-57 months, from eight ASD preschools, participated in the current study. Thirty-three (7 girls) attended preschools in which ESDM was integrated, and twenty-five (3 girls) attended eclectic preschools. Groups were matched on age and developmental level. Both groups received 30 hours per-week of educational intervention and 10 treatment hours per-week by a multidisciplinary team (psychologist/psychotherapist, occupational therapist, speech and language pathologist, physiotherapist, behavior analyst). The implementation of the ESDM included the use of the model's curriculum and treatment practices, and therapists' adherence to the ESDM fidelity rating system. Educational staff incorporated ESDM principles and objectives into the daily preschool routine. In addition, in the ESDM-based program, parents attended weekly parent-child therapy sessions.

Changes in children's cognitive ability (MSEL) and adaptive behaviors (teacher and parent reported VABS-II) as well as parent reported sense of stress (PSI-SF) and competence (P-SOC) were measured pre- and post- 8 months of intervention.

Results:

Both groups showed significant gains in MSEL visual reception, fine motor, receptive and expressive language age-equivalent scores. However, the ESDM-based intervention group showed significantly higher increases in receptive and expressive language, and in fine-motor age-equivalent scores, compared to the eclectic intervention group.

Both groups showed significant gains in all teacher and parent-reported VABS-II subscales. However, the ESDM-based group showed significantly higher gains in the teacher-reported receptive and expressive language, domestic and coping skills subdomains, and in parent-reported play and domestic skills. Parent-reported sense of competence increased in both groups. Additionally, in the eclectic group, parents' perceived stress decreased at post-intervention, while no such decrease was observed in the ESDM-based group.

Conclusions:

The current study's results indicate that the ESDM is cross-culturally valid in Israel, and that it can be integrated into existing community preschools, with positive child outcomes. Cultural and logistical barriers and adaptations introduced to overcome such barriers will be discussed. Additionally, parental involvement in the intervention improves parental competence, but maintains parental stress in the ESDM group, possibly due to the intensive parental involvement and commitment required in the current program, as well as the time-consuming and emotionally charged nature of the treatment process.

133 **110.133** Developmental, Adaptive and Parental Characteristics of High- and Low-Responders to a Preschool-Based Esdm Intervention

Y. Sinai[1], *T. Gev*[1,2], *G. Vivanti*[3], *I. Mor Snir*[2] *and O. Golan*[1,2], *(1)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel, (2)Association for Children at Risk, Givat-Shmuel, Israel, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background:
In the effort to move towards evidence-based treatment individualization for children with ASD, current research attempts to characterize developmental, functional and familial profiles of children with different levels of response to treatment. The Early Start Denver Model is a relationship- and play-based behavioral intervention shown to be effective in home and group settings (Dawson et al. 2010, Vivanti et al. 2014). Previous research exploring outcome predictors in children receiving the ESDM in a group setting has pinpointed chronological age, autism severity, functional use of objects, and imitation abilities as predictive variables of intervention gains.

Objectives:

To identify the profiles of high- and low-responders to treatment in a group of preschool children receiving the ESDM in community specialized-preschool settings in Israel.

Methods:

Thirty-three children (7 girls), aged 34-57 months from four ASD-preschools participated in the current intervention. The ADOS-2 was administered to validate ASD diagnosis. Children received 40 hours per-week of educational and therapeutic preschool-based intervention. The implementation of the ESDM included the use of the model's curriculum and treatment practices, and therapists' adherence to the ESDM fidelity rating system. Educational staff incorporated ESDM principles and objectives into the daily preschool routine. Additionally, parents attended weekly parent-child therapy sessions.

To evaluate intervention gains, children were assessed with the Mullen Scales of Early Learning (MSEL) and parent and teacher reports on the Vineland Adaptive Behavior Scales-II (VABS-II), collected pre- and post an 8-month intervention period. Additionally, parents filled out the Parenting Scales of Competence (PSOC) at both timepoints. Total MSEL age-equivalent score differences were compared to overall treatment-length (in months). High treatment-response was defined as a gain equal to or higher from treatment-length, while smaller gains defined a low-response.

Results:

High treatment-responders showed higher age-equivalent scores pre-intervention on the MSEL visual reception, fine-motor, and receptive and expressive language scales. Furthermore, they had higher communication and daily-skills scores pre-intervention, as reported by teachers and parents, higher parent-reported socialization skills, and higher teacher-reported motor skills. The high-responding group also showed lower levels of autism symptom severity, pre-intervention. The groups were not significantly different on age at entry to the program. While not statistically significant, all girls in the sample pertain to the high-responders group. Parents of high responders have reported higher levels of parental satisfaction pre-intervention.

Conclusions:

Higher levels of developmental and adaptive skills, together with lower ASD symptom severity are related to a more significant response to the preschool-based ESDM. Children may need to have a certain baseline of developmental and adaptive skills to benefit from this program. Children with low developmental and adaptive scores may need to receive individual, intensive treatment before they could benefit from preschool-based ESDM.

The current analysis also indicated that high parental satisfaction might be a facilitating factor in response to the ESDM. In the current program, parents participated in weekly joint ESDM-sessions with their children. High parental satisfaction might be associated with higher motivation to take part in the therapy process and to apply learnt principles in other contexts.

134 **110.134** Early Intervention Focused on Social and Communicative Abilities for Autism: A Systematic Review and Meta-Analysis

Á. Bejarano[1], *M. Magan Maganto*[2], *C. Fernandez Alvarez*[2], *S. L. Jonsdottir*[3], *E. Saemundsen*[3], *A. M. Vicente*[4], *C. Café*[5], *C. Rasga*[6], *M. Posada*[7] *and R. Canal-Bedia*[2], *(1)UNIVERSITY OF SALAMANCA, Salamanca, Spain, (2)University of Salamanca, Salamanca, Spain, (3)State Diagnostic and Counseling Center, Kopavogur, ICELAND, (4)Instituto Nacional Saude Doutor Ricardo Jorge, Lisbon, PORTUGAL, (5)Hospital Pediátrico de Coimbra, Coimbra, Portugal, (6)Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisbon, Portugal, (7)Carlos III Health Institute, Madrid, Spain*

Background: Interventions based on social and communicative skills have become the core of most therapies for children with Autism Spectrum Disorder (ASD), as the demand for such interventions has increased for this population (Wang, Parrila and Cui, 2012). Social reciprocity allows children to participate in shared activities, while improving joint attention and other communicative and social behaviours with peers (Kasari, Gulsrud & Wong, 2010). A wide range of focused practice models have been developed with the aim of helping children with ASD to enhance their social and communicative skills and reduce the number of symptoms in this area. However, comparisons of these models are limited. The quality and effectiveness of these therapies should be further studied to have a better understanding on the subject and suggest best practices.

Objectives: The aim of this study is to conduct a systematic review and meta-analysis to explore the effects of early intervention focused practices in children with ASD on the following 6 abilities: imitation; eye contact; joint attention; pointing; gestures; and play. Furthermore, the analysis aims to identify the most effective interventions according to the characteristics of the participants and the programs, as well as the participation of caregivers.

Methods: Six systematic searches, one for each target ability, were conducted in Medline, PsycINFO, CINAHL and ERIC, to identify peer-reviewed publications from 2000 to April 2017 using ASD and social-communicative intervention-related terms. Inclusion criteria required that studies include participants of 0-6 years of age and described intervention programs, excluding systematic reviews and meta-analyses. A quality review was performed to screen the references, using the EBP inclusion criteria checklist. Meta-analytical methods were implemented, including quality assessment, sensitivity analysis, meta-regression and meta-analysis of studies of different metrics.

Results: 1418 non-duplicate citations were retrieved, and 54 studies were eligible for inclusion in the meta-analysis. Results suggest that socio-communicative interventions lead to positive, medium to large effects in terms of acquisition of imitation (0.48), eye contact (0.88), joint attention (0.57), gestures (0.68), pointing (0.67) and play (0.52) skills. The effects are greater in programs with naturalistic approaches based on behavioural child development, with effect sizes approaching 0.6, and also in those in which caregivers play an active role in therapy conjointly with the main therapist (0.64). Meta-regression analyses show larger effects with younger participants and higher levels of cognitive development, language and dosage intervention.

Conclusions: Naturalistic and behavioural-based development programs are the most effective to improve socio-communicative skills. In addition, if intervention begins as early as possible and caregivers actively participate in high intensity therapy, better outcomes should be expected. As cognitive and language development is a key factor for intervention outcome, further research should be conducted to identify interventions that are effective for children with severe delays. Professionals and caregivers should take into account these results, in order to provide children with ASD the most effective interventions possible. Furthermore, as caregivers' role in therapy seems to be important, this suggests that early intervention programs should be adapted to the characteristics and needs of each child with ASD.

135 **110.135** Early Intervention for Toddlers with Autism Spectrum Disorder Affects Outcome at Adolescence: A Long-Term Follow-up Study

D. A. Zachor[1] *and E. Ben-Itzchak*[2], *(1)The Autism Center/Pediatrics, Tel Aviv University / Assaf Harofeh Medical Center, Zerifin, Israel, (2)Bruckner Center for Research in Autism, Communication Disorder, Ariel University, Ariel, Israel*

Background:

Most studies in autism spectrum disorder (ASD) have examined short-term intervention outcomes after 1-4 years, and showed positive gains in cognitive and adaptive skills. Studies have suggested that individuals with 'optimal outcome' generally received earlier and more intense interventions before three years of age. The current study focused on outcome in young adolescents diagnosed with ASD at a very early age.

Objectives:

To examine long-term outcomes 8-15 years after an early childhood ASD diagnosis (<3 years). The study compared outcomes in autism severity and adaptive skills of children who were enrolled in center-based early intensive intervention programs for ASD to those who were not.

Methods:

The study included 53 participants, 49 males and 4 females, with an age range of 11:0 – 17:10 years (M=13:8, SD=1:10 years). All the participants were diagnosed with ASD (T1) in the age range of 1:3-3:1 years (M=2:2, SD=0:5 years) and were reassessed after 8:7-15:7 years (M=11:7 (SD=1:10) years (T2). The diagnosis of ASD at baseline was obtained using two standardized tests, the Autism Diagnosis Interview-Revised (ADI-R) and the Autism

Diagnosis Observation Schedule (ADOS). Outcome measures included adaptive skills using the Vineland adaptive behavior scales (VABS), and autism severity using the ADOS social affect calibrated severity scale (SA-CSS) and restrictive and repetitive behaviors severity scale (RRB-CSS) at T1 and T2.

The study population was divided into two groups based on the toddlers' educational placement after the ASD diagnosis. One group (n=29) received early intervention in an ASD-specific center-based program for six days per week (total of 40h/w) for at least one year. The second group (n=23) was enrolled in regular day care centers or stayed at home at least until the age of 36 months.

Results:

To examine the outcome at T2, two 2X2 MANOVAS (2 GroupsX2 Times) for ADOS-CSS and VABS scores and 2X2 ANOVA with repeated measures for time were performed.

Autism severity: A significant Time X Group interaction was observed [F(2,48)=4.03, p=.024, h^2 =.144]. The interaction was significant for ADOS-SA-CSS, but not for ADOS-RRB-CSS. While the group of early ASD-specific intervention showed a decrease in SA severity [T1: 7.18(2.19); T2: 6.82(2.98)] the non-ASD-specific placement group showed an increase [T1: 6.74(2.28); T2: 8.65(1.11)] in this measure.

Adaptive behaviors: The analysis showed a significant Time main effect [F(3,35)=3.39, p=.029, h^2 =.225]. A significant increase in the VABS communication scores [T1: 68.79(9.47); T2: 76.95(18.75)] and in the daily living skill scores [T1: 67.92(6.97); T2: 77.46(18.35)] was noted (p=.016, .005 respectively), but not in the socialization subdomain. No significant Time X Group interaction was found.

Conclusions:

Outcome in social communication abilities in adolescents who received ASD-specific intensive early intervention in a center-based setting is more favorable than in those who were not enrolled in these types of centers. Communication and daily living, but not socialization adaptive skills, significantly improved with time and intervention in adolescents with ASD. This study emphasizes the importance of early intensive ASD-specific intervention and indicates improved functioning over time.

136 **110.136** Early Intervention Provider Ratings of Strategies to Promote Social Communication: Differentiating “All” Children from Children with ASD

*M. Maye[1], **V. E. Sanchez**[2], A. K. Stone MacDonald[1] and A. S. Carter[1], (1)University of Massachusetts Boston, Boston, MA, (2)Division of Developmental Medicine, Boston Children's Hospital, Boston, MA*

Background: Several evidence-based naturalistic, developmental, and behavioral interventions (NBDIs) exist for toddlers with autism spectrum disorder (ASD; Schreibman et al., 2015; Wong et al., 2015). However, these types of interventions have been rarely tested within community settings (Nahmias, Kase, & Mandell, 2014; Vivanti, Zierhut, Dawson, & Rogers, 2017). Yet, toddlers with ASD receive early intervention services from Early Intervention (EI) providers who translate research findings into practice (Campbell & Halbert, 2002; Fleming, Sawyer, & Campbell, 2011). Translation will require identification of interventions’ common active ingredients as well as strategies that are more easily disseminated in community settings (Kasari 2012, Pellecchia et al., 2015). Given that EI’s are implementing these strategies in the community, their perceptions about the clinical effectiveness of evidence-based NBDI strategies are needed to inform dissemination efforts and to identify specific behavioral strategies to evaluate as potential active ingredients in future research.

Objectives: To explore early intervention providers’ perceived beliefs of the clinical effectiveness of various intervention strategies on specific behaviors in “children with an ASD” and “all children.”

Methods: Early interventionists who reported providing early intervention services for a toddler with ASD between 12-to-36 months of age within the last 12 months were recruited via email to complete an Internet based survey evaluating the perceived effectiveness of 31 strategies on specific target behaviors. Of 48 early intervention directors invited to distribute surveys to all of their EI providers, 28 responded and 22 agreed to distribute our survey. Ninety-three EI providers completed our survey. EI providers were predominantly female (n=91) and were highly educated (75 MA, 17 BA, 1 PhD). EI providers rated 31 behavioral strategies from 1-to-5 from least to most effective for each group (i.e., ASD, all children). Providers ranged in years of experience between 0 to 33 years (M= 9.25, 8.34).

Box-cox transformations were completed on 38 (of 62) variables to address non-normality. Then, paired samples t-tests were completed for 31 intervention strategies comparing EIs ratings of efficacy for each strategy across “children with an ASD” and “all children.” Effect sizes were calculated for all significant pairs.

Results: Twenty-two of the intervention strategies were rated as significantly more effective for “all children” than for children with ASD. Effect sizes were robust with 6 strategies having large effect sizes (>0.8), 10 strategies having medium effect sizes (≥0.5, and ≤0.8), and 6 strategies having small effect sizes (≥0.2, and ≤0.5). No intervention strategies were rated as being statistically more effective for children with ASD on any of the behavioral targets. EI provider ratings did not result in significant mean differences for children with ASD or “all children” for the remaining strategies.

Conclusions: EI provider ratings indicated different effectiveness expectations for intervention strategies when applied to children with autism versus all children. Strategies related to make-believe play resulted in the largest effect sizes (*d*=.99-1.05) whereas strategies related to establishing routines and some aspects of joint attention were rated comparably. These findings could be useful in developing interventions that are sensitive to community settings (i.e., inclusive versus special education).

137 **110.137** Early Robot-Based Intervention May Reduce the Degree of Gestural Delay in Children with Autism

***M. K. Y. Wong**[1], W. Y. Lam[1], C. H. E. Cheng[1], J. Yang[1], H. Ying[2], H. C. J. Man[3], A. Pang[1] and W. C. So[4], (1)The Chinese University of Hong Kong, Hong Kong, Hong Kong, (2)The Chinese University of Hong Kong, HONG KONG, China, (3)The Chinese University of Hong, Hong Kong, Hong Kong, (4)Educational Psychology, The Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background: Abundant research has shown that children with autism spectrum disorders (ASD) have delayed gestural development throughout their childhood (Charman et al., 2003; Mastrogiuseppe et al., 2015; So et al., 2015b). Particularly, they have challenges in producing intransitive gestures (those include socio-communicative intent, e.g., waving hand for bye-bye, arms opening wide for welcoming others). However, there is a lack of effective intervention techniques designed to teach ASD children intransitive gestures. Recently, So and her team pioneered the use of

social robots in teaching school-aged children with ASD gestural communication skills. Robots are operated on predictable and lawful systems, thereby favoring children with ASD (empathizing-systemizing theory;Baron-Cohen, 2009). Their results reported robot-based intervention yielded significant differences between pretests and posttests in gestural production (So et al., 2016b; 2017). Yet, it is not known about whether ASD children still have delayed gestural production, in comparison to their age-matched typically-developing(TD) peers, after completion of training.
Objectives: The present study investigated whether ASD children could catch up to the level of gestural production in age-matched typically-developing (TD) peers in both trained and novel situations. If so, their accuracy in producing intransitive gestures would be on par with that of age-matched TD peers. Otherwise, children with ASD would still performed poorer than their TD peers.

Methods: ASD children(N=30;4;2-6;11;SD=.62) were randomly assigned to two conditions: intervention and wait-list control. ASD children in the intervention condition(N=15) were taught 14 intransitive gestures (e.g., welcome, awesome) demonstrated by a social robot, NAO, who was narrating different stories. There were four training sessions, twice per week. ASD children in the wait-list control condition(N=15) and all TD children(N=15;4;3-6;3;SD=.65) could opt for training after completion of research. At the beginning of the experiment, all children had their motor skills, attention, language and communication ability, and gestural recognition assessed. They also took the pre-tests before training in the intervention condition began. In the pretests, an experimenter asked the child, "Show me an action for welcome?", when narrating stories and gave him/her 10s to demonstrate the gesture. The pre-tests were completed after 14 gestures were tested. Immediate and delayed posttests, which were identical to the pretest, were administered right after and two weeks after training respectively. Generalization pretests and posttests were also administered for novel stories not presented during training. A gesture was considered accurately produced when all four parameters (use of hands, handshapes, movements and directionalities) were correct.

Results: Table 1 shows the task performance for three groups of children. After controlling for the language, cognitive, and motor skills, there was significant time(pretests,posttests)xgroup(ASD,TD)xstory(trained,novel) interaction, F(4,82)=10.91,p<.001,η^2=.34. Specifically, for trained stories, ASD children generally performed poorer than TD in the pretests, ps<.04, but ASD children in the intervention condition outperformed TD in the immediate and delayed posttests,ps<.04. However, for novel stories, ASD children performed poorer than TD in the delayed posttest,p<.03.

Conclusions: Early robot-based intervention may reduce the degree of gestural delay in children with autism but its effectiveness is only salient in the trained stimuli. Further study should improve the power of generalizations.

138 **110.138** Educating Parents of Children with Autism Spectrum Disorder on Direct and Interactive Teaching Techniques – Editt Program

*K. Rajaraman[1], **A. Jayaraman**[2] and N. Mundkur[1], (1)Centre for Child Development and Disabilities, Bangalore, India, (2)Center for Child Development and Disabilities, Bengaluru, Karnataka, India*

Background: In India, >10 million children are affected by autism spectrum disorder (ASD). With improvements in diagnosis, the number of cases is expected to greatly increase; however, there continues to be a deficit of professionals in the field of autism intervention. Parent-implemented intervention has shown better outcomes for both children and parents compared to other forms of intervention for ASD, and has extended the benefits of intervention to the home environment. We have designed and implemented two programs that empower parents as interventionists as well as provide development appropriate activities in the four developmental domains – Socio- emotional, Receptive communication, Expressive communication, and Play.
Objectives: To develop programs to involve and support parents in the developmental intervention of children with ASD.

Methods: We have developed an online parent-based program called SCoPE (**S**ocial **Co**mmunication **P**lay and **E**motional) that provides development appropriate activities for children with developmental delays including ASD. In addition, we have developed EDITT (**E**ducating parents on **D**irect and **I**nteractive **T**eaching **T**echniques), a novel hands-on training program to empower parents with home-based parent-delivered developmental intervention using SCoPE. In the EDITT program, parents (n = 30) received 4 group-training sessions with their child and 4 individual sessions in the first month. They were assessed by the trainer for knowledge acquisition and practical application on a weekly basis. After the first month, parents have the option of enrolling for monthly maintenance sessions of 1 h for 6 months. At the end of 6 months, parents will be assessed for retention of knowledge and practical application. In addition, we also assessed the mental status of parents using modified Beck's Depression Inventory (BDI) and SF-36 forms before and after the training sessions. Data were analyzed using paired t-test with a significance level of 0.05.

Results: The mental status of parents in the EDITT program showed significant improvement between pre-training and post-training (p = 0.0018). Although there was no significant difference in the knowledge acquisition level between weeks 1 through 4, the parents showed significant improvements in the practical application between weeks 1 and 2 (p = 0.0001) and between week 2 and weeks 3-4 (p = 0.0008). The 6 month-data will be available for analyses in the coming months.

Conclusions: Based on our pilot data, we can conclude that the EDITT program is helping parents to be more sensitive and responsive to their children with ASD as well as training them to facilitate socio-emotional, functional communicative and play development through theoretical and practical knowledge. We have already seen significant improvements in parents as interventionists who extend their training to their home environment and everyday activities of their children. We also observed a significant improvement in their depression status and quality of life after the training and a sense of empowerment.

139 **110.139** Effect of Parent and Teacher Training with Project Impact on the Social Communication of Children with Autism Spectrum Disorder during Play

***S. Van der Paelt**, H. Roeyers and P. Warreyn, Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background: There is growing consensus that intervention for children with autism spectrum disorder (ASD) should include their natural interaction partners to make the intervention cost-effective and to help children generalize skills to a range of situations. Project ImPACT (Ingersoll & Dvortcsak, 2010) is a social communication intervention originally developed to train parents, which makes use of interactive and more direct behavioural techniques. Since children with ASD spend a large part of their day at school, there could be an additional benefit of training not only parents, but also teachers to stimulate the social-communicative skills of children with ASD during the school day.
Objectives:

1. To study the effect of Project ImPACT on social-communicative skills of children with ASD at home and at school.
2. To assess whether progress in these skills starts already after the introduction of interactive techniques or only after the introduction of behavioral techniques.

Methods: We used a multiple baseline design with four children with ASD between 2.5 and 6 years old. Parents and teachers each received 24 semi-weekly sessions at home and in the school respectively. Teacher training started 5-7 weeks after the start of the parent training. Children were followed-up until 4-6 months after completion of the intervention. Treatment effect was assessed by weekly video-observations of parent-child and teacher-child interaction, in which social engagement, requesting and imitation were coded. The data were analyzed visually and by calculating an effect size *d1*.

Results: A clear effect was found of the parent training on the duration of *social engagement*. For two children this effect was clear during the phase where only interactive techniques were used (*d1* = 1.6-7.2). For the other two the effect only became clear in the phase where behavioral techniques were introduced (*d1* = 1.1-1.7). There was no added effect of the teacher training on social engagement. Three out of four children showed an increase in the number of *requests* to their parents after the introduction of interactive techniques (*d1* = 1.5-2.0). All children showed an increase in the number of requests after the start of the teacher training. For three of them this effect was visible from the beginning of the intervention (*d1* = 1.7-4.2). Only one child started to *imitate* more during parent-child-interaction after the start of the parent training. All children imitated their teachers more after the start of the teacher training. Two children already did this during the interactive teaching phase (*d1* = 0.5-0.6), while the other two needed more direct instruction (*d1* = 0.5-1.5). Most of these effects were maintained until follow-up.

Conclusions: Project ImPACT had the clearest effect on the requesting skills of the children, since these skills improved with both parents and teachers, soon after the introduction of the intervention in the respective contexts. Social engagement only improved during parent-child interaction, while imitation skills only improved during the teacher-child interaction. For some children these effects were only visible after the introduction of behavioral techniques, providing support for the effect of both types of techniques.

140 **110.140** Effectiveness of Community-Based Early Intervention for Children with Autism Spectrum Disorder- a Meta-Analysis

A. S. Nahmias[1], *M. Pellecchia*[2] *and D. S. Mandell*[3], *(1)MIND Institute, UC Davis Medical Center, Sacramento, CA, (2)University of Pennsylvania, Philadelphia, PA, (3)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: Research trials of early intervention programs for children with ASD generally produce medium-to-large gains, on average, compared to "treatment as usual," in cognition, communication, social ability, and adaptive behavior (Hedges's *g* 0.4 – 1.2). Almost all children with ASD receive their treatment through community-based services, however, and previous research has suggested that evidence-based interventions rarely make their way into community practice. Understanding the effects of community-based early intervention is the first step in developing strategies to improve wide-scale implementation of effective early intervention.

Objectives: To estimate the average effects and predictors of cognitive, social, communication, and adaptive behavior outcomes among children receiving community-based early intervention.

Methods: Studies of community-based early intervention for children with autism were identified through a systematic search of online databases, hand-searching relevant journals, and reviewing references. Community-based early intervention was defined either as "treatment as usual" control groups in randomized or quasi-experimental trials or in studies that explicitly examined treatment outcome in community settings. Changes in cognitive, communication, social, and adaptive behavior functioning from pre-treatment to post-treatment were assessed using standardized mean gain scores. Uncontrolled effect sizes (Hedges's g) were calculated by dividing the mean change from pre-to post-treatment by the pooled standard deviation of the difference score. Overall effect sizes were estimated using random effects models. The Q-statistic and the I^2 index were used to examine heterogeneity of effect sizes. Moderators of interest included type of community EI program, year of publication, intervention duration, and total intervention hours, sample selection methods, age at intake, their effects were assessed using analysis of variance of mixed-effects models and meta-regression analyses.

Results: Forty groups from 29 studies met inclusion criteria (1496 participants, mean age 37.4 months, 84.9% male). There was significant improvement in each of the four domains; however, the gains were small. Hedges's *g* ranged from 0.21 for adaptive behavior to 0.31 for communication outcomes, after removing outliers and correcting for publication bias. "Model" early intervention programs (e.g., those associated with universities and hospitals) were generally superior to other community early intervention program types across all four outcomes (Hedges's *g* ranged from 0.4 - 0.5 for "Model" programs and from 0.01 – 0.3 for other community programs). Only communication outcomes demonstrated increasingly larger effect sizes in more recent years. Intervention duration and total intervention hours were negatively associated with effect sizes for communication and adaptive behavior outcomes. Studies in which participants were randomly assigned to receive community treatment had smaller effect sizes for social outcomes than studies utilizing other treatment group allocation strategies. Age at intake did not significantly moderate outcomes in any of the four domains.

Conclusions: These results indicate that there remains a large gap between research and community practice, and that for most outcomes community-based early intervention has not improved over time. Further research is needed to close the gap in outcomes observed in children receiving treatment in randomized trials and those observed in children receiving treatment in community settings.

141 **110.141** Effects of School-Based Literacy Interventions for Preschoolers with ASD: 1 Year Follow up

R. F. Hudson, *E. Sanders and C. Gasamis, University of Washington, Seattle, WA*

Background: It is well established that readers need to develop proficiency in word reading and general language comprehension to read with comprehension (Oakhill, Cain, & Bryant, 2003). This study compares two school-based interventions that target one side of the simple view of reading. Both interventions were 1:1, 4 days a week for 20 weeks. One intervention was Interactive Book Reading (IBR), which was found to increase expressive vocabulary (*d = .29)* and listening comprehension (d = .30) in comparison to a BAU control group immediately after intervention. The other intervention was phonological awareness (PA), which increased phonological awareness (*d* = .39) immediately after intervention. A remaining question is whether these gains have maintained 1 year later.

Objectives: Determine the longer term effects of treatments for preschool children with ASD

Methods: This study followed a sequential cohort design. Across the three years, children with ASD were randomly assigned to IBR (n = 48), PA (n= 43) or BAU control (n = 44) group. The inclusion criteria were (a) a medical diagnosis of ASD or an educational identification, (b) an active IEP and receive services for ASD, (c) enrolled in their last year of preschool, (d) no known co-occurring neurological or genetic disorders, and (e) a minimum standard score of 55 on the OWEPVT. Children were given the following measures pre- and post-intervention and one year later: Peabody Picture Vocabulary Test–IV, Expressive One-Word Picture Vocabulary Test–IV, Oral Communication, Letter-Word Identification, and Following Directions subtests of the Woodcock-Johnson III Tests of Achievement, the Phonological Awareness and Concepts About Print subtests of the Test of Preschool Early Literacy. In the spring of Kindergarten, children were also administered the Passage Comprehension subtest of the WJ-III and Oral Reading Fluency on two first grade passages.

Results: A multilevel modeling approach for testing differences among three conditions, while adjusting for pretest, was employed to account for dependencies in the data due to classroom and site. Initial results indicate that children in the IBR condition had generally better outcomes one year later despite the initial results favoring IBR on language variables. Specifically when looking at Standard Scores, the PA group was significantly higher than the IBR group on the following variables: receptive vocabulary, listening comprehension, passage comprehension, and oral reading fluency. In addition, the PA group was significantly higher than the BAU group on letter-word ID. No differences between BAU and IBR were found.

Conclusions: These results are somewhat surprising given that the PA intervention focused on developing phonological awareness and not oral language and these effects were not found immediately after intervention. However, it is in line with the findings of Dynia et al. (2017) that found PA to be an important emergent literacy predictor for kindergarten decoding among children with ASD. They are also somewhat surprising given that children with ASD tend to have difficulties in listening and reading comprehension, which one might expect to find improved after an intervention that demonstrated a large gain in vocabulary and listening comprehension immediately after intervention.

142 **110.142** Engaging Peers in Play: Community Partnered Adaptation of a Social Communication Intervention to Support Pairs of Toddlers with Autism

S. Y. Shire[1], *W. I. Shih*[2], *C. McCracken*[3], *S. Bracaglia*[4], *M. Kodjoe*[4] *and C. Kasari*[2], *(1)University of Oregon, Eugene, OR, (2)University of California, Los Angeles, Los Angeles, CA, (3)Loyola Marymount University, Los Angeles, CA, (4)New York Center for Child Development, New York, NY*

Background: Community Partnered Participatory Research can support the adoption of research-based practices in real world settings. To match the needs and context of a community center-based toddler program, the current project focused on adapting a one-to-one social communication intervention for children with autism, to include a peer in play based interactions. A randomized controlled trial was conducted where paraprofessionals in half the classrooms were taught to deliver the adapted peer intervention while half continued to deliver the original one-to-one model, both designed to target children's social communication and play skills.

Objectives: First, to explore paraprofessional teaching assistants' (TAs) implementation of a naturalistic developmental behavioral intervention-Joint Attention, Symbolic Play, Engagement, and Regulation (JASPER: Kasari et al., 2008; 2014) adapted to include a peer (referred to as jasPEER). Second, to examine children's social communication and play skills for those randomized to the novel jasPEER sessions (including a TA and two children) versus one-to-one TA-child JASPER sessions.

Methods:

Forty-eight TAs, and 113 toddlers (mean age=32.28 months) across 4 classrooms were randomized to JASPER with a peer present (jasPEER) or one-to-one JASPER waitlist control. Children had received an autism spectrum disorder (ASD) diagnosis (n=1 with Down Syndrome). All but two TAs, and two children were members of an ethnic minority group.

Intervention. Significant effects of JASPER over treatment as usual on joint engagement, joint attention gestures, play skills, and language were demonstrated with this center in a prior trial (Shire et al., 2017). Building upon TAs' knowledge of one-to-one JASPER, they were provided with two weeks of in-vivo training and ongoing video feedback from the research team to learn the jasPEER adaptation. Children in waitlist classrooms received JASPER for 30 minutes a day for 11 weeks, while children in immediate jasPEER received the adapted peer version during this time.

Measures. Ten-minute video recorded TA-child interactions at entry, midpoint, and exit were coded for children's joint engagement (JE), and TAs' implementation. Independent assessors also administered the Short Play and Communication Evaluation, a brief semi-structured measure of play, and joint attention.

Results: TAs in jasPEER demonstrated significant gains in implementation scores from entry to exit ($f(1,74)=10.23$, $p=0.002$), with average exit scores of 72%. Children in jasPEER started with significantly lower JE in session with TA and peer ($f(1,246)=2.95$, $p<.01$). However, the children made significant gains in JE to exit ($f(1,246)= 5.14$, $p<.01$), such that the groups were not significantly different in JE by exit ($p=.64$). Overall, children in both groups demonstrated significant gains in initiations of joint attention ($f(1,162)=52.71$, $p<0.001$) and play diversity across levels (simple: $f(1,162)=5.56$, $p=0.019$; combination: $f(1,162)=7.68$, $p=0.006$; pre-symbolic: $f(1,162)=24.42$, $p<0.001$; symbolic: $f(1,162)=29.24$, $p<0.001$). No significant between group differences were found.

Conclusions: TAs learned to implement a peer adaptation of JASPER well by exit. Limited child JE at entry in jasPEER may be influenced by the learning curve required of TAs for the adaptation while JASPER TAs could continue with existing skills and strategies. Overall, children in both groups made significant gains in core skill domains including social communication and play.

143 **110.143** Examining Mediators of an Adaptive Communication Intervention for Young Children with Autism Spectrum Disorders

E. Fuller[1], *L. H. Hampton*[2] *and A. P. Kaiser*[1], *(1)Special Education, Vanderbilt University, Nashville, TN, (2)Northwestern University, Evanston, IL*

Background: As many as 30% of children diagnosed with ASD are classified as nonverbal or minimally verbal at age 5 despite access to early intervention (Tager-Fluberg & Kasari, 2013). Persistent minimal verbal status is associated with poor long-term prognoses for social and adaptive functioning (DeMyer et al., 1973; Liss et al., 2001). In order to better address the skill deficits of young, preverbal preschoolers who are at risk for becoming minimally verbal children, an intervention combining two evidence-based treatments, J-EMT (Kasari et al., 2014) and DTT (Smith, 2001) was developed and manualized for implementation in a RCT. The intervention was designed to specifically target foundational skills for communication that individual children did not display and to modify instruction based on their progress during intervention. These foundational skills included: joint attention, receptive language, imitation, and proficiency in using a speech-generating device (SGD). These skills have shown to be predictive of long-term outcomes in language and communication (e.g. Charman, 2003; Luyster, et al., 2007; Gernsbacher, 2008; Kasari, et al., 2014).

Objectives: The objective of the current study is to examine how changes in foundational communication skills mediated the outcomes of an adaptive communication intervention by asking the following question: Do joint attention initiations, receptive language ability, imitation skill, and SGD proficiency mediate the effect of group assignment on social communication outcomes?

Methods: Data for this analysis are from a RCT (R40MC27707). Seventy-three children with ASD were randomly assigned to either a 36-session intervention combining DTT and J-EMT including an SGD or a business as usual control group. The dependent variable, defined as the total number of social communicative utterances, was measured in a 20-min language sample with an unfamiliar assessor. The putative mediators were measured as follows: initiating joint attention (IJA) was measured from the Early Social Communication Scales (ESCS; Mundy et al., 2003); receptive language was measured from the auditory comprehension subscale of PLS-5 (Zimmerman, et al., 2011); verbal imitation was measured as the number of attempted consonants during the Profiles of Early Expressive Phonology (PEEPS; Williams & Stoel-Gammon, 2014); SGD proficiency was measured as the size of visual field from which the child is able to identify an object on the SGD. Mediators were measured at posttest; the dependent variable was measured 2-months following posttest.

Results: Baseline characteristics are presented in Table 1. There were no significant between-group differences on relevant variables at pretest. Coding and analysis for all time-points are currently 80% complete. Mediation analyses will be used to examine the underlying mechanism driving the relationship between the independent variable (group assignment) and dependent variable (social communicative utterances; Hayes, 2009).

Conclusions: Findings of this study will identify foundational skills that mediate language and communication outcomes for preschooler-aged children with ASD who are at risk for becoming minimally verbal. These findings may lay the foundation for developing and testing a decision-making framework for early intervention targets, including establishing criterion levels of behavior change on specific malleable factors required to benefit from interventions based in naturalistic principles.

144 **110.144** Examining the Stability of Social Communication Measures for Young Children with Autism Spectrum Disorders

J. K. Heidlage[1]*, L. H. Hampton*[2]*, E. Fuller*[3] *and A. P. Kaiser*[3]*, (1)Vanderbilt, Nashville, TN, (2)Northwestern University, Evanston, IL, (3)Special Education, Vanderbilt University, Nashville, TN*

Background:

Identifying stable measures of social communication has important implications for evaluating the impact of early intervention. This may be especially important for the estimated 30% of children with ASD who are preverbal or minimally verbal because these children often show floor effects on standardized assessments of language (Anderson, et al., 2007; Kasari et al., 2013). Initiating joint attention (IJA) gestures are predictive of later language use (Charman 2003; Kasari et al., 2012) and frequently used to characterize emerging communication skills. Evaluating changes in these gestures, as well as language is used to indicate the effectiveness of interventions as well as to evaluate child progress.

Objectives:

The objective of this analysis was to (1a) use a generalizability study (G-study) to evaluate the stability of early measures of IJA and language across two different observational measurement contexts and (1b) use a decision study (D-study) to estimate the number of additional observations required to provide optimal estimates of IJA and language in preverbal children with ASD.

Methods:

Data were analyzed from pre-intervention assessments of 73 participants enrolled in a recently completed RCT (HRSA #R40MC27707) examining outcomes for young, preverbal children with ASD between the ages of 36 and 54 months (mean age=42.88 months) who were at risk for remaining minimally verbal. Occurrences of IJA were coded from two different observational measurement contexts: a standardized language sample (LS) and the Early Social Communication Scales (ESCS; Mundy et al., 2003). A G-study was conducted to assess the stability of IJA by evaluating the *g* coefficient, which provides an index of the amount of variance that is attributable to true variance in measurement rather than to sources of measurement error. A higher *g* co-efficient indicates less measurement error; a *g* co-efficient that ranges from 0.6 to 0.8 is considered to produce a stable estimate (Bakeman et al., 1997). After conducting the G-study, a D-study was conducted to estimate the number of different measurement contexts needed to achieve a stable estimate of IJA. An additional G-study is currently being conducted to evaluate the stability of a measure of language (number of different words produced) across two observational measurement contexts (LS and parent-child interaction). A D-study will be conducted to estimate the number of additional observations needed to achieve a stable estimate.

Results:

Results from the G-study indicated that two measures of IJA were not sufficient for achieving a stable estimate (*g*=0.43). Results from the D-study indicated that up to four observations of IJA may be required to achieve a stable estimate in preverbal children with ASD (*g*=0.60), and that up to 10 observations may be required to achieve an optimal stability estimate (*g*=0.80).

Conclusions:

The low value of the *g* coefficient across the two measures indicates a need for additional measures of IJA to increase the stability of existing measures. An aggregated measure of IJA may provide a better measure of the predictive value of these skills on spoken language. These results are important given use of gestures is often evaluated by a single measure.

145 **110.145** Feasibility, Acceptability and Effect on Classroom Teaching of Delivering Early Intervention in an Inclusive Setting

K. Capes[1]*, K. Hudry*[2,3]*, S. Upson*[1]*, J. Feary*[1]*, E. Duncan*[1]*, C. A. Bent*[4,5]*, R. Rankin*[1,5]*, C. Dissanayake*[3]*, K. Pye*[1] *and G. Vivanti*[6,7]*, (1)Victorian Autism Specific Early Learning and Care Center, La Trobe University, Melbourne, Australia, (2)Victorian Autism Specific Early Learning and Care Center, Olga Tennison Autism Research Centre, Melbourne, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (4)Victorian Autism Specific Early Learning and Care Centre, La Trobe University, Melbourne, Australia, (5)Olga Tennison Autism Research Center, La Trobe University, Melbourne, Australia, (6)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (7)AJ Drexel Autism Institute, Philadelphia,*

PA

Background: A small body of empirical research has focused on the outcomes achieved by young children with ASD in inclusive and specialized settings, providing mixed results. Little experimental research addresses whether early intervention for pre-schoolers with ASD is feasibly delivered in inclusive settings (vs. established autism-specific settings) and whether such delivery would be acceptable to families and staff and not detrimental to the quality of classroom teaching for all children.
Objectives: In the context of a pilot randomised controlled trial, whereby we assigned pre-schoolers with ASD to receive the Group-Early Start Denver Model (G-ESDM; Vivanti et al., 2017) within either mainstream inclusive classrooms or specialised autism-specific classrooms, we took a number of measures to evaluate classroom- and teacher-level outcomes. These served to inform the feasibility and acceptability of delivering G-ESDM in inclusive setting.

Methods: Twenty-nine pre-schoolers with ASD (aged 18-36 months) were randomly assigned to receive G-ESDM intervention across the 2015 and 2016 school calendar years in an Autism-Specific classroom or an inclusive classroom with mostly typically-developing children. Educators in both settings were supported to implement the G-ESDM through participation in a three day ESDM skills training workshop and ongoing coaching delivered in the classrooms by Senior ESDM therapists (certified for more than 5 years) and ESDM Trainers. Feasibility, acceptability and effect on classroom teaching quality was measured by examining the degree of fidelity to the ESDM achieved by key staff implementing the intervention within each setting, and by comparing blind-rated Sustained Shared Thinking and Emotional Well-Being (SSTEW; Siraj, Kingston, & Melhuish, 2015) scores across each setting, and against the current local benchmark within Australia.

Results: Average ratings for ESDM fidelity in the Specialized Setting exceeded 80% in both calendar years and, in the Inclusive setting, exceeded 72% in 2015 and 76% in 2016. Results from the SSTEW indicated that teaching quality in the classrooms was classified as ‘good’ overall, across both the Inclusive and Specialized settings. Subscales scores varied from ‘adequate’ to ‘excellent’ with no substantive differences between Settings on any indicator. The overall ratings were well above the benchmark reported across 54 local Australian early childcare centres.

Conclusions: Data from this pilot RCT highlighted that delivery of G-ESDM to children with ASD within inclusive early childhood education settings is, 1) feasible, acceptable and not detrimental to the quality of the general classroom teaching and learning environment, and 2) able to be successfully adopted by inclusive early childhood educators with ongoing support from Senior Certified therapists and ESDM trainers. Further research on this topic should include measures of 1) staff and management attitudes to inclusive education and to working with children with ASD, 2) staff buy-in to the particular model of early intervention adopted and to the training program provided, , and 3) staff well-being in the work place. These would advance knowledge on the feasibility and considerations for the effective implementation of early intervention training for staff working with children with autism in inclusive settings.

146 **110.146** From Emotion Production to Emotion Comprehension: An Emotional Training Proposal for Children with ASD

N. Mazzoni[1]*, J. Rizzotto*[1]*, E. Tonelli*[1]*, A. Bentenuto*[1]*, T. Del Bianco*[1]*, I. Basadonne*[1]*, I. Landi*[2] *and P. Venuti*[1]*, (1)Psychology and Cognitive Science, University of Trento, Rovereto, Italy, (2)Bruno Kessler Foundation, Trento, Italy*

Background: According to the “direct-matching” hypothesis (Rizzolatti et al., 2001), there is a link between motion perception and execution and the comprehension of an observed action is underlay by the activation of the internal representation of the same action in the observer’s brain. Toddlers with ASD show signs of motor impairment - emotional expressions included - that often persists in adulthood. This atypical kinematic might lead to an abnormal perception of others’ actions. For instance, the motoric schema for expressing emotions in people with ASD could be different from the emotional expressions observed in other people and this mismatch could explaind the difficulties in comprehending other people's emotions.
Objectives: The aim of the present study was to investigate the link between motion perception and execution in ASD, by testing the effects of training the production of emotional expressions - both facial and bodily - on emotion comprehension. We hypothesized that training the emotion production would have favoured a reorganization of motoric schema for emotion expression and in turn improved the emotion recognition.

Methods: 17 children with ASD (age (M=5.38, SD=1.92); IQ (M=74.85, SD=18.9); ADOS (M=6.8, SD=2.18)) participated to one week of training. The daily sessions focused on joy and anger separately on alternate days. Children initially watched a cartoon clips with characters experiencing anger/joy; then they listened nursery rhymes about emotions and produced the corresponding expressions; finally, children imitated emotional expressions with the help of pictures.To assess the children’s comprehension of emotions, they underwent naming, comprehension, and match-to-sample tasks before and after the training, using pictures of facial and bodily expressions.

Results: Separated repeated measures ANOVAs were performed in each behavioural task. Results showed that the *naming* accuracy generally increased over time (F= 8.88; p=0.015; ges=0.079), and was greater for faces than for bodies (F=14.42; p=0.004; ges=0.278). Interestingly, only the naming accuracy for bodily expressions increased significantly (t=-2.447, p=0.037). *Comprehension* was higher for facial than bodily expressions (F=5.989; p=0.044; ges=0.022). The effect of Time on comprehension was marginally significant (F=3.595; p=0.1; ges=0.036), and the interaction between Time and emotion approached significance (F=4.395; p=0.074; ges=0.005), with increased accuracy for happiness over time. In the *match-to-sample* task, accuracy was higher for faces than for bodies (F=17.364; p=0.004; ges=0.199) and the effect of Time approached significance (F=4.276; p=0.077; ges=0.076).

Conclusions: The results show a tendency towards improvement in all the behavioural tasks after the training, suggesting that training the production of emotional expressions can foster the emotion comprehension. In general, emotion recognition resulted more accurate with facial than bodily expressions, suggesting that recognition of bodily expression is still developping in preschooler with ASD. In line with that, our results suggest a major effect of the proposed training on the recognition of bodily expressions. These finsings highlights the importance of including the body language in the emotional trainings for children with ASD.

147 **110.147** Integrated Naturalistic Developmental Behavioral Interventions for Toddlers with ASD: A Preliminary Analysis of Treatment Effectiveness within a Community Setting

B. Vibert[1]*, J. Winter*[2]*, C. Martin*[3]*, Y. B. Choi*[4]*, N. Benrey*[5]*, C. Lord*[6] *and* ***S. H. Kim***[7]*, (1)Psychiatry, Center for Autism and the Developing Brain, Weill Cornell Medical College, White Plains, NY, (2)Center for Autism & the Developing Brain, NYP, White Plains, NY, (3)Weill Cornell Medicine, White Plains, NY, (4)Psychiatry, Weill Cornell Medical College, White Plains, NY, (5)Weill Cornell Med School, New york, NY, (6)University of California Los Angeles,* *Los Angeles, CA, (7)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

Background: Randomized Controlled Trials (RCTs) of Naturalistic Developmental Behavioral Intervention (NDBI) programs have demonstrated improved symptoms and functioning in toddlers with autism spectrum disorder (ASD). Yet, treatment effectiveness of these RCTs have mainly been demonstrated within university-based research contexts. Thus, examination of treatment efficacy of integrated NDBI implemented in community-based clinics is necessary to evaluate intervention feasibility.
Objectives: We aim to evaluate preliminary effectiveness of a short-term (6 month) NBDI program implemented in a community-based clinic for toddlers with ASD.

Methods: A total of 14 toddlers underwent a 6-month NDBI program that integrates multiple intervention modalities (see Table 1 for the details of the program). Child assessments and parent interviews were conducted at treatment entry (Time 1; mean age= 24.1 months, SD= 4.6) and treatment exit (Time 2; mean age= 32 months, SD=5.98) based on Autism Diagnostic Observation Schedule (ADOS), Mullen Scales of Early Learning-Second Edition (MSEL), Vineland Adaptive Behavior Scales-Second Edition (Vineland-II), and the Early Start Denver Model-Curriculum Checklist (ESDM-CC). Generalized Linear Mixed Models (GLMM) were used to examine the changes in autism symptom severity (ADOS), developmental skills (Mullen, ESDM-CC), adaptive functioning (Vineland) while controlling for baseline cognitive levels, symptom severity, language level, and age, and other demographic factors (i.e., race, gender, and maternal education).

Results: Despite the small sample size, significant improvements were found in these areas ($p<0.05$; see Table 2); 1) nonverbal and verbal domains measured by the MSEL, including visual reception, fine motor, receptive and expressive language as well as several areas of development measured by the ESDM-CC, including Expressive Communication, Social Skills, Imitation, Cognitive, Fine Motor, Joint Attention and Personal Independence; 2) autism symptom severity measured by the ADOS algorithm total scores; 3) adaptive expressive language and personal daily living skills measured by the Vineland-II. Effect sizes (Cohen's D ranged from .3-1.5). In addition, baseline symptom severity and language levels consistently predicted improvements across these domains.

Conclusions: Based on 14 toddlers who received a short-term NDBI program implemented in a state-funded, community-based setting, significant improvements across various developmental nonverbal and verbal domains, ASD symptom severity, and adaptive functioning were found using (non-treating) clinician ratings, parent report, and therapist ratings. Results indicate that baseline clinical features such as language and symptom severity may mediate the improvements in these skills over the course of treatment. Our research did not include a control group for treatment; therefore, based on these promising results for the potential feasibility of the community-implemented NDBI program, a randomized control trial is underway to examine the treatment efficacy and the mechanisms of treatment effects in toddlers with ASD.

148 **110.148** Mediation of Treatment Effect in Teacher-Implemented Social Communication Intervention for Young Children with Autism

Y. C. Chang[1], *S. Y. Shire*[2], *W. I. Shih*[3] *and C. Kasari*[3], *(1)Special Education and Counseling, California State University, Los Angeles, Los Angeles, CA, (2)University of Oregon, Eugene, OR, (3)University of California, Los Angeles, Los Angeles, CA*

Background:
Few studies have examined mediators of treatment outcomes for young children with autism (e.g., Gulsrud et al., 2015; Pickles et al., 2014), and none for teacher-implemented interventions. Previous studies have examined specific strategies, or active ingredients, within interventions; however, it is important to consider that interventions are often packaged for optimal effect. Thus, we have identified and grouped strategies within the intervention into three tiers of support (Basic, Foundational, and Advanced) to examine how these different sets of strategies mediate the outcome measure of joint engagement.

Objectives:

The current study is a secondary data analysis from two previously published teacher implemented intervention studies (Chang et al., 2016; Shire et al., 2016). The aim of this study is to examine whether sets of strategies mediate joint engagement.

Methods:

Participants. 179 children age 2-5 years (mean age=38 months; SD = 9.35) from two independent community intervention deployment studies (Chang et al., 2016 and Shire et al., 2016) were included in the study. Children in both studies were randomized to immediate JASPER (Joint Attention, Symbolic Play, Engagement, and Regulation) treatment (IT) or school as usual control (WL) for 3 months.

Intervention. Teachers and paraprofessionals received training and in-vivo coaching with the research team to learn the JASPER intervention. In the IT group, teachers implemented JASPER 30 minutes a day with their students for 3 months, while WL teachers continued with standard school curriculum.

Ten-minute Teacher-child play interactions (TCX). Teachers' accurate implementation of JASPER was coded at entry and exit. Seven main strategy subscales were coded. Each subscale was summarized in a percentage score where higher score indicates greater implementation accuracy. Three tiers of strategies were created: Tier 1 (Basic) included supporting regulation/engagement, environmental arrangement, and imitation/modeling. Tier 2 (Foundational) included play routines and language strategies. Tier 3 (Advanced) included play expansion and programing for social communication gestures. Children's time jointly engaged was coded as proportion of the play interaction that children were jointly engaged with their teachers (1 minute intervals).

Results:

Basic and Advanced strategies partially mediated the effect of treatment (% mediated: 36% and 28% respectively; p-values<0.01) while *Foundational* strategies had close to full mediation (50% mediation; $p<0.01$).

Conclusions:

All three sets of strategies mediated the effect of treatment on joint engagement. Joint engagement was most influenced by *Foundational* strategies. These results highlight the importance of *Foundational* strategies, which include establishing developmentally appropriate play routines and responding to and expanding children's communication. It may be that *Basic* strategies, such as setting up the environment, may not be enough support to engage children with autism, and *Advanced* strategies, such as expanding routines, may be more effective after *Foundational* strategies, such as having a solid play routine, are established to create a context for social communication.

149 **110.149** Overcoming Barriers to Mass Dissemination: A Pilot Online Pivotal Response Treatment Training Program for Parents of

Toddlers with Autism Spectrum Disorder

E. McGarry, *A. Baktha, A. Tharakan and T. W. Vernon, University of California Santa Barbara, Santa Barbara, CA*

Background: Despite advances in evidence-based treatment for autism spectrum disorders (ASD), disparities in service access remain a serious concern. The current delivery format of many interventions represents a critical roadblock to treatment access. Most models require parents to commute to a clinic or have a clinician visit their home many hours per week. This format may not be feasible for families who live in remote geographical regions, do not have the resources to travel or pay for weekly therapy services, and/or are headed by single parents with competing work obligations. To address this, recent studies have begun to explore parent-implemented interventions via an online or telehealth format (Nefdt et al., 2009; Vismara et al., 2012; Wainer & Ingersoll, 2013). These approaches are particularly beneficial as they improve access to training for families, can fit into busy family schedules, and lower the cost of expensive treatments (Nelson, Bui & Velasquez, 2011). The current pilot study examined a newly developed 5-week online course designed to help parents implement an evidence-based intervention, Pivotal Response Treatment (PRT), for their child with ASD.

Objectives: This study's objective was to investigate the impact of an online course to disseminate PRT strategies for parents of young children with ASD.

Methods: Participants were 20 families of toddlers with ASD, ages 24-48 months. PRT presentations consisting of informational slides, video examples, and brief quizzes were delivered through Qualtrics each week. Topics focused on core intervention strategies to elicit communication and social engagement through playful interactions, child-selected materials, and positive behavior principles. Parents submitted weekly videos capturing their use of these treatment strategies, which were coded for PRT fidelity of implementation (FOI). FOI was defined as the parent properly demonstrating all PRT components with competency at least 80% of the time. Fidelity summary scores were obtained at multiple time points (pre-intervention and once per weekly session). Social validity measures were also obtained.

Results: Data from families who have completed the course were analyzed. A paired samples t-test was conducted to compare parent treatment fidelity pre- and post-intervention. Analysis revealed that parent's treatment fidelity improved significantly from baseline (M= 2.5, SD= 1) to Week 5 (M= 4.5, SD= 1.29), *p*= .016. These results were supported by social validity data from families indicating high satisfaction with the course. On a 0-6 scale, (0= Strongly Disagree, 6= Strongly Agree) all families reported that their child's level of social engagement had improved over the course of intervention (M= 5.00). Additionally, all families indicated that they would recommend this course to a friend in need of intervention for their child (M= 5.33).

Conclusions: The data indicate that PRT implementation fidelity significantly improved following participation in the online course. These results suggest that an online intervention may be a feasible approach to disseminating PRT strategies. This innovative format has the potential to reduce disparities in access to evidence-based intervention.

150 **110.150** Parent Perspectives of a Parent-Teacher Communication App after Use in a Classroom for Preschoolers with ASD

M. Pizzano[1] *and C. Kasari*[2]*, (1)Education, University of California, Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA*

Background:

Communication between families of children with ASD and their school remains understudied. Parent participation in their child's education improves skill maintenance and generalization, but parents of children with ASD are more dissatisfied with the level of communication with their child's school versus parents of TD children (Moes and Frea, 2002; Zablotsky, 2012). Parent support remains the lowest level of implementation of the NRC recommendations for autism research (Tincani et al., 2013).

Telehealth approaches to intervention are a promising but remain nonexistent for parent communication (Vismara, 2013). An app was used to track positive behavior, but has not been examined for communication between parents of children with ASD and their child's service team (Jordan, 2016). Electronic communication is investigated in other health fields, but not in autism intervention (Eysenbach, 2004).

Objectives:

To explore how parents of children with ASD perceive using an app to communicate with their child's preschool team.

Methods:

Parents completed a questionnaire describing their experience using a cellphone communication app. The app, part of a 4-week long preschool program for 11 students aged 42-86 months with ASD, was used by the classroom team to communicate with parents.

1 teacher and 6 aides posted updates on the app. Updates appear like a social media feed, with accounts for each individual student and one account for the classroom as a whole. Each parent has access to the classroom's and their student's account. Posts give updates of the day and include videos, images, and written private messages. Over the course of the program, 608 posts were shared with parents, with an average total of 40.09 posts per student and an average of 2.22 posts per student per day. Posts per student ranged from an average of 1 to 4.7 per day.

12 parents of the 11 students were emailed, and 9 completed, a questionnaire at the end of the program. It consisted of six open-ended questions about how frequently parents used the app, whether they had previously used a similar method of communication, and their perceptions of using the app.

Results:

Parents rated their experience using the app favorably. All parents checked the app at least daily, with 44.4% checking it 1-2 times per day and 55.6% checking it over 3 times per day. None had used a communication app previously with their child's team. All 9 reported positive feelings toward using the app. All 9 parents reported feeling more connected to the classroom as a result of using the app. 8 of the 9 parents reported that their favorite part of the app was the picture updates, with others commenting that the app let them be part of their child's day and gave up-to-date information about the day's events.

Conclusions:

Parents checked their child's activities daily, reported enjoying the app, and feeling connected to their child's classroom, given a high frequency of app use. The next step is to incorporate the app as part of a controlled examination, with particular attention to the potential to reduce parent anxiety.

151 **110.151** Parent-Led Training for Motivating Eye Contact in Young, Low-Functioning Children with Autism

M. Muuvila[1]*, T. M. Helminen*[2]*, K. Eriksson*[3]*, T. Charman*[4] *and A. Kylliainen*[2]*, (1)Tampere University Hospital, Tampere, Finland, (2)Tampere University, Tampere, Finland, (3)Tampere University and Tampere University Hospital, Tampere, Finland, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Difficulties in the use of eye contact are widely reported in children with autism spectrum disorder (ASD). Following this, it may be important to motivate them to look towards other people's eyes and faces as early as possible to reduce further abnormalities in social development. Involving parents in interventions of early social communication skills has been shown to reduce autistic behaviour and improve parent-child interaction.

Objectives: The aim of the study was to pilot a parent-led training method targeted to improve eye contact in young children with ASD. The planned training method was in addition to treatment as usual (TAU) which also includes eye contact encouragement but not as systematically and explicitly as in this training method. It was predicted that children's motivation towards faces would increase if eye contact is reinforced by trying to make it rewarding. It was further assumed that children's interaction with their parents would improve.

Methods: Twenty young (age range: 2.5-5.5 years of age) and low-functioning children with severe ASD were randomly divided into an intervention group (N=10) and a control group (N=10). The parents of the intervention group were taught to do three kinds of daily activities with their child for 4 months. The activities included encouraging the child to use eye contact for requesting food, toys or physical play activity, and imitating the child's actions in a specific manner. The training was based on combining behavioural and developmental principles of early intervention. Baseline and outcome measures included observations, questionnaires and psychophysiological measures. There were short-term measurements 4-6 months and long-term measurements two years after the baseline measurements in both groups. Orientations toward the parent's face (indicative of eye contact) and the state of engagement were analysed from play sessions with the parent in the laboratory and at home. The number of eye contacts was analysed in addition to the information as to whether the eye contact was an overture or a response, and whether it was linked to other forms of social communication.

Results: The laboratory observation analyses showed that in the intervention group eye contacts, especially responsive eye contacts, increased in the short-term outcome ($Z = 2{,}61$; $p = 0.009$). Eye contact was also connected more often to other forms of social communication (e.g., gestures and facial expressions) in the intervention group ($Z = -2{,}51$; $p = 0.012$). The increase of eye contacts was not significant in the control group. Preliminary analysis of the long-term follow up indicated that these findings remained stable. The significant improvement of the joint engagement ($Z = -2{,}19$; $p = 0.028$) was evident only after the long-term follow-up and was shown in the intervention group only (Fig.1).

Conclusions: It seems beneficial to encourage eye contact initiation in young, low-functioning children with ASD. The parent-led eye contact focused training did not only increase the use of eye contact but, importantly, also the state of engagement seemed to improve in the long run.

152 **110.152** Parent-Mediated Intervention Increasing Parent-Child Engagement and Improving Cognitive and Behavioural Outcomes of Toddlers with Autism Spectrum Disorder

M. Couture[1]*, A. J. Beaudoin*[2] *and G. Sebire*[3]*, (1)Rehabilitation, Universite de Sherbrooke, Sherbrooke, QC, Canada, (2)Rehabilitation, Université de Sherbrooke, Sherbrooke, QC, Canada, (3)Pediatrics, McGill University, Montreal, QC, Canada*

Background:
Now that it is possible to identify a child with autism spectrum disorder (ASD) in the first two years of life, efforts are being made to develop early effective interventions for toddlers at high risk of ASD. Thus, age-specific strategies have to be used to offer effective early intervention to these toddlers with a diagnosis or a suspicion of ASD (Rogers & Wallace, 2011) including parent involvement. By participating in parent-mediated interventions, parents develop skills to promote their toddler's development. Parent-mediated interventions that focus on joint attention, imitation and play can capitalize on teachable moments as they occur, provide learning opportunities during daily routines, and facilitate the generalization of learned skills across environments.

Objectives: this study aims to evaluate the effects of parent-mediated intervention for toddlers with a suspicion or a diagnosis of ASD on quality of parent-child interactions and children developmental outcomes using a crossover randomized controlled trial.

Methods: The 12-week parent-mediated intervention was an adaptation of the parent delivery of the Early Start Denver Model (P-ESDM, Rogers, Dawson, & Vismara, 2012) and the Social Communication Emotion Regulation Transaction Support (SCERTS, Prizant, Wetherby, Rubin, & Laurent, 2003) Model. The intervention was delivered in the family's home (60 to 90 minutes). The 19 parent-child dyads were randomized either in the Intervention group or the Waitlist group (participants in this group had to wait three months before getting access to the intervention). The primary outcome was the quality of dyadic engagement between the child and his parent as measured by the total score of the *Engagement state, Child and Caregiver Behavior, and Shared Topic* (Adamson, Bakeman, Deckner, & Nelson, 2013). Based on Adamson's and colleagues protocol (Adamson et al., 2013), four cluster scores were also analyzed, which are 1) Child Joint Engagement, 2) Child Behavior, 3) Caregiver Behavior, and 4) Shared Topic. Secondary outcomes were related to children's development. These outcomes include cognitive abilities, motor skills, and adaptive behaviors all assessed via the *Bayley Scales of Infant Development – 3rd edition* (Bayley, 2006), a widely used tool for early childhood assessment

Results: This crossover randomized trial highlights the positive effect of the parent-mediated intervention on parent-child dyadic engagement ($p=.012$; effect size=.51). Also, the participation to the intervention stimulates the child development that is manifested by a mild-to-moderate normalization of toddlers' cognitive abilities ($p=.010$; effect size=.57) and motor skills ($p=.071$; effect size=.38) compared to typically developing peers.

Conclusions: Very promising effect sizes underline trends toward moderate-to-large improvement in parent-child dyadic engagement and a mild-to-moderate normalization of children's developmental outcomes after a 12-week parent-mediated intervention. These results also highlight greater benefits on proximal outcomes, specifically the way parent and child interact with one another in play compared to more distal child-related outcomes (Helm & Kozloff, 1986; Mahoney & Perales, 2003; Mahoney & Perales, 2005; Oono et al., 2013).

153 **110.153** Parenting Stress, Self-Efficacy and Empowerment in Primary Caregivers of Children with Autism Spectrum Disorder Receiving Ipad-Based Early Intervention: Outcomes from the Toby Trial

Background: A diagnosis of an autism spectrum disorder (ASD) and the start of a range of early and intensive behavioural interventions (EIBI) to ameliorate ASD symptoms in young children are significant life events and potential stressors that can impact on parental stress, satisfaction, self-efficacy, sense of competence and empowerment. The use of technology to complement EIBI may assist caregivers in delivering timely therapy at low cost. However, the impact of any EIBI on parents is limited, so we investigated parent attributes to better understand their needs during EIBI in a bid to develop interventions with parent focused components.

Objectives: As part of an iPad-based early intervention (Therapy Outcomes By You: TOBY) for young children with ASD, this study aimed to investigate the effects of TOBY on perceived parental factors such as 1) parenting stress 2) satisfaction 3) self-efficacy and 4) empowerment among primary caregivers whose children participated in the TOBY randomised controlled trial (RCT). Parental outcomes were assessed at 3 and 6 months post-baseline.

Methods: The TOBY app provides a learning curriculum within which a combination of solo on-screen, partner-on-screen and real world tasks are encouraged and implemented by parents. Children aged 51 months or younger with a clinical diagnosis of ASD (received in the past 12 months) and parents were randomised to the TOBY (>20 mins/day) plus therapy as usual group (TOBY, n = 41) or the control - therapy as usual only (TAU, n = 39) group for 6 months. In addition to children diagnostic, functional and developmental assessments, primary caregivers self-completed the Parenting Stress Index, Parenting Sense of Competence Scale and Family Empowerment Scale at baseline, 3 and 6 months post-intervention.

Results: Primary caregivers (mothers) were 34.38 (*SD* = 4.74) years of age at baseline. One quarter (23.4%) of all parents reported clinically significant stress scores at baseline. Non-parametric tests were used to examine differences between and within the TOBY and TAU groups due to non-normal distributions. No significant differences between the TOBY and TAU groups emerged. However, primary caregivers within the TOBY group perceived less parental stress at 3-months (*Mdn* = 86.5) compared to their baseline stress scores (*Mdn* = 95.5, *z* = -2.54, *p* = .011) but their stress scores did not differ significantly at 6 months post intervention (*Mdn* = 91.5, z = -1.24, *p* = .212). There were no significant differences within the TOBY group for parenting satisfaction, self-efficacy and empowerment at 3- or 6 month follow up.

Conclusions: Some parents of newly diagnosed children with ASD experience high levels of stress at the start of therapies. A reduction in parenting stress among TOBY parents in the first 3-months was observed but not at 6 months post-intervention. Although this requires exploration, the results suggest parent screenings to determine stress levels with a view to assess clinical needs and services aimed to support parents during early intervention. The findings have implications for future research in EIBI and the development of comprehensive early interventions for ASD with embedded parent support components.

154 **110.154** Pilot RCT of Early-Intervention Delivered in Inclusive Vs. Autism-Specific Settings: Blinded Proximal Outcomes from LENA Recordings and Classroom Footage

K. Hudry[1,2], *C. A. Bent[3,4], J. Maya[5], R. Rankin[4,5], C. Dissanayake[2], S. Upson[5], J. Feary[5], K. Capes[5], E. Duncan[5], G. Vivanti[6] and T. Victorian ASELCC Team[5], (1)Victorian Autism Specific Early Learning and Care Center, Olga Tennison Autism Research Centre, Melbourne, Australia, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)Victorian Autism Specific Early Learning and Care Centre, La Trobe University, Melbourne, Australia, (4)Olga Tennison Autism Research Center, La Trobe University, Melbourne, Australia, (5)Victorian Autism Specific Early Learning and Care Center, La Trobe University, Melbourne, Australia, (6)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA*

Background: Little experimental research addresses the relative benefits of different intervention approaches for children with autism or differential effects of specific delivery methods. Further, understanding relative benefits is complicated by a lack of outcome measures that are both meaningful and sensitive to change over time among young children with autism who may also present with substantial developmental delays.

Objectives: We examined growth in proximal outcome measures in toddlers and pre-schoolers with autism during receipt of a manualized early intervention. Children were randomly assigned to receive the Group-Early Start Denver Model (G-ESDM; Vivanti et al., 2017) within either mainstream inclusive classrooms or specialised autism-specific classrooms within a community childcare service. We hypothesised that children receiving their intervention within mainstream settings might make greater or more rapid gains in proximal outcome measures than those in the autism-specific setting, given the opportunity afforded for regular interaction with typically-developing peers, alongside the specialist input from classroom staff.

Methods: We randomly assigned 29 preschoolers with ASD (aged 18-36 months) to receive intervention across the school calendar year either in classrooms that included 1) only children with ASD (n=15; i.e., Autism-Specific Setting) or 2) mostly typically-developing children (n=14; i.e., Inclusive Setting). Two proximal measures were sampled at the start and end of the school year, and at three intermediate times. Language ENvironment Analysis (LENA) was used to record rates of spontaneous child vocalisation from 40-minute semi-structured interaction samples, with automated data extraction. Following Clifford et al. (2010) we collected footage of free-play and snack time sessions to sample spontaneous child intentional communication bids within classrooms, and coding by blinded researchers demonstrated excellent inter-rater agreement (ICC=.93).

Results: Children showed increased rates of spontaneous vocalisation and intentional communication bids – including both initiations and responses toward others – across the intervention year, particularly within the first half of the year. There was no differential effect of randomisation group. However, children randomised to the inclusive setting showed greater rates of intentional communication at the start of the year and maintained this advantage over time.

Conclusions: Spontaneous child vocalisations, recorded and extracted automatically via LENA, and intentional communication bids, coded from naturalistic 10-minute classroom behaviour samples, appear to be sensitive measures of growth in children's skills over time. Advantages of these methods include the ability for repeated sampling across an intervention period and automated extraction (LENA) and blinded coding (Classroom

Footage) with high inter-rater agreement. While we did not observe differential effects of randomisation, we may have been underpowered to do so with this relatively small pilot sample. Replication with a larger sample would also permit the use of more sophisticated method of growth analysis and allow examination of potential moderators and mediators of outcome.

155

110.155 Pilot Research Prevents Anxiety Problems in Young Children with Autism

N. L. Bischof[1], R. M. Rapee[2], K. Hudry[3,4] and ***J. K. Bayer***[1,5,6]*, (1)School of Psychology and Public Health, La Trobe University, Melbourne, Australia, (2)Centre for Emotional Health, Macquarie University, Sydney, Australia, (3)Victorian Autism Specific Early Learning and Care Center, Olga Tennison Autism Research Centre, Melbourne, Australia, (4)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (5)Murdoch Children's Research Institute, Melbourne, Australia, (6)Psychology and Public Health, La Trobe University, Melbourne, Australia*

Background: Autism is highly comorbid with anxiety. Meta-analysis of studies of children and adolescents with autism report prevalence of anxiety disorders at 40% (Steensel, Bogels & Perrin, 2011). Research with school age children with autism finds that cognitive behavioural treatment reduces comorbid anxiety (Chalfant, Rapee & Carroll, 2007; Sukhodolsky, Bloch, Panza & Reichow, 2013). To date there have been no published early intervention studies for anxiety among preschool children with autism.

Objectives: This pilot study aimed to explore acceptability to parents and outcomes for young children with autism of a preventive intervention for anxiety problems. The study focused on children with autism who were participating in a wider population-based randomised trial of the Cool Little Kids parenting group program.

Methods: The population trial included 545 temperamentally inhibited preschool children recruited across eight economically diverse areas of Melbourne, Australia. Within this sample, 26 parents reported that their child had received an autism diagnosis. The trial measures included baseline inhibited temperament and developmental problems, post-intervention quantitative and qualitative feedback on the program, and child mental health outcomes (anxiety diagnoses and internalising symptoms) one and two years post baseline.

Results: The rate of autism cases in the sample of inhibited young children was 4.8%, or one in 20, compared to population prevalence estimates between 1 and 2%. Sample retention over two years for children with autism in the trial was strong (92%). At follow up, fewer intervention than control children with autism had anxiety disorders (25% *vs.* 77%, $p = .03$) and separation anxiety symptoms (*M (SD)* = 4.22 (2.68) *vs.* 9.38 (5.91), $p = .03$). Parents of children with autism in the trial intervention arm reported that Cool Little Kids was "quite useful" in relation to their child's anxiety but also gave feedback that they would appreciate some tailoring of program content to the context of autism.

Conclusions: These pilot findings suggest that Cool Little Kids may be helpful for reducing comorbid anxiety in young children with autism. This warrants further research to develop an autism-specific adaptation that can be trialed with a larger sample of children with corroborated autism diagnosis.

156

110.156 Pivotal Response Treatment 2.0: Development and Evaluation of an Enhanced Model to Target Social Motivation and Engagement Using Microanalytic and RCT Methodologies

T. W. Vernon[1]*, A. Barrett[1], A. Navab[1], J. A. Ko[1], E. McGarry[1], J. Bradshaw[2], J. Gong[1], E. Horowitz[1] and T. German[1], (1)University of California Santa Barbara, Santa Barbara, CA, (2)Department of Psychology, University of South Carolina, Columbia, SC*

Background: Effective early intervention models have been a life-alternating development in the field of autism spectrum disorders, offering the hope of normalized developmental functioning and outcomes. Applied behavior analysis offered a transformative leap forward in intervention technology, offering a framework for systematically teaching children new behaviors through repetition and reinforcement. The introduction of Pivotal Response Treatment (PRT) and other Naturalistic Developmental Behavioral Interventions (NDBIs) constituted a paradigm shift of comparable magnitude, utilizing motivational and developmental elements within natural learning contexts to significantly increase skill acquisition. However, even with an ever-growing empirical foundation for PRT, the issue of differential response to intervention remains. Modification of the PRT model to directly target social motivation and engagement may further enhance developmental outcomes and eventually pave the way for third generation intervention paradigms.

Objectives: To use a series of studies to systematically develop and evaluate an enhanced PRT model's effect on child engagement, parent-child interactions, and developmental outcomes.

Methods: Across the three interrelated studies, the existing PRT framework was modified to embed engaging social components. Specifically, participants' preferred nonsocial activities were analyzed to identify the motivating sensory elements that yielded high levels of engagement. These elements were extracted and embedded into socially analogous activities to leverage this existing motivation and transfer it into dynamic exchanges with adults.

Study I was an ABAB design with three children aged 3:1-3:5. Clinician-delivered traditional PRT and an enhanced social PRT model were contrasted to examine within session effects on child social engagement and eye contact.

Study II was a multiple baseline design with three children aged 2:0-4:11 and their parents. During baseline, parents were taught traditional PRT procedures. During intervention, enhanced social PRT model strategies were introduced. Session data were gathered on parent and child social behaviors using moment-by-moment sequential analysis techniques.

Study III was a randomized controlled trial with 24 children aged 1:6-4:6 and their parents. Twelve were randomly assigned to the enhanced social PRT condition (10 hours a week) and twelve were assigned to a community treatment group for six months. Mullen, ADOS-2, PLS-5, Vineland-II, and SLO data were analyzed using mixed MANOVA procedures.

Results: Studies I & II yielded data confirming superior child social engagement in the enhanced PRT condition. Study II's lag sequential analyses revealed significant increases in the total number and transitional probability of parent-child social exchanges.

Study III yielded significant Group X Time effects across several measures, with the treatment enhanced PRT group experiencing superior improvements in developmental, autism symptom severity, language, and adaptive skill measures.

Conclusions: The results from this progression of studies demonstrate the potential of an enhanced social PRT framework. Specifically, Study I yielded a significant increase in child social initiations and responses at the micro level. Next, Study II demonstrated that increased child receptivity and parent-introduced motivational exchanges can generate crucial social momentum in the form of sustainable parent-child transactions and synchrony. Finally, Study III demonstrated that continued exposure to this enhanced PRT model has the potential to significantly alter the developmental trajectories of young children with ASD.

157 **110.157** Pivotal Response Treatment: Effectiveness of Group Versus Individual Parent Training on Pivotal and Collateral Skills

R. Verschuur[1,2] *and B. Huskens*[1]*, (1)Research, Development, & Innovation, Dr. Leo Kannerhuis, Doorwerth, Netherlands, (2)Behavioural Science Institute, Radboud University, Nijmegen, Netherlands*

Background: Effective and efficient parent training is essential to meet to the increased demands for treatment services for children with Autism Spectrum Disorder (ASD). Several studies have indicated that parent training in Pivotal Response Treatment (PRT) is effective to teach parents to implement PRT with their child (e.g., Coolican et al., 2010; Hardan et al., 2015; Minjarez et al., 2011; Symon, 2005), but research comparing the effectiveness of group versus individual of parent training in PRT is lacking.

Objectives: This study investigated the effectiveness of group versus individual parent training in PRT on parent-created opportunities and children's self-initiations, and explored collateral changes in parental stress and children's maladaptive behavior.

Methods: Participants were 26 parents and their children with ASD, aged between 3;0 and 14;9 years. Thirteen parent-child dyads participated in group parent training in PRT and thirteen parent-child dyads participated in individual parent training. Both group and individual parent training consisted of instruction in PRT-techniques, practice, and video-feedback, but individual training also included guided practice. One multiple baseline design across groups and two multiple baseline designs across participants were used to investigate the effectiveness of group and individual parent training on parent-created opportunities and children's self-initiations. To explore collateral changes parents completed two questionnaires during baseline and post-intervention. Data analysis included visual analysis (Lane & Gast, 2014) and statistical analyses (i.e., Tau and Reliabilty of Change Index [RCI]; Jacobson & Truax, 1991; Parker et al., 2011)

Results: Preliminary results of 21 parent-child dyads indicated that 5 parents participating in group training (N = 11) created significantly more opportunities during intervention (overall Tau = 0.53; $p < 0.001$). Reliable reductions in parental stress were observed in 7 parents (RCI < -1.96); one parent reported a reliable increase in stress (RCI > 1.96). Self-initiations increased significantly for 2 children (overall Tau = 0.35; $p < 0.001$). Maladaptive behavior reliably decreased in 5 children, but significantly increased in 3 other children. Nine parents participating in individual training (N = 10) created significantly more opportunities during intervention (overall Tau = 0.81; $p < 0.001$), but only for 2 parents reductions in stress were reliable; one parent reported a reliable increase in stress. Self-initiations significantly increased for 4 children (overall Tau = 0.54; $p < 0.001$). Maladaptive behavior reliably decreased in 5 children, but increased significantly in 2 other children.

Conclusions: These preliminary findings suggest that individual parent training in PRT is more effective in increasing parent-created opportunities than group training, but group training appears to be more effective in reducing parental stress. In both groups only a minority of children demonstrated significant improvements in self-initiations and for both groups results concerning maladaptive behavior were mixed. Explanations for findings and recommendations for future research will be discussed.

158 **110.158** Predictors of Treatment Response in the Social ABCs Parent-Mediated Intervention for Toddlers with ASD

J. A. Brian[1]*, S. E. Bryson*[2]*, L. Zwaigenbaum*[3] *and I. M. Smith*[4]*, (1)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Dalhousie University, Halifax, NS, Canada, (3)University of Alberta, Edmonton, AB, Canada, (4)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA*

Background: The *Social ABCs* is a parent-mediated intervention for toddlers with, or at-risk for, autism spectrum disorder (ASD). Following pilot evidence of efficacy (Brian et al., 2016), a recent RCT demonstrated that toddlers who received the *Social ABCs* made significant gains, relative to controls, in functional vocal responsivity to parent prompts, vocal initiations, positive affect, and social orienting; parents learned the techniques (achieved implementation fidelity) and reported increased empowerment (Brian et al., 2017). As with most behavioural/ developmental interventions, outcomes varied across individuals in both studies, raising the question of what factors were associated with degrees of responses. Identification of moderators and mediators of treatment response has been identified as an urgent research priority (Vivanti et al., 2014; IMFAR SIG, 2017), with potential to inform personalized intervention pathways and resource allocation.
Objectives: To explore factors associated with response to *Social ABCs* treatment.

Methods: Demographics, video-coded indices, and standardized assessment data from 50 parent-child dyads, all of whom had received the *Social ABCs* intervention, were included (mean child age = 24.0 months; SD = 4.5; range: 12-32 months). Putative predictors were examined using univariate ANOVA and linear regression, with child vocal responsivity (baseline to post-training change; z-transformed) as the primary outcome.

Results: The vast majority (98%) of parents achieved implementation fidelity, and 92% of toddlers demonstrated some improvement, but with individual variability. Regression analyses revealed two significant child-level baseline predictors, with small-to-medium effects (f^2): Expressive language (Mullen age equivalent; $R^2 = .12$, $p = .016$; $f^2 = .14$), and rate of spontaneous initiations ($R^2 = .09$, $p = .035$; $f^2 = .10$), with a negative association for both. Notably, parent fidelity of implementation post-training, but not at baseline, significantly predicted outcome ($R^2 = .14$, $p = .008$) with a medium effect ($f^2 = .16$). The following baseline variables were explored but not associated with treatment response: ASD symptoms (ADOS-2 calibrated severity score; $p = .40$), toddler age ($p = .38$), parental education ($p = .06$), sibling status ($p = .19$), number of words used ($p = .56$). However, a significant effect was found for child sex ($p < .001$), wherein boys in our sample demonstrated a greater response. This is likely related to lower baseline expressive language in boys (Mullen t-score; $p = .04$), and the negative association between baseline language (age equivalent) and response. These relations need further examination.

Conclusions: Preliminary investigation of factors associated with treatment response revealed the importance of baseline language/communication abilities, with greater gains for toddlers who began the program with relatively lower verbal proficiency. This may be explained by a ceiling effect in some, but not all, cases. Parental implementation fidelity following training was the greatest single predictor of children's progress, supporting the efficacy of the program. Severity of ASD symptoms and age were not associated with treatment response, indicating that this intervention is appropriate for a range of high-risk toddlers. Findings will guide development of a combined moderator/mediator model including interactions between factors, and examination of other key outcomes (e.g., positive affect, social orienting).

159 **110.159** Preschool Peer Social Intervention: Study Outcome and Integrative Summary

N. B. Bauminger-Zviely[1], *S. Hoshmand*[2], *O. Rajwan, Ben - Shlomo*[2] *and D. Eytan*[1], *(1)School of Education, Bar Ilan University, Ramat Gan, Israel, (2)School of Education, Bar - Ilan University, Ramat Gan, Israel*

Background: Peer relations in typical development are cardinal for children's development of ample cognitive, linguistic, and social skills (e.g., Hay, et al., 2009). Longitudinal evidence shows that individual variations in behavior and in responding to peers' behavior as well as in playing and conversing with peers at early ages predict later social competence (e.g., Coplan & Arbeau, 2009). These areas do not develop typically in children with ASD, thus limiting peer relationship experiences in young children with ASD and forming the basis for reduced peer engagement across development (Manning & Wainwright, 2010). Yet, relevant manualized evidenced-based social curriculum to enhance peer-interaction that are developmentally-based, ecological-school-based for preschoolers with ASD are scarce.
Objectives: To provide an integrative view on learning goals related to peer- social intervention through the summary of the *Preschool Peer Social Intervention (PPSI*) – Evidenced-based school social curriculum to promote Peer Play Conversation and Interaction for preschoolers with ASD. The objective of this talk is to present comparative results between treatment modalities (play, conversation, and interaction) and to teach us about the links between play, language, interaction and overall social competence in ASD. These young children's ability to generalize from a treated social domain to an untreated one will be reviewed (e.g., from play to conversation and vice versa). Furthermore, we aimed to provide a critical overview of current literature.

Methods: The PPSI project included 65 children with high-functioning ASD (HFASD) randomly divided between four main groups: three intervention groups (play, conversation and interaction) and a waitlisted no-treatment control group. PPSI manualized curriculum is holistic, integrating CBT as well as developmental and ecological orientations, targeting three major areas of children's social deficiency in ASD: splay, conversation and interaction with typical age-mates. Multi-method assessment procedures included pre-post behavioral measures of children's social competence completed by parents and teachers, and observations of children's play, conversation and interaction with their peers. Post-treatment gains in untreated domains will identify generalizability of the groups' treatments.

Results: Overall, as expected, children in each treatment modality showed higher improvement in their learned skills compared to the other groups. For example, the play group improved play capabilities more than the conversation group that improved their quality of speech better than the interaction group. However, we also found two levels of important generalizations: 1.From one modality to the other (e.g., 20% of the children in the conversation group improved their social play complexity, and children in the interaction group improved their paralinguistic capabilities on the pragmatic scale) 2. Of the learned skills to the child's natural free-play situation in the preschool according to the blind teacher's report.

Conclusions: The PPSI outcome can help the future design of more individualized approaches to the treatment of core deficit in peer interaction, resulting in mitigation of the social withdrawal and isolation in older ages. Furthermore, the ecological nature of the PPSI can teach us about the implementation of social intervention within the child's natural social environment-his preschool, involving his natural peers. These issues will be further discussed.

160 **110.160** Randomized Comparison of Two Instructional Sequences for Imitation Intervention for Children with Autism Spectrum Disorder

E. Espanola[1], *A. Gutierrez*[2] *and M. N. Hale*[1], *(1)University of Miami, Coral Gables, FL, (2)University of Miami, Miami, FL*

Background:
Children as young as 24 months of age diagnosed with Autism Spectrum Disorder exhibit poor imitation skills. Amongst the many skills often targeted during early intervention, imitation is particularly important because of the integral role it plays in the development of communication and social skills. However, the published curricula provide a sequence for selecting imitation targets for intervention that has never been directly tested and are not empirically validated. This lack of information is a potential pitfall, because it is impossible to know whether the sequence of skills in these curricula accurately represent a continuum of complexity. A shortfall, that could result in less responding, more trials to mastery and less skill acquisition. The use of an empirically validated protocol may result in more faster and more efficient learning.
Objectives:
The aim of this study was to determine differences in effectiveness and rate of skill acquisition between a recently developed and empirically validated instructional sequence, Motor and Vocal Imitation Assessment (MVIA), and a commonly used instructional sequence in a curriculum guide, Verbal Behavior Milestones Assessment and Placement Program (VB-MAPP).
Methods:
Children with ASD were randomly assigned to two treatment groups to determine difference in imitation performance. The treatment group followed the instructional sequence proposed in the MVIA. The comparison group followed the instructional sequence proposed in the VB-MAPP. Initial levels of imitation were assessed via the MVIA. The intervention consisted of discrete trial training (DTT). A trained therapist presented a fixed number of stimuli in massed trial format. Prompted and unprompted imitative responses were reinforced using edibles. A most-to-least with a progressive time delay prompting strategy was used to help the learner engage in the target response.
Results:
Participants in the MVIA treatment group had significantly more skill acquisition than participants in the VB-MAPP comparison group. Participants in the MVIA treatment group also acquired these skills more efficiently, spent less time on skills that never reached mastery and demonstrated higher levels of responding. Additionally, pre-treatment imitation was found to predict autism severity and expressive language.
Conclusions:
These results indicate that the MVIA protocol provides an appropriate sequence ordered from simple to complex for selecting targets for intervention. These findings suggest that organizing and sequencing skills in increasing difficulty, as with the MVIA protocol, leads to more appropriate target selection. Targeting skills that are appropriate for the child's current skill level, in turn leads to more effective and efficient intervention. Results also replicate previous findings that demonstrate that imitation performance plays a critical role in other areas of development.

161 **110.161** Short-Term Parent-Mediated PRT: Teaching Social Initiation to Children with Autism Spectrum Disorder through Question

Asking

S. Popovic[1] *and E. M. Starr*[2]*, (1)University of Windsor, Windsor, ON, Canada, (2)Faculty of Education, University of Windsor, Windsor, ON, CANADA*

Background: Parents of children with ASD report high wait times between diagnosis and service referral (between 22-39 months (Gordon, 2015)). In addition, the financial cost of many early intervention programs can be prohibitive and are difficult to continue at home. Pivotal Response Treatment (PRT) is a naturalistic evidence-based intervention based on principles of Applied Behaviour Analysis that may occur at home, can be taught to parents, and targets a number of pivotal behaviours including social initiation. Social initiations are imperative for development; however, many children are only taught to request. Teaching social initiations allows children to advance from requesting to engaging in self-learning. There is support for the idea that parents can be taught to implement evidence-based practices, such as PRT, in the natural environment after engaging in short-term training. By increasing parents' skills through short training, continual opportunities for learning may emerge beyond intervention.

Objectives: Investigate whether caregivers can be taught to implement PRT procedures for question-asking in the home after participating in a brief training in PRT. The study also investigated whether children increased their frequency of social initiation through question asking (specifically "What's that?") and whether these results maintained and generalized beyond intervention.

Methods: Participants included three mother-sons dyads. The children ranged in age from 45 to 56 months; all had a confirmed diagnosis of ASD. Prior to the study, the researcher obtained full certification as a trainer in PRT from the Koegel Autism Center. A single-subject multiple baseline design was used. After a stable baseline was obtained, training was introduced to each mother in a one-week staggered manner. Each mother completed 12 hours of training in PRT across three weeks (i.e., two hours twice a week) after which intervention was initiated. Each mother implemented the intervention with their child three times a day in 10-minute sessions with one session video-recorded daily by the researcher**.** Immediately succeeding intervention, the mother conducted generalization probes every day for one week. Follow-up occurred after one month.

Results: Results of visual analysis showed that all three mothers were able to successfully implement PRT procedures for question asking and achieved fidelity during intervention, with one mother attaining fidelity at follow-up. All three children showed an increase in their frequency of asking, "What's that?" These results generalized to various novel items, family members, and environments. Follow-up data showed that all three children continued asking, "What's that?" but at a lower rate than during the intervention.

Conclusions: Results of the study demonstrate that parents are able to learn, and effectively implement PRT procedures for question asking after completing a short training. Furthermore, all three children increased their frequency of asking "What's that?" Short-term parental training thus offers a viable option to reduce both wait-times and costs of early intervention experienced by parents of children with ASD.

162 **110.162** Speech Language Pathologists' (SLPs) Knowledge and Use of Factors Found in Research to Predict, Moderate, and Mediate Response to Augmentative and Alternative Communication (AAC) Intervention for Children with Autism

S. B. Sievers[1]*, D. Trembath*[2] *and M. Westerveld*[3]*, (1)Allied Health, Griffith University, West End, Australia, (2)Menzies Health Institute, Griffith University, Australia, (3)Allied Health, Griffith University, Southport, Australia*

Background:

Individuals with Autism Spectrum Disorder (ASD) may experience a wide range of communication difficulties, with as many as 30% of children receiving comprehensive early intervention programs commencing school unable to speak in sentences (Rose, Trembath, Keen, Paynter, 2016). Augmentative and alternative communication (AAC) interventions have the potential to enhance communication skills. However, implementing AAC interventions is challenging due to the heterogeneous population, limited AAC training for speech-language pathologists (SLPs), a lack of research evidence regarding what works for whom and why, and the research to clinic gap. Research has identified factors that predict, moderate, and mediate AAC intervention outcomes for children with ASD, however, it is unknown is if SLPs have knowledge of these factors and if these factors are used in their clinical practice.

Objectives:

The aims of this study were to (a) investigate SLPs knowledge and use of factors that predict, moderate, and mediate AAC intervention outcomes for children with ASD and (b) to identify additional factors that SLPs believe warrant further research.

Methods:

A mixed methods survey using close and open-ended questions was distributed internationally to certified SLPs who have experience working with children with ASD and AAC interventions. SLPs were recruited through professional organizations in Australia, the United States, Canada, and the United Kingdom; online communities (e.g., AAC for SLPs); and through the research team's professional network. Survey questions were based on a systematic review of factors that predict, moderate, and mediate outcomes to AAC for ASD. Questions investigated SLPs' knowledge and use of these factors as well as their views on where future research should be focused and barriers to implementing best practice in AAC interventions.

Results:

The survey, which opened in September 2017, yielded 176 responses within the first two weeks. The survey will close in November 2017, and the results will be presented. Preliminary data analysis indicates that SLPs had knowledge of the 18 factors presented, with an average clinician rating for "great extent/very familiar" and "some knowledge" was 35.76% and 40.65% respectively. High rating included *communication competence, joint attention,* and *frequency of AAC Exposure* and low rating included *duration of therapy session, motor skills,* and *duration of therapy session.* Preliminary data also indicated that clinicians consider these 18 factors found in research when making decisions in clinical practice. Of the 18 factors, the average clinician rating for "frequently consider" was 56.69% and "sometimes consider" 26.76%. High ratings for frequently consider were *AAC input at school, motor skills,* and *frequency of AAC exposure* and low ratings were *duration of therapy session, age of therapy onset,* and *chronological age.* Additional factors clinicians indicated were important included motivation of AAC user and communication partner.

Conclusions:

Based on preliminary data collected to date, the majority SLPs were familiar, and took into consideration factors identified in research that may predict, moderate, and mediate AAC intervention outcomes when working with children with ASD. However, further research is needed to examine clinician-identified factors which to date have not been investigated in research.

163 **110.163** Strategies to Engage Underrepresented Parents in Child Intervention Services: A Review of Effectiveness and Use

M. Pellecchia[1], H. J. Nuske[2], D. Straiton[3], E. McGhee Hassrick[4], A. Gulsrud[5], S. Iadarola[6], S. F. Vejnoska[7], B. Bullen[8], R. Haine-Schlagel[9], C. Kasari[10], D. S. Mandell[2], T. Smith[6] and ***A. C. Stahmer***[11]*, (1)University of Pennsylvania, Philadelphia, PA, (2)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (3)Psychology, Michigan State University, East Lansing, MI, (4)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (5)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA, (6)University of Rochester Medical Center, Rochester, NY, (7)University of California, Davis, Sacramento, CA, (8)University of Rochester, Rochester, NY, (9)Child and Adolescent Services Research Center, San Diego, CA, (10)University of California, Los Angeles, Los Angeles, CA, (11)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: Parent involvement is considered to be a key ingredient in successful interventions for children with autism spectrum disorders (Benson, et al., 2008). Effectively engaging parents in their child's treatment contributes to improvements in the child's symptoms, parent-child interactions, and family functioning (Dowell & Ogles, 2010; Haine-Schlagel & Walsh, 2015). Engaging parents from traditionally underrepresented families is particularly important, as children and families from ethnic minority backgrounds are less likely to engage in services (Dickson, et al., 2017), and retention in parent training programs is lower among parents from ethnic minority and low income households (Chacko et al., 2016; Kazdin & Whitley, 2003). Little is known about which strategies are most effective in engaging underrepresented families, many of whom are at high risk for poor treatment outcomes. Information about how strategies are routinely combined to support parent engagement is still emerging (Michie, Fixsen, Grinshaw & Eccles, 2009), but could provide valuable insight into how engagement strategies can be delivered in combination to enhance parent engagement.

Objectives: To estimate the impact of parent engagement strategies in improving engagement among underrepresented (i.e., minority race or ethnicity and/or low income) families of children with ASD and related social, emotional, or behavioral disorders, and to describe the combinations in which these strategies are commonly used together.

Methods: A systematic literature review of parent engagement strategies with underrepresented families of children with ASD and related disorders was conducted. The PracticeWise Engagement Coding System was used to identify which strategies had the strongest empirical support for engaging underrepresented families receiving psychosocial services for their children. Linear regression was used to estimate the impact of each strategy on parent engagement, using attrition as a proxy for non-engagement. Social network analyses were used to identify the frequency of strategy use and how strategies were combined to engage underrepresented families.

Results: Thirty-five studies met inclusion criteria for the review. Less parent attrition was predicted by interventions that were based in the community or home (vs. in a clinic), less therapist monitoring/positive reinforcement from therapists, and more pairing of parents with peers for guidance and support. Social network analyses found that more effective strategies were more frequently implemented alone and less effective strategies were commonly combined with each other.

Conclusions: Findings point to the need for more community-based intervention trials for children with ASD that explicitly report on measures of parent engagement, development of implementation measures to better characterize the quality of engagement strategies, and the need to better understand how income and education level may interact with the use of engagement strategies and outcomes. Multiple aspects of parent engagement (e.g., participation, attendance, retention) should be examined as potential mediators and moderators of treatment outcome. As parent-mediated intervention techniques become more common, there is an urgent need to explicitly measure and discuss the contributions of combining parent engagement strategies and practices.

164 **110.164** Targeting Joint Engagement in Toddlers with ASD: What Predicts Sustained Engagement at Study Follow-up?

A. J. Schlink[1]*, L. M. Baczewski[2], K. Sterrett[3], C. Kasari[4] and A. Gulsrud[5], (1)UCLA Semel Institute for Neuroscience and Human Behavior, Los Angeles, CA, (2)Education, UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)University of California Los Angeles, Los Angeles, CA, (4)University of California, Los Angeles, Los Angeles, CA, (5)UCLA Semel Institute for Neuroscience & Human Behavior, Los Angeles, CA*

Background:

Parent-mediated interventions for toddlers with autism spectrum disorder (ASD) can improve core social communication deficits such as joint engagement, and these improvements are maintained over time (Green et al., 2010; Kasari et al., 2015). Toddlers with ASD may receive intensive therapist-mediated behavioral intervention (BI), however, these approaches may not prioritize targeting specific core deficits of autism, like joint attention (Kasari et al., 2008). Given that toddlers often receive both parent-mediated intervention and BI concurrently, it is unclear whether one approach can better predict toddler outcomes of joint engagement after a research study is terminated.

Objectives:

The present study aimed to assess whether parent mediated intervention fidelity (JASPER) or behavioral intervention hours (treatment as usual) was more predictive of increased joint engagement in a group of young children with ASD at the study's 6-month follow up.

Methods:

The present study included 86 toddlers (range 22 – 36 months) with ASD and their primary caregiver. These dyads participated in an intervention trial comparing the effects of a parent-mediated JASPER intervention and a parent education counterpart on social communication outcomes. The primary outcome was time spent in joint engagement at the 6-month follow up coded from an unstructured parent child play interaction. Upon exiting study, toddlers returned to receiving behavioral intervention hours as usual. A multiple linear regression was calculated to predict child's time joint engaged with the parent based on parent implementation fidelity and hours of behavioral intervention. This analysis controlled for autism severity (as measured by ADOS Clinical Severity Scores), IQ (Mullen developmental quotient), and time spent in the joint engagement state at exit. Insignificant predictors were excluded from presented analyses.

Results:

Parents' implementation fidelity uniquely predicted toddler's time spent in joint engagement. Parents' successful adherence to JASPER principles significantly predicted their toddlers' increased time jointly engaged ($t(61)=3.62$, $p<.005$), while toddlers' total hours of behavioral intervention during the follow-up period did not ($t(61)=-0.59$, $p = .56$). Additionally, ADOS severity and Mullen developmental quotient scores were not significant predictors of joint engagement outcomes. Toddlers' time spent jointly engaged at exit predicted time spent jointly engaged at follow up ($t(61)=3.56$, $p<.005$), indicating maintenance of joint engagement outcomes across a 6-month span.

Conclusions:

Parent's use of JASPER strategies emerged as a significant predictor of toddler joint engagement at follow-up above and beyond the effect of hours of behavioral intervention received during the follow-up period. This suggests that merely more hours accrued across numerous community based behavioral interventions do not translate to better joint engagement. Parents' implementation fidelity strongly predicted toddler's time spent in joint engagement states, further supporting the benefit of brief, specific, parent-mediated interventions. The further use of targeted parent-mediated interventions has implications to greatly reduce time and money otherwise spent on other BI resources. These findings may have practical implications for clinicians who seek to recommend interventions that successfully predict gains in the skills most impacted by ASD. Future research should investigate feasibility and effects of other parent-mediated interventions targeting core deficits of autism.

165 **110.165** Teaching Object Labeling during Play to Children with Autism Spectrum Disorders

A. D. Duenas[1,2] *and J. B. Plavnick*[1], *(1)Counseling, Educational Psychology, and Special Education, Michigan State University, East Lansing, MI, (2)Michigan State University, Okemos, MI*

Background:

Language impairment is a significant area of delay for many children with autism spectrum disorder (ASD). Children with ASD do not engage in early play interactions with adults or frequently label objects as a means to share information with others and learn about the environment. This limits their opportunities to engage in social interaction related to objects of interest (Paul, 2008). Although interventions have been developed to teach object labeling to children with ASD, these protocols are administered in highly structured arrangements separate from the naturally occurring conditions typically known to occasion language (Reichow, Barton, Boyd, & Hume, 2014).

Natural language interventions combine a behavior analytic and developmental approach to language in which an adult embeds opportunities for learning in socially relevant contexts throughout the child's daily routine (Lane, Lieberman-Betz & Gast, 2016). Despite the effectiveness of natural language training procedures for teaching requests to children with ASD, few researchers have applied a similar approach to other types of functional responses, such as object labeling. Procedures that teach object labeling within a naturalistic context need to be developed and empirically tested to offer additional instructional strategies to service providers.

Objectives:

The purpose of the present investigation was to test the efficacy of a procedure that incorporated strategies used within natural behavioral interventions for teaching requests and imitation while embedding repeated object labeling trials within a play-based routine for children with ASD.

Methods:

Three 4-year-old children diagnosed with ASD attending an Early Intensive Behavior Intervention (EIBI) program housed within a child development laboratory preschool participated. A multiple-probe across behaviors design (Gast & Ledford, 2014) was used to evaluate the effectiveness of the play-based procedure on acquisition of targeted object labels. Experimental sessions involved a play routine consisting of three distinct subroutines (e.g. pulling toys out of a box, playing with toys, and cleaning up toys). The play routine was centered on a thematic set in order to create an environment similar to those observed when children play in early childhood environments. Subroutines were developed to contrive opportunities for participants to label target stimuli three times within a session, creating a total of nine object labeling trials per session.

Results:

Participants demonstrated rapid acquisition of object labeling during the training procedure and maintained responses during a two-week follow-up probe. The results demonstrate play-based intervention procedures that mimic the conditions and environment in which language occurs may be beneficial for children with ASD.

Conclusions:

In addition to rapid acquisition of all targets, two participants for whom we administered transfer of training assessments both labeled objects in novel contexts (i.e., transfer of training). Early childhood providers rated the procedures as highly acceptable. The procedures and outcomes of the present investigation extends naturalistic interventions to teach object labeling to children with ASD.

166 **110.166** The Effect of Parental Involvement in Preschool-Based Intervention on Parent-Teacher Agreement Regarding the Adaptive Skills of Children with ASD

ABSTRACT WITHDRAWN

Background: Multi-informants' ratings of developmental and adaptive functioning form an essential tool in assessing children with autism spectrum disorder (ASD). Together, they provide an updated developmental profile of the child, essential for classification and treatment planning (McDonald et al., 2015; Klin et al., 2006). However, previous studies adressing parent-teacher agreement on children's adaptive skills, have revealed significant discrepancies between raters, when teachers' ratings were usually higher than parents' (Murray et al., 2009; Achenbach, 2011; McDonald, et al., 2016). Such disagreement between parent and teacher ratings on the functioning of children with ASD may present a challenge to both assessment and intevention planning.

Objectives: In the current study we examined whether parent-teacher agreement on the child's adaptive functioning improves when parents join a preschool-based intervention program for children with ASD. The Early Start Denver Model (ESDM) was integrated into the therapeutic program of Israeli preschools for children with ASD. Since parents play a key role in the ESDM (Rogers et al., 2012) and in order to facilitate generalization, parents joined the preschool-based program for weekly parent-child therapy sessions. Since research on the ESDM has shown strong working alliance between parents and therapists (Rogers et al., 2012), we hypothesized that the agreement between parents' and teachers' reports on child adaptive functioning will improve following this intervention.

Methods: Thirty-two children (7 girls), aged 34-58 months, from four ASD preschools in which ESDM was integrated, participated in the current study. All children received 40 hours of intervention from educators and para-professionals. Parents attended weekly parent-child therapy sessions. Teachers and parents reported on children's adaptive functioning using the Vineland Adaptive Behavior Scales (VABS-II) pre- and post- 8 months of intervention (at the beginning and end of the school year). Parent-Teacher discrepancies were assessed by comparing the standard scores.

Results: Before the intervention, significant parent-teacher discrepancies have been found, with parents rating their child higher on areas of receptive language, expressive language, and community and coping skills. Post-intervention, parent-teacher discrepancies on those areas became non-significant. However, in the area of interpersonal relationships, parents rated their children significantly higher than teachers in both pre- and post- intervention assessmants, elbait with smaller discrepancy post-intervention. In the area of play and leisure time skills parents also rated their child significanly higher than teachers, however, their reports were even higher post-intervention and the inter-rater discrepancy increased.

Conclusions: Results indicate that parental involvement in preschool-based ESDM intervention impacted on descrepencies between parents and teachers perceptions of the childs' adaptive functioning. Whereas teacher-parent agreement improved in areas of language, daily living skills and social skills, discrepancies in the area of play and leisure increased. This difference may be attributed to the new play skills provided to parents in the ESDM program, gaining increased play and leisure functioning at home that may have yielded new experiences bewtween parents and their children and higher parent ratings of their child's play skills post treatment.

167 **110.167** The Effects of Prospectively Following High-Risk Infant Siblings with ASD: Observation Positively Alters Outcome

M. Micheletti[1]*, W. Jones*[2]*, S. Shultz*[2]*, A. Klin*[2]*, S. Hoffenberg*[1]*, C. A. Saulnier*[2] *and C. Klaiman*[2]*, (1)Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA*

Background: The past 10 years have seen a substantial increase in prospective studies of the infant siblings of children with autism spectrum disorder (ASD), whose risk of also having the condition is approximately 20%. Direct observation of this population from the first months and years of life provides a unique window into the early emergence of ASD. Despite the large number of infant siblings enrolled in prospective longitudinal research, few studies have examined how this early developmental surveillance may, in and of itself, influence development. Drawing on the concept of 'the observer effect' in physics—that the act of observing a phenomenon necessarily changes that phenomenon—this study investigates how prospective longitudinal surveillance may impact the course of a child's development.
Objectives: Measure the effects of prospectively following infants later diagnosed with ASD on parent-reported first concerns, clinical presentation, and service utilization.

Methods: Children were selected to form two groups: 1) a *prospectively-followed cohort* (children who completed a prospective infant sibling study that included 10 visits from birth to 36 months); and 2) a *community-referred cohort* (children referred to the center for clinical assessment at a single time point). All children in each cohort: 1) received a clinical best-estimate diagnosis of ASD at 24-36 months; 2) had an older sibling already diagnosed with ASD; and 3) had completed measures of child demographics, development, and service use patterns. Cohorts were then matched on sex, race, cognitive ability, maternal age, maternal history of infertility, pregnancy complications, and gestational age (all factors known to impact parent-reported age of first concern), to yield final samples of n=18 prospectively-followed and n=18 community-referred.

Results: *Parent-Reported First Concerns:* Age of first concern was significantly earlier in the prospectively-followed cohort (11.7 months) than the community-referred cohort (15.5 months), $p = .039$. Furthermore, domains of first concern were more diverse in the prospectively-followed cohort (Figure 1). *Clinical Presentation:* The prospectively-followed cohort had lower ADOS severity scores ($p = .027$), and higher receptive ($p = .013$) and expressive ($p = .011$) language abilities relative to the community-referred cohort. *Service Utilization:* Although there were no differences in age at therapy onset, community-referred children were often enrolled in speech and occupational therapy, whereas prospectively-followed children were more often enrolled in comprehensive early intervention ($p = .026$). See Table 1b for all between-group comparisons.

Conclusions: Compared to a community-referred cohort, matched on age of diagnosis, sibling status, and other factors known to influence parent-reported first concerns (Table 1a), children enrolled in the longitudinal study had earlier and more diverse parent concerns, a higher enrollment rate into early intervention, and a less severe clinical presentation of autism symptom severity and language ability. These differences were observed despite similarities in nonverbal cognitive levels and parents' experience with a child on the spectrum. These findings support early developmental surveillance as a framework in which to aid parents in early identification of a broad range of ASD symptoms, and to aid in accessing early intervention services for their children, likely to have profound positive cascading effects on future development.

168 **110.168** The Stability of ASD Symptoms after One Year of Applied Behaviour Analysis

F. Rad[1]*, I. Mihailescu*[2]*, A. Buica*[3]*, M. C. Nedelcu*[4]*, C. Anghel*[3] *and I. Dobrescu*[1]*, (1)Child and Adolescent Psychiatry Department, Carol Davila University of Medicine and Pharmacy, Psychiatry Clinical Hospital Alexandru Obregia, Bucharest, Romania, (2)Child and Adolescent Psychiatry Department, Prof. Dr. Alex Obregia Psychiatry Hospital, Bucharest, Romania, (3)Child and Adolescent Psychiatry Department, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania, (4)Cabinet Individual de Psihologie Maria Cristina Nedelcu, Bucuresti, ROMANIA*

Background:
To establish a diagnosis of certainty at younger ages implies certain uncertainties, especially when such a heterogeneous disorder as Autistic Spectrum Disorder is involved, all the more so as the clinical aspect is complicated with characteristic elements of ADHD. In the process of development, the symptoms may change - some manifestations become more obvious, others pass in the secondary plane. Behaviour therapy improves the characteristic deficits of the comorbidity between Autism Spectrum Disorder and ADHD (based on theoretical hypotheses and clinical observations).

Objectives:

This paper aims to analyse the evolution of children diagnosed with Autism Spectrum Disorder (ASD) comorbid with ADHD type symptoms involved in an Applied Behaviour Analysis program with the identification of potential evolutionary models.

Methods:

We conducted an observational study on a group of 52 subjects (2-5 years old) diagnosed with Autism Spectrum Disorder (according to DSM IV-TR diagnostic criteria) comorbid with ADHD-specific symptoms, without significant comorbid disorders (psychiatric and somatic). Each of the subjects included in the clinical group followed a psychotherapist-conducted applied behaviour analysis program for one year, which was structured as such: 2 hours / day, 5 days / week. To standardize behaviour intervention among subjects, supervision of the intervention programs was performed by the same psychologist for all subjects.

Data collection involves a longitudinal direction by assessing the main symptomatology domains of ASD (using ADOS scores) and ADHD (using

ADHD - RSboth at moment of inclusion in the study (T0) and after one year of applied behaviour analysis program (T1).

Results:

In our group, after one year of applied behaviour analysis (T1), only 27% of children still met the DSM IV-TR criteria for Autism (compared to 63% at T0), 50% meet criteria for PDD-NOS (compared to 35% at T0) and 23% of children no longer met the diagnostic criteria for Autism Spectrum Disorder. In other words, after therapy, the evolution was favourable for a significant number of children, with the diminishing and even disappearance of the clinical elements suggestive for ASD.

The favourable evolution of ASD symptoms after 1 year of therapy also results from the statistically significant differences between ADOS scores averages from T0 and T1 moments. Differences are established both in the total ADOS-C+Is domain and separately in each of the two domains. Also, there are statistically significant positive correlations between T0 and T1 scores. The average total score difference between the two moments is 2.44±2.72.

The results of the study show that 71% of the subjects had a favourable evolution of the ADOS-C+Is score, whereas only 32% of the subjects had a favourable evolution of total ADHD-RS score.

Conclusions:

Applied behaviour analysis significantly improves the ASD-specific symptomatology among children with ASD-ADHD polymorphic clinical features.

Behaviour therapy improves ADHD-specific symptomatology among children with polymorphic ASD-ADHD clinical features, but the observed differences are smaller than those highlighted for ASD symptomatology. The most frequent evolutionary pattern after one year of behaviour therapy is represented by the association between a favourable evolution of ADOS-G score and a stagnation of ADHD-RS scores.

169 **110.169** The Therapeutic Relationship As Outcome Predictor in Music Therapy with Children with Autism

W. Schmid[1], *C. Gold*[2] *and K. Mössler*[2], *(1)The Grieg Academy - Department of Music, University of Bergen, Bergen, Norway, (2)GAMUT, Uni Research Health, Uni Research, Bergen, Norway*

Background: Shaping sensory perceptions, regulating affective dynamics, or joining attention are abilities that enable human beings to relate. Children with an autism spectrum condition (ASC) can face challenges in all of these areas. However, their bodily and emotional expressions form and inform relational abilities. By creating music that is embodied and attuned to the child's relational resources, therapists might effectively strengthen the child's social skills on a generalized level.

Objectives: The aim of the present study was to examine whether a therapeutic relationship, in which the therapist is attuned to the child's expression and behavior, predicts generalized changes in social skills in children with ASC.

Methods: This predictor study included music therapy sessions from 48 children from 7 countries worldwide who were between 4 and 7 years of age and diagnosed with ASC. Improvisational music therapy was provided weekly over a period of 5 months. Generalized interaction skills were measured using the Autism Diagnostic Observation Schedule (ADOS) and the Social Responsiveness Scale (SRS) questionnaire at baseline, 5 and 12 months. The therapeutic relationship was assessed using the evaluation tool for Assessing the Quality of Relationship (AQR). Associations between the therapeutic relationship and generalized outcomes have been analyzed using a linear mixed effect model.

Results: This study found significant interaction effects between the therapeutic relationship and generalized changes in social skills in children with ASC. A symptom reduction as measured with the Autism Diagnostic Observation Schedule (ADOS) was found after 12 months (B = -3.89; CI = -7.51, - 0.26; p = 0.0399), if a relationship was developed in which the therapist was emotionally and musically attuned to the child's affective and relational needs. ADOS subgroup analysis showed a significant decrease of symptoms especially in the area of language and communication (B = -1.79; CI = -3.46, -0.12; p = 0.0402). Also problems in social responsiveness decreased more over the course of 5 months as measured with the SRS (B = -23.46; CI = -45.63, -1.29; p = 0.0426). However, this effect waned after 12 months.

Conclusions: These results emphasize a therapeutic relationship, in which the therapist attunes to the child's expressions musically and emotionally, as important mechanism of change. These results might challenge a behavioristic paradigm in autism treatment focusing on training strategies rather than relational factors such as affect attunement as intervention strategy to improve social skills.

170 **110.170** Types of Parent Responsiveness: Longitudinal Changes Associated with a Parent-Mediated Intervention for Children at-Risk for ASD

A. A. Alzamel[1], *D. Garrido*[2], *L. R. Watson*[3], *M. DuBay*[4], *E. Crais*[3], *G. Baranek*[5], *G. Carballo*[2], *R. Garcia-Retamero*[2] *and L. Turner-Brown*[6], *(1)Department of Allied Health Sciences, University of North Carolina - Chapel Hill, Chapel Hill, NC, (2)University of Granada, Granada, Spain, (3)Department of Allied Health Sciences, University of North Carolina at Chapel Hill, Chapel Hill, NC, (4)University of North Carolina, Chapel Hill, NC, (5)Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (6)UNC TEACCH Autism Program, University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background:

Early interventions have effectively increased parent responsiveness (PR) to children at-risk for ASD. Few studies have examined these effects longitudinally, and little is known about the impact of interventions targeting PR on changes in parental nonverbal and verbal responses.

Objectives:

Examine longitudinal effects of a PR intervention, Adaptive Responsive Teaching (ART), on PR in parents of young children at-risk for ASD.

Methods:

Two groups of community-recruited infants at-risk of ASD and their parents were randomized to ART or to "referral to early intervention and monitoring" (REIM). Data were collected at pre-treatment (mean age:13.8 months, ART [n=45], REIM [n=42]), post-treatment (mean age: 22.5 months, ART [n=44], REIM [n= 39]), and follow-up (mean age: 53.91 months, ART [n=27], REIM [n=18]). The *Parent Responsiveness Coding System* measured PR using 5-second intervals in a 10-minute video of unstructured play. General linear mixed models examined a range of PR behaviors. Due to variance in children's chronological age (CA) at follow-up, CA was used as the metric of time for estimating outcome trajectories.

Results:

Significant group by time interaction for *total responses,* F(1, 203.097) = 5.717, *p* = .018, and *total nonverbal responses, F*(1, 205) = 4.373, *p* = .038, indicated more responses in ART compared to REIM at post-treatment, *p* = <.001, but not follow-up, *p* = >.05. For *nonverbal expansion responses,* the interaction was nonsignificant, but comparisons of predicted values suggested a similar marginal linear trend in both groups *F* (1, 207) = 3.521, *p* = .062. A marginal group by time interaction emerged for *nonverbal non-expansions, F* (1, 205) = 3.314, *p* = .070, and simple comparisons showed more ART group responses at post-treatment, *p* = <.001, but more REIM group responses at follow-up, *p* = <.001. The *total follow-in verbalizations* interaction was nonsignificant, but there was an effect of time *F*(1, 137.013) = 45.365, *p* = <.001. Similarly, only a significant effect of time was found in *follow-in directive verbalizations F*(1, 142.641) = 27.187, *p* = < .001, suggesting an increase of follow-in directive verbalizations in both groups over time. The *follow-in non-directive verbalizations* interaction was significant, *F*(1, 200.945) = 5.744, *p* = .017, and simple comparisons showed more ART responses only at post-treatment.

Conclusions:

ART was effective in increasing overall PR, nonverbal responses, and non-directive verbalizations at post-treatment, but these effects were not maintained at follow-up. Because our measure of PR heavily focused on contingency, it might not have tapped into other important aspects of PR for preschoolers. That is, contingency in PR is associated with positive outcomes for infants and toddlers, but may be less important for preschoolers, who have attained greater cognitive and linguistic competency. Future longitudinal research should examine broader dimensions of PR to determine if parents who increase their contingent responses to at-risk infants/toddlers differ in other dimensions of PR with their preschool children, such as the syntactic complexity and semantic richness of verbal responses.

171 **110.171** Using the VABS-II Item Sets As Predictors of Outcome in Preschool-Based Esdm Vs. Preschool-Based Eclectic Intervention

ABSTRACT WITHDRAWN

Background: Identification of child related factors that may serve as predictors of outcome in early intervention plays a key role in the personalization of treatments in ASD (Sherer, Schreibman & Cunningham, 2011).

Objectives: The current study aimed to identify these differential factors while comparing two types of preschool-based intervention models: The Early Start Denver Model (ESDM), a manualized early intervention, integrated into ASD community preschools in Israel, and an eclectic intervention commonly implemented in the country. Child factors were assessed utilizing content analysis of specific Vineland Adaptive Behavior Scales (VABS-II) item-sets related to play and communication skills.

Methods: Fifty-eight children, aged 35-57 months, from eight ASD preschools, participated in the current study. Thirty-three children attended preschools in which ESDM was integrated, and twenty-five children attended eclectic preschools. Groups were matched on age, developmental level and autism severity, both receiving equal numbers of therapy hours per week. Changes in children's adaptive behaviors (teacher reported VABS-II) and cognitive ability (MSEL) were measured pre- and post- 8 months of intervention. Four item-sets reflecting early behaviors that may affect treatment outcome (Vivanti et al., 2013) and may be impaired in children with ASD (Balboni et al., 2015) were chosen as predictive variables to intervention related changes in child MSEL scores. These item-sets include 'beginning to talk', 'following instructions', 'playing' and 'imitation'.

Results: The 'following instructions' item-set predicted developmental gains in the areas of expressive language, visual reception and fine motor across intervention groups. The 'imitation' item set predicted improvement for both groups in receptive language and was also found to predict greater gains in fine motor scores in the ESDM group, but not in the group receiving the eclectic intervention. However, the 'play' item-set yielded an opposite trend, predicting higher fine motor scores in the eclectic intervention group in contrast to the ESDM group. Finally, the 'beginning to talk' item-set predicted significantly higher gains in expressive language scores in the ESDM group but not in the eclectic intervention group. A similar trend was marginally significant in predicting receptive language scores (*p=0.058).*

Conclusions: Results indicate that both imitation and following instructions skills are important learning mechanisms that underlie children's ability to gain from both interventions. However, differential gains in fine motor and expressive language abilities reflect the notion that different children might gain more from different intervention models. In the ESDM model, imitation and spoken language abilities are marked as central early social learning abilities. Put together, these results further broaden current knowledge regarding child-related intervention outcome predictors. The current study also offers a possible use of the VABS-II item-sets in community settings, in order to identify children who might benefit more from the ESDM.

172 **110.172** Video Modeling Intervention for Toddlers with ASD

***M. N. Hale**[1], E. Espanola[1], A. Gutierrez[2], M. Sanchez[3], I. Deveaux[1] and N. V. Roman[1], (1)University of Miami, Coral Gables, FL, (2)University of Miami, Miami, FL, (3)Florida International University, Miami, FL*

Background: Video modeling (VM) is an empirically-supported therapeutic technique for individuals with ASD, which serves to remediate behavioral deficits and foster improvements of desirable behavior. The VM technique generally involves having an individual watch and then mimic a video model engaging in specific desirable behavior or act. The VM technique is robust in that it has been used successfully to improve behavior across a variety of skill domains including communication, perspective taking, self-care skills and play skills. VM has additional benefits of being portable, cost-effective and easily transferable. Interestingly, for some individuals with ASD, VM serves as a more effective and efficient therapeutic technique that other more traditional therapeutic strategies. However, several researchers have noted a subset of individuals with ASD for whom the VM technique appears minimally- or non-effective. Lack of responsiveness, unfortunately, serves to limit the range of potential treatment options and strategies for those individuals.

Objectives: The goal of this study was to identify toddlers with ASD who showed minimal- to no -responsiveness to the VM technique and then expose them to a systematic instructional intervention designed to improve their ability to mimic video models. Efficacy of the instructional intervention for improving responsiveness to VM technique was systematically evaluated.

Methods: Three toddlers (ages 2-4) with ASD who demonstrated limited responsiveness to VM interventions were selected to participate. Each received direct one-on-one instruction whereby they were taught to mimic a series of progressively more complex acts depicted on video. Instruction involved applied behavior analytic (ABA), discrete trial teaching technique. Efficacy and generality of the intervention was evaluated using a single-subject research design, and a multiple-baseline across individuals.

Results: Throughout the instructional intervention, all three participants demonstrated improvements in their ability to mimic actions of video models. Furthermore, post-intervention, improvements generalized to similar and more complex novel (un-trained) behavioral acts depicted via video model.

Conclusions: VM is an effective, non-invasive and robust intervention technique for individuals with ASD. However, little to no attention has been given toward the subset of individuals with ASD who do not readily respond to the VM technique. Results of this study indicate that toddlers with ASD, can be successfully taught to imitate video models and subsequently demonstrate increased responsiveness to the VM. Given the utility of VM, early intervention programs may benefit from incorporating systematic instruction on the imitation of video models as part of the curriculum.

173 **110.173** Videogame Based on Full-Body Interaction Used As a Tool to Foster Social Conducts in Children with Autism Spectrum Disorders: A Feasibility Study on Pico's Adventure

M. A. Mairena[1], *J. Mora*[2], *L. Malinverni*[3], *V. Padillo*[4], *L. Valero*[5], *A. Hervás*[5,6] *and N. Pares*[7], *(1)Hospital Sant Joan de Déu, Barcelona, Spain, (2)InflightVR Software GmbH, Barcelona, Spain, (3)Pompeu Fabra University, Barcelona, Spain, (4)Ayuntamiento de Montornès de Vallès, Barcelona, Spain, (5)Instituto Global de Atención al Neurodesarrollo (IGAIN), Barcelona, Spain, (6)Mutua Terrassa Universitary Hospital, Barcelona, Spain, (7)ICT, Pompeu Fabra University, Barcelona, Spain*

Background: Game-based interventions have shown to facilitate motivation and learning processes in Autism Spectrum Disorders (ASD). Moreover, interventions that use Information and Communication Technologies are attractive for children with ASD and have demonstrated to be useful to increase social behaviors.
Objectives: The main purpose of this project was to conduct a feasibility study to compare the amount of social initiation conducts performed during a full-body interaction videogame versus the amount of social initiation conducts occurred during a free-play activity in children with ASD. We hypothesized that the videogame could elicit a higher number of these conducts and therefore could be proposed as a tool to promote social initiation skills.

Methods: A total of 15 children (ages 4 to 6) were recruited. Diagnoses were confirmed using the Autism Diagnostic Observation Schedule (ADOS) and the Autism Diagnostic Interview-Revised (ADI-R). In order to be included in the study, subjects had to obtain cognitive capacity above 70. Children participated in four consecutive weekly sessions with two sections: a section where they played with the videogame Pico's Adventure (a Kinect-based game developed for high functioning children with ASD) and a section that just involved free play time. Sessions involved different conditions; playing alone, with a parent, and with a peer the subject did not know before. Social skills conducts were codified according to an observational scale.

Results: Results show that the videogame elicited more social initiation conducts than free play in children with ASD when playing alone [t(11)= 2,438, p= 0,033] or playing with a peer [t(13)= 3,60, p=0,003]. Furthermore, it showed to be as effective as free play in promoting social initiation while playing with parents. In addition, results indicate that repetitive behaviors were less frequent during the videogame (Mdn = 0) than during free play (Mdn = 2), Z = 2.05, p = 0.040. Along with social initiation we calculated the number of spontaneous gestures performed by the children in both Pico's Adventure and free play. Results show significant differences in emotional gestures during the two situations where the child was playing with a parent [t (12) = 2,420; p = ,032; t (12) = 2,360; p = ,036] and during a situation where the child was playing with the peer [t (13) = 2,879; p = ,013]. In the three aforementioned cases more emotional gestures were reported in Pico's Adventure than in free play. Similarly, a significant difference in the amount of pointing gestures was found between the videogame and free play.

Conclusions: The videogame Pico's Adventure elicited more social initiation behaviors than free play in children with ASD when they were playing alone or playing with a peer. The videogame was also effective in reducing repetitive behaviors and increasing both emotional and pointing gestures. Therefore, the game could be useful as a tool to increase social behaviors. Future work is needed to obtain further data that supports this hypothesis.

Poster Session
111 - Social Cognition and Social Behavior
11:30 AM - 1:30 PM - Hall Grote Zaal

174 **111.174** Celebrating in Your Success, Suffering in Your Defeat: Self-Conscious Emotion Understanding in Adolescents with Autism

K. Jankowski *and J. H. Pfeifer, University of Oregon, Eugene, OR*

Background:
A two hit model of autism argues that adolescents with ASD experience a critical secondary wave of impairments in social cognition and peer interactions, enhanced by neural maturation and socioaffective changes related to puberty. Self-conscious emotions (SCEs), such as embarrassment and pride, are complex emotions representing self-awareness, perspective-taking, and social conceptual knowledge processing. SCEs are critical for supporting/maintaining interpersonal relationships; thus, atypical SCE understanding may underlie social difficulties in ASD.

Objectives:

We investigated the subjective experience and neural correlates of SCE understanding in adolescent males with high-functioning ASD and age-matched neurotypical (NT) males.

Methods:

Study I investigated group differences in SCE attributions (the ability to recognize SCEs) and empathic SCEs (the ability/tendency to feel SCEs for others) in 56 adolescents (ASD=30, NT=26). It also explored associations with a triad of social cognitive abilities (self-awareness, perspective-taking, empathy) and autistic traits. Study II investigated the neural correlates of SCE processing in 52 adolescents (ASD=27, NT=25).

During an MRI scan, participants completed the novel Self-Conscious Emotions Task, which included 24 salient, ecologically-valid videos of adolescents in a singing competition. Videos represented two factors: emotion (embarrassment, pride) and perspective-taking (PT) demands (low, high). In low PT clips, singers' emotions matched their performance (sing poorly, act embarrassed); in high PT clips, they did not (sing well, act embarrassed). Participants rated how intensely embarrassed and proud singers felt. They made congruent ratings, which matched the conveyed emotions (rating how embarrassed an embarrassed singer felt), and incongruent ratings, which did not match the conveyed emotions (rating how proud an embarrassed singer felt). Outside the scanner, participants rated how empathically embarrassed and proud they felt for the singers and completed social cognition tasks/questionnaires.

We conducted 2(group) x 2(emotion) x 2(PT) repeated measures ANOVAs investigating inferred and empathic SCE ratings. We also conducted 2x2x2 repeated measures ANOVAs investigating neural activity across the whole brain and in regions of interest.

Results:

Groups made similarly intense inferred congruent SCE ratings; however, the ASD group made more intense inferred *incongruent* SCE ratings during high PT demands. Inferred incongruent SCE ratings correlated negatively with PT abilities and positively with autistic traits. Groups made similarly intense empathic SCE ratings, which correlated positively with self-reported empathy.

Groups recruited broadly similar neural patterns during SCE processing. However, there were group differences within social cognition regions (medial prefrontal cortex, temporal pole), modulated by PT demands, and salience (anterior insula, anterior cingulate cortex) and sensorimotor regions, modulated by the situational context (singing quality).

Conclusions:

Results reveal that adolescents with ASD can recognize SCEs and feel empathic SCEs. However, more intense incongruent SCE ratings during high PT demands suggest that emotion attributions may be more strongly impacted by the situational context. An over-reliance on contextual cues may reflect a strict adherence to rule-following and serve as a compensatory strategy for attenuated reflexive mentalizing. Additionally, adolescents with ASD broadly recruit similar neural patterns during SCE processing; however, atypicalities within social cognition, salience, and sensorimotor regions may reflect an over-reliance on abstract social conceptual knowledge. Implications for intervention are discussed.

175 **111.175** Atypical Conjunctive Visual Processing in ASD: Domain General or Face Specific?

F. Shafai[1], *M. D. Barense*[2], *S. Ferber*[2] *and R. A. Stevenson*[3], *(1)The University of Western Ontario, London, ON, Canada, (2)Department of Psychology, University of Toronto, Toronto, ON, Canada, (3)Western University, London, ON, Canada*

Background: The human face is arguably the most socially-informative visual stimulus available, conveying relevant social information such as identity and emotional expressions. Individuals with autism spectrum disorder (ASD) have demonstrated difficulties with identifying faces in a variety of studies. Eye-tracking studies have suggested that individuals with ASD may process faces atypically, but it is still an open question as to whether these differences are with faces processing per se, or with conjunctive visual processing more generally.

Objectives:

1) Determine whether conjunctive processing in ASD varies across face and object stimulus types similarly to TD.

2) Determine if atypical conjunctive processing in ASD is face specific, or is more broadly observed, in this case across stimulus ambiguity.

Methods: We used eye-tracking to assess visual conjunctive processing in a 2x2 design, varying between face and object stimuli, and high- and low-ambiguity. Pairs of face and object stimuli were presented, while individuals reported whether faces/objects were the same or different. Stimuli were either high or low ambiguity. High-ambiguity objects shared 2/3 features, while low-ambiguity shared 0/3 features. Face identities were morphed, so that low-ambiguity pairs differed by 60%, and high-ambiguity pairs by 10% (Figure 1). Eye-gaze data was analyzed based on within-item saccades relative to between-item saccades. Higher proportions of within-item saccades are representative of greater conjunctive processing (Figure 1).

The paradigm was first conducted in TD individuals (n=20), with data related to autistic traits. Following a significant finding relating ASD traits and visual conjunctive processing, we recruited an additional 33 TD (n=53 total) and 10 ASD individuals (diagnosis confirmed via ADOS, data collection ongoing) ranging in ages from children to young adults to measure between-group differences in patterns of visual conjunctive processing.

Results: The initial study of TD adults (n = 20) showed that visual conjunctive processing was significantly correlated with autism traits severity (r = -0.38, p = 0.05) – the higher the level of autistic traits, the lower the level of conjunctive processing (Figure 2A). In the primary experiment, comparing conjunctive processing with low- and high-ambiguity faces and objects across TD and ASD, we observed a significant 3-way, group-by-stimulus-by- ambiguity interaction (Figure 2B-D; $F_{(1,61)} = 4.33$, $p = 0.04$, $\eta_p^2 = 0.07$). A greater impact of ambiguity level was found for the TD group compared to individuals with ASD ($F_{(1,61)} = 3.88$, $p = 0.05$, $\eta_p^2 = 0.06$). TD participants showed greater conjunctive processing with high- relative to low-ambiguity objects (t = 8.20, p < 0.001, d = 0.89) but showed no difference for faces, as predicted (Figure 2B). Autistic individuals, however, showed no differences across any of the four conditions (Figure 2C).

Conclusions: Results from this on-going study suggest gaze patterns during visual conjunctive processing are being influenced by autism traits. As face and object stimuli were processed similarly, our results indicate that individuals with ASD are employing a more general-purpose visual processing strategy. Together, the results suggest that further investigation is warranted to characterize the relationship between autism traits and visual conjunctive processing for low- and high-ambiguity stimuli.

176 **111.176** Atypical Connectivity in Adults with Autism Spectrum Disorder during Complex Facial Emotion Recognition: An EEG Imaginary Coherence Study

M. H. Black[1,2], *T. Almabruk*[3,4], *M. A. Albrecht*[5], *O. V. Lipp*[6], *S. Bolte*[7,8,9], *T. Tan*[2,10] *and S. J. Girdler*[1,2], *(1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)Department of Computing, Curtin University, Perth, Western Australia, Australia, (4)Computer Science Department, Omar Almukhtar University, Elbeida, Libya, (5)Curtin Health Innovation Research Institute, School of Public Health, Curtin University, Perth, Western Australia, Australia, (6)School of Psychology and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (7)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (8)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (9)Child and Adolescent Psychiatry, Center for Psychiatry Research, Stockholm County Council, Sweden, (10)School of Mechanical Engineering, Curtin University, Perth, Western Australia, Australia*

Background:

Atypical cortical connectivity is commonly associated with individuals diagnosed with Autism Spectrum Disorder (ASD). However, there is a paucity of research measuring cortical connectivity in autistic people during cognitive tasks, such as facial emotion recognition (FER). While FER is considered impaired in autistic people, the contributing mechanisms remain inconclusive. Here, electroencephalography (EEG) coherency measures were used to provide an indication of the functional communication between cortical regions during FER.

Objectives:

We examined the alpha (8-15 Hertz), theta (4-8 Hertz) and beta (16-30 Hertz) EEG imaginary coherency of autistic adults during a complex, dynamic FER task to provide insights into the mechanisms underlying altered FER.

Methods:

Twenty-two autistic adults and 24 non-autistic typically developing (TD) age, gender, and IQ matched control participants were included. They completed a complex emotion recognition task utilising stimuli selected from the Cambridge Mind Reading Face-Voice Battery (CAMs), a battery consisting of videos of male and female actors displaying positive and negative complex emotions. EEG was simultaneously recorded during the FER tasks and the imaginary part of the coherency was used as our measure of connectivity. The imaginary part of coherency is able to resolve some of the limitations associated with the regular coherence, in particular the spurious connectivity driven by volume conduction and the use of a common reference.

Results:

During positive and negative FER, autistic adults showed reduced coherency between short and long range interhemispheric electrodes and reduced long range anterior-posterior connectivity. In response to positive emotion (figure 1), this reduction in coherency was most notable in the beta band, while reduced coherency in the theta and alpha bands was most commonly observed in response to negative emotion (figure 2). These reductions in coherency were paired with an increase in short range intrahemispheric connectivity restricted to frontal and occipital regions in autistic adults.

Conclusions:

These findings suggest that altered network functioning involved in FER may contribute to FER impairments in autistic people. The fact that coherency differences between autistic and non-autistic participants differed in accordance with the emotional valence may indicate that divergent processes contribute to ASD-linked impairment during negative and positive FER. Reduced beta coherency during positive FER may indicate inadequate recruitment of task-relevant networks and reduced saliency of social information, while reduced connectivity in theta and alpha bands may indicate reduced integration of sensory systems with higher order cognitive functions (such as top-down attention allocation) during negative FER.

177 **111.177** Complex Emotion Processing in Adults with Autism: Evidence of Atypical Brain Response Modulation

M. H. Black[1,2], *K. Iyer*[3,4], *M. A. Albrecht*[5], *O. V. Lipp*[6], *S. Bolte*[7,8,9], *T. Tan*[2,3] *and S. J. Girdler*[1,2], *(1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)School of Mechanical Engineering, Curtin University, Perth, Western Australia, Australia, (4)School of Biological Sciences, University of Western Australia, Perth, Western Australia, Australia, (5)Curtin Health Innovation Research Institute, School of Public Health, Curtin University, Perth, Western Australia, Australia, (6)School of Psychology and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (7)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (8)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (9)Child and Adolescent Psychiatry, Center for Psychiatry Research, Stockholm County Council, Sweden*

Background:

The processing of facial emotion in adults diagnosed with Autism Spectrum Disorder (ASD) is poorly understood and it is possible that past studies may not adequately reflect facial emotion recognition (FER) functioning of autistic adults. Using more socially relevant and complex stimuli may provide greater insights into the mechanisms underlying FER impairment in ASD. Electroencephalography (EEG) measures are capable of dynamically capturing electrical activity of neural networks and may provide further insights into the nature of FER impairment in adults with ASD during a complex and dynamic FER task.

Objectives:

We investigated the neural oscillations of autistic adults and non-autistic adults to provide insights into the mechanisms underlying ASD-linked FER impairment.

Methods:

Behavioural performance (accuracy) and neural oscillations of 22 autistic adults and 24 non-autistic typically developing (TD) age, gender and IQ matched controls were examined during a complex FER task. Participants were required to actively recognize positively and negatively valenced complex, dynamic facial emotion stimuli taken from the Cambridge Mind Reading Face-Voice Battery (CAMS).

Alpha (8-15 Hertz), theta (4-8 Hertz), beta (16-30 Hertz) and mu (8-12 Hertz) rhythms were extracted from the EEG data collected during the FER task. Median power values for positive and negative emotions were extracted for each frequency and electrode. EEG data were examined according to region (frontal, central, temporal, parietal, and occipital) and hemisphere (left, right) to examine potential differences in the distribution of power in the frequency bands.

Results:

Autistic adults were less accurate during facial emotion recognition, particularly in response to positive emotions. A reduction in accuracy was present concomitant with increased power primarily in the theta band in the left occipital hemisphere during positive FER. A global increase in theta activity was seen in response to negative emotions. Autistic adults also showed altered differentiation of mu rhythm activity. Mu suppression was reduced to positive emotion relative to negative emotion in autistic adults, with the opposite being true for TD adults.

Conclusions:

Increased theta power for autistic adults may represent hyper-reactivity to emotional stimuli and greater requirements for top-down cognitive control during the processing of negative emotion. Altered differentiation of the mu rhythm to emotional stimuli suggests atypical functioning of the mirror neuron system that may also contribute to ASD-linked FER impairments.

178 **111.178** Examining Complex Facial Emotion Processing in Typical Development and Autistic Traits: An Investigation of Dimensional Models of Emotion

M. H. Black[1,2], *N. T. Chen*[1,2,3,4], *O. V. Lipp*[4], *S. Bolte*[5,6,7], *M. Falkmer*[8,9] *and S. J. Girdler*[1,6], *(1)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)School of Psychological Sciences, University of Western Australia, Perth, Australia, (4)School of Psychology and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (5)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (6)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (7)Child and Adolescent Psychiatry, Center for Psychiatry Research, Stockholm County Council, Sweden, (8)Curtin University, Bentley, Australia, (9)School of Occupational Therapy and Social Work, Curtin University, Perth, Western Australia, Australia*

Background:

Impairments in facial emotion recognition (FER) are commonly associated with Autism Spectrum Disorders (ASD). While longstanding research has typically shown this in clinical ASD, emerging evidence suggests that FER impairment may also extend to the broader autism phenotype including non-clinical populations with high autistic-like traits. However, the precise nature of this impairment remains equivocal. It is possible that past investigation of FER in ASD is clouded by the conceptualizations of emotion used in these studies, which rely on discrete conceptualizations or the categorization of emotions based on the valence alone. A dimensional approach, which considers emotions to arise from the intersection of independent neural systems, may provide insights into the mechanisms underlying ASD-linked FER impairment.

Objectives:

To explore the effect of autistic traits on the perception of complex facial emotions to determine what dimensions of processing may drive ASD-linked impairment in emotion processing.

Methods:

A total of 100 typically developing individuals completed the Autism Quotient (AQ) and viewed 52 complex facial emotion stimuli from the Cambridge Mind Reading Face-Voice Battery (CAMs). Participants were required to rate each stimulus based on "How you think the person is feeling" on 9-point Likert scales relating to the valence, arousal, dominance and approach dimensions. To observe the effect of autistic traits on the perception of the stimuli, correlations between AQ score and ratings on each of the four dimensions were examined. As correlations can be conducted only one dimension at a time, further analysis was subsequently conducted to calculate the absolute difference between high and low autistic trait groups within the four dimensional space whereby larger values indicated a greater degree of distance between low and high AQ groups. Individual dimensions were also examined to investigate which dimensions contributed the greatest to this difference.

Results:

Autistic traits were shown to influence the perception of emotion on all four dimensions. Correlation analysis showed that higher autistic traits were associated with more positive valence ratings for emotions labelled as 'guarded' and greater approachability ratings for 'insincere', 'confronted' and 'appalled emotions'. Higher autistic traits were also associated with lower arousal ratings for emotions labelled as 'lured'. When examining the absolute difference between high and low AQ groups within the four dimensional space, valence and arousal ratings appeared to contribute to only half of the difference between high and low autistic traits. Differences on dominance and approach dimensions appeared to account for larger differences between high and low autistic trait groups for many of the complex emotions.

Conclusions:

These findings suggest that under-examined dimensions of emotions such as dominance and approach may also underlie ASD-linked FER impairment. There is a need to consider these other underlying dimensions when examining FER impairment in clinical ASD samples to accurately capture potential underlying mechanisms.

179 **111.179** Autism Severity, Social Identity and Well-Being in Autistic Young People

K. Cooper[1] *and A. Russell*[2], *(1)University of Bath, Bath, United Kingdom, (2)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom*

Background: Autistic people are more likely to struggle with mental health problems than the general population, and autistic traits are also associated with poor psychological well-being. Individuals who strongly identify as an autistic person (referred to as autism identity) and feel positively about this identity (autism collective self-esteem) have been found to have improved mental health compared to individuals who feel negatively about their autism identity. This is consistent with findings from other stigmatised groups in the social identity literature. However there has been no research to date investigating the relationship between autism traits and autism identity in autistic people, despite the importance of these two factors for psychological well-being. Developing and maintaining a sense of affiliation with in-group members, i.e. other autistic people, may be a particular challenge for individuals high in autistic traits, due to the social communication deficits characteristic of this group.

Objectives: This study aimed to investigate the impact of self-reported autism severity on autism identity and psychological well-being in autistic young people aged 17 and 18, using well validated measures. It was hypothesised that individuals with higher self-reported autism severity would have a lower sense of autism identity and collective self-esteem, lower well-being and higher social anxiety scores.

Methods: Participants (n=49) were young people with a clinical diagnosis of an Autism Spectrum Disorder (ASD). The Social Responsiveness Scale-Short was used to divide participants into high and low severity groups, based on whether they scored above or below the average score across participants. Participants also completed two self-report measures of psychological wellbeing; the Social Anxiety Scale for Adolescents and the Warwick-Edinburgh Mental Well-being Scale. Finally, participants completed measures of their autism identity and autism collective self-esteem.

Results: A one-way ANOVA with the factor group (high vs low autism severity) was conducted with the dependent variables autism identity, autism collective self-esteem, mental well-being and social anxiety. There was no significant effect of group on autism identification or autism collective self-esteem. There was a significant effect of autism severity on mental well-being $F(1,47)=4.24$, $p=.045$, with higher well-being in the low severity group (Mean=45.7, SD=1.28) compared to the high severity group (Mean = 41.67, SD=1.47). There was also a significant effect of autism severity on social anxiety *F*(1,47)=10.69), *p*=.002, with higher social anxiety in the high severity group (Mean=68.33, SD = 2.55) compared to the low severity group (Mean = 57.28, SD = 2.21).

Conclusions: In line with the hypothesis, high autism severity was associated with lower mental well-being and higher social anxiety scores. This fits with the well-established link between autism and poor mental health. We predicted that higher autism severity would decrease sense of autism identity, however it seems that autism severity does not impact on sense of identity as an autistic person. This means that autistic individuals from all parts of the spectrum are equally likely to identify (or not identify) as autistic, suggesting that severe autistic traits are not a barrier to a sense of affiliation with other autistic people.

180 **111.180** Autistic Person or Person with Autism? the Effect of Diagnostic Terminology on First Impressions

K. M. DeBrabander, *K. E. Morrison and N. J. Sasson, University of Texas at Dallas, Richardson, TX*

Background:

The terms people use to describe autism can vary widely. Professionals continue to favor person-first language (e.g., “person with autism”), whereas members of the autism community increasingly prefer identify-first language (e.g., “autistic person”) (Kenny et al., 2016). We previously reported that first impressions of autistic adults made by their typically-developing (TD) peers improve when their diagnosis is known relative to when it is withheld (Sasson and Morrison, in press), but it is unclear whether these impressions differ depending upon how their diagnosis is described.

Objectives:

This study examined whether different diagnostic terms for autism affect how TD people form first impressions of autistic adults, and whether these patterns differ depending upon the observer’s level of knowledge and familiarity with autism.

Methods:

203 TD undergraduate raters (171 female; mean age=21.30) viewed 10 second videos of 20 autistic adults (17 male; mean age=24.5; mean full-scale IQ=106.4) performing a mock audition for a television program (see Sasson et al., 2017 for details). Individuals in the videos were labeled either as having “no diagnosis”, “has autism”, “is autistic”, “is on the autism spectrum”, “has Asperger’s”, or “has a disability”. Raters provided impressions on ten items for each video using a four point scale: six trait items (attractiveness, awkwardness, intelligence, likeability, trustworthiness, and dominance) and four intentions to interact items (e.g., likelihood of hanging out with the person; see Sasson et al., 2017). Raters also completed the Autism Awareness Scale (Gillespie-Lynch et al., 2015) and the Level of Contact Report (Holmes et al., 1999).

Results:

Using multi-level modeling, providing any label yielded more favorable impressions compared to a “no diagnosis” label (p‘s<.002). Specific comparisons of labels revealed participants labeled as autistic were rated higher on attractiveness and hanging out with compared to all other labels (p’s<.01) except has autism (p=.053), and higher on likeability compared to has a disability and on the autism spectrum (p’s<.03). The autistic label also resulted in higher ratings on intelligent compared to all other labels (p’s<.01) except for on the autism spectrum. Level of contact with autism predicted higher first impressions for participants labeled as autistic (p=.001), but lower impressions for the autism, on the autism spectrum, and Asperger’s labels (p’s<.048). Autism knowledge predicted higher first impressions when any label was provided relative to when presented as having “no diagnosis” (p=.001), but individually autism knowledge was only positively associated with the autistic label (p=<.01).

Conclusions:

Results suggest the identifying an individual as autistic evokes more favorable first impressions by unfamiliar TD observers relative to other common terms used to describe autism. The benefit of using the term autistic was particularly beneficial for those with higher autism knowledge and with personal connections to autism. Taken together, these findings indicate that the identify-first language preferred by many autistic adults results in more favorable first impressions, which in turn may increase the quantity and quality of their social experiences (Sasson et al., 2017).

181 **111.181** Can Neurotypical Adults Identify Autism Based on Brief Samples of Behaviour?

E. Sheppard[1] *and J. Macgillivray*[2]*, (1)University of Nottingham, Nottingham, United Kingdom of Great Britain and Northern Ireland, (2)University of Nottingham, Nottingham, United Kingdom*

Background:

In recent years, considerable resources have been spent on raising public awareness of autism. Autism awareness within the general population is frequently tested using questionnaires, where knowledge and understanding of autism is assessed by self-report. Recent studies have suggested that the general public has relatively good understanding of the features of autism (Dillenberger et al., 2013; Stewart et al., 2008). However, it is not known whether people bring such knowledge to bear when they encounter people with autism in everyday circumstances.

Objectives:

This study aimed to determine whether neurotypical adults could identify who does or does not have an autism diagnosis based on brief samples of behaviour. The study also aimed to determine the relationship between people’s ability to recognise autism, their knowledge of autism features, and the amount of contact thay have had with autistic individuals.

Methods:

Neurotypical adults (perceivers) watched videoclips of 20 male autistic adolescents and adults and 20 male neurotypical comparison individuals (targets), created by Sheppard et al. (2016). Each muted video showed the target’s reaction to one of four events enacted by the researcher. Targets were either told a joke, paid several compliments, told about the researcher’s unfortunate day, or kept waiting while the researcher carried out irrelevant activities.

Perceivers were told which event the target had experienced prior to each video and were asked to indicate whether or not they believed the target was autistic. They were then asked to verbally state the reason for their choice. Perceivers also completed questionnaires that tested their understanding of core features of autism and asked about the amount of contact they had had with autistic individuals.

Results:

Overall, perceivers were able to judge whether or not targets were autistic at above chance levels. However, further analysis revealed that for the waiting scenario performance was not above chance. Perceivers' ability to jduge whether or not targets were autistic correlated with the amount of contact they reported having had with autistic individuals, but not with knowledge of autism features. Perceivers' most frequently stated reasons for their choices included aspects of facial expression, references to eye movements or eye contact, comments on rapport with the (off camera) experimenter, and whether the reaction was 'normal' for the context.

Conclusions:

Neurotypical individuals are capable of judging who does or does not have an autism diagnosis based on very brief samples of behaviour. They were above chance for three of the four scenarios included in the study, suggesting that differences between those with and without autism may be more apparent in some situations than others. Along with studies that have used more implicit measures (Sasson et al., 2017; Sheppard et al., 2016), these results suggest that autistic people can be perceived differently from neurotypical individuals based on just a few seconds of their behaviour. More prior experience of autism was associated with better task performance, suggesting that neurotypical individuals can develop expertise in recognising autism through exposure, in the absence of explicit diagnostic training.

182 **111.182** Autism Spectrum Disorders in Girls and Women with Turner Syndrome

***J. Wolstencroft**[1], W. Mandy[2] and D. H. Skuse[3], (1)UCL GOS ICH, London, United Kingdom, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland, (3)Behavioural and Brain Sciences Unit, Population Policy and Practice Programme, UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom*

Background:

Turner Syndrome (45,X; TS) is one of the most common sex chromosome aneuploidies. It is associated with physical morbidities affecting nearly every body system, but the research into the psychological wellbeing of girls with TS is scarce and seldom systematic. Girls with TS experience social skills difficulties but the previously reported association between TS and Autism Spectrum Disorders (ASD) is controversial.

Objectives:

This study aims to determine the prevalence of autism spectrum disorders in girls and women with TS using structured psychiatric assessments and examine the profile of the social skills deficit.

Methods:

Participants (N=70) were recruited through the IMAGINE ID (national UK study of behavioural adjustment) and SOAR (social skills and relationships in Turner Syndrome) research studies. Assessments were administered online to the caregivers of girls and women with TS aged 4-20. To date a structured psychiatric interview called the Development and Wellbeing Assessment (DAWBA) has been completed by 58 families and the Social Responsiveness Scale (SRS) has been completed by 40 families. The DAWBA responses are reviewed by a psychiatrist to generate clinical diagnoses and the SRS measures autistic traits. Both instruments are widely used and validated.

Results:

21% of the girls with TS met criteria for a diagnosis of an ASD, which is substantially higher than the UK national rates of ASD in females (0.3%). Of these, on the total SRS standardised score 29% of participants scored within the 'moderate' range and 71% scored in the 'severe' range. When looking at the SRS subscales, participants meeting criteria for diagnosis scored in the 'severe' range for all subscales.

Of the girls that did not meet criteria for a clinical diagnosis of ASD, on the SRS standardised total score 18% scored in the 'normal range', 21% scored in the 'mild' range, 55% scored in the 'moderate' range and 6% scored in the 'severe' range. When looking at the SRS subscales, all participants that did not meet clinical criteria scored in the 'moderate' range for the communication as well as the restrictive interests and repetitive behaviours subscales. However, they scored in the 'mild' range for the awareness, cognition and motivation subscales.

Overall, regardless of clinical diagnosis girls with TS were the least impaired in the social motivation subscale on the SRS, where they obtained their lowest subscale scores.

Conclusions:

TS is associated with higher rates of autism compared to the UK national population. Substantial sub-diagnostic social skills difficulties were identified in the girls and women with TS who did not meet criteria for a diagnosis of an ASD, specifically in domains of social communication, as well as restrictive interests and repetitive behaviours. These difficulties warrant further research as they are likely to have a significant impact on everyday social interactions. Overall, girls with TS were the least impaired in the social motivation domain of the SRS, which may be indicative of a desire for social interactions and suggests that delivering social skills interventions may be appropriate for this group.

183 **111.183** Can You Spot a Liar? Lie Detection and Mindreading Abilities in Adults with Autism Spectrum Disorder

***C. Grainger**[1], T. Nicholson[2], S. E. Lind[3], P. Carruthers[4] and D. M. Williams[5], (1)University of Stirling, Stirling, United Kingdom, (2)University of Kent, Canterbury, England, United Kingdom, (3)Psychology, City, University of London, London, United Kingdom, (4)University of Maryland, College Park, MD, (5)University of Kent, Canterbury, United Kingdom*

Background: Detection of deception is of fundamental importance for everyday social life. Intuitively, the abilities to lie and detect lies are an aspect of mindreading – the ability to explain and predict behaviour in terms of underlying mental states (beliefs, desires, intentions etc.). People with diminished mindreading, such as those with autism spectrum disorder (ASD), might be at risk of manipulation and exploitation as a result of lie detection difficulties. However, surprisingly, no study to date has explored lie detection abilities in ASD.

Objectives: Given the important role accurate lie detection plays in everyday social interactions, it is important to establish lie detection abilities in individuals ASD. As such this research aimed to assess whether a) lie detection abilities relate to ASD traits/mindreading abilities in the general population, and b) whether lie detection abilities are impaired in adults with ASD.

Methods: In Experiment 1, performance among 216 neurotypical adults was assessed on a realistic lie detection paradigm. During this task, participants were shown interviews of individuals being questioned about whether they had cheated during a game they previously played. In all videos, the interviewee reports that they had not cheated. However, crucially, only half of the videos included individuals who had not cheated (truth-tellers) and the other half included individuals who had cheated and who lied about this in the interview (liars). Participants watched each video once and made a categorical judgement about whether the person being interviewed was lying or telling the truth about whether they cheated during the experiment. Participants also completed two classic test of mindreading ability (The 'Reading the Mind in the Eyes' task; Baron-Cohen et al., 2001, and the 'Animations Task'; Abell et al., 2000) and a measure of autistic traits (the Autism-Spectrum Quotient; AQ, Baron-Cohen et al., 2000). In experiment 2, the same battery of tasks was completed by 27 adults with a diagnosis of ASD and 27 age-, sex-, and IQ-matched comparison participants.

Results: In Experiment 1, performance among neurotypical adults on the lie detection paradigm was significantly negatively associated with number of ASD traits, but not with mindreading ability. Moreover, in Experiment 2, lie detection was significantly impaired in adults with a diagnosis of ASD relative to comparison participants. Of particular note was the finding that participants with ASD failed to distinguish truth-tellers from liars even when "transparent" behavioural cues were emitted (i.e., when judging individuals who were "bad" liars) that allowed neurotypical participants to make highly accurate judgements.

Conclusions: The results of both experiments suggest that that people with ASD (or sub-clinical ASD traits) are poorer at detecting when someone is lying. This may leave individuals with ASD open to manipulation and future research should explore the benefits of lie detection training, to help individuals with ASD recognise signs of deception.

184 **111.184** Capture the Face: Motion-Capture Patterns of Dynamic Facial Expressions in ASD

E. Zane[1]*, L. Pozzan*[2]*, Z. Yang*[3]*, T. Guha*[3]*, S. Narayanan*[3] *and R. Grossman*[4]*, (1)FACE Lab, Emerson College, FACE Lab, Boston, MA, (2)Amazon, Cambridge, MA, (3)University of Southern California, Los Angeles, CA, (4)CSD, Emerson College, Boston, MA*

Background:

Neurotypical (NT) individuals struggle to interpret emotional facial expressions of people with Autism Spectrum Disorder (ASD) (Brewer et al., 2016). Research attempting to determine why this is so has reported different findings. Some describe expressions as atypically flat in ASD (Kasari et al., 1993; Stagg et al., 2014; Yirmiya et al., 1989), while others report expressions that are less "natural" than NT individuals (Faso et al., 2015; Grossman et al., 2013).

Much of this research uses human observation to assess facial-expression quality in ASD. However, this type of subjective coding cannot elucidate underlying differences in facial movement that might lead to facial-expression ambiguity.

Objectives:

Use facial motion-capture (mocap) to objectively quantify the facial movements that make expressions of individuals with ASD difficult for NT individuals to interpret

Methods:

We presented 18 videos of actors making emotional facial expressions to 19 children and adolescents with ASD and 18 NT individuals (Age *M* = 12;8 and 12;11, respectively). Groups did not differ significantly on age, gender, IQ and language. We asked participants to mimic facial expressions they saw while wearing 32 reflective markers on their face. The movement of markers was recorded using mocap technology.

Mocap data were grouped by the Valence (positive vs. negative) and Intensity (high vs. low) of the expression being mimicked. We used Growth Curve Analysis (GCA) (Mirman, 2008; 2014) to test whether facial movement patterns were predictable by the valence and intensity of the expressed emotion and by participant group.

Results:

Facial movement patterns were significantly predicted by an interaction between group (ASD vs. TD), the Valence of the expression being mimicked (Positive vs. Negative), and the Intensity of expression (High vs. Low). This result reflects differences in facial expressions between the diagnostic groups, which vary as a function of the Intensity and Valence of the expression. Post-hoc tests within group show that Valence significantly predicts movement in the NT group, but not the ASD group. Both group's movement patterns are predicted by Intensity.

Conclusions:

For NT individuals, Intensity and Valence significantly predict facial expressions movements. For individuals with ASD, facial movement is predicted by Intensity, but not Valence. This demonstrates a lack of quantifiable differentiation between positive vs. negative expressions in the ASD group, which could provide an objective explanation for why NT individuals struggle to interpret the facial expressions of their ASD peers.

185 **111.185** Classic Social Psychological Phenomena across the Autism Spectrum: Three Empirical Tests of the Integrated Self-Categorization Model of Autism

D. Skorich*, K. Bertschy, S. A. Haslam, K. S. Karimi and C. J. Santos, University of Queensland, Brisbane, Australia*

Background: Skorich and colleagues (2016; 2017) have proposed a model of autism that integrates the theory of mind (ToM) and weak central coherence (WCC) features of the disorder, which they term the Integrated Self-Categorization Model of Autism (ISCA). This model leads to a number of novel hypotheses, in particular predicting that people with autism should be less susceptible to classic social psychological phenomena, such as ingroup favoritism, cooperative social interdependence, and outgroup homogeneity. The current paper reports 3 experiments exploring the degree to which participants show each of these effects as a function of their autistic tendencies.

Objectives: The research reported in the current paper aims to test the ISCA model, by way of 3 empirical studies investigating some of the novel hypotheses of the model. The first experiment explores the degree to which autistic tendencies relate to ingroup favoritism, the second explores the degree to which autistic tendencies relate to social interdependence, and the third explores the degree to which autistic tendencies relate to outgroup homogeneity.

Methods: All three studies were conducted online, with the Autism Quotient (AQ) used as a measure of autistic tendencies in the general population samples recruited. In the first study, participants were asked to complete the minimal group paradigm, in which participants are randomly placed into made-up groups and then asked to allocate resources to ingroup and outgroup members, as a measure of ingroup favoritism. In the second study, participants were asked to complete the prisoners' dilemma, in which participants are paired with another player and then asked to decide between mutually beneficial and individually beneficial outcomes, as a measure of their tendencies toward cooperative social interdependence. In the final study, participants were asked to rate either their own national (in)group or another national (out)group on a number of traits, as a measure of the degree to which they perceive the outgroup as more or less homogenous than their ingroup.

Results: The first study revealed a negative relationship between AQ and ingroup favoritism, such that high AQ participants showed less ingroup favoritism than low AQ participants. The second study revealed a negative relationship between AQ and cooperative, socially interdependent decisions, such that high AQ participants showed less cooperation and more competition than low AQ participants. The final study revealed that high AQ participants perceived both their ingroup and their outgroup as less homogenous than low AQ participants.

Conclusions: These results suggest that autistic tendencies are associated with decreased susceptibility to classic social psychological phenomena. Taken together, they provide strong evidence for the ISCA model, and for its contention that people with autism have a decreased tendency to self-categorize, which is related to WCC, and which results in the ToM and associated social-communication problems on which diagnosis is based.

186 **111.186** Contribution of the Social Cognition Evaluation Battery "Clacos"

E. Houy-Durand[1], *S. Morel-Kohlmeyer*[2], *A. Thillay*[3], *M. Barbier*[4], *I. Amado*[5], *L. Brenugat-Herne*[5], *I. Carteau-Martin*[6], *C. Danset-Alexandre*[5], *B. Gaudelus*[7], *J. Graux*[2], *E. Peyroux*[8], *Z. Prost*[8] *and F. Bonnet-Brilhault*[9], *(1)UMR930 Inserm, Université François-Rabelais de Tours, Tours, France, (2)UMR Inserm U930 Imagerie et Cerveau, Université François-Rabelais de Tours, CHRU de Tours, TOURS, France, (3)UMR INSERM U930, Tours Cedex 9, France, (4)UMR Inserm U930 Imagerie et Cerveau, Université François-Rabelais de Tours, TOURS, France, (5)SHU Centre Hospitalier Sainte Anne, PARIS, France, (6)groupe de travail « Cognition » - Institut de Psychiatrie - GDR 3557, TOURS, France, (7)Centre référent de réhabilitation psychosociale et remédiation cognitive CL3R-SUR, Le Vinatier Hospital, Lyon, France, (8)Le Vinatier Hospital, LYON, France, (9)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France*

Background: Autism Spectrum Disorders (ASD) is a range of neurodevelopmental disorders characterized by impairments in social communication and interaction and limited interests and repetitive behaviour according to DSM-5 (American Psychiatric Association, 2013). Although social communication impairments are probably shared across several psychiatric disorders including autism, schizophrenia, anxiety disorders and ADHD, they are not well characterized, due to a lack of standardized evaluation tools, especially in adult populations. Our multicentric research group in psychiatry GDR3557 developed since 2011 a new battery for social cognition evaluation named "ClaCoS", in order to discriminate specific profiles of social cognition disorders that could be common or specific, respectively to autism and schizophrenia (Pinkham et al., 2008). Thus, clinical evaluation of social cognition impairments is still controversial and remains poorly documented. Moreover, we considered social cognition as a multidimensional process (Pinkham et al., 2014), and examined different components some of which are known to be impaired in ASD.

Objectives: Our aim is to assess the sensibility of the 'ClaCoS' battery in the evaluation of social cognition impairments in autism. This battery examines multiple domains of social cognition, namely: subjective perception of social impairments, empathy, emotional facial expression recognition, theory of mind, attribution style (i.e. the interpretation of other people's behaviour), social perception and knowledge of social rules.

Methods: We compared the social cognition abilities of 18 autism spectrum disorders adult patients without intellectual disability and 18 neurotypically developed peers using ClaCoS.

Results: The ASD group showed deficits in facial expression recognition, empathy, theory of mind adjustment as well as social perception and convention knowledge. Furthermore, ASD adults reported subjective complains regarding their social abilities. We also showed correlations between these different components of social cognition, which suggest the relevance of our battery and its interest to discriminate possible ASD sub-group phenotypes.

Conclusions: A larger sample would be of great value to discriminate specific profiles that could be common to autism and schizophrenia. Shared social cognition profiles could help us to apply social cognitive remediation programs more adjusted to a "transnosographic" impairment following a clinical neurodevelopmental approach.

187 **111.187** Correlates of Social Functioning in Autism Spectrum Disorder and Typical Development: A Systematic Review and Meta-Regression Analysis

K. Bottema-Beutel[1], *S. Y. Kim*[1], *S. Crowley*[1] *and J. Cuda*[2], *(1)Lynch School of Education, Boston College, Chestnut Hill, MA, (2)Boston College, Chestnut Hill, MA*

Background: Differences in social functioning are a core feature of autism spectrum disorder (ASD). Several psychological constructs have been put forth as correlates of social functioning, in order to provide developmental and/or theoretical explanations for the social phenotype in ASD, as well as in typical development (Carter et al., 2013).

Objectives: The goal of this study is to synthesize literature reporting Pearson's *r* effect sizes between social functioning and 8 putative correlates, including (a) central coherence, (b) executive functioning, (c) initiating joint attention (IJA), (d) responding to joint attention (RJA), (e) theory of mind (ToM), (f) imitation, (g) symbolic play, and (h) visual attention patterns to faces. Using a meta-regression framework, we generated summary effect sizes for correlations between social functioning and each construct, for children with ASD and for children who are TD. Further, we determined if summary effect sizes differ between populations with ASD and TD.

Methods: We conducted a structured search using ERC, ERIC, Medline, PsychINFO, and ProQuest Dissertations and Theses databases. To generate summary effect sizes and to conducted meta-regressions, we used a robust standard error approach to account for the nesting of effect sizes within studies.

Results: Currently, 100 studies (nearly half from grey literature) comprising a total of 725 effect sizes have been located. Effect sizes were calculated on a total of 9,906 participants. Average chronological ages of participants was 6 years 8 months for TD children, and 16 years 5 months for children with ASD. Summary effect sizes were weak (range = .05 - .48) across all constructs for both ASD and TD groups. In the TD group, summary effect sizes were significant and positive for Pearson's *r* correlations calculated on social functioning and (a) executive function, (b) IJA, (c) RJA, and (d) ToM. The effect size for Play was positive, but not significantly different from zero. There were too few effect sizes available to calculate summary effects for central coherence and visual fixation in this group. In the ASD group, summary effect sizes were significant and positive for Pearson's *r* correlations calculated on social functioning and (a) executive function, (b) imitation, and (c) ToM. The effect sizes for central coherence, IJA, and visual fixation were positive, but not significantly different from zero. There were too few effect sizes available to calculate summary effects for RJA and symbolic play in this group. An illustration of these results can be found in Figure 1. Across all constructs, effect sizes were larger in the ASD group as compared to the TD group, even after controlling for age ($p = 0.02$). We did not find any evidence of publication bias.

Conclusions: The results of this study indicate there are only modest associations between the several psychological correlates proposed to undergird social functioning, but that associations are generally stronger in ASD. Future studies should be conducted to further investigate these associations so that summary effects can be calculated, to better understand potential moderators of these associations, and to propose novel constructs that may better explain social functioning.

188 **111.188** Does Gender Affect Mood in Children and Adolescents with Autism Spectrum Disorder?

***J. L. Lillis**[1] and M. A. Stokes[2], (1)Deakin University Australia, Melbourne, Australia, (2)Deakin University, Burwood, Australia*

Background: This study follows on from findings of high levels of anxiety, depression, suicide, bullying and loneliness in adolescents with Autism Spectrum Disorders (ASD).

Objectives: The present study investigated differences in mood between adolescents with ASD and their typically developing (TD) peers. The study also examined gender differences in the mood of adolescents with ASD. We hypothesised that adolescents with ASD would have more negative affect and less positive affect than TD adolescents. We also hypothesised females with ASD will have more negative affect than males with ASD and males with ASD will have lower positive affect than females with ASD.

Methods: We recruited 69 participants aged 10-20 years, comprising of 35 TD participants and 34 individuals independently assessed as having ASD. The study utilised the Positive and Negative Affect Schedule (PANAS) to measure mood as positive and negative affect.

Results: Independent bootstrapped *t*-tests found no differences in affect between TD participants and those with ASD, or for positive affect across gender within ASD. Importantly though, despite the hypothesis, the study found that males with ASD had significantly more negative affect than females with ASD (Cohen's $d=0.85$, $p<.01$).

Conclusions: An understanding of these gender differences in mood is needed to provide appropriate mental health services to those with ASD, and to understand what strengths may be present to better capitalize upon for those with ASD. This study recommends a focus on the communication challenges of males with ASD and how their friendship behaviours and coping strategies impact upon their negative affect levels in future research.

189 **111.189** Dyadic Physiological Interdependence and Social Reciprocity in ASD

***O. Saunders Wilder**[1], J. Sullivan[2], K. T. Johnson[1], R. V. Palumbo[2], C. Cumpanasiou[2], R. W. Picard[3] and M. S. Goodwin[2], (1)MIT Media Lab, Cambridge, MA, (2)Northeastern University, Boston, MA, (3)MIT, Cambridge, MA*

Background: Converging evidence in the social and affective neuroscience literature suggests that the same brain regions activated while experiencing emotion are also recruited when observing or inferring affective experiences in another person. This offers a potential process by which inferring another's affective state automatically influences one's own affective state. Understanding how this underlying process of *interpersonal interoceptive inference* may be impacted in individuals with social reciprocity impairment is an important step towards developing an etiological understanding of socio-affective impairment in Autism Spectrum Disorder (ASD). Interpersonal physiology may ultimately help further scientific understanding of the underlying etiology of socio-affective impairment in ASD by providing a feasible, sensitive, and interpretable means of measuring these underlying neurophysiological processes in a variety of contexts.

Objectives: In order to investigate the relationship between interpersonal physiology and social reciprocity impairment, we engaged child-parent dyads in semi-structured social-emotion regulation tasks while collecting ambulatory physiology data and a standard informant report measure of social reciprocity. In addition to simultaneous parent-child physiology, we also collected and analyzed physiological data from a researcher and the child in which they interacted with the child independent of the parent while administering several relevant presses from the ADOS-2. This allowed us to examine interpersonal physiological dynamics when a child is interacting with an unfamiliar adult, as is commonly the case in many diagnostic and assessment settings such as the ADOS-2.

Methods: Using ambulatory electrodermal activity (EDA) sensors, we collected interpersonal physiology data from 30 young children who were either typically developing (TD; N=22) or had an ASD diagnosis (N=8), their parent, and a researcher during semi-structured social interaction and emotion regulation tasks (ADOS-2; LABTAB) adapted from social presses in existing validated paradigms for assessing socio-affective functioning in young children. In addition, parents completed the Social Responsiveness Scale 2nd Edition (SRS-2) about their child, a well-validated 65-item informant-report measure of social reciprocity impairments in autism.

Results: To assess dyadic physiological interdependence, we fit a series of hierarchical linear models following the procedure used by Baker et al. (2015) with the child's EDA as the dependent variable and child movement, time, and adult EDA (either parent or researcher depending on the task being analyzed) and an interaction term consisting of adult EDA × SRS-2 Total Score as independent variables. Our results for both ASD and TD indicated a statistically significant dependence of child EDA on both adult EDA and adult EDA × SRS-2 Total Score, suggesting that physiological interdependence between adult and child was partially moderated by the child's social reciprocity impairment as measured by the SRS-2. Furthermore, a simple slopes decomposition indicated that physiological interdependence diverged significantly for children with different levels of social reciprocity impairment and varied depending on whether the child was interacting with the parent or the researcher.

Conclusions: Our findings suggest that physiological interdependence between a child and parent or unfamiliar adult is related to standard measures of social reciprocity in young children with and without ASD and may differ depending on dyad familiarity.

190 **111.190** Emotion Regulation, Emotionality, and Expression of Emotions: A Link between Social Functioning and ASD Symptoms in Children with ASD and Their Peers

N. Reyes[1]*, R. S. Factor*[2] *and A. Scarpa*[3]*, (1)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO, (2)Virginia Polytechnic Institute and State University, Blacksburg, VA, (3)Virginia Polytechnic Institute & State University, Blacksburg, VA*

Background: It is well documented that children with Autism Spectrum Disorders (ASD) experience profound social problems (American Psychiatric Association, 2013; Bauminger, 2013; Kanner, 1943), and demonstrate difficulties in emotional competence (Begeer, Koot, Rieffe, Terwogt, & Stegge, 2007; Hepburn & Wolf, 2013; White et al., 2013). To date, the link between emotional competence and social skills remains unexplored in young children with ASD.

Objectives: The goals of this study were (1) to investigate differences between emotion regulation (ER), emotionality, and expression of emotions in children with ASD and their typically developing (TD) peers; and (2) to examine the potential link between these areas of development and social skills and ASD symptoms.

Methods: Forty-six children with ASD (n=22) and their TD peers (n=24) were included in this study. The mean age for the ASD group was 69.36 months and for the TD group was 60.25 months. Parents reported information about their children's social and emotional skills on the Emotion Regulation Checklist (ER), Social Communication Questionnaire (SCQ), the Emotion Reaction Questionnaire (ERQ), Vineland Adaptive Behavior Scales–2nd Edition (VABS-2), and the Social Responsiveness Scale (SRS). Children also completed the Autism Diagnostic Observation Scheduled (ADOS).

Results: *Differences in Emotion Regulation, Emotionality, and Expression of Emotions between Groups.* Results indicated decreased ER skills, $F(1, 41) = 56.69$, $p < .001$, increased emotionality $F(1, 41) = 27.11$, $p < .001$, and decreased expression of emotions (anger, $F(1, 41) = 6.58$, $p = .014$, fear, $F(1, 41) = 4.69$, $p =.036$, and positive affect, $F(1, 41) = 13.93$, $p = .001$) in children with ASD compared to TD children.

Associations between Emotion Regulation, Emotionality, Social Skills, and Autism Symptoms. While better social skills were associated with decreased emotionality and increased expression of emotions in both groups (all p-values <0.05), better social skills in the VABS-2, r(20) = .67, $p<.05$, and the SRS-T, r(20) = -.47, $p<.05$, were linked to enhanced ER in the ASD group only. Also, enhanced ER, r(20) = -.53, $p<.05$, and increased expression of emotions, such as positive affect, r(20) = -.40, $p<.05$, and sadness, r(20) = -.50, $p<.05$, were also correlated with decreased ASD symptoms in the ASD group.

Conclusions: These results support differences in emotional competence between children with and without ASD and shed light on a potential link between social-emotional development in children with ASD. Consistent with previous research, children with ASD demonstrate decreased ER skills, increased emotionality, and decreased expression of emotions in comparison to TD peers. Further, we generally found a strong relationship between social skills and ER, emotionality, and expression of emotions in the ASD group. Thus, treatment packages that target both ER and social skills could improve the utility of these interventions (Bauminger, 2002; Scarpa & Reyes, 2011; Prizant, Wetherby, Rubin, & Laurent, 2003; Sofronoff, Attwood, & Hinton, 2005; Sofronoff, Attwood, Hinton, & Levin, 2007). Given that these specific difficulties tend to be present across the lifespan, addressing them in early childhood could ultimately improve the quality of life for individuals with ASD.

191 **111.191** Emotional Language Use in Descriptions of Social and/or Emotional Pictures By Younger and Older Children with ASD

E. J. Teh[1]*, M. J. Yap*[1] *and S. J. Rickard Liow*[2]*, (1)Psychology, National University of Singapore, Singapore, Singapore, (2)Otolaryngology, National University of Singapore, Singapore, Singapore*

Background: Compared to typically developing children, children with autism spectrum disorders (ASD) reportedly show deficits in recognizing and describing emotions in others, and may have difficulty deriving meaning in social contexts. One method used to study emotion-processing in children with ASD is indexing their emotional language production in story-telling tasks using picture-books. However, a limitation of existing studies is that experimental stimuli tend to conflate emotional and social information, making it difficult to separate deficits in the two domains. Moreover, while social and emotional processing skills improve with age in typical development, little is currently known about their development in children with ASD.

Objectives: First, we aimed to systematically investigate the effects of emotional valence and social information on the production of emotional terms in picture descriptions by children with and without ASD. Second, we aimed to examine developmental changes in these effects across younger (preschool) and older (school-age) groups.

Methods: Participants were 10 younger (5-6 years old) and 10 older (8-12 years old) children with ASD, and 20 typically developing children matched-pairwise to the participants with ASD on age, gender, non-verbal IQ (all >70), and socioeconomic status. The experimental stimuli were 48 pictures varying on valence (positive/negative/neutral) and social engagement levels (high or low). All pictures depicted one or more person(s) in common everyday situations (see example in Figure 1). Participants were asked the task prompt, *"What is happening in this picture?"*, and allowed to respond freely with their descriptions. The frequency of emotional terms produced by each group was compared across valence and social engagement conditions using mixed ANOVA.

Results: While children with ASD generally produced fewer emotional terms than the control children in all negatively- and positively-valenced conditions, we found two significant three-way interactions. First, valence effects were moderated by social engagement information differently in ASD and control groups. Children with ASD produced fewer emotional terms in high-social than low-social emotional conditions; whereas typically developing children produced most emotional terms under high-social and negatively-valenced conditions. Second, age effects were moderated by group and social engagement information. For children with ASD, emotional terms increased with age and lower social engagement; whereas for typically developing children, higher social engagement increased emotional terms in the older group only.

Conclusions: Children with ASD showed deficits in emotional language use compared to typically developing children, which remained evident despite age-based increases in production. Our results are consistent with existing studies reporting reduced use of emotional language by children with ASD, and extend them by showing that increased social information may adversely impact emotional language production in ASD. The combination of emotional and social cues appears to create a cognitive-processing overload in children with ASD. Our findings also provide preliminary support for a model of separable components of social-cognitive processing in ASD, which contrasts with integrated processing of social and emotional information in the neurotypical brain. Future research directions for social cognition and emotion-processing in ASD are suggested, as well as practical applications for researchers and clinicians in the field.

192 **111.192** Evaluations of Social Interactions By Adolescents with and without ASD

L. V. Usher[1]*, C. A. Burrows*[2]*, D. S. Messinger*[2] *and H. A. Henderson*[3]*, (1)University of Wisconsin-Madison Waisman Center, Madison, WI, (2)University of*

Miami, Coral Gables, FL, (3)University of Waterloo, Waterloo, ON, Canada

Background:

Engaging in social interactions with unfamiliar peers requires adolescents with and without autism spectrum disorder (ASD) to coordinate multiple abilities, such as managing social anxiety and employing social cognitive abilities (Aiken et al., 2014; Usher et al., 2015; Usher et al., in press). However, less is known about how adolescents evaluate their own interactions with unfamiliar peers. This study aimed to quantify adolescents' global evaluations of the first few minutes of a social interaction, and to examine dyadic associations between those evaluations and observed behavior.

Objectives:

1. Evaluate how adolescents with and without ASD evaluate brief dyadic social interactions with unfamiliar peers in terms of how well the interaction went overall and how likely they would be to continue a friendship with the peer.
2. Examine the association between adolescents' evaluations of how well the interaction went and their likelihood to continue a friendship with the unfamiliar peer.
3. Examine dyadic associations between evaluations of the interaction and likelihood to continue a friendship with observed social reciprocity and social initiative during the social interaction.

Methods:

Fifty adolescents interacted in pairs consisting of one adolescent with ASD (M_{age}=14.66, SD=1.43; $M_{VerbalIQ}$=105.00, SD=14.79) and a gender-, age-, and verbal IQ-matched unfamiliar typically developing (TD) adolescent (M_{age}=14.21, SD=1.34; $M_{VerbalIQ}$=108.48, SD=13.83). Dyads were instructed to get to know each other for five minutes. During the interaction, participants were coded for social reciprocity (seeking, eye contact, conversational efficacy, social ease) and social initiative (proportion of time talking, reversed latency to first utterance, reversed latency to first spontaneous utterance, sharing). Immediately following the interaction, each participant responded to two questions on a 5-point scale from 1 (not at all) to 5 (the most): "How well did your interaction with____ go overall?" and "How much would you want to continue a friendship with _____ after today?"

Results:

Adolescents with and without ASD comparably reported that social interactions went well, ASD M=3.80(1.04), TD M=4.00(.96) and that they would continue a friendship with the peer, ASD M=3.24(.93), TD M=3.08(1.19). Ratings of the interaction and likelihood to continue a friendship were significantly associated within person, ASD *r*(25)=.44, *p*=.027, TD *r*(25)=.62, *p*=.001. Neither rating was significantly associated with age, IQ, or ASD symptoms for either group, *p*s>.05.

Across both diagnostic groups, adolescents who displayed higher reciprocity rated the interaction as having gone well overall, b=.64, t(33)=2.95, p=.006. Adolescents with higher social initiative rated the interaction as having gone well overall, b=.57, t(41)=2.82, p=.007, and were likely to want to continue a friendship with the peer, b=.71, t(33)=3.17, p=.003.

Adolescents whose peers displayed more reciprocity were likely to want to continue a friendship with the peer, b=.48, t(39)=2.09, p=.043. Those whose peers displayed more social initiative rated the interaction as having gone well overall, b=.46, t(36)=2.22, p=.033.

Conclusions:

Findings reveal comparable associations between positive evaluations of social interactions and observed social behavior for adolescents with and without ASD. Future research investigating how specific aspects of the interaction impact adolescents' evaluations over time would provide a fuller picture of social dynamics during this developmental stage.

193 **111.193** Examining Reciprocal and Predictive Relations Among Social, Language and Emotion Regulation Skills across Early Childhood in a Longitudinal Sample of Children with ASD.

V. P. Reinhardt[1], *J. B. McCauley*[2], *C. W. Nordahl*[3], *D. G. Amaral*[3] *and M. Solomon*[4], *(1)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (2)UC Davis MIND Institute, Sacramento, CA, (3)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (4)Department of Psychiatry & Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, University of California, Davis, Sacramento, CA*

Background:

Developmental science draws on transactional models to understand stability and change across the lifespan (Sameroff & Mackenzie, 2003; Gottlieb, 2001). Phenotypic presentations of Autism Spectrum Disorder (ASD) are dynamic across development, and variability in individual symptom presentation is well documented across the lifespan. Early social and language skills predict later language, developmental, and social outcomes in ASD (Landa & Kalb, 2012; Smith, Mirenda & Zaidman-Zait, 2007), and emotion regulation (ER) skills have been identified as a key predictor of social and academic development within typically developing (TD) samples (McClelland & Cameron, 2011). Understanding how social, language, and ER skills interact to influence development may provide insight into the mechanisms and processes underlying developmental heterogeneity in ASD.

Objectives:

(1) To examine the stability of and reciprocal relations between social and language skills across early childhood, and (2) To model predictive relations between early ER and later social and language skills during this period.

Methods:

Participants were 277 children with ASD (26% female) drawn from the Autism Phenome Project (APP) at UC Davis MIND Institute. The APP is an ongoing longitudinal investigation of young children with ASD and TD. Participants completed comprehensive behavioral evaluations at study visits 1 (M_{age} = 35.67 months; SD = 5.68) and 3 (M_{age}=66.77 months; SD= 10.23). ASD diagnoses were confirmed using the Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview-Revised (ADI-R).

Models were developed to represent social, language, and ER latent variables using parent ratings (Vineland Adaptive Behavior Scales; Child Behavior Checklist; Social Responsiveness Scale) and clinician administered measures (ADI-R; ADOS; PPVT-III; Mullen Scales of Early Learning;

Differential Ability Scales-II). Measurement models at visits 1 and 3 evidenced good fit (CFI/TLI > 0.93; SRMR <.08; RMSEA < 0.08). Latent variables allow for the estimation of specific constructs using multiple sources of information, while taking the contributions of measurement error into account, providing a more robust estimate of the hypothesized construct (Kline, 2016). Predictive and reciprocal relations between ER, and social and language skills were examined using structural equation modelling, controlling for the influence of early nonverbal IQ.

Results:

Models were estimated using MPlus software 7.4. Results documented stability in language ($\beta = 0.80$; $p < 0.001$) and social skills ($\beta = 0.63$; $p < 0.001$). Early language skills predicted later social skills ($\beta = 0.23$, $p < 0.001$), while early social skills did not account for unique variance in later language ($\beta = 0.06$, $p = 0.47$). Predictive associations were observed between early ER and later social skills ($\beta = 0.19$, $p < 0.05$), with fewer ER difficulties predicting better social skills. ER was not associated with later language.

Conclusions:

These findings suggest that early ER and language skills contribute to variation in social development in ASD. Social and language abilities were relatively stable across early childhood. Further investigation into the mechanisms by which early ER and language skills impact social development is necessary. Illuminating these pathways contributes to increased understanding of the developmental heterogeneity in ASD, and may inform assessment and intervention practices.

194 **111.194** Examining the Intertwined Development of Prosocial Skills and ASD Symptoms in Adolescence

A. M. Sluiter-Oerlemans[1], *N. N. J. Rommelse*[2,3], *J. K. Buitelaar*[4,5] *and C. A. Hartman*[1], *(1)Department of Psychiatry, Interdisciplinary Center Psychopathology and Emotion Regulation (ICPE), University Medical Center Groningen, Groningen, Netherlands, (2)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (3)Department of Psychiatry, Donders Institute for Brain, Cognition and Behaviour, Radboud university medical center, Nijmegen, Netherlands, (4)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (5)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands*

Background:

Autism Spectrum Disorder (ASD) and reduced prosocial behaviour are strongly intertwined. However, social interactions with peers may be increasingly practiced over the course of development and may instigate a reduction in ASD symptoms and vice versa. This may particularly hold during adolescence, a crucial phase for developing long term social relationships.

Objectives:

The current study set out to examine if, during adolescence, possible improvements in prosocial behaviors and ASD symptoms may benefit one another over time.

Methods:

Participants were 2,773 adolescents from the Tracking Adolescents' Individual Lives Survey (TRAILS) cohorts. Measurements took place over three waves (mean ages: 11.1y, 13.4y, and 16.2y). Parent-reported ASD symptoms were measured using the Child Social Behavior Questionnaire (CSBQ). Prosocial skills were teacher-rated, representing real life prosocial behaviors towards peers in a classroom setting, an important developmental context in adolescence. Longitudinal associations between prosocial skills and ASD symptoms were examined using the random intercept cross-lagged panel model (RI-CLPM). In addition to estimating the stable, between-person associations, the dynamical effects between prosocial skills and ASD symptoms over time were estimated at the within-person level. We tested whether the model fitted equally well across gender (male, female), cohort (population, clinically referred), and diagnostic status (ASD cases versus non-cases). In addition, we reran the model separately for social and communication behaviors and for stereotypic interests and repetitive behaviors to test whether the association between prosocial skills in the classroom and ASD depended on type of ASD symptoms.

Results:

At the between-person level, prosocial skills and ASD symptoms were substantially negatively correlated. At the within-person level, a small and unexpected positive cross-lagged effect from wave 1 ASD symptoms on wave 2 prosocial skills was observed, see Figure 1. For prosocial skills, no associations were found at the within-person level. Fixing across gender, cohort and for ASD versus non-ASD did not significantly impair model fit. The parameter estimates for social and communication symptoms were highly similar to the parameter estimates of the full model. The cross-lagged effect from wave 1 stereotypic and repetitive behaviors to wave 2 prosocial skills was not significant.

Conclusions:

We added to the existing literature by showing that, in addition to replicating the already firmly established between-person association between low prosocial skills and ASD, we found no evidence that improvements in ASD symptoms and in prosocial skills over time during adolescence do not appear to influence each other for the better.

195 **111.195** Examining the Relationship between Level of Autistic Traits, Social Anxiety, and Social Network Size Among First Year University Students

J. Lei[1], *A. Russell*[2], *C. Ashwin*[3] *and M. Brosnan*[4], *(1)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (3)University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (4)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background: Students transitioning to first year of university encounter significant changes in their social network size (SNS) and composition, which have been associated with perceived social support (PSS) and transition outcome. Factors known to affect social communication such as autistic traits and social anxiety may play a role in these relationships but have not yet been examined. High rates of social anxiety co-occur in individuals with Autism Spectrum Disorder. Investigating the role of such factors will help stakeholders better understand student vulnerabilities relevant to planning transitional support services, to ultimately improve educational outcomes.

Objectives: Evaluate the relationship between level of autistic traits, social anxiety, SNS, network composition, and PSS among typically developing (TD) first-year university students. We hypothesised that: 1) higher levels of autistic traits will be related to smaller SNS; 2) this relationship will be mediated by co-occurring level of social anxiety; 3) bigger SNS will be related to higher levels of PSS; 4) networks of individuals with higher autistic traits will contain lower proportion of friends and higher proportion of family members.

Methods: First-year TD university students (N=92; 79F/13M; Age M = 18.21) completed online questionnaires during the first week of autumn semester. For SNS, participants named up to 20 individuals they considered important to them and with whom they had been in contact with over the past 3 months. Social network composition was indexed by type of relationship between self and the named individual (i.e., family, friends, teachers etc). Participants completed self-reported measures of autism traits (Autism Quotient-Short version (AQ-S)), social anxiety (Social Anxiety Scale –Adolescent version (SAS-A)), and PSS (Multidimensional Scale for Perceived Social Support (MSPSS)). Controlling for age and sex, we conducted partial correlation to assess the relationship between level of autistic traits, social anxiety, SNS, network composition, and PSS, and a mediation analysis to examine social anxiety as a mediator between level of autistic traits and SNS.

Results: Participants reported a large range of autistic traits, social anxiety, SNS, and PSS (Table 1). Consistent with hypotheses 1,2, and 3, a smaller SNS was associated with higher levels of autistic traits (r = -.212, p = .045), higher social anxiety (r = -.415, p = .000), and lower PSS (r =.233, p = .027). Higher level of autistic traits significantly correlated with higher social anxiety (r = .571, p = .000). Social anxiety fully mediated the relationship between level of autistic traits and SNS (Sobel's Z = -3.169, p =. 002; Figure 1). Hypothesis 4 was not supported, no significant relationship between autistic traits and proportion of family/friends in social network were observed.

Conclusions: Findings show that autistic traits in first-year university students are negatively associated with SNS, and this association is mediated by social anxiety. SNS is positively related to how supportive students viewed networks. Higher level of autistic traits may be related to having fewer relationships in general, but not disproportionately fewer friends. Implications of the findings include recommendation that transitional interventions should aim to support students in overcoming anxiety about social situations.

196 **111.196** Measuring Social Networks and Perceived Social Support in Autism Spectrum Disorder: Development and Feasibility Pilot Study of an Online Tool

J. Lei[1]*, A. Russell*[2]*, C. Ashwin*[3] *and M. Brosnan*[4]*, (1)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (2)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (3)University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland, (4)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background:

Social networks are complex, multi-dimensional, and difficult to measure. Adolescents with Autism Spectrum Disorder (ASD) receive support from their social network members to meet different academic, daily-living, and social demands. Understanding individual differences in adolescents with ASD's social network structure (SNS) and how they perceive support provided by network members, offer a valuable perspective to help stakeholders plan more focused and effective support.

Objectives:

1) Develop an online questionnaire to characterise differences in SNS and perceived social support (PSS)

2) Explore the relationship between SNS and autism symptom severity

Methods:

Previous research informed generation of items in a novel online questionnaire (delivered via Qualtrics) relating to SNS and PSS, which was tested in a feasibility pilot with 10 high-functioning adolescents with ASD (8M/2F) aged 17-19 years old (M;SD = 17.90;0.74). For SNS (i.e., size, composition, density), participants: 1) named up to 20 individuals they considered to be important to them and have been in contact with over the past three months (size); 2) stated their relationships with self (composition, i.e., family, friends, or "other": teachers/support workers etc); 3) reported whether each pair of individuals they named knew and were in contact with each other (density). For PSS, participants reported the types, frequency, and perceived quality of support provided by each network member across academic, daily-living, and social domains (5 items/domain). Parent-reported Social Communication Questionnaire (SCQ) measured autism symptom severity. Verbal and written feedback about the questionnaire was gathered. Preliminary analysis used Pearson's correlations, though is constrained by the small sample size.

Results:

Participants found items to have good face validity, and took ~20 minutes to complete. A wide range of social network size (M(SD) = 11.2(6.49) people) and density (M(SD) =0.55(0.28)) were reported, and can be presented visually using Gephi (Figure 1). On average, participants named 3.8 family members, 5.9 friends/acquaintances, and 1.5 "other" members. Social network size was not associated with autism symptom severity (r = .127, p = .726). Networks of participants with higher autism symptom severity were associated with lower proportion of friends (r = -.689, p = .028), and higher proportion of "other" members (r = .760, p = .011). Higher network density was associated with smaller size (r =-.867, p = .001), and a higher proportion of family members (r = .69, p = .027). Of the network members reported to provide support for each participant, differences in frequency and quality of PSS were observed (Figure 2).

Conclusions:

Participants reported good acceptability and feasibility of this novel online questionnaire that characterised individual differences in SNS and PSS. Participants perceived family members to provide better daily-living support, friends better social support, and "other" members better academic support, findings consistent with intuitive hypothesis suggesting that the online tool can help discriminate different social network dimensions. Feedback about item phrasing and streamlining have been incorporated for the next stage of the research. Stakeholders can benefit from considering individual differences in both SNS and PSS, and help social network members provide more focused support for adolescents with ASD.

197 **111.197** Examining the Relationship between Social Anxiety and Quality of Social Skills Among Adolescents with ASD Following the UCLA PEERS® Intervention

J. Wu[1]*, P. Johnson*[2]*, N. E. Rosen*[3]*, M. Jolliffe*[3] *and E. A. Laugeson*[3]*, (1)PEERS lab: UCLA PEERS Clinic, Los Angeles, CA, (2)UCLA PEERS Clinic, Los Angeles, CA, (3)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA*

Background: Deficits in social skills, such as poor reciprocal social communication, restricted interests, and repetitive behavior are hallmarks of those with Autism Spectrum Disorder (ASD; Murphy et al. 2016). As a result of these deficits, adolescents with ASD often experience less successful implementation of social skills and integration into social settings (Little et al. 2014). These difficulties in social integration often contribute to the development of anxiety, which tends to worsen during the adolescent years (White et al. 2009). Previous research on the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®), an evidence-based social skills intervention for adolescents with ASD, demonstrates improved social skills following treatment (Laugeson et al. 2012). However, the extent to which social anxiety at baseline predicts social skills outcomes has yet to be examined.
Objectives: The present study examines the relationship between social anxiety and improved social skills among adolescents with ASD following a 16-week social skills intervention.

Methods: Participants from two cohorts included 98 adolescents (males=84, females=14) with ASD ranging from 11-17 years of age (M=13.86; SD=1.68) and their parents, who participated in a parent-assisted intervention, and a separate group of 73 adolescents (males=59; females=14) with ASD ranging from 12-18 years of age (M=15.05; SD=1.71), who participated in a school-based intervention. Adolescent participants had clinically-elevated ASD symptoms as determined by the Social Responsiveness Scale-2 (SRS-2; Constantino, 2012) and clinically-elevated social anxiety as determined by the Social Anxiety Scale (SAS; La Greca, 1999). Baseline social anxiety was measured using adolescent- and parent-reported SAS scores prior to intervention. Participants then completed a 16-week parent-assisted or school-based PEERS® social skills intervention. Treatment outcome was assessed by examining parent-reported change in social skills using the Social Skills Improvement System (SSIS; Gresham and Elliot, 2008) and change in social responsiveness on the SRS-2 pre- and post-intervention.

Results: Simple linear regressions revealed that baseline adolescent- and parent-reported social anxiety scores were not significantly related to change in social responsiveness on the SRS-2 in the parent-assisted sample (F=.213, p>.10, R^2=.002; F=.116, p>.10, R^2=.001). Likewise, social anxiety was not predictive of change in social skills (F=.352, p>.10, R^2=.004; F=.169, p>.10, R^2=.002) or problem behaviors (F=.084 p>.10, R^2=.001; F=1.743, p=.190, R^2=.019) on the SSIS in the same sample. In the school-based sample, simple linear regressions also revealed that baseline adolescent- and parent-reported social anxiety scores were not significantly related to change in social responsiveness (F=2.201, p=.143, R^2=.031; F=.009, p>.10, R^2=.000), social skills (F=.490, p>.10, R^2=.007; F=.828, p=.366, R^2=.012), or problem behaviors (F=.087, p>.10, R^2=.001; F(1.72)=.005, p=.945, R^2=.000).

Conclusions: Findings reveal that adolescent baseline social anxiety, though a common comorbid symptom of ASD, is not predictive of improvement in social responsiveness or social skills behavior among adolescents with ASD following the PEERS® intervention in parent-assisted and school-based settings. These findings are encouraging in that they suggest that adolescent anxiety does not appear to impact treatment outcome following PEERS®.

198 **111.198** For Better or for Worse? Social Camouflaging, Mental Health and Wellbeing in Autistic Adults.

L. Levy[1], *L. Hull*[2], *M. C. Lai*[3,4,5,6], *S. Baron-Cohen*[4], *C. Allison*[4], *P. Smith*[7] *and W. Mandy*[2], *(1)University College London, London, United Kingdom, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland, (3)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (6)Centre for Addiction and Mental Health, Toronto, ON, Canada, (7)University of Cambridge, Cambridge, United Kingdom*

Background: Social camouflaging is the name given to the social coping strategies used by autistic people to cover up their autism in order to 'pass' as neurotypical (Tierney, Burns & Kilbey, 2016). Previous work on this phenomenon has been predominantly qualitative and focused on the experiences of autistic adults. In such studies, participants report benefits of social camouflaging, for example as a way of fitting in, 'feeling normal' and making connections. However, they also identify costs, stating that social camouflaging can be draining, stressful and can feel inauthentic (Hull et al., 2017). To date, only one published study has examined social camouflaging using quantitative methods (Lai et al., 2016), finding that higher levels of social camouflaging predicted higher levels of depression in men, but not women. Thus, whilst social camouflaging is common amongst autistic people, little is known about its associated costs and benefits.
Objectives: To investigate the costs and benefits of social camouflaging by investigating its links to internalizing disorders (social anxiety, generalized anxiety and depression) and wellbeing amongst autistic adults.

Methods: Participants (315 autistic adults aged 18-75; 177 female) were recruited online and via autism networks, and completed a series of well-validated self-report questionnaires measuring internalizing problems (social anxiety, generalized anxiety and depression) and wellbeing. A recently-developed, validated quantitative measure of social camouflaging, the Social Camouflaging in Autism Questionnaire (SCAQ) was used (Hull et al., 2017). In addition, demographic characteristics and autism severity were assessed.

Results: Females (mean=169) had higher average SCAQ scores than males (mean=102; p<.001, d=.56), though social camouflaging was common in both males and females. For males and females, SCAQ scores did not significantly differ based on either occupation status (in education, training or employment vs not in education, training or employment) or relationship status. In analyses controlling for autism symptom severity, higher SCAQ scores predicted higher scores on all measures of internalizing psychopathology; for social anxiety (p <.05; β=.298), generalized anxiety (p <.001; β=.331) and depression (p <.05; β=.214). None of these effects were moderated by gender; they were observed in males and females. There was no significant association between SCAQ score and wellbeing score.

Conclusions: This is the most comprehensive quantitative study to date on mental health difficulties associated with social camouflaging. Preliminary findings suggest that on average, females engage in higher levels of camouflaging than males as measured by the SCAQ. Nevertheless, in this sample social camouflaging was widespread in both genders, challenging the idea that camouflaging is primarily a female phenomenon. Further, our findings accord with reports in the qualitative literature (Bargiela et al., 2016; Hull et al., 2017), that social camouflaging is a risk factor amongst autistic people for the development of internalizing problems. Further longitudinal work is needed to investigate whether social camouflaging really is a causal risk factor for internalizing problems of autistic people

199 **111.199** Higher Tonic Alerting and Lower Reactivity to Exogenous Stimuli Predict Social Cognition in Autism: A Pupillometry Marker of Sensory Processing

N. Mueller[1,2], *L. Poustka*[3] *and C. M. Freitag*[4], *(1)Department of Child and Adolescent Psychiatry and Psychotherapy, University Hospital Frankfurt, Frankfurt, Germany, (2)none, none, Germany, (3)Medical University of Goettingen, Goettingen, Germany, (4)Autism Research and Intervention Center* *of Excellence Frankfurt, University Hospital Frankfurt, Frankfurt am Main, Germany*

Background: Aberrant attentional function in autism spectrum disorder (ASD) was proposed to explain impaired social cognition, although empirical evidence is sparse. Previous findings indicated elevated tonic alerting and attenuated orienting as aberrant attentional functions in ASD. Deviant activity of the locus coeruleus – norepinephrine (LC-NE) system was assumed as underlying mechanism, which can be captured by pupillometry. Here, we investigated the effect of attentional function represented in pupil dilation (PD) during sensory processing of social stimuli on social cognition performance.

Objectives: (1) We hypothesize a distinct PD time course in ASD characterized by the metrics of elevated tonic dilation and delayed pupillary reactivity. (2) We assume principal components within the PD time course to represent attentional functions of alerting and orienting, which correlate with the time course metrics of the PD time course. (3) These principal components are hypothesized to predict social cognition performance, with a negative effect of elevated early alerting and a positive effect of intermediate orienting moderated by ASD group affiliation.

Methods: 23 adolescents with ASD and 23 neurotypical controls (TD) matched for age, gender, and verbal IQ were included. Pupillometry was carried out while participants worked on a validated social cognition test (MASC) consisting of dynamic social stimuli. Video stimuli are each followed by a related social cognition question. Between-group variation of PD time course was estimated by linear mixed models (LMMs) controlling for random effects of participant. PD time course was segmented to attentional-function components by principal component analysis. Factors indicating differential attention functions were correlated with time course metrics derived from previous studies and applied to predict social cognition performance.

Results: A distinct pupil-dilation time course in autism was indicated by the best-fit LMM with a significant interaction of group x time course on PD. The distinct time course was characterized by increased relative tonic dilation and elevated dilation latency compared to TD (d = .50 - .54). Three attentional-function components were extracted from the PD time course. An early alerting/pupillary-light-reflex (PLR) component positively correlated with relative tonic dilation, and an intermediate orienting component negatively correlated with dilation latency. We also extracted a late attentional control component. The three attentional-function components and group affiliation substantially predicted social cognition performance with $F(15, 30) = 2.32$, $p = .02$, R^2 *adj.* = .31. Significant interactions indicated an enhanced negative effect of early alerting/PLR (ASD: $\beta = -.36$, TD: $\beta = -.27$, *partial* $\eta^2 = .17$), and a positive effect of intermediate orienting specific to the ASD group (ASD: $\beta = .45$, TD: $\beta = -.04$, *partial* $\eta^2 = .16$).

Conclusions: A distinct pupil-dilation time course in ASD predicted impaired social cognition performance. Higher relative tonic dilation suggested increased tonic LC-NE activity as underlying mechanism of elevated tonic alerting. Elevated tonic LC-NE activity may attenuate reactivity to exogenous stimuli as represented by elevated dilation latency in ASD. This likely impairs sensory processing of dynamic and complex environments as indicated by lower social cognition performance. Pupil-dilation time course is outlined as promising biomarker for future ASD research.

111.200 Imagination Matters: Effects of Autistic Traits on Stereotyping and Stereotype Reduction in Non-Clinical Population

L. S. Iao *and E. Jones, Department of Psychology, Nottingham Trent University, Nottingham, United Kingdom*

Background: Stereotyping heuristically provides perceivers with information that are necessary in social contexts. As an energy-saving device, stereotyping may be useful for individuals with Autism Spectrum Conditions (ASC) who find social situations taxing although recent studies suggested reduced implicit stereotyping in ASC. Recent research also showed that elaborated imagined contact (EIC) reduces stereotypes, suggesting a relationship between imagination and stereotyping. Given that individuals with ASC also tend to have difficulties in spontaneous imagination, this study investigated stereotyping and stereotype reduction in ASC, focusing on the traits related to social and imagination skills.

Objectives: This study investigated whether ASC traits were related to stereotyping on one recent prominent target of stereotyping (i.e., Muslims) and whether ASC traits had an effect on the effectiveness of EIC in reducing stereotypes.

Methods: Sixty-one native English-speakers (53 females; mean age = 21.41 years, *SD* = 3.31 years, range = 18 – 38 years) who were not Muslims first completed the Autism Spectrum Quotient questionnaire (AQ; Baron-Cohen et al., 2001) and the stereotype endorsement scale (SES; Feret, Conway & Austin, 2006), which was adapted to assess stereotypes on Muslims. They then participate in an EIC task and completed the SES for a second time.

Results: The total AQ score and the Imagination subscale score (ISS), but not the Social Skills subscale score, were correlated with the first SES score. A 2x2 mixed ANOVA with group (low vs. high AQ score) and time (before vs. after EIC) showed a main effect of time, $F(1, 59) = 35.92$, $p < .001$, suggesting that the SES scores after EIC ($M = 61.48$, $SD = 5.39$ for the low AQ group and $M = 62.72$, $SD = 3.81$ for the high AQ group) were significantly lower than those before EIC ($M = 66.72$, $SD = 5.58$ for the low AQ group and $M = 67.34$, $SD = 5.82$ for the high AQ group). There was no other main effect or interaction. Another 2x2 mixed ANOVA with group (low vs. high ISS) and time showed a main effect of time, $F(1, 59) = 34.64$, $p < .001$, and a significant interaction, $F(1, 59) = 8.27$, $p < .01$. There was no other main effect. Post hoc tests indicated that EIC significantly reduced the SES score from 64.73 ($SD = 4.99$) to 62.38 ($SD = 4.70$) for the low ISS group ($p = .05$) and from 68.77 ($SD = 5.59$) to 61.94 ($SD = 4.64$) for the high ISS group ($p < .001$). Moreover, the high ISS group had a higher SES score than the low ISS group before EIC ($p < .01$) but not after EIC ($p = .72$). These findings suggested that EIC was more effective for the high ISS group due to a higher SES score before EIC.

Conclusions: Individuals with higher ASC traits, particularly traits related to imagination, were more likely to show enhanced explicit stereotyping on Muslims. Moreover, EIC was effective in reducing stereotypes across the autism spectrum in a non-clinical population.

201

111.201 Impairments in Cognitive Empathy and Alexithymia Occur Independently of Executive Functioning in College Students with Autism

T. Ziermans[1]*, Y. de Bruijn*[2]*, R. Dijkhuis*[3]*, W. G. Staal*[4,5,6] *and H. Swaab*[2]*, (1)University of Amsterdam, Amsterdam, Netherlands, (2)Leiden University, Leiden, Netherlands, (3)University of Leiden, Leiden, Netherlands, (4)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Department of Cognitive Neuroscience, Nijmegen, Netherlands, (5)Karakter Child and Adolescent Psychiatry University Centre, Nijmegen, Netherlands, (6)Institute for Brain and Cognition, Leiden University, Leiden, Netherlands*

Background: Impairments in the cognitive domains of empathy and alexithymia are commonly reported across the autism spectrum and are associated with social dysfunction. Such cognitive impairments in autism may arise as the result of underlying differences in executive functioning (EF), although previous findings are inconclusive about their relative contribution. Furthermore, it is unknown whether such cognitive domains are relatively spared in intellectually advanced individuals with autism spectrum disorder (ASD).
Objectives: To examine whether college students with ASD experience difficulties in empathy and alexithymia, and whether this can be partially explained by their cognitive levels of EF.

Methods: The ASD sample consisted of 51 college students, aged 18.3 to 28.1 years old, 72% male. This group was compared to an age- and gender-matched group of typically developing students (n = 29) on empathy and alexithymia, as measured with well-validated parent- and self-report questionnaires. Furthermore, a broadly used cognitive test battery was used to measure EF. For the ASD group, associations between the relevant constructs were further investigated with analyses of covariance and regression analyses.

Results: The ASD group scored significantly higher on cognitive alexithymia (d = 0.70) and lower on cognitive empathy (d = 0.84), while no group differences on the affective components appeared. The difference in cognitive empathy remained significant after controlling for the potential influence of (cognitive) alexithymia. No significant relations between executive functioning and cognitive alexithymia or empathy were detected.

Conclusions: Intellectually advanced individuals with ASD experience serious impairments in the cognitive processing of social-emotional information. However, these impairments cannot be attributed to individual levels of EF. This suggests that interventions aimed predominantly at enhancing EF skills are likely to have limited benefits for social-emotional information processing in ASD individuals with intact intellectual functioning.

202

111.202 Implicit Versus Explicit Metacognition in ASD

D. M. Williams[1], *T. Nicholson*[2], *C. Grainger*[3], *P. Carruthers*[4] *and S. E. Lind*[5], *(1)University of Kent, Canterbury, United Kingdom, (2)University of Kent, Canterbury, England, United Kingdom, (3)University of Stirling, Stirling, United Kingdom, (4)University of Maryland, College Park, MD, (5)Psychology, City, University of London, London, United Kingdom*

Background: The few existing studies of metacognitive monitoring (awareness of one's own mental states/cognition) in ASD have employed tests that require participants to make explicit judgements about the state of their own knowledge. The closer the correspondence between *judgements* of one's knowledge and *actual* (objectively-measured) knowledge, the more accurate metacognitive monitoring is. Findings using such explicit tasks have been mixed. In the current investigation, we employed not only a standard test of explicit metacognitive monitoring, but also a paradigm adapted from one used in comparative psychology to assess metacognitive monitoring non-verbally/implicitly.
Objectives: The aim of the present study was to investigate implicit *and* explicit metacognition, and their relations to mentalizing ability, in ASD.

Methods: 21 participants with ASD and 21 age- and IQ-matched comparison participants completed an "uncertainty monitoring" paradigm based on that used among non-human primates. This involved a visual discrimination task (e.g., judging the most pixelated of two squares). On each trial (see Figure 1), two squares and a red ("opt out") arrow appeared. If participants chose the most pixilated square, they gained money, whereas if they chose the least pixilated square they lost money. Choosing the arrow moved on to the next trial without penalty or loss. Adaptive performance would be indicated by use of the opt-out arrow on difficult trials that the participant would likely have got incorrect.

In a second session, participants completed the same monitoring task, but requiring different visual discriminations and without the presence of the opt-out arrow (see Figure 2). This time, after each discrimination trial, participants were asked to choose between the options "confident" or "not confident". Accurate metacognitive monitoring was indicated by a greater tendency to choose "confident" on successful visual discrimination trials than on unsuccessful trials and, vice versa, to choose "not confident" more on unsuccessful than successful trials.

Results: In the implicit task, discrimination difficulty was significantly higher on trials that were opted out of than trials that were opted into, reflecting adaptive performance. There was no difference between the groups in this respect, p = .33, d = 0.31. However, in the explicit task, the judgements of confidence (JOC) were significantly less accurate (i.e., less in line with actual performance) among ASD than comparison participants, reflecting diminished explicit metacognitive monitoring, p = .04, d = 0.66. Importantly, mentalizing ability (measured using the Animations and Reading the Mind in the Eyes tasks) accounted for a significant 14% of the variance in explicit task performance, but only a non-significant 2% of the variance in implicit task performance.

Conclusions: These results show an impairment in explicit metacognition that is related to established mentalizing impairments in ASD, which supports the "one-system" theory of the relation between mentalizing and metacognition (e.g., Carruthers, 2009). However, they also suggest that decision-making can be adaptive in people with ASD. Nonetheless, the extent to which such decision-making is truly metacognitive/metarepresentational will be discussed.

111.203 It's All Good: Contextual Emotional Incongruity in Spontaneous Facial Expressions of Children with ASD

R. Grossman[1,2], *M. Sager*[2], *H. Ventresca*[2], *K. Gallery*[2], *J. Mertens*[1] *and E. Zane*[3], *(1)FACE Lab, Emerson College, Boston, MA, (2)CSD, Emerson College, Boston, MA, (3)FACE Lab, Emerson College, FACE Lab, Boston, MA*

Background: Facial expressions of children with ASD are often perceived as awkward (Grossman, 2015) or ambiguous (Yirmiya, Kasari, Sigman, & Mundy, 1989), and are more difficult to recognize (Brewer et al. 2016). Young children with ASD show emotional facial expressions that aren't always congruent with social context (McGee, Feldman, & Chernin 1991), particularly when positive expressions are paired with negative behaviors (Costa, Steffgen, & Samson 2017). Most previous data into expression incongruity rely on posed or mimicked facial expressions, which may not be representative of spontaneous expressiveness. On the other hand, it can be difficult to determine the contextual valence of social interactions.
Objectives: Analyze facial expressions produced spontaneously by children with and without ASD in response to brief video clips whose emotional content was well defined.

Methods: We presented a pseudo-randomized sequence of funny and disgusting YouTube clips to neurotypical (NT) and autistic children. Participants' mean age was 13:8 (ASD) and 13:1 (NT). Groups were not significantly different in age, sex, IQ, and language ability. Participants with ASD had significant higher scores (p < .0001) on the Social Communication Questionnaire Lifetime form (SCQ), indicating greater social communication impairment.

We videotaped participants' facial responses to the videos and coded the durations (in ms) of positive/negative/flat expressive valence during the most evocative six seconds of each video. All coders were blind to diagnosis and all videos were independently double coded. When coders disagreed, a third coder was involved and final disagreements were resolved via discussion (Ventresca et al. 2017).

We calculated the percentage of positive, negative, and flat expressive duration relative to the duration of each 6,000ms clip. We then grouped responses to four happy video clips (funny kitten videos and laughing babies) and four disgusting video clips (people eating grubs, brains, and spiders, disgusting things being pulled out of a nose) and calculated the percentage of positive, negative, and flat responses to those composites.

Results: Neurotypical (NT) children were significantly more likely to have flat responses (Disgusting videos: F (1, 34) = 6.59, p = .015, Happy videos: F (1, 34) = 6.86, p = .013), while ASD children were significantly more likely to show positive responses (Disgusting videos: F (1, 34) = 7.03, p = .012, Happy videos: F (1, 34) = 7.42, p = .01). There were no group differences for negative expressions. There was a significant positive correlation between the SCQ and positive expressions in response to videos (disgusting videos: r = .47, p = .007; funny videos: r = .4, p = .028).

Conclusions: Children with ASD are more expressive overall in response to video stimuli and make more positive expressions regardless of stimulus valence. For disgusting stimuli this results in a mismatch between the emotional quality of the content they are watching and the facial expression they produce. This bias toward positive expressions and resulting expressive incongruity for stimuli with negative content seems to be related to greater social communication impairment and could lead to misunderstandings in social context.

204 **111.204** Joint Attention Behavior for Children with Autism Spectrum Disorder (ASD) Interacted with Social Robots

W. Cao[1], *W. Song*[2], *X. Li*[3], *S. Zheng*[4], *G. Zhang*[5], *Y. Wu*[3], *S. He*[2], *H. Zhu*[2,6] *and J. Chen*[1,7], *(1)South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (2)Centre for Optical and Electromagnetic Research, South China Academy of Advanced Optoelectronics, South China Normal University, Guangzhou, China, (3)School of Psychology, South China Normal University, Guangzhou, China, (4)School of Physics and Telecommunication Engineering, South China Normal University, Guangzhou, China, (5)Caihongqiao children rehabilitation and service center of Panyu district, Guangzhou, China, (6)Child Developmental & Behavioral Center, Third Affiliated Hospital of SUN YAT-SEN University, Guangzhou, China, (7)School of Electrical Engineering and Computer Science, KTH Royal Institute of Technology, Stockholm, Sweden*

Background: Joint attention has been the target of interventions of the autism spectrum disorder (ASD). Researches, however, did not yet find consistent evidence to support a joint attention deficit in the ASD population (Guillon, Hadjikhani, Baduel, & Rogé, 2014). Recently, social robots have been involved in the diagnosis and intervention of the ASD in social behaviors, language, imitation, and stereotyped behaviors, but robots seemed to reduce the joint attention behaviors when interacting with ASD population compared to the human agent. To address the problem whether interaction with social robots could improve joint attention of the autism spectrum disorder (ASD), we introduced a novel algorithm based on longest common subsequence (LCS) to quantify how the participant's gaze dynamically follow the given logic of the videos, in order to further capture the dynamic feature of eye movement data collected from the joint attention tasks.

Objectives:

By utilizing a commercial humanoid robot NAO, this study compared the difference of joint attention behaviors induced by both the human and robot stimuli. Based on the analysis of fixation time, gaze transitions and LCS algorithm, the study could reveal both the static and dynamic process underlying the joint attention ability and compare the difference between the ASD and typically developing (TD) children.

Methods:

15 ASD (mean age: 4.96±1.10) and 15 age-matched TD children (4.53±0.90) participated in this eye- tracking study. Video stimuli were used to induce joint attention behaviors of participants. Each video consisted of an agent (human or robot) sitting behind the table together with three objects on the left, middle and right side of the table. The agent would turn the head to one of the three truck toys, and the eye movement was recorded by the Tobii X3-120 eye-tracker system. Besides the traditional fixation time and gaze transition analysis, we introduced an LCS algorithm to measure the complexity of transition distributions between area of interests (AOIs).

Results:

Data analysis showed that the TD group fixated longer on the agent face (p=0.002) than the ASD group, and the ASD group gazed on the frame (p=0.045) and non-target (p=0.036) longer than the TD group. All participants spent more time on face area in the "Robot" condition (p=0.038), and more on target (p=0.004) and non-target in the "Human" condition (p=0.045). However, we did not found any significant difference in gaze transition analysis between the ASD and TD group. The LCS analysis revealed a significant effect of group (F(1, 28)=11.18, p=0.002, partial η^2=0.898), indicating that the TD participants have significantly higher LCS scores than the ASD. It implied the TD could better follow the logic of the video.

Conclusions:

This research showed a complex joint attention profile of the participants with ASD. Compared to the human agent, the robot attracted more interests of all participants, but was not able to facilitate the gaze transitions towards the targets or following the stimuli's logic. It implies a negative impact on joint attention behavior when children were interacted with social robots.

205 **111.205** Moral Identity and Perceptions of Moral Exemplars in Young Adults with Autism Spectrum Disorder

A. K. Senland, *Psychology, Trinity College, Hartford, CT*

Background: The popular press and social media often contribute toward a stereotype of individuals with autism spectrum disorder (ASD) as lacking empathy and morality ("Myth of the Autistic Shooter," 2015). While individuals with ASD can distinguish moral from conventional transgressions (Shulman et al., 2012), compared to their typically developing (TD) peers, they experience subtle difficulties on more advanced moral tasks requiring the interpretation of others' intentions (Mathersul et al., 2013), and have less advanced moral reasoning (Senland & Higgins-D'Alessandro, 2016). However, little is known about whether individuals with ASD and their TD peers differ in the degree to which they hold moral concerns such as caring and justice as central to their sense of self (moral identity) and in who they perceive as being highly moral and why (moral exemplars).

Objectives: This study aimed to investigate similarities and differences in moral identity and identification of moral exemplars between young adults aged 18 to 39 with ASD and their TD peers.

Methods: The ASD group included 83 participants, aged 18 to 39-years-old (83% female); the TD group included 69 participants, aged 18 to 39-

years-old (87% female). The ASD group scored significantly higher than the TD group on Hoekstra et al.'s (2001) abridged version of the Autism Spectrum Quotient (AQ-Short) ($t(145) = 11.32$, $p < .001$), confirming two distinct groups characterized this study's sample. Participants completed an online questionnaire that included: (a) two measures of moral identity, and (b) two open-ended questions, adapted from Walker et al. (1999), which asked participants to 1) name a person that they regarded as highly moral and 2) explain why they regarded this person as highly moral. Qualitative data were analyzed with inductive content analysis.

Results: ASD and TD groups did not differ significantly on either moral identity measure. Qualitative data indicated that compared to the TD group, the ASD group was more likely to identify moral exemplars who were fictional characters (e.g., book, movie, video game characters) or whom they had learned about but did not know personally (e.g., historical figures, political figures, religious figures). In contrast, the TD group was more likely to identify moral exemplars who they knew personally (e.g., parents, friends). Similar themes emerged as the ASD and TD groups explained why they considered their moral exemplars to be highly moral; both groups emphasized the kind/caring, honest, generous, fair/just, and/or accepting nature of their moral exemplars.

Conclusions: ASD and TD groups are similar in their perceptions of how important moral concerns such as fairness and caring are to their sense of self, combating the tendency for the popular press and social media to stereotype those with ASD as immoral. Moral and character education programs, as well as support programs for those with ASD, may also want to consider how to effectively use fictional characters, as well as historical figures, political figures, and religious figures, as moral role models for individuals with ASD, given that those with ASD more readily identified individuals in these categories as moral exemplars than their TD peers did.

206 **111.206** Oxytocin Treatment Modulates Social Affect in Autism

A. Mayer[1]*, A. K. Wermter*[2]*, S. Stroth*[3]*, M. Haberhausen*[2]*, T. Stehr*[4]*, I. Kamp-Becker*[5]*, F. Paulus*[6] *and S. Krach*[7]*, (1)Lübeck University, Lübeck, Germany, (2)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Philipps University of Marburg, Marburg, Germany, (3)Philipps University Marburg, Marburg, Germany, (4)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Philipps University Marburg, Marburg, Germany, (5)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, Philipps University Marburg, Schutzenstr 49, Germany, (6)Philipps-University Marburg, Marburg, Germany, (7)Center of Brain, Behavior and Metabolism, Luebeck, Germany*

Background: Persons with the diagnosis of Autism Spectrum Disorder (ASD) are characterized by substantial social deficits. One of the core symptoms is the reduced capacity to intuitively represent their own and others' mental states (*1–3*). However, it has remained unresolved, whether persons with the diagnosis of ASD can empathically share others' feeling states in an embodied manner (*4*). This deficit has been attributed to malfunctions of the interoceptive cortex (*5*), a network comprising the anterior insula cortex (AIC) and the anterior cingulate cortex (ACC) (*4*, *6*). First fMRI studies revealed that intranasal administration of the neuropeptide oxytocin modulates social processing on a behavioral and neural level (*7*, *8*) in healthy participants, while an in-depth investigation of the effects of oxytocin on social processes underlying neural networks in ASD is still lacking.

Objectives: In the present study we aimed at characterizing the effects of intranasal oxytocin treatment on the neural pathways involved in social affect in a group of persons with ASD. We pursued this question on three levels of affective experiences: understanding others basic emotional states ('Emotions'), sharing others physical pain ('Physical Pain'), and more complex social pain ('Social Pain'). We hypothesized that oxytocin treatment would modulate social affective experiences and activity in underlying neural networks compared to the placebo condition.

Methods: Twenty-six young men who matched the DSM IV criteria for ASD and who had a confirmed ICD-10 diagnosis of high-functioning ASD underwent a double-blind, cross-over, placebo controlled fMRI protocol including three experiments to examine social affect on distinct levels. Stimuli within all three conditions consisted of pictures or sketches displaying another either being in a sad, neutral or happy mood ('Emotions'), showing another's physically painful bodily injury or non-painful situation ('Physical Pain'), or a complex social scenario depicting a protagonist threatening his or her social integrity ('Social Pain') (*9*). Stimuli were presented for 6-12s, followed by a rating period to indicate the intensity of the vicarious embarrassment experience with a button press and low-level baseline.

Results: On the behavioural level we observe that oxytocin only slightly attenuates the affective response across the different domains of social affect. This was complemented by the fMRI data yielding a more distributed engagement in brain areas implicated in processing of arousal and affect as well as mentalizing regions.

Conclusions: The present results offer a new perspective on how intranasal oxytocin administration modulates brain networks for social affect in patients diagnosed with ASD. While our results show that persons with high-functioning ASD are capable to correctly assess basic emotions, physical pain as well as more complex social pain experiences, oxytocin treatment still attenuates the self-reported social affect. The underlying brain networks, in particular those implicated in processing of arousal and mentalizing show similar effect, highlighting a potential neural system mechanism for oxytocin treatment in ASD.

207 **111.207** Positive Affect Facilitates Eye Gaze Following in Preschoolers with Autism

A. N. Dennis[1]*, D. Hedley*[2]*, G. Vivanti*[3]*, C. Dissanayake*[2] *and H. J. Nuske*[4]*, (1)Department of Psychology, Haverford College, Haverford, PA, (2)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (3)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (4)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background:

The ability to follow another person's gaze is a critical component of joint attention. Joint attention difficulties are a defining characteristic of autism spectrum disorder (ASD). Many therapists working with children who have ASD intentionally use a positive affective framework (e.g., smiles) to increase the child's attention to their face. However, little research to date has specifically investigated whether positive affect increases eye gaze following.

Objectives:

This study sought to investigate the effectiveness of positive affect in increasing eye gaze following. Given that children with ASD have been found to have difficulty processing subtle expressions of emotion (e.g., a small smile), subtle and exaggerated positive affect were examined separately to assess how emotion intensity influences eye gaze following in children with ASD, relative to typically developing (TD) children.

Methods:

Eye tracking technology was used to capture the eye gaze behavior of 19 preschoolers with ASD and 23 typically developing preschoolers as they observed the eye gaze shifts of actors displaying neutral, subtle positive, or exaggerated positive expressions. The actors first looked into the camera to establish mutual gaze (simulating eye contact), and then shifted their gaze to one of three pictures on the wall next to them. These pictures were coded as target (congruent with the actor's gaze) or non-target (incongruent with the actor's gaze; see Figure 1). Participant eye gaze following was assessed in two ways. First, by calculating the proportion of time the child looked at the target picture compared to the rest of the screen (proportion to target analysis); second, by assessing whether the child had the correct first look to the target picture (correct first look analysis).

Results:

The proportion to target analysis showed no group differences between TD children and those with ASD, however a main effect of emotion condition was found ($F(2,39) = 3.56$, $p = .038$, $\eta^2 = .155$). Between-condition pairwise comparisons showed a marginally significant difference between the neutral and subtle conditions ($p = .072$) with higher values in the subtle condition (see Figure 2), such that there was a higher proportion of eye gaze following to the target picture after the actor displayed the subtle positive facial expression, in both groups. Additionally, the correct first look analysis showed a significant group difference in the exaggerated positive emotion condition only ($\chi^2= 7.532$, $p = .023$). The ASD group was more likely to have the correct first look to the target animal when viewing an actor with an exaggerated positive affect (68%) than the TD group (26%).

Conclusions:

These results provide empirical support for the use of positive affect to engage a child's attention in early intervention. They specifically highlight the potential benefit of exaggerated positive affect for children with ASD, though these preliminary findings still require validation in larger samples.

208 **111.208** Quantifying the Social Gaze in Ongoing Triadic Interaction

A. Hartz[1], *M. Jording*[2], *B. Guth*[1], *K. Vogeley*[2] *and M. Schulte-Ruther*[1], *(1)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital RWTH Aachen, Aachen, Germany, (2)Department of Psychiatry and Psychotherapy, University Hospital Cologne, Cologne, Germany*

Background: We use our eyes to obtain social information about others, but they also convey information about our inner mental state. Gaze encounters can therefore be considered as a social reciprocal process. Referring to our recently proposed theoretical framework of a "social gaze (state) space" that differentiates five different gaze states of an agent in triadic interactions: '*partner-oriented*', '*object-oriented*', '*introspective*', '*initiating joint attention*', and '*responding joint attention*', we aim to empirically and systematically investigate gaze behavior in typically developing and clinical populations across the life span.

Objectives: Social gaze behavior and its deviations in psychiatric conditions has typically been investigated using static, non-interactive settings (e.g. image or video stimuli) neglecting the highly dynamic character of real life gaze encounters. Increasingly, gaze contingent settings are being employed, but these are often restricted to atomic units of interactions (e.g. single trials of joint attention). We propose to employ an empirically informed agent that oscillates between different gaze states, thus mimicking typical human gaze behavior. This approach will allow to fully explore the dynamics of ongoing triadic encounters in a much more ecologically valid research setting.

Methods: We experimentally induced social gaze states in 37 adult volunteers (19 identifying themselves as female, 17 as male, 1 as queer) with no record of neurological or psychiatric conditions who were interacting with an algorithm-controlled virtual agent in ongoing triadic interactions. Behavioral parameters (e.g. temporal lag of gaze following after agent initiates attention, duration of object fixation after agent has responded to initiating joint attention,...) in different combinations of the five different gaze states were obtained to describe typical human gaze behavior.

Results: We extracted behavioral parameters including their dynamics and distribution within the investigated sample and used these to create an empirically informed, algorithm-controlled virtual Markovian agent that allows to study the full range of gaze-contingent triadic interactions.

Conclusions: We provide a reference space for investigating gaze behavior in clinical populations with impairments in social interactions, such as autism.

209 **111.209** Re-Evaluating the Reduced Social Motivation Theory of Autism

I. Dubey[1], *S. Brett*[2], *L. Ruta*[3], *M. Belmonte*[4], *V. Patel*[5], *G. Divan*[6], *J. Dasgupta*[7], *S. Gulati*[8], *S. Bhavnani*[7], *D. Mukherjee*[7], *R. Bishain*[9], *S. Chandran*[10], *G. Estrin*[11], *T. Gliga*[11], *M. H. Johnson*[12] *and B. Chakrabarti*[1], *(1)Centre for Autism, School of Psychology & Clinical Language Sciences, University of Reading, Reading, United Kingdom, (2)School of Psychology and Clinical Language Sciences, University of Reading, Reading, United Kingdom, (3)Institute of Applied Sciences and Intelligent Systems, "Eduardo Caianiello" (ScienceApp) – National Research Council of Italy (CNR), Messina, Italy, (4)Com DEALL Trust, Bangalore, India, (5)Department of Global Health and Population, Harvard Medical School, Boston, MA, (6)Sangath, Bardez, Goa, India, (7)Centre for Chronic Conditions and Injuries, Public Health Foundation of India, Gurgaon, India, (8)Child Neurology Division Department of Pediatrics, All India Institute of Medical Sciences, Delhi, India, (9)Computer Science and Engineering, Indian Institute of Technology, Bombay, India, (10)Computer Science and Engineering, Indian Institute of technology, Mumbai, India, (11)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (12)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom*

Background: Autism spectrum conditions (ASC) have been suggested to be characterised by reduced social motivation, resulting in lower social seeking behaviour and poorer learning of social skills (Chevallier, Kohls, Troiani, Brodkin, & Schultz, 2012). This 'social motivation hypothesis' presupposes that typically developing children have higher social motivation which helps them in seeking out social contacts and learning the associated skills. However, some empirical reports suggest that typically developing children do not show the expected pattern of high seeking behaviour for social stimuli, and that their preference for social stimuli might be at a chance level (Ewing, Pellicano, & Rhodes, 2013; Ruta et al., 2017). This observation emphasises the need for a systematic examination of social reward seeking in a large sample of typically developing children, and its relationship with autism-related trait measures.

Objectives: To test if a) typically developing children demonstrate higher social reward seeking behaviour, as measured by a simple button-press task (Ruta et al., 2017), and b) if individual differences in such social reward seeking behaviour are related to risk for autistic features.

Methods: 111 children aged 2-9 years were tested on a simple two-button task on a tablet PC, pressing one button to watch a social video (smiling child) and another button to watch a video of moving geometric patterns (Ruta et al., 2017). The stimuli were visually matched for their colour and level of movements. Participants were also tested on the Social Aptitude Scale (SAS) which has demonstrated high sensitivity and specificity (0.936 and 0.934 respectively) in identifying children at risk of autism (Liddle, Batty, & Goodman, 2009). In keeping with the hypothesis of reduced social motivation, we predicted that 1) these typical children would press the button more often for social than for non-social stimuli, and 2) children with lower scores on SAS would show less of this social seeking button preference.

Results: Similarly to earlier reports, typical children did not have any significant preference for social over non-social stimuli (t (111) = 1.03, p = 0.30). However, the number of social button presses correlated significantly with SAS score (r (83) = .28, p = .010).

Conclusions: Consistent with the previous report on this task (Ruta et al., 2017), current results show that comparable seeking behaviour for social and non-social stimuli in children might not indicate atypical development or poor social skills *per se*. However, lower seeking behaviour for social stimuli might be linked dimensionally with a higher risk for ASC.

210 **111.210** Relations between Spontaneous and Explicit Mentalizing in Autism and Typical Development

K. R. Warnell[1]*, S. Maniscalco*[2]*, K. A. Schaefer*[1]*, J. K. Ifesinachukwu*[1]*, S. Menssor*[1]*, L. A. Kirby*[3] *and E. Redcay*[2]*, (1)Department of Psychology, Texas State University, San Marcos, TX, (2)Department of Psychology, University of Maryland, College Park, MD, (3)Yale Child Study Center, New Haven, CT*

Background: Recent research on mentalizing—or thinking about others' thoughts, feelings, and desires—suggests that deliberate mental state reasoning may be dissociable from more spontaneous mentalizing. This possibility is especially relevant to autism spectrum disorder (ASD), where explicit social cognition often outpaces real-world social success. Previous ASD research investigating relations between different types of mentalizing, however, has used a limited set of tasks and produced mixed findings. Quantifying links between explicit and spontaneous mentalizing may illuminate cognitive mechanisms underlying real-world social behaviors in ASD.
Objectives: To evaluate, in both ASD and typical development, whether explicit measures of mental state reasoning are related to the tendency to spontaneously mentalize about naturalistic social stimuli.

Methods: Participants were 26 typical individuals (15 males, average age=19.86 years) and 24 individuals with ASD (17 males, average age=21.70 years) matched on age, sex, and verbal IQ. Participants completed two measures of spontaneous mentalizing: (1) the Spontaneous Theory of Mind Protocol (STOMP; Rice et al., 2014), in which participants described videos depicting complex social scenes and (2) the Describe-a-Friend task (Meins et al., 2008), in which participants described a close friend or family member. Both tasks yielded a measure of spontaneous mental state language (i.e., references to thoughts, feelings, and desires). Further, participants answered explicit questions about the mental states of characters in the videos and control questions about physical events. Participants also completed two conventional explicit mentalizing measures: (1) Mind in the Eyes (Baron-Cohen et al., 2001), involving inferring mental states from photographs of eyes and (2) Strange Stories (White et al., 2009), involving reasoning about mental states from stories.

Results: There were no significant group differences in the amount of spontaneous mentalizing for either the STOMP or Describe-a-Friend task. For the explicit questions about the STOMP videos, however, adults with ASD showed diminished performance when reasoning about mental states, but intact performance when reasoning about physical events. Controlling for age and verbal IQ, performance on those explicit mental state questions was related to the tendency to spontaneously mentalize for participants with ASD (r=.46, p=.048), but not for typical adults (r=-.264, p=.35). Across tasks, levels of spontaneous mentalizing were correlated for typical adults (r=.54, p=.01), but not for adults with ASD (r=-.076, p=.76). For the Mind in the Eyes and Strange Stories, typical adults performed significantly better than those with ASD, and, within each group, the two tasks were significantly correlated. For neither group, however, did the Mind in the Eyes or Strange Stories significantly relate to spontaneous mentalizing.

Conclusions: Overall, the relation between implicit and explicit mentalizing is complex, task-dependent, and varies between typical development and ASD. Intriguingly, only adults with ASD showed a relation between the tendency to offer spontaneous mental state description about naturalistic, socially-complex scenes and explicit measures of accurate mental state reasoning about those same scenes. These findings may suggest different routes to explicit and implicit mentalizing in typical development and ASD, and future research should continue to explore this possibility by including measures of mentalizing during social interaction.

211 **111.211** Relative Expressive Language Deficits Predict Anxiety in Youth with Autism Spectrum Disorder

P. E. Young[1]*, L. A. Santore*[2]*, C. M. Esposito*[3]*, A. H. Gerber*[2] *and M. D. Lerner*[4]*, (1)The Social Competence and Treatment Lab at Stony Brook University, Stony Brook, NY, (2)Stony Brook University, Stony Brook, NY, (3)Stony Brook University, Staten Island, NY, (4)Psychology, Stony Brook University, Stony Brook, NY*

Title: Relative Expressive Language Deficits Predict Anxiety in Youth with Autism Spectrum Disorder
Authors: Paul Young, Lee A. Santore, Christopher M. Esposito, Alan Gerber, Matthew D. Lerner

Affiliations: Stony Brook University

Background: Language deficits are characteristic of many youth with autism spectrum disorder (ASD; Van der Paelt et al. 2014), especially impairments in expressive language relative to receptive language (Grossman & Tager-Flusberg, 2012). Research indicates that expressive and receptive language deficits are associated with symptoms of anxiety, particularly social anxiety, in typically developing children (Snowling et al., 2006; Carson et al., 1998; Wadman et al., 2011). Anxiety disorders (AD), particularly social anxiety, are common in youth with ASD (Simonoff et al. 2008), and are strongly related to ASD symptom severity (Renno et al., 2014; Sukhodolsky et al., 2008). Thus, ASD symptom severity and expressive language deficits may both impact anxiety symptoms in ASD youth. However, whether relative expressive language deficits, controlling for ASD symptomatology, directly impact anxiety in ASD youth has not been tested.

Objectives: This study examined the relationship between relative expressive language deficits and elements of anxiety in ASD youth. We hypothesized that these deficits would be positively related to anxiety, specifically social anxiety, even after controlling for ASD symptom severity.

Methods: Fifty-six youth (Mage=12.43, SDage=2.78) with ADOS-2 (Lord et al., 2012) confirmed diagnoses completed the Kaufman Brief Intelligence

Test-2 (KBIT-2; Kaufman, 1997) and the Multidimensional Anxiety Scale (MASC; March, 1997) to measure language ability and anxiety, respectively. The two verbal sub-scales of the KBIT-2 were used to represent measure receptive and expressive language skills, as the Verbal Knowledge sub-scale measures receptive vocabulary (Kaufman & Kaufman, 2004), and the Riddles sub-scale parallels the expressive language sub-scale used in the original KBIT (Bain & Jaspers, 2010). The standardized difference score method (De Los Reyes & Kazdin, 2004) was used to evaluate the difference between the KBIT-2 verbal knowledge and riddles sub-scales. This difference was used to quantify the relative impairment gap between receptive and expressive language. Parents completed the Social Responsiveness Scale-2 (SRS-2; Constantino & Gruber, 2012) as a measure of ASD symptoms.

Results: Hierarchical multiple regression controlling for SRS-2 revealed that expressive language deficits, relative to receptive language, predicted increased levels of self-reported anxiety (*b*=.629, *p*=.027), specifically generalized anxiety disorder symptoms and separation, humiliation and rejection, social, and physical anxieties (all *bs*<.770, *ps*<.043), while controlling for individual differences in ASD symptomatology. Neither receptive nor expressive language alone were predictors of anxiety (all *ps*>.051).

Conclusions: Deficits in expressive language, relative to receptive, predicted levels of anxiety in ASD youth. These results suggest a need for providers to be aware of these deficits, as they are important predictors of anxiety. These findings also better characterize the phenotype of ASD and comorbid AD by addressing the deficits which contribute to this relationship.

212 **111.212** Self-Identified Motivations for Engaging in Sexual Offending By Offenders with Autism Spectrum Disorder

K. L. Payne[1]*, K. L. Maras*[2]*, A. Russell*[3] *and M. Brosnan*[4]*, (1)Psychology, University of Bath, Bath, United Kingdom, (2)Psychology, Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (3)Psychology/Centre for Applied Autism Research, University of Bath, Bath, United Kingdom, (4)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background:

People with autism spectrum disorder (ASD) are suggested to be over-represented in forensic populations. Research suggests that offenders with ASD are more likely commit certain types of crime (e.g., sexual offences, assault, robbery) than others (e.g., burglary, arson, trespass, driving, drug offences). Rehabilitation programmes largely target specific offences (e.g., sex-offences) and behaviours (e.g., anger) so it is important to understand the specific motivations of a specific group of offenders in order to effectively tailor programmes. This research focussed solely on individuals with ASD who engaged in sexual offending. To date, little is known about the motivations of individuals with ASD who engage in sexual offending. The limited available literature to date highlights potential factors such as social skills deficits, theory of mind deficits and a history of childhood abuse in sexual offending in ASD. Research to date has largely utilised evaluations from professional reports, however taking a person-first approach to addressing the reasons for engaging in offending behaviour is crucial to the success of rehabilitation programmes.

Objectives:

This research aimed to identify the self-identified motivations for engaging in sexual offences in adults with ASD.

Methods:

Nine male sexual offenders with ASD took part in a semi-structured interview. Participants were recruited from four prisons and two probation services in the UK. ASD diagnosis was confirmed by professionals working with the offenders. The mean age of participants was 29.56 (SD=8.68). Offences included rape, sexual assault (adult and child) and the downloading and possession of indecent images.

Once transcribed verbatim data were analysed using thematic analysis. Due to the subject area being under-researched coding was conducted in an inductive fashion where the researcher did not try to code the data according to a previously determined coding framework or analytic preconceptions; rather the coding was data driven. The identified themes were strongly linked to the data.

Results:

Results indicated a thematic separation between internal and external factors within the data. The three externally-occurring motivations for offending included disequilibrium (difficult life events; life instability; major life events), vulnerability (lack of familial support; lack of professional support; immaturity) and substance abuse (drugs; alcohol). The five internally occurring motivating factors identified were social difficulties (social skills deficits; loneliness), misunderstanding (lack of awareness of: the consequences, seriousness, and the rules/law; misbelief as to what is available online; lack of perspective), interpersonal relationships (transgressive relationships; lack of appropriate relationships; misunderstanding people; misunderstanding consent), self-discipline (loss of control; getting carried away) and sexual drive (contact and non-contact sexual drive).

Conclusions:

Overall this research concludes that the most commonly occurring motivations for offending revolve around misunderstanding (e.g., regarding the seriousness of behaviour and the law) and social skills deficits coupled with a lack of appropriate relationships. Future research should look to develop early interventions for individuals demonstrating sexually inappropriate behaviours which address the law, social skills deficits, what appropriate relationships are and how to access these.

213 **111.213** Sex Differences in Social Attention and Motivation in Autism: An Eye Tracking Study

C. Harrop[1]*, D. R. Jones*[2]*, S. Zheng*[3]*, S. Nowell*[4]*, B. A. Boyd*[5] *and N. J. Sasson*[2]*, (1)University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Texas at Dallas, Richardson, TX, (3)Psychiatry, University of California, San Francisco, San Francisco, CA, (4)University of North Carolina at Chapel Hill, Carrboro, NC, (5)Juniper Gardens Children's Project, University of Kansas, Kansas City, KS*

Background: The sex ratio in autism spectrum disorder (ASD) has remained constant and weighted toward males. As a result, considerably less is known about females, with the majority of published research including largely, or in some cases exclusively, males. However, subtle but important differences exist between the male and female phenotype of ASD, including greater social motivation in ASD females (Sedgewick et al., 2016) and fewer and more typical circumscribed interests (CI; Sutherland et al., 2017). Eye-tracking has quantified abnormalities in visual attention to social stimuli and CI in ASD, but these studies have relied primarily on male samples.

Objectives: The aim of this study is to use eye-tracking to understand sex differences in attention to social and CI stimuli.

Methods: 57 children (ages 6 to 10) provided sufficient eye-tracking data for inclusion (>20% fixation time on screen): 35 children with a diagnosis of ASD (15 female) and 23 typically developing (TD) children (13 female). Subjects completed a validated eye-tracking paradigm (Sasson & Touchstone, 2014; Unruh et al., 2016), with twenty slides of paired social and non-social (object) images presented. Half of the object images represent frequently occurring CI in ASD, known as high autism interest (HAI) objects (e.g., trains; South et al., 2005, Turner-Brown et al., 2011), and the other half represent objects not associated with CI in ASD (e.g., plants).

Results: There was a strong effect of sex on initial orientation to faces (F=5.81, p=.02) with females faster to prioritize social stimuli, particularly when paired with HAI stimuli (F=5.91, p=.01; Figure 1a). ASD females attended to social stimuli faster than all other groups and ASD males were the slowest (Figure 1a). There was a Sex*Diagnosis interaction for the number of fixations to social stimuli (F=5.77, p=.02), with ASD males fixating to social stimuli fewer times than TD males (p=.006) and a marginal effect when compared to ASD females (p=.06; Figure 1b). This was particularly apparent for faces paired with HAI images, with ASD males attending fewer times compared to all other groups (p=.04). There was marginal Sex*Diagnosis interaction for overall fixation time to social stimuli (F=3.60, p=.06), with ASD males fixating less than ASD females (p=.03; Figure 1c).

Conclusions: Our data for ASD males replicates that of previous studies consisting largely, or exclusively, of males (Sasson & Touchstone, 2014; Unruh et al., 2016). However, our findings for ASD females differed; ASD females demonstrated an opposite pattern of attention to social stimuli, with attention patterns more comparable to TD females. This could reflect a *protective effect* in ASD females. Our data differ both from a recent ERP study that found attenuated responses to social stimuli in ASD females (Coffman et al., 2015), suggesting there may be a disconnected profile in ASD females, with heightened visual attention in females not leading to greater processing and encoding of social stimuli. Further work includes examining the neural correlates of social attention as well as examining the pupil responses of ASD females to social stimuli and more complex, ecologically valid eye tracking paradigms.

214

111.214 Social Cognition Contributes to Social Functioning in Adults with Autism

***K. E. Morrison**, A. E. Pinkham and N. J. Sasson, University of Texas at Dallas, Richardson, TX*

Background: Adults with Autism Spectrum Disorder (ASD) are characterized by poor social functioning that contributes to smaller social networks, occupational challenges, and reduced quality of life. Identifying mechanisms of this poor social functioning offers promise for treatment and intervention.

Objectives: We examined the contribution of social cognitive ability to social functioning above and beyond general intellectual capacity and demographic features. Although social functioning has been most commonly evaluated in adults with ASD using self- and informant-report questionnaires, here we used performance-based measures that offer a more direct assessment of real-world social and functional abilities.

Methods: Adults with ASD (n=103; Age: M=24.28; IQ: M=105.64) completed a broad assessment of social cognitive ability: 1) emotion recognition tasks (Penn Emotion Recognition Task (ER-40) and the Bell Lysaker Emotion Recognition Task (BLERT)); 2) social appraisal tasks (The Awareness of Social Inference Task (TASIT), Reading the Mind in the Eyes, Cartoon Theory of Mind (CToM), and the Hinting task); 3) social perception tasks (Relationships Across Domains (RAD) and the Benton Facial Recognition Test); 4) an attribution style task (AIHQ); and 4) the Trustworthiness task.

Participants also completed two performance-based social functioning measures: 1) the Social Skills Performance Assessment (SSPA), a naturalistic role-play task enacting two real-life situations (e.g., meeting a new neighbor, negotiating with a landlord) later coded for discrete social skills (e.g., eye gaze, affect) and an overall index of social ability; and 2) the UCSD Performance-Based Skills Assessment (UPSA) assessed financial skills (e.g., counting change) and communication skills (e.g., scheduling appointments).

Results: A hierarchical regression was conducted for each outcome, entering general cognitive and demographic characteristics (e.g., Age, Gender, IQ, and Race) in the first block, followed by all social cognitive tasks in the second block. These predictors accounted for 52% of the variance in UPSA scores (F(17, 81)=5.13, p<.001), with cognitive and demographic information accounting for 33% of the variance (p < .001) and social cognitive tasks accounting for 19% (p=.006). Age and IQ, but not gender and race, were positively related to social functioning scores (p's<.014). For social cognitive tasks, only the CToM individually predicted higher social functioning (p=.04), and no other tasks were significant predictors (p's>.10).

Predictors together accounted for 29% of the variance in SSPA scores (F(17,75)=1.80, p=.04), however each block did not uniquely predict a significant proportion of variance (p's>.08). Higher TASIT and Trustworthiness scores significantly predicted higher social skills scores (p's<.03), and neither the demographic variables (p's>.14) nor the other social cognitive variables (p's>.26) significantly predicted social skills ability.

Conclusions: Social cognition contributes to social functioning for adults with autism over and above other characteristics including IQ and demographic variables. However, our results suggest different abilities may uniquely contribute to social skill and functional ability: general cognition and social appraisal were predictive of functional ability, but only social appraisal and trustworthiness performance were related to better social skills. Taken together, this may suggest that treatment of functional skills, but not social skill, may benefit from focusing on general cognitive ability in addition to specific social cognitive components.

215

111.215 Social Interaction between Friends and Non Reciprocal Friends in a School-Aged Boy with Autism.

***J. Rodríguez-Medina**[1], H. Rodríguez-Navarro[2], M. Jiménez Ruiz[2], V. Arias[3], B. Rubia-Avi[2] and B. Arias[4], (1)Center for Transdisciplinary Research in Education, University of Valladolid, Valladolid, Spain, (2)Department of Pedagogy, University of Valladolid (Spain), Valladolid, Spain, (3)University of Salamanca (Spain), Salamanca, Spain, (4)Department of Psychology, University of Valladolid (Spain), Valladolid, Spain*

Background: Children with autism spectrum disorder have been shown to be on the periphery of their social networks more often; to receive lower scores on companionship, closeness, intimacy and help; and to have fewer reciprocal friendships compared to their typical peers. Non-reciprocal friendships are a relatively unexplored phenomenon; however, analysis of this phenomenon could contribute to a better understanding of these relationships between children with autism and their peers in mainstream schools and could be used to support the design and implementation of social interaction skills interventions.

Objectives: The current study's aim was to identify the reciprocal and non-reciprocal friendships of a boy with autism and to observe his social interaction behavior while attempting to identify the presence of differential patterns. These behavioral patterns may be related to accuracy in social network perception, so we were also interested in comparing friendship network perception accuracy between the boy and his peers.

Methods: This mixed-methods study examined differences in social interaction patterns between a school-aged boy with autism and his reciprocal, non-reciprocal, and non-friends during recess time at a mainstream school. The participants were a student with autism, aged 10 years and 3 months, and his 14 classmates (eight males) from a third-grade elementary-education classroom. Observational methodology was used with an idiographic, follow up, and multidimensional design approach. Polar coordinates analysis was used to identify the activation or inhibition relationships that occurred between interactive behaviors according to relationship types. Using cognitive social structures to assess the children's perceptions of their friendship networks provided a complete cognitive map of their perceptions concerning who was friends with whom in the group.

Results: Children displayed a moderate level of agreement with peers with regard to the friendship social network. It was more difficult for them to accurately identify the friendships of the boy with autism compared to those of newcomers. Correlation analysis revealed that the boy with autism exhibited lower levels of agreement with the consensus than the more peripheral actors did. After 40 sessions, the results showed significant mutual activation relationships in terms of the social responses and initiations to non-reciprocal friendships and joint engagement and a significant inhibitory effect on the solitary category, while the responses to reciprocal friends did not show this effect.

Conclusions: Consistent with previous findings, we found little evidence of a relationship between reciprocal nominations received by the student and real social interactions in the playground during systematic observation. Although the interactions with non-friends and with non-reciprocal friends may be a factor related to stress and anxiety and may pose a higher social challenge for children with autism spectrum disorder compared to interactions with friends, this factor could reduce in importance as the relationship develops. Studying non-reciprocal friendships can help to improve the knowledge of the processes that could contribute to the development of significant relationships among children with autism and their peers in ordinary school settings.

216 **111.216** Social Pain and Emotional Egocentricity in High-Functioning Autism-Spectrum-Disorder: Behavioral and Neurophysiological Evidence

H. M. Hartmann[1]*, H. H. Hitz*[2]*, P. Stepnicka*[2]*, L. Lengersdorff*[1] *and G. Silani*[2]*, (1)Social, Cognitive and Affective Neuroscience Unit, Department of Basic Psychological Research and Research Methods, University of Vienna, Vienna, Austria, (2)Department of Applied Psychology: Health, Development, Enhancement and Intervention, University of Vienna, Vienna, Austria*

Background: Empathy is a crucial social skill that is relevant for everyday social interactions, and therefore has already been widely studied in both neurotypical as well as clinical populations. It is defined as the individual ability to feel with and understand another person's emotional state (Singer & Lamm, 2009). Given that humans primarily use their own emotions and perceptions in guiding their thoughts about conspecifics, self-projection mechanisms can lead to empathic judgments that are sometimes egocentrically biased towards one's own perspective – a so called emotional egocentricity bias (EEB) may occur (Silani, Lamm, Ruff, & Singer, 2013). Therefore, a cognitive component of empathy, called self-other distinction (SOD), plays an essential role during empathic interactions, mainly to avoid confusion between the self and emotions of others. This ability is necessary in order to generate a full empathic response. Multiple studies have shown impairments in empathic responses in individuals with autism spectrum disorders (ASD) (e.g. Dziobek et al., 2008). To date, only few studies have tried to investigate if reduced empathic responses can be due to an impairment of SOD.

Objectives: To investigate SOD abilities in ASD as indicated by the occurrence of emotional egocentricity biases.

Methods: Using a virtual ball-tossing game called Cyberball, we aimed to induce congruent as well as incongruent feelings of social inclusion/exclusion between the participant and a confederate, in order to test the occurrence of the EEB. The paradigm was first validated in a pilot study with 52 healthy subjects. In our main study, we then investigated 17 participants with high-functioning ASD as well as 17 matched neurotypical (NT) controls by means of a behavioral task as well as functional magnetic resonance imaging (fMRI).

Results: Replicating the results from the pilot study, the results of the main study indicated a significant EEB during incongruent emotional empathic judgments. However, no significant group differences regarding the EEB could be found, suggesting similar ability for SOD in both the NT and ASD participants in this sample. In spite of a similar behavioral EEB in the NT and ASD populations, brain differences in the right temporo-parietal junction (rTPJ) and right dorso-lateral prefrontal cortex (rDLPFC), two key areas involved in Theory of Mind and SOD, were detected in situations of incongruent emotions between the self and other.

Conclusions: The present study adds valuable preliminary insights to the investigation of social cognition in this population and expands them to the domain of social pain. Furthermore, the results suggest neurophysiological differences between neurotypical and autistic individuals, possibly underpinning differences in the neural processes involved in SOD during empathic judgments. Investigating the ability of SOD in ASD will ultimately pave the way to better understand their social and emotional impairments and provides an important contribution for current and future research in this area.

217 **111.217** Social Partner Gaze Direction and Conversational Phase; Factors Affecting Social Attention during Face-to-Face Conversations in Autistic Adults?

M. Freeth[1] *and P. Bugembe*[2]*, (1)Psychology Department, University of Sheffield, Sheffield, United Kingdom, (2)Psychology department, University of Sheffield, Sheffield, United Kingdom*

Background:

Social attention in autism is atypical (see Chita-Tegmark, 2016 and Guillon et al. 2014 for recent reviews). However, the vast majority of evidence for this claim comes from studies where the social partner is not physically present. Consequently, to ensure acquisition of a comprehensive overview of social attention in autism, systematic analysis of factors known to influence face-to-face social attention in neurotypicals is necessary.

Objectives:

The current study assessed the influence of social partner gaze direction (direct or averted) and conversational phase (speaking or listening) on social attention in autistic adults and matched neurotypical adults.

Methods:

Thirteen adults with a diagnosis on the autism spectrum (11 males; 2 female) and 13 neurotypical adults (10 males; 3 females) participated in this study. Participants were matched one-to-one on age (within 5 years), verbal IQ and performance IQ assessed using the Wechsler Abbreviated Scale of Intelligence. All participants scored in the average/above average range for IQ. Participants completed a live, one-to-one informal conversation with the experimenter. Experimenter gaze direction was systematically modified between being “direct” towards the participant’s face, or “averted” away from the participant’s face. The following topics were discussed: opinions on home-town; weekend plans; national traits; hobbies. Participants’ eye movements were recorded using a mobile eye-tracking device during the conversation.

Results:

In relation to modification of the experimenter’s gaze direction (direct/averted), findings indicated that when the experimenter looked directly at the participant, autistic adults looked at the experimenter’s face less than did neurotypical adults, though there were striking between individual differences in the autistic group on this measure. However, the difference between the autistic group and neurotypical group in relation to face fixations was significantly reduced when the experimenter’s gaze was averted. In relation to assessing the potential influence of conversational phase, a greater proportion of time was spent fixating the experimenter’s eye region when participants were speaking compared to listening, this was evident both for neurotypical participants and autistic adults.

Conclusions:

These findings suggest that opportunities for reciprocal social gaze are missed by autistic adults when the social partner makes direct eye-contact. Secondly, this study found that autistic adults displayed a similar modulation of attention in relation to conversational phase as did neurotypical participants. Overall, this study provides a rich picture of the nature of social attention in face-to-face conversations adopted by autistic adults and demonstrates high individual variation of social attention styles in this population.

218 **111.218** Social Proficiency Relates to Socially-Adaptive Mirror System Functioning

J. Prinsen[1] *and K. Alaerts*[2]*, (1)Rehabilitation Sciences, KU Leuven, Leuven, Belgium, (2)Rehabilitation Sciences, University of Leuven, KU Leuven, Leuven, Belgium*

Background: Individuals with a diagnosis of autism spectrum disorders (ASD) have impairments in social communication and interaction. Also in the neurotypical population, individual differences in terms of social proficiency are prevalent. Researchers have proposed the fronto-parietal action observation network or ‘mirror system’ as a basic neural mechanism for socio-cognitive (dys)functioning. In contrast to the well-known but controversial ‘Broken Mirror Hypothesis’, Wang and Hamilton’s (2012) social top-down response modulation (STORM) model proposed that people with social difficulties (such as patients with ASD) may have an intact mirror system, but unlike social proficient participants, fail to modulate mirror system functioning according to the social context.

Objectives: In this study, we explored whether inter-individual differences in social proficiency and/or attachment towards others are related to one’s ability to show socially-adaptive mirror system functioning.

Methods: A total of 56 neurotypical participants were assessed on adaptive neurophysiological mirror system functioning by means of a well-established single pulse transcranial magnetic stimulation (TMS) paradigm. While undergoing TMS, participants observed video stimuli of an actress performing simple hand movements combined with either direct or averted gaze. In general, TMS-assessed mirror-motor responses are significantly larger upon the observation of actions accompanied by direct eye contact, compared to averted eye gaze. To assess inter-individual differences in social proficiency, participants completed the self-report versions of the Social Responsiveness Scale (SRS) and the State Adult Attachment Measurement (SAAM). The data-driven k-means cluster analysis technique was used to identify subgroups based on the standardized questionnaire scores.

Results: Cluster analysis revealed two meaningful profiles of social proficiency. Cluster 1, labeled the ‘Secure’ cluster, represented participants with secure attachment styles and high levels in social proficiency (n = 26). Cluster 2, the ‘Avoidant’ cluster, represented participants that are highly socially avoidant and have mild to severe impairments in social responsiveness (n = 30). The two subgroups showed a clear differentiation in terms of socially-adaptive mirror system functioning (Gaze × Cluster interaction: $F(1,49) = 7.85$, $p < .01$). Particularly, only for the ‘Secure’ social profiles, direct gaze specifically enhanced ‘mirroring’ ($p = .02$). For participants belonging to the ‘Avoidant’ cluster however, direct eye contact did not facilitate mirroring ($p = .18$). The general level of mirroring was similar for each group ($p = .51$). In other words; in participants that are less socially proficient, mirroring is intact; but it is not socially modulated by relevant social cues, such as eye gaze.

Conclusions: Our results provide further support to the STORM model by showing that the process of mirroring is adaptive to relevant social cues (such as eye contact). Specifically, the observation that not mirroring per se but socially-adaptive mirroring is diminished in individuals with low social proficiency argues against a strong account of the Broken Mirror Theory. Instead our results provide evidence that the top-down response modulation of the mirror system is altered in individuals with social difficulties. Although established in the neurotypical population, these findings may also be highly relevant for people with ASD.

219 **111.219** Social Stress and Autonomic Arousal in Young, High-Functioning Adults with Autism Spectrum Disorder.

R. Dijkhuis[1]*, H. Swaab*[2]*, W. G. Staal*[3]*, S. Van Rijn*[4] *and T. Ziermans*[5]*, (1)University of Leiden, Leiden, Netherlands, (2)Leiden University, Leiden, Netherlands, (3)Institute for Brain and Cognition, Leiden University, Leiden, Netherlands, (4)Leiden University, Leiden, Leiden, Netherlands, (5)University of Amsterdam, Amsterdam, Netherlands*

Background: Despite the hypothesized link between autonomic self-regulation and the social difficulties seen in many individuals with autism spectrum disorder (ASD; Klusek et al., 2014; Neuhaus et al., 2014; Smeekens), little is known about autonomic reactivity to socially stressful situations in young adults with ASD.

Objectives: To examine whether young adults with ASD show deviating autonomic regulation during social stress, and whether it is related to their subjective experience of stress.

Methods: During social stress we compared autonomic arousal, gaze behavior and subjective experience between young adults with high-functioning ASD (HFASD; N = 53) and their typically developing (TD) peers (N = 31). Heart rate and skin conductance were measured as indicators of sympathetic and parasympathetic functioning of the autonomic nervous system. Gaze behavior was indicated by eye tracking (fixation duration in seconds) for multiple customized areas of interest. Additionally, participants were asked to report on experienced stress during the task.

Results: Compared to their TD peers, the HFASD individuals showed less reactivity in heart rate variability (HRV) and lower sympathetic activation (skin conductance level) during social stress, while displaying similar gaze behavior and subjective. However, contrary to TD controls, the experience of stress was not related to task-induced arousal in HFASD individuals. No significant differences in gaze behavior and relations between gaze behavior and autonomic arousal were detected.

Conclusions: Our results suggest reduced awareness of arousal and less regulation of arousal during socially stressful events in young adults with HFASD compared to TD peers. These results add to the existing literature in showing that deviant functioning of the ANS might be key in the stress regulation problems seen in so many individuals with autism, also in young adults with HFASD. These conclusions pertain important implications for daily life and give insight in the role of stress regulation in adaptive social behavior.

220 **111.220** Subjective Beliefs about Social Skills Importance, but Not about Social Skills, Predict Peer Interactions in Adolescents with Autism Spectrum Disorder

L. A. Santore[1], *E. Kang*[1], *S. L. Sommer*[1], *C. E. Simson*[1], *D. Kumar*[1] *and M. D. Lerner*[2], *(1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY*

Background: Adolescents with autism spectrum disorder (ASD) exhibit frequent deficits in peer interactions (Rao et al., 2008). Recent work has highlighted that such adolescents' beliefs about their own social skills may importantly differentiate them from their typically developing peers (Lerner et al., 2012). Such beliefs can be broken down into two components: beliefs about what skills one actually uses (social skills behaviors; Gresham, 1986), and beliefs about whether those skills are important (social skills importance; Gresham & Elliot, 1990). Adolescents with ASD often believe social skills are important (Rankin et al., 2015; McMahon & Solomon, 2015), and over-report their use of social skills behaviors (Lerner et al., 2012). However, little work has examined the relative contribution of these beliefs in predicting actual peer interaction in adolescents with ASD.
Objectives: This study sought to investigate the relationship between self-reported social skills importance ratings, self-reported social skill behaviors, and observed unstructured peer interactions. It was hypothesized that high levels of self-reported beliefs about social skills behaviors would exhibit an additive relationship in predicting peer interactions among adolescents with ASD.

Methods: 25 Adolescents (M_{age}= 14.984, SD_{age}= 1.480, 19 male) with ADOS-2 (Lord et al., 2012) confirmed ASD diagnoses were assigned to social groups of 5-9 peers for one video recorded twenty-minute free interaction session (e.g., Lerner & Mikami, 2012). Peer interaction duration was coded by a team of blinded and reliable (ICC = .79) coders via the Social Interaction Observation System (SIOS; Bauminger, 2002). Participants completed a self-report measure of both social skill behaviors and social skill importance (SSIS; Gresham and Elliot, 2008).

Results: Multiple linear regression determined social skills importance ratings *negatively* predicted the duration of time spent interacting with peers, even when controlling for self-reported overall social skill behavior (b = -0.162, p = 0.006). This relationship was driven by high importance ratings for communication (b = -1.505, p = 0.002), cooperation (b= -.871, p = .015), engagement (b = -8.55, p = 0.005), and self-control (b = -0.794, p = 0.019). Self-reported social skill behavior was not a significant predictor of peer interactions (p = 0.251), nor was the interaction between such behavior and social skills importance (p = .73).

Conclusions: Contrary to hypotheses, high social skills importance ratings predicted *fewer* social interactions with peers, regardless of self-reported social behavior. It is possible that adolescents with ASD may place higher importance on areas where they need the most improvement (McMahon & Solomon, 2015) – that is, they may in fact identify deficits by labeling them as *important*. The four significant subdomains of importance ratings (e.g. communication, cooperation, engagement, and self-control) are all specific to interactions (Meier, DiPerna, & Oster, 2006), which may provide a window into how youth with ASD perceive their social behavior, even as they rate themselves to have greater social skills (Rankin et al., 2015). This finding reveals a complex and unexpected way in which social cognition may relate deferentially to social behavior in adolescents with ASD.

221 **111.221** Subtle Differences in Subjective Wellbeing for Adolescents with Autism Spectrum Disorder.

P. Ashton *and M. A. Stokes, Deakin University, Burwood, Australia*

Background: Adolescents with autism spectrum disorders (ASD) are prone to negative life experiences due to challenging social experiences and ASD symptomology. This is thought to have a detrimental effect on their subjective wellbeing compared to their typically developing (TD) peers, resulting in differences in levels of subjective wellbeing. Results to date have been equivocal, some finding reductions in wellbeing, other not.
Objectives: Therefore, the current study aimed to establish how wellbeing differs across gender and across diagnosis in a group of adolescents with and without ASD.

Methods: Participants aged 10-21 including high functioning adolescents with ASD (n=59), and a TD control group (n=35). Participants were then gender and aged matched giving 24 pairs. Participants completed the Personal Wellbeing Index – School Children Edition as measure of subjective wellbeing, the Rosenberg General Self-Esteem scale, and the Autism Spectrum Quotient to assess number of autistic traits.

Results: A difference between ASD and TD adolescents was found (p<0.05). No differences were found between adolescent males and females with ASD on wellbeing scores. Mediation analysis indicated that self-esteem fully mediated the relationship between the strength of autistic traits and subjective wellbeing. Linear regression analyses indicated that autistic traits did not predict wellbeing in the ASD group, but were negatively associated with wellbeing in the TD group (p<0.05). Self-esteem was a significant predictor of wellbeing in both groups (p<0.05), although strongest in the TD group. ASD and TD pairs were matched based on age and gender, with a significant difference found on wellbeing scores between matched pairs (p<0.05). Pairs were then separated and reanalysed with ASD participants having higher or lower wellbeing than their TD matched pair placed into two separate analyses. Matched pairs t-tests revealed that there for those with lower wellbeing were significantly lower than their matched pair, while those who were higher also were significantly higher.

Conclusions: Matched participants indicated that adolescents with and without ASD differ on wellbeing. But interestingly, not all adolescents with ASD had lower wellbeing, being higher than their age and gender matched pair. Nonetheless, in more instances the participant with ASD had lower wellbeing than their TD partner. These results suggest a considerably more complex picture with wellbeing in ASD, and may indicate something of the nature of ASD, in that those with ASD may not have sufficient insight to address scales such as the PWI. Alternatively, these differences may suggest an approach to intervening in subjective wellbeing among those with ASD. Either way, these results suggest further research would be useful.

222 **111.222** Temperament Mediates the Relationship between Symptom Severity and Adaptive Functioning in School-Aged Children with Autism Spectrum Disorder

__V. Lee__[1], E. Duku[2], L. Zwaigenbaum[3], T. Bennett[4], P. Szatmari[5], S. E. Bryson[6], M. Elsabbagh[7], E. Fombonne[8], P. Mirenda[9], W. Roberts[10], I. M. Smith[11], W. J. Ungar[12], T. Vaillancourt[13], J. Volden[3], C. Waddell[14], A. Thompson[2] and S. Georgiades[2], (1)McMaster Universtiy-Offord Centre, Hamilton, ON, Canada, (2)McMaster University, Hamilton, ON, Canada, (3)University of Alberta, Edmonton, AB, Canada, (4)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (5)The Hospital for Sick Children, Toronto, ON, Canada, (6)Dalhousie University, Halifax, NS, Canada, (7)McGill University, Montreal, PQ, Canada, (8)Psychiatry, Pediatrics & Behavioral Neurosciences, Oregon Health & Science University, Portland, OR, (9)University of British Columbia, Vancouver, BC, Canada, (10)isand, Toronto, ON, Canada, (11)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (12)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (13)University of Ottawa, Ottawa, ON, Canada, (14)Simon Fraser University, Vancouver, BC, Canada

Background: Temperament is defined as a set of individual differences in behavioural tendencies. An extensive body of literature establishes the association between temperament and childhood psychiatric disorders and more recent studies have documented specific temperament profiles in infants with Autism Spectrum Disorder (ASD). Previous studies have found that infants and children with ASD, when compared to a control group, tend to have a particular temperament profile characterized by higher negative affect, lower urgency and lower effortful control, relative to peers who do not have ASD. However, little is known about how temperament varies within the ASD population and how that variability is associated with later outcomes, such as the development of adaptive skills, in children with ASD.
Objectives: The objective of this study was twofold: a) to identify subgroups of school-aged children with ASD with distinct temperament profiles; and b) to examine whether temperament subgroup membership mediates the relationship between ASD symptom severity and adaptive functioning outcomes.

Methods: Data came from the Pathways in ASD study, a large Canadian longitudinal study of children with ASD. The sample was composed of 185 school-aged children with ASD at T_1 (mean age: 7.8 years; males = 155). Temperament profile was indexed using the T_1 Temperament in Middle Childhood Questionnaire (TMCQ). Children were followed over a 3-year period (T_1-T_3, with T_1 as the first assessment between age 7-8 years and one assessment every 12 months for 2 consecutive years). Seventeen TMCQ dimension scores were used in hierarchical cluster analysis to derive subgroups of children. A test of binary mediation was conducted to test whether the relation between T_2 autism symptom severity (Autism Diagnostic Observation Scale; ADOS) and T_3 adaptive functioning level (Vineland Adaptive Behaviour Scale; VABS II) was mediated by a child's temperament profile.

Results: A 2-cluster solution was selected as the best fit to the data; the two clusters were characterized by distinct temperament profiles (for most TMCQ dimensions). Compared to children in Cluster 2 (60.5% of sample), children in Cluster 1 (39.5% of sample) had higher scores on activation control, affiliation, assertiveness, attentional focusing, fantasy/openness, and soothability, and lower scores on anger/frustration, impulsivity, discomfort, fear, sadness, and shyness. Children in Cluster 1 had significantly lower adaptive functioning skills compared to children in Cluster 2 (F(1,165) = 44.98, p < 0.01). The total direct effect of ASD severity at T2 was a significant predictor of adaptive functioning outcome at T_3, before entering the mediator variable (t(161) = - 3.51, p <0.001). The mediation test revealed that the total indirect effect for temperament profile was significant (p < 0.001; point estimate = -0.16, 95% CI = -0.41 to -0.13), and influenced the relation between ASD severity and adaptive functioning outcome.

Conclusions: Study findings show that in school-aged children with ASD, distinct temperament profiles influence the relation between ASD severity and adaptive functioning outcome. These findings suggest that temperament may be a previously under-researched but important child-level characteristic to consider when investigating developmental outcomes and intervention mechanisms in children with ASD.

223 **111.223** The Aesthetic Perception Ability in Autism Spectrum Disorders: A Behavioural and Eye-Tracking Study

__S. Peretti__[1], M. C. Pino[1], M. Mariano[1], C. Di Dio[2], M. Valenti[1,3] and M. Mazza[1], (1)Department of Applied Clinical Sciences and Biotechnology, University of L'Aquila, L'Aquila, Italy, (2)Department of Psychology, Università Cattolica Sacro Cuoire, Milano, Italy, (3)Reference Centre for Autism of the Abruzzo Region, L'Aquila, Italy

Background:
The ability to experience aesthetics plays a fundamental role in social interactions. For instance, attractive individuals are commonly perceived as possessing positive personality attributions. This suggest that beauty is an important social cue that may affect the ability to experience pleasure playing a pivotal role in social behavior.

A crucial capacity for successful social interactions is Social Cognition (SC), that is a complex cognitive construct that allows to encode and decode the social world. It is known that people with Autism Spectrum Disorder (ASD) have an impairment of SC abilities. These abilities seem to be related with aesthetic perception that allow a person to anticipate interaction or action of others.

Objectives: The study aims at evaluating the ability of aesthetic perception in individuals with ASD compared to typically developing controls (TD), using the Golden Beauty (GB) behavioral task and adapted for eye-tracking.

Methods: 10 individuals with ASD (mean age±SD:20.7±4.64) selected by the Reference Regional Centre for Autism of L'Aquila, and 10 TD individuals (mean age±SD:20.17±0.98) selected by the University of L'Aquila, Italy, participated in the study. All participants underwent SC battery and then GB task with stimuli (sculptures with canonical and modified proportions) presented in three experimental conditions: objective aesthetic judgment (OAJ), subjective aesthetic judgment (SAJ) and proportion judgment (PJ).

Results: Preliminary results showed that ASD group have an impairment in all SC measures, compared to TD group. In the TD group, but not in the ASD one, we found significant correlations between same SC measures and all conditions of GB task. Regarding GB performance, ASD group have a lower ability to judge as objectively beautiful and subjectively pleasing (aesthetic judgments) the sculptures, compared to TD. The same happens for the proportion judgment that is related to the perceptual-cognitive component of the task. TD group evaluated the sculptures with canonical proportion as more pleasant and more proportionated, compared to the sculptures with modified proportion. No differences in the evaluation between canonical or modified sculptures were found in ASD group. It is worth noting that the evaluation of subjective pleasure was always lower in ASD people compared to the evaluation of objective beauty and proportion of sculptures. Finally, the eye-tracking data showed that individuals with ASD have lower gaze parameters for face and bust of sculptures in each condition of GB task, compared to TD people.

Conclusions: This study showed, for the first time, that persons with ASD have an impairment in the aesthetic perception ability. The incapacity to perceive aesthetic features of ASD people has relevance in influencing their incapacity to experience interpersonal and social pleasure. This could have a significant negatively impact on social interactions. Indeed, the perception of beauty is strongly linked with the SC ability as demonstrated by the correlations between SC measures and GB task in TD people. Our findings support the idea that SC and aesthetic perception are in close relationship to each other and this relation is lost or at least impaired in persons with ASD

224

111.224 The Impact of Attention-Deficit/Hyperactivity Disorder and Motor Deficit on Socio-Emotional Behaviors of School-Aged Children with Autism Spectrum Disorder

Y. J. Shen[1]*, S. J. Chew*[2] *and L. C. Chen*[2,3]*, (1)National Taiwan University, Taipei city, Taiwan (Province of China), (2)School and Graduate Institute of Physical Therapy, College of Medicine, National Taiwan University, Taipei, Taiwan, (3)Department of Physical Therapy, Fooyin University, Kaohsiung, Taiwan*

Background: Autism spectrum disorder (ASD) is a group of developmental disorders marked by impaired social interaction and communication, restricted and repetitive behaviors. In addition to core symptoms, children with ASD often have various comorbidities, including attention-deficit/hyperactivity disorder (ADHD) and motor deficit (MD). Both the core symptoms and comorbidities of ASD have adverse effects on children's socio-emotional behaviors that are major concerns of their parents and teachers. However, previous studies mostly focused on ASD core symptoms but rarely investigated the impact of comorbidities on children with ASD.

Objectives: The purpose of this study was to examine the influence of comorbidities, including ADHD and MD on socio-emotional behaviors of school-aged children with ASD.

Methods: Forty-four children with high-functioning ASD (8.8±1.1 years of age, 38 boys) participated in this study. ASD and ADHD diagnoses were determined by child psychiatrists. Bruininks-Oseretsky Test of Motor Proficiency, Second Edition was used to determine MD of children with a cut-off standard score of 40. Children's socio-emotional behaviors were assessed using parental reports of the Child Behavior Checklist (CBCL). Cut-off T scores were 70 for the 8 CBCL narrow band syndromes and 63 for internalizing, externalizing, and total behavior problems. Two-way ANOVA was applied to examine the impact of ADHD and MD on socio-emotional behavior problems of children with ASD. Considering the influence of intellectual function on children with ASD, children's intellectual ability was controlled in the analyses.

Results: Among the 44 children with ASD, 20 (45%) were also diagnosed with ADHD. Nine out of 20 (45%) children with ASD and with ADHD and 13 out of 24 (54%) children with ASD but without ADHD were found to have MD. Statistical analyses revealed that comorbidity of ADHD significantly increased attention problems (F=5.620, P=0.023), aggressive behavior (F=5.901, P=0.02), and externalizing problems (F=4.685, P=0.037) in children with ASD while comorbidity of MD only significantly increased children's social problems (F=5.634, P=0.02). After controlling children's intellectual quotient, however, the effect of MD on social problems in children with ASD was diminished and became borderline (F=3.979, P=0.053). No ADHD*MD interaction effect was found for socio-emotional behaviors of children with ASD.

Conclusions: Comorbidities of ASD, including ADHD and MD have further negative impact on various domains of children's socio-emotional behaviors during school age. Medical professionals, teachers, and parents should be aware of the impact of comorbidities on functioning of children with ASD to help better plan for intervention or teaching strategies. Future research needs to consider possible influence of various comorbidities when investigating socio-emotional behaviors of children with ASD.

225

111.225 The Impact of Autistic Traits on Prosody and Gesture Perception

L. Shim[1]*, F. E. Pollick*[2] *and I. M. Eigsti*[3]*, (1)School of Psychology, University of Glasgow, Glasgow, United Kingdom, (2)School of Psychology, University of Glasgow, Glagow, United Kingdom, (3)University of Connecticut, Storrs, CT*

Background: The integration of speech and gesture is an essential ability that helps humans to participate in daily communication and social interactions. Various studies support that this integration relates to the development of language and communication. However, deficits in communication and social reciprocity are commonly presented in Autism Spectrum Disorders (ASD) and several studies suggest that individuals with ASD have more difficulty in the integration of speech stimuli as well as in discriminating temporal asynchrony in linguistic and other scenarios. These differences in speech and gesture integration in ASD may impact on social and emotional communication and multisensory temporal integration.

Objectives: To investigate differences of speech-gesture processing between typical individuals and those with high levels of autistic traits using three different stimuli conditions, including auditory, visual, and audio-visual conditions.

Methods: We used a cutoff of above 29 on the Autism Quotient score to enter the High AQ (HAQ) group and below 18 to enter the Low AQ (LAQ) group. The ongoing study involves 24 right-handed individuals (17 LAQ and 7 HAQ) between the ages of 18 and 40 years old. All participants took the WASI to measure IQ. Three experiments were conducted: (1) Experiment 1 investigated performance differences in prosody perception between the two groups with 5 different tasks, (2) Experiment 2 investigated differences in processing gestures between the two groups and (3) Experiment 3 explored differences in the ability to distinguish emotional congruence and incongruence of prosody and gesture and between the two groups.

Stimuli- Two stimuli sets were used in this experiment: (1) From the Egisti et al.(2012) study, emotional (Angry, Neutral) and grammatical (Statement, Question) sentences with audio-only condition and (2) From the Piwek et al.(2015) study, emotional (Angry, Happy, Neutral) sentences in an audio-only condition, point-light displays in a video-only condition, and audio-visual stimuli including two different conditions (emotional congruence and incongruence) were used.

Results: The results of Experiment 1 revealed that there was no difference between LAQ and HAQ groups in prosody perception. However, in one task that involved finding emotional and grammatical prosody together, the HAQ group showed lower accuracy than the LAQ group ($p<0.05$). Experiment 2 showed that while both groups exhibited low accuracy in correctly perceiving emotions from the gestures (LAQ: 67.7%, HAQ: 56.75%), the LAQ group performed better ($p<0.05$) than HAQ. In Experiment 3, there was no group difference between LAQ and HAQ to find emotional congruence between auditory and visual stimuli. In overall reaction times, there were no group differences, but both groups showed the slowest reaction times in the gesture-only condition.

Conclusions: This study investigated how autistic traits impact on prosody and gesture perception. Two differences were found in that the HAQ group obtained lower accuracy performance in complex prosody and gesture-only task than the LAQ group. These results emphasise that although both groups performed similarly for several tests, significant performance differences exist between individuals with low and high autistic traits, suggesting that consideration of these differences can help to find how autistic traits impact on social communication.

226 **111.226** The Respiratory Sinus Arrhythmia in Young, Low-Functioning Children with and without Autism Spectrum Disorder

J. Lauttia[1]*, T. M. Helminen*[2]*, S. M. Kivimäki*[3]*, K. Eriksson*[4] *and A. Kylliainen*[2]*, (1)University of Tampere, Tampere, Finland, (2)Tampere University, Tampere, Finland, (3)City of Helsinki, Helsinki, Finland, (4)Tampere University and Tampere University Hospital, Tampere, Finland*

Background:

Heart rate variability, and more specifically, respiratory sinus arrhythmia (RSA) is considered as a peripheral biomarker of social competence and emotion regulation. Earlier research has often found lowered RSA in individuals with ASD and it has been associated with various difficulties in social cognition, such as emotion recognition, social responsiveness and spontaneous use of eye gaze. There have, however, been also contradictory findings showing no ASD specific differences in RSA. It is assumed that the decreased RSA is not unique to ASD but shown to relate social difficulties in other neurodevelopmental disorders too. In addition, the earlier studies have mainly been done in school-aged, high-functioning children with ASD leaving open the question whether lowered RSA evokes early in autistic development and relates to social difficulties also in low-functioning children with ASD.

Objectives:

The main aim of the study was to investigate baseline RSA in young, low-functioning children with severe ASD. In order to study the effects of developmental level to RSA, we had an IQ-matched comparison group of developmental delay children (DD) without ASD. Age-matched typically developing children (TD) served as a normative control group. In addition, the connections between RSA and reciprocal social interaction, communication and restricted, repetitive, and stereotyped patterns of behaviour were studied in all the groups.

Methods:

The final sample consisted of 14 children with ASD, 17 TD children and 16 children with DD. Every group included 2 girls and the age ranged from 29 to 81 months. Heart rate was measured whilst the children looked at a neutral video about a person building with Lego bricks for 3 minutes. Data was carefully offline video analysed in order to reject artefacts. RSA was analysed in 0,24–1,04 Hz using a Matlab-based in-house program. The parents filled Social Communication Questionnaire (SCQ) as a measure of autistic behaviour.

Results:

The findings revealed significant difference in RSA between the groups (Kruskal-Wallis H = 6,324, p = .042). Paired comparison showed that the children with ASD had lower RSA than TD children and children with DD. There were no differences in RSA between TD and DD children. SCQ domains of reciprocal social interaction and communication were not associated to RSA in any of the groups. However, a trend of interaction between RSA and restricted, repetitive, and stereotyped behaviour (RRB) was found both in the ASD and DD groups. The higher RSA was connected to more RRB in children with ASD whereas in children with DD higher RSA was connected with less RRB.

Conclusions:

The findings of the study indicated that lowered RSA is detectable early in the autistic development and is not related to the developmental delay without ASD. Interestingly, the RSA connection to restricted, repetitive, and stereotyped behaviour seemed to be reversed in children with ASD and children with developmental delay. Restricted and repetitive behaviour as an aid for self-regulation in ASD deserves further clarification.

227 **111.227** The Role of Social Awareness and Motivation in Interpersonal Behavior and Imitation in Children with Autism

E. Moody[1]*, C. Ledbetter*[2]*, B. Barger*[3]*, N. Reyes*[4] *and S. Rosenberg*[2]*, (1)University of Colorado, Denver, Aurora, CO, (2)University of Colorado Anschutz Medical Campus, Aurora, CO, (3)Georgia State University, Atlanta, GA, (4)JFK Partners, University of Colorado Anschutz Medical Campus, Aurora, CO*

Background: Imitation is one of several important social matching behaviors (Moody & McIntosh, 2006) implicated in numerous outcomes (e.g., Bavelas, Beavin-Black, Lemery, & Mullett, 1987). Imitation deficits are associated with autism (Rogers & Williams, 2006); although, there is variability in the consistency of this finding (Charman & Baron-Cohen, 1994). Deficits in social motivation have been proposed as a possible explanation for imitation deficits in autism (Rogers & Williams, 2006).

Objectives: This study investigates the relationship between social factors (i.e., motivation, social cognition, social communication and social awareness), and social and imitative ability in children with autism. This will provide a better understanding of the mechanisms underlying imitation deficits and social behavior and will guide future research on improving social abilities in individuals with autism.

Methods: Data for this analysis came from the Study to Explore Early Development (SEED; n = 628), a multi-site case-control study on risk factors for autism. Participants were included if they received a final classification of autism, and completed the following measures: 1) Social Responsiveness Scales (SRS), 2) Vineland Adaptive Behavior Scales-II (Vineland), 3) Autism Diagnostic Observation Schedule (ADOS) and 4) demographics. Separate models were computed for the Vineland Interpersonal Relationships subdomain and for a subset of Vineland items from the same subscale that relate to imitation (items 8, 12, 16, 18, and 21). Linear regression was used for all analyses; p-values less than 0.05 were considered significant. The primary exposures for these analyses were the social constructs from the SRS: social motivation, social cognition, social awareness, and social communication subscales. All analyses were adjusted for age, sex, maternal race, maternal ethnicity, and income. Autism severity (Calibrated Severity Score (CSS) from the ADOS) was tested as an effect modifier. However, no effect modification was found, therefore, CSS was included as a covariate. Due to the non-normal distribution of the Imitation score, a bootstrapped regression was conducted. All analysis was performed in R version 3.1.2 (2014-10-31). The *car* package v(2.0.25) was used for the bootstrap regression.

Results: Social awareness is significantly associated with the Vineland Interpersonal Relationships v-score (p = 0.0043). For every 10 point increase in Social Awareness there was a 0.36 decrease in the mean Interpersonal Relationship score after adjusting for Social Motivation, Communication, Cognition, autism severity, age, race, sex, ethnicity, income, and maternal education. Social Motivation was significantly associated with Imitation (p = <0.05). For every 1 point increase in Social Motivation there was a 0.038 (95% CI: 0.067-0.011) decrease in the mean Imitation score after adjusting for Social Awareness, Communication, Cognition, autism severity, age, race, sex, ethnicity, income, and maternal education.

Conclusions: There is a significant association between Social Motivation and Imitation, and between Social Awareness and Interpersonal Relationship skills after adjusting for other social domains, autism severity, and socioeconomic status. This suggests that separate social

constructs relate to social and imitative abilities in children with autism. This may help guide targets of intervention in the future; however, additional research is needed to better understand this association.

228 **111.228** Toddlers with Autism Observe the World in a More Variable Manner Exhibiting Large Intra-Individual Variability

I. Avni[1]*, A. Bar-Sinai*[2]*, I. Menashe*[3]*, G. Meiri*[4] *and I. Dinstein*[5,6,7]*, (1)Cognitive and Brain Sciences, Ben Gurion University of the Negev, Israel, Be'er sheva, Israel, (2)Ben Gurion University of the Negev, Beer Sheva, Israel, (3)Public Health Department, Ben-Gurion University, Beer Sheva, Israel, (4)Soroka Medical Center, Beer Sheba, Israel, (5)Department of Psychology, Ben Gurion University of the Negev, Beer Sheba, Israel, (6)Negev Autism Center, Ben Gurion University of the Negev, Beer Sheba, Israel, (7)Department of Cognitive and Brain Sciences, Ben Gurion University of the Negev, Beer Sheba, Israel*

Background: Previous eye-tracking studies have reported that children with autism do not fixate on social stimuli in the same manner as neurotypical children, perhaps interfering with their ability to learn social interactions. For example, children with autism exhibit reduced preference for social stimuli including faces, eyes, and biological motion. A lack of social preference may lead to idiosyncratic gaze preferences, large between-subject variability, and low inter-subject correlations. In the current study, toddlers with autism and matched controls observed several movies containing social stimuli twice. This design enabled us to determine whether between-subject variability was driven by reduced preference for social stimuli and quantify within-subject variability across the two presentations of each movie. All participating children were part of the regional autism database initiative at the Negev Autism Center in Israel (www.negevautism.org).
Objectives: To compare social preference, between-subject variability, and within-subject variability across autism and control children presented with naturalistic and animated movies containing social stimuli.

Methods: We recorded eye tracking data from 68 toddlers with autism and 29 control toddlers while freely viewing two animated movies and one naturalistic movie containing social interactions. Each of the movies was presented twice during the experiment. We then computed inter-subject correlations across individuals and intra-subject correlations across presentations from each group of subjects.

Results: Toddlers with autism exhibited significantly smaller inter-subject correlations (i.e. larger between-subject variability) in comparison to controls. Furthermore, toddlers with autism exhibited significantly smaller intra-subject correlations (i.e. larger within-subject variability) in comparison to controls.

Conclusions: Neurotypical children exhibit strong inter-subject correlations in gaze patterns, likely due to their preference for social stimuli. Children with autism, on the other hand, are not only different from each other, they also exhibit weak intra-subject correlations across presentations of the same movie. This indicates that their idiosyncratic gaze patterns are also less stable across repeated presentations of the same structured stimulus. Hence, toddlers with autism view the world in a more variable less consistent manner. This variability may have important implications for their ability to learn and explore the visual world.

229 **111.229** Where Do Children with ASD Look for Information in Ambiguous Social Situations?

A. Porthukaran[1]*, M. Hooper*[2]*, M. Davies*[1]*, J. Abrams*[1,3] *and J. M. Bebko*[1]*, (1)York University, Toronto, ON, Canada, (2)York University, Toronto, ON, CANADA, (3)Durham Catholic District School Board, Toronto, ON, Canada*

Background: Children with autism spectrum disorders (ASD) process information differently than typically developing peers (Loveland et al., 2001). Studies in social information processing have found that children with ASD do not attend to social contingencies (Schroeder, 2013). In a study by Klin and colleagues (2002), individuals with ASD looked at videos of social situations using eye-tracking technology to pinpoint gaze patterns. Individuals with ASD tended to fixate more on mouths and other objects rather than the eyes. Children with ASD are especially susceptible to bullying experiences and respond in different ways compared to typically developing children. Schroeder (2013) suggested that the way these children process social information increases their susceptibility to misunderstand bullying experiences as normative.
Objectives: The focus of this study was to identify what aspects of social bullying scenes children with ASD would attend to compared with TD children. Understanding what is salient to children with ASD is important in determining some of the causes of high rates of social difficulties among this population.

Methods: Twenty-three children with ASD (83% male), and 24 in the TD comparison group (79% male) were matched based on age, IQ and PIQ using a brief measure of intelligence (WASI). Participants were presented with two short videos depicting social interactions in which the intent of the perpetrator was ambiguous (e.g., may have been hostile or accidental) and one short video in which the intent was more clearly hostile. These videos were filmed from the first-person perspective. Participant eye movements were recorded using an eye-tracker. Areas of interest (AOI) were defined as the central components of each video (e.g., a child's face, a game board, child's arm) and total time spent looking at each AOI was recorded.

Results: Dynamic areas of interest were added to the social scenes to cover those areas most informative in the scene. In the clearly hostile scene, there were no differences compared with TD children in the amount of time during which children with ASD looked at social aspects of the scene ($p = 0.78$). However, in the two ambiguous scenes, children with ASD spent more time than typically developing controls looking at non-social aspects of the scene; for example, a backpack (TD = 4.8s, ASD = 9.2s; $p = 0.006$) instead of a potential thief (TD = 4.9s, ASD = 3.9s; $p = 0.01$).

Conclusions: In scenes where it was most crucial for children with ASD to focus on social information (i.e., those scenes where someone's intent was ambiguous), they instead focused on non-informative stimuli such as objects. In situations of bullying, such as those presented in these videos, this may lead children with ASD to miss details that help them to clarify the nature of these interactions. Children with ASD more frequently experience bullying than their typically developing peers. Emerging evidence suggests that how they process information in their environments is linked to difficulty in handling potential bullying situations. This research can help inform how children with ASD process complex information in more naturalistic settings.

230 **111.230** Young Adults' Autistic Behaviors Predict P1 and N170 ERP Responses to Emotion Stimuli

S. C. Taylor[1,2] *and C. L. Dickter*[1]*, (1)College of William and Mary, Williamsburg, VA, (2)Neuroscience Graduate Group, University of Pennsylvania, Philadelphia, PA*

Background: In addition to the core deficits of Autism Spectrum Disorder (ASD), deficits in emotional processing, especially with negative emotions and surprise, have been identified (Uljarevic & Hamilton, 2013). These behavioral deficits are reflected in differences in neural responses, specifically with the P1 and N170 event-related potential components (Black et al., 2016).
Objectives: Given that subclinical levels of autistic behaviors have been observed in the general population and have been associated with various psychosocial and interpersonal difficulties (e.g. Wainer et al., 2011), this study aimed to examine how the neural differences in emotion processing that have been identified in clinical populations are modified by autistic behaviors in a subclinical, college-aged population. This study further sought to determine if differences in emotion processing were modified by the facial features available, the emotion being displayed, or the task type.

Methods: This study examined 34 subclinical college students, comparing those with a higher number of autistic behaviors (n=12) to those with a lower number (n= 2), as measured by the Broad Autism Phenotype Questionnaire (Hurley, Losh, Parlier, Reznick, & Piven, 2007). Emotion processing was examined using a task composed of a series of still pictures that varied by emotion (angry, fearful, happy, neutral, and surprised) and facial features available (eye region, full face). Task type varied by instructions intended to modify the type of processing occurring. The matching task indicated to respond based on whether the emotion of the face matched that of the face presented before it. Alternatively, the valence task indicated to respond whether the emotion of the face was the target valence (i.e. positive or negative) or not.

Results: Those with low levels of autistic behaviors demonstrated greater neural attention to fearful stimuli, measured by N170 amplitude, while those with high levels did not, indicating a difference between the two groups in processing fear; $t= -2.68$, $p=.01$. This effect emerged in trials showing the eye region in the valence task (Figure 1a) and not in those in the matching task (Figure 1b). Analyses using autistic behaviors as a continuous variable showed higher autistic behaviors were related to decreased neural attention in response to surprise as measured both by P1 ($r= -.49$, $p =.00$) and N170; $r= -.42$, $p=.02$. Additionally, the results demonstrated that in participants with high levels of autistic behaviors, less neural attention occurred in response to faces in which only the eye region was shown, contrasting the increase in neural attention in those with low levels of autistic behaviors when presented the same stimuli.

Conclusions: In this study we demonstrated, in a rarely investigated population of subclinical young adults, that the neural processing of faces varies by emotion as well as by the facial features available differently based on the degree of self-reported autistic behaviors and that this effect is modulated by task type. This study helps reveal the early neural components during emotion processing in young adults representing the broader autism phenotype, which may be responsible for some of the social challenges associated with autism.

231 **111.231** The Role of Receptive and Expressive Language on Social Initiations in Young Children with Autism

***R. A. Bowler**, E. A. Bisi, A. Thomas, C. Carlson and B. J. Wilson, Seattle Pacific University, Seattle, WA*

Background: Children with autism spectrum disorder (ASD) often experience challenges with social interaction from an early age, which may be associated with social withdrawal and emotional and behavioral dysregulation later in life (Krasch, 2015). Additionally, many children with ASD have deficits in the usage and/or production of language (Farrar, Seung, & Lee, 2017; Hudry et al., 2009). Previous research suggests that for children with ASD, receptive language may be more delayed than expressive language (Hudry et al., 2009). Lower receptive and expressive skills may make it particularly challenging for children with ASD to initiate or engage in social interactions.
Objectives: The purpose of this study was to examine the unique roles of expressive and receptive language on social initiative behaviors for children with ASD compared to their TD peers. We hypothesized that both receptive and expressive language would moderate the association between developmental status and social initiation, such that children with ASD and lower levels of either receptive or expressive language would initiate less frequently than TD children.

Methods: Our sample included 115 children (ages 3:0 to 6:11), 71 (49% female) with TD and 44 children with ASD (20% female). Videotaped recordings of an 8-minute parent-child free-play task were coded using an adapted version of the Modified-Classroom Observation Schedule to Measure Intentional Communication (M-COSMIC; Clifford, Hudry, Brown, Pasco, & Charman, 2010), from which a percentage of child social initiations was later calculated. Child language ability for expressive and receptive language was assessed through the Verbal Comprehension and Naming Vocabulary subtests of the DAS-II (Elliott, 2007).

Results: A double moderation model was conducted using the PROCESS macro for SPSS (Hayes, 2013), to evaluate the effects of receptive and expressive language on the association between developmental status and the percentage of social initiations. Age and gender were controlled for in the analysis. Results indicated the main effect of status on percentage of initiations during a parent-child free-play task was significant ($B = -.581$, CI_{95} [-.937, -.225], $p = .002$). The main effects of expressive ($B = .000$, CI_{95} [-.003, .003], $p = .980$) and receptive language ($B = .001$, CI_{95} [-.003, .005], $p = .722$) on social initiations were not significant. The interaction effect of receptive language and status was significant ($B = .006$, CI_{95} [.001, .012], $p = .033$) but expressive language and status was not ($B = .003$, CI_{95} [-.003, .008], $p = .336$). Children with ASD and lower receptive language had the lowest percentage of social initiations. Results indicated that 39% of the variance in social initiation was accounted for by the variables in our model.

Conclusions: Supporting previous research, children with ASD in this study exhibited fewer social initiations than their TD peers. In the current study, social initiative behaviors were moderated by receptive but not expressive language, consistent with prior research on differences in receptive and expressive language for children with ASD (Hudry et al., 2009). Our findings suggest receptive language may be an important target for intervention to increase social initiation in young children with ASD.

Poster Session
112 - Miscellaneous
11:30 AM - 1:30 PM - Hall Grote Zaal

232 **112.232** Do Kids with Autism Get "the Feels"?; Making Sense of Interoception

***C. Tierney-Aves**[1], K. Mahler[1], A. Lazzara[2], M. Veglia[2], C. Lucas[2] and E. Miller[2], (1)Penn State Hershey Medical Center, Hershey, PA, (2)Penn State Hershey College of Medicine, Hershey, PA*

Background:

Professionals suspect that children with Autism Spectrum Disorder (ASD) have differences with their interoceptive system, defined as the sensory system that allows us to experience internal physiological sensations. Awareness of these interoceptive sensations is what underlies our ability to clearly interpret our emotions such as anger, anxiety, calm and distractibility.

Objectives:

The purpose of our study was to compare how parents of teens with and without high functioning autism interpret their child's levels of interoceptive awareness.

Methods:

Our study consisted of a 55 item Likert Scale survey administered to parents of teens with and without high functioning autism, and the responses were compared. For the purpose of this poster, we calculated average composite scores for eleven questions that targeted general emotional awareness (general emotional composite, GEC), three that targeted the perception of anger (anger composite, AC) and three that targeted the perception of calm (calm composite, CC). Lower scores indicate less interoceptive awareness. A two-sampled t-test was used to compare averages between ASD and controls and Cohen's d was used to determine effect size.

Results:

The ASD group consisted of 81 parents of teens. The average age of the teens in the ASD group was 13.65 years and 75% were boys. The control group consisted of 96 parents of teens. The average age of the teens in the control group was 12.91 years and 50% were boys. The ASD group had a significantly lower GEC than the control group (1.80 vs. 2.58, p<0.001, Cohen's d 2.19). The ASD group also had a significantly lower AC than the control group (1.82 vs. 2.48, p<0.001, Cohen's d 1.46) and lower CC than the control group (2.07 vs. 2.57, p<0.001, Cohen's d 1.05).

Conclusions:

Our study was the first to survey interoceptive awareness in teenagers with and without high functioning autism. Our results suggest that when compared to neurotypical controls, the parents of high functioning autistic teens interpret their children as less aware of their interoceptive sensations leading to reduced emotional awareness.

233 **112.233** Evaluating Digital Social Stories

E. Smith[1], *H. Johnson*[1], *A. Constantin*[2] *and M. Brosnan*[3], *(1)University of Bath, Bath, United Kingdom, (2)University of Edinburgh, Edinburgh, United Kingdom of Great Britain and Northern Ireland, (3)Centre for Applied Autism Research, University of Bath, Bath, United Kingdom of Great Britain and Northern Ireland*

Background:

Social stories are a widely used intervention for people with a diagnosis of Autism Spectrum Disorder (ASD). Practitioners perceive them to be highly effective but meta analyses of the research literature reveals mixed findings. Crucial influences upon the effectiveness of social stories is argued to be in the consistency of their development and delivery as well as the behaviours targeted for intervention. The majority of existing research literature has focussed on evaluating effectiveness relating to either increasing or decreasing a specific behaviour. However, in practice the most common use of social stories by parents and practitioners is for supporting children with novel events and transitions.

Objectives:

The Digital social stories iPad app has been developed through participatory design and was evaluated for its impact upon supporting children with ASD in preparation for a novel event.

Methods:

Participants were 10 autistic children (8 male; 2 female), aged 7-11. All children were due to attend a 4-day school summer camp and their teacher had identified a specific area/event that was anticipated to cause a high level of concern/anxiety and problematic behaviours (e.g. being away from their family, eating different food). A unique social story was written for each child within the digital social stories app and presented on the iPad. The researcher read the social story with the child every day during the week before the camp. The child's teacher rated their level of anxiety, understanding and closeness to their individual target goal (identified in the social story) on an 11 point scale (0-10) before and after the social story intervention. A rating of problem severity during camp was also obtained.

Results:

Results revealed a significant increase in the child's perceived level of understanding (t = 2.34, p = 0.044), a move towards achieving the child's individual goal (t = 4.15, p = 0.002), and a decrease in perceived anxiety levels (t = 4.49, p = 0.002) when comparing the pre- and post- intervention teacher ratings. Problem severity during camp was also significantly correlated with getting closer to the goal (difference between pre- and post measure) r = 0.66, p = 0.038. Changes in anxiety (r = .57, p = 0.089) and understanding (r = 0.50, p = 0.14) were not significantly correlated with problem severity but did indicate a trend in the right direction.

Conclusions:

Empirical support was found for using Digital social stories to help children prepare for a novel, potentially challenging event by decreasing anxiety, increasing understanding and facilitating a move towards the child's individual target goal. Much research on social stories to date has been single case study design and this study represents a relatively large sample size, as well as focussing upon supporting upcoming events that may be challenging, rather than a specific challenging behaviour (which is typically the focus within the research literature).

Individual child profiles will be presented (anonymously) as well as the group data. Funding for the project was provided by The Leverhulme Trust.

234 **112.234** Video Self-Modeling to Modify Aggressive Behaviors in Students Significantly Impacted By Autism Spectrum Disorder

K. M. Sadler, *Curry School of Education and Human Development, University of Virginia, Charlottesville, VA*

Background:

Research has demonstrated that Video Self-Modeling (VSM) is an effective intervention for children with ASD, often producing substantial changes in the student's behavior (Bellini, 2016; Dowrick, 2012). VSM has tremendous potential to address disruptive behavior and aggression for students significantly impacted by ASD. For example, processing visual information is preferable to those with limited symbolic communication (Corbett & Abdullah, 2005; Foss-Feig, et al., 2016; Snell, et al., 2008). In addition, the modeled applications of skills presented in the videos is preferable to individuals with extreme dislike of social interactions (Buggey, 2005; Corbett & Abdullah, 2005). Furthermore, restricted interests or hyper-focused attention, could be utilized by individualizing the VSM to allow for higher likelihood of engagement (Dowrick, 2012; Gelbar, et al., 2012). Essential to the present study is the fact that within the published research, the use of VSM to reduce aggressive behavior was only demonstrated in one study, with an individual mildly impacted by ASD (Buggey, 2005). Despite it's potential, this is the only documented study that used VSM to decrease aggressive behaviors of students with ASD and there is no record of using VSM to decrease aggressive behaviors in students severely impacted by ASD.

Objectives:

The following research questions were addressed; (1) Can an antecedent based VSM technique be used to decrease high rates of aggressive behaviors for individuals severely impacted by ASD? (2) What effect will adding a direct instruction component to the antecedent based VSM technique have on the frequency of aggressive behavior? It is hypothesized that pre-planned, direct instruction in addition to regular viewings of the VSM, would aid in the acquisition of pro-social skills, and decrease incidents of aggressive behavior in a population of students with exacerbated ASD symptoms.

Methods:

A three series multiple baseline design was used with an intervention introduction at a different point in each series (Horner, et al., 2005). In this model each participant serves as his own control (baseline data on the dependent variable was collected for each participant until a trend emerged). A preference assessment, using a semi-structured interview, was conducted with the student's caregiver, classroom teacher, and behavior analyst. Preferences identified in the interview were tested by the primary researcher by applying reinforcement for various behaviors, not targeted in this study, and observing the consequential behaviors.

Results:

All participants demonstrated decreases in overall disruptive behavior according to the data collected (frequency counts, teacher interviews, field notes) during the intervention phase. Pro-social skills, demonstrated increases at differing rates per participants. Two students generalized skills to various settings and contexts.

Conclusions:

From the data, it appears that a VSM technique can be used to decrease the aggressive behaviors of individuals severely impacted by ASD. Further exploration needs to occur before a causal relationship between the dependent and independent variables can be determined. However, this experiment provides convincing evidence that combining a school-based functional assessment with a VSM intervention has the potential to treat persistent aggression often seen in students with ASD.

Oral Session - 1A
Diagnostic, Behavioral & Intellectual Assessment
113 - Detecting and Diagnosing ASD in Toddlers

1:45 PM - 2:35 PM - Grote Zaal

1:45 **113.001** Validating a New Visual Screener for Autism in an Unselected Sample of Low Income and Ethnic Minority Children

J. Harris[1], *Y. M. Janvier*[2], *C. N. Coffield*[3], *D. S. Mandell*[4], *Z. Cidav*[5], *M. Lopez*[6] *and N. V. Gonzalez*[6], *(1)Children's Specialized Hospital, Mountainside, NJ, (2)Medical, Lehigh Valley Medical Center, Allentown, PA, (3)Pediatrics, Rutgers RWJ Medical School, New Brunswick, NJ, (4)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (5)University of Pennsylvania, Philadelphia, PA, (6)Autism, Children's Specialized Hospital, Fanwood, NJ*

Background:

Significant disparities exist in early access to care among low income and minority children at risk for ASD. These disparities may be due in part to the lack of ASD screening tools designed for this population. Existing tools typically require parents to have sophisticated reading comprehension and understanding of developmental milestones. The Developmental Check-In (DCI), a primarily visual tool with minimal literacy demands, was developed specifically for this population. Previous research with the DCI found that it outperformed the Modified Checklist for Autism in Toddlers-Revised (MCHAT-R) and Social Communication Questionnaire (SCQ) at identifying ASD among young underserved children at risk for ASD.

As a next step in validating the DCI, we examined its psychometric properties in an unselected sample of young underserved children.

Objectives:

To compare the performance of the DCI with that of other, validated ASD screening tools (M-CHAT-R & SCQ) in detecting ASD among an unselected sample of young underserved children.

Methods:

Subjects were 24 to 60 month old children enrolled at Head Start programs, which are located in underserved communities and serve low income families. Parents completed the DCI, MCHAT-R, SCQ, medical history form, adaptive behavior measure (ABAS) and demographic information. Parents provided consent for their child’s Head Start teacher to complete the same 3 screening tools. Evaluations were offered to children at risk on any parent or teacher-completed screening tool. The children were evaluated using the Mullen Scales of Early Learning and the ADOS-2. Clinical diagnosis was determined by a licensed, experienced clinician (developmental pediatrician, psychologist or advanced practice nurse) based on patient history, clinical observation and ADOS-2 classification. Differences in performance were estimated using receiver operating characteristic curves.

Results:

Completed parent-report measures were collected for 439 children. Child care providers also completed screening for 68% of the sample. Forty-one children (9%) were subsequently diagnosed with ASD. The parent-completed DCI better identified children at risk for ASD than the MCHAT-R ($p<0.0001$) or the SCQ ($p= 0.0139$). Area under the curve in the ROC analysis was 0.84, 0.67, and 0.76, respectively. For teacher-completed tools, there were no significant differences between the DCI and the MCHAT-R ($p = 0.06$) or SCQ ($p = 0.48$).

Conclusions:

The parent-report version of the DCI performed better than two validated screening tools in identifying young children with ASD who were from families with low income, and/or who were non-white, Hispanic, and/or for whom English was not the primary language spoken in the home. When considered with previous findings that the DCI also performed better among young, underserved children at-risk for ASD, the DCI is a promising tool for reducing disparities in diagnosing ASD. Based on the rate of ASD (9%) among children with completed parent screens, this study also suggests that ASD screening in underserved childcare settings is a useful method for identifying children at risk.

1:57 **113.002** Cognitive and Behavioural Differences in Toddlers with Autism Spectrum Disorder from Multiplex and Simplex Families

C. Dissanayake[1,2,3]*, J. P. Searles*[4]*, J. Barbaro*[1] *and N. Sadka*[1]*, (1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)Olga Tennison Autism Research Centre, Bundoora, Australia, (4)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, Australia*

Background: Studies of 'high-risk' siblings have provided valuable information regarding the early Autism phenotype and our understanding of the early developmental trajectories of affected individuals later diagnosed with Autism Spectrum Disorder (ASD). However, it remains unclear whether these cases of affected siblings are representative of the wider population of children with ASD. To date there is only one published (Taylor et al., 2015) and one unpublished (Pandey, 2008) study on this topic, with inconsistent findings, and both failing to take account of birth order in determining whether children are from Simplex families.

Objectives: Our objective was to investigate whether the early development of toddlers with ASD from Multiplex (MPX) families, who have an affected older sibling, is similar to toddlers from Simplex (SPX) families where there is no affected sibling or family member. A further aim was to determine the pattern of association between ASD symptom severity and cognitive functioning within each group to help shed light on possible mechanisms for group similarities/differences.

Methods: Behavioural and cognitive assessment data, as well as demographic details, from an un-selected sample of 244 toddlers, diagnosed with ASD (183 males) at age 2-years, were utilised to address the study aims. The sample comprised 45 MPX children, 127 first-born (FB) SPX children and 72 later born (LB) SPX children. Children in each group, matched on age, gender and parental education, had been administered the Autism Diagnostic Observational Schedule (ADOS) and the Mullen Scales of Early Learning (MSEL) to assess their autism symptoms and cognition, respectively. Parents had been administered the Autism Diagnostic Interview (ADI-R). The test administrators were blind to the study aims.

Results: MPX children had significantly higher developmental quotients (DQ), with differences found on Verbal, Nonverbal, and Overall DQ between the MPX group and each of the FB SPX and LB SPX groups; the SPX groups were not different from each other. The three groups did not differ on overall symptom severity as measured on the ADOS, or on their Social Affect (SA) and Restricted and Repetitive Behaviour (RRB) scores. No group differences were found on the ADI-R Social Interaction or Communication domains, with the only difference being that the SPX LB children had lower scores on the RRB domain compared with the other groups. Although autism symptom severity (ADOS and ADI-R scores) and the MSEL DQ scores were negatively correlated in each group, the groups were similar in the pattern of relationship found between autism severity and cognitive ability.

Conclusions: The different cognitive profiles between MPX and SPX groups suggest that findings from high-risk sib studies may not generalise to other samples of children with ASD. It is important that future research examine biological and environmental factors that may explain the enhanced cognitive development of children with ASD from MXP families.

2:09 **113.003** Early Identification of ASD through Telemedicine: Potential Value for Underserved Populations

N. A. Broderick[1]*, P. Juárez*[2]*, A. S. Weitlauf*[3]*, A. Nicholson*[4]*, A. Pasternak*[5]*, J. F. Hine*[2]*, A. Stainbrook*[6] *and Z. Warren*[2]*, (1)Pediatrics, Vanderbilt University Medical Center - Treatment and Research Institute for Autism Spectrum Disorder, Nashville, TN, (2)Vanderbilt University Medical Center, Nashville, TN, (3)Vanderbilt Kennedy Center, Vanderbilt University Medical Center, Nashville, TN, (4)Vanderbilt University, Pleasant View, TN, (5)Vanderbilt Kennedy Center/TRIAD, Nashville, TN, (6)Vanderbilt Kennedy Center, Nashville, TN*

Background: There is growing evidence that accurate, stable diagnosis of ASD is possible during the second year of life and very young children with ASD receiving early behavioral intervention services demonstrate substantial gains in functioning. Although early diagnosis of ASD is possible in the first years of life, children from traditionally underserved communities are often not identified until much later ages. Substantial evidence suggests that families from low-resource communities struggle to access evaluation services through diagnostic centers, even when universal screening programs are implemented. Such diagnostic delays and health disparities contribute to family stress and restrict access to ASD intervention services. These struggles highlight the need for novel approaches to ASD screening, evaluation, and diagnostic decision-making that will realistically advance early detection and intervention, particularly for families facing geographical and resource barriers. Telemedicine and telehealth initiatives have improved access and care outcomes in other populations and may be a mechanism for accurately identifying young children with ASD.

Objectives: This work evaluated the benefit of a telemedicine evaluation procedure for young children at risk for ASD. First, we assessed telemedicine-based diagnostic accuracy in relation to blinded gold-standard evaluations. Second, we evaluated feasibility and family- and provider-rated acceptability of implementation in a telehealth facility serving a rural catchment

Methods: Children (n=20) and caregivers in the diagnostic accuracy study participated in a telemedicine evaluation [diagnostic interview and observation using Screening Tool for Autism in Toddlers (STAT)] with a licensed clinical psychologist (mean practice = 6.2 years) and then immediately were evaluated in person by a blinded clinician utilizing comprehensive assessment methods (Mullen, Vineland, ADOS-2, and diagnostic interview).

Children (n=45), their caregivers, and clinicians in the feasibility and acceptability study participated in the telemedicine procedures within a rural health clinic and provided data regarding the diagnostic experience via an anonymous follow-up survey.

Results: In the diagnostic accuracy study, all cases of ASD identified via telemedicine were confirmed by comprehensive in-person evaluation. However, 20% of children ultimately diagnosed with ASD in-person had not been assigned an ASD diagnosis as a result of the telemedicine procedure. Both clinician best estimate diagnosis and telemedicine assessment instrument yielded these results.

In the follow-up study, families and clinicians in the rural health clinic model indicated high levels of satisfaction with telemedicine procedures.

Remote diagnostic clinicians felt it appropriate to issue an ASD diagnosis for approximately 62% of children evaluated with this model; approximately 24% were not diagnosed with ASD. They did not feel definitively capable of ruling-in or out ASD based on this consultation in a minority of (approximately 13%) of cases.

Conclusions: The findings support the feasibility, preliminary accuracy, and potential clinical utility of telemedicine-based assessment procedures for accurately identifying young children with ASD in traditionally underserved rural communities. Both families and system providers indicated that telemedicine consultation may be desirable and overcome traditional barriers to diagnosis in underserved communities. Future evaluation of broader applications of telemedicine-based diagnostic assessment procedures is warranted to more fully understand ultimate potential clinical and service system benefit.

2:21 **113.004** Effectiveness of the STAT and STAT-Q within a Multidisciplinary Assessment for Early Identification of Autism Spectrum Disorder

***V. Nanclares-Nogues**, Pediatric Developmental Center, AIMMC, Advocate Children's Hospital, Chicago, IL*

Background: To date, no consistent assessment protocol is used across health care systems to establish early diagnosis of autism spectrum disorders (ASDs). The American Academy of Pediatrics (AAP) has suggested the use of both Level I screening of all children starting at 18 months using the M-CHAT (Robins et. al., 2001) or similar tools, and comprehensive evaluations for children who screen positive for autism risk. While the AAP recommends ongoing screening starting at 18 months, these guidelines are not being implemented consistently. In Illinois, children who are seen for early diagnosis are assessed by a multidisciplinary team within a Medical Diagnostic Evaluation (MDX) with no consistent protocol. Implementation of a consistent protocol utilizing a standardized level II screener -the Screening Tool for Autism in Toddlers and Young Children (STAT: Stone, Coonrod, Turner & Pozdol, 2004) along with developmental testing and clinical judgment - has the potential to enhance accuracy of ASD diagnosis in young children in a cost-effective manner. In addition, the STAT-Q Parent Questionnaire allows for parent input and increases understanding of the child.

Objectives: This study aims to analyze the specificity and sensitivity of both the STAT and the STAT-Q as part of a consistent protocol for identifying young children with ASD in an effort to develop a standardized screening protocol that is both clinically effective and financially viable.

Methods: 95 children 18 and 36 months of age, both English and Spanish-speaking, were assessed through the MDX utilizing developmental testing, autism specific validated instruments, as well as clinical judgment. Three groups were developed to compare sensitivity and specificity of the STAT and STAT-Q within this multidisciplinary evaluation: Group I- STAT compared to overall diagnosis; Group II-STAT-Q with overall diagnosis; and Group III- STAT-Q with positive screen on the STAT.

Results: Diagnostic Odds Ratios (DOR) was used as a measure of the overall diagnostic power of each tool. Receiver-operating-characteristic (ROC) analysis was performed to assess and compare the sensitivity and specificity of the STAT and STAT-Q when compared to overall diagnosis. Preliminary results show strong sensitivity and specificity of the STAT (97.5% and 73% respectively), with slightly lower sensitivity and specificity of the STAT-Q with clinical diagnosis (approximately 65% and 40% respectively); higher sensitivity when comparing the STAT-Q with the STAT (mothers 78% versus fathers 65%) and lower specificity of the STAT-Q with the STAT (mothers 20% and fathers 36%). A much larger sample (>150) will be available by April 1, 2018 to further describe positive predictive value of using these instruments within a multidisciplinary assessment. We will also examine impact of age, gender, and language on these relations.

Conclusions: This project hopes to demonstrate the effectiveness of the STAT and STAT-Q within multidisciplinary assessment of young children utilizing a standardized tool, including parent concerns, along with clinical judgment. These tools are efficient, sensitive, and cost effective; thus, the project has the potential to contribute to the creation of a standardized protocol for accurate early identification of ASD, allowing children to get into appropriate intervention programs at younger ages.

2:40 **114.001** Investigating the Factors Underlying Discrepancies in IQ and Adaptive Functioning in ASD in the EU-AIMS Longitudinal European Autism Project (EU-AIMS LEAP)

***J. Tillmann**[1], T. Banaschewski[2], S. Bolte[3], J. K. Buitelaar[4], A. San Jose Caceres[5], C. H. Chatham[6], D. V. Crawley[5], R. Holt[7], E. Loth[5], B. Oakley[5], E. Simonoff[8] and T. Charman[9], (1)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom of Great Britain and Northern Ireland, (2)Child and Adolescent Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany, (3)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (4)Department of Cognitive Neuroscience, Donders Institute for Brain, Cognition and Behaviour, Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (5)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Neuroscience, Ophthalmology, and Rare Diseases (NORD) Roche Pharma Research and Early Development. Roche Innovation Center Basel, Hoffmann La Roche, Basel, Switzerland, (7)University of Cambridge, Cambridge, United Kingdom, (8)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (9)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Individuals with Autism Spectrum Disorder (ASD) exhibit significant impairments in their adaptive functioning. A recurrent finding is that the level of adaptive functioning is significantly lower than would be expected based on cognitive ability, and that this discrepancy is particularly prominent among higher-ability individuals. This suggests that despite having intact verbal and non-verbal processing skills, many individuals with ASD are having difficulty functionally applying their cognitive strengths to daily contexts. The factors that underlie these

discrepancies remain however poorly understood.
Objectives: We investigated IQ-adaptive functioning discrepancies in relation to age, sex, IQ, levels of ASD symptom severity and associated psychiatric symptomatology (e.g. symptoms of ADHD, anxiety and depression) in the EU-AIMS LEAP cohort.

Methods: 299 children and adults with ASD between the ages of 6 and 30 years with IQs varying between 75 and 148 were included in the analysis. First, binary logistic regressions were used to examine predictors of an "IQ-adaptive functioning deficit" across Vineland domains following Duncan & Bishop (2015), whereby a deficit was determined differently for subjects with full-scale IQ (FSIQ) between 75-99 (IQ-Vineland difference score of at least 1SD: ≥ 15) than for subjects with FSIQs ≥ 100 (Vineland domain score falling below the adequate range: i.e. <85). For those that had a deficit as defined above, multivariate regressions were then used to examine predictors of the magnitude of the IQ-adaptive discrepancy.

Results: Across Vineland domain scores, 60-75% of subjects with ASD had an IQ-adaptive functioning deficit (e.g. IQ-Vineland composite discrepancy: $M = 30.9$, $SD = 17.2$, $Min = -21.1$, $Max = 78$). Model comparisons using binary logistic regression accounting for age, sex and full-scale IQ showed that including ASD symptom measures significantly improved the model fit over and above measures of psychiatric symptom measures, but not vice versa. In relation to unique predictors of an adaptive functioning deficit, we found that higher scores (i.e. greater symptoms) for repetitive/ restrictive behaviours or interests (RBS-R; p from .028 to .007) and greater social communication symptoms (SRS-2; p from .08 to .005), significantly predicted an adaptive functioning deficit across most domains. Conversely, we found little evidence that other psychiatric symptoms affected the likelihood of exhibiting a deficit. Older age and higher FSIQ were significant predictors for adaptive functioning deficits; for the adaptive behaviour composite only, males had significantly higher odds of exhibiting a deficit. For those subjects with a deficit, multivariate regression models demonstrated that higher SRS-2 ($p < .001$) and higher RBS-R scores ($p = .03$), but not scores on measures of associated psychiatric conditions, were significant predictors of the IQ-adaptive functioning magnitude.

Conclusions: The findings demonstrate that both the presence/absence of an adaptive functioning impairment in individuals with ASD, as well as the magnitude of such a deficit in relation to cognitive skills, is related to core ASD symptom characteristics more so than to other commonly associated psychiatric symptoms.

2:52 **114.002** Psychometric Properties of Questionnaires and Diagnostic Measures for Autism Spectrum Disorders in Adults: A Systematic Review

S. Wigham[1], *J. Rodgers*[2], *T. Berney*[3], *A. LeCouteur*[3], *B. Ingham*[4] *and J. R. Parr*[2], *(1)Institute of Neuroscience, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (3)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (4)Northumberland Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom*

Background: Accurately diagnosing autism spectrum disorders (ASD) in adulthood can be challenging. Structured questionnaires (SQs) and diagnostic measures (DMs) are frequently used to assist case recognition and diagnosis.
Objectives: This study reviewed research evidence on SQs and DMs published since the UK National Institute for Health and Care Excellence evidence update (NICE; 2014).

Methods: The Cochrane library, Medline, Embase and PsycINFO were searched.

Results: Nineteen studies met inclusion criteria. Sensitivity and specificity of SQs was best for individuals with previously confirmed ASD diagnoses, and reduced in participants referred for diagnostic assessments, with discrimination of ASD from mental health disorders especially limited. For adults with intellectual disability diagnostic accuracy increased when a combination of SQs were used. Evidence suggests some utility of DMs in identifying ASD amongst clinic referrals, though specificity for diagnosis was relatively low.

Conclusions: In mental health settings the use of a single SQ is unlikely to accurately identify adults without ASD, or differentiate ASD from mental health disorders. This is important as adults seeking an ASD diagnostic assessment are likely to have co-existing mental health disorders. Robust ASD assessment tools specifically for use in adult diagnostic health services in the presence of co-occurring mental health and neurodevelopmental disorders is a research priority.

3:04 **114.003** Self-Reports Vs Observer Ratings of Autistic Traits: A Comparison of Their Validity over the Adult Lifespan

A. Roestorf[1], *S. B. Gaigg*[2], *D. M. Williams*[3] *and D. M. Bowler*[4], *(1)Psychology, City University London, London, United Kingdom of Great Britain and Northern Ireland, (2)City, University of London, London, United Kingdom, (3)University of Kent, Canterbury, United Kingdom, (4)Autism Research Group, City, University of London, London, United Kingdom*

Background: Autism Spectrum Disorder (ASD) is a lifelong condition, yet prevalence rates in adulthood are thought to be "underestimated, under-reported and underdiagnosed due to generational effects, evolving diagnostic criteria and developmental changes across the life course" (Wright et al., 2016). Recent research (Ashwood et al., 2016) has highlighted that self-report measures of autistic traits, which are often used as screening instruments for pre-diagnostic referrals (Sizoo et al., 2015), do not correlate with observer-rated measures (ADOS-2). This has important implications for the use of self-report measures as diagnostic screeners and raises questions about factors that might play a role in poor diagnostic validity of self-reports. Age and general intellectual functioning might play an important role in this context because greater life experience and ability to contemplate ones strengths and weaknesses may render self-reports more accurate. Mental health difficulties, such as anxiety and depression, and meta-cognitive difficulties such as those characterising Alexithymia, may also be involved since such co-morbidities may skew perceptions of personal strengths and weaknesses, whilst also moderating the expression of certain clinical features (e.g., repetitive behaviours).
Objectives: We examined the association between self-report (AQ) and observer-rated (ADOS) autistic traits and explored possible moderating effects of age, age of diagnosis, intellectual ability, co-morbid mental health difficulties and alexithymia.

Methods: 109 younger (<50yrs; n = 76) and older (>50yrs; n = 33) adults with a clinical diagnosis of ASD, recruited across three sites, completed the ADOS-2, the AQ and a measure of general intellectual functioning (WAIS or WASI). A sub-sample of 40 adults completed self-report measures of anxiety (BAI), depression (BDI) and alexithymia (TAS-20).

Results: Data from 109 participants confirmed previous reports of lack of association between self-reported autistic traits (AQ) and observer-based ratings (ADOS-2; r=.128, ns). Contrary to predictions, this was true for both younger and older adults, independent of age-of-diagnosis, and for individuals with above- and below-average IQs of 100. Interestingly, however, both age (r=.34) and IQ (r=.30) were positively correlated with AQ (p<.001) but not ADOS-2 scores, suggesting that older and more able autistic adults tend to report greater autism-related difficulties even when this is not necessarily borne out in their expressed behaviour. In the sub-sample of 40 adults, anxiety, depression and alexithymia could again not account for the absent correlation between AQ and ADOS-2 scores. However, whilst AQ scores were strongly correlated with BAI (r=.47), BDI (r=.60) and TAS-20 (r=.56) scores, none of these correlated with ADOS-2 (r<.12, *ns*).

Conclusions: The findings replicate previous observations of a lack of correlation between self-report and observer-rated measures of autistic traits in older and younger autistic adults of varying ability levels. The reliable correlations between the AQ (but not ADOS) and measures of anxiety, depression and alexithymia suggest that the AQ may be sensitive to non-specific mental-health vulnerabilities rather than to the defining characteristics of ASD specifically. These findings hold important implications for clinical practice concerning referral for diagnosis in adulthood and later life, and post-diagnostic support pathways that enable autistic individuals to achieve better quality of life.

3:16 **114.004** Predictors of Adaptive Behavior in Adolescents with ASD

B. Tomaszewski[1]*, S. Odom*[1]*, L. E. Smith DaWalt*[2] *and K. Hume*[1]*, (1)Frank Porter Graham Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC, (2)University of Wisconsin-Madison Waisman Center, Madison, WI*

Background: Individuals with ASD demonstrate adaptive behavior difficulties regardless of intellectual functioning. Adaptive behavior is considered critical for performing tasks independently and better adaptive behavior skills are associated with greater opportunities for postsecondary employment. Prior research on adaptive behavior in adolescents with ASD typically includes only individuals with high functioning ASD (i.e., IQ > 70) and is from predominantly White samples. The present study aims to examine adaptive behavior in ASD in a large, diverse national sample of high school students with ASD across the full range of intellectual functioning and autism symptomology.
Objectives: The purpose of the current study was to (1) describe the communication, daily living skills, and socialization adaptive behavior profiles in adolescents with ASD and (2) examine the effects of intellectual functioning and autism symptomology on the adaptive behavior profiles in adolescents with ASD.

Methods: Adolescents with ASD (n=547) were part of a larger RCT of a comprehensive treatment model for high school students with ASD (mean chronological age= 16.2 years SD=1.44 years, range=14-21 years). 43% of the sample was non-White. The current study utilizes data collected prior to the intervention. Nonverbal IQ (NVIQ) was assessed using the Leiter International Performance Scales- 3rd edition. Teachers completed the Vineland Adaptive Behavior Scales, 2nd edition- Teacher Report as a measure of adaptive behavior and the Social Responsiveness Scale-2nd edition (SRS-2) as a measure of autism symptomology. A multivariate multiple regression was performed to examine the extent to which intellectual functioning and autism symptomology predicted communication, daily living skills, and socialization domains of adaptive behavior.

Results: Findings indicated that adolescents with ASD had an average NVIQ of 85.5 (SD=27.2, range=30-141) and SRS-2 score of 70.4 (SD=12.2, range=39-110). The average adaptive behavior scores on communication were 77.6(SD=18.2., range=20-122), daily living skills were 80.8(SD=17.6, range=20-121), and socialization were 73.8(SD=14.4, range=30-122). Intellectual functioning and autism symptomology were significant predictors of adaptive behavior and accounted for 52% of the variance in communication, 52% of the variance in daily living skills, and 51% of the variance in socialization. Increases in NVIQ scores were associated with higher communication (B = .36, SE=.02, p <.001), daily living skills (B= .33, SE=.02, p <. 001), and socialization (B= .13, SE=.02, p <.001) standard scores controlling for autism symptomology. Higher autism symptomology was associated with lower communication (B = -.51, SE= .05, p <.001), daily living skills (B = -.50, SE=.50, p < .001), and socialization (B=-.71, SE=.04, p < .001) standard scores controlling for intellectual functioning.

Conclusions: This study represents the largest current sample of high school students with ASD. Adolescents with ASD in this diverse sample represented the full range of intellectual functioning and autism symptomology. On average, adaptive behavior scores were significantly below the standardization sample mean indicating that this sample demonstrates adaptive behavior difficulties. Higher intellectual functioning and lower autism symptomology were associated with greater adaptive behavior skills. Findings suggest the significance of adaptive behavior as an important area for targeted interventions during adolescence.

Background: Understanding the developmental trajectory of neuronal mechanisms underlying autism spectrum disorder (ASD) is critical to developing effective treatments. Resting state EEG provides an index of cortical neuronal oscillations that reflects brain function. Previous studies have used resting state EEG to compare local and long-range synchronization of neuronal oscillations between individuals with ASD and neurotypical controls. Although ASD-related alterations have been described in a large number of studies, findings are very heterogeneous and inconsistent. Well-powered studies providing an unbiased evaluation of putative resting-state EEG abnormalities in ASD are urgently needed.
Objectives: The present study evaluates the developmental trajectories of resting state power spectrum and functional connectivity in high

functioning ASD from childhood to adulthood in a comprehensive and large dataset and in comparison to TD.

Methods: EEG data were acquired as part of the EUAIMS Longitudinal European Autism Project (LEAP) (www.eu-aims.com). Clinical diagnosis of ASD was established with DSM-IV / ICD-10 or DSM-5. In this analysis, 141 TD and 153 ASD participants between 6 and 30 years and IQ>70 were included. Subjects underwent a resting state EEG (2 min eyes open, 2 min eyes closed in alternating blocks of 30 sec, 5 centers, 60 or more EEG channels). Power spectra and functional connectivity were evaluated in sensor and source space. Source time series were extracted using beamforming and finite element forward models built from individual MRIs. Power spectra (1-32) Hz were computed with Morlet wavelet transform. Functional connectivity was estimated between sensors and between 50 regions of interest (source space analysis) using phase and amplitude synchronization measures (phase locking value, phase lag index and power correlations). Statistical modeling was performed with linear-mixed effects models with group, age, gender, IQ, and all interactions with group as fixed effects, recording site as a random effect, and allowing for different variances for ASD and TD groups (nlme package in R). The analysis was unbiased with respect to directionality of the effect, spatial location, and frequency; cluster based permutation techniques were employed to account for multiple comparisons.

Results: Highly significant age-related changes were found both for power spectrum and functional connectivity. Relative power decreased with age at lower frequencies (2-6Hz) and increased at higher frequencies (10-32Hz). Functional connectivity showed complex patterns of age modulations. Whole brain averaged functional connectivity values increased robustly with age in 4-20 Hz range for power correlations and phase locking value. These age-related modulations are in line with previous literature demonstrating the validity and sensitivity of our power spectral and functional connectivity estimates. No significant group effects (p>0.05, main effect or interactions with age, IQ or gender) in mean or variance were found in power spectrum or functional connectivity.

Conclusions: Both resting state power spectrum and functional connectivity showed strong age-related maturation from childhood to adulthood in high functioning ASD and TD cohorts. However, we did not find differences between ASD and TD in both measures. This indicates that, across brain rhythms, local and long-range synchronization in high functioning ASD may mature according to a typical developmental trajectory.

1:57 **115.002** Altered Resting-State Functional Connectivity in Individuals with ASDs and Impaired Cognitive Functioning

M. A. Reiter[1,2]*, L. E. Mash*[1,2]*, J. Liu*[2]*, C. H. Fong*[3]*, A. C. Linke*[3]*, I. Fishman*[3] *and R. A. Mueller*[3]*, (1)Joint Doctoral Program in Clinical Psychology, SDSU / UC San Diego, San Diego, CA, (2)Brain Development Imaging Laboratories, Department of Psychology, San Diego State University, San Diego, CA, (3)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA*

Background: General functional level, as measured by IQ, is an important correlate of adaptive functioning (Liss et. al, 2001), a set of cognitive, social, and practical abilities enabling mastery of age-expected daily-living skills. Although >50% of individuals with Autism Spectrum Disorders (ASDs) exhibit IQ scores below 85 (CDC, 2014), little is known about functional brain organization in this population, as high-quality fMRI data can usually only be collected from high-functioning individuals. Improved understanding of brain mechanisms that predict long-term outcome in broader segments of the ASD spectrum is an urgent research priority.

Objectives: To examine intrinsic functional connectivity (iFC) in children and adolescents with ASDs and IQ≤85 (L-ASD) in comparison with typically developing (TD) and ASD peers with higher IQ (H-ASD).

Methods: T1-weighted anatomical and eyes-open fMRI resting-state scans from 88 individuals (44 ASD, 44 TD) were taken from in-house data (SDSU: n=36) and two sites (NYU: n=28; OHSU: n=24) from the Autism Brain Imaging Data Exchange (ABIDE). The full sample was split by diagnosis and IQ scores into 4 groups of 22 individuals (L-ASD [IQ≤85] mean IQ: 77±6; H-ASD: 123±8; Average-TD [A-TD]: 100±7; High-TD [H-TD]: 124±8). All groups were matched within and across scanning-sites on head-motion, age, gender, and handedness.

Following standard preprocessing, mean timeseries were extracted from seeds in the medial prefrontal cortex (mPFC), posterior cingulate cortex (PCC), posterior superior temporal sulcus (pSTS), insula, and amygdala, and entered into a subject-level GLM. Whole-brain group differences in iFC for 4 contrasts of interest (L-ASD vs. H-ASD, L-ASD vs. A-TD, H-ASD vs. H-TD, and A-TD vs. H-TD; Figure 1) were examined using AFNI 3dttest++. All results were significant at a voxelwise $p < .005$, corrected to control for false-discovery rate ($\alpha < .05$) using permutation testing.

Results: Compared to the H-ASD group, the L-ASD group showed significantly weaker positive iFC between the mPFC and PCC, and between pSTS bilaterally and occipital cortices (Figure 2). Compared to the A-TD group, the L-ASD group showed increased connectivity between mPFC and cuneal and intracalcarine cortex. Compared to the H-TD group, the H-ASD group had higher connectivity (mostly reduced anti-correlations) between the PCC and right superior frontal gyrus, right anterior insula, and left Crus-1 of the cerebellum. Group differences were largely consistent across scanning sites. There were no significant iFC differences between the two TD groups.

Conclusions: Our findings suggest that within the autism spectrum, general functional level may be associated with specific patterns of functional network abnormalities, affecting social-processing regions and core hubs of the default-mode and salience networks. Remarkable in L-ASD participants was atypical iFC with visual cortices, reduced for social cognition (pSTS), but increased with a default mode region (mPFC). Some earlier findings have suggested that visual cortex may play compensatory roles in ASDs (Simard et al., 2015), and our findings suggest that any such mechanisms may be less engaged in individuals with L-ASDs. Our preliminary study illustrates the importance of including individuals with L-ASDs in research seeking to relate brain functioning in autism to long-term outcome variables.

2:09 **115.003** Autistic Syndrome Modulates Interpersonal Neural Synchronization in Children with Autism Spectrum Disorder in Cooperative Interactions

Q. Wang[1]*, T. Liu*[2]*, Z. Han*[3]*, X. Hu*[4]*, H. Wang*[3]*, Y. Wu*[5] *and L. Yi*[6]*, (1)Peking University, Beijing, China, (2)School of Management, Zhejiang University, Hangzhou, China, (3)Beijing Normal University, Beijing, China, (4)Department of Special Education, Beijing Normal University, Beijing, China, (5)School of Psychological and Cognitive Sciences, Peking University, Beijing, China, (6)School of Psychological and Cognitive Sciences and Beijing Key Laboratory of Behavior and Mental Health, Peking University, Beijing, China*

Background: The core symptom of individuals with autism spectrum disorder (ASD) includes social deficits in communication and interpersonal interaction. However, most neuroscience studies exploring the neural subtracts of the social deficits in ASD have mainly examined single participants' brain responses to pictures or video-clips displayed on a monitor from a perspective of a passive observer, due to the limitation of the brain-imaging technique.

Objectives: Our goal was to fully understand the neural processing in children with ASD during real interpersonal interactions. Especially, we wanted to test whether interactive cooperation behaviors could evoke higher interpersonal neural coherence (INC) than solo, non-interactive behaviors in children with ASD, as previously found in typically-developing individuals (e.g., Cui et al., 2012). Furthermore, we aimed to examine whether the degree of the synchronization was modulated by the severity of autistic syndrome in children with ASD.

Methods: We used a functional near-infrared spectroscopy (fNIRS) based hyper-scanning technique to simultaneously measure the prefrontal activations in 15 pairs of children with ASD (6- to 11-year-old) and their parents in a two-person key-press task. The children's task was to press a key when a "go" signal was present to show synchronized behavior with their parents in a cooperation condition or to press a key as fast as possible under observation of their parents in a single condition. We also measured these children's severity of autistic syndrome using the autism spectrum quotient (AQ).

Results: Behavioral results were shown in Figure 1. Children showed worse performance in the cooperation condition than in the single condition. Additionally, we found positive correlations between DRT (difference of response time between the children and their parents in the cooperation condition) and AQ communication and imagination subscale scores, indicating that children with ASD with higher levels of autistic syndrome had lower action synchronization with their parents.Concerning the neural results (Figure 2), the child-parent pairs showed higher INC across their right superior frontal cortex (SFC) in the cooperation condition than in the single condition. Importantly, there were negative correlations between DINC (difference of INC between the single and cooperation conditions) and AQ communication, imagination subscale and total scores. That means children with ASD with higher levels of autistic syndrome showed less increased neural synchronization with their parents when they were engaged in interactive cooperation behaviors than in solo, non-interactive behaviors. In addition, we found a negative correlation between DRT and DINC.

Conclusions: The present study examined inter-brain communication between children with ASD and their parents in real social interactions. We found that children with ASD showed increased interpersonal neural synchronization in the right SFC in the cooperative interactions with their parents than their solo, non-interactive behaviors. Furthermore, this neural synchronization was modulated by the children's autistic syndrome, which also covaried with their cooperation task performance. Our study moved a major step forward to understanding of neural correlates underlying social deficits in ASD.

2:21 **115.004** The Non-Psychoactive Cannabinoid Cannabidivarin (CBDV) Modulates the Functional Connectivity of the Default Mode Network in Adults with ASD but Not in Controls.

C. M. Pretzsch[1]*, J. Freyberg*[2]*, B. Voinescu*[2]*, R. A. Bethlehem*[3]*, M. Leming*[4]*, M. A. Mendez*[5]*, R. H. Wichers*[6]*, L. Ajram*[7]*, E. Daly*[6]*, D. G. Murphy*[8]*, S. C. Williams*[9]*, J. Suckling*[10] *and G. M. McAlonan*[11]*, (1)IoPPN King's College London, London, United Kingdom, (2)King's College London, London, United Kingdom, (3)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (4)University of Cambridge, Cambridge, United Kingdom, (5)Forensic and Neurodevelopmental Sciences, King's College London, London, United Kingdom, (6)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)Institute of Psychiatry, London, United Kingdom, (8)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (9)Centre for Neuroimaging Sciences, King's College London, London, United Kingdom, (10)University of Cambridge, Cambridge, United Kingdom of Great Britain and Northern Ireland, (11)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Research in epilepsy indicates that the brain's endocannabinoid system is an important regulator of neural activity. The endocannabinoid system has also been suggested as a treatment target in conditions linked to epilepsy, including autism spectrum disorder (ASD). However, there is no direct evidence that cannabinoids regulate brain function differently in ASD compared to controls.

Objectives: Therefore, the aim of this pilot study was to compare brain network activity in otherwise healthy men with and without ASD following a single dose of cannabidivarin (CBDV), using functional MRI. We focused on the dorsal and ventral Default Mode Network (DMN) because of the DMN's role in social and self-reflective processes, known to be affected in ASD.

Methods: A total of 19 adults with ASD and 19 healthy controls (age-matched) were recruited to a double-blind, randomised, cross-over design. Scans were acquired 2 hours (corresponding with peak plasma levels) after oral administration of either placebo or CBDV; and were a minimum of 13 days apart to ensure adequate drug wash-out between scans. We conducted pre-planned contrasts tested with non-parametric inference at a false discovery rate (q=0.05) to examine significant DMN functional connectivity (FC): i) group differences (control n = 19; ASD n = 19) at baseline (placebo); and ii) group differences (control n = 15; ASD n = 13) in the CBDV condition.

Results: There was no statistically significant between-group difference in the dorsal or ventral DMN at baseline; there was no group difference in the dorsal DMN in the CDBV condition. However, there was a significant group difference in FC of the ventral DMN in the CBDV condition. Specifically, the ASD group had lower FC than controls between the left parahippocampal gyrus and the right posterior cingulate cortex ($t(26) = 4.78$, $p<.0001$, $d = 1.80$) and between the right parahippocampal gyrus and left posterior cingulate cortex ($t(26) = 3.44$, $p=.04$, $d = 1.32$). Post hoc testing within groups revealed that CBDV caused a significant reduction in FC between the left parahippocampal gyrus and the right posterior cingulate cortex compared to baseline ($t(28) = -2.5$, p=.02, $d = 0.91$) in ASD only; and no change in controls.

Conclusions: Our results reveal a difference in responsivity to CDBV in individuals with and without ASD. Whether this translates into a therapeutic response, and/or provides a means to identify individuals with ASD who may respond to CBDV, is not known; but this deserves further study.

116 - Neural Development in Infants at Increased Risk of ASD
2:40 PM - 3:30 PM - Willem Burger Zaal

2:40 **116.001** Early Salient Network Connectivity and Attention to Faces in Infants at High-Risk for ASD

T. Tsang[1]*, J. Liu*[1]*, L. P. Jackson*[2]*, C. Ponting*[1]*, S. Jeste*[1]*, S. Y. Bookheimer*[3] *and M. Dapretto*[3]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

Background: Attenuated attention to social stimuli during infancy, including faces, has been recognized as a risk marker for developing ASD (Chawarska, Macari, & Shic, 2012; Jones & Klin, 2013). However, little is known about its neural underpinnings, which may inform the ontogeny of autism symptomatology. Mounting evidence implicates early alterations in functional brain connectivity in the emergence of ASD (Emerson et al., 2017). Of particular interest is the Salience Network (SN), a functional brain network involved in detecting and guiding attention to the most salient aspects of one's internal and external environment. Altered SN connectivity complement behavioral observations of heightened attention to non-social sensory inputs at the expense of developmentally relevant social stimuli in ASD (e.g., Green et al., 2016). As faces represent a highly salient class of stimuli for young infants, SN connectivity may relate to trajectories in face-looking in infants at high-risk for ASD.
Objectives: The current study aims to determine whether patterns of SN connectivity at 6 weeks predict individual trajectories in social attention to faces during the first year in infants at high- (HR) and low-risk (LR) for ASD.

Methods: 50 HR and LR infants participated in a longitudinal study; risk status was determined by virtue of having at least one older sibling with a confirmed ASD diagnosis. At 6 weeks, infants completed an 8-minute resting-state fMRI scan during natural sleep. Eye-tracking was conducted at 3-, 6-, 9-, and 12-months of age while infants viewed video excerpts of *Charlie Brown* and *Sesame Street*. Percent fixation to the character's faces was recorded and longitudinally analyzed with a Bayesian hierarchical linear model. SN connectivity at 6-weeks was identified using the right anterior insula (rAI) seed derived from an infant atlas (Shi et al., 2011), and estimates of individual rate of change in face-looking from 3- to 12-months was used as a covariate in the SN connectivity analysis.

Results: The eye-tracking analyses revealed a significant interaction between risk and age, such that LR infants increasingly attended to faces at a faster rate than HR infants (95% CI: 0.38-10.54; $p<0.001$). When eye-tracking data were incorporated in the 6-week resting state fMRI analyses, greater functional connectivity between the hub of the SN (i.e., rAI) and regions associated with social processing (i.e., anterior cingulate cortex, orbitofrontal cortices, inferior frontal gyrus) in LR infants, relative to HR infants, predicted greater increases in attention to faces ($Z>2.3$, $p<0.01$).

Conclusions: Six-week-old patterns of SN connectivity predicted developmental trends in social attention to faces, suggesting that very early functional connections between regions implicated in salience detection and social processing may be foundational to the perceived salience of faces observed in typical development. Conversely, the lack of a relationship between SN connectivity and social attention to faces in HR infants may imply a disruption in normative processes underlying the development of social attention; we found HR infants trailed LR infants in normative face-looking trajectories. Differences in SN connectivity at 6 weeks strongly suggest that neural underpinnings of ASD likely begin before birth, with cascading effects on social attention.

2:52 **116.002** Functional Connectivity during Language Processing in Infants with Familial Risk for ASD

***X. A. Tran**[1], N. M. McDonald[2], A. H. Dickinson[1], J. Frohlich[3], M. Dapretto[4] and S. Jeste[1], (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)University of California Los Angeles, Los Angeles, CA, (4)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

Background: At the circuit-level, autism spectrum disorder (ASD) is characterized by disruptions in neural connectivity. Studies in early childhood have shown that resting-state frontal EEG power in the gamma (Benasich 2008, Gou 2011) and alpha bands (Levin 2017) relate to language ability. Infants are at elevated risk for developing ASD (familial-risk) if they have an older sibling with ASD; these infants are also at risk of language delay (Messinger 2015, Charman 2017). Given these elevated risks, neural connectivity during language processing in familial-risk infants warrants further investigation, particularly as it relates to language outcomes.
Objectives: We asked if: 1) there are differences in baseline EEG power and connectivity during a language processing task between 3-month old familial-risk and low-risk (no family history of ASD) infants, and 2) connectivity correlates with language ability and ASD symptoms at 18 months. Our overarching hypothesis is that neural connectivity is disrupted in infants with familial risk for ASD, with the largest differences found in infants with delayed or atypical development.

Methods: Participants included 33 familial-risk infants and 30 low-risk infants, from an ongoing longitudinal study at the UCLA Autism Center for Excellence. EEG was acquired at 3-month while each subject listened passively to a continuous stream of syllables for 2 minutes (EGI 128 channels). EEG was collected using NetStation, filtered at 1-50 Hz, and cleaned using EEGlab and independent component analysis. Relative spectral power was calculated using Welch's method on average re-referenced data. Phase coherence was calculated using *newcrossf* on Laplacian filtered data. Frontal and temporal relative power and coherence were calculated in the theta (4-6 Hz), alpha (6-12 Hz), beta (12-30 Hz), and gamma (30-50 Hz) bands. Language ability and ASD symptoms were assessed at 18-month using the Mullen Scales of Early Learning (MSEL) and Autism Diagnostic Observation Schedule-Toddler Module (ADOS-T), respectively. Independent samples t-tests were used to compare group differences in power and coherence; Pearson's correlations were used to relate coherence to MSEL verbal t-score (average of expressive and receptive language) and ADOS-T overall score.

Results: **P-values from independent samples t-tests are in Table 1; significant behavioral correlations are in Table 2**. 1) There were no significant group differences in frontal and temporal power ($p > 0.05$, Table 1). Across the frequency bands, familial-risk infants generally have hypoconnectivity in interhemispheric frontal and left frontal-right temporal connections; and hyperconnectivity in right-frontal and right frontal–left temporal connections. 2) Across the 50 subjects with 18-month behavioral data, right frontal-left temporal coherence in the beta band negatively correlated with 18-month MSEL verbal t-score ($R=-0.283$, $p=0.046$), and positively correlated with 18-month ADOS-T overall score ($R=0.471$, $p=0.001$).

Conclusions: Familial-risk infants show evidence of aberrant frontal-temporal connectivity at 3-month of age during a language processing task, and connectivity was associated with language ability and ASD symptoms at 18-month. Our findings suggest that neural connectivity during auditory language processing in early infancy is important for subsequent language development. We will expand our connectivity analysis to 6-12-month time points to examine potential divergent developmental trajectories in infants with atypical development.

3:04 **116.003** Application of Inter-Trial-Coherence Methods to Investigate Early Visual Processing in Infants at Familial Risk for ASD or ADHD

***E. S. Piccardi**[1], E. J. Jones[2], T. Charman[3], M. H. Johnson[4], T. Gliga[1] and &. The BASIS Team[1], (1)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (4)Centre of Brain and Cognitive*

Development, Birkbeck College, University of London, London, United Kingdom

Background: Atypicalities in sensory perception are observed in individuals diagnosed with Autism Spectrum Disorders (ASD) and Attention Deficit Hyperactivity Disorders (ADHD) but have rarely been contrasted in experimental studies. In the visual domain, superior performance on visual search tasks in ASD individuals and hypersensitivity to flickering lights in both ASD and ADHD populations have been cited as evidence of unusual sensory profiles. Investigating similarities and differences in early sensory symptomatology may help in unraveling common or distinct developmental pathways.

Objectives: To measure a reliable visual response, black-and-white checkerboards were presented under free-viewing conditions to three groups of 10-month-olds: infants at familial risk for ASD (HR-ASD, N=47), ADHD (HR-ADHD, N=21) and low risk controls with no family history of ASD or ADHD (LR-CT, N=18).

Methods: 138 checkerboards were presented during two blocks lasting 4 minutes each. Continuous EEG was recorded and three indices time-locked to checkerboards presentation computed: 1) early visual-evoked potentials (VEPs); 2) alpha band (6Hz-10Hz) inter-trial phase coherence (ITC); 3) neural habituation of early VEPs (i.e., change in amplitude/latency of VEP components between first *vs*. second half of the first block presentation).

Results: Analysis of VEPs amplitude and latency revealed statistically significant group differences in the first 200ms post-stimulus onset. The P100 component was enhanced in amplitude and delayed in latency in infants at familial risk for ASD or ADHD compared to controls (*ps*<.05) (Fig.1). Analysis of ITC revealed a statistically significant increase in alpha band phase alignment (p<.05) occurring in HR-ASD and HR-ADHD infants compared to controls. Furthermore, in line with research describing VEPs as resulting from a phase alignment of the ongoing EEG, a positive correlation between P1 peak amplitude and ITC was found in the whole sample (p<.05) (Fig.2). Finally, analysis of neural habituation of VEPs indicated that reduction in the peak-to-peak amplitude of the N1-P2 complex with repeated stimulus presentation was absent in infants at familial risk for ASD, whereas an overall sensitization to repeated visual stimulation was observed in infants at familial risk for ADHD (*ps*<.05).

Conclusions: Neural hypersensitivity to low-level visual information might represent a common pathway to later behavioral atypicality in both infants at familial risk for ASD or ADHD. Despite this similarity, distinct profiles of neural tuning to repeated low-level visual stimulation were observed in HR-ASD and HR-ADHD infants. While absence of habituation to repeated visual stimulation in HR-ASD infants might result from consistent cortical hyperexcitability, sensitization to repeated visual stimulation in HR-ADHD infants might result from reduced cortical inhibition. In turn, these atypicalities might contribute to aberrant top-down sampling of visual information. The nature of these atypicalities will be further characterized by investigating alpha band pre-stimulus phase properties and by relating EEG indices to parent report measures of infants' sensory processing.

3:16 **116.004** Cortical Source Analysis of ERP Responses to Faces in Etiologically Distinct Groups of Infants at High-Risk for ASD

M. Guy[1]*, J. E. Richards*[2] *and J. E. Roberts*[3]*, (1)Loyola University Chicago, Chicago, IL, (2)University of South Carolina, Columbia, SC, (3)Psychology, University of South Carolina, Columbia, SC*

Background:

The aim of this study was to examine cortical sources active during face processing in two groups of infants at high-risk of autism spectrum disorder (ASD). Event-related potentials (ERPs) associated with specialized face processing (i.e., N290) were measured in response to faces and toys across high-risk groups, including infant siblings of children with ASD (ASIBs) and infants diagnosed with fragile X syndrome (FXS), as well as low-risk control (LRC) infants (Guy, Richards, Tonnsen, & Roberts, 2017). All groups demonstrated greater amplitude N290 responses to faces than toys. Infants with FXS displayed the greatest amplitude N290 and most differentiated responses to faces and toys.

Objectives:

Cortical source analysis was utilized to investigate whether group differences in ERP responses corresponded to different levels of activation in brain regions most closely linked to specialized face processing or differences in areas active during face processing.

Methods:

Twelve-month-olds were recruited for this study, including 21 ASIBs, 15 infants diagnosed with FXS, and 21 LRC infants. All participants completed an ERP experiment including face and toy stimuli. Structural MRIs were collected from a subset of the participants and a group-specific (ASIB, FXS, or LRC) average head model was used to complete source analysis in infants that did not contribute their own MRI (Guy, Richards, & Roberts, 2017). Realistic head models were created from the MRIs. Current density reconstruction (CDR) of the N290 was calculated to examine activation in regions of interest (ROIs) believed to be relevant to face processing. CDR activity was analyzed in an ANOVA including the factors of participant group, stimulus type, and ROI.

Results:

There was a significant main effect of stimulus type, $F(1, 55) = 21.47$, $p < .0001$, reflecting greater activation to faces than toys. There was a stimulus type by ROI interaction, $F(17, 935) = 4.91$, $p < .0001$, due to higher levels of activation in response to faces than toys in the middle fusiform gyrus and nearby temporal and occipital brain areas. Additionally, an interaction of group, stimulus type, and ROI was observed, $F(34, 935) = 1.45$, $p = .0465$. As shown in Figure 1, LRC infants demonstrated greatest levels of activation in response to faces in brain areas most closely linked to specialized face processing (i.e., middle fusiform gyrus, anterior fusiform gyrus, parahippocampal gyrus, lingual gyrus), but infants with FXS were the only participant group to display higher levels of activation to faces than toys across all ROIs examined.

Conclusions:

The results provide evidence for unique patterns of neural activation during face processing across infants at high- and low-risk for ASD, and across distinct high-risk groups. All infants demonstrated greater activation to faces than toys in brain areas most associated with specialized face processing, but only infants with FXS consistently displayed higher levels of activation to faces across a broad range of areas analyzed. These results indicate that greater amplitude N290 responses observed in infants with FXS are due to an increased area of activation during face processing, rather than greater activation in specialized face processing areas.

1:45 PM - 2:35 PM - Willem Burger Hal

1:45 **117.001** Special Interests and Subjective Wellbeing in Autistic Adults

R. Grove[1], *R. A. Hoekstra*[2], *M. Wierda*[3] *and S. Begeer*[4], *(1)University of New South Wales, Sydney, Australia, (2)Department of Psychology, King's College London, London, United Kingdom, (3)VU University, Amsterdam, Netherlands, (4)VU University Amsterdam, Amsterdam, Netherlands*

Background: Restricted, repetitive patterns of behaviour, activities and interests are core characteristics of autism. However, there is limited research evaluating the role of special interests in the lives of autistic adults. It has been reported that 75 to 95% of autistic individuals have special interests in particular topic areas (Turner-Brown et al., 2011). A better understanding of the role and significance of special interests is needed.

Objectives: To explore special interests topics, intensity and motivation in autistic adults. To evaluate the association between special interests and quality of life, including subjective wellbeing and domain specific life satisfaction.

Methods: Participants were recruited through the Netherlands Autism Register (NAR), a longitudinal database of autistic individuals including 687 autistic adults (338 females (Mean age = 45.3); 349 males (Mean age = 32.5)). Participants were asked whether they have one or more special interests, and, if present, to list their topics of special interest and the number of days per week and hours per day spent engaged in their special interest(s). They were also asked to rate their overall wellbeing, as well as domain-specific areas including satisfaction with health, education, workplace, leisure activities, social contact and contribution to society. The Special Interest Motivation Scale (Grove et al., 2015) was administered to evaluate motivation for engaging in special interests, including extrinsic motivational factors ‘prestige' and 'achievement' and intrinsic motivational factors linked to 'personal life values and goals', 'intrinsic interest and knowledge' and 'engagement and flow'. Data were analysed using regression and confirmatory factor analyses.

Results: Two thirds of the sample reported having a special interest, with more males reporting a special interest than females ($p < 0.01$). Autistic women most frequently endorsed special interests in autism, nature and art. Computers, music and autism were the most popular special interest topics for men. Most autistic adults engaged in more than one special interest, highlighting that these interests may not be as circumscribed as previously described. Both autistic men and women self-reported that their special interests had a positive impact on their life and were no obstacle to functioning. However, there was a negative correlation between time spent engaging in special interests and subjective wellbeing ($p < 0.05$). Intrinsic motivation factors were more frequently endorsed than extrinsic factors. Intrinsic motivation for engaging in special interests was associated with increased subjective wellbeing ($p < 0.01$). Intrinsic motivation factors positively predicted satisfaction with social contact and leisure ($p < 0.05$).

Conclusions: Engagement in special interests was associated with positive outcomes, such as increased subjective wellbeing and satisfaction across specific life domains including social contact and leisure. However, a very high intensity of engagement with special interests was negatively related to wellbeing. Intrinsic motivation to engage in special interests may play an important role in our understanding of special interests in autism and be key to both general and domain-specific wellbeing and quality of life. Combined, these findings have important implications for the role of special interests in the lives of autistic adults.

1:57 **117.002** Patterns of Cognitive Reappraisal and Expressive Suppression Use and Relationship with Psychological Wellbeing in Youth on the Autism Spectrum: A Cluster Analysis Approach

R. Y. Cai[1], *A. L. Richdale*[1] *and M. Uljarevic*[2,3,4], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, CA, (4)Stanford Autism Center, Department of Psychiatry and Behavioral Sciences, Stanford University, CA*

Background: Emotion regulation (ER) has been proposed to be a trans-diagnostic factor in the development and maintenance of psychopathology in the general population, yet the nature of the relationships between ER strategy use and psychological wellbeing has not been comprehensively explored in individuals on the autism spectrum. Additionally, although positive and negative aspects of psychological wellbeing are distinct constructs and the habitual use of certain ER strategies has been shown to be related to both positive and negative aspects of psychological wellbeing, ER research in autism have exclusively focused on negative aspects of wellbeing (primarily anxiety and depression).

Objectives: The overall aim of this study was to assess how the individual differences in self-reported ER strategy use, specifically cognitive reappraisal and expressive suppression, relate to levels of both positive and negative psychological well-being, incorporating both hedonic and eudaimonic approaches. We first explored individual differences in patterns of self-reported reappraisal and suppression strategy use among youth on the spectrum We then examined how individual differences in ER strategy use relate to self-reported levels of positive and negative psychological wellbeing. It was hypothesised that individuals characterized by high reappraisal and low suppression would have better psychological wellbeing than those with low reappraisal and high suppression.

Methods: Fifty-six individuals aged 14 – 24 years ($M_{\text{age}} = 18.15$; $SD_{\text{age}} = 2.30$) completed the ER Questionnaire (ERQ), Diagnostic and Statistical Manual of Mental Disorders-5 Dimensional Anxiety Scales (DSM-5 DAS), Patient Health Questionnaire-9 (PHQ-9), Warwick-Edinburgh Mental Well-being Scale (WEMWBS), and Autism-Spectrum Quotient-Short (AQ-Short). Individuals were grouped into four clusters based on their ERQ subscale scores. A K-means cluster analysis was conducted in SPSS version 21 to classify participants according to their pattern of reappraisal and suppression subscale scores. The optical number of clusters was determined by plotting the within-group sum of squares for each cluster by applying the k-means procedure using R version 3.3.0 and identifying the elbow in the resulting scree plot. Further analyses were then conducted to test the hypothesis.

Results: Four clusters were chosen based on the scree plot for the K-means cluster analysis. The participant clusters were: 1) high suppressors and high reappraisers (HSHR); 2) high suppressors and low reappraisers (HSLR); 3) low suppressors and high reappraisers (LSHR); and 4) low suppressors and low reappraisers (LSLR). Individuals in the HSLR group expressed higher depressive symptoms ($U = 31$, $z = -2.20$, $p = .028$, $r = .45$) and lower positive wellbeing (mean difference via the Turkey HSD test = 16.11, $p < .001$) when compared with the LSHR group. Interestingly, individuals who self-reported using both high suppression and reappraisal expressed relatively high positive wellbeing and low depression symptoms.

Conclusions: Our findings demonstrate, for the first time, that individuals on the spectrum who self-reported using both high suppression and reappraisal expressed relatively high positive wellbeing and relatively low levels of depression symptoms. We suggest the maladaptive effect of habitual suppression use may be buffered by the habitual use of reappraisal, and this interaction between adaptive and maladaptive ER strategy use has clinical implications.

2:09 **117.003** Quality of Life in the Adult Autism Population in the UK

***A. Petrou**[1], D. Mason[2], J. Rodgers[3], J. R. Parr[3], D. Garland[4] and H. McConachie[5], (1)Newcastle University, Newcastle Upon Tyne, United Kingdom, (2)Institute of Neuroscience, Newcastle University, Newcastle-upon-Tyne, United Kingdom, (3)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (4)Northumberland, Tyne & Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (5)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom*

Background:

Previous research suggests Quality of Life (QoL) in autistic adults may be higher in males than in females, that QoL does not vary consistently with age, that QoL may be predicted by available support and having paid or voluntary employment, and that behavioural characteristics may be related to an individual's QoL. As a multidimensional subjective construct, QoL is conceptualised as having different domains that represent different aspects of a person's life, for instance, physical, psychological, or social QoL.

Objectives:

(1) To describe the QoL of adults on the autism spectrum in the UK and to compare it to that of the general population of adults. (2) To investigate what factors may predict QoL in adults on the autism spectrum.

Methods:

Participants are 370 autistic adults, and relatives/carers acting as 'consultees' for adults lacking capacity to consent for themselves to research participation, who are part of The Adult Autism Spectrum Cohort–UK (ASC-UK) (males=199, females=158, other gender=13; mean age=41.6 years, range=17–80; mean age at diagnosis=36.5 years, range=2-74). The ASC-UK enables longitudinal research aiming to investigate the life experiences of adults on the autism spectrum. Autistic adults were recruited through health teams, voluntary sector organisations, and the autism community. They completed a questionnaire about health and experiences, the Social Responsiveness Scale (a measure of autism severity), and the World Health Organisation Quality of Life questionnaire (WHOQoL-BREF). The WHOQOL-BREF consists of 26 questions that measure 4 domains: physical, psychological, social, and environment. Raw scores for each subscale were transformed into standardised scores from 0-100; higher scores indicate better QoL. Analyses on gender as well as age included male and female participants only. Age groupings were as follows: 16-25 years (n=62), 26-40 years (n=108), 41-60 years (n=149), and 61+ years (n=38).

Results:

Compared to the UK adult population, reported QoL was lower across all four domains of the WHOQoL-BREF for adults on the autism spectrum (effect sizes from 0.74 to 1.63). Males reported higher QoL than females in the physical domain (mean=52.6 vs 46.7) whereas females reported higher QoL than males in the social domain (mean=44.6 vs 38.4). Participants aged 16-25 years reported higher psychological QoL than participants aged 26-40 years (mean=48.8 vs 41.3). Participants aged 16-25 years reported higher environment QoL than participants aged 41-60 years (mean=60.4 vs 53.4). Being employed, receiving support, and being in a relationship positively predicted physical, social, and environmental QoL, respectively. In contrast, having a mental health condition and increased autism severity predicted lower QoL in each domain, and being female predicted lower physical, psychological, and environmental QoL.

Conclusions:

QoL is lower for adults on the autism spectrum than for the UK general population, with social QoL the lowest subscale. Contrary to some previous literature, an effect of age on QoL was found with younger participants reporting better QoL. In most domains, men fared better than women. There are several notable predictors of QoL, such as employment status and relationship status that could act as protective factors for autistic adults.

2:21 **117.004** Ageing with Autism: A Later Lifespan Approach to Cognition, Mental Health and Quality of Life

***A. Roestorf**[1], P. Howlin[2,3], C. Povey[4] and D. M. Bowler[5], (1)Psychology, City University London, London, United Kingdom of Great Britain and Northern Ireland, (2)King's College London, London, United Kingdom, (3)The University of Sydney, Sydney, Australia, (4)The National Autistic Society, London, United Kingdom, (5)Autism Research Group, City, University of London, London, United Kingdom*

Background: Several commentators have highlighted the need for research on ageing and autism spectrum disorder (ASD), yet few have explored the effects of growing older with autism (Perkins & Berkman, 2012; Wright et al., 2016). Little is known about long-term outcomes for cognitive ability, mental health and quality of life (QoL: Physical, Psychological, Social and Environmental). Cross-sectional studies of older autistic adults have identified poorer QoL compared to typically ageing (TA) groups, but selectively preserved cognitive ability in older autistic adults with average to above-average intellectual ability (Geurts & Lever, 2015), including our own cross-sectional study (Roestorf & Bowler, 2016). We followed our sample in a longitudinal study across 4-years to establish a clearer picture of ageing with autism.

Objectives: Our focus was to understand the effects of growing older with ASD on memory, executive function, language and intellectual ability, as well as autism-related symptoms, mental health and QoL. Our aim was to identify strengths and difficulties that exist for autistic adults across the lifespan, and ways in which QoL can be improved and maintained into later life.

Methods: Our study involved younger and older adults with a confirmed diagnosis of ASD (n=63), and a typically ageing (TA) comparison group (n=44) matched on age (mean=49.79, SD=15.30) and IQ (mean=114.37, SD=14.50). Time-1 (T1) involved cross-sectional comparisons between ASD-TA groups, which extended to longitudinal follow-up at Time-2 (T2; ASD,n=35; TA,n=22; mean interval 2.5 years). Participants completed standardized assessments of cognitive functioning (IQ, memory, language, executive function), and self-report measures of mental health (anxiety, depression) and QoL.

Results: In our original cross-sectional study we reported no age-related effects in ASD, and comparable performance to TA groups on all cognitive measures, but poorer quality of life and higher rates of anxiety and depression in ASD (Roestorf & Bowler, 2016), which replicated the findings from previous observations (Geurts & Vissers, 2012; Lever & Geurts, 2015). In the current, longitudinal study, the preliminary analyses on T2 data show a similar patterning: mental health difficulties at T2 persisted in ASD for anxiety (*p*<.001, η^2.33) and depression (*p*=.002, η^2.22), the latter presenting greater difficulties for autistic women (*p*=.004, η^2.30). The analyses of cognitive data are ongoing, but show promising outcomes for older autistic adults: whereas, younger-ASD participants presented ongoing difficulties in selective cognitive functions (e.g. rapid information processing, *p*=.017,η^2.21), a preserved level of ability was observed in older-ASD.

Conclusions: Across our studies, we observed ASD as undergoing a different kind of late-life ageing from that seen in TA. Whilst our cross-sectional work indicated either no difference or “parallel” profiles (Geurts & Vissers, 2012) in older-ASD compared to older-TA adults (Roestorf & Bowler, 2016), longitudinally, we observed a preserved level of cognitive ability in older-ASD adults, despite greater severity of anxiety and depression and poorer QoL. These findings highlight the need for continued mental health supports for autistic adults into later life, and the identification of the cognitive strengths that need to be developed to enable autistic adults to lead autonomous and rewarding lives across the adult lifespan.

2:40 **118.001** 16p11.2 Autism Risk Gene Kctd13 Deletion Reduces Synaptic Transmission Via Increased RhoA

***C. M. Powell**[1], C. O. Escamilla[2], I. Filonova[2,3], A. K. Walker[2], Z. X. Xuan[2], R. Holehonnur[2], F. Espinosa[2], S. Liu[2], S. B. Thyme[4], I. A. Lopez-Garcia[2], D. B. Mendoza[2], N. Usui[2,5,6], J. Ellegood[7], A. J. Eisch[2,8], G. Konopka[2], J. P. Lerch[9], A. F. Schier[10] and H. Speed[2], (1)Neurobiology, UAB School of Medicine, Birmingham, AL, (2)The University of Texas Southwestern Medical Center, Dallas, TX, (3)Okinawa Institute of Science and Technology, Okinawa, Japan, (4)Molecular and Cellular Biology, Harvard University, Cambridge, MA, (5)Division of Developmental Mental Functions, University of Fukui, Fukui, Japan, (6)United Graduate School of Child Development, Osaka University, Osaka, Japan, (7)Hospital for Sick Children, Toronto, ON, Canada, (8)Department of Anesthesiology and Critical Care Medicine, The Children's Hospital of Philadelphia Research Institute, Philadelphia, TX, (9)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada, (10)Harvard University, Cambridge, MA*

Background: 16p11.2 deletions and duplications are genetic risk factors for multiple neuropsychiatric conditions including autism, intellectual disability, attention-deficit/hyperactivity disorder (ADHD), schizophrenia, bipolar, epilepsy, and obesity as well as alterations in brain size and head circumference. This chromosomal region contains ~29 genes, none of which has been individually linked to 16p11.2-associated neuropsychiatric disorders. Additional human genetic findings, however, do suggest a smaller critical region of 5 genes or less that includes the potassium-channel-tetramerization-domain-containing 13 gene (*KCTD13*, a.k.a. *BACURD1*, *POLDIP1*, *PDIP1*, *TNFAIP1-like*). *Kctd13* has been implicated in brain size in 16p11.2 CNVs via morpholino-mediated knockdown of *Kctd13* in zebrafish. 16p11.2 copy number variants (CNV) are among the most prevalent CNVs in autism spectrum disorders (ASDs). Of many 16p11.2 genes, *KCTD13* has been implicated as a major driver of neurodevelopmental phenotypes. The function of KCTD13 in mammalian brain, however, remains unknown. Because KCTD13 is known to regulate levels of the small GTPase RhoA in HeLa cells in culture and because RhoA regulates actin dynamics, we hypothesized that KCTD13 modulates synaptic transmission in the brain.

Objectives: To determine the role of *Kctd13* in mammalian brain using a novel genetic mouse model lacking the Kctd13 gene.

Methods: We characterize our novel *Kctd13* deletion mouse model using protein biochemistry, acute hippocampus slice electrophysiology whole-cell and extracellular recordings, neuronal morphological analysis, molecular biology tools, and behavior along with in vitro pharmacology.

Results: Here we delete *Kctd13* in mice and demonstrate reduced synaptic transmission in the hippocampus. Reduced synaptic transmission correlates with increased levels of RhoA, a KCTD13/CUL3 ubiquitin ligase substrate, and is reversed by RhoA inhibition with two distinct inhibitors, suggesting increased RhoA as an important mechanism. Similar effects on synaptic transmission were observed at cortical synapses. In contrast to a previous knockdown study, deletion of *Kctd13* does not increase brain size or neurogenesis in mice or zebrafish.

Conclusions: These findings implicate *Kctd13* in regulation of neuronal function relevant to neuropsychiatric disorders and clarify the role of *Kctd13* in neurogenesis and brain size. Our data also reveal a potential role for RhoA as a therapeutic target in disorders associated with *KCTD13* deletion.

2:52 **118.002** A Cellular and Molecular Basis for Social Behavior Deficits in Autism

***M. P. Anderson**, Pathology and Neurology, Harvard Medical School/Beth Israel Deaconess Medical Center, Boston, MA*

Background: Diverse genetic defects, immunological insults, and certain forms of epilepsy (infantile epileptic encephalopathies) are implicated in the pathogenesis of autism spectrum disorder (ASD). Maternal 15q11-13 triplications cause a highly penetrant autism with comorbid epilepsy that is linked to increased *UBE3A* dosages, a ubiquitin-ligase and transcriptional co-regulator. While the impressive deficits in sociability make them a core diagnostic criteria in ASD, the specific brain locus, neuronal cell-types, and molecular and cellular deficits in these circuits that give rise to this behavioral deficit have remained largely unknown.

Objectives: Define the neuronal circuit defects and molecular mechanisms whereby increased UBE3A and/or seizures impair sociability.

Methods: We combine a range of techniques including conditional genetic mouse models, genome-wide transcriptional profiling, protein interaction network analysis, conditional viral vectors, *in vivo* chemogenetics, and slice optogenetic electrophysiology with extensive behavioral analysis.

Results: Nuclear-confined increases of UBE3A impair sociability by repressing *Cbln1* gene expression, a key node in an autism gene network of protein-protein interactions that trans-synaptically binds NRXN and GRID, two gene families frequently deleted in autism. Separately, epileptic seizures (causing activity-dependent *Cbln1* repression) synergize with "asymptomatic" increases of *Ube3a* to impair sociability and do so through neurophysiological effects on glutamatergic neurons of the ventral tegmental area (VTA). Importantly, the seizures and UBE3A-induced sociability deficits are rescued by chemogenetic activation of, or Cbln1 delivery to, these brainstem VTA glutamatergic neurons.

Conclusions: Thus we show that experiencing seizures can uncover the effects of hidden asymptomatic gene mutations that make them prone to seizure-induced autism-related difficulties with social interaction. We also identify a major function of the enigmatic population of glutamatergic neurons in the brainstem VTA establishing their role as a key element of the neuronal circuitry that promotes sociability behavior. We also identify this brain locus and specialized cell-type as a major site where seizures and increased UBE3A synergize to impair sociability.

118.003 Evaluation of Convergent Molecular Pathways during Neuronal Development Using Autism-Specific Induced Pluripotent STEM CELLS

D. Dykxhoorn[1]*, B. A. DeRosa*[2]*, D. Van Booven*[1]*, C. Garcia-Serje*[3]*, L. Wang*[4]*, M. L. Cuccaro*[1]*, J. M. Vance*[3]*, M. W. Nestor*[5]*, H. N. Cukier*[1] *and M. A. Pericak-Vance*[1]*, (1)John P. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL, (2)Molecular and Medical Genetics, Oregon Health & Science University, Portland, OR, (3)Hussman Institute for Human Genomics, Miami, FL, (4)Hussman INstitute for HUman Genomics, Miami, FL, (5)Hussman Institute for Autism, Baltimore, MD*

Background:
Autism is a phenotypically and etiologically complex group of neurodevelopmental conditions that are behaviorally defined based on the presence of social-communicative problems and restricted and repetitive behaviors. Recent studies have shown that autism risk loci are highly enriched in genes expressed during early neocortical development and genes which encode proteins that function in biological pathways involved in regulating transcription, chromatin remodeling, cell adhesion, signaling complexes, and synapse function. However, there has been a considerable lag in understanding the relationship between suspected ASD risk variants and how these variants result in the cell-based phenotypes with which they are associated.

Objectives: The aim of this study is to use induced pluripotent stem cell (iPSC)-based approaches to identify key differences in important neurobiological processes by evaluating the expression of gene networks that regulate these processes, both in a temporal and neural-specific manner.

Methods: We examined the transcriptional differences between iPSC-derived cortical neurons from individuals with autism and cognitively normal control individuals over a 135 day cortical neuron differentiation approach using RNA-Seq. Bioinformatic analysis was performed by weighted gene coexpression network analysis (WGCNA) and Ingenuity Pathway Analysis (IPA). This transcriptional analysis was complemented by functional examination of these neurons using electrophysiological, morphological, and biochemical analyses.

Results: Transcriptional analyses of autism and control neurons in culture at days 35 and 135 of their *in vitro* development showed autism-specific transcriptional signatures mainly affecting pathways/networks involved in neuronal differentiation, the cytoskeletal matrix structure formation (i.e. axon guidance and cell migration), regionalization, patterning, DNA and RNA metabolism. Additionally, developing networks of neurons were analyzed using multi-electrode array (MEA) recordings, measurements of calcium transients, immunocytochemical analyses for important morphological markers, and cell migration assays at time-points aligning with the transcriptional analyses. Neurons from autism individuals demonstrated significantly decreased network spiking activity from MEA recordings (40-80% decrease, $p<0.05$) as well as decreased numbers of calcium transients (30-60% decrease, $p<0.01$). Additionally, autism lines showed significant differences in neurite morphology and decreased cell migration ($p<0.05$) at early neuronal differentiation times.

Conclusions: The results of this study suggest that iPSC-derived neurons from individuals with ASD may have early deficits in network activity and morphology based on a combination of cell based assays, including MEA, calcium transients, and quantification of neurite outgrowth that complement their transcriptomic profiles. Taken together, these data suggests a convergence of pathophysiological processes that effect neuronal functionality in autism.

3:16

118.004 Using Induced Pluripotent Stem Cells Derived from Patient Blood for Transcriptional Modeling and Drug Repositioning in Phelan-Mcdermid Syndrome

A. Browne[1]*, E. Drapeau*[2]*, M. S. Breen*[2]*, H. Harony-Nicolas*[2] *and J. Buxbaum*[3]*, (1)Neuroscience, Icahn School of Medicine at Mount Sinai, New York, NY, (2)Seaver Autism Center for Research and Treatment, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY*

Background: Autism spectrum disorder (ASD) has high heritability and a prevalence of nearly 1% worldwide, but heterogeneity of patients has made identifying the underlying etiology difficult. By focusing on monogenic disorders with high penetrance for causing ASD, common pathways might be identified. Phelan-McDermid syndrome (PMS) is one such monogenic ASD-associated syndrome that is caused by haploinsufficiency of the gene *SHANK3*, which encodes for a scaffolding protein of the post-synaptic density at glutamatergic synapses. While animal models provide great insight into the pathways involved in PMS, many features of the disease may not be captured because of brain variation across species. One approach to deal with this shortcoming is to generate induced pluripotent stem cells (iPSCs) from patients that can then be differentiated into neural progenitor cells (NPCs) and neurons. Researchers from other groups using iPSC-derived neurons from PMS patients have found excitatory synaptic deficits similar to those seen in animal models.

Objectives: NPCs and neurons derived from patient and sibling iPSCs illuminate two distinct time points in the neurodevelopmental trajectory of PMS and allow for the identification of disrupted pathways that can be targeted through drug repositioning. With this project, we aim to 1) generate high-quality iPSC clones from blood samples collected from PMS patients and their unaffected siblings; 2) differentiate these iPSCs into both NPCs and neurons to capture the neurodevelopmental profile of PMS; 3) identify PMS-associated differential gene expression in iPSC-derived neural cells by RNA sequencing; 4) integrate the results with other PMS and ASD models to identify convergent findings; and 5) identify candidate drugs by comparing gene expression patterns for FDA-approved drugs with PMS-associated expression.

Methods: Blood samples from 6 patient/sibling pairs were collected and reprogrammed using a modified, non-integrating Sendai virus protocol. For each individual, 2-3 iPSC clones were validated and banked before using them for monolayer-based NPC generation, followed by 6 weeks of terminal differentiation into neurons. NPC and neuron samples were validated with immunolabeling for established NPC and neuron markers before subjecting them to RNA sequencing and differential expression. A transcriptional signature for PMS was generated and compared with expression data from a SHANK3 rat model from our lab to identify convergent pathways. For drug discovery, compounds with known expression profiles were ranked by their anticorrelation to the PMS signature.

Results: Differentially expressed genes between case and control lines were identified for each cell type and used for gene ontology enrichment analysis to identify the most significantly disrupted pathways. Comparing the iPSC-derived neural cells with a SHANK3 knockout rat model of PMS from our lab revealed convergent dysregulation of Wnt signaling and extracellular matrix-related genes, while the top candidates from drug repositioning endeavors were enhancers of GABAergic signaling.

Conclusions: Elucidating the transcriptional profile of neural cells derived from PMS patient iPSCs provides both a unique perspective on the neurobiological underpinnings of PMS, and a template that can be used with known drug expression profiles for repositioning and screening.

Oral Session - 4A
Sensory, Motor, and Repetitive Behaviors and Interests
119 - Mechanisms for Atypical Sensory Processing
1:45 PM - 2:35 PM - Jurriaanse Zaal

1:45 **119.001** Neural Mechanisms of Habituation to Sensory Stimuli and Generalization of Response in Youth with and without ASD

S. A. Green[1]*, L. M. Hernandez*[2]*, K. E. Lawrence*[2]*, J. Liu*[2]*, T. Tsang*[2]*, J. E. Yeargin*[3]*, M. Dapretto*[1] *and S. Y. Bookheimer*[1]*, (1)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA, (2)University of California, Los Angeles, Los Angeles, CA, (3)Brain Mapping Center, UCLA, Los Angeles, CA*

Background: Sensory over-responsivity (SOR) is an impairing condition that is extremely common in children with ASD, and is manifested as negative reactions to sensory stimuli (e.g., noisy environments, scratchy clothing; Liss et al., 2006; Ben-Sasson et al., 2007). Prior results from our lab showed that SOR in ASD was related to greater brain activity and reduced habituation to auditory and tactile stimuli in amygdala and somatosensory cortex (Green et al, 2015), suggesting that treatment of SOR needs to take into account fundamental differences in neural mechanisms of response to sensory information, including initial arousal, habituation, and generalization of response. In this study, we extend our findings on neural responses to sensory stimuli by examining neural mechanisms of generalization in children with and without ASD and differing levels of SOR.

Objectives: To examine (1) differences in brain responses to auditory and tactile stimuli in youth with and without ASD; (2) the extent to which ASD and TD youth generalize responses to new but similar stimuli; and (3) brain responses and generalization as a function of SOR severity.

Methods: Participants were 38 children and adolescents with ASD and 22 TD matched controls, aged 8-17 years. During fMRI, participants were presented with mildly aversive auditory (pulsing white noise) and tactile (scratchy sponges) stimulation. Stimuli were presented first in a habituation phase (6 blocks of 15-sec trials each of auditory and tactile stimuli together). Subsequently, different but similar stimuli matched for aversiveness (i.e. different frequencies of white noise; different sponge material) were presented in a generalization phase (4 blocks of 15-sec trials each of the stimuli). Participants' parents rated their symptoms of SOR with the Short Sensory Profile (Dunn, 1999) and the Sensory Over-Responsivity Inventory (Schoen et al. 2008). Scores on the auditory and tactile sensitivity subscales were standardized and combined to create a sensory composite score.

Results: Within- and between-group analyses were conducted using FSL and corrected for multiple comparisons ($p<.05$). In the first (Habituation) phase, the ASD group showed significantly greater activation in widespread regions including limbic areas, sensory cortices, and medial prefrontal cortex (Figure 1). Activity in these regions was positively correlated with parental report of SOR severity within the ASD group. In the second (Generalization) phase, the ASD group showed significantly greater activation only in sensory-motor cortex (Figure 2). However, in this phase, SOR was correlated with greater activity in right amygala and orbital and medial prefrontal cortex but not with activity in auditory or somatosensory cortex.

Conclusions: We replicate prior findings that SOR in ASD is related to hyperactivation in response to sensory stimuli in sensory and limbic regions, and further highlight potential mechanisms for deficits in generalizing responses to sensory stimuli. Specifically, ASD youth may have a deficit in generalizing primary sensory processing of tactile stimuli, and those with SOR may have a distinct deficit in modulating amygdala response to sensory stimuli. Results suggest that ASD youth with SOR may respond to new but similar stimuli as if they are novel and salient, with implications for intervention.

1:57 **119.002** Differential Processing of Body Odors and Common Odors in ASD: Sensory-Motor Vs. Emotional Analysis

V. Parma[1]*, M. Furlan*[2,3]*, D. N. Top*[4]*, K. G. Stephenson*[4]*, J. S. Beck*[5]*, N. C. Russell*[4]*, A. W. Carr*[4]*, L. Peacock*[5] *and M. South*[6]*, (1)William James Center for Research, ISPA - Instituto Universitário, Lisbon, Portugal, (2)International School for Advanced Studies, Trieste, Italy, (3)University of Padova, Padova, Italy, (4)Brigham Young University, Provo, UT, (5)Psychology, Brigham Young University, Provo, UT, (6)Psychology & Neuroscience, Brigham Young University, Provo, UT*

Background: There is emerging evidence from ASD samples for associations between olfactory processing and social engagement as well as for manifestations of anxiety. There is likewise evidence for links between neuroanatomical networks implicated in ASD and networks known to support typical olfactory processing. Studies of social and nonsocial olfaction may shed light on these associations. Body odors provide a wealth of social information and their brain processing is distinguished from that of common odors in typical individuals. However, there are no reported neuroimaging studies of either social or nonsocial olfactory processing in ASD.

Objectives: The goal of the present study was to compare the neural bases of social body odors versus common, nonsocial odors in adults with ASD and neurotypical controls. Specifically, we are interested in dissociating familiar and unfamiliar masked body odors to evaluate detection for signals of implicit threat.

Methods: Preliminary results are based on 45 healthy adult volunteers including ASD (n=22) and neurotypical comparison (NT; n=23) participants. During fMRI scanning, participants were asked to indicate the intensity and pleasantness of various odors including clean air (baseline), a neutral common odor (cedarwood oil), and two body odors masked with the neutral odor (i.e., participants could consciously only smell the cedarwood).

One odor was from a familiar individual (family or roommate) and the other was the odor of a stranger. We conducted two-way ANOVA with diagnosis as between-subject factor and odor condition as a within-subject factor. These preliminary results are uncorrected, p<0.008.

Results: Results indicate that both groups processed body odors in distinct networks from the nonsocial common odor. However, the ASD group activated more sensory areas than controls for both body odor conditions. In contrast, the control group activated insula and amygdala more than the ASD group for familiar but not unfamiliar body odors.

Conclusions: These results suggest that individuals with ASD are able to distinguish social from common odors, but do so on based on analyzing sensorimotor properties of the stimuli rather than relying on the relevant social information embedded in body odors. To our knowledge, this is the first neuroimaging study to reveal the neural basis for atypical odor-mediated social communicative behaviors in ASD. Difficulties with discrimination of implicit emotional stimuli may likewise contribute to ongoing states of uncertainty that underlie anxiety in many people diagnosed with ASD.

2:09 **119.003** Atypical Basic Psychophysics in Autism: Violation of Weber's Law in Vision and in Haptic

B. S. Hadad *and S. Schwartz, University of Haifa, Haifa, Israel*

Background: Perceptual atypicalities are increasingly invoked as contributory causes of the fundamental characteristics of Autism Spectrum Disorders (ASD). The mechanism underlying these alterations remains unclear, as the literature mostly focuses on high-level perceptual processes without much recourse to potential underlying constraints of basic sensory-perceptual processing.
Objectives: Reduced perceptual inference by which processing is more sensitive to the absolute metrics of the environment has been generally demonstrated in ASD. However, despite the potential role of elementary inferential encoding of stimuli in this altered perception in autism, sensory and perceptual calibration, based on immediate stimulation, has hardly been tested. To characterize this basic psychophysics in autism we tested adherence to Weber, a principle subserving one of the most fundamental function of transient plasticity, where the output of perceptual processes depends not only on the absolute change but also on its calibration based on the immediate standard stimulation. Sensitivity along stimulus intensities changes according to a rule of D*I*/*I*=*C*, where D*I* is the increase in stimulus intensity to a stimulus of intensity *I* that is required to produce a detectable change in intensity. *C* (Weber fraction) should thus remain constant. We tested the adherence to this principle in both vision and haptic.

Methods: JNDs for size judgments were tested in the visual domain in Exp. 1 (20 high-functioning ASD and 20 TD), and JNDs for weight discrimination were tested in the haptic domain in Exp. 2 (12 high-functioning ASD and 11 TD). JNDs were calculated based on the actual psychometric functions of each individual, for each condition.

Results:

Exp. 1. Weber's fraction (D*I*/*I*) computed for each disc size, for each subject, varied with disc size for the ASD but not for the TD group, $F(3,135) = 3.31$, $p < .02$, $\eta^2_p = .07$. The fractions for the autistic group, which decreased linearly with disc size, $F(3,75) = 6.93$, $p < .0001$, $\eta^2 = .22$, demonstrated violation of Weber. In a clear contrast, these fractions remained fairly constant across disc sizes for the TD group, $F(3,60) = 2.63$, $p > .10$, $\eta^2 = .09$, demonstrating the expected adherence to Weber.

Exp. 2. As in vision, a significant interaction between group and weight was found, F(3, 69) = 2.62, p<0.03, η2p =.13, and further analysis of this interaction confirmed Weber law, with fractions remaining constant across the different weights for the TD group, F<1. For the ASD group, in contrast, Weber's fraction again decreased linearly with increased weight, F(3, 36)=2.69, P<0.06, η2=.2.

Conclusions: In a striking contrast to its consistency in typical perception, results for the ASD group show that Weber's law does not hold in visual and haptic perception in autism. The results identified a general mechanism underlying alterations in basic psychophysics that may account for sensory symptoms in autism, and for the atypical perception demonstrated for higher level perceptual processing.

2:21 **119.004** Impaired Auditory Habituation Correlates with Symptom Severity in Children with Autism Spectrum Disorder

W. Jamal[1], A. Cardinaux[1], R. Cheung[1], L. Vogelsang[2], A. Agarwal[1], E. Losordo[3], L. Denna[1], S. Diamond[1], ***M. Kjelgaard***[4] *and P. Sinha[1], (1)Massachusetts Institute of Technology, Cambridge, MA, (2)Insttiute of Neuroinformatics, University of Zurich, Zurich, Switzerland, (3)MGH Institute of Health Professions, Boston, MA, (4)Marymount Manhattan College, New York, NY*

Background: It is estimated that nearly 90% of all children with autism suffer from sensory abnormalities, often hypersensitivities, to stimuli that neuro-typical individuals could easily ignore (Leekam et al., 2007). However, empirical data show that these hypersensitivities are not caused by abnormally acute sensory capabilities (DePape et al., 2012; Bölte et al., 2012). Here, we consider habituation as an alternative account of hypersensitivities in autism, and investigate its relationship with behavioral traits. Habituation involves reduction of neural and behavioral response over the presentation of repeated, predictable stimuli. Our group recently proposed a theoretical account of autism as a disorder of prediction, positing that the ability to predict and therefore habituate to regular stimulus sequences would be reduced in autism.
Objectives: We aimed to investigate whether autism may be associated with reduced sensory habituation in the auditory domain, and the degree to which auditory habituation patterns correlate with behavioral characteristics.

Methods: To investigate whether habituation is indeed reduced in autism, EEG data were recorded from neurotypical (NT) and autistic children during 300 trials of repeated auditory tone bursts. ERPs were calculated for each subject in 50 trial segments using a sliding window. We calculated the line of best fit across successive potentials (amplitude) of the most prominent ERP peak using the least squares method. Slopes of the best-fit line for each subject were used to determine the habituation profiles for each participant, which were then correlated with the ADOS comparison score and other measures used for clinical characterization.

Results: Figure 1A shows sample ERP peaks and the best-fit line from one NT and one ASD participant in response to auditory tones. The NT participant shows gradual reduction in ERP amplitude over time, while the ASD participant shows a slight increase. The bar-plot (Figure 1B) shows the habituation slopes of individual ASD (n=9) and NT (n=21) participants. NT participants exhibit pronounced habituation, in contrast to those with ASD. ASD and NT groups show significant differences in their auditory habituation profiles (p=0.0078). Figure 1C shows that the rates of habituation in the ASD group are significantly (p<0.05) correlated with their ADOS scores with a Pearson correlation coefficient, r = 0.712. Conducting this analysis across multiple behavioral metrics reveals interesting groupings of those traits that are, or are not, significantly correlated with habituation rates.

Conclusions: The initial data support the hypothesis that autism is associated with reduced habituation to sensory stimuli and may help explain commonly observed features of ASD: sensory hypersensitivities (aversion to stimuli with negative valence) as well as restricted and repetitive interests (sustained engagement with positive valence stimuli). Furthermore, these results provide support for the broader hypothesis of impaired prediction in autism.

Oral Session - 4B
Communication and Language
120 - On Gestures and ASD (Perspectives Across the Lifespan)
2:40 PM - 3:30 PM - Jurriaanse Zaal

2:40 **120.001** Gesture Development and Maternal Responsiveness between 12-24 Months

A. B. Choi[1]*, P. Shah*[2]*, M. Rowe*[3]*, C. A. Nelson*[4] *and H. Tager-Flusberg*[5]*, (1)Harvard University, Cambridge, MA, (2)Boston University, Boston, MA, (3)Harvard Graduate School of Education, Cambridge, MA, (4)Boston Children's Hospital, Boston, MA, (5)Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Pre-linguistic infants use gestures to communicate. Children's early gestures also predict subsequent language learning (Rowe & Goldin-Meadow, 2009). One potential mechanism, through which gesture may facilitate language learning is that an infant's gestures elicit responses from communicative partners, which, in turn, help develop the infant's language skills (Tamis-LeMonda et al., 2001). For example, when the infant points to a cookie, her mother responds by saying, "You want the cookie," providing the label for the object. The response then helps the infant to learn the word "cookie." Despite the important roles gestures play in language learning, surprisingly few studies have directly examined the relations between infant gesture production, maternal responsiveness, and language outcomes (Iverson & Goldin-Meadow, 2005). Here, we studied such relations, specifically in infant siblings of children with ASD, who show deficits in gestural communication (Winder et al., 2012).

Objectives: To investigate whether (1) infant siblings of children with ASD (high-risk; HRA) exhibit differences from low risk infants (low-risk; LRC) in gesture production between 12 and 24 months, (2) mothers of high- and low-risk infants differ in the proportion of infant gestures they respond to, and (3) early gestures, maternal responsiveness, and language outcomes are related.

Methods: 70 mother-child dyads were videotaped in the lab during a 10-minute free-play interaction at 12, 18, and 24 months. The ADOS and best clinical estimate at 18-36 months were used to determine ASD diagnosis (+) or lack thereof (-) and classify infants into outcome groups: HRA+: *n* = 17; HRA-: *n* = 25; LRC: *n* = 29. The MSEL was administered at 36 months, and raw scores from Expressive and Receptive Language subscales were combined to calculate language outcomes. Gestures were reliably coded from videotaped sessions following Özçalışkan and Goldin-Meadow (2009). Maternal contingent responses to infants' gestures were coded and defined as verbal or nonverbal behaviors that occurred within one utterance of each gesture and involved translation, repetition, or expansion of the gesture.

Results: (1) Kruskal-Wallis tests revealed significant differences between groups in the total number of gestures produced at 12 and 18 months (Figure 1). Follow-up pairwise comparisons showed that HRA+ and LRC groups produced significantly fewer gestures, compared to HRA- infants at 12 months. At 18 months, HRA+ and HRA- groups produced significantly fewer gestures than the LRC group. (2) Kruskal-Wallis tests indicated no significant group differences in the proportions of maternal responses to infant gestures between 12 and 24 months (Figure 2). (3) Using Pearson correlations, we found maternal responses at 12 months were significantly negatively related to infants' language scores at 36 months for the HRA+ group, but were positively trending in the HRA- and LRC groups.

Conclusions: Despite the differences in early gesture production in infant siblings, their mothers provided similar contingent responses to infants' gestures, as did mothers of low-risk infants. Understanding both infant and parent behavior in high-risk dyads may shed light on the language learning process of this population and have implications for early intervention practices.

2:52 **120.002** Maternal Gestures and Infant Responses in High- and Low-Risk for Autism Spectrum Disorder Dyads

P. Shah[1]*, A. B. Choi*[2]*, M. Rowe*[3]*, C. A. Nelson*[4] *and H. Tager-Flusberg*[5]*, (1)Boston University, Boston, MA, (2)Harvard University, Cambridge, MA, (3)Harvard Graduate School of Education, Cambridge, MA, (4)Boston Children's Hospital, Boston, MA, (5)Psychological and Brain Sciences, Boston University, Boston, MA*

Background: Language, including gestural communication, is delayed in infant siblings of children with autism spectrum disorder (ASD), who are at high risk for the disorder (high-risk; HRA). Factors such as parental communication influence infant language development. In typically developing infant-mother dyads, maternal gestures tend to remain stable over time (Iverson et al. 1999), but this has not been extensively studied in mothers of HRA children. Talbott et al. (2015) found that mothers of HRA 12-month infants not diagnosed and later diagnosed with ASD produced similar rates of total gestures. The responsivity of infants during communication may relate to parental communicative actions (Goodman et al. 2005) or to future ASD diagnosis (Wan et al. 2013). However, it remains unclear whether infants and their mothers respond contingently to each other's gestures. Here, we specifically examined maternal gestures and their infants' responses as the initial step toward a better understanding of the nature of maternal gestures and bi-directionality of communicative synchrony.

Objectives: To investigate whether: (1) mothers of high- and low-risk (LRC) infants change over time in gesture production at 12, 18, and 24 months of infant age; (2) infant responsivity to maternal gestures differs between diagnostic groups at the three age groups.

Methods: 70 mother-child dyads were videotaped in the lab during a 10-minute free-play interaction at 12, 18, and 24 months. The ADOS and best clinical estimate at 18-36 months were used to determine ASD diagnosis (+) or lack thereof (-) and classify infants into outcome groups: HRA+: *n* = 17; HRA-: *n* = 25; LRC: *n* = 29. Gestures were reliably coded and further classified into two categories following Özçalışkan and Goldin-Meadow (2009): gestures produced alone (e.g., pointing to a dog) or with speech (e.g., "look at the dog!" + pointing to a dog). Infant responses to maternal gestures were coded and defined as verbal or nonverbal behaviors that occurred within one utterance of each gesture.

Results: (1) Mothers of HRA+, HRA-, and LRC infants produced similar rates of gestures, with or without speech, at 12, 18, and 24 months (Kruskal-

Wallis; Figure 1). (2) Infants produced significantly more overall responses to maternal gestures over time, and the groups did not differ in their responses (repeated measures ANOVA). Infants responded differently to maternal gestures produced with or without speech (Figure 2). Visual inspection suggests that infants responded proportionally more to gestures alone than to gesture-speech combinations. In addition, while infants remained stable in their responses to gestures produced alone over time, they significantly increased responses to gestures produced with speech between 12-24 months.

Conclusions: In our sample, HRA+, HRA-, and LRC mothers and their infants demonstrated comparable gestural input and responses, respectively. Infants – regardless of group – responded differentially to maternal gestures depending on whether the mother produced the gesture with speech or if the mother gestured without speech. These findings can guide further research and inform our understanding of infant and maternal behavior in the development of infants' communication.

3:04

120.003 Early Language and Gesture Profiles of Toddlers with ASD As Measured By Developmental Screeners

*H. Grosman[1], C. Beacham[2], **C. Klaiman**[3] and S. Richardson[4], (1)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (2)Marcus Autism Center, Children's Healthcare of Atlanta, and Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Children's Healthcare of Atlanta and Emory University School of Medicine, Atlanta, GA, (4)Marcus Autism Center, Atlanta, GA*

Background: Parent-report measures identifying early concerns and Autism Spectrum Disorders (ASD) red-flags are critical for informing appropriate referrals to diagnostic evaluations and services. One of the most salient early concerns related to ASD leading to early evaluation is language delay (Coonrod & Stone, 2004). The Ages and Stages Questionnaire (ASQ-3) is a broadband developmental screener that includes a Communication domain, focusing on receptive and expressive language skills as well as early social communication and gesture use. Prior studies on the ASQ-3 suggest that the Communication domain is sensitive to ASD red-flags, with a significant number of children falling in the "fail" range of concern receiving a diagnosis of ASD (Hardy et al., 2015). The MacArthur-Bates Communicative Development Inventory (MCDI) is a parent-report measure of early language and social communication that focuses on children's larger inventory of the same skills measured by the ASQ-3 Communication domain. Our study assesses the MCDI profiles of children who do not screen in the concern range on the ASQ-3 Communication domain.

Objectives: Understand the relationship between broadband developmental screeners and parent-report measures of early language and gesture inventory in an ASD evaluation.

Methods: Our sample includes 59 children (81.4% male) all of whom received an ASD diagnosis following a gold-standard evaluation. Out of 59 children, 9 individuals (15.3%) did not come up in the concern range on the ASQ-3 Communication domain. Children were between the ages of 16-31 months (mean=24.8, SD=3.91) and referred based on parental concerns and/or referrals from pediatricians or early interventionists. Parents completed the ASQ-3 and MCDI, and children were evaluated with the Mullen Scales of Early Learning and Autism Diagnostic Observation Schedule, Second Edition (ADOS-2, Toddler Module). Comparisons between groups were analyzed using independent t-tests. Data from 50 additional participants is expected to be collected before May 2018.

Results: Significant differences were observed in MCDI scores by the ASQ-3 "concern" and "no concern" groups, with parents of individuals who did not screen in the concern range on the ASQ-3 Communication domain as per scoring guidelines outlined in the ASQ-3 manual reporting larger gesture inventory and stronger receptive and expressive language skills ($t(55)=4.8$, $t(57)=7.3$, $t(57)=2.9$, all p's$<.005$) on the MCDI. When measures of gesture inventory were divided into early gestures (such as reaching, pointing, waving and routine based games like peek-a-boo) and late gestures (such as complex imitation and pretend play), differences between screening groups remained significant at the $p<.001$ level.

Conclusions: Consistent with previous research, this study revealed that the ASQ-3 Communication domain was sensitive to red-flags of ASD in early social communication and language development. In addition, the results show strong agreement between communication concerns as picked up by broadband developmental screeners and metrics of early word and gesture inventory. These results provide further support for the utility of parent-report screeners specific to language use in ASD diagnostic assessments, as the brief communication survey aligned with a much larger and nuanced measure of word inventory and social communication skills.

3:16

120.004 Adults with ASD Signal Conversational Turn Taking with Their Hands

__A. de Marchena__[1,2], A. Bagdasarov[3], E. S. Kim[4], Z. M. Dravis[4], B. B. Maddox[5], E. F. Ferguson[2], L. Adeoye[6], A. A. Pallathra[7], L. Bateman[2], A. Pomykacz[8], E. S. Brodkin[9], J. Pandey[4], J. Parish-Morris[4] and R. T. Schultz[4], (1)University of the Sciences, Philadelphia, PA, (2)The Center for Autism Research/CHOP, Philadelphia, PA, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (5)University of Pennsylvania, Philadelphia, PA, (6)The Center for Autism Research/CHOP, Phladelphia, PA, (7)Department of Psychiatry, Catholic University of America, Washington, DC, (8)Children's Hospital of Philadelphia- Center for Autism Research, Philadelphia, PA, (9)Department of Psychiatry, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Background:

Co-speech hand gestures serve many communicative functions, often denoted by gesture "types." For example, gestures can be *deictic* (pointing), or *representational* (depicting physical properties of referents, e.g., shape/movement). The evidence for whether or not verbally fluent people with ASD use gestures to fulfill similar functions as those without ASD is mixed. However, to date, no ASD study has examined *interactive* gestures, which serve primarily pragmatic and discourse functions, such as indicating uncertainty or regulating conversational turn-taking.

Objectives:

Co-speech gestures in ASD have primarily been studied via elicited narratives, which offer limited opportunities for back-and-forth interaction, and thus, reduced performance of interactive gestures. Gestures serve different functions based on social context, thus, the objective of the current study was to examine communicative functions of co-speech gestures during back-and-forth conversation.

Methods:

Adults with ASD (n=21) and age-, gender, and IQ-matched typically developing controls (TDC; n=21) completed a five-trial collaborative referential communication task designed to elicit spontaneous back-and-forth conversation in a controlled setting. We examined whether gestures broadly fulfill different communicative functions in ASD vs. TDC by coding gesture types; gestures were coded as *interactive, representational*, *deictic*, *beat* (i.e., moving hands in time to speech), *numeric* (e.g., holding up two fingers to indicate two of something), and *other* (primarily unclassifiable gestures). As described below, a surprising finding emerged, which prompted us to further explore the varied functions of *interactive* gestures used by this sample. Interactive gestures were thus further coded according to the pragmatic/discourse function served, as follows: regulating *turn-taking*, expressing *uncertainty*, marking language as reflecting *shared information*, indicating *agreement*, and indicating *disagreement*.

Results:

Participants with ASD gestured at a marginally lower rate overall (*p*=.09, *d*=0.54). Across groups, participants primarily used representational gestures, with beat and interactive gestures the next most common (main effect of type, *p*<.001, η^2=.79, see Figure). Groups differed in terms of their preference for different types (group X type interaction, *p*=.002, η^2=.45), a large effect that was primarily driven by an *increased* rate of interactive gestures (*p*=.03, *d*=0.78), and other/unclassifiable gestures (*p*=.01, *d*=1.00) in ASD. This finding ran counter to our original hypothesis that adults with ASD would use *fewer* interactive gestures, so we conducted an exploratory analysis to investigate the interactive functions adults with ASD may be signaling in gesture. Groups were comparable across all subcategories of interactive gestures, with the exception of *turn-taking*, which was signaled via gesture over three times as often in the ASD group (*p*=.01, *d*=0.98, see Table).

Conclusions:

Adults with ASD surprisingly used *more* gestures than controls to serve interactive functions in their discourse. An exploratory analysis of these functions suggested that adults with ASD may use gesture to regulate conversational turn taking to a greater extent than controls. Conversational turn taking in general has been understudied in ASD, and the results of the current study provide compelling evidence that we should broaden our units of analysis to include nonverbal communication (including gesture, but also including, e.g., eye gaze, body movements, and prosody) to fully understand conversational strengths and weaknesses in ASD.

Oral Session - 5A
Epidemiology
121 - Prenatal Autism Risk Factors
1:45 PM - 2:35 PM - Arcadis Zaal

1:45 **121.001** Is the Tdap Vaccine Administered during Pregnancy Associated with Autism Spectrum Disorder in Offspring?

__T. A. Becerra-Culqui__, H. F. Tseng, D. Getahun and V. Chiu, Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA

Background: Prenatal infections and fever are associated with increased autism spectrum disorder (ASD) risk. The increasing practice to vaccinate pregnant women to protect mother and child makes it important to assess not only short-term but also longer-term safety events potentially linked to prenatal vaccination. Except for influenza vaccination, no study to our knowledge has investigated the association between the Tetanus, diphtheria, acellular pertussis vaccine (Tdap) during pregnancy and ASD.

Objectives: To investigate the association between prenatal Tdap vaccination and ASD risk in offspring.

Methods: This retrospective cohort study included 81,993 children born at Kaiser Permanente Southern California (KPSC) from January 1, 2011 to December 31, 2014. Information on maternal Tdap vaccination from pregnancy start to delivery date and children's clinical diagnoses of ASDs were obtained from the KPSC electronic medical record (EMR). ASD was identified by International Classification of Diseases, 9th edition codes 299.0, 299.8, or 299.9 and 10th edition codes F84.0, F84.5, F84.8, F84.9 recorded after age one. They were followed from birth to first ASD diagnosis, end of membership, or end of follow-up (June 30, 2017), whichever came first. Cox hazards models were used to estimate the unadjusted and adjusted hazard ratios (HR) to assess the association between maternal Tdap vaccination and ASD. We used propensity score analyses with inverse probability of treatment weighting to adjust for confounding.

Results: Prenatal Tdap vaccination ranged from 26% to 79% during the study years. The 2012 year had the lowest uptake and 2014 had the highest. Women vaccinated during pregnancy were more likely to be Asian/Pacific Islander, have a bachelors or higher educational degree, be pregnant for the first time, also have received the flu vaccine prenatally, and give birth at term.

Follow-up time ranged between 1.2 and 6.5 years. ASD was diagnosed in 1,341 children (1.6%). Diagnosis ranged from 1.9% in children born in 2011 to 1.2% in children born in 2014. ASD incidence rate was 4.05 per 1,000 person-years in the unexposed and 3.78 per 1,000 person-years in the Tdap exposed group. The unadjusted hazard ratio was 0.98 [95% confidence interval (CI): 0.88, 1.09].

The propensity score adjusted analyses showed that prenatal Tdap vaccination was not associated with increased ASD risk (HR: 0.85, CI: 0.77, 0.95). Results were consistent among women who were pregnant with their first child (HR: 0.87, CI: 0.75, 1.01) and across children born in the 2011-2014 study years (HR: 0.87, CI: 0.70, 1.07; HR: 0.79, CI: 0.62, 1.02; HR: 0.98, CI: 0.79, 1.22; HR: 0.86, CI: 0.65, 1.14; respectively).

Conclusions: Getting vaccinated with Tdap during pregnancy was not associated with increased risk of ASD in offspring, and the association was consistent among women pregnant for the first time and by year of birth. Indication of decreased ASD risk in the overall results could be due to unmeasured confounding, such as evolving practices in Tdap vaccine and ASD service implementation during the study years. Future studies with updated data are warranted to further evaluate potential associations between Tdap and ASD.

1:57 **121.002** Prenatal Inflammation and Autism Risk in a Swedish Birth Cohort

__R. Gardner__[1], C. Dalman[2], B. K. Lee[3] and H. Karlsson[4], (1)Karolinska Institutet, Stockholm, Sweden, (2)Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden, (3)Epidemiology and Biostatistics, Drexel University, Philadelphia, PA, (4)Department of Neuroscience, Karolinska Institutet, Stockholm, Sweden

Background:

Mounting evidence from both animal and human studies indicates that maternal immune function during pregnancy can influence neurodevelopmental outcomes relevant to autism. Most human studies of inflammatory markers measured in biosamples collected during the perinatal period conduct analyte-by-analyte statistical analyses, which can be problematic in terms of the number of statistical tests conducted and the underlying correlations among immune markers.

Objectives:

We aimed to measure acute phase proteins and cytokines in maternal serum samples collected during early pregnancy, as markers of prenatal inflammation and immune function, and to determine associations with later risk of autism spectrum disorders (ASD).

Methods:

We performed a case-control study of 430 ASD cases and 589 unaffected controls born 1998-2000 in Sweden, with case ascertainment as of December 2011. Maternal sera samples were collected from regional biobanks. Nine acute phase proteins (α-2 microglobulin, C-reactive protein, haptoglobulin, serum amyloid P, procalcitonin, ferritin, tissue plasminogen activator, fibrinogen, and serum amyloid A) and seventeen cytokines (IL-1beta, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12p70, IL-13, IL-17, IFN-gamma, G-CSF, GM-CSF, MCP1, MIP-1beta, TNF- alpha) were measured using a magnetic bead-based multiplex panel. Markers were individually examined, as well as combined into an inflammatory risk score based on ridge regression coefficients. We used logistic regression models adjusted for sex, birth year, maternal age, maternal immigration (Swedish born or not), parity, gestational week at sampling, and season at sampling.

Results:

Our preliminary analyses indicate that higher maternal levels of two cytokines were individually associated at $p < 0.05$ with increased risk of ASD in continuous analysis of log2-transformed concentrations: IL-17 (OR 1.12, 95% CI 1.01-1.25) and G-CSF (OR 1.13, 95% CI 1.02-1.27). None of the nine APP markers were associated with offspring ASD risk. A one standard deviation increase in the inflammatory risk score (including information for all analytes measured) was associated with an 85% increase in odds of ASD, OR: 1.85, 95% CI 1.42-2.42.

Conclusions:

The maternal immune system, assessed in early pregnancy, is associated with subtle changes in risk for offspring ASD. These risks were apparent when examining certain markers individually. The individual markers related to ASD are interesting for their previously documented roles. Animal studies have shown that maternal IL-17 is required for offspring behavioral changes after maternal immune activation. G-CSF promotes neurogenesis within the central nervous system. Risks were also apparent when examining a composite inflammatory risk score. The risk score approach moves beyond analyte-by-analyte testing in order to avoid multiple comparisons and over-fitting of the data, as well as to improve generalizability of the results and address the underlying correlations among analytes.

2:09 **121.003** Prenatal Air Pollution Exposure and Autism: Preliminary Findings from Two Prospective High-Familial Risk Birth Cohorts

H. E. Volk[1], *B. Y. Park*[2], *F. Lurmann*[3], *H. Minor*[3], *R. McConnell*[4], *S. Ozonoff*[5], *L. A. Croen*[6], *M. D. Fallin*[1], *I. Hertz-Picciotto*[7] *and C. J. Newschaffer*[8], *(1)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Mental Health, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (3)Sonoma Technology, Inc., Petaluma, CA, (4)University of Southern California, Los Angeles, CA, (5)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA, (6)Division of Research, Kaiser Permanente, Oakland, CA, (7)University of California at Davis, Davis, CA, (8)AJ Drexel Autism Institute, Philadelphia, PA*

Background: Prenatal air pollution exposure has been associated with autism spectrum disorder (ASD) in case-control studies, but not yet examined in a prospective cohort in the US.

Objectives: To examine the relationship between prenatal air pollution exposure and risk of ASD and non-typical development in the Early Autism Risk Longitudinal Investigation (EARLI) and Markers of Autism Risk in Babies, Learning Early Signs (MARBLES) cohorts.

Methods: EARLI and MARBLES enrolled pregnant mothers who already have a child with ASD and followed the new infant longitudinally through 36 months of age. Maternal residences and corresponding dates from pregnancy to birth were collected via questionnaire and extracted from prospective follow-up contact reports. Monthly near-roadway air pollution (NRAP) estimates were assigned to geo-coded locations using the CALINE line-source dispersion model, for California locations, or the MOVES model for locations outside of California. Weekly measures of exposure to criteria air pollutants (nitrogen dioxide (NO_2), ozone, and particulate matter less than 2.5 or 10 microns in diameter ($PM_{2.5}$, PM_{10})) were assigned to each location using inverse distance weighting from the nearest Environmental Protection Agency (EPA) monitor. ASD diagnosis at 36 months was determined based on Autism Diagnostic Observational Schedule (ADOS) score and by meeting DSM-IV-TR criteria for Autistic Disorder or PDD-NOS. Typical development was defined as not meeting ASD criteria and having Mullen Scales of Early Learning Scores within 1.5 SD of the mean, and ADOS more than 3 points below the ASD cut-off. Separate logistic regression models were used to examine the association between NRAP exposure during pregnancy and ASD risk. Distributed lag models (DLM) were used to identify windows of susceptibility to NO_2, ozone, PM_{10}, and $PM_{2.5}$ exposure. All models were adjusted for recruitment site / parent study, child gender, child race, ethnicity, and birth year, maternal age at birth and education level. Analyses were conducted on 114 children from EARLI and 96 from MARBLES.

Results: Average NRAP and NO_2 exposure was elevated for US East Cost EARLI study locations (Maryland and Pennsylvania), compared to West Cost EARLI and MARBLES study locations (Northern California). PM_{10} and $PM_{2.5}$ exposure was similar across study locations. Ozone level was lower at the Kaiser Permanente EARLI site, compared to others. After adjustment for confounders, increased prenatal NRAP exposure was associated with increased ASD risk, compared to TD, in EARLI (OR=2.2 per 1 SD (~3ppb) change in exposure, 95% Confidence Interval (95%CI) 1.2-4.3), but not in MARBLES (OR=0.85, 95%CI 0.4-1.6). DLM results from MARBLES suggest that increasing exposure to ozone during mid-gestation and to NO_2 and $PM_{2.5}$ during mid-late gestation may be associated with modestly increased ASD risk OR per five unit changed ranged from OR=1.1-1.5. Windows of susceptibility were not identified in EARLI.

Conclusions: Preliminary findings suggest that prenatal exposure to air pollution may be associated with increased ASD risk. However, variation in air pollution exposure based on geographic location, that could suggest different patterns of regional confounding, pollution source, and background susceptibility from other environmental and genetic factors all need additional exploration.

2:21 **121.004** An Environmental-Wide Association Study (EnWAS) of Pre- and Perinatal Factors Associated with Autism Spectrum Disorders

S. Lamballais[1], ***E. Geenjaar***[2], *R. Muetzel*[3], *T. Henning*[4] *and T. White*[5], *(1)Erasmus University, Rotterdam, Netherlands, (2)Technical University Delft, Rotterdam, Netherlands, (3)Erasmus MC / Sophia Children's Hospital, Rotterdam, Netherlands, (4)Department of Psychiatry, Erasmus MC-University Medical Center, Rotterdam, Netherlands, (5)Child and Adolescent Psychiatry, Erasmus University Medical Centre, Rotterfdam, Netherlands*

Background: A number of environmental factors present during pre- and perinatal life have been shown to be associated with the later development of autism spectrum disorders (ASD). These factors include biomarkers, such as maternal levels of vitamin D, measures of inflammation, exposure to selective serotonin reuptake inhibitors, and mixed studies of pollution and folate. In addition, a family history of specific forms of psychopathology can also increase the risk for a child later developing ASD. Many epidemiological studies evaluate one exposure with one outcome, while carefully controlling for potential confounding factors. However, similar to hypotheses proposed in genetics, it may be that multiple environmental factors are involved in emerging ASD, with each contributing a small effect.
Objectives: It is the *goal* of this proposal to test the hypothesis that multiple variables presenting in pre- and perinatal life are associated with the development of ASD. We will test this by performing an environmental-wide association study of ASD. Using such an approach, we can identify potentially new environmental factors associated with ASD, and compare prior positive factors with the new hits. Finally, we can create a 'polyenvironmental risk score,' similar to a polygenic risk score, to assess whether multiple environmental factors can predict the emergence of ASD.

Methods: The study is embedded in the Generation R Study, a prospective, longitudinal birth cohort in which nearly 10,000 pregnant mothers were recruited. The total number of children in which the social responsiveness scale (SRS) for autistic symptoms and who had less than 60% missing data was 3,891. This group was split into a discovery set of 2,920 and a replication set of 971 children. The variables entered into the environmental-wide association study included only questionnaire and biomarker data that were collected either during prenatal life or at the time of birth and included 912 variables. We assessed each variable first using univariate regression analyses, followed by multiple regression analyses correcting for maternal age at birth, parity, maternal education, birth weight, ethnicity, sex, and birth year. Multiple correction on the discovery cohort was performed using false discovery rate (FDR).

Results: A total of 578 of the 912 variables were significant after FDR correction, suggesting confounding due to the high covariance structure of environmental and questionnaire variables. After controlling for the eight covariates typically used in epidemiological studies of ASD, 311 of the 912 variables were significant above the FDR correction. Of these 311 significant variables, 97 were significant in the replication sample. A 'Manhattan' plot of the environmental variables adjusted for covariates are show in in the Figure.

Conclusions: Using data collected during pre- and perinatal life, we show that multiple variables, especially those linked to parental psychopathology and maternal health, were associated with the later development of ASD.

2:40 PM - 3:30 PM - Arcadis Zaal

2:40 **122.001** Live Birth Bias May Play a Role in Epidemiological Analyses of Air Pollution and Autism Spectrum Disorders

R. Raz[1]*, M. A. Kioumourtzoglou*[2] *and M. Weisskopf*[3]*, (1)The Hebrew University of Jerusalem, Jerusalem, Israel, (2)Department of Environmental Health Sciences, Columbia University Mailman School of Public Health, New York, NY, (3)Harvard T.H. Chan School of Public Health, Boston, MA*

Background: There has been increasing interest in the scientific literature recently on the role of air pollution exposures on the development of autism spectrum disorder (ASD). Findings and conclusions across epidemiological studies, reviews and meta-analysis however, are not consistent. In a recent publication testing the associations between prenatal exposure to NO_2 and autism, a distributed lag model was implemented with population-based ASD data and weekly NO_2 exposures from Israel in order to identify critical windows of vulnerability. When mutually adjusted in a distributed lag model, postnatal exposures presented positive associations (more NO_2, more ASD) while prenatal associations varied by week of pregnancy, and gradually reached a negative, statistically significant peak around the end of the first trimester. We suggest that the negative associations do not represent protective effects of air pollution, but are the result of live birth bias.
Objectives: Explaining the causal structure and the assumptions needed for live birth bias to create biased negative associations between air pollution and ASD.

Methods: A directed acyclic graph (DAG) was built to represent the causal structure and the underlying assumptions.

Results: As presented in our DAG (see graphical abstract), live-birth bias could arise from the fact that ASD can only be assessed in live-born children, and many pregnancies do not end in a live birth. This inevitable selection of only live births into the analysis in question may lead to bias of the observed association from the actual causal association if a) air pollution is a risk factor for pregnancy loss, and b) there are other factors ("U", likely unmeasured, even unknown) that influence both pregnancy loss and ASD. In the causal inference terminology, the selective analysis of only live births opens the backdoor path: ASD <-- U --> Pregnancy Loss <-- Air Pollution, which creates an association between air pollution and ASD and biases the causal association in question, which is represented by the dashed arrow between Air Pollution and ASD.

Conclusions: We suggest that live-birth bias can create an observed negative association between air pollution and ASD. Several lines of evidence in the literature support the first assumption of air pollution as a risk factor for pregnancy loss. The second assumption is harder to assess, since U is undefined, but one possible example is prenatal stress: the existing literature supports its involvement as a risk factor for both pregnancy loss and ASD in the offspring. Thus, prenatal stress may be a possible example for our variable "U", although the suggested bias mechanism is not limited to this specific factor. This bias has implications for all air pollution-ASD studies, and it may also be relevant to other neurodevelopmental conditions. It could create an apparent protective association, and it could mask an increased risk.

2:52 **122.002** Social Determinants of Prevalence of Children with Autism Spectrum Disorder: A Population Level Study

A. Siddiqua*, E. Duku and M. Janus, McMaster University, Hamilton, ON, Canada*

Background: The presence of socioeconomic disparities in children's health, known as the socioeconomic gradient, is well established and there has been some research exploring the relationship between socioeconomic status (SES) and prevalence of Autism Spectrum Disorder (ASD). While there is mixed evidence regarding the association between individual-level SES and prevalence of ASD, the association between neighbourhood-level SES and prevalence of ASD remains largely unexplored. Nonetheless, regional differences in ASD prevalence are well established – it is

possible that children who are otherwise similar but live in different areas receive ASD diagnosis at different ages, not due to their individual characteristics, but to characteristics of the regions they live in. This may be the case in Canadian jurisdictions, where the process of diagnosis of ASD may vary across different health regions depending on the available resources.
Objectives: (1) To examine the association between neighbourhood SES and prevalence of kindergarten-aged children with ASD in Canadian provinces and territories, and (2) to determine the strength of this association across health regions in each province/territory, which represent clusters of neighbourhoods in each jurisdiction.

Methods: This project will use data from a large, population-wide database of child development in kindergarten, measured with the Early Development Instrument (EDI). The EDI is completed by kindergarten teachers, includes records of childhood health disorders and diagnoses, and has been administered at the population level in most Canadian provinces and territories. The EDI data for children with ASD have been merged at the neighbourhood level with close to 2000 SES variables (e.g. neighbourhood SES, rural/urban) from the Canadian 2006 Census, the 2011 National Household Survey, and 2005 and 2010 Taxfiler data. An SES index has been created using principal component analysis and includes a subset of 10 variables. Since the EDI has included information on children's medical diagnosis from 2010 and variables from the Canadian 2006 Census were used to construct the SES index, EDI data collected in 2010 – if available – were considered the most relevant. However, EDI data were not available in all provinces in 2010, thus those collected closest to 2010 for each province and territory will be used (Table 1). Multilevel modeling will be applied to examine associations between the SES index and prevalence of ASD at the neighbourhood and health region levels for each province/territory.

Results: The neighbourhood-level prevalence of ASD ranged between 0% and 5.3% among the provinces/territories (Table 2). In each province/territory, there were neighbourhoods with SES index z-score below average for that jurisdiction. The strength of association between neighbourhood SES and prevalence of ASD among the provinces/territories was weak. Results of the multilevel modelling will be presented at the conference.

Conclusions: Findings of this project will contribute meaningfully to the understanding of the relationship between neighbourhood-level SES and prevalence of children with ASD, as well as facilitate customized service planning according to different needs of jurisdictions. From a public health planning perspective, this is a pragmatic first step for reducing socioeconomic inequalities in health of children with ASD in different areas.

3:04 **122.003** Antidepressants during Pregnancy and Autism Risk: Evidence of Confounding

*H. Heuvelman[1], K. Franklin[2], A. Havdahl[3], H. Jones[4], J. Golding[1], G. Davey Smith[4] and **D. Rai**[5], (1)University of Bristol, Bristol, United Kingdom of Great Britain and Northern Ireland, (2)University of Bristol, Bristol, United Kingdom, (3)MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom, (4)Population Health Sciences, Bristol Medical School, MRC Integrative Epidemiology Unit, Bristol, United Kingdom, (5)Population Health Sciences, Bristol Medical School, Centre for Academic Mental Health, Bristol, United Kingdom*

Background: A number of studies have reported associations between maternal antidepressant use during pregnancy and childhood autism. The causal meaning of these associations is still unclear. The possibility of genetic confounding and confounding by severity of underlying depression (the indication for the medications) has been hypothesised but has not been directly investigated to date.
Objectives: In a large population-based cohort we aimed to assess whether mothers with greater genetic risk for autism are more likely to take antidepressants during pregnancy and whether severity of depression is associated with autism risk

Methods: We used data from the Avon Longitudinal Study of Parents and Children (ALSPAC), a birth cohort study in England which recruited 14,541 pregnant women in the Bristol area in 1991-1992, resulting in 14062 live births. Medication use was ascertained prospectively via questionnaires and coded into WHO Anatomical Therapeutic Classification codes by a pharmacologist. Children with an ASD diagnosis were identified by record linkage with health and education records and parental reports. Autism related traits were ascertained by 4 scales that independently predict ASD in ALSPAC: the Social and Communication Disorders Checklist, the Children's Communication Checklist (coherence subscale), a repetitive behaviour measure, and the Emotionality, Activity and Sociability temperament scale (sociability subscale). These measures were dichotomised, with approximately 15% defined on each scale as having highest autistic traits. Maternal polygenic risk scores (PRS) for autism were constructed using summary data from the Psychiatric Genomics Consortium GWAS. Maternal depression was assessed prospectively at 18 and 32 weeks gestation using the Edinburgh Postnatal Depression Scale.

Results: Mothers in the top decile of an optimal polygenic risk score for autism (p-value threshold 0.05) had a 2-fold odds of taking antidepressants during pregnancy [Odds Ratio 1.97 (95%CI 1.05-3.70)] and for having a child with autism [2.19 (1.30-3.68)] as compared to those in the lower 90 percentiles. There was no evidence of an association between the mother's autism PRS and severity of depression (assessed both by continuous EPDS scores and in quintiles). A dose response association was observed between higher severity quintiles of maternal depression during pregnancy and social communication, speech coherence and repetitive behaviours but not with a diagnosis of autism.

Conclusions: The results demonstrate the potential for a significant contribution of genetic confounding, and confounding by severity of indication in the associations between antidepressant use during pregnancy and offspring autism. The implications of these findings to the wider literature will be discussed.

3:16 **122.004** Measuring Quantitative Autism Traits in Families Using the Social Responsiveness Scale: Informant Effect or Intergenerational Transmission?

__W. De la Marche__[1], I. Noens[2,3], S. Kuppens[4], J. L. Spilt[5], B. Boets[6] and J. Steyaert[6], (1)Youth Department, OPZ Geel, Geel, Belgium, (2)Parenting and Special Education Research Unit, University of Leuven, Leuven, Belgium, (3)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium, (4)Erasmus School of Health Policy & Management, Erasmus University Rotterdam, Rotterdam, Netherlands, (5)KU Leuven, School Psychology and Child and Adolescent Development Research Unit, Leuven, Belgium, (6)Center for Developmental Psychiatry, KU Leuven, Leuven, Belgium

---

Background:
Autism spectrum disorders (ASDs) have a high degree of heritability, but there is still much debate about specific causal genes and pathways. To gain insight into patterns of transmission, research has focused on the relatedness of quantitative autism traits (QAT) between family members, mostly using questionnaires. Yet, different kinds of bias may influence research results.
Objectives:

To examine possible informant effects in an ASD family study using the Social Responsiveness Scale (SRS) as a QAT measure, and, taking these into account, assess possible intergenerational transmission of QAT.

Methods:

We used multiple informant data retrieved via the Social Responsiveness Scale from 170 families with at least one member with ASD. Using intra class correlations (ICCs) and mixed model analyses we investigated inter-informant agreement and differences between parent and teacher reports on children and between self- and other-reports on adults. Using structural equation modelling (SEM) we investigated the relatedness of QAT between family members in ASD families.

Results:

Parent-teacher agreement for social responsiveness was modest (ICC total sample = .55), but poor for children with ASD (ICC = .06-.09). Agreement between parents was moderate to strong for affected (ICC = .52) and unaffected (ICC = .80) children. Agreement between self- and other-report in adult men was good (ICC = .70), but only moderate in women (ICC = .57). Agreement did not differ between adults with and without ASD. While accounting for informant effects, our SEM results corroborated the assortative mating theory and the intergenerational transmission of QAT from both fathers and mothers to their offspring. In a post-hoc analysis, however, this association appeared to be insignificant from fathers to their affected offspring (β=.03, *p*=.880).

Conclusions:

Since we demonstrated that the inter informant agreement varies depending on the diagnostic status of the participants, we state that the SRS, and possibly also other questionnaires, should be used cautiously when researching familial correlations and transmission of QAT in clinical populations. Furthermore, the the context of the use of the questionnaire (screening vs diagnostic assessment; family research with risk of contrast effect) may influence the results. Our findings also support intergenerational transmission of QAT as measured by the SRS.

1 **126.001** "It's Not As Bad As All That": The Psychosocial Outcomes of Adult Autistic Women in Comparison to Their Neurotypical Peers

__F. R. Sedgewick__[1], E. Pellicano[2] and V. C. Hill[3], (1)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland, (2)Macquarie University, Sydney, Australia, (3)Psychology and Human Development, UCL Institute of Education, London, United Kingdom

Background:

Research has repeatedly found that autistic individuals have worse psychosocial outcomes in adulthood than their neurotypical peers. These studies, however, have generally focused predominantly on male participants, and therefore may miss the specific experiences of autistic women, particularly women who are diagnosed later in life and have therefore had to navigate the world without the supports now often provided to young autistic people.

Objectives:

This research sought to examine the psychosocial outcomes of a group of autistic women in direct comparison to a group of neurotypical women, of similar age and intellectual ability. These outcomes included psychosocial outcomes, such as employment status and relationship closeness, alongside mental health issues and overall life satisfaction.

Methods:

We recruited 19 autistic women (M age = 30 years 2 months) and 19 neurotypical women (M age = 28 years 8 months) and assessed them on demographic factors, the Unidimensional Relationship Closeness Scale (URCS: rating their most significant relationship); the General Anxiety Disorder-7 (anxiety: GAD-&); the Patient Health Questionnaire-9 (depression: PHQ-9); the Zohar-Fineberg Obsessive Compulsive Screen (OCD: Z-FOCS); the SCOFF (disordered eating); the CAGE (problematic drinking); and the Satisfaction with Life Scale (overall life satisfaction: SWLS).

Results:

The majority of autistic women were in work or education (n=14, 74%) and enjoyed close relationships with friends and romantic partners. Indeed, there were no group significant differences in the degree of perceived closeness of their most significant relationship. The findings on mental health outcomes were more mixed, however. While autistic women were significantly more likely to have clinical levels of anxiety and depression than neurotypical women, and to screen positively for obsessive compulsive disorder, there were no significant group differences in terms of problematic drinking or disordered eating. Autistic women nevertheless rated themselves to be significantly less satisfied with their current life circumstances than neurotypical women, and this was significantly correlated with their higher depression scores.

Conclusions:

In contrast to much earlier research which has found poor adult outcomes for autistic individuals, this study shows, rather encouragingly, that late-diagnosed autistic women may achieve lives which are very like those of their neurotypical peers in terms of employment and long-term relationships. Autistic women, however, faced more mental health difficulties than neurotypical women. This latter finding may partly explain why autistic women rated themselves as less satisfied with their current life circumstances, regardless of their employment and relationship status – and suggests that improving the mental health support available for autistic women could yield concomitant improvements in their quality of life.

2

126.002 - the Periodic Risk Evaluation: A Tool to Identify Risk for Unwanted Outcomes Among Adults with Autism

L. Shea[1]*, S. Nonnemacher*[2]*, P. F. Turcotte*[3] *and C. J. Newschaffer*[4]*, (1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)Pennsylvania Bureau of Autism Services, Harrisburg, PA, (3)Drexel University, Philadelphia, PA, (4)AJ Drexel Autism Institute, Philadelphia, PA*

Background: Clinicians and providers who deliver services have a limited array of valid and reliable assessment tools to assess service needs of adults with autism. The lack of tools is especially concerning with respect to identifying those with the most complex needs that, if unidentified and unaddressed, escalate to crises such as hospitalization, homelessness, and police interactions. The Periodic Risk Evaluation (PRE) was designed to detect adults with autism having complex needs in order to flag them for additional services and intervention.

Objectives: This presentation will define the process used to design the PRE and demonstrate initial results, including sensitivity and specificity, of the PRE in identifying adults with autism with complex needs.

Methods: The PRE was established by clinical experts who identified conceptual clinical domains predicting characteristics of adults with autism who were complex cases in crisis, and/or need of additional services and support. Domains were organized into discrete question areas with scoring criteria and feedback from service providers on PRE content and design was solicited. The PRE was implemented by two Medicaid-funded programs administered by the Bureau of Autism Services in Pennsylvania, the Adult Autism Waiver and Adult Community Autism Program, which included 794 adults over age 21 with autism. The PRE questionnaire was completed by 530 individuals from January-July of 2017. ROC curves were used to determine optimal scoring cutoffs for identifying complex cases in a training sample and tested in a single validation sample. Analyses utilizing random forests to a best possible subset of classifying items are underway.

Results: The PRE was completed on a training sample of 86 adults with ASD. Gold-standard outcome designation (complex or non-complex service needs) was completed by the Clinical Team at the Bureau of Autism Services, who operate with individual-level knowledge of each program participant and were blind to PRE score. An ROC curve indicated a score of 13 yielded a sensitivity of 86% and a specificity of 84.8%. Using the initial cut point of 13 in a validation sample of n=530, the PRE with the initial cut point of 13, yielded sensitivity of 54.2%, specificity of 86.8%, positive predictive value of 43.3%, and negative predictive value of 91.1%. Additional analysis with approximately 300 additional participants and added time points employing random forest models with cross-validation are underway to determine if there is a better performing classification approach.

Conclusions: The PRE represents the first effort to establish a tool for adults with autism to identify individuals with complex service needs. The relatively large sample size in a government-funded program provides a natural laboratory to develop, test, and implement the PRE. Once optimal scoring for the PRE is established, testing of the PRE in additional programs, including those not funded by Medicaid, and expanding the age range are immediate priorities and would support generalization of the tool.

126.003 A Danish Pilot Study Investigating Effects of a Psychosexual Training Program for Adolescents with Autism Spectrum Disorder

L. S. Thomsen[1,2]*, K. Bøtkjær*[1]*, L. Pedersen*[1]*, G. M. Hald*[3]*, S. Tellier*[2] *and J. Christiansen*[1]*, (1)Centre for Autism, Herlev, Denmark, (2)School of Global Health, University of Copenhagen, Copenhagen, Denmark, (3)Institute of Public Health, University of Copenhagen, Copenhagen, Denmark*

Background:

Current literature emphasises the need for guidance of adolescents with ASD in stimulating healthy psychosexual development and preventing potential inappropriate sexual behaviour. This requires specific knowledge and skills in all domains of psychosexual functioning (i.e. sexual behaviour, sexual selfhood, and sexual socialization).

Objectives:

Hence, we assessed the utility of the individual Tackling Teenage Training (TTT) intervention program to provide psychosexual-education and practice skills related to puberty, sexuality and relationships.

Methods:

This pilot study systematically investigated the effect of the TTT intervention program on primary outcome (i.e. psychosexual knowledge) and secondary outcomes (i.e. self-concept and sexual behaviour problems) in adolescents with ASD (69 % male, mean age = 15.1 years, mean intelligence index = 100,6) in Denmark. The outcomes were assessed using self-report and parent-report questionnaires at baseline (T1), posttreatment (T2; after 6 months), and follow-up (T3; after 12 months).

Results:

Findings of this study show a strong primary outcome effect, which validates the TTT intervention program. Thus, the study found a statistical significant increased level of psychosexual knowledge from T1 (M = 21.2) to T2 (M = 30.4), and from T1 to T3 (M = 31.2), but not from T2 to T3. Second, it is concluded from the findings, that the secondary outcome, level of positive self-concept, statistical significantly increased in the participants from T1 (M = 44.0) to T2 (M = 50.3), but not from T2 to T3, and T1 to T3. Third, results from this study, indicate that the level of sexual behaviour problems in the participants decreased from T1 to T3.

Conclusions:

It seems quite reasonable to conclude that the effect of the TTT program in 12-17 years-old adolescents with ASD in a Danish context, are a significantly increased level of psychosexual knowledge and positive self-concept, as well as a significantly decreased level of sexual behaviour problems. This is reasonable, even without a control group. These preliminary findings indicate that the TTT program might be an important step towards improving psychosexual functioning in adolescents with ASD in Denmark.

4

126.004 Academic Achievement during Early Childhood As a Predictor of Adult Outcomes in ASD: Longitudinal Follow-up from Age 2 to 26 Years

***N. Benrey**[1], Y. B. Choi[2], L. A. Pepa[3], C. Lord[4] and S. H. Kim[5], (1)Weill Cornell Med School, New york, NY, (2)Psychiatry, Weill Cornell Medical College, White Plains, NY, (3)Weill Cornell Medicine, White Plains, NY, (4)University of California Los Angeles, Los Angeles, CA, (5)Psychiatry, Center for Autism and the Developing Brain, White Plains, NY*

Background: Recent research highlights the wide variability in outcomes during adulthood in individuals with ASD (Howlin, 2004). Academic skills are associated with behavioral and mental health outcomes in typically developing children (Bond et. al, 2007); however, we know little about the link between early childhood academic skills and adult outcomes such as independent living, employment, and quality of life in individuals with ASD.

Objectives: Given our previous findings that children with ASD demonstrated relative delays in achievement compared to IQ (Kim et al., 2017), we examined if achievement levels relative to cognitive skills at age 9 would predict adult outcomes at age 26.

Methods: Participants included 111 children referred for possible ASD at age 2 (n=76 with a final diagnosis of ASD). Academic achievement was measured by the Wide Range Achievement Test (WRAT). Difference scores between achievement and full-scale IQ (FSIQ) were calculated for reading, spelling, and arithmetic domains. At age 26, the following outcomes were measured: Employment (full/part time paid job vs. no paid job); Independent Living (living independently vs. living with parents/in group homes); Driving (yes vs. no); Vineland Adaptive Behavioral Scale (VABS), and Psychological Well-Being Questionnaire (WBQ; Table 1). Regression analyses were used to examine if the achievement-FSIQ difference scores at age 9 would predict age 26 outcomes.

Results: Relative delays in achievement in reading, spelling, and arithmetic compared to FSIQ at age 9 predicted age 26 employment, independent living, and driving status, while controlling for age, gender, maternal education, and ASD diagnosis. Relative delays in achievement in reading, spelling, and arithmetic compared to FSIQ also predicted more impairments in the VABS Socialization, Communication, and Daily Living domains and lower scores for psychological well-being (WBQ). When FSIQ was controlled, relative delays in spelling compared to FSIQ at age 9 still remained as a significant predictor of lower scores for psychological well-being (WBQ). All $p<0.05$.

Conclusions: Results based on a longitudinal cohort of children with ASD followed from age 2 to 26 suggest that the patterns of academic achievement at age 9 have significant, longer-term impacts on adult outcomes. Results highlight the importance of developing effective interventions tailored to improving academic skills in individuals with ASD during early childhood, which would have cascading effects on their quality of life and well-being during adulthood.

5

126.005 Adult Medicare Beneficiaries with Autism Spectrum Disorder: Case Identification and Characterization of Young Adults in the 2010 Limited Data Set Medicare Claims

***T. Benevides**[1], H. J. Carretta[2] and K. Graves[3], (1)Augusta University, Martinez, GA, (2)Behavioral Sciences and Social Medicine, Florida State University College of Medicine, Tallahassee, FL, (3)School of Physician Assistant Practice, Florida State University College of Medicine, Tallahassee, FL*

Background: Although Medicaid is the most well-known public insurer of individuals with ASD it is limited to individuals who can meet eligibility and means testing rules, and Medicaid covered services differ by state. Although less well known, persons younger than 65 are eligible for Medicare if they receive a disability determination. Approximately 25% of all beneficiaries in the 2008-2010 Medicare fee-for-service (FFS) files are younger than 65 and are eligible by virtue of their disability status.

Objectives: A challenge in using claims data is identification of ASD cases to ensure accurate characterization. In pediatric validation studies, some work suggests that relying on 1 claim could reliably identify probable ASD (e.g. Burke et al., 2014). The purpose of the current study was to compare the demographic characteristics and number of ASD cases identified using one claim versus a two claim case identification criterion in FFS Medicare files.

Methods: Claims files for Medicare Limited Data Sets for 2008-2010 were used. See Figure 1 for case identification process and exclusion criteria. After case identification, unique beneficiaries in the last claim year of 2010 were classified as having at least 1 ASD claim (1+ sample), or at least 2 ASD claims (2+ sample); intellectual disability (ICD9-CM 317.xx-319.xx) was also used to classify beneficiaries. We conducted univariate and bivariable descriptive statistics on each sample using Stata V14.1 (StataCorp, 2015). Proportions and exact binomial 95%CI for sample characteristics (age, gender, race, ethnicity, ACG® concurrent risk score, Medicaid state buy-in months) for ASD individuals with and without intellectual disability (ID) were produced and differences were examined with the two-sample test of proportions. Significance was set at $p<.008$ after Bonferroni correction.

Results: A total of 5,547 young adults with at least 1 ASD were identified, of whom 63% (n=3,499) had no ID claim, and 37% (n=2,048) had both an

ASD and ID claim. When restricting the sample to those with a minimum of 2 claims, a total of 2,816 young adults with ASD were identified, of whom 66% (n=1,847) had no ID claim, and 34% (n=969) had both ASD and ID claims. No differences were found in proportional demographic characteristics for the 1+ versus the 2+ groups (Table 1). For both the 1+ and 2+ claim analyses, the ASD and ID group was more likely to be older, Hispanic, non-white, and have 12m of Medicaid state-buy in than the ASD-only group. Additional analyses (not presented) will be shared regarding differences in predictive models analyzing the impact of using 1 versus 2 claims for service utilization analyses.

Conclusions: Researchers, policy makers, and service providers need to be aware of the availability and types of utilization afforded by Medicare. This study is the first step in validating the identification of a national sample of publicly insured adults with autism. Implications of using the 1 versus 2 claim criteria for claims analysis using Medicare to understand service utilization will be discussed, along with comparisons of models which predict service utilization when using the 1 or 2+ criteria.

6 **126.006** Priority Setting Among Autistic Adults to Develop a Research Agenda to Address Health Outcomes

T. Benevides[1], *S. Shore*[2] *and A. Lesko*[3], *(1)Augusta University, Martinez, GA, (2)Adelphi University, Newton, MA, (3)Gobal Autism Consulting Organization, Pensacola, FL*

Background: Evidence about the healthcare experiences among autistic adults and their caregivers is minimal and lacking (e.g. Nicolaidis et al., 2012). Given that this group has been marginalized and under-represented in research, it is imperative to provide voice to the priorities that the adult autism community see as next research steps. To accomplish this purpose, this Project Team, comprised of 3 autistic investigators and 2 neurotypical investigators, implemented a participatory action research approach.

Objectives: 1). Discuss the initial process of priority setting a research agenda with a small group of autistic adults (n=16), family members (n=8), and research/educational community members (n=14); 2). Discuss specific recommendations for improved researcher-autism community relationships.

Methods: Participatory action research methods were used, and included: large group meetings with stakeholders, small meetings with community members, and action steps driven by previous community preferences. Initially, large group and small group face-to-face meetings were conducted during a 1-day conference to discuss gaps and next steps for addressing needs of autistic adults. Member checking through reporting meeting outcomes and requesting feedback from a 15 member community council of autistic adults resulted in additional clarification of priorities. Continued use of face-to-face and social media engagement has informed actions and decisions.

Results: Attendees at the large group meeting reported that lack of mutual respect and trust inhibited participation and involvement in research activities for adults with autism. Actions which undermined trust included: lack of reporting results in a way that the autism community could understand or benefit from, lack of adequate compensation to be involved as research collaborators or participants, and lack of involvement in research decisions, including the development of what research questions are important. Preferred allocation of hypothetical research dollars for adult needs among meeting participants included: mental health interventions and outcomes (33% of funding), improving social well-being (24%), improving access to services (24%), addressing knowledge/skills/attitudes of providers and environments where care occurs (13%), addressing physical health outcomes (10%), and injury and mortality risks (5%).

Conclusions: As a result of this process, a Compensation Guide was drafted to outline roles and associated guidelines for compensation of autistic individuals. Collaborations with mental health providers and organizations are being developed and discussing findings with researchers are underway. More work needs to be done to fully include the autism community in defining the funding priorities, researcher activities, and approaches to ensure equitable participation in the research process. The current work represents a fraction of the autistic adult community, however, provides an initial framework for exploring more specific needs of this group.

7 **126.007** An Optimistic Outlook Concerning Employment: High Tech Meets Autism Spectrum Disorder

D. Hedley[1], *J. Spoor*[2], *M. Uljarevic*[3,4], *R. Y. Cai*[1,5], *S. Moss*[6], *A. L. Richdale*[1,5], *T. Bartram*[2] *and C. Dissanayake*[1], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)La Trobe Business School, La Trobe University, Melbourne, Australia, (3)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (4)Stanford Autism Center, Department of Psychiatry and Behavioral Sciences, Stanford University, CA, (5)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Australia, (6)Charles Darwin University, Darwin, Australia*

Background: Individuals with ASD face some of the highest rates of underemployment and unemployment of all disability groups (Shattuck et al., 2012). When successful at gaining employment, outcomes can still be poor if appropriate workplace supports are not in place (Hedley et al., 2017). However, there are advantages to hiring people with ASD. Many individuals exhibit high intellectual ability (Happe & Frith, 2006), or specific skills and interests that may help them thrive in particular occupations and roles (Donovan, 2008). Employees with ASD tend to be reliable, trustworthy and conscientious, often completing work to a high standard (Hagner & Cooney, 2005; Hillier et al., 2007). Research is needed to better understand strategies that support the success of adults with ASD at work.

Objectives: The present study employed qualitative methodology to examine the work experiences (past and current), expectations, and perceptions concerning a modified recruitment and selection process, of individuals with ASD who were employed in the Dandelion Program. This program is aimed at employing people with ASD in information technology (IT) positions. Work colleagues, support workers and family members also participated in the study.

Methods: Twenty-eight people, including nine employees with ASD (89% male; M_{age} = 23.97, SD = 3.00), seven support staff (29% male; M_{age} = 36.83, SD = 8.52), six co-workers (67% male; M_{age} = 42.21, SD = 6.46), and six family members (33% male; M_{age} = 43.92, SD = 13.89), participated in the study. Employees with ASD provided written evidence of their diagnosis by a medical professional when they applied for the program, and additionally self-reported a formal diagnosis of ASD and completed the Autism Spectrum Quotient (AQ). Seven focus groups were conducted using a semi-structured approach with set questions. Data were analyzed following established consolidated criteria for reporting qualitative research to identify themes (thematic analysis).

Results: Four themes associated with work experiences and program implementation were identified: Limitations in Previous Work Experiences (Theme 1), Pessimistic Expectations (Theme 2), Recruitment and Selection Adaptations (Theme 3), and Training and Transition (Theme 4). The themes that emerged from the focus groups demonstrated that individuals with ASD were motivated to work but experienced difficulty finding and maintaining suitable and interesting employment. Previous failures in obtaining meaningful work had led to a mood of pessimism regarding the future. The results indicated specific strengths of the program, particularly the revised human resource protocols and support provided to the trainees. The alternate pathway in to employment provided individuals with an opportunity to demonstrate their abilities over a lengthened time.

Conclusions: This study examined the perspectives of employees with ASD who were participating in a supported employment program. On the basis of these findings we can conclude that alternate approaches to entering the workplace, support when needed, and co-worker training can contribute to workplace success. Our results also suggested improvements to the program, for example, by personalization of support based on individual abilities. Employment programs that include appropriate modifications for people with ASD may help to promote a more optimistic outlook among participants.

8 **126.008** Changes from 2001 to 2012 in the Characteristics of Youth on the Autism Spectrum Receiving Special Education Services in the U.S.

P. Shattuck[1], *J. Rast*[1], *A. Roux*[2], *K. Anderson*[3], *C. M. Kerns*[4], *T. Benevides*[5] *and E. McGhee Hassrick*[1], *(1)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Life Course Outcomes Research Program, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (4)University of British Columbia, Vancouver, BC, Canada, (5)Augusta University, Martinez, GA*

Background: The autism spectrum encompasses a range of abilities and challenges. In childhood, lower rates of intellectual disability and impairment severity have been documented in more-recent cohorts. However, we know very little about corresponding changes in the distributions of characteristics and needs among the population of transition - age youth and young adults which hinders development of effective services, policies and practices for this vulnerable population .

Objectives: Describe how the characteristics of the identified population of high school students in the autism special education category changed from 2001 to 2012. Dependent variables included impairment and health characteristics, youth demographics, household and family characteristics.

Methods: We used secondary data from two related cohort studies that were funded by the U.S. Department of Education and conducted 10 years apart: Wave 1 (2001-2002) of the National Longitudinal Transition Study-2 and the National Longitudinal Transition Study-2012. Both studies were designed to yield nationally representative estimates of the characteristics and experiences of youth with special needs who received special education services. We limited analyses to youth who were ages 13 to 17 years. We used logistic regression to estimate differences in cohorts for each variable, while controlling for weights and sample characteristics. Rates of missing data per variable ranged from 0% to 12% across both surveys. We imputed missing data using multivariate imputation by chained equations (MICE) methods to create 50 implicates.

Results: The 2012 cohort was less racially diverse than the 2001 cohort (78% White v. 65%) and included more households receiving food stamps (19% in 2012 vs. 8% in 2001). Reported age when disability or concern was first noted was older, on average, among the more-recent cohort (3.0 years vs. 2.3 years). On average, members of the recent cohort had less severe communication impairments. For instance, in response to a question about how well youth could carry on a conversation, parents of 35% of recent cohort members said “Not at all” or “With a lot of trouble” vs. 55% of the 2001 cohort members. The recent cohort had higher scores on most functional skills measures. For instance, 58% were able to get to places outside the home “Very well” or “Pretty well” compared to 47% for the earlier cohort. Sex ratio, overall health, and the rate of psychotropic medication use were comparable across cohorts.

Conclusions: The average severity of parent-reported functional and communication impairments among youth identified with autism decreased from 2001 to 2012. Members of the recent cohort of teens served in the autism special education category are, on average, diagnosed later, are less impaired and have higher functional skills across a variety of survey questions asked of parents. The design of services and policies need to become more nuanced and specific to particular subpopulations because there can be no one-size-fits-all solutions for such a diverse and changing population.

9 **126.009** Assessing and Comparing Health-Related Independence for Physical and Mental Health Conditions in Youth with Autism Spectrum Disorder

N. C. Cheak-Zamora[1] *and A. Maurer-Batjer*[2], *(1)Health Sciences, University of Missouri, Columbia, MO, (2)University of Missouri, Columbia, MO*

Background: Physical and mental health conditions are prevalent among youth with Autism Spectrum Disorder (YASD). Youth’s ability to management their health care needs is imperative as YASD transition to adult health care services. It is unclear what health care management skills YASD have, including describing and seeking care for their health and mental health needs.

Objectives: This study aimed at increasing our understanding of health-related independence and transition needs by examining YASD’s ability to describe and seek care for their physical and mental health conditions and conducting the first analysis to examine what predicates describing and care seeking behaviors for YASD.

Methods: Caregivers (n=500) from five distinct Autism Treatment Network centers participated in a survey examining Health-Related Independence. Eligibility criteria for caregivers included being the primary caregiver/guardian of a youth age 16-25 with a diagnosis of ASD and being English speaking. YASD diagnosis and age were verified through chart records. Unadjusted and adjusted analyses determined 1) prevalence of physical and mental health conditions within the population; 2) associations between describe and care seeking behavior for physical and mental health conditions; and 3) potential predictors of describing and care seeking behaviors for both physical and mental health conditions.

Results: Ninety percent of caregivers who completed the survey were female, with just over 40% having a bachelor or higher-level education. The majority of caregivers lived in two-person households (77%) with moderate to high incomes ($50,000 or more) (71.2%). The average age of YASD was 19 years, with the majority being male (79%) and white non-Hispanic (82%). Most caregiver reported their youth as having Autistic (35%) or Autism Spectrum Disorder (28%) with moderate daily limitations (57%).

The majority of caregivers reported their youth had or currently have mental health conditions (90%) with 43% reporting 3 or more (e.g., ADHD, anxiety, and depression). Less than half of caregivers reported their youth needing mental health services (46%) within the last 12 months, over 90% received the mental health services they needed. Caregivers reported that 53% of YASD were able to describe their physical health condition and 45% were able to seek care for them. Regarding mental health conditions, caregivers reported 45% of YASD were able to describe their condition and 33% were able to seek care. Describe and care seeking behavior was significantly higher for physical versus mental health conditions (p<.001). Regression analysis showed similar predictors for describing and seeking behaviors regardless of whether the condition type. Intellectual disability was a strong predictor of each outcome (p>.005), while demographic and family-level variables accounted for little variance.

Conclusions: YASD have high rates of mental health conditions but are less like to use, describe, and identify mental health service/needs compared to physical health services/needs. These finding can inform much needed health care transition and YASD empowerment interventions focusing on both physical and mental health conditions.

10

126.010 Association of Activity Engagement with Severity of Depressive Symptoms in Adults with ASD

*P. Radoeva[1], K. Ballinger[1], S. J. Webb[2] and **G. Stobbe**[3], (1)University of Washington, Seattle, WA, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)Psychiatry & Behavioral Medicine, Seattle Children's Autism Center, Seattle, WA*

Background: Adults with Autism Spectrum Disorder (ASD) are at a higher risk for having comorbid mental health conditions, such as depression and anxiety. The patient health questionnaire-9 (PHQ-9) is a widely used self-administered questionnaire used to screen for depression and measure severity of depressive symptoms, identifying mild to severe depressive symptoms. Community participation has been associated with reduced risk of depressive symptoms in certain subpopulations (e.g., in older women in the general population (Ahern and Hendryx, 2008) or post-stroke (White et al., 2014)). In individuals with ASD, community participation has been found to decrease significantly during the transition from adolescence into adulthood (Myers et al., 2015).

Objectives: Our goal was to determine which factors are associated with severity of depressive symptoms in adults with ASD.

Methods: Using retrospective medical record chart review study design, we abstracted data for adults with prior clinically established ASD diagnosis, who presented for initial evaluation at the UW Medicine Adult Autism Clinic between January and August 2015, and had completed a PHQ-9 at the initial visit (n=32). ANOVAs were conducted using PHQ-9 as the dependent variable, and each of the following binary categorical variables as independent variables: sex, family history of anxiety and/or depression, engagement in community/recreational/educational activities, current employment/school status, change in living arrangement (over the preceding year) or current psychotherapy.

Results: Engagement in community/recreational/educational activities was associated with severity of depressive symptoms: PHQ-9 scores were lower (less depression) in patients engaged in one or more activities (M=9.5 SD=5.7) compared to patients not involved in activities (M=15.5 SD=5.8) (F=6.6, p<0.05). Individuals who were currently receiving psychotherapy had significantly higher depression scores (M=14.3 SD=5.4) compared to those who were not (M=8.4 SD=5.7) (F=8.7, p<0.01). Adults with family history of depression and/or anxiety had higher depression scores (M=13.0 SD=6.2) as compared to individuals without reported family history of depression and/or anxiety (M=8.4 SD=5.4) (F=4.8, p<0.05).

Conclusions: Our finding of association between current psychotherapy and severity of depressive symptoms likely reflects that patients with higher depression scores have an indication to receive psychotherapy (e.g., ongoing depressive episode). The association between depressive symptoms and involvement in activities (community participation, recreational and/or educational activities) suggests an important relationship between co-morbid depression symptoms in adults with ASD and ability to engage in activities of adulthood. While a causative relationship cannot be determined through our current methods, our results suggest that access to community participation, recreational, and/or educational activities is related to lower depressive symptom severity. It will be important to understand the direction of this finding as promotion of community-based, educational and recreational activities for adults with ASD may be an important component of treatment plans for depression in ASD.

11

126.011 Better at How but Worse at Why: Comparing Writing Produced By Autistic College Students and Non-Autistic Mentors

***E. Hotez**[1], A. Riccio[2], N. Gaggi[3], D. DeNigris[4], M. C. Zajic[5] and K. Gillespie-Lynch[6], (1)City University of New York, Hunter College, New York, NY, (2)Department of Psychology, The Graduate Center, City University of New York (CUNY), New York, NY, (3)College of Staten Island, Staten Island, NY, (4)Psychology & Counseling, Fairleigh Dickinson University, Madison, NJ, (5)University of California at Davis MIND Institute, Davis, CA, (6)Department of Psychology, College of Staten Island; CUNY Graduate Center, Brooklyn, NY*

Background: Although a rapidly growing literature focuses on the social, executive functioning and self-advocacy needs of autistic college students (Gelbar et al., 2014), the writing skills and writing self-efficacy of autistic college students have received almost no empirical attention (Gerstle & Walsh, 2010). This is surprising given that writing is essential for success in college and professional workplaces ("The Neglected R", 2003). In addition, discrepancies between often high cognitive skills and variable writing skills have been documented since the earliest accounts of autism (Asperger, 1991). Autistic school-age children and adolescents demonstrate difficulties with both transcription and translation abilities (Brown et al., 2014; Griswold et al., 2002; Mayes et al., 2017; Zajic et al., 2016), but the nature of these difficulties is not well understood (e.g., Asaro-Saddler, 2015). Difficulties associated with autism may impact writing skills; anecdotal evidence from one autistic college student suggests that some autistic college students may struggle with writing for an audience due to Theory of Mind (ToM) challenges (Jurecic, 2007).

Objectives: Our primary aims were to determine if: 1) autistic college students face unique writing difficulties and 2) challenges associated with autism, such as difficulty understanding others' perspectives and/or generating and organizing ideas, contribute to writing difficulties.

Methods: Autistic college students in a mentorship program (*n* = 27) and non-autistic mentors (*n* = 14) completed the Social Responsiveness Scale-2; Woodcock Word Comprehension; Reading the Mind in the Eyes, a writing self-efficacy measure (MacArthur et al., 2016); the Test of Nonverbal Intelligence; measures of generativity (e.g., how many uses for a brick and a bottle they could generate in a minute each), a verbal fluency measure (Jolliffe & Baron-Cohen, 2000), and a personal essay, wherein they were asked to share something interesting they had learned recently. A subset of participants also completed fictional (ASD = 19; non-ASD = 7) and persuasive (ASD = 14; non-ASD =9) writing tasks. After obtaining reliability, independent coders blind to diagnosis coded writing samples for perspective taking, contextual information, and elaboration. We used paper.rater.com to assess length (number of sentences), errors (number of grammar errors), and quality (AutoGrader).

Results: Autistic students reported heightened belief in writing conventions (e.g., "Good writers don't make errors in grammar"), less frequently provided a reason for another's perspective in their personal essays and fiction, and exhibited *better* grammar in their personal essays relative to mentors (Table 1; *p*s < .05). Among autistic students, lower belief in writing conventions and greater word comprehension, generativity, and ToM were associated with higher quality personal essays.

Conclusions: Findings suggest that the writing skills and writing self-efficacy of autistic college students are highly variable; few differences between autistic and non-autistic students were observed. Autistic students reported more perfectionistic attitudes toward writing and produced fewer grammatical errors than non-autistic students. Despite often high quality writing, they exhibited subtle difficulties using ToM in their writing. Low-stakes multimodal writing assignments wherein students can practice generativity and address others' perspectives through enjoyable activities are likely to be beneficial for autistic college students.

12

126.012 An Evaluation of the Tackling Teenage Training Program and Its Effects on Achieving Healthy Psychosexual Functioning in Adolescents with High Functioning Autism

O. Healy[1]*, J. Summerville*[2]*, K. Visser*[3]*, K. Greaves-Lord*[4]*, F. Boudesteijn*[5] *and J. Holloway*[6]*, (1)School of Psychology, Trinity College Dublin, Dublin, Ireland, (2)Trinity College Dublin, Dublin, Ireland, (3)Yulius, Barendrecht, Netherlands, (4)Erasmus MC, Rotterdam, Netherlands, (5)Yulius Academy, Barendrecht, Netherlands, (6)Psychology, National University of Ireland Galway, Galway, Ireland*

Background: The main characteristic difficulties facing a person with Autism Spectrum Disorder (ASD) are impairments in social interaction: poor social development, especially interpersonal development; deficits in language and communication, both verbal and non-verbal, and repetitive behaviours. These difficulties can be especially compounded during the adolescent years (Sullivan & Caterino, 2008). Adolescence is considered a difficult period in ASD with problems often arising in relation to psychosexual functioning. It has been proposed that such problems may originate in limited knowledge and skills related to appropriate psychosexual functioning (Dekker et al., 2014; Stokes et al., 2007; Stokes & Kaur 2005; Sullivan & Caterino 2008). Recently, an individualised training program has been developed, specific to adolescents with ASD, to fully cover psychosexual development and the challenges that may arise- the Tackling Teenage Training (TTT) Program. Pilot results of this training program point to positive effects, in adolescents with ASD in the Netherlands. Specifically, significant increases in psychosexual knowledge was shown for those participants who received the training (Dekker et al., 2014).

Objectives: This presentation will examine the findings of a pilot study currently underway in Ireland, examining the effects of the TTT program on the psychosexual development of adolescents with ASD.

Methods: Thirty five adolescents and their parents participated in this study. We assess the participants on measures of psychosexual knowledge, sexual functioning, anxiety and behavioural and emotional problems. Self-report and parent-report on measures, across three time points during intervention are gathered, at baseline (T1), post-treatment (T2 18 weeks), and follow-up (T3 6 months post-intervention).

Results: Outcomes have been analysed in relation to changes on measures across the three time points of the study. Additional analyses have been conducted on age and trainer-reported difficulty of the adolescent during intervention, on changes in psychosexual knowledge and sexual functioning, as a result of receiving the training program.

Conclusions: Results are discussed in relation to current research and theory in the area of sexual functioning and psychosexual development during adolescence in ASD.

13

126.013 Clinical Characterizations of Women and Men with ASD, Diagnosed As Adults.

A. Backman[1,2] *and T. Hirvikoski*[2,3]*, (1)Center of Neurodevelopmental Disorders at Karolinska Institutet (KIND), Stockholm, Sweden, (2)Habilitation & Health, Stockholm County Council, Stockholm, Sweden, (3)Karolinska Institutet, Stockholm, Sweden*

Background: Although based on but a few studies, it has been suggested through both clinical trials, in population-based studies, as well as expert testimonials that ASD is associated with long-term impairments in major life activities, also regarding intellectually able individuals with ASD. These include areas such as mental well-being, education, occupation, living situation, and coping with everyday hassles. Many of these studies have primarily focused on the situations of male individuals with ASD (diagnosed as children), leaving a gap in the knowledge regarding females with ASD and possible extant gender differences.

Objectives: The focus of the study is to explore the clinical characteristics of a clinical cohort of young women and men with ASD, diagnosed as adults. The characteristics involve psychiatric comorbidity, cognition, and adult life outcomes (relationships, education, employment, and living situation). Potential gender differences will be analysed.

Methods: Between 2001 and 2013, 830 adult patients were enrolled in the study at a tertiary outpatient clinic in Stockholm, Sweden. Out of these, n=348 patients were diagnosed with ASD. Patient's case files and life situation questionnaire were used as data sources regarding life outcomes. Comprehensive neuropsychological testing was conducted to assess general intellectual ability, and cognitive profile and clinical interviews were conducted to assess psychiatric co-morbidity.

Results: Of the n=348 adults diagnosed with ASD, out of these a sizeable proportion were female (ASD-ID, n=104; ASD+ID, n=19). At least one additional lifetime DSM-IV diagnosis was established in 84% of the individuals with ASD. Most common were additional neurodevelopmental disorders and mood disorders followed by anxiety disorders. Mood disorders were more prevalent among women with ASD, as compared to men with ASD. Otherwise, no significant gender differences were seen with regard to psychiatric comorbidity. The analyses regarding cognitive profile and current life situation are in progress.

Conclusions: It is very common among individuals with ASD diagnosed as adults to also have psychiatric comorbidity from a broad spectrum of disorders, especially additional neurodevelopmental disorders and mood disorders.

14

126.014 Correlates of Quality of Life in Adults with ASD: A Systematic Review and Meta-Regression Analysis

S. Y. Kim*, K. Bottema-Beutel and S. Crowley, Lynch School of Education, Boston College, Chestnut Hill, MA*

Background: Quality of life (QoL) is a multi-dimensional construct that includes subjective well-being, personal characteristics, and environmental variables (Schalock, 2004). When applied to individuals with ASD, QoL provides a criterion by which to assess satisfaction with various domains of their life as an outcome measure. Previous studies on the relationship between personal and contextual factors and QoL of individuals with ASD have provided inconclusive results (Chiang & Wineman, 2014). As improvement of QoL is one of the main objectives in interventions and social services of adults with ASD (Hong et al., 2016), it is important to identify factors associated with a favorable QoL to develop services that effectively support this goal.

Objectives: This study is a structured literature search and meta-analysis. The goal of this exploratory meta-analysis study was to synthesize the extant research to investigate the following hypotheses:

1. Are IQ, social functioning, and autism severity positively associated with QoL?
2. Is the correlation between QoL and social functioning higher than those between QoL and IQ or autism severity?
3. Is there a relationship between age and QoL?

Methods: This study used a structured search in ERIC, ERC, Medline, PsychINFO, and ProQuest Dissertations and Theses databases to locate studies that included correlations between QoL and (a) age, (b) IQ, (c) autism severity or (d) social functioning of adults with ASD (over 18 years). The first and third author independently reviewed the 117 articles in full, and two studies were included (Figure 1). Reliability of decisions on inclusion/exclusion was 100%. The authors of 22 studies that included measures of interest but did not report Pearson's r or partial r were contacted, and 14 provided the requested information. The first and third authors independently coded the email correspondences. For continuous variables, the average ICC was .855 (range 0.74–0.95). For categorical variables, the average agreement was 85.48%. This analysis utilized a robust variance estimation approach to meta-analysis and meta-regression using the ROBUMETA macro in Stata (StataCorp, 2013).

Results: The meta-analysis was conducted on a total of 80 effect sizes (16 studies), which represented 1000 participants with ASD (mean age= 29.6; male= 83.55%). A total of 14 reports and 75 effect sizes were gathered from unpublished sources. The coefficients in the simple meta-regression for age, IQ and autism severity were close to zero and statistically insignificant while the coefficient for social functioning was statistically significant (p=0.0476), and with coefficient 0.259. See table 1 for coefficients and p-values.

Conclusions: The meta-analysis shows that social functioning is more highly correlated with QoL than age, IQ and autism severity. The strong relationship between social functioning and QoL suggested by this study has implications for future studies to target social functioning to effectively support better QoL of adults with ASD. Increasing awareness and acceptance on the part of neurotypical individuals and improving social support are discussed as methods to improve social functioning.

Table 1. Summary effect sizes in unconditional models

Correlate constructs	Coefficient	P-value
Age	-0.0337	0.5934

15 **126.015** Dating Experience and Subjective Wellbeing in Autism Spectrum Disorder

M. A. Stokes[1]*, G. Hancock*[1] *and L. Pecora*[2]*, (1)Deakin University, Burwood, Australia, (2)School of Psychology, Deakin University, Burwood, VIC, Australia*

Background:

Research and clinical accounts both suggest that many individuals with ASD express a clear desire for relationships with others. However, they experience difficulties establishing such relationships. Previous systematic reviews and meta-analyses suggested that difficulties in this area are more commonly experienced by individuals with ASD compared to typically developing (TD) individuals (Hancock, Stokes, Mesibov, 2017). However, there is very little empirical evidence concerning the impact of ASD on the establishment of romantic relationship. Understanding of this would assist in providing well-informed and effective supports for adolescents with ASD in transition to adulthood and for adults with ASD who are seeking support around relationship difficulties.

Objectives:

The aim of this study was to contrast those with ASD to TD individuals for 1/. the level of interest in relationships, 2/. the rate of dating experience, and then 3/. the subsequent difficulties establishing a relationship. If differences between groups were found, the clinical impact of these difficulties was to be explored by assessing whether the association between ASD symptomology and overall wellbeing was moderated by the relationship difficulties.

Methods:

An online questionnaire comprising of the Sexual Behaviour Scale – third edition (SBS-III; Hancock, 2017), a measure of socio-sexual functioning validated by item response analysis, the Autism Quotient (AQ), and the Personal Wellbeing Index (PWI) was completed by 232 individuals with ASD (Age M=25.13, SD=7.96) and 227 TD individuals (Age M=22.16, SD=5.25).

Results:

Compared to TD individuals, individuals with ASD did not differ to the degree that they were interested in having a relationship (*p*=ns). However, those with ASD more commonly reported having never been on a date, *t*(411)=2.15, *p*<.05, Cohen's *d*=0.30, and having had difficulties establishing a relationship, *t*(437)=4.58, *p*<.001 Cohen's *d*=0.62. A regression model of the relationship between level of ASD symptomology and level of wellbeing, moderated by difficulty establishing relationships was significant, *F*(3,451)=43.44, *p*<.001, R^2=.22, with the moderator providing significant explanation of this relationship, *b*=-.64, *t*=-2.35, *p*<.05.

Conclusions:

Individuals with ASD have the same level of interest in relationships as TD individuals, however are less likely to have been on a date and if they have, they are more likely to have difficulty establishing a relationship. Results also demonstrated that the impact of ASD symptomology on one's wellbeing is moderated by these difficulties establishing romantic relationships. For clinicians, these findings suggest that primary interventions and supports in this domain should focus on understanding and skills related to the initial stages of meeting a potential partner and building a relationship. This is of particular importance given that difficulty in this area can reduce subjective wellbeing for those on the autism spectrum.

16 **126.016** Developing a Research Protocol to Investigate Stress, Workload, and Driving Apprehension during Driving Lessons in

Young Adults with an Autism Spectrum Disorder: A Feasibility Study.

V. Ross[1]*, D. J. Cox*[2]*, M. Noordzij*[3]*, K. Geryl*[4] *and A. Spooren*[5]*, (1)School for Transportation Sciences, Transportation Research Institute, Hasselt University, Diepenbeek, Belgium, (2)Departments of Psychiatry, Internal Medicine and Opthalmology, Virginia Driving Safety Laboratory, University of Virginia Health System, Charlottesville, VA, (3)Department of Psychology, Health and Technology, University of Twente, Enschede, Netherlands, (4)Faculty of Medicine and Health Sciences, Ghent University, Ghent, Belgium, (5)Faculty of Medicine and Life Sciences, Rehabilitation sciences, Hasselt University, Diepenbeek, Belgium*

Background:

Autism Spectrum Disorders (ASD) are known to impact quality-of-life (QoL). Driving can increase autonomy and QoL by enabling maintenance of work and social contacts. Research suggests people with ASD experience difficulties in complex driving situations. These difficulties may induce increased stress, workload, and driving apprehension (i.e., fear or worry), discouraging the pursuit of licensure and potentially interfering with safely learning to drive.

Driver instructors can be seen as key players in the development of safe driving skills, already during the learning phase. Internationally, attention went to the development of educational modules for driver instructors to learn how to deal with ASD learner drivers. Especially in the Netherlands, and recently in Belgium, several driving schools adopt a distinct approach for ASD learner drivers. However, effect evaluations often lack, neither has it been investigated whether these approaches lead to less stress, workload, and driving apprehension. Moreover, to avoid extra stress, too demanding research protocols are best avoided.

Objectives:

We conducted a feasibility study with wearable technology and questionnaires to determine levels of stress, workload, and driving apprehension during driving lessons. To this end, we developed a research protocol and asked a pilot sample to evaluate the procedure.

Methods:

The protocol included Q-sensor wristbands to indicate levels of stress and workload during driving lessons via measurement of electrodermal activity. We also included the Rating Scale of Mental Effort (RSME), together with the Driving Attitude Scale Parent-Report (DAS-PR) & Self-Report (DAS-SR) from Cox and colleagues as indicators for signs of apprehensive driving. Participants wore Q-sensors during each lesson and completed the RSME after each lesson, as their instructors also did. After the first, middle, and final driving lesson, participants and their parents completed the DAS questionnaires. Besides that, we included questionnaires to determine baseline levels of anxiety and ASD characteristics. We followed a similar procedure for participants that took a driving test. The pilot sample included 4 ASD diagnosed (1 male) and 2 control (1 male) learner drivers, age 18-25. Participants received the instructions once, at reception of the materials.

Results:

Procedures and measures were evaluated positively. However, to avoid incomplete or unusable data, special attention should go to clear enough instruction of the correct procedure. For instance, two participants wore sensors on the upper instead of the lower wrist, leading to unusable data. Furthermore, questionnaires were not always completed consistently. The non-parametric group comparison tests were not significant, probably due to the limited sample size. Only one ASD learner driver completed the driving exam during the study (i.e., one academic year).

Conclusions:

The developed protocol was evaluated positively and therefore can be used to investigate levels of stress, workload, and driving apprehension during driving lessons. However, sufficient attention to the instructions is warranted (e.g., inclusion of practice sessions and reminders). Finally, to include the driving exam, sufficient time allocation to the study is required.

17 **126.017** Getting from A to the Bahama's: An Exploratory Study of People with an Autism Spectrum Disorder

V. Ross[1]*, A. Neven*[1]*, K. Brijs*[1]*, E. Jongen*[2]*, V. Cops*[1] *and E. Hermans*[1,3]*, (1)School for Transportation Sciences, Transportation Research Institute, Hasselt University, Diepenbeek, Belgium, (2)Faculty of Psychology and Educational Sciences, Open University, Heerlen, Netherlands, (3)Department of Earth and Environmental Sciences, Division of Geography and Tourism, KU Leuven, Leuven, Belgium*

Background:

Most scientific studies on autism spectrum disorders (ASD) started from a medical perspective, investigating causes, prevention, and treatment. Recently, research started to focus more on the daily problems experienced by people with ASD, requiring the identification of specific barriers (Hamed, 2013). It appears that people with ASD are limited in autonomy and social inclusion (Ross et al., 2015). This, for example, due to possible impairments related to use of public transport and driving, but also to the less explored domain of tourism (Feeley et al., 2015; Hamed, 2013; Ross et al., 2015). To the best of our knowledge these three components were not yet combined in one single study.

Regarding public transport, a number of potential obstacles can be categorized in 3 main categories: social contact (buying tickets, interacting with other passengers), imagination (next stop, transfer), and communication (buying tickets, asking questions, asking to stop at the correct stop). Moreover, structural problems may complicate traveling, such as availability or infrastructure (pedestrian routes, traffic lights, traffic density, etc.). Research in New Yersey (Feeley et al., 2015) confirms the use of public transport entails various potential difficulties. Similarly, independent car driving is a complex task with several subtasks to be executed in parallel (e.g. shifting gears, steering, changing lanes, and keeping traffic rules into account). In addition, driving conditions are variable (e.g. traffic jams, road blocks, and detours). Driving thus depends on driving experience, perception, and cognitive abilities. ASD features, such as cognitive dysfunction can interfere with driving (Ross et al., 2015). Similar problems can arise in the area of travel and tourism since travel can be overwhelming for people with ASD, especially when routines change. The latter can result in fear, and sensory problems. Despite that, most tourism related publications concern children with physical or significant cognitive impairments, instead of ASD (Hamed, 2013).

Objectives:

This cross-sectional survey study explores possible problems related to autonomy and social inclusion. More specifically, we developed a questionnaire focusing on the use of public transport, driving skills, and tourism.

Methods:

Questionnaires were distributed via schools, ASD societies, and social media. Inclusion criteria were a certified ASD diagnosis, and a signed consent form. Respondents could participate from the age of 17 years since this is the age at which people are allowed to learn to drive in

Belgium.

Results:

A total of 87 respondents started the questionnaire. Exclusion of incomplete questionnaires resulted in a final sample of 50 respondents (52% male, age: 17-48). Data analysis is currently ongoing.

Conclusions:

Via this study, we hope to provide practical guidelines to stakeholders in the domains of public transport, driving, and tourism.

18 **126.018** Enhancing the Validity of a Quality of Life Measure for Autistic People

D. Mason[1]*, H. McConachie*[2]*, J. R. Parr*[3]*, D. Garland*[4]*, C. Wilson*[5] *and J. Rodgers*[3]*, (1)Institute of Neuroscience, Newcastle University, Newcastle-upon-Tyne, United Kingdom, (2)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (3)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom, (4)Northumberland, Tyne & Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (5)Autism advocate, Sunderland, United Kingdom*

Background: Quality of life (QoL) is an important outcome to measure in research and services. The World Health Organisation Quality of Life questionnaire (WHOQoL-BREF) is validated internationally and has been used in several studies with autistic adults. However, to date it has not been validated specifically for this use.

Objectives: (1) To develop additional items which address important quality of life issues for autistic adults. (2) To explore the validity of the WHOQoL-BREF (26 items), WHO Disabilities module (WHOQoL-DIS, 13 items), and additional items with a sample of autistic adults.

Methods: Four focus groups of autistic adults were held to discuss the WHOQoL-BREF and WHOQoL-DIS (subscales are Autonomy, Inclusion and Discrimination). Eleven proposed items were developed from themes derived from transcripts from the recorded discussions. Fifteen cognitive interviews were carried out with autistic adults to assess the face and content validity of these items. A Delphi survey (N=374) was conducted over two rounds to refine the items and establish their importance and clarity. From this process, nine items (hereafter ASQoL) were carried forward for further testing.

309 participants (mean age=43.0 years, SD=13.8) took part in a validation study recruited via the Adult Autism Spectrum Cohort-UK (ASC-UK). Participants completed the WHOQoL-BREF, the WHOQoL-DIS, the ASQoL items, the Hospital Anxiety and Depression Scale (HADS), the Craig Hospital Inventory of Environmental Factors short form (CHIEF-SF), the Comprehensive Quality of Life Scale (COMQOL), and the Interpersonal Support Evaluation List-12 (ISEL-12). Measures were completed on paper and returned via post, or electronically via Qualtrics.

Results: *Construct validity*: Exploratory factor analysis (EFA) suggested a four factor model and confirmatory factor analysis showed acceptable fit overall (CFI=0.83, $p<.001$). *Criterion validity*: The COMQOL satisfaction subscale was significantly correlated with all WHOQoL-BREF domains (r_s 0.59-0.79, all $p<.001$). *Convergent/divergent validity*: The WHOQoL-BREF domain scores were significantly correlated with all measures but showed stronger associations with hypothesised subscales (e.g. CHIEF-SF scores correlated significantly more strongly with the Environmental domain than the Psychological domain; $z=5.63$, $p<0.001$; ISEL-12 scores correlated significantly more strongly with the Social domain than the Physical domain; $z=3.90$, $p<0.001$). *Discriminant validity*: QoL scores for all subscales were significantly lower with increased depression and anxiety (HADS). *Reliability*: Overall internal consistency was excellent ($\alpha=0.93$) and subscale consistency was acceptable to good (αs=0.68-0.87).

Conclusions: The findings on validity of the WHOQoL-BREF supports its use with autistic adults and strengthens conclusions from previous research. This is the first study to use the WHOQoL-DIS with autistic people, and alongside the proposed ASQoL items, makes a unique contribution to further representing, measuring and understanding their QoL needs.

19 **126.019** Evaluating a Health Service Intervention for Adults with Autism Spectrum Disorder

C. Koning[1]*, D. B. Nicholas*[2]*, E. L. Kelly*[3]*, A. Orimalade*[4]*, L. Zwaigenbaum*[5] *and F. Orimalade*[6]*, (1)Clinical Support, Glenrose Rehabilitation Hospital, Edmonton, AB, Canada, (2)University of Calgary, Edmonton, AB, Canada, (3)Communication Disorders, Alberta Health Services; Glenrose Rehabilitation Hospital, Edmonton, AB, Canada, (4)Psychiatry, University of Alberta, Edmonton, AB, Canada, (5)University of Alberta, Edmonton, AB, Canada, (6)FACS Forensic Assessment & Community Services, Edmonton, AB, Canada*

Background:

Adults with ASD and their families report difficulty locating knowledgeable medical professionals, and a lack of coordinated services and provider-patient communication. Based on needs assessments including input from community stakeholders, a model of service delivery for adults was implemented and evaluated. This intervention incorporated adult diagnostic services, primary care for adults with ASD, and health care monitoring and consultation for complex health and ASD needs. Evaluation aims included process outcomes and qualitative experiences of service users and program delivery personnel.

Objectives:

To examine intervention outcomes such as utilization and patient satisfaction patterns

To examine perceived impact of service provision for adults with ASD, families, community ASD advocates and stakeholders, and clinical service providers

Methods:

This intervention evaluation-based study drew on participatory action research methodology, with a mixed data collection methods (qualitative and quantitative measures). Self-advocates and families were central to this evaluation design and process. Quantitative indicators consisted of patient demographics, service utilization patterns, and patient satisfaction/impact survey data. Qualitative data consisted of videoethnography-based interviews, resulting in video footage from service constituents offering commentary about the perceived impact of this intervention, including the needs of adults with ASD and the extent to which these needs are addressed by the intervention. Evaluation data were subjected to appropriate quantitative or qualitative analysis. As an example, video data was subjected to coding, categorization of codes and the determination of themes based on identified domains of need, as indicated by self-advocates and their families.

Results:

Findings indicate strong stakeholder engagement of and value placed on diagnostic and consultation services for adults with ASD. Service needs and demands for this intervention have already outpaced current service availability thresholds. Accordingly, core services have been well-utilized and viewed as impactful, and self-advocates report high levels of satisfaction with the intervention, based on surveys. Intervention users appreciate and strongly endorse clinical services that entail an understanding of ASD and its manifestation in adulthood. Of note, 60% of referrals for adult diagnostic services have resulted in a confirmed diagnosis of ASD, thereby seemingly identifying a substantial cohort of adults with ASD in the community who have remained undiagnosed and likely under-served over time. Impact measures suggest that this model of coordinated adult health services addresses a critical need, including benefits of adult-based accessible diagnostic services, clinical expertise for complex health and mental health care, and continued community capacity building in ASD. The videoethnographic findings yield illustrative video commentary that convey key interventional learnings for program development. Outcomes including lessons learned, benefits and service gaps will be identified in this presentation.

Conclusions:

This intervention study informs accessible healthcare services for adults with ASD. For individuals with ASD and complex health and mental health needs, findings support a community-based 'medical home' approach, including accessible diagnostic and consultation services. Findings invite ongoing capacity building across the healthcare continuum to proactively address gaps such as support for transition to adulthood, resources for seniors with ASD, and employment and housing needs within this population. Recommendations for program implementation and evaluation will be offered.

20 **126.020** Evaluating the Psychometric Properties of Social Cognitive Tasks for Adults with Autism

N. J. Sasson*, K. E. Morrison and A. E. Pinkham, University of Texas at Dallas, Richardson, TX*

Background: Although social cognition offers a promising treatment target for adults with autism, this effort is hindered by a lack of well-validated measures of social cognition for use in clinical trials. Many tasks measure the same constructs (e.g., emotion recognition), and little work has been done to assess which measures are the most reliable and valid for identifying social cognitive impairments in adults with autism.
Objectives: Similar challenges in the schizophrenia literature prompted the Social Cognition Psychometric Evaluation (SCOPE; Pinkham et al., 2015), which evaluated the psychometric properties of common social cognitive tasks and provided recommendations regarding their future use. Because related deficits in social cognition characterize autism (Sasson et al., 2011), we tested the reliability and discriminant validity of measures examined in SCOPE for use with adults with autism.

Methods: Adults with autism (n=103; Age: M=24.28; IQ: M=105.64) and typically-developing (TD) controls (n=94; Age: M=24.04; IQ: M=107.80) completed eight tasks from the SCOPE study spanning four domains of social cognition: 1) the Ambiguous Intentions and Hostility Questionnaire (AIHQ) measured hostile attribution style; 2) social appraisal was measured by a) The Awareness of Social Inference Task (TASIT), b) Hinting Task, and c) Reading the Mind in the Eyes; 3) emotion recognition was measured by a) Bell Lysaker Emotion Recognition Test (BLERT), and b) The Penn Emotion Recognition Test (ER-40); 4) social perception was measured with the Relationships Across Domains (RAD). Additionally, the Trustworthiness task was added as it overlaps with each domain. The Cartoon Theory of Mind Task (CToM), which measures non-verbal inferences of intentionality, and the Benton Facial Recognition Test were also added for their relevance to autism.

Results: Reliability was assessed using Cronbach's alpha. Social appraisal, social perception, and emotion recognition tasks showed moderate to strong reliability: TASIT (α=.86), Hinting (α=.74), CToM Attribution of Intention (α=.72), and Eyes (α=.73); Benton (α=.72) and RAD (α=.81); and BLERT (α=.72), ER-40 (α=.67). The Trustworthiness task also showed strong reliability (α=.92). The AIHQ Blame score showed high reliability (α=.87), but the Hostility (α=.48) and Aggression subscales (α=.43) did not.

We also tested the discriminant validity of the tasks for autism and TD groups. A MANOVA with Group (autism, TD) as a between subjects factor found significant differences across all measures (λ=.636, F(12, 173)=8.27, p< .001). TD adults preformed significantly better than adults with autism on all tasks (p's< .02) except for the AIHQ Blame (p=.86), Hostility (p=.48), and Aggression (p=.85) subscales, as well as the CToM (p=.58) and Trustworthiness task (p=.10).

Conclusions: Most of the social cognitive tasks assessed demonstrated strong internal consistency and were sensitive at revealing impairments in the autism group relative to the TD group. Specifically, the BLERT, Hinting, ER-40, Eyes, TASIT, RAD, and Benton performed well and are recommended for use with adults with autism. Although further psychometric evaluation is warranted, these findings are largely consistent with SCOPE (Pinkham et al., 2015) and indicate many tasks developed for evaluating social cognitive impairments in schizophrenia are equally applicable to autistic adult populations.

21 **126.021** Evaluation of a Mentorship Program for Undergraduates with ASD

***D. A. Trevisan**[1], S. Leach[2], G. Iarocci[3] and E. Birmingham[1], (1)Faculty of Education, Simon Fraser University, Burnaby, BC, Canada, (2)Simon Fraser University, Centre for Students with Disabilities, Burnaby, BC, Canada, (3)Simon Fraser University, Burnaby, BC, Canada*

Background:

The prevalence of students with ASD in university is rising (White et al., 2011), necessitating universities to offer support systems for promoting academic success and degree completion.

Objectives:

This study evaluated the effectiveness of Simon Fraser University's (SFU) Autism Mentorship Initiative (AMI), a peer mentorship program that matches undergraduates with ASD with upper level undergraduates and graduate students from SFU in order to help them navigate the social, emotional and academic demands of university life.

Methods:

Participants included 23 undergraduates previously diagnosed with ASD or Asperger Syndrome (mentees), and 21 undergraduate or graduate neurotypical students (mentors) from SFU.

Mentors and mentees both completed program evaluation surveys assessing the educational and personal benefits they experienced as a result of their involvement with AMI.

Mentees also completed a number of questionnaires including: Behavior Assessment Scale for Children – Self-report, College (BASC-SRP-COL), Behavior Rating Inventory of Executive Function (BRIEF), Learning and Study Strategies Inventory (LASSI), and the Student Adjustment to College Questionnaire (SACQ).

Selected Results:

Table 1 provides descriptive data about the mentees who participated in AMI. The percentile rank scores represent the relative standing of the AMI mentees on each of these variables in comparison with the population norms.

Table 1

Variable	Measurement Tool	Directionality	Mean Percentile Rank
Internalizing Problems	BASC-SRP-COL	Higher percentiles indicate more problematic behaviors.	72
Inattention/Hyperactivity	BASC-SRP-COL		55
Emotional Symptoms Index	BASC-SRP-COL		77
Full Scale	BRIEF	Higher percentiles indicate *worse* executive functions.	76
Metacognition Index	BRIEF		92
Behavior Regulation Index	BRIEF		56
Anxiety	LASSI	Higher percentiles indicate *better* learning strategies.	45
Motivation	LASSI		53
Test Strategies	LASSI		42
Attitude and Interest	LASSI		23

Table 2

Pre-Post Gains in University Adjustment

SACQ Subscales	Semester 1 mean percentiles	Semester 2 mean percentiles	t-score	p-value	Cohen's d
Academic Adjustment	27	42	1.86	.085	.32
Emotional Adjustment	16	31	4.13	<.001	.36
Social Adjustment	18	31	3.29	.005	.59
University Adjustment (Full Scale)	18	34	4.25	<.001	.49

Table 3

Educational and Personal Benefits from Survey (Mentees)

Question	% Disagreement	% Neutral	% Agreement
AMI helped with socialization and meeting other students	6.25%	43.75%	50%
AMI helped me improve my study skills	25%	43.75%	31.25%
AMI has helped me improve my time management skills	0%	12.5%	87.5%
AMI has helped me manage anxiety	12.5%	50%	37.5%

Table 4

Personal and Professional Benefits (Mentors)

Question	% Disagreement	% Neutral	% Agreement
Learned more about Autism and Mentorship	9.09%	0%	90.91%
Benefitted Professionally	20%	20%	60%
Benefitted Personally and Enjoyed Involvement in AMI	9.52%	0	90.48%

Conclusions:

Compared to the general college population, our mentees displayed higher than average internalizing symptoms, lower executive functioning, poorer study strategies and lower college adjustment, highlighting the need for individualized support systems for undergraduates with ASD in universities. Mentees demonstrated significant pre-post improvements in college adjustment, and survey data revealed that both the mentors and mentees in our program experienced personal, educational and professional benefits from their involvement in AMI. Peer mentorship programs are an effective tool for supporting undergraduates with ASD, and provide important professional benefits for neurotypical mentors.

22 **126.022** Executive Function and Social Cognition Impairments in Autism Spectrum Disorder, Attention-Deficit/Hyperactivity Disorder and Comorbid Presentation

S. Lukito[1]*, O. O'Daly*[2]*, D. J. Lythgoe*[2]*, I. Cummings*[3]*, A. Galanopoulos*[3]*, M. Nyakunengwa*[3]*, K. Rubia*[4] *and E. Simonoff*[5]*, (1)Department of Child and Adolescent Psychiatry, Institute of Psychiatry, Psychology, and Neuroscience, King's College London., London, United Kingdom of Great Britain and Northern Ireland, (2)Department of Neuroimaging, King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (3)The Adult Attention-Deficit/Hyperactivity Disorder (ADHD) and Autism National Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (4)Department of Child and Adolescent Psychiatry, King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (5)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom*

Background: Attention-deficit/hyperactivity disorder (ADHD) frequently co-occurs among people with autism spectrum disorder (ASD), prompting studies of individuals with the "pure" disorders and their "combined" (i.e., ASD+ADHD) form. Social cognition (SC) deficits were often reported in ASD. Furthermore, executive function (EF) deficits were often reported in individuals with ADHD and with ASD, although the latter finding might be associated with the co-occurring ADHD symptoms in the population. [1,2] To date, only one study of EF and SC in adults in this population have been conducted,[3] the findings of which were confounded by uneven distributions of sex and ADHD subtypes across groups.
Objectives: This study compared the EF and SC impairments of young adult males with ASD, ADHD, ASD+ADHD against those with typical development (TD). Medication intake and ADHD subtypes were balanced across groups with ADHD diagnoses. We expected the ADHD and the ASD+ADHD groups to be impaired primarily in EF, and the ASD in SC, relative to the TD group.

Methods: We tested 105 young adult males (age 20-27 years, FSIQ ≥ 70) with ASD (n = 26), ADHD (n = 27), ASD+ADHD (n = 27) against TD controls (n = 25) on a battery of computerized EF (response inhibition, sustained attention, visuospatial working memory, cognitive flexibility, temporal discounting) and SC tasks (theory of mind [ToM] and facial emotion recognition [FER]). Behavioral data were analyzed using omnibus MANOVAs and further explored using univariate ANOVAs with Group as a predictor. Analyses were conducted with and without IQ added as a covariate and contrasts were planned between each clinical group against TD.

Results: Omnibus MANOVAs revealed an effect of Group in EF ($p = .001$) and SC performance ($p = .002$). Univariate ANOVAs revealed that, relative to TD, the ASD, ASD+ADHD and ADHD groups were impaired on primary measures of response inhibition (commission errors), sustained attention (omission errors) and working memory ($ps \leq .03$), but these findings did not survive in the ASD group after IQ was covaried. Impairments in temporal discounting were specific to ADHD ($p = .03$), and remained when IQ was covaried. Cognitive flexibility did not differ across groups. The ASD and ASD+ADHD groups committed more errors during both SC tasks than the ADHD and TD groups, but only the FER errors in the ASD group ($p < .001$) remained after IQ was covaried.

Conclusions: Response inhibition, sustained attention, and working memory were not only impaired in the ADHD and ASD+ADHD, but also in the ASD group, although in the latter only when IQ was not included. Temporal discounting deficits was specific to ADHD and suggested the pervasive executive dysfunction in this population. SC impairments were found in the ASD and ASD+ADHD groups, although mostly did not survive when IQ was covaried. These demonstrate the associations between EF deficits and ADHD, SC deficits and ASD symptoms. There was some support for additivity of impairments in the combined diagnosis and the role of IQ as an explanatory factor for the variation of cognitive findings in adults in the populations.

23 **126.023** Neural Correlates of Unsuccessful Inhibition and Selective Attention in Young Adults with ASD, ADHD and Comorbid Presentation during the Modified Stop-Signal Task

S. Lukito[1]*, O. O'Daly*[2]*, D. J. Lythgoe*[2]*, S. Maltezos*[3]*, M. Pitts*[3]*, E. Simonoff*[4] *and K. Rubia*[5]*, (1)Department of Child and Adolescent Psychiatry, Institute of Psychiatry, Psychology, and Neuroscience, King's College London., London, United Kingdom of Great Britain and Northern Ireland, (2)Department of Neuroimaging, King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (3)The Adult Attention-Deficit/Hyperactivity Disorder (ADHD) and Autism National Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (4)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (5)Department of Child and Adolescent Psychiatry, King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom*

Background:
Individuals with attention-deficit/hyperactivity disorder (ADHD) or with autism spectrum disorder (ASD) often demonstrate motor response inhibition deficits. Neurobehavioural findings in the ASD population suggest that these deficits could be associated with co-occurring ADHD symptoms.[1, 2] A recent study showed that boys with ASD showed over-activation in the bilateral inferior frontal gyri (IFG) in contrast to age-matched ADHD boys who demonstrate under-activation in the IFG instead.[3] To what extent the neural correlates of motor inhibition in individuals with combined presentation (i.e., ASD+ADHD) are similar or different to the "pure" condition is presently unknown, however.

Objectives:

This study investigated the neural correlates of motor response inhibition and selective attention in young adult males with ASD, ADHD, ASD+ADHD and typical development (TD) using the functional magnetic resonance imaging (fMRI).

Methods:

We tested 91 adult males (age 20-27 years, FSIQ ≥ 70) with ASD (n = 21), ADHD (n = 25), ASD+ADHD (n = 23) against TD controls (n = 22) on a modified stop-signal task, that included oddball trials to control for selective attention. Medication intake and ADHD subtypes were balanced across groups with ADHD diagnoses. The task comprised 200 "Go", 40 "Oddball" and 60 "Stop" trials and required participants to cancel responses already initiated upon the arrival of an infrequent stop signal. A tracking algorithm was implemented to adjust the stop-signal arrival time to ensure that task performance converged to 50% success rate. Analyses were undertaken using the Statistical Parametric Mapping (SPM8) software. The correlates of successful/unsuccessful response inhibition, controlling for selective attention, was studied by contrasting the successful/unsuccessful Stop *vs.* Oddball trials. Selective attention was examined by contrasting the Oddball *vs.* Go trials. Whole-brain comparison was conducted with univariate ANCOVAs (peak threshold $p < .001$ and extent threshold $p <.05$, family-wise error corrected) on these contrasts, covarying for volume-to-volume total movement. Significant clusters of activation across groups were extracted using MarsBaR toolbox for *post-hoc* pairwise comparison, Dunn-Sidak corrected.

Results:

Univariate ANCOVAs revealed significant group effects during unsuccessful response inhibition in left insula/IFG/superior temporal/middle temporal gyri ($p < .001$) and right insula/IFG/thalamus/parahippocampal gyrus ($p < .001$) with *post-hoc* pairwise comparison showing that the ASD+ADHD group was significantly under-activated (all *ps* ≤ .001) in these clusters compared to all other groups, which did not differ from one another. A group effect was also found during selective attention in right precuneus with the ASD and ASD+ADHD groups demonstrating over-activation relative to the TD and ADHD groups (all *ps* ≤ .01). The neural correlates of successful inhibition did not differ across groups. All results remained after covarying for IQ.

Conclusions:

During unsuccessful inhibition, young adults with comorbid ASD+ADHD demonstrate impairments in key regions of motor response inhibition typically found in boys with ADHD, which was neurofunctionally associated with error monitoring or late-arriving motor inhibition activation. The over-activation found in right precuneus in the ASD and ASD+ADHD groups could signify reduced de-activation of the default mode network, which is typically suppressed during task positive condition.

24

126.024 Executive Functioning in Adults with Autism. Do They Have a Characteristic Brief-a Profile?

K. E. Jager*, M. L. Bezemer and E. M. Blijd-Hoogewys, INTER-PSY, Groningen, Netherlands*

Background:

Adults with ASD are known to have executive function (EF) problems, especially with cognitive shifting. EF research in ASD is mainly based on results from neuropsychological tests. However, this way of testing has its limits concerning the ecological validity and takes a considerable amount of time. The Behavior Rating Inventory of Executive Function for Adults (BRIEF-A) does not have these disadvantages. The BRIEF-A screens for potential problems, measured by nine nonoverlapping theoretically and empirically derived clinical scales: Inhibit, Self-monitor, Plan/Organize, Shift, Initiate, Task monitor, Emotional control, Working memory, and Organization of materials.

Various studies have shown that the BRIEF is able to identify EF problems in children with ASD, with the most profound elevation on the scale Shift. This could be considered a 'characteristic' ASD profile. Little research has been conducted on the existence of such a profile in adults with ASD. Research using the BRIEF-A informant version shows that adults with ASD have elevated scores on the scales Shift and Plan/Organize. It is unclear whether the same is true for the self-report version.

Objectives:

We want to investigate whether there is a characteristic BRIEF-A-score profile for adults with ASD.

Methods:

The sample consisted of 254 adults ($M = 34.28$, $SD = 12.05$ years; 181 men, 73 women). Trained clinicians diagnosed the participants with ASD, using the DSM-IV-TR criteria (N = 14 AD, N = 114 AS, N = 126 PDD-NOS). All participants filled in a BRIEF-A self-report questionnaire. T-scores were calculated for all eight scales. The normative sample of the Dutch BRIEF-A manual was used as a reference group.

Results:

The ASD group has significant higher BRIEF-A scores – indicative of more EF problems – than the normative group, on all nine scales ($M >= 50$, $p < .001$, $d = 0.75\text{-}1.60$). The scales Shift, Initiate, Working Memory and Plan/Organize even show a clinical elevation ($M > 65$, $p <= .001$, $d = 0.25\text{-}0.40$).

Concerning differences based on sex, women with ASD have significant higher scores than men on the clinical scale Shift ($M = 74.27$, $SD = 11.70$, $M = 68.41$, $SD = 12.56$ respectively, $t(252) = -3.435$, $p = .001$, $d = 0.48$) and Emotional control ($M = 64.15$, $SD = 11.62$, $M = 58.97$, $SD = 12.16$ respectively, $t(252) = -3.110$, $p < .002$, $d = 0.44$).

Conclusions:

Adults with ASD report the most profound EF problems with shifting, initiating, working memory, and planning/organizing. Women with ASD report more problems than men concerning shifting and emotional control. Note that the effect sizes are small. More research is warranted before conclusions can be made concerning a possible characteristic BRIEF-A profile for adults with ASD.

25

126.025 Factors Associated with Post-Secondary School Independence Among Young Australian Adults on the Autism Spectrum

L. P. Lawson[1,2] *and A. L. Richdale*[3]*, (1)Olga Tennison Autism Research Centre, La Trobe University OTARC, Melbourne, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia*

Background:

Limited research has been conducted examining transition to adult life among young people on the autism spectrum. Existing evidence has shown low levels of employment, post-secondary study, and independence in individuals on the autism spectrum regardless of intellectual functioning. However, most studies examine adults across a wide age range and the few that have focused on individuals that have recently transitioned from secondary school often rely on parent report. The Study of Australian School Leavers with Autism (SASLA) is the first Australian longitudinal study to examine the transition period from secondary school to post-secondary school using self-report measures.

Objectives:

The aim of this study was to evaluate the levels of employment, post-secondary study, and independence in a sample of Australian individuals on the autism spectrum that have recently transitioned from secondary school.

Methods:

Individuals aged 15-25 years were invited to complete an online questionnaire measuring a range of outcome variables. The current study focuses on individuals who have already transitioned from high school. To date 68 post-secondary school individuals (M (SD) = 20.1 (2.3) years) have completed the survey (seven with an associated Intellectual Disability). Participants were asked to answer a range of questions relating to their current employment/post-secondary study status, presence of comorbid conditions (e.g. anxiety and depression), and other demographic variables. The Vocational Index was used as a measure of independence, where higher scores indicate more independence. Participants also completed the Autism-Spectrum Quotient-Short (AQ), the Patient Health Questionnaire-9 (PHQ-9), and the DSM-5 Generalised Anxiety Disorder Dimensional Scale (GAD-D).

Results:

High proportions of the sample reported experiencing a current anxiety (62%) or depression (31%) disorder. Sixty-two percent of the sample reported that they were currently studying (55% full-time) and 30% were currently employed; 16% were both currently employed and studying. Twenty-three percent of the sample were neither studying nor currently employed and 46% reported they were currently looking for work. The mean vocational index for this sample was 7.48 (SD 2.66), indicating a high level of independence. Hierarchical linear regression models controlling for age, found no association between the vocational index and AQ, GAD-D, or PHQ-9 scores.

Conclusions:

The results from the current study illustrate that there is a high level of independence in this sample of post-secondary Australian individuals on the autism spectrum. A high proportion of the sample reported that they were either currently studying or working. Level of independence was not significantly associated with autistic traits or levels of anxiety or depression. However, this study is limited by the small proportion of individuals with intellectual disability included in the sample. Nevertheless, previous research has reported that levels of independence are also low among high-functioning individuals on the spectrum. This study provides preliminary evidence that level of independence is not associated with autistic traits, anxiety or depression among young adults on the spectrum.

26 **126.026** Factors Underpinning the Successful Employment of Adults with Autism

J. Dreaver[1,2], *S. J. Girdler*[2,3], *C. Thompson*[4,5], *S. Bolte*[5,6,7], *M. H. Black*[2,3] *and M. Falkmer*[1,8], *(1)School of Occupational Therapy and Social Work, Curtin University, Perth, Western Australia, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (3)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (4)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Australia, (5)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (6)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden, (7)Child and Adolescent Psychiatry, Center for Psychiatry Research, Stockholm County Council, Sweden, (8)Curtin University, Bentley, Australia*

Background:

While obtaining successful employment is a primary ambition for young adults as they transition to the post-secondary years, this aspiration too often remains unrealized for individuals with Autism Spectrum Disorder (ASD). Given its bio-psycho-social approach the International Classification of Functioning, Disability and Health (ICF) has particular utility in conceptualising the employment of people with ASD. The ICF supports a holistic view of the individual and consideration of the role of contextual factors relevant to employment and the abilities and strengths of individuals with ASD in the workplace.

Objectives:

This study explored factors facilitating the successful employment of individuals with ASD across Australia and Sweden, examining these in reference to the ICF.

Methods:

Twenty semi-structured interviews, guided by the ICF, were conducted with company directors and line managers with in-depth knowledge of at least one case of successful employment of a person with ASD from Australia and Sweden. 'Successful employment' was defined as an individual with ASD maintaining competitive employment for six months or more. Thematic analysis extracted meaningful concepts which were collapsed into common themes relating to factors associated with successful employment. Strategies and supports underpinning employment success were also identified. Meaningful concepts were subsequently linked to the relevant ICF core-sets for ASD domains and codes.

Results:

While the experiences of company directors and line managers in Australia and Sweden were subtly different, three interrelated and overarching themes emerged including 'Knowledge and Understanding of ASD', 'Work Environment' and 'Job Match'. This research also identified, across countries, those social, adaptive, cognitive, employment and vocational supports and strategies that facilitated successful employment outcomes for people with ASD. Secondary data analysis linked 1083 unique meaningful concepts to the ICF. The most frequently linked category in the Environment was e430 *Individual attitudes of people in positions of authority*, followed by e330 *People in positions of authority* and e325 *Acquaintances, peers, colleagues, neighbours and community members*. The most frequently discussed categories in Activity and Participation were d740 *Formal relationships*, followed by d570 *Looking after one's health*. Only one of the eight chapters of the Body functions component were discussed by participants with these linking to *Mental functions*. The most prevalent categories within this chapter included b156 *Perceptual functions*, b122 *Global psychosocial functions*, b126 *Temperament and personality functions*, b167 *Mental functions of language*, b130 *Energy and drive functions*, b140 *Attention functions*, b164 *Higher level cognitive functions* and b160 *Thought functions*.

Conclusions:

Findings from this study revealed that knowledge and understanding of ASD underpinned employers' ability to make appropriate workplace modifications and match individuals to jobs. Linking of meaningful concepts to the ICF highlighted the importance of environmental factors, including support and relationships and attitudes in the workplace, in underpinning positive employment outcomes. This research provides practical strategies and supports which facilitate the successful employment of people with ASD, providing a basis for the development of future interventions and models of service delivery.

27 **126.027** Feedback from College Students with Autism Spectrum Disorders on the Transition into College and on a Social Support Program for College Students with ASD

D. Davidson[1], *I. Misiunaite*[2] *and E. Hilvert*[3], *(1)Psychology, Loyola University Chicago, Chicago, IL, (2)Loyola University Chicago, Chicago, IL, (3)Loyola University, Chicago, IL*

Background: The transition into college for adults with Autism Spectrum Disorders (ASD) is a precarious life stage. Commonly cited challenges include a lack of structure, difficulty with new routines, social communication issues, and increased anxiety and depression (Cai & Richdale, 2015). As the number of students with ASD pursuing higher education is projected to increase substantially in the upcoming years (Government

Accountability Office, 2016), it is imperative that colleges and universities develop adequate supports for these students.
Objectives: The primary objectives of this pilot project were to obtain information from college students with ASD about (1) their unique college transition experiences; and (2) their feedback about the design of a social support program for college students with ASD, i.e., the College Excellence in Students with Autism program (CESA).

Methods: Fifteen college students with ASD from 11 different states participated in this study. Participants were recruited through the host university's Office of Services for Students with Disabilities, an additional local university, and postings on various websites (e.g., Autistic Self Advocacy Network). Through an online platform, participants completed a questionnaire that asked them about their college experiences, their access to academic and social services at their institutions, and their ideas about the CESA program.

Results: Overall, students with ASD rated their college experience as positive. However, 60% of students with ASD reported being overwhelmed by their transition to college. Additionally, we found that over 80% of students reported feeling anxious and/or depressed because of the social demands of college, whereas 73% of students reported feeling anxious and/or depressed because of the academic demands of college. Correlational analyses revealed a trend that students who were overwhelmed by the transition to college were more likely to report greater anxiety and depression because of the *social demands* of college. No relations were found between students' reports of difficulty transitioning to college and their feelings of anxiety/depression because of *academic demands*. Interestingly, 73% of participants reported receiving academic services (e.g., extra time on exams) at their institutions, but only 33% of students reported receiving non-academic services (e.g., social support groups).

With regards to the design of the CESA program (see Table 1), the majority of college students with ASD surveyed believe it would be beneficial to have monthly social support group meetings during the entirety of the school year. Moreover, they believe it would be beneficial for the support group to have designated topics for discussion and that the support group would serve as a helpful way to meet other students on the spectrum and improve their social networks.

Conclusions: Overall, our findings demonstrate the need for additional services that support the transition to college for students with ASD, specifically services that provide greater access to social supports and social networks.

28

126.028 Highways to Happiness for ASD Adults: Perceived Causal Relations Among Clinicians

M. K. Deserno[1]*, S. Begeer*[2]*, D. Borsboom*[1] *and H. M. Geurts*[3]*, (1)Department of Psychology, University of Amsterdam, Amsterdam, Netherlands, (2)VU University Amsterdam, Amsterdam, Netherlands, (3)University of Amsterdam, Amsterdam, Netherlands*

Background:

Up until today, we lack sophisticated understanding of the potential causal pathways that channel the heterogeneity in adult outcome of the Autism Spectrum Disorder (ASD) population. The rapidly evolving toolbox of the *network approach* to psychological phenomena enables us to investigate the interrelation between ASD and well-being in a much more detailed manner. This toolbox additionally offers promising tools to quantitatively integrate the knowledge of clinical experts.

Objectives:

In this study, we present a novel approach by combining the Perceived Causal Relation (PCR) methodology and network analysis in order to (i) identify causal pathways in the well-being system in ASD, (ii) compare the results to validate the networks found in empirical data on well-being in ASD, and (iii) quantitatively integrate the knowledge of clinical experts in scientific endeavors.

Methods:

Trained clinicians (N=29) served as raters in a PCR task of 34 variables spanning different domains of daily functioning and well-being as well as ASD symptomatology. In this task, they were asked to complete 374 cause-effect ratings. In a follow-up question, we asked them to choose three targets of intervention in the resulting (averaged) network of their answers. Analyses included centrality analysis of the resulting cause-effect model and correlational comparisons with a network model of the exact same variables based on empirical data instead of ratings.

Results:

First, he PCR network reveals the causal model ASD clinicians adhere to: *reduced social insight* is seen as the underlying cause of most other ASD symptoms, i.e., *reduced empathy*, *reduced social contact*, *violations of social conventions* and *insistence on sameness*. A strong impact on domains of well-being and daily functioning was also attributed to *insistence on sameness*. Second, from all ASD characteristics, *sensory stimulation/motor stereotypies* was the one with least connections in the network as it was only rated as a cause for *problems associated with daily life*. Third, the clinicians' choices regarding their targets of intervention (depression, drug problems and aggressive behavior) were related to the respective centrality of these nodes.

Conclusions:

We found that the way clinicians perceive cause-effect relations between ASD symptoms, well-being and daily functioning is highly similar to the interrelatedness of these factors found in empirical self-reported data. In addition, we have provided the first validation of psychological network estimation procedures that have recently been energizing different clinical fields in psychological science. We have shown that the PCR methodology combined with network analysis is a promising tool to assess and include the knowledge of clinical experts.

29

126.029 Hoarding in Adults with Autism; A Preliminary Study of Prevalence, Risk Factors and Protective Factors.

J. Acland[1]*, K. L. Ashwood*[2]*, C. M. Murphy*[2]*, S. Blainey*[3]*, F. Dekastrou*[4]*, K. Mehta*[4]*, E. L. Woodhouse*[5]*, V. Stoencheva*[6]*, R. H. Wichers*[2]*, M. Pitts*[7]*, A. Galanopoulos*[7]*, A. Nolan*[6]*, I. Broch-Due*[6]*, R. McNally*[6]*, S. Maltezos*[7]*, D. Robertson*[6]*, G. M. McAlonan*[6] *and D. G. Murphy*[8]*, (1)South London & Maudsley NHS Trust, Camberwell, United Kingdom of Great Britain and Northern Ireland, (2)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (3)Forensic and Neurodevelopmental Sciences, IOPPN, Denmark Hill, United Kingdom, (4)FANS, IOPPN, London, United Kingdom, (5)Forensic & Neurodevelopmental Sciences, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (6)Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (7)The Adult Attention-Deficit/Hyperactivity Disorder (ADHD) and Autism National Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (8)Department of*

Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom

Background: Hoarding includes difficulties with discarding, saving items, and accumulating large numbers of possessions or pets that result in clutter and adversely impact on daily-life. Hoarding disorder (HD) has been listed in DSM-5 as a standalone condition in 2013, affecting 1.5%-5.8% of the general population. In addition, there is preliminary evidence that some people with ASD and ADHD may have hoarding behaviours.
Objectives: Hoarding in adults with ASD and ADHD has had little investigation. It has been suggested that cognitive and behavioural difficulties may contribute to hoarding behaviour in people with ASD (restricted interests/difficulties with routine changes) and ADHD (poor attention/disorganization), respectively. The prevalence of hoarding/hoarding-type, risks associated with developing hoarding and factors protective against developing hoarding in adults with ASD/ADHD are unknown. Research is required into factors that influence HD in individuals with an ASC to aid in targeting effective psychological interventions.

Methods: We aimed to investigate hoarding in male and female adults with ASD, risk factors such as co-morbidity with ADHD symptomology, depression and anxiety disorder symptoms and, gender distribution.

We aimed to investigate hoarding in male and female adults with ASD, risk factors such as co-morbidity with ADHD symptomology, depression and anxiety disorder symptoms and, gender distribution.

Results: 53.47% of participants had high hoarding symptomology (score 6 or more). Gender distribution was, 40.5% male and 12.5% female with HHS, 29.8% male and 17.2% female with LHS. High HADS scores for depression were found with 59.5% and for anxiety with 59.7% with HHS. HHS also correlated with inattentive symptoms (63%) and hyperactive symptoms (61%) when compared to the LHS group ($p< .001$).

Conclusions: Males were 1.3 times more likely to be in the HHS group. The HHS group also exhibited a higher association with OCD symptoms, anxiety symptoms, social anxiety symptoms and depressive symptoms when compared to the LHS. The OCI-R hoarding subscales provide limited information regarding severity and other co-morbid factors. Further investigation using hoarding specific measures and focus groups would provide accurate results with regards to the severity of hoarding.

30 **126.030** Is Young Adulthood Really so Different for Young Adults with ASD? a Study Investigating Developmental Themes.

L. Mattys[1]*, I. Noens*[2,3] *and D. Baeyens*[4]*, (1)KU Leuven, Leuven, Belgium, (2)Parenting and Special Education Research Unit, University of Leuven, Leuven, Belgium, (3)Leuven Autism Research (LAuRes), KU Leuven, Leuven, Belgium, (4)Thomas More University College/Catholic University Leuven, Antwerp, Belgium*

Background:
The description of emerging adulthood as a separate developmental phase between the ages of roughly 18 to 25 is a fairly recent one (Arnett, 2007).

During this important transition to adulthood, Taylor and Selzer (2011) reported that young adults with ASD are three times more likely to have no daytime activities if they have no intellectual disability, suggesting that current clinical practices fail to accommodate to the needs of this group. Following Arnett's definition of emerging adulthood, the Inventory of Dimensions of Emerging Adulthood (IDEA; Reifman, Arnett, & Colwell, 2007) was published to quantify the relevance of six prototypical developmental themes. This tool has, to our knowledge, never been used to study young adults with ASD before. As such, there is currently no frame of reference to understand developmental themes that are relevant for young adults with ASD specifically.
Objectives:

To further our knowledge about developmental themes that are relevant for young adults with ASD, we studied how an ASD diagnosis influenced the relevance of prototypical developmental themes.

To do so, we first assessed the IDEA's construct validity in a Flemish population.

Methods:

The IDEA (Reifman, Arnett, & Colwell, 2007) was included in an online questionnaire that was filled out by 570 young adults between 17 and 27 years old (220 males and 285 females), of which 65 (50 males and 15 females) had a diagnosis of ASD. An exploratory factor analysis was performed to assess the factor structure of the IDEA in a Flemish population and determine relevant scales for further interpretation of results. Consequently, means of the two participant groups were compared for each new scale.
Results:

Following results are preliminary. An exploratory factor analysis using principal axis factoring suggested a latent structure of which five factors were selected. Five new scales were calculated based on these factors, and named Experimentation and Possibilities, Feeling in Between, Negativity and Instability, Reflection, and Commitment.

Participants with ASD scored significantly lower on items assessing their perception of having possibilities ($U = 10105$, $p < .000$) and items that indicate commitment ($U = 13509$, $p = 0.019$). Participants with ASD reported significantly higher levels of negativity and instability ($U = 12225$, $p = 0.001$). Participants, however, did not differ significantly on items assessing the extent of feeling in between adulthood and adolescence ($U = 15795$, $p = .620$), as well as items assessing reflection ($U = 14604$, $p = .143$). Further analyses will investigate the effects of group differences and how these findings relate to quality of life observations.

Conclusions:

Preliminary results suggest that young adults with ASD show similarities with their peers. However, it seems that young adults with ASD are less optimistic about the opportunities they have, experience more negativity and instability, and are less occupied with commitment to their future adult lives. These findings can inspire clinical practice by targeting interventions on developmental themes, for example by discussing possibilities and opportunities with young clients with ASD.

31 **126.031** Life Quality and Challenges in Taiwanese Young Adults with Autism Spectrum Disorders: Combined Quantitative and Qualitative Approaches

Y. L. Chien[1]*, Y. N. Chiu*[1]*, W. C. Tsai*[1] *and S. S. F. Gau*[2]*, (1)Department of Psychiatry, National Taiwan University Hospital, Taipei, Taiwan, (2)Department of Psychiatry, National Taiwan University Hospital & College of Medicine, Taipei, Taiwan*

Background:
As the incidence of autism spectrum disorder (ASD) increases in Taiwan, the difficulties in the real life that adults with ASD face become a critical issue. Many of high functioning ASD stay home unemployed, or hardly maintain a regular job to earn their living. There is a significant gap between needs and services provided in adulthood. How the young adults with ASD view their quality of life (QoL) remains unclear, not to say the determinants for their QoL. Moreover, the concerns and worries of their parents, who are usually the main caregivers of Taiwanese young adults with ASD, are rarely investigated.

Objectives:

This study aims to quantitatively examine the subjective QoL in Taiwanese young adults with ASD, and investigate the determinants for different domains of QoL. Meanwhile, a qualitative approach was taken to explore the parents' concerns as the major life challenges of these young adults.

Methods:

The study comprised 65 young adults with ASD (mean age, 26.9 years, SD, 7.3; males 53, 81.5%). We used Taiwanese version of World Health Organization Quality of Life-BREF to measure QoL. Four domains of QoL were compared with 61 typically-developing controls, including physical, psychological, social, and environment. To identify the correlates of four QoL domains, we assessed IQ, personality trait, family support, anxiety/depression, autistic symptoms, and sensory symptoms by various questionnaires, and assessed their relationships with QoL by correlation analyses and model selection. On the other hand, focus groups were held to explore the difficulties and challenges of adults with ASD from parents' view of points.

Results:

Adults with ASD reported lower QoL in four domains of QoL compared to controls. In correlation analyses, we found that IQ was not correlated with any of QoL domains, whereas, autistic symptoms, harm avoidance, and family support were significantly associated with different domains of QoL. In model selection, males was associated with lower QoL. Poor support from father and depressive symptoms were associated with several domains of QoL including physical and psychological domains. The severity of autistic symptoms was associated with the social domain. Besides, anxiety and sensory symptoms were associated with the environment domain of QoL. As for parents' focus groups, the major concerns are four aspects, including (1) independence (e.g., basic life skills, self-care, self-sufficient, self-satisfaction, etc.), (2) negative emotions (e.g., sensitive to negative feedback, undifferentiated and prolonged negative emotions, etc.), (3) repetitive/stereotyped behaviors and rituals, (4) others (e.g., sexual needs, being taken advantage of, too eager for making friends, potential legal problems, etc). For adults with higher function, interviewing for a job and maintaining the job are usually a significant challenge.

Conclusions:

Our results suggest lower QoL in Taiwanese adults with ASD and its potential correlates, providing a hope that treating co-occurred symptoms may influence their QoL. Parents' concerns point out the needs of specific resources and services to assist independence, to coach coping strategy for negative emotions, and to establish an understanding environment for them to live in a happier and meaningful way.

32 **126.032** Life Satisfaction, Anxiety and Camouflage in Adults with and without a Diagnosis of ASD

***E. Milne**, The University of Sheffield, Sheffield, United Kingdom*

Background:
A growing number of people are being diagnosed with autism spectrum disorder (ASD) in adulthood. Relatively little is currently known about quality of life in people who are diagnosed with ASD in adulthood.

Objectives:

The aim of this work was to investigate subjective life satisfaction, anxiety, and trait-masking (camouflage) in people who have received a diagnosis of ASD in adulthood, and in individuals who self-identify with the autism phenotype but who do not have a clinical diagnosis.

Methods:

Eighty-nine people took part: twenty-nine had a diagnosis of ASD and sixty participants did not. The undiagnosed group represented a wide range of individuals including some people who strongly identified with the autism phenotype. Eighteen of the sixty participants in the undiagnosed group scored above the RAADS-R cut-off for ASD (hereafter referred to as undiagnosed high-trait group). Participants completed the Ritvo Autism Asperger Diagnostic Scale (RAADS-R), the Beck Anxiety Inventory – trait version and the Satisfaction with Life Scale (Diener et al. 1985). In addition to total scores, a "camouflage" variable was calculated by creating a composite score from the three questions in the RAADS-R that probe the extent to which respondents hide their autistic traits in order to 'fit-in'. Four factor scores, reflecting social-relatedness, circumscribed interests, sensory / motor issues and social anxiety, were created based on previous factor analysis of the RAADS-R.

Results:

Participants who obtained RAADS-R scores below the cut-off for ASD had lower anxiety and higher life satisfaction than both the autistic adults and the undiagnosed high-trait group ($p<.01$). Autistic adults had increased anxiety and higher RAADS-R scores than the undiagnosed high-trait group ($p<.05$). Levels of life satisfaction did not differ between these two groups ($p>.05$). In both the autistic adults and the undiagnosed group ($N = 60$), RAADS-R scores positively correlated with anxiety, and negatively correlated with life satisfaction (all $\rho >$ +/- .402). In the undiagnosed group, all four of the RAADS-R factor scores correlated with life satisfaction, whereas in the autistic group ($N = 29$) only the social-relatedness factor correlated with life satisfaction ($\rho = -.458$). In the undiagnosed group ($N = 60$), camouflage was significantly related to both anxiety and life satisfaction ($\rho = -.292$ and .277 respectively). This was not the case in the diagnosed group (all $\rho > -.1$).

Conclusions:

Reduced life satisfaction and increased anxiety are associated with the autism phenotype. In particular, the extent to which someone feels able to socially connect may impact life satisfaction in autistic adults. Camouflage of autistic traits is associated with increased anxiety and reduced life satisfaction in undiagnosed participants, but not in those with an ASD diagnosis. Anecdotal reports from some autistic participants indicated that one of the positive consequences of receiving an ASD diagnosis included greater acceptance which reduced the pressure and expectation to camouflage symptoms. This research suggests that diagnosis of ASD in adulthood can have a positive effect on life satisfaction and that improving social-relatedness could be one way to improve life satisfaction in autistic adults.

33 **126.033** Mapping Patterns and Correlates of in-Vivo Social Interactions of Adults with and without ASD Via Ecological Momentary Assessment

A. H. Gerber[1], *S. B. Scott*[2], *M. Finsaas*[2], *J. M. Girard*[3] *and M. D. Lerner*[2], *(1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY, (3)Psychology, University of Pittsburgh, Pittsburgh, PA*

Background: Research suggests that adults with Autism Spectrum Disorder (ASD) have limited social interactions, both in number and in normative patterning of such interactions (i.e., socializing when others prefer to do so); however, these data are almost exclusively provided via caregiver interview (Orsmond, Krauss, & Seltzer, 2004). Indeed, to date virtually no research has directly examined whether adults with ASD have limited social contact. Ecological momentary assessments (EMA) collected via smartphone represent a method of enhancing reporting accuracy through reducing retrospective biases. Only one study has addressed the social interactions of individuals with ASD using EMA, indicating low levels of social participation relative to other activities (Chen et al., 2017). Caregiver report indicates that age, ASD symptom severity, and functional impairment significantly predict total social interactions for adults with ASD (Orsmond et al., 2004); likewise, recent work suggests that alexithymia may be a particularly strong predictor of social-emotional deficits in ASD (Cook et al., 2013).
Objectives: We investigated patterns and predictors of social interactions in adults with ASD over one week. We hypothesized that individuals with ASD would report fewer total social interactions. Additionally, we hypothesized that alexithymia and ASD severity would negatively relate with number of social interactions, while IQ (proxy for functional impairment) would positively relate with interactions, when controlling for age.

Methods: Seventy-seven adults (26 ASD, 34%), ages 18 to 47 years (*M*=22.50 years, *SD*=5.84; 34 male, 44%) completed an EMA protocol in which they reported all social interactions via their smartphone over one week. Participants received 12 random-interval reminders each day between 9 am and 9 pm. Participants completed measures of ASD symptomatology (AQ; Baron-Cohen et al., 2001), IQ (K-BIT; Kaufman & Kaufman, 2004), and alexithymia (TAS; Parker, Taylor, & Bagby, 2003) prior to the EMA period.

Results: Results demonstrated no difference in total number of social interactions between participants with ASD (M=50.25, SD=37.96) and those without ASD (M=48.04, SD=25.80), t(27.11)=0.24, *p*= .81. Nonetheless, participants with ASD appeared to have more variation in their total interaction counts (see Figure 1). Negative binomial regression was used to examine predictors of total interaction counts. Age, gender, IQ, ASD severity, and alexithymia severity were entered into the model. Results indicated that alexithymia and age were significant predictors of the total number of interactions (both *p*s <.04; see Figure 2).

Conclusions: This is the first study to map patterns of in-vivo social interactions of adults with ASD in comparison to typically developing adults. We found no difference in the total number of social interactions between adults with and without ASD; however, high variability among individuals with ASD suggests that individual differences may best account for anecdotal reports of reduced social interaction among those with ASD. Through use of a novel measure of social activity, findings extend recent research indicating alexithymia, not ASD symptom severity, may drive social isolation for individuals with ASD (Shah et al., 2016). Given the high levels of alexithymia in ASD (Hill, Berthoz, & Frith, 2004), pre-treatment levels are an important factor when implementing social skills interventions.

34 **126.034** Needs of Postsecondary Students with Autism Spectrum Disorder: Perspectives and Recommendations from College Professionals

S. L. Jackson, *L. A. Hart, J. T. Brown and F. R. Volkmar, Child Study Center, Yale School of Medicine, New Haven, CT*

Background: The number of students with autism spectrum disorder (ASD) entering into post-secondary academics is increasing (Shattuck et al., 2012). However, despite academic proficiency, students with ASD are less likely to graduate (39%) than the general student-body (52%), and students with other disabilities (41%; Gelbar, Shefcyk, & Reichow, 2015). As completion of a college degree is significantly related to positive adult outcomes in ASD (Newman et al., 2011), a better understanding of why these students are struggling is needed. Current literature on this topic has primarily relied on student or parental perspectives to address this question, overlooking the valuable insights of the post-secondary professionals who work directly with this student population.
Objectives: The current study aims to expand our understanding of the experiences and needs of college students with ASD by examining the insights and perceptions of college/university professionals who work with these students.

Methods: The current sample consists of 15 professionals (12 Disabilities Office staff, 2 Therapists/Counselors, and 1 Health-Care Provider), from a range of post-secondary institutions (3 from 2-year/Community Colleges, 6 from Public Universities, 6 from Private Universities) across the USA. All data was collected through an anonymous online survey (Qualtrics) and data collection is on-going.

Results: All college professionals surveyed either 'somewhat' or 'strongly' agreed with the statement that there has been an increase in students with ASD at their institution over the past few years. The number of registered students with ASD ranged from 4-280 (*M*=56.4, *SD*=72.2), with an average male:female ratio of 4.6:1. Surveyed professionals reported that the majority of students with ASD utilize at least one of the school-provided support services (*M*=76.7%, *SD*=32.8), but on average they reported these services as only slightly-moderately effective. In general, surveyed professionals somewhat-strongly disagreed with the statement that students with ASD were adequately prepared for their transition to college, with navigating social settings, conflict resolution, group work, and study habits/organization being identified as the areas of greatest need. All surveyed professionals noted psychiatric comorbidities as a prevalent issue, with the most commonly reported being ADHD, SAD, Depression, and GAD. Professionals from larger schools (10,000+ students) noted significantly greater difficulty with campus/community navigation for their students with ASD (*U*=10.5, *p*<0.05). Professionals from smaller schools (less than 10,000 students) noted significantly more problems with the personal hygiene and self-care of their students with ASD (*U*=6.5, *p*<0.05), however, this is thought to be related to easier recognition of such issues in a smaller student-body. As data collection continues, additional analyses will be performed.

Conclusions: In support of findings from student/parental perspectives, professionals working with college students with ASD believe the greatest challenges faced by this population generally stem from non-academic aspects of collegiate life. Greater transition preparation before embarking into postsecondary academics, improved and broader support services for students with ASD, and more specific trainings for college staff on ASD-related issues were all recommended by the study participants as ways to improve the outcomes for this student population. Additional research on how best to implement these suggestions is still needed.

35 **126.035** Needs of Spanish University Students, As Perceived By Their Relatives

***M. E. Merino**, ULIAZPI, San Sebastian, Spain*

Background:

The number of university students diagnosed with autism is increasing. Providing these students with effective support is crucial to ensure they have opportunities to attend and succeed at university. The European project “Autism and Uni” was designed and developed to broaden knowledge on the transition to adulthood, with a specific focus on the transition to university. Although previous projects have used case studies and assessments of counseling interventions to describe students’ anxiety about higher education, the literature about the on-going needs of autistic university students remains thin.

Objectives: To identify opportunities for improvement of support services that parents of autistic university students believe would promote postsecondary success for students with autism.

Methods: A survey of 48 parents in Spain inquired about parents’ perceptions of their autistic children’s needs at university and the type of support their students received throughout higher education. Parents also offered recommendations for solutions to challenges they've seen their students experience in adulthood.

Results: Responses from parents indicate that the types of support provided to university students with autism varied widely. Fully 31% of the respondents indicated their students with ASD did not receive any support during university study. However, 27% had a specific teaching assistant inside the college, 27% received adjustments to exams, 25% had a tutor outside of the university, and 8% had a support group or adaptations in coursework.

Moreover, 78% of the responding parents reported that meeting with the institution’s disabilities support team before starting at university was important to help the ASD student successfully transition to university. Campus visits were important for 73% of respondents, while 60% felt they needed information about getting assistance with lectures prior to the start date. Only about half (53%) of the parents, however, considered it important to raise awareness amongst other students about autism.

Overall, 75% of parents of university students with autism felt “quite” or “very” confident in the academic ability of their children, though 48% of the parents would have preferred that their children had stayed at home instead of moving to another city to study.

Conclusions:

Although most families felt confident about their child’s academic achievement, many parents worried about their child’s ability to live independently and integrate with peers at university. Other concerns related to helping their students set up their schedules and cope with unexpected changes that inevitably happen at university. To mitigate those concerns, families considered it particularly important to meet with the institution’s disabilities support team before students start at university. In particular, parents would have liked the universities to have an awareness of the common challenges linked to ASD, provide assistance with homework, and offer support for group projects. Results from this study, therefore, offer important guidance to both the families of college students with autism and the leaders of the postsecondary institutions they attend.

36 **126.036** Parent Characteristics As Predictors of Social Skills Outcomes Among Young Adults with ASD Following the UCLA PEERS® Intervention

***N. E. Rosen**[1], R. Ellingsen[2], M. Jolliffe[1] and E. A. Laugeson[1], (1)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA, (2)Psychiatry, University of California Los Angeles, Los Angeles, CA*

Background: The effectiveness of parent and caregiver assistance in social skills treatment programs has been established in studies with those with ASD from childhood (Frankel et al. 2010) through adulthood (Laugeson et al. 2015; Van Hecke et al. 2015). The durability of treatment gains following these parent- and caregiver-assisted programs has also been established months to years following intervention in studies with children (Mandelberg et al. 2014), adolescents (Laugeson et al. 2012; Mandelberg et al. 2014), and young adults with ASD (Laugeson et al. 2015). While research suggests that caregiver-assisted programs provide robust treatment outcomes for youth with ASD, the influence of parent characteristics on treatment outcomes has yet to be examined extensively across age groups. Although there is limited research investigating parent characteristics impacting treatment outcome for children and adolescents (Chang et al. 2014), the impact of these characteristics for young adults requires further examination.

Objectives: The present study examines parent characteristics including education level, ethnicity, and marital status as predictors of social skills outcomes among young adults with ASD following a 16-week caregiver-assisted social skills intervention.

Methods: Participants included 59 young adults (78% male; *M*=21.39, *SD*=2.59) and their caregivers. All young adult participants had clinically-elevated ASD symptoms, as determined by a total score ≥ 60 on the Social Responsiveness Scale-Second Edition (SRS-2; Constantino 2012) at baseline. Participants attended the UCLA Program for the Education and Enrichment of Relational Skills (PEERS®), a 16-week empirically-supported caregiver-assisted group social skills intervention for young adults with ASD. Baseline caregiver characteristics were assessed using demographic questionnaires prior to start of the program. Treatment outcome was assessed pre- and post-intervention using caregiver-reported change in frequency of social engagement on the Quality of Socialization Questionnaire (QSQ; Laugeson & Frankel 2010), social responsiveness on the SRS-2, and social and behavioral functioning on the Social Skills Rating System (SSRS; Gresham & Elliott 1990).

Results: Paired samples t-tests revealed that caregiver ethnicity and education level were not significantly related to change in frequency of social engagement on the QSQ, social responsiveness on the SRS-2, or social and behavioral functioning on the SSRS. Paired samples t-tests also revealed that caregiver marital status was not significantly related to change in frequency of social engagement or social and behavioral functioning. However, marital status was related to change in social responsiveness at trend-level significance ($t=1.835$; $p<.05$), such that caregivers with no marital partner reported greater improvement in young adult social responsiveness pre- to post-intervention.

Conclusions: Findings reveal that parent ethnicity, education level, and marital status are not predictive of improvement in social engagement, social responsiveness, or social and behavioral functioning among young adults with ASD following the PEERS® intervention. However, at trend-level significance, marital status was related to change in social responsiveness, such that caregivers with no marital partner reported greater improvement in young adult social responsiveness. These findings are useful in determining who is most likely to benefit from caregiver-assisted social skills interventions and the caregiver characteristics potentially impacting treatment outcomes.

37 **126.037** Peer Responses to Autism-Related Behaviors in a Postsecondary Classes: An Experimental Examination

***B. E. Cox**, Educational Leadership and Policy Studies, Florida State University, Tallahassee, FL; College Autism Network, Tallahassee, FL*

Background:

Fewer than 39% of postsecondary students with autism in the United States earn any form of postsecondary credential within 6 years of starting higher education (Newman et al., 2011). These students often struggle with classroom behaviors that negatively affect their course performance, particularly if classes include group assignments (Cai & Richdale, 2015; Freedman, 2010; Gobbo & Shmulsky, 2014). Moreover, because students with autism are strongly affected by their peers' acceptance of them academically and socially (Causton-Theoharis, & Malmgren, 2005), the challenges of working on group assignments are likely magnified when peers hold negative attitudes toward the students with autism. Although initial evidence (e.g., Butler & Gillis, 2011; Nevill & White, 2011) suggests college students are generally accepting of other students with autism, such openness appears to be conditional on the scenario in which the autism-related behaviors occurred and whether a study's respondents realized they were answering questions about a student with autism.

Objectives:

This study examined college students' attitudes towards other students who display autism-related behaviors in one of their classes and assesses how open college students are to working with their autistic peers. In doing so, the current study overcame several limitations in the related literature by employing an experimental design to assess the attitudes of a large sample (n=1,499) of diverse college students who reviewed randomly assigned vignettes that varied in two distinct ways.

Methods:

This study employed an experimental design in which participants were randomly assigned to view 2 vignettes that varied across two conditions: academic setting and respondent priming for ASD. The "Quiet_Neighbor" vignette presented a student displaying autism-related characteristics in a classroom setting, while the "Group_Gamer" vignette was situated in an out-of-class meeting about a group assignment. Version "A" of each vignette made no mention of ASD, whereas Version "B" insinuated the student might be on the autism spectrum. Vignette presentation order was randomly assigned.

Respondents' attitudes toward the students depicted in the vignettes were assessed using Likert-scale items adapted from Nevill & White (2011) and White et al. (2016) (e.g., "I would not mind this student in my classroom") via a series of ANOVAs.

Results:

Across all six questions measuring attitudes toward their autistic peers, a comparison of marginal means indicates the presence of main effects for both the vignettes and the priming conditions. Participants consistently responded more positively to a student displaying autism-related characteristics in the Quiet_Neighbor scenario than in the Group_Gamer scenario. Moreover, participants who were primed to think the behaviors on display in the vignettes were related to autism reported positive attitudes toward the students displaying those behaviors.

Conclusions:

Classroom peers are more accepting of and friendly toward college students with autism when they 1) don't have to interact with the autistic student directly, or 2) can attribute some autism-related behaviors to a diagnosis. Thus, students with autism may benefit from disclosure to peers *if* their autism-related behaviors are likely noticeable to other students, particularly if they have to work with peers on group assignments.

38 **126.038** Predictors of the Agreement between Diagnostic Instruments and Clinical Diagnosis of ASD in Adults without Intellectual Disability

***L. Fusar-Poli**[1,2], N. Brondino[2], M. Rocchetti[2], U. Provenzani[2], S. Damiani[2] and P. Politi[2], (1)Department of Clinical and Experimental Medicine, Psychiatric Unit, University of Catania, Catania, Italy, (2)Department of Brain and Behavioral Sciences, University of Pavia, Pavia, Italy*

Background: Diagnosing autism spectrum disorders (ASD) in adulthood often represents a challenge. Clinical diagnosis should be supported by the use of standardized tools, such as the Autism Diagnostic Observation Schedule (ADOS) or the Autism Diagnostic Interview (ADI).

Objectives: To evaluate potential predictors of the agreement between diagnostic instruments (ADOS-2 and ADI-R) and clinical diagnosis in a population of adults who were formally diagnosed with ASD for the first time.

Methods: After an extensive clinical evaluation, 95 adults with an IQ ≥ 70 were diagnosed with ASD according to DSM-5 criteria. ADOS-2 was separately administered to all participants and 81 caregivers underwent ADI-R interview. Binary logistic regressions were conducted to find potential predictors of the agreement (gender, age, IQ, severity levels of criteria A and B of DSM-5).

Results: Female gender was a negative predictor of the agreement between ADOS-2 and clinical diagnosis ($B = -1.59$, $OR = 0.204$, $p = 0.03$). IQ seemed to negatively predict the agreement between ADI-R and DSM-5 ($B = -0.03$, $OR = 0.968$, $p = 0.04$), while people with higher severity levels at criterion B better agreed with clinical diagnosis ($B = 1.20$, $OR = 3.326$, $p = 0.03$).

Conclusions: Clinicians' training and experience remains of primary importance while assessing adults who could potentially belong to the autism spectrum. Women and individuals with higher IQ, in fact, seem to have more camouflaging strategies and less pronounced symptoms. In these subsamples, it is more difficult to correctly identify ASD only by means of standardized instruments.

39 **126.039** Psychological Predictors of Alcohol Use and Misuse in Adults with Autism Spectrum Conditions

***M. Bowri**[1], L. Hull[2], M. C. Lai[3,4,5,6], S. Baron-Cohen[4], C. Allison[4], P. Smith[7] and W. Mandy[2], (1)University College London, London, United Kingdom, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland, (3)Department of Psychiatry, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan, (4)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom, (5)Department of Psychiatry, University of Toronto, Toronto, ON, Canada, (6)Centre for Addiction and Mental Health, Toronto, ON, Canada, (7)University of Cambridge, Cambridge, United Kingdom*

Background: Alcohol misuse is associated with a variety of adverse physical, psychological and social consequences. The limited existing research on substance use (including alcohol use) in adults with autism spectrum conditions (ASC) has yielded mixed findings, with some studies concluding that autism is a protective factor against substance use and others suggesting that autism may increase an individual's risk for

substance misuse. Qualitative and anecdotal evidence suggests that demographic factors, co-morbid mental health difficulties and autistic traits may contribute to alcohol use in this population.
Objectives: This study sought to quantitatively investigate psychological predictors of alcohol use and misuse in a sample of adults with ASC using a web-based cross-sectional survey.

Methods: Participants were 237 adults with ASC who were recruited via social media, internet forums and clinical databases. An online survey was used to obtain data on demographic information, autistic traits, depression, anxiety, social anxiety, mental wellbeing and alcohol use. All relevant constructs were measured using gold-standard, well-validated self-report measures. The sample was divided into three groups (non-drinkers, non-hazardous drinkers and hazardous drinkers) and multinomial logistic regression models were used to explore associations between alcohol use and independent variables.

Results: Thirty percent of participants were classified as non-drinkers, 54.8% as non-hazardous drinkers and 15.2% as hazardous drinkers. Using comparative data from the general population, the proportions of non-drinkers and hazardous drinkers among autistic adults were higher than those for neurotypical adults (20.9% and 14% respectively; $X^2(1)=69.15$, $p<.001$). Compared to autistic non-hazardous drinkers, autistic non-drinkers were more likely to be female (OR: 2.57; 95% CI: 1.32-5.00) and had higher levels of autistic traits (OR: 1.02; 95% CI: 1.00-1.04), depression (OR: 1.05; 95% CI: 1.00-1.09), anxiety (OR: 1.06; 95% CI: 1.01-1.12) and social anxiety (OR: 1.01; 95% CI: 1.00-1.02). Compared to autistic non-hazardous drinkers, autistic hazardous drinkers also had higher levels of autistic traits (OR: 1.02; 95% CI: 1.00-1.04), depression (OR: 1.09; 95% CI: 1.04-1.16), anxiety (OR: 1.10; 95% CI: 1.03-1.17) and social anxiety (OR: 1.02, 95% CI: 1.00-1.03) and lower levels of mental wellbeing (OR: 0.95; 95% CI: 0.91-0.99). These results demonstrate a U-shaped pattern among autistic adults, with both non-drinkers and hazardous drinkers scoring higher than non-hazardous drinkers on levels of autistic traits, depression, anxiety and social anxiety.

Conclusions: Non-hazardous use of alcohol is associated with fewer autistic traits and positive mental health outcomes in adults with ASC, while abstinence and hazardous alcohol consumption are associated with more autistic traits and higher levels of depression, anxiety and social anxiety. Alcohol use in adults with ASC is multifaceted and complex and this group should not be considered a homogenous population. Screening for alcohol use should form part of routine healthcare assessments for ASC given that a significant proportion of these individuals may be misusing alcohol. An individualised approach should be taken to explore the unique contribution of factors involved in alcohol use for those identified to be at-risk, paving the way for tailored treatment and support.

40 **126.040** Putting People on the Spectrum in the Driver's Seat of Their Own Lives: The Clinical Utility of a Goal-Setting Tool That Enables Genuine Self-Determination

*V. Tomkins[1] and **J. Ashburner**[2], (1)Research and Business Development, Autism Queensland, Sunnybank, Australia, (2)Autism Queensland, The University of Queensland, Sunnybank, Australia*

Background: Adolescent and adults on the spectrum often encounter barriers to genuine participation in person-centred planning, including difficulties communicating their aspirations due to social and communication challenges, and low expectations of self-determined behaviour on the part of professional staff and family members. With the aim of overcoming these barriers, we developed a picture-based card-sort goal-setting tool for people on the spectrum. A card-sorting process is inherently suitable for people on the spectrum, as it accommodates their preferences for information presented in a concrete pictorial format with minimal written text.
Objectives: The aim of this project was to (a) develop the *Adolescent/Adult Goal Setting Tool* (AAGST) using participatory action research, and (b) examine the clinical utility of using this tool to enable people on the spectrum to prioritise their goals.

Methods: Three cycles of action research were used to refine the goal items and the pictures and words on the cards. The cards were adjusted in response to feedback provided by over 100 adolescents and adults on the spectrum, and family members through a purpose-designed survey. The adaptive function of the participants on the spectrum was assessed using The *Adaptive Behaviour Assessment System, Third Edition* to ensure that the sample included participants on the spectrum with a wide range of abilities. A generic qualitative methodology was then used to explore the experiences of people on the spectrum, their families, and professional staff when they used the tool to set their goals. Participants on the spectrum were assessed using The *Kaufman Brief Intelligence Test, Second Edition* to examine the applicability of the AAGST to a range of individuals across the spectrum. The level of support required to support people with an intellectual disability to participate in the card-sort process was documented. Information on the benefits of using the AAGST and areas for potential improvement was gathered using semi-structured interviews of persons on the spectrum and family members, and a focus group for professional staff. The qualitative data was analysed using content analysis by two coders working independently.

Results: Seventy-two cards with pictures and minimal text were generated and refined through input from people on the spectrum, family members and professional staff. They are grouped into the following categories: (a) social relationships, (b) self-care/home living, (c) study/training, (d) work/employment, (e) health/fitness, (f) community participation, (g) communication, (h) managing finances, and (i) emotional wellbeing**.** The user sorts the cards into three piles including "*Yes – now*", "*Maybe"* and "*No – not now*", and then further prioritises goals within the "*Yes – now*" pile. People on the spectrum, their families and professional staff reported that card-sorting simplified the goal setting process. Participants on the spectrum reported feeling empowered and having greater ownership of the outcomes.

Conclusions: The AAGST has excellent clinical utility and is highly valued by people on the spectrum, their families and professional staff. As it enables people on the spectrum to prioritise goals that are meaningful and relevant to their lives, the AAGST enhances feelings of autonomy and engagement.

41 **126.041** Rates of Autism in a Population of Homeless Adults

*M. Ryder[1], A. Churchard[1] and **W. Mandy**[2], (1)UCL, London, United Kingdom, (2)University College London, London, United Kingdom of Great Britain and Northern Ireland*

Background:
It is well documented that people with autism spectrum condition (ASC, also known as 'autism spectrum disorder') are at high risk of having a number of problems adapting to adult life, such that they experience high rates of unemployment, social isolation and difficulties living independently. In the general population, these types of problem are risk factors for becoming homeless. This raises the question of whether

autistic adults experience elevated levels of homelessness. To date there has been no peer-reviewed research into whether or not ASC is associated with an increased risk of homelessness.

Objectives:

This study aimed to investigate systematically the rates of ASC in a long-term homeless population; and to increase understanding of the characteristics and needs of autistic homeless people.

Methods:

The entire caseload of a UK homeless outreach team was screened (n = 106). A new assessment tool, the 'DSM-5 Autistic Traits in Homeless Individuals' (DATHI) interview, was developed specifically for this study. This used reports from keyworkers to identify diagnostic features of ASC in their clients. The inter-rater reliability and criterion validity of the DATHI were evaluated.

Results:

The DATHI showed adequate inter-rater reliability (Kappa=.69). Criterion validity, assessed via agreement with the Autism Spectrum Disorder Adult Screening Questionnaire, was strong (r=.81, p=.01). The DATHI identified 13 individuals who showed strong evidence of meeting diagnostic criteria for ASC, which as a proportion of the overall sample was 12.3%, 95% CI [7.0%, 20.4%]. Compared to non-autistic homeless people, those with autistic difficulties showed higher odds of becoming homeless due to being unable to live independently (OR: 3.48, 95% CI [1.03,11.79]). Once homeless, they showed increased odds of consistently declining offers of statutory accommodation (OR: 2.79, 95% CI [1.04,7.48]) and of being socially isolated (OR = 4.62, 95% CI [3.66, 33.35]). Based on keyworker report, those with elevated autistic traits showed reduced odds of currently using drugs or alcohol (OR = 2.92, 95% CI [1.07, 7.98]).

Conclusions:

This study has provided initial evidence that rates of ASC are raised among homeless people, suggesting that ASC is a major risk factor for homelessness. Further, participants with autistic symptoms appeared to be a distinct subpopulation, with autism-specific pathways into homelessness and characteristics whilst homeless. As such they are likely to require tailored support, to reflect their autistic strengths and difficulties. More work is needed to understand the mechanisms whereby ASC confers risk for becoming homelessness, in order to inform the development of preventative strategies.

42 **126.042** Relationship between Co-Occurring Psychiatric Conditions and Adaptive and Cognitive Ability

K. J. Feldman[1]*, A. J. Fischer*[1]*, J. Davis*[2]*, H. Coon*[3] *and D. A. Bilder*[3]*, (1)University of Utah, Salt Lake City, UT, (2)Educational Psychology, University of Utah, Salt Lake City, UT, (3)Psychiatry, University of Utah, Salt Lake City, UT*

Background:

Adults with ASD commonly experience co-occurring psychiatric conditions, low adaptive abilities, and varying levels of cognitive functioning. Limited research reports mixed findings on the relationship between adaptive abilities and psychiatric conditions in adults with ASD. Anxiety and depression are common among adults with ASD and may impact functional outcomes such as employment and independence. Understanding the relationship between adaptive ability and psychiatric comorbidity may shed light onto why adults with ASD experience suboptimal life outcomes in relation to their cognitive functioning.

Objectives:

To explore the relationship between level of adaptive and cognitive ability and the presence of depression and anxiety in adults with ASD.

Methods:

Participants for this study (*N* = 304, aged 18-64, *M* = 32.20, *SD* = 10.47, 88.2% male) were identified from a larger sample of adults with ASD who were ascertained in childhood or during transition into adulthood. Inclusion in the analysis required the presence of (1) assessments for adaptive behavior and intellectual ability and (2) record of psychiatric conditions. Co-morbid anxiety/depression were determined through the presence of either corresponding electronic medical record diagnostic code data and/or an in-person Mini PAS-ADD assessment of psychiatric co-morbidity. The Vineland Adaptive Behavior Scales (Survey, First and Second Edition) were used to assess adaptive behavior. An individual's intellectual ability was identified using the most complete assessment of cognitive ability available in research records. The following categories of adaptive and intellectual ability were used: normal ≥ 70, mild = 50-69, and severe < 50. Logistic regression was used to predict anxiety and depression case status based on adaptive functioning/intellectual ability category with the normal category used as the reference variable.

Results:

Tables 1 and 2 report logistic regression results. Depression was less common among participants with severe and mild intellectual abilities (*b* = -1.47, *p* = 0.008; *b* = -1.09, *p* = 0.003) and severe impairment in daily living skills of adaptive ability (*b* = -1.11, *p* = 0.002). Anxiety had no association with severe and mild intellectual ability (*b* = 0.11, *p* = .82; *b* = .30, *p* = 0.39) but is predicted by adaptive functioning in the composite score, communication and social scales predicted anxiety (*b* = 0.83, *p* = 0.023; *b* = 0.70, *p* = 0.050; *b* = 0.90, *p* = 0.012).

Conclusions:

Depression was less commonly identified among individuals with severely limited daily living adaptive skills and mild to severe ID. This may reflect the challenge in identifying internalizing depressive symptoms in individuals with intellectual and adaptive impairment, necessitating exploration into the manner in which individuals with these impairments manifest their experience of depression. Limited composite adaptive and social abilities, predicted anxiety, though the cause and effect aspect of this relationship is unknown. Anxiety may be caused by increased challenges in daily functioning, or anxiety may interfere with learning adaptive skills when anxiety-provoking experiences are avoided. Alternatively, both may share a common underlying etiology. More research is warranted to clarify the nature of this association.

43 **126.043** Self-Determination in Young Adults with Autism Spectrum Disorder

K. White[1] *and T. D. Flanagan*[2]*, (1)National University of Ireland, Galway, Galway, Ireland, (2)Department of Educational and Counselling Psychology, McGill University, Montreal, QC, Canada*

Background: Autism Spectrum Disorder (ASD) is a lifespan diagnosis impacting opportunities into adulthood. Self-determination (SD), which refers to the “volitional actions that enable one to act as the primary causal agent in one’s life and to maintain or improve one’s quality of life” (Wehmeyer, 2005, p. 177), has been associated with positive adult outcomes such as education, employment, and quality of life. However, information about SD for young adults with ASD (without intellectual disability (ID)), including the factors that may impact and promote its development into adulthood, is scarce.
Objectives: The aim of this study is to investigate the possible factors and predictors that explain the levels of SD of young Canadian adults with ASD (without ID) using an online survey. Self-reported facilitators and barriers to developing SD will also be reported.

Methods: Participants were 125 young Canadian adults with ASD without ID. Female (*M* = 23.81, *SD* = 3.85), male (*M* = 22.62, *SD* = 3.39), and transgender (*M* = 22.33 *SD* = 2.57) participants all ranged in age from 18 to 30 years (*M* = 23.15, *SD* = 3.65). All participants were retained in the sample if their *AQ* total score was at or above 26 (*M* = 33.46, *SD* = 5.82, *range* = 26 - 46). Participants were recruited widely across Canada via flyers and letters of invitations. The comprehensive online survey included descriptives and brief indicators of ASD and SD, including the *Autism-Spectrum Quotient – Adult Version* (AQ; Baron-Cohen et al., 2006) and *Arc’s Self-Determination Scale* (*SDS*; Wehmeyer & Kelchner, 1995).

Results: The reported SD levels differed in relation to age and education. Using a median split (median age = 23) to designate older and younger age categories, an independent samples *t*-test showed that older (*M* = 87.63, *SD* = 18.80) young adults reported higher levels of SD, based on the *SDS*, than younger (*M* = 78.38, *SD* = 19.04) adults, *t* (123) = -2.73, p = .007. In regards to education, *SDS* total score increased from junior high (*M* = 71.00, *SD* = 1.41) to partial college (*M* = 81.95, *SD* = 19.93), and college/university (*M*= 90.15, *SD* = 18.08), *Welch’s F* (5, 27.530) = 10.10, *p* < .001. However, level of SD did not significantly differ in relation to gender, living situation, or employment status. Further, a hierarchical multiple regression analysis indicated that a person’s age (β = .20, *t* (118) = 2.63, p = .01), capacity (β = .51 *t* (118) = .61, p <.01), and level of SD importance (β = .15, *t* (118) = 1.98, p = .05) significantly predicted level of SD, explaining 50.1% of the variance. Finally, SD skills, mental health, societal perceptions about disability, support networks, opportunities, and early educational and life experiences were reported common facilitators and barriers to developing SD.

Conclusions: The knowledge gained from this study will allow researchers and practitioners a better window into the factors and predictors of SD, and will highlight invaluable information concerning effective and individualized support services.

126.044 Self-Reported Sex Differences in High-Functioning Adults with Autism: A Meta-Analysis

***R. Moseley**, R. A. Hitchiner and J. A. Kirkby, Bournemouth University, Poole, United Kingdom*

Background: Sex differences in autistic symptomatology are believed to contribute to the mis- and missed diagnosis of many girls and women with an autism spectrum condition (ASC). Whilst recent years have seen the emergence of clinical and empirical reports delineating the profile of young autistic girls, recognition of sex differences in adulthood is far more limited. We chose to investigate these as they emerge in self-report screening instrument, the Ritvo Autism Asperger Diagnostic Scale-Revised (RAADS-R), which is recommended by the National Institute for Health and Care Excellence (NICE, 2016) for the identification of autistic adults in Great Britain.
Objectives: To compare autistic symptomatology, in autistic men and women, on RAADS-R domains of Social Relatedness, Circumscribed Interests, Sensory Motor (henceforth Sensorimotor), and Language symptoms.

Methods: The analysis employed a two-factorial design: by comparing autistic men and women to each other as well as to typically-developing (TD)men and women, it was possible to tease out normative sex differences in cognition which might or might not be present in autism. To supplement data gathered by our research group, we conducted a meta-analysis of studies which had used the RAADS-R, and obtained a total 961 datasets. Eventually, datasets from 137 TD men and 136 TD women (age-matched to autistic groups), 118 autistic men and 136 autistic women (age-matched to each other) were analysed. Analysis of variance (ANOVA) searched for the presence of main effects of Sex and Diagnosis and for interactions between these factors.

Results: In social relatedness and circumscribed interests, main effects of Diagnosis revealed that as expected, autistic adults reported significantly greater lifetime prevalence of symptoms in these domains; an effect of Sex, in circumscribed interests, also suggested that males generally reported more prevalent symptoms than females. An interaction of Sex and Diagnosis in language symptomatology revealed that a normative sex difference in language difficulties was attenuated in autism. An interaction of Sex and Diagnosis in the sensorimotor domain revealed the opposite picture: a lack of sex differences between typically-developing men and women and a greater prevalence of sensorimotor symptoms in autistic women than autistic men.

Conclusions: Not all childhood sex differences, such as the male overrepresentation in repetitive behaviours and interests and the female advantage in social skills, were reflected in adult self-reports. Where childhood sex differences failed to emerge in RAADS-R scores, several interpretations exist; it may be that sex differences are attenuated with age, but an inherent sampling bias may mean that only autistic women most similar to the male presentation are diagnosed and thus included in studies such as ours. The finding that sensorimotor symptomatology is more highly reported by autistic women is a finding requiring objective confirmation, given its potential importance in diagnosis.

45

126.045 Sex Similarities and Differences in Autism Presentation in Adulthood

***E. Jarzabek**[1], B. Lewis[1], K. S. Ellison[1], J. Wolf[1], M. J. Rolison[1], T. Winkelman[1], T. C. Day[1], K. A. McNaughton[1], J. Foss-Feig[2] and J. McPartland[1], (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY*

Background: Previous research regarding the clinical autism phenotype across males and females reveals mixed findings. For instance, some studies indicate that females with ASD display more severe social and communication difficulties but fewer restricted and repetitive behaviors than males with ASD. Furthermore, research to date has focused on examining gender differences within the ASD group only. This is problematic given that many aspects of social functioning in typically-developing (TD) individuals are known to vary as a function of sex. Lastly, there is limited research examining self-perception and sex differences in adults with ASD.
Objectives: Examination of sex-differential cognitive and behavioral presentations of adults with ASD.

Methods: Collected as part of a larger study, the sample consists of 46 adults with ASD (34 males; Mean age=24.2) and 49 TD adults (31 males; Mean age=25.8). To examine cognitive profiles the *Wechsler Abbreviated Scale of Intelligence, 2nd Edition (WASI-II)* was used. Subjective perception of social functioning was assessed using the *Social Responsiveness Scale, Second Edition (SRS-2)–Adult Self-Report* and the *Autism Quotient Form (AQ).* Clinician-rated levels of social functioning were measured using the *ADOS-2, Module 4*.

Results:

Individuals with ASD demonstrated significantly lower verbal reasoning abilities (*WASI-II, Similarities*) and overall verbal skills (*WASI-II, VCI*) than the TD group [*F*(1,87)=3.74, *p*=.056; *F*(1,87)=4.22, *p*=.043, respectively]. There were no significant sex differences in cognitive profiles within or across diagnostic groups.

The *AQ* total scores were significantly higher in the ASD group compared to TD group [*F*(1,90)=57.89, *p*<.001]. Furthermore, there was a significant interaction between sex and diagnosis [*F*(1,90)=6.17, *p*=.015], reflecting that sex differences were larger in the ASD group. A subsequent *T*-test showed that ASD females self-reported more autism-related traits than ASD males [*t*(44)=2.16, *p*=.036; Female (*M*=29.1, *SD*=8.1) and Male (*M*=23.5, *SD*=7.5)]. Likewise, the *SRS-2* Total *T*-score and all subscale *T*-scores were significantly higher in the ASD group compared to TD group. Again, sex differences were significantly different by diagnostic group. In the ASD group, females reported significantly more deficits in *Social Cognition* [*t*(41)=2.57, *p*=.014], *Social Communication* [*t*(43)=2.55, *p*=.014], *Social Motivation* [*t*(43)=2.68, *p*=.011], and *Restricted Interests and Repetitive Behaviors* [*t*(43)=2.94, *p*=.005]. In the TD group, an opposite pattern was found with males reporting significantly more deficits than females with regard to *Social Awareness* [*t*(45)=-4.35, *p*<.001] and *Social Communication* [*t*(45)=-2.18, *p*=.034].

The *ADOS-2* subdomains total scores (i.e., Communication, Social Interaction, and Stereotyped Behaviors and Restricted Interests) were all significantly higher for the ASD group compared to the TD group. Significant sex differences were found in the ASD group, but not the TD group. Specifically, ASD males scored significantly higher than ASD females in the *Communication* domain [*t*(43)=-3.31, *p*=.001]. There were no significant sex differences in *Social Interaction* or *Stereotyped Behaviors and Restricted Interests Total* scores.

Conclusions: While women and men with ASD show many similarities, there also appear to be distinct differences in their clinical presentations. Notably, females with ASD self-reported higher levels of social-communicative difficulties, despite receiving lower clinical ratings of communicative impairment. Self-perception of individuals with ASD offers important insight and directions for further investigations.

46

126.046 Sex-Specific Variations in Perceived Facial Masculinity/Femininity across Levels of Autistic-like Traits

D. W. Tan[1]*, M. T. Maybery*[1]*, M. Evans*[2]*, R. Di Lorenzo*[3] *and A. J. Whitehouse*[4]*, (1)School of Psychological Science, University of Western Australia, Perth, Australia, (2)University of Western Australia, Perth, Australia, (3)Utrecht University, Utrecht, Netherlands, (4)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia*

Background: Autism spectrum disorder (ASD) is two to four times more prevalent in males than in females. From a biological perspective, one hypothesis suggests that the male preponderance in ASD may be influenced by the exposure to elevated concentrations of testosterone *in utero*. A parallel stream of research found that heightened levels of prenatal testosterone derived from umbilical cord blood is related to facial morphology. During foetal development, the brain and the face evolve from the neural crest in synchrony. This has led to the speculation that facial morphology may hold crucial information to further our understanding of aberrant neurodevelopment. In our recent work, we reported hypermasculinised facial features among prepubescent boys and girls with ASD compared to children without ASD.

Objectives: The current study examined whether facial masculinisation extends to neurotypical adults with varying degrees of autistic-like traits.

Methods: A total of 1,995 undergraduate students completed the autism-spectrum quotient (AQ). Students aged between 18 and 25 years, and with an AQ score that fell in the bottom, middle and top 15% of the distribution were invited to participate further in this study. Seventy-two Caucasian men and 81 Caucasian women completed the study in which their facial photographs were obtained. Then, on a 100-point scale anchored by 'not at all masculine/feminine' and 'extremely masculine/feminine', the male faces were rated for masculinity and the female faces for femininity by a separate group of naive raters (n = 41; 23 females).

Results: For men, analyses revealed a significant U-shape relationship between facial masculinity ratings and levels of autistic-like traits. Specifically, men with mid-range level of autistic-like traits received lower masculinity ratings than did their counterparts with either low or high trait levels (see attached Figure). For women, a negative linear relationship was observed between facial femininity ratings and the degrees of autistic-like traits, that is, facial femininity ratings decreased across groups of women with low, mid and high levels of autistic-like traits respectively.

Conclusions: It appears that the relationship between perceived facial masculinity/femininity and autistic-like traits is sex-specific whereby a negative linear relationship is observed between facial femininity and levels of autistic-like traits in women whereas a U-shaped trend is found between facial masculinity and autistic-like traits in men. Findings in the present sample of post-pubertal women are consistent with masculinised facial features observed in prepubescent girls with ASD. However, the current outcomes for men are inconsistent with our previous findings. Taken together, these results suggest the facial structures associated with autistic traits may be stable across development for females but non-linear for males.

47

126.047 Sexual Risk Profiles for Male and Female Adults on the Autism Spectrum

L. Graham Holmes[1]*, A. R. Nilssen*[2]*, D. S. Strassberg*[2] *and M. Himle*[3]*, (1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Psychology, University of Utah, Salt Lake Cty, UT, (3)University of Utah, Salt Lake City, UT*

Background:
Many adults with ASD are interested and engage in sex and relationships. However, research suggests they have lower sexual knowledge than neurotypical adults and learn about sex from questionable sources. For adults with ASD, lower sexual knowledge has been linked to higher probability of past sexual victimization, and with higher incidence of engaging in inappropriate courtship and/or sexual behavior. Beyond this, little is known about the sexual risk profiles of adults with ASD, including potential gender differences, complicating the provision of effective sex education and healthcare.

Objectives:

1. Examine gender differences in sexual orientation, prevalence of sexual activity, and relationships.
2. Investigate risks, including (a) sexual behavior and provision of sexual healthcare (e.g., STI testing), (b) technology-mediated sexual

behaviors (e.g., sexting, online dating, viewing sexually explicit material or SEM), and (c) sexual victimization.

Methods:

Adults with formal ASD diagnoses (*N*=216, *M* age=22.5, *SD*=3.17), recruited from a national database, completed an anonymous online survey about sexuality, relationships, health, and the Autism Spectrum Quotient (AQ). 32% of the participants identified as female (*n*=70), 5.5% as transgender (*n*=12), and 62.6% as male (*n*=137, 62.6%). Analyses included Pearson Chi Squares and logistic or linear regression models.

Results:

1. As expected, women were more likely than men to identify as LGB (30% vs. 11%) or asexual (20% vs. 11%, *p*=.001). Controlling for age and AQ score, women were 2.5 times more likely to report current relationship of >3 months duration (40% vs. 14% of men, *p*<.001) and rated romantic relationships as a more important priority (*p*<.01). Women were also more likely to report history of intercourse (53% vs. 25%, *p*<.001).
2. Sexual health: Among participants with history of partnered sexual behavior (*n*=94, 44%), few reported STI diagnosis (3%), yet only 52% had been tested due to anxiety ("too scared") or simple lack of knowledge. Only 41% reported using a condom at last intercourse for reasons including embarrassment and committed relationships. Technology-related risks: Participants engaged in normative technology-mediated behaviors, including sexting photos (25% vs. ~50% in neurotypical samples) and online dating (35%). While common, these carry risks easily addressed through education (e.g., 42% of participants who sexted did so as minors). While 92% of online daters reported positive experiences, some (*n*=9) experienced sexual coercion or assault. Similar to neurotypical samples, most participants (76%) had used SEM. Most reported no problems associated with SEM, but 13% of users reported SEM caused misunderstandings about sex and 26% found it difficult to stop using SEM. Sexual victimization: 8% of participants had first sexual contact ≤ age 14, and 16% reported unwanted first sexual contact (no gender difference; *p*=.07).

Conclusions:

Young adults with ASD are less likely to report history of partnered sexual behavior compared to neurotypical adults, yet are affected by various sexual health risks. These findings demonstrate the importance of healthcare providers, schools, and parents collaborating to provide evidence-based sex and relationship education that targets these specific risks and accessible healthcare. Finally, these gender differences suggest that sex research with male-only samples may not generalize to women.

48 **126.048** Symptom Profile and Mental Health Conditions in Older Adults with Autism Spectrum Disorder (ASD)

K. L. Ashwood[1,2], *E. L. Woodhouse*[1,3], *V. Stoencheva*[1], *R. H. Wichers*[1], *A. Galanopoulos*[4], *A. Nolan*[2], *I. Broch-Due*[2], *R. McNally*[2], *S. Maltezos*[4], *D. G. Murphy*[5], *D. Robertson*[2], *G. M. McAlonan*[2,6] *and C. M. Murphy*[1,2], *(1)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (3)Forensic & Neurodevelopmental Sciences, Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom, (4)The Adult Attention-Deficit/Hyperactivity Disorder (ADHD) and Autism National Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom, (5)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Although Autism Spectrum Disorder (ASD) is a lifelong condition, few studies have examined age-related changes in symptom profile. This is important, as the prevalence of ASD in older adults (50 years +) can be expected to increase with an aging population. To improve service provision for older adults, there is first a need to assess whether ASD symptomatology changes with age and if co-occurring mental health conditions influence presentation.

Objectives: To conduct an exploratory analysis of ASD symptomatology and co-occurring mental health conditions of younger (18-49 years) and older (aged 50-75 years) adults with ASD, compared with gender and age matched clinical controls without ASD (nil ASD).

Methods: A retrospective review of the medical records of 330 patients assessed for ASD at a specialist adult ASD diagnostic clinic between March 2003 and July 2017 identified 171 older adults (ASD N=108, Nil ASD N= 63). A comparison sample of 159 younger adults (ASD N= 101, Nil ASD N= 58) attending the same clinic was randomly selected. The groups were balanced on diagnosis and gender (older: M:F= 124:47; younger M:F= 109:49). Patient clinical records included the Autism Spectrum Quotient (AQ: self-report and informant), Autism Diagnostic Observation Schedule Generic and 2nd Edition (ADOS-G/2), Hospital Anxiety and Depression Scale (HADS) and clinician identified current diagnoses (ICD-10). ANOVA and Chi-square analyses examined the effects of diagnosis (ASD vs nil ASD) and age (younger vs older), on autism symptoms (self-report, informant and clinician rated) and co-occurring diagnoses (number and type). Post-hoc correlation analyses were used where appropriate.

Results: There were significant main effects of diagnosis (ASD > nil-ASD) on the AQ [F(1,119)=472.64, p=.02] and social impairments [F(1,227)=121.23, p<.001], communication impairments [F(1,227)=96.10, p<.001] and repetitive and stereotyped behaviours on the ADOS-G/2 [F(1,224)=16.09, p<.001]. There was a significant main effect of age (older > younger) on social and communication impairments on the ADOS-G/2 [F(1,227)=70.39, p<.001, (F(1,227)=96.10, p<.001, respectively]. The diagnosis by age interaction was significant [F(1,227)=15.64, p<.001], revealing an age-related decline in communication difficulties and increase in social interaction impairments in ASD. There were no differences in the number of adults with mental health conditions (other than ASD). However, older adults were more likely to have anxiety and depression [*χ2*(1) = 6.31, *p* = .01, *χ2*(1) = 6.17, *p* = .01, respectively], whereas younger adults were more likely to have ADHD, [*χ2*(1) = 4.32, *p* = .04], regardless of diagnostic group. Older adults showed significant associations between social interaction impairments and self-rated HADS anxiety and depression scores [*r* = .31, *p* =.04 and *r* = .42, *p* < .001 respectively].

Conclusions: With increasing age in ASD, communication abilities improve but social interaction difficulties persist and worsen. Symptoms of anxiety and depression appear to contribute to greater impairment in older adults with ASD. More work is needed to confirm our findings and establish whether better identification and treatment of mental health conditions in older people with ASD will improve quality of life.

49 **126.049** Testing a Theoretical Model of Loneliness in Adults on the Autism Spectrum

D. Ee[1,2], *S. Arnold*[1,3], *Y. I. (. Hwang*[1,2], *S. Reppermund*[1], *K. R. Foley*[1,2], *P. Srasuebkul*[1] *and J. Trollor*[1,2], *(1)The University of New South Wales, UNSW Sydney, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Queensland, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia*

Background:

Loneliness is an experience of negative affect as a result of a discrepancy between the relationships one desires and what one perceives to have and, feeling a lack of intimacy. This is the first study to assess the experience of loneliness in adults on the autism spectrum in comparison to adults not on the spectrum. It is also the first study to examine a theoretical model of loneliness for adults on the spectrum based on a systematic literature review and an adaptation of the 1987 De Jong-Gierveld loneliness model.

Objectives:

The aims of this study were to assess the extent of self-reported loneliness in adults on the autism spectrum compared to other adults and to investigate the determinants of loneliness in adults on the spectrum based on a theoretical model of loneliness.

Methods:

Data was obtained from the Australian Longitudinal Study of Adults with Autism (ALSAA). Participants were recruited nation-wide to complete a self-report questionnaire. A total of 264 participants were included from the ALSAA: 156 adults on the spectrum aged 25 to 80 years (*Mean* (*M*)=42.8, *Standard deviation* (*SD*)=12.7), and 108 control participants not on the spectrum aged 25 to 77 years (M=42.8, SD=13.0). Variables including demographics, autistic traits, social support characteristics, depression, anxiety, and self-efficacy were assessed through regression models for their impact on loneliness, measured by the 8-item UCLA Loneliness Scale (ULS-8). The study was grounded in an inclusive research approach that involved a research advisory panel of adults on the spectrum providing feedback on questionnaire development and the interpretation of findings.

Results:

Adults on the spectrum scored significantly higher on the ULS-8 (M=23) than adults not on the spectrum (M=15, p<0.001). Adults on the spectrum had lower education and employment, and higher depression and anxiety compared to control participants. Having a diagnosis of autism spectrum disorder accounted for the greatest variance in loneliness in univariate regression analyses (B = 8.37, 95% CI [7.15, 9.59], p <0.001, R^2=0.41). In multiple regression analyses, social skill deficit and dissatisfaction with social support were associated with greater loneliness in both groups (p<0.05). Reduced frequency of contact with family was associated with loneliness only in the group on the spectrum (p=0.051), whereas female gender (p=0.02) was associated with loneliness in only the control group.

Conclusions:

Adults on the autism spectrum were significantly lonelier than adults not on the spectrum. While the determinants of loneliness in both populations were similar (social skill deficits and dissatisfaction with social support), their influence on loneliness was much greater in adults on the spectrum. Adults on the spectrum may rely less on friends for social support; support from and contact with family should be encouraged. Strategies to assist adults on the spectrum to improve their social skills should be developed. Future research could further explore the phenomenon of loneliness in adults on the spectrum, including adults with co-existing intellectual disability, to fill gaps in knowledge around social anxiety, depression, conceptual understanding of loneliness, and the change in these factors over time through longitudinal analysis.

50 **126.050** The Australian Longitudinal Study of Adults with Autism (ALSAA): Inclusive Research Protocol Development and Baseline Sample Characteristics

S. Arnold[1,2], *K. R. Foley*[1,3], *Y. I. (. Hwang*[1,3], *J. Trollor*[1,3] *and T. Autism CRC Program 3*[3], *(1)The University of New South Wales, UNSW Sydney, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Queensland, Australia*

Background:

There is a reported disconnect between autism researchers' aims and opinions, and those of adults on the autism spectrum. Including people on the spectrum in the execution of research is ethically important, and ensures findings are relevant to the autism community. Despite a growing body of literature on inclusive research with people on the spectrum, there are few protocols or guidelines, with none regarding longitudinal studies. Further, most autism research is focused on children. There is a need for longitudinal studies to understand changing needs and causality among adults.

Objectives:

The Australian Longitudinal Study of Adults with Autism (ALSAA) aims to contribute to a broad, rigorous understanding of adulthood, guided by adults on the spectrum. We describe the inclusive research protocol developed through consultation with a network of autistic advisors, that is used to guide on-going design, interpretation and dissemination of ALSAA research. We also describe the current baseline sample, and how participant feedback and other consultation processes were incorporated into subsequent data gathering.

Methods:

The ALSAA is a questionnaire based study incorporating a wide array of primarily standardised measures. Autistic advisors were recruited via advertisement and targeted invitation, such as members of the Autism CRC Research Academy, which focuses on training peer researchers. Topic areas were selected in consultation with autistic advisors, who also reviewed and piloted content to ensure comprehension for an autistic audience. Autistic advisors were tasked with identifying any ambiguous or inappropriate language, formatting issues, or potential for misinterpretation.

A voluntary sample of autistic adults and non-autistic controls living in Australia and aged 25+ were then gathered via targeted advertising with various autism organisations, other service or support providers, and online autism communities. Three versions of the questionnaire were developed: self-report, informant and carer/family member, to allow greater accessibility for people who are unable or do not wish to self-report. All specific findings are reviewed by autistic advisors, who are provided with a condensed, lay summary of findings and suggested interpretations and implications.

Results:

The ALSAA Inclusive Research Protocol has been reviewed by autistic advisors and operationalised. Autistic advisors have enhanced design and outputs from ALSAA, including: rejecting some potential scales, improved usage of literal language, advice on clearer, less visually overloading layouts, and providing additional, insightful interpretations and implications of specific findings.

As at October 2017, 267 autistic adults have participated in the ALSAA baseline, with 50 meeting criteria for intellectual disability. 129 neurotypical control participants and 102 carers participated to date. There is an over-representation of autistic females (50.2%), in common with other online autism research. The majority of autistic participants (63%) are satisfied or very satisfied with the questionnaire.

Conclusions:

Autism is a life-long condition with more focus needed on adulthood. Including people with autism in autism research ensures more relevant and valid findings. The ALSAA Inclusive Research Protocol could be applied to other studies striving to conduct inclusive research with adults on the autism spectrum.

51 **126.051** The Autism Spectrum Quotient in Mathematicians

C. Buckingham[1]*, V. Warrier*[1]*, P. Smith*[1]*, R. Kenny*[1]*, C. Allison*[2]*, H. Brunel*[1]*, R. Holt*[1] *and S. Baron-Cohen*[2]*, (1)University of Cambridge, Cambridge, United Kingdom, (2)Autism Research Centre, Department of Psychiatry, University of Cambridge, Cambridge, United Kingdom*

Background:

Previous studies have identified a higher number of autistic traits in mathematicians, and a higher rate of formal diagnosis of autism in mathematicians (Baron-Cohen and Wheelwright, 2007). The reason for this link between autistic traits/autism and mathematics may be because autistic traits/autism includes excellent attention to detail and a strong interest in patterns ("systemizing"). Here we measure the distribution of autistic traits using the Autism Spectrum Quotient (AQ) in maths students/graduates of mathematics with and without autism. We also tested a group of mathematicians who suspect they have autism but had not pursued a formal diagnosis.

Objectives:

Our study had the following three objectives: 1. To investigate if mathematicians score significantly higher on the AQ than the general population; 2. To investigate sex differences in AQ scores in mathematicians; 3. To investigate differences in AQ scores by diagnosis in mathematicians.

Methods:

1049 university students or graduates of mathematics from top mathematics departments worldwide completed an online version of the AQ. Participants were grouped as either mathematicians with ASC (n = 80 (63 male)), mathematicians with suspected ASC (n = 222 (158 male)), and mathematicians without ASC (n = 747 controls (433 male)). We included a general population sample for comparison (n=3466 (898 male)).

Results:

Male mathematicians without ASC scored significantly higher than general population males (p=0.00017), and female mathematicians without ASC also scored higher than general population females ($p=4.36x10^{-13}$). Unlike the general population (Ruzich *et al.,* 2015), where males score higher than females (means 17.89 and 14.88 respectively), male mathematicians without ASC (mean = 21.35, SD = 7.94) did not score significantly higher than their female counterparts (mean = 20.46, SD = 7.90). Mathematicians with ASC and mathematicians with suspected ASC did not differ from each other, but both scored significantly higher than mathematicians without ASC ($p < 2.2x10^{-16}$). The subdomain scores of female mathematicians without ASC were lower than the mathematicians with ASC and the mathematicians with suspected ASC on all subdomains except 'attention to detail', where there was no difference. Male mathematicians without ASC scored significantly lower than mathematicians with ASC (p<0.038) and mathematicians with suspected ASC (p<0.013) on the 'attention to detail' subdomain. No sex differences were observed within groups for AQ or on any subdomain scores.

Conclusions:

AQ scores are higher in mathematicians with ASC and suspected ASC compared to mathematicians without ASC, irrespective of sex, reflected by significantly higher scores in the subdomains of 'communication', 'social skills', 'imagination', and 'attention switching'. The typical sex difference in AQ in the general population is absent amongst all groups of mathematicians, just as it is absent or attenuated in people with ASC. The absence or attenuation of the typical sex difference may reflect biological factors such as prenatal sex steroids, which are elevated in those with ASC. This study confirms the strong association between autistic traits and mathematical talent. Ongoing research is exploring the basis of this association at a genetic level.

52 **126.052** The Relationship between Social Anxiety, Depression, and Levels of Empathy in Young Adults with ASD

A. Mendoza[1]*, R. Ellingsen*[2]*, E. Veytsman*[3]*, A. Ganel*[4] *and E. A. Laugeson*[5]*, (1)UCLA PEERS Clinic, Los Angeles, CA, (2)Psychiatry, University of California Los Angeles, Los Angeles, CA, (3)Graduate School of Education, University of California Riverside, Riverside, CA, (4)Psychiatry, UCLA PEERS Clinic, Los Angeles, CA, (5)Semel Institute for Neuroscience and Human Behavior, UCLA, Los Angeles, CA*

Background:

Identification of other people's emotions through brief emotional expressions can be fundamental to many social processes (Clark, Winkielman, & McIntosh, 2008). Research has shown that individuals with Autism Spectrum Disorder (ASD) have difficulties with emotion processing regardless of gender and age (Clark, et. al. 2008). Previous research has shown a strong positive relationship between individuals with ASD and associated psychiatric symptoms, specifically depression (Sterling, Dawson, Estes, 2008). Additionally, it has been shown that empathy deficits are correlated with Major Depressive Disorder (Hoffman, Banzhaf, Kanske, Gartner, Bermpohl, & Singer, 2016). A relationship between higher levels of anxiety and lower levels of empathy was also shown in a study examining college students (Deardoff, Kendall, Finch, & Sitarz, 1977). Although this relationship has been studied extensively with typically developing young adults, there has yet to be a thorough exploration of the relationship between social anxiety, depression and empathy in young adults with ASD.

Objectives:

This study seeks to examine the relationship between social anxiety, depression and levels of empathy in cognitively able young adults with ASD.

It is hypothesized that young adults reporting higher social anxiety and higher levels of depression will exhibit lower levels of empathy.

Methods:

Thirty-three young adults ranging from 18 to 27 years of age (*M*=20.42; *SD*=2.03) presenting for social skills treatment as part of the UCLA PEERS for Young Adults program participated in this study. In order to examine the relationship between social anxiety, depression and empathy, young adults completed the Social Anxiety Scale (SAS-YA; La Greca, 1999), the Empathy Quotient (EQ; Baron-Cohen & Wheelbright, 2004), and the Major Depression Inventory (MDI-YA; Bech, Rasmussen, Olsen, Noerholm, Abildgaard, 2001) prior to treatment. Pearson correlations were calculated to examine the relationship between ratings of social anxiety on the SAS and levels of depression on the MDI in comparison to levels of empathy on the EQ.

Results:

Pearson correlations revealed a significant negative relationship between the Social Skills Subscale of the EQ and social anxiety as measured by the SAS ($p<.05$). In particular, the Social Skills Subscale of the EQ was negatively correlated with the SAS subscale of Social Avoidance and Distress-General (p<.05), and negatively correlated at trend levels with the SAS subscales of Social Avoidance and Distress-New ($p<.10$) and Fear of Negative Evaluation ($p<.10$). The Social Skills Subscale of the EQ was also negatively correlated with depression as measured by the MDI at a trend level ($p<.10$). There were no significant associations between the other EQ subscales (Cognitive Empathy & Emotional Reactivity) with the SAS or MDI.

Conclusions:

Findings support the original hypothesis that young adults reporting higher social anxiety exhibit lower levels of empathy. There also appears to be a relationship between empathy and depression, but this correlation was not significant. These findings are important in that they suggest that the difficulties with empathy that individuals with ASD experience may be exacerbated by symptoms of social anxiety and/or depression.

53 **126.053** Transition of Students with Autism Spectrum Disorder to Higher Education

T. C. Bakker[1], *S. Begeer*[2], *A. C. Krabbendam*[3] *and S. Bhulai*[4], *(1)Vrije Universiteit Amsterdam, Amsterdam, Netherlands, (2)VU University Amsterdam, Amsterdam, Netherlands, (3)Clinical Developmental Psychology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, (4)Mathematics, Vrije Universiteit Amsterdam, Amsterdam, Netherlands*

Background: A growing number of individuals with Autism Spectrum Disorders (ASD) is enrolling in higher education (Zeedyk et al., 2016). Despite this, studies on the transition of individuals with ASD from secondary school to higher education are limited. A systematic review of the literature (Gelbar et al., 2014) found only 20 articles, mostly case studies or self-reported experiences of in total no more than 69 college students diagnosed with ASD. Empirical research on college students with ASD is needed to complement existing qualitative insights and support policy making.

Objectives: The first objective of this study is to advance empirical research on college students with ASD. The second objective is to improve our understanding of the transition of students with ASD to higher education, comparing it to the transition of students with other conditions and students without known conditions.

Methods: Using an administrative data set with enrollments in bachelor programs of a major university in Europe from 2010 to 2016 consisting of 99 students formally diagnosed with ASD, 2,312 students with other conditions such as ADD/ADHD and dyslexia (OC), and 26,218 regular students (RS). The data set contains features on demographics, ethnicity, secondary education and examination grades, family background and support, orientation and planning, application, enrollment, matching, participation in an introduction program, language proficiency, disabilities and comorbidity.

Results: Preliminary analyses show differences between students with ASD and their peers. Most students with ASD were male (ASD: 71.7%; OC: 41.6%; RS: 45.4%). On average, students with ASD were older (ASD median = 20; OC median = 19; RS median = 19) and more often had non-standard pre-education degrees (ASD 9.09%; OC 2.77%; RS 2.44%). Students with ASD with a high school degree had similar examination grades compared to regular students, and better examination grades compared to students with other conditions. No differences were found in the way students with ASD orientated themselves. They had higher scores on help awareness and lower scores on self-reported extra-curricular activities and work compared to students with other conditions and regular students. Ethnicity of students with ASD was similarly distributed compared to regular students. On language proficiency, they scored better than students with other conditions and regular students, especially with regard to vocabulary. Comorbidity in students with ASD was more common than in students with other disabilities; most common combinations were dyslexia and ADD/ADHD.

Conclusions: The current findings are promising with regard to our empirical understanding of the characteristics and transition of college students with ASD. It appears that students with ASD need more time to reach higher education. On the other hand, students with ASD who do have a high school or comparable degree, show more similarity with regular students and have a better starting point compared to students with other conditions. Combined, these insights might indicate the importance of early diagnosis of ASD for transition to higher education.

This study was funded by the Vrije Universiteit Amsterdam. Conflict of interest: None.

54 **126.054** Transitioning to Adulthood: Tracking Adult Outcomes in a 25-Year Longitudinal Study

L. A. Pepa[1], *A. Megale*[1], *G. Gunin*[2], *M. Heyman*[1] *and C. Lord*[3], *(1)Weill Cornell Medicine, White Plains, NY, (2)Psychiatry, Weill Cornell Medical College, White Plains, NY, (3)University of California Los Angeles, Los Angeles, CA*

Background: Over the past 20 years, our knowledge about autism spectrum disorder (ASD) has made considerable advances. However, as the population of individuals with ASD continues to grow and change, there is still very little known about adult outcomes. Data from published studies suggest that adults with ASD are at significant risk of poor global outcomes, reporting low rates of independent living (Gotham et al., 2014), decreased post-secondary education (Farley et al., 2009), underemployment (Howlin et al., 2013), minimal reciprocal social contact (Orsmond et al., 2004), and high rates of comorbidity (Buck et al., 2014). While studies of adults are growing in number, many are limited by the longevity of data collection and the generalizability of the population sampled. Study populations are largely comprised of adults who actively engage with ASD clinics, and likely reflect those of the highest need. Studies of adults in the broader community may shed new light on a more diverse range of outcomes.

Objectives: This study aims to describe adult outcomes in a sample of individuals with ASD across 1) demographic areas and daily activities, 2) social participation and relationships, 3) comorbidity and behavior problems, and 4) general health outcomes.

Methods: Participants were young adults who have been seen as part of an ongoing 25-year long longitudinal outcome study. Participants were first referred to the study at age two following concern about possible ASD, and have been followed in the community over their lifetime. The current analyses include 141 young adults (66% of the original sample) who have contributed data through mail-based questionnaires and/or in-person visits after the age of 18. Data was gathered through a battery of diagnostic and clinical measures, interviews, and questionnaires. Of the 141 young adults in this sample, 84% (n=119) have received a lifetime diagnosis of ASD, and 16% (n=22) are considered to be non-spectrum (NS). In the ASD sample, 50% have a Verbal IQ of 70 or greater (68% in the NS group).

Results: The ASD sample falls within the reported limits of other studies in the area of daily activities. 63% of individuals live at home with their parents and only 18% received post-secondary degrees. 39% of the ASD sample was reported to be unemployed, compared to only 14% of the NS sample. However, looking at general health outcomes and psychiatric comorbidity, the current sample was more minimally impacted than other adult samples. 21 out of 74 (28%) individuals with ASD seen at age 25 endorsed a psychiatric comorbidity; rates that are much lower than other reports, though significantly higher than the general population mean for adults (17.9%; SAMHSA, 2015). Very few needed emergent psychiatric care (4%) or hospitalizations (1%), and the mean number of psychiatric medications taken is only 1.7 per individual. Results of social functioning will also be reported and discussed.

Conclusions: Preliminary findings suggest that adult ASD populations seen in the community are impaired with regard to daily activities, though may be less impacted by psychiatric comorbidity and general health problems than clinically-active samples.

55 **126.055** Using Machine Learning to Identify Patterns of Lifetime Health Problems in Decedents with Autism Spectrum Disorder

L. Bishop-Fitzpatrick[1]*, A. Movaghar*[2]*, J. S. Greenberg*[3]*, D. Page*[2]*, L. E. Smith DaWalt*[3]*, M. H. Brilliant*[4] *and M. Mailick*[3]*, (1)University of Wisconsin - Madison, Madison, WI, (2)University of Wisconsin-Madison, Madison, WI, (3)University of Wisconsin-Madison Waisman Center, Madison, WI, (4)Marshfield Clinic Research Institute, Marshfield, WI*

Background: As a large wave of individuals with autism spectrum disorder (ASD) diagnosed in the 1990s enters adulthood and middle age, knowledge about the patterning of lifetime health problems will become increasingly important for prevention efforts. However, although studies do suggest the presence of heightened morbidity and early mortality in ASD, we are aware of no studies conducted to date that have examined health problems throughout the life course of individuals with ASD using representative, population-level data.

Objectives: We sought to characterize lifetime health problems in a sample of decedents with ASD and matched controls.

Methods: We retrospectively analyzed diagnostic codes associated with de-identified electronic health records (EHRs) from the Marshfield Clinic, a multi-specialty group practice with more than 700 physicians providing integrated, comprehensive care to over one million people across more than 50 locations in northern, central, and western Wisconsin. Previous research has validated EHR data from the Marshfield Clinic and found that patients are representative of northern, central, and western Wisconsin. Notably, 97% of the population in this region receives the majority of their care at the Clinic.

Our analysis included 91 decedents with ASD who were matched based on their sex and birth year (within 5 years) to a sample of 6,186 decedent community controls (a 1:68 ratio). Mean age of death for decedents with ASD was 67.3 (range=60-89). We used a machine learning algorithm to classify participants into groups (ASD or control) based on their ICD-9 codes, V-codes, and E-codes using a 10-fold cross validation procedure. Information gain (IG) scores, which take into account information entropy for each class (ASD versus decedent community control) and feature (ICD-9 code, V-code, E-code), were used to measure the amount of information in each feature with respect to target class. Diagnoses related to developmental disabilities and mental health conditions (i.e., Chapter 5: Mental Disorders) were excluded from our algorithm to reduce overfitting.

Results: Diagnostic patterns distinguished decedents with ASD from matched decedent community controls with high sensitivity and specificity (AUC=0.88) and weighted average precision (98.2%) solely based on their ICD-9 codes, V-codes, and E-codes. Decedents with ASD had higher rates of epilepsy, choking, accidents, long-term medication use, cardiovascular screening, hypothyroidism, urinary tract dysfunction, motor abnormalities, skin conditions, respiratory problems, and digestive problems than decedent community controls. Decedents with ASD had lower rates of hypertension and cancer diagnosis and treatment than decedent community controls.

Conclusions: This study is the first study to characterize health problems in decedents with ASD, the majority of whom were older adults, and the first to use a machine learning algorithm to differentiate decedents with ASD from decedent community controls with a high level of sensitivity, specificity, and precision based on ICD-9 codes, V-codes, and E-codes identified in EHRs. This analysis found distinctive lifetime profiles of health problems among decedents with ASD compared to decedent community controls. While preliminary, these findings have the potential to inform best practices for prevention and monitoring of health problems in ASD across diverse healthcare settings if replicated in additional population-level datasets.

5:30 PM - 7:00 PM - Hall Grote Zaal

56 **127.056** Aberrant Cerebellar-Cerebro Functional Connectivity in Children and Adolescents with Autism Spectrum Disorder

R. Hanaie[1]*, I. Mohri*[2]*, K. Kagitani-Shimono*[1]*, M. Tachibana*[1] *and M. Taniike*[1]*, (1)United Graduate School of Child Development, Osaka University, Suita, Japan, (2)United Graduate School of Child Development, Osaka University, Osaka, Japan*

Background:

The cerebellum is one of the brain regions most consistently reported to have neuropathological findings in patients with autism spectrum disorder (ASD). Previous resting state functional connectivity (rsFC) studies in healthy adults have reported that the cerebellum forms widespread functional networks with the cerebral cortices and contributes to various cognitive functions (Buckner et al., 2011). However, studies on cerebellar-cerebro rsFCs in patients with ASD were very sparse.

Objectives:

Aim of this study was to investigate cerebellar-cerebro FC in children and adolescents with ASD using resting state functional magnetic resonance imaging (MRI) and to know whether its abnormalities are related to executive and socio-communicative deficits in children and adolescents with ASD.

Methods:

Echo planar imaging functional volume and T_1-weighted images of 16 subjects with ASD (all males; age: 11.1 ± 2.0 years) and 20 typically developing (TD) subjects (all males; age: 10.5 ± 2.5 years) were acquired on a 3 tesla MRI scanner. Furthermore, we added 130 male subjects extracted from the Autism Brain Imaging Data Exchange (ABIDE) II (ASD = 42, age: 10.7 ± 1.8 years; TD = 88, age: 10.3 ± 1.7 years). Final sample included 58 subjects with ASD (all males; mean age: 10.8 ± 1.9 years) and 108 TD subjects (all males; mean age: 10.3 ± 1.8 years). Seed-based rsFC analysis was performed using the CONN toolbox (http://www.nitrc.Org/projects/conn/). Cerebellar ROIs were created using the probabilistic MR Atlas of the human cerebellum (Diedrichsen, 2009). Group differences in FCs were examined using two sample *t*-tests, covarying for full-scale intelligence quotient (FSIQ) and mean frame wise displacement (FD) scores, and imaging sites. Correlation analyses were performed between FC values showing significant group differences and scores in the Social Responsiveness Scale (SRS), the Behavior Rating Inventory of Executive Function (BRIEF), and the Autism Diagnostic Observation Schedule (ADOS) in the ASD group.

Results:

The ASD group showed aberrant cerebellar-cerebro FCs relative to TD children. Findings of aberrant FCs with the cerebral regions converged mainly on the posterior lateral hemisphere and vermis of the cerebellum. The increased FCs between several posterior cerebellar subregions and left insula, left middle frontal gyrus, and right supramarginal gyrus were found. In addition, the decreased FCs between right dentate nucleus and several cerebral regions were found. In the ASD group, connectivity between right Crus II and left insula was negatively related to the Global Executive Composite (GEC) score in the BRIEF ($r = -0.408$, $p = 0.002$) and connectivity between vermis X and left angular gyrus was positively related to the total score in the ADOS-G ($r = 0.408$, $p = 0.034$) .

Conclusions:

Findings of aberrant FCs converged mainly on the posterior lateral hemisphere, the right dentate nucleus, and the posterior inferior vermis of the cerebellum. These results were consistent with those of previous studies reporting structural and neuropathological abnormalities in the cerebellum (D'Mello et al., 2015; Riva et al., 2013; Wegiel et al., 2014). Our findings may help to provide effective therapeutic interventions in children and adolescents with ASD.

57 **127.057** Adolescents with ASD Show Atypical Electrophysiological (EEG) Responses to a Novel Theory of Mind Reasoning Task: An ERP Study

E. J. Libsack[1], *C. M. Keifer*[1], *T. Clarkson*[2], *J. M. Mayor Torres*[1] *and M. D. Lerner*[3], *(1)Stony Brook University, Stony Brook, NY, (2)Psychology, Temple University, Philadelphia, PA, (3)Psychology, Stony Brook University, Stony Brook, NY*

Background: Theory of Mind (ToM) reasoning involves making attributions about others' mental states and is critical for understanding and predicting others' behavior in social situations. Impairments in social communication, including deficits in ToM, are a core feature of autism spectrum disorders (ASD). Previous research using electroencephalography (EEG) has examined event-related potentials (ERPs) elicited during ToM reasoning tasks in TD youth (Liu, et al., 2004, 2009b; Meinhardt, et al. 2011; Sabbagh & Taylor, 2000), suggesting that correct ToM reasoning is associated with two distinct ERP components. The Late Positive Complex (LPC) is thought to index more automatic processing of conditional salience or expectancy, while the Late Slow Wave (LSW) is related to mental state attributions. However, prior research has not examined ERP correlates of ToM reasoning in adolescents with ASD, hindering understanding of the neurocognitive elements and time-course of ToM in ASD. Objectives: Investigate whether LPC and LSW ERP amplitudes differ in TD relative to ASD adolescents in a novel ToM task.

Methods: 33 Adolescent participants (22 male; M=13.0 years, SD=1.8) included 19 TD and 14 ASD with ADOS-2 confirmed diagnosis and IQ > 70. During EEG acquisition, participants viewed illustrated, narrated ToM vignettes and were asked to make mental state inferences about the characters' behavior (McKown et al., 2015). Individual response options were presented sequentially after the conclusion of the vignette, allowing target ERPs to be time-locked to the presentation of correct and incorrect response options. ERPs were measured at parietal electrode sites and extracted as mean area amplitudes within discrete post-stimulus time windows (LPC 300-600ms; LSW 600-1200ms). An independent groups t-test was used to assess group differences in behavioral response accuracy. LPC and LSW ERP data were analyzed in two separate 2 (ASD, TD) by 2 (correct, incorrect) repeated measures ANOVAs (RM-ANOVAs).

Results: The ASD group made significantly more errors than the TD group on the ToM task (t(39)=2.185, *p*=.035). RM-ANOVA revealed significant main effects at the LPC (F(1,31)=14.86, p=.009) and the LSW (F(1,31)=4.167), p=0.05), such that correct responses were larger than incorrect responses (Figure 1). Diagnosis x Response Accuracy interactions were marginally significant for the LPC (F(1,31)=3.71, p=.063) and significant for the LSW (F(1,31)=4.36, p=.045) (Figure 2). During both epochs, the TD group evinced a greater neural response to correct relative to incorrect responses compared to the ASD group.

Conclusions: Results indicate that youth with ASD demonstrate neural and behavioral deficits in complex ToM reasoning. Individuals with ASD demonstrated marginally attenuated differentiation between correct-vs-incorrect ToM vignettes at the LPC, and attenuated differentiation at the LSW. The LPC has been associated with more attentional aspects of ToM reasoning, whereas the LSW has been associated with more elaborative processing of mental states (Meinhardt et al. 2011. This could suggest that early differences in the LPC might be contributing to later observed differences in the LSW. To probe this effect, future studies should examine the relative contribution of individual ERP components to complex ToM in order to best pinpoint the processing stage at which ToM deficits first occur.

58 **127.058** Altered Plasticity of Prefrontal Cortex in Adult Autism Spectrum Disorder

M. Nakamura[1], *T. Itahashi*[1], *T. Izuno*[2], *J. Fujino*[1], *H. Ohta*[1], *R. Hashimoto*[3] *and N. Kato*[1], *(1)Medical Institute of Developmental Disabilities Research, Showa University, Tokyo, Japan, (2)Kanagawa Psychiatric Center, Yokohama, Japan, (3)Tokyo Metropolitan University, Tokyo, Japan*

Background: Altered metaplasticity is hypothesized in psychiatric disorders including neurodevelopmental disorders. However, stimulation-induced neuroplastic changes in human prefrontal cortex have not been sufficiently elucidated due to lack of reliable biomarkers like motor evoked potentials (MEP).
Objectives: The study was aimed to establish reliable biomarkers of TMS-evoked potentials (TEP), which could evaluate the neuroplasticity in the heteromodal association cortices.

Methods: Neurophysiological changes followed by rTMS over dorsolateral prefrontal cortex (DLPFC) were longitudinally investigated using resting-state EEG (64ch recording) and TEP. TEP measurements followed by intermittent theta burst stimulation (iTBS) or sham stimulation were applied to twenty adult patients with autism spectrum disorder (ASD) and 21 matched healthy adults of typical development (TD).

Results: TEP components (mainly N45) revealed that facilitatory iTBS could enhance prefrontal TEP amplitudes for around an hour in healthy volunteers as compared with sham condition (t=2.37, p=0.026), accompanied by tentative cognitive enhancement in working memory task. However, adult ASD patients did not show the enhancement of TEP components and also cognitive enhancement. In terms of responder rate, 67% of TD adults and 25% of ASD adults were electrophysiological responders, which showed N45 amplitude enhancement more than 2 SD range of N45 amplitude variation observed in the sham group.

Conclusions: The TEP component of N45 could be a candidate for biomarker for functional neuroplasticity induced by rTMS. The present result suggested that prefrontal cortex of adult ASD may not have enough capacity to induce the long-term potentiation (LTP)-like effects, possibly due to saturated synaptic strength.

59

127.059 Altered Prefrontal Functional Connectivity and Anatomy in Mice Lacking Autism-Associated Gene Shank3

M. Pagani[1,2]*, A. Liska*[1,2]*, A. Galbusera*[1]*, M. Sabbioni*[3]*, M. L. Scattoni*[3] *and A. Gozzi*[1]*, (1)Istituto Italiano di Tecnologia, Functional Neuroimaging Lab, Centre for Neuroscience and Cognitive Systems, Rovereto, Italy, (2)University of Trento, CIMEC, Rovereto, Italy, (3)Istituto Superiore di Sanità, Neurotoxicology and Neuroendocrinology Section, Department of Cell Biology and Neurosciences, Rome, Italy*

Background: Mutations in postsynaptic scaffolding protein Shank3 have been strongly implicated in 22q13 deletion syndrome (Phelan–McDermid syndrome) as well as other non-syndromic forms of autism spectrum disorder (ASD). A number of recent reports have investigated basal ganglia function in mouse lines harboring Shank3 mutations, revealing specific striatal circuit impairments underlying self-injurious repetitive grooming exhibited by these mutants. However, Shank3 mutations in humans are often associated with intellectual disability and cognitive impairments, leading to the hypothesis that functional alterations in this gene can affect extra-striatal brain substrates, including higher order neocortical regions.
Objectives: Our work probes the hypothesis that Shank3 mutations impair function and anatomy of extra-striatal neocortical substrates, including higher-order cognitive substrates. To this aim, we used high resolution structural MRI and in vivo resting-state fMRI (rsfMRI) to map regional gray matter volume and brain-wide functional connectivity in male Shank3B$^{-/-}$ mutants.

Methods: Adult male Shank3B$^{-/-}$ (n=11) and control wild type littermates (n=10) were imaged at 7T under shallow halothane anesthesia (0.75%) using a single-shot EPI sequence as previously described (Liska et al., 2017, Cerebral Cortex). The protocol preserves large-scale functional connectivity in rodents (Gozzi & Schwarz, 2016, NeuroImage). We calculated global and local brain connectivity maps for all subjects and mapped voxelwise inter-group differences in both measures. We also employed post-mortem voxel based morphometry (VBM) and automated anatomical labeling on high resolution images obtained with a FLASH sequence with an isotropic voxel size of 70µm. The same brains underwent DTI imaging using 80 directions, a 120x120x240 voxel size, and b=3000, d=6 and D=13 ms as recently described (Liska et al., 2017, Cerebral Cortex).

Results: Whole-brain rsfMRI connectivity mapping revealed large foci of reduced global and local connectivity in prefrontal and anterior cingulate hub regions of the mouse brain (A-B). This effect was associated with diminished long-range connectivity in midline integrative areas of the mouse default mode network (C), as well as impaired striato-cortical coupling (D). A correlation between impaired ultrasound vocalization and decreased prefrontal connectivity was also observed. No overt genotype-dependent alterations in white macrostructure or fiber-organization were observed, as documented by DTI-based mapping and tractographic analyses (G). In keeping with the observed functional alterations, prefrontal and parietal regions exhibiting impaired connectivity also showed prominent reductions in gray matter volume (E-F), suggesting of a hypotrophic maturation of these areas. Cortical regions of Shank3$^{-/-}$ mutants also exhibited idiosyncratic variability in homotopic connectivity.

Conclusions: We show that Shank3B deletion leads to cortical volumetric loss and reduced local and long-range functional connectivity within prefrontal and posterior connectivity hub region, an effect that is associated with social communication deficits. These findings suggest a pivotal role for Shank3B in the establishment of functional and neuroanatomical coupling between integrative higher order neocortical areas, and suggest that mutations in this gene may predispose to autism via a selective trophic and functional downregulation of prefrontal circuits.

60

127.060 Anxiety in Adolescents with ASD Modulates Neural Responses during Simulated Social Interactive Paradigm.

M. L. McNair*, A. Naples, K. A. McNaughton, T. C. Day, T. Winkelman, M. J. Rolison, K. S. Ellison, E. Jarzabek, B. Lewis, J. Wolf and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Anxiety affects 40-50% of individuals with autism spectrum disorder (ASD) and potentiates the social difficulties experienced by these individuals. Prior work demonstrates atypical brain activity and patterns of attention to social stimuli in both individuals with ASD and anxiety. However, most research has relied on passive observation of static and dynamic stimuli, and there is little research investigating the relationship of anxiety and brain response in interactive contexts.
Objectives: We developed a novel interactive paradigm in which on-screen faces responded to participants' looking patterns to assess: (1) brain and gaze response to faces that respond in a reciprocal manner between individuals with ASD and typically developing (TD) controls and (2) the moderating effect of anxiety on brain activity and looking patterns. We hypothesized that anxious symptomology would differentially impact the expression of temporally early social brain function in the context of social vulnerabilities in ASD.

Methods: EEG and eye-tracking were collected from adolescents with ASD (n=45, age=14.68 years, IQ=110.44) and age/IQ matched TD controls (n=43, age=13.68 years, IQ=109.52). Following an arrow cue, participants would look to the eyes or mouth of an on-screen face, which responded by opening its eyes or mouth. In this way, faces would display reciprocal (eye-to-eye; mouth-to-mouth) and nonreciprocal (eye-to-mouth; mouth-to-eye) facial movement. We examined temporally early brain responses at face sensitive ERP components, the P100 and N170, and measured their relationships to social and anxious symptomatology using parent-report on the Child Behavior Checklist (CBCL).

Results: Participants with ASD exhibited significantly greater parent-reported anxiety, as determined by the CBCL's Anxiety Problems (*F*(1,58)=12.063, *p*=0.001), Social Problems (*F*(1,58)=25.678, *p*<0.000), and Anxious Depressed T-Scores (*F*(1,58)=9.954, *p*=0.003). A significant main effect of condition (eye-to-eye/mouth-to-mouth) for N170 peak amplitude (*F*(1, 86)=48.512, *p*<0.000) demonstrated that reciprocal eye-contact elicited the largest effect on N170 response across groups. Individuals with ASD, compared to TD controls, exhibited greater N170 amplitudes to reciprocal eye-contact in the right hemisphere (*F*(1, 86)=10.783, *p*<0.001) and this effect correlated with increased anxiety, such that greater levels of anxiety correlated with greater neural response to eye-contact (Anxiety Problems (r(28)=-0.369, *p*=0.053), Social Problems (r(28)=-0.346, *p*=0.072), and Anxious Depressed (r(28)=-0.482, *p*=0.009)). Furthermore, a diagnosis by condition interaction at the P100 amplitude revealed that, across both hemispheres, individuals with ASD exhibited greater P100s to mouth movements while controls exhibited greater P100s to reciprocal eye-contact (*F*(1, 86)=4.074, *p*=0.047), suggesting that participants with ASD exhibit atypical patterns of preparatory vigilance during reciprocal social interactions. Eye-tracking data analysis is ongoing.

Conclusions: Our findings show that anxiety modulates neural responses to social interaction simulations in participants with ASD and that these individuals exhibit both hypersensitivity to reciprocal eye-contact and atypical patterns of vigilance when viewing faces. Given the prevalence of anxiety in ASD and the differential neural responses to social interactions observed in these individuals, anxiety could serve not only as a treatment target for alleviating ASD symptomatology but also as a specific subtype of ASD. The particular neural responses seen in our participants with ASD may also act as a potential biomarker for ASD and anxiety.

61 **127.061** Atypical Brain Connectivity during a Theory-of-Mind Task in Adults with and without Autism Spectrum Disorder

V. Yuk[1,2]*, E. Anagnostou*[3] *and M. J. Taylor*[1,2]*, (1)The Hospital for Sick Children, Toronto, ON, Canada, (2)University of Toronto, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Individuals with autism spectrum disorder (ASD) exhibit atypical functional brain connectivity across a variety of tasks, generally showing a pattern of long-range underconnectivity and short-range hyperconnectivity in task-relevant networks. For instance, studies find reduced connectivity between the nodes of the theory-of-mind (ToM) network, which mainly consists of the medial prefrontal cortex, temporoparietal junction, posterior superior temporal sulcus, and precuneus, and this decreased connectivity is thought to contribute to the social cognitive deficits that characterize ASD. However, the specific differences in the temporal-spatial dynamics of this ToM network have yet to be determined, and analyzing how brain connectivity differs across time and frequency bands may demonstrate that these differences are more nuanced than previously found.

Objectives: To utilize the excellent temporal and spatial resolution of magnetoencephalography (MEG) to examine timing and frequency differences in brain connectivity between adults with and without ASD during a ToM task.

Methods: We studied 35 control adults (23 M, 12 F; mean age = 26.4±4.9 years) and 43 adults with ASD (30 M, 13 F; mean age = 26.7±5.5). Participants performed a false-belief task, based on the classic Sally-Anne task, to assess ToM, while in the MEG scanner. The task required participants to infer whether a character had a true or false belief about an object's location. Time series of activity during this task at various brain areas were reconstructed from the MEG data using a vector beamformer. Connectivity between sources was estimated using the weighted phase lag index (wPLI) metric, which was then averaged within several canonical frequency bands (theta, alpha, beta, and low and high gamma) and within a series of 100-ms time windows from 100-600 ms following stimulus onset. Brain connectivity in the false vs. true belief trials were compared. Significant results are reported at a FWE-corrected p<0.05.

Results: Whole-brain network analyses revealed a mixed pattern of under- and overconnectivity in adults with ASD during our ToM task. Between 100-200 ms, adults with ASD showed decreased right temporoparietal junction and ventromedial prefrontal cortex connectivity, and decreased anterior and posterior cingula connectivity in the theta frequency band, as well as increased precuneus and ventromedial prefrontal cortex connectivity, and increased left inferior frontal gyrus and dorsomedial prefrontal cortex connectivity in the beta frequency band. Between 300-400 ms, the ASD group also showed reduced left superior parietal lobule and ventromedial prefrontal cortex connectivity in the low gamma frequency band.

Conclusions: Our results indicate that adults with ASD show distinct patterns of brain connectivity compared to controls across a number of frequency bands, between areas within and outside the ToM network. The most prominent effects seen in the ASD group were the reduced connections in the theta frequency band, which is known to reflect long-range connectivity during cognitive processing. Additional analyses will correlate these connectivity findings with behavioural performance on tasks involving understanding the emotions and intentions of others.

62 **127.062** Atypical Brain Connectivity in Children with Autism Spectrum Disorder during a Music Familiarity Task (POND Network)

C. P. De Barros Freitas[1,2]*, L. Ristic*[1]*, S. Fragiadakis*[3]*, S. Chow*[1]*, S. M. Wong*[4]*, A. Iaboni*[3]*, B. Dunkley*[5]*, M. J. Taylor*[6]*, J. P. Lerch*[7] *and E. Anagnostou*[3]*, (1)Bloorview Research Institute, Toronto, ON, Canada, (2)Institute of Medical Science, University of Toronto, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Division of Neurosurgery, Hospital for Sick Children, Toronto, ON, Canada, (5)Diagnostic Imaging, Hospital for Sickkids, Toronto, ON, Canada, (6)The Hospital for Sick Children, Toronto, ON, Canada, (7)Mouse Imaging Centre, Hospital for Sick Children, Toronto, ON, Canada*

Background: Emerging evidence suggests autism is a disorder of brain connectivity and atypical reward processing has been proposed as an explanation for social deficits in ASD. Music is a valuable tool to study human cognition, emotion and reward networks and it is also an auditory stimulus that interests and motivates children with ASD.

Objectives: To examine neural synchrony in the reward networks associated with familiarity and liking of music listening in children with ASD.

Methods: 23 children with autism (ASD) and 23 typically developing children (TDC) children, between 7 to 14 years old, matched on age and sex were recruited. Magnetoencephalography (MEG) was used to measure brain activation and neural synchrony, while listening to different types of music (familiar liked, familiar disliked, unfamiliar liked and unfamiliar disliked). These music selections were chosen by the children and then modified (and matched with unfamiliar songs of the same genre, tempo, mode and dissonance) for presentation in the MEG.

Preliminary Results: 23 ASD (mean age 10.09 ± 1.41) and 23 TDC (mean age 10.26 ± 1.85) of IQ>70 have been recruited. Whole brain connectivity revealed significant group differences in the theta band (4-8 Hz) frequency while listening to different types of music (familiar liked, familiar disliked, unfamiliar liked and unfamiliar disliked). ASD group engaged different networks, showing over-connectivity in frontal areas and under-connectivity in posterior areas including the occipital and parietal lobes. MEG analyses of the reward networks are currently underway, using reward network seeds (such as the nucleus accumbens).

Conclusions: These findings reinforce functional disconnection in brain networks mediating music listening in children with ASD. The outcome of this research will enhance our understanding of the neurobiology of music listening and reward processing in ASD population so that meaningful translation can occur into innovative music therapy interventions.

63 **127.063** Atypicality of the N170 Event-Related Potential in Autism Spectrum Disorder: A Meta-Analysis

***E. Kang**[1], C. M. Keifer[1], E. J. Levy[2], J. Foss-Feig[3], J. McPartland[4] and M. D. Lerner[5], (1)Stony Brook University, Stony Brook, NY, (2)Duke University, Durham, NC, (3)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (4)Child Study Center, Yale University School of Medicine, New Haven, CT, (5)Psychology, Stony Brook University, Stony Brook, NY*

Background: Autism spectrum disorder (ASD) is associated with impaired processing of social information, such as faces (Lozier et al., 2014; McPartland et al., 2004). However, the neurocognitive processes that underlie social deficits in ASD are poorly understood. The N170 event-related potential (ERP) indexes early face processing in humans by electroencephalogram (EEG; Bentin et al., 1996) and has been used to index face processing impairments in psychiatric disorders (Feuerrigel et al., 2015; McCleery et al., 2015). Although the N170 is considered among the most promising biomarkers of ASD (Jeste & Nelson, 2009; McPartland et al., 2016), published literature on the N170 is not consistent, and studies often suffer from small sample sizes. No quantitative review to date has integrated the literature to assess whether N170 response to faces in individuals with ASD differs from that of typically-developing (TD) individuals.

Objectives: This meta-analysis examined the corpus of literature investigating differences in N170 response to faces in individuals with and without ASD. In addition, to examine the specificity of differential N170 response to face stimuli in particular, this study also meta-analyzed differences in a) N170 response to non-face stimuli and b) P1 response to faces in the same sample of studies.

Methods: Web of Science, PubMed, and PsycINFO databases and citation lists from past systematic reviews on the topic were searched. Data from 23 studies (N_{ASD}=374, N_{TD}=359; Table 1) were reviewed and double-coded by two independent raters (ICC>0.90). Meta-analysis was used to examine the effect size (Hedges' *g*) of the difference in N170 and P1 latency and amplitude among individuals with and without ASD, averaged across all relevant facial (e.g., different emotions) and non-facial (e.g., objects, houses) stimuli for each study. Analyses were also conducted examining potential moderators (mean age and IQ of participants, sex distribution of participants, use of gold-standard ASD diagnostic measures, and ASD symptom severity) and publication bias.

Results: On average, N170 latencies to faces were delayed in individuals with ASD relative to TD participants (g=0.36, 95% CI [0.06, 0.67], p=0.02; Figure 1A), but amplitudes did not differ between ASD and TD groups overall (g=-0.03, 95% CI [-0.33, 0.26], p=0.82; Figure 1B). Moderator analyses revealed that N170 amplitudes were smaller in magnitude in the ASD relative to TD participants in adult samples (Q[1]=10.87, p=0.001) and in those with higher cognitive ability (b=0.08, p=0.006). No evidence of publication bias was found. N170 latency and amplitude to non-faces and P1 latency and amplitude to faces in the ASD group were not statistically different when compared to TD controls (all *p*s>0.12).

Conclusions: Atypicality of N170 response to faces, particularly increased latency, appears to be a robust biomarker of social-communicative dysfunction in ASD. This marker may relate to differential developmental experiences and use of compensatory cognitive mechanisms. Future research should further examine phenotypic differences contributing to N170 heterogeneity in ASD, as well as its malleability in response to treatment.

64 **127.064** Brain Activity Underlying the Recognition of Vocal Affect Bursts in Autism Spectrum Disorder

***V. Yap**[1,2], A. Connelly[3], I. E. Scheffer[3,4,5,6] and S. J. Wilson[1,2], (1)Melbourne School of Psychological Sciences, The University of Melbourne, Melbourne, VIC, Australia, (2)Florey Institute of Neuroscience and Mental Health, Melbourne, VIC, Australia, (3)Florey Institute of Neuroscience and Mental Health, Melbourne, Australia, (4)Department of Medicine, The University of Melbourne, Melbourne, Australia, (5)Department of Paediatrics, Austin Health, Melbourne, Australia, (6)Department of Neurology, Royal Children's Hospital, Melbourne, Australia*

Background: Functional MRI research has shown that individuals with Autism Spectrum Disorder (ASD) demonstrate atypical neural responses while processing emotional prosody in speech. Specifically, enhanced activation in brain regions for attention and executive function has been reported in ASD, suggesting a greater reliance on cognitive resources to process emotional cues in the voice. Previous studies have not utilised nonlinguistic emotional stimuli or vocal affect bursts (e.g., laughter, screams), although these expressions represent purer markers of affective states that do not contain the linguistic and semantic components of prosodic speech. Further, most studies have employed implicit tasks and ratings of emotional intensity or valence to elicit brain activation, instead of using tasks that explicitly assess the identification of emotions in vocal stimuli.

Objectives: We aimed to examine brain activity associated with the recognition of vocal affect bursts in ASD using a forced-choice discrimination task.

Methods: We assessed 16 participants with high-functioning Autism and 16 healthy controls (12 males per group) matched on age (M_{ASD} =23.00, $M_{Controls}$=23.19) and Full-Scale IQ (M_{ASD}=112.56, $M_{Controls}$=116.88). The in-scanner paradigm included blocks of tasks assessing emotion recognition (experimental condition) and gender recognition (baseline condition). On the emotion task, participants listened to vocal affect bursts representing the six basic emotions and identified the correct emotion from two options. On the gender task, participants listened to neutral voices and identified whether the speaker was male or female. We specified an "emotion > gender" contrast to isolate activity related to the cognitive and affective processes that underlie vocal emotion recognition.

Results: Analysis of in-scanner task performance revealed no significant difference in emotion recognition accuracy between both groups, suggesting that the ASD group reliably performed the task. Despite this, whole-brain, fixed effects analyses revealed that the ASD group demonstrated significantly higher activation across several brain regions at a cluster-corrected threshold. These included regions sensitive to emotional voices, such as the left inferior frontal gyrus and superior temporal sulcus, which belong to the mirror neuron system (MNS). The ASD group also showed more activation in structures for autobiographical memory retrieval (e.g., bilateral hippocampus, precuneus, posterior cingulate cortex) and visual processing (e.g., bilateral occipital gyri, fusiform gyri). Other regions of enhanced activation included the bilateral angular gyri and cerebellum. No region with significantly lower activation was found in the ASD group.

Conclusions: Compared to healthy controls, participants with ASD required greater activation across multiple brain regions to successfully perform the emotion task. Our findings suggest that the ASD group used additional cognitive effort to identify vocal affect bursts. It is possible that the ASD group relied more on compensatory strategies to perform the task, including cross-modal processing (e.g., mental imagery) and self-referential processing (e.g., autobiographical memory retrieval). Greater activation in the inferior frontal gyrus and superior temporal sulcus also indicates atypical MNS response to the recognition of vocal affect bursts in ASD. Our findings are consistent with fMRI research on emotional prosody perception in ASD, suggesting that enhanced brain activation to emotional voices is robust across different vocal stimuli and task demands.

65 **127.065** Brain Correlates of Automatic Detection of Emotional Prosody in Children and Adults with Autism Spectrum Disorders

M. Gomot[1], *J. Charpentier*[1], *J. Malvy*[2], *F. Bonnet-Brilhault*[3], *E. Houy-Durand*[1] *and M. Latinus*[4], *(1)UMR930 Inserm, Université François-Rabelais de Tours, Tours, France, (2)CHRU Tours, Tours, France, (3)UMR 1253, iBrain, Université de Tours, Inserm, Tours, France, (4)UMR INSERM U930, Tours, France*

Background: Although intolerance of change is a main feature of Autistic Spectrum Disorder (ASD), the brain processes underlying this aspect of the disorder remain poorly understood. This oversensitivity to changes may lead to an inability to adapt to new sensory inputs, and especially to the ever changing social environment. In this respect the processes involved in pre-attentional detection of changes in stimulus features have been investigated in ASD using the mismatch negativity (MMN), an event-related potential that reflects error detection caused by a deviation from a learned regularity. Although ASD is also characterized by an inability to detect and adapt to changes in emotional states, only few MMN studies in this population have investigated automatic deviancy detection in an emotional context. These studies used different deviant emotions that where always compared to neutral standards, and showed that emotional MMN was smaller or less lateralized in ASD than in controls.

Objectives: In order to determine if particularities observed in emotional prosody processing are related to emotion processing or to change detection abnormalities, the present study addresses direct comparison of automatic change detection of neutral and emotional deviants with strictly controlled acoustic parameters, in children and adults with ASD.

Methods: Thirty-two adults (16 typical; 16 ASD) and thirty 7-12 years old children (15 typical; 15 ASD) were presented with two voice deviants, neutral (p=.085) and angry (p=.085) (prosodic variation of the vowel 'aaa') embedded in a repetitive sequence of neutral stimuli. Brain electrical activity was recorded using a 64-channels Biosemi EEG system, while participants were watching a silent movie. MMN was measured for each condition as the subtraction of the stimuli presented in an equiprobable sequence from the same deviant stimuli in the oddball sequence.

Results: Comparisons of age groups during typical development indicate a late maturation of the brain processes associated with emotional prosody discrimination. Findings in both children and adults with ASD revealed an overall impairment of change detection with an earlier MMN and a larger P3a compared to controls. In children with ASD, the amplitude of the responses to voice stimuli from the equiprobable sequence was smaller than in controls for both the neutral and the emotional prosody, as where the responses to deviancy, and with no modulation of change detection by emotion. In adults with ASD responses to voice stimuli were found normal regardless prosody. Though the discrimination between different vocal emotions seems efficient, the MMN to neutral and emotional deviancy presented atypical brain distributions.

Conclusions: The detection of prosody deviancy was found altered in children with ASD, together with atypical responses to voice, and this regardless of expression. In adults despite a normalization in voice processing, the detection of vocal deviancy remains affected. Altogether these findings suggest that voice and prosody processing can improve with age in ASD, but that the lack of expertise in vocal encoding during childhood would lead to a long lasting difficulty in the online processing of emotional changes, which potentially plays a crucial role in social interaction deficits.

66 **127.066** Brain-to-Brain Synchrony during Social Cooperation in Autism – a NIRS-Based Hyperscanning Study

J. A. Kruppa[1,2], *V. Reindl*[2,3], *J. Prinz*[2], *E. Oberwelland Weiss*[1,2], *C. Gerloff*[4], *W. Scharke*[2], *K. Konrad*[1,2,3], *B. Herpertz-Dahlmann*[2] *and M. Schulte-Ruther*[1,3], *(1)Cognitive Neuroscience, Institute of Neuroscience and Medicine (INM-3), Research Center Jülich, Jülich, Germany, (2)Department of Child and Adolescent Psychiatry, Psychosomatics and Psychotherapy, University Hospital RWTH Aachen, Aachen, Germany, (3)JARA Brain, University RWTH Aachen & Research Center Jülich, Aachen, Germany, (4)Advanced Analytics, School of Business and Economics, RWTH Aachen University, Aachen, Germany*

Background: In healthy adults, synchronization of brain activation has repeatedly been demonstrated during joint social tasks, and may play an important role for successful dyadic social interaction. Pioneering studies have demonstrated diminished brain-to-brain synchrony in adults with autism spectrum disorder (ASD) during such tasks, e.g. during performance of a real-time joint-attention task. To date, no study has investigated brain-to-brain synchrony in children with ASD during social interaction. Importantly, the familiarity of the interaction partner (i.e. a familiar person or a stranger) may modulate synchronization of brain activation.

Objectives: We investigated brain-to-brain synchrony in children and adolescents with and without ASD during a social cooperation game that the participants played with either a parent or an adult stranger as their interaction partner.

Methods: Using functional Near-Infrared Spectroscopy (fNIRS) hyperscanning, we assessed brain-to-brain synchrony during performance of a cooperative and a competitive computer game in 43 typically developing (TD) children, 15 children with ASD (8-18 years, all males) while playing with one of their parents, mostly mothers. In addition, adult strangers performed the identical game with each participating child. Participants were instructed to either respond jointly (as simultaneously as possible) via button press in response to a target (cooperation task), or to respond faster than the other player (competition task). Within each dyad, wavelet coherence was calculated for corresponding channels as a measure of brain-to-brain synchrony.

Results: On the behavioral level, preliminary results showed that the dyad's cooperative performance was neither influenced by the interaction partner (parent or stranger) nor by the group (TD or ASD group). However, during competition, the child won more often against the parent than against the stranger, and children with ASD won more often against parent/stranger than TD children. On the neural level, preliminary results revealed a significant interaction of partner and group for coherence in channels 2 and 4, which correspond to Brodmann areas 8 and 9. Breaking down the two-way interaction, results revealed that coherence in the ASD group was significantly smaller when playing with the parent compared to an adult stranger. No significant effect of partner was observed in the TD group.

Conclusions: Data collection in the ASD sample is ongoing. Preliminary results suggest differential coherence in ASD with respect to the familiarity of the interaction partner. In a larger sample it remains to be seen, whether fNIRS hyperscanning represents a valuable tool for investigating brain synchrony during social tasks as a proxy for typical and atypical social interaction. To this end, we will also analyze the relation of brain-to-brain synchrony with symptom severity measures and treatment related changes.

67 **127.067** Broadly Reduced Intrinsic Functional Connectivity in Girls Compared to Boys with Autism Spectrum Disorders

L. Olson[1,2]*, A. C. Linke*[2]*, L. E. Mash*[1,3]*, M. A. Reiter*[1,3]*, R. A. Mueller*[1,2] *and I. Fishman*[1,2]*, (1)Joint Doctoral Program in Clinical Psychology, SDSU / UC San Diego, San Diego, CA, (2)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (3)Brain Development Imaging Laboratories, Department of Psychology, San Diego State University, San Diego, CA*

Background: The high male:female prevalence ratio of autism spectrum disorders (ASDs) has been recognized dating back to Leo Kanner's initial description in 1943 (Kanner, 1943). The majority of research studies in autism reflect this strong male bias. Although a growing body of research suggests that ASDs may affect females differently than males (Werling & Geschwind, 2013), little is known about possible female variants. Further research with adequate samples is necessary to inform our understanding of gender-related neurobiological differences in ASDs. Knowledge of gender-specific differences in ASDs promises to inform novel, targeted therapeutic interventions (Constantino, 2017).

Objectives: Investigate gender-based differences in iFC, and within- versus between-domain connectivity, in children and adolescents with and without ASDs.

Methods:

Resting-state functional MRI data for 142 children and adolescents (ages 7-18 years) were selected from the Autism Brain Imaging Database Exchange (ABIDE I and II; n = 111; DiMartino et al., 2014 & 2017) and an in-house sample (n = 31), with 70 datasets from children with ASDs (36 females) and 72 datasets from typically developing (TD) children (36 females). Within each diagnostic group, boys and girls were matched on age, handedness, cognitive functioning, head motion, and study site. Group independent component analysis (ICA) and dual-regression were used to generate intrinsic functional networks for each subject. The spatial maps were thresholded at 90th percentile to extract separate functional clusters (ROIs). Functional connectivity (FC) was estimated by generating intra-individual ROI-ROI correlation matrices, with mean connectivity matrices averaged across participants. ROIs were categorized into three domains: sensorimotor, default mode, and executive. Chi-square tests of independence were used to test for differences in the proportion of significant within- and between-domain ROI-ROI correlations ($rs > |0.4|$).

Results: Within the TD group, boys (TD-B) showed significantly more positive correlations within the sensorimotor domain than girls (TD-G) ($X^2 = 14.7$, $p < 0.001$). TD-B and TD-G did not differ in their within- or between-domain connectivity for any other domains. In contrast, girls with ASDs (ASD-G) showed broad underconnectivity compared to boys with ASDs (ASD-B). Specifically, ASD-G showed fewer positive correlations between the sensory networks and executive and default mode networks ($X^2 = 5.11$, $p = 0.02$); fewer positive correlations within the DMN ($X^2 = 5.00$, $p = 0.03$); fewer positive correlations between the DMN and other domains ($X^2 = 15.78$, $p = < 0.0001$); fewer positive correlations within the executive domain ($X^2 = 6.12$, $p = 0.01$); and fewer positive correlations between executive and other domains ($X^2 = 10.85$, $p < 0.0001$).

Conclusions: We found a pattern of pervasive underconnectivity in girls compared to boys with ASDs, whereas in the TD group, gender differences in connectivity were seen only within the sensorimotor domain. Our study includes a substantially larger sample than previous reports. Use of ABIDE data, however, precluded inclusion of puberty status and hormonal changes, which are likely to affect brain organization.

68 **127.068** Cerebellar Topography in Autism and Rescue of Autism-Related Behaviors in Autism Mouse Models

ABSTRACT WITHDRAWN

Background:

Autism Spectrum Disorders (ASDs) are prevalent neurodevelopmental disorders marked by social impairments, repetitive behaviors, and cognitive inflexibility. Despite a prevalence exceeding 1%, underlyingmechanisms are poorly understood while targeted therapies and their guiding parameters are needed. Recent evidence has implicated the cerebellum in ASD pathogenesis, and we have recently demonstrated that cerebellar dysfunction is sufficient to generate autism-relevant behaviors in mice. However, the cerebellar topography regulating autism-related behaviors and the neural circuits regulating those behaviors remain poorly understood.

Objectives: to identify cerebellar topography and cerebellar-regulated circuits underlying autism-related behaviors

Methods: To achieve these objectives, we have combined genetic mouse models, MR imaging, and targeted, *in vivo* chemogenetic- mediated neuromodulation paired with *in vivo* electrophysiology and detailed behavioral analyses.

Results: Using these methods, we have identified the clinically implicated cerebellar sub-region, Right Crus I, as a critical region in the regulation of autism-related behaviors. We determine that inhibition of this domain is sufficient to generate social, repetitive, and inflexible behaviors in mice. Moreover, we demonstrate that stimulation of this sub-region is sufficient to rescue social deficits in an ASD mouse model even during adulthood. We then identified functional connectivity between right Crus I and cortical association areas, connectivity that is disrupted in this ASD mouse model and in children with ASD. Modulation of these cortical areas in turn mediates cerebellar-regulated ASD behaviors.

Conclusions: These findings, thus, not only further our mechanistic understanding of the cerebellar contribution to ASD but also offer novel therapeutic targets and strategies for the treatment of autism-related behaviors.

69 **127.069** Differences in Resting State EEG Spectral Power in Infants at Elevated Risk for ASD

M. J. Rolison[1]*, A. Naples*[1]*, T. McAllister*[1]*, T. Kim*[1]*, H. Reuman*[1]*, R. Tillman*[2]*, C. E. Mukerji*[3]*, K. K. Powell*[1]*, S. Macari*[1]*, K. Chawarska*[1] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)University of Maryland, College Park, MD, (3)Harvard University, Cambridge, MA*

Background: Clinical diagnosis of autism spectrum disorder (ASD) can be made by two years of age, but experimental evidence suggests earlier emergence of differences in attention and brain activity in infants that later develop ASD. Prior work using resting state EEG has found attenuated spectral power in infants at elevated risk for developing ASD (HR-ASD) compared to normal risk (NR) infants (Tierney, 2012). Additionally, HR-ASD infants demonstrate different developmental trajectories compared to NR infants as indexed by spectral power. Resting state EEG offers an inexpensive, non-invasive measure of cortical activity, with potential to serve as a practicable biomarker of atypical development.
Objectives: Examine differences in resting EEG spectral power between HR-ASD and NR infants throughout the first two years of life.

Methods: EEG data was recorded from 41 HR-ASD and 42 NR infants at 3, 6, 9, 12, 18, and 24 months of age. At each time point, 2 minutes of EEG was recorded in a dimly lit room using a 128-channel HydroCel Geodesic Sensor Net. Infants sat on their parent's lap while a research assistant blew bubbles to keep them still. EEG data were filtered from 0.1-100 Hz, segmented into 1 second epochs, and baseline corrected. Bad channels were interpolated and epochs containing artifact were removed. EEG recordings that did not have a minimum length of 20s were omitted from further analysis. Spectral power was extracted from frontal regions of the scalp. Delta (2-4 Hz), theta (4-6 Hz), low alpha (6-9 Hz), high alpha (9-13 Hz), beta (13-30 Hz), and gamma (30-50 Hz) frequency bands were defined based on prior research examining EEG power in HR-ASD infants (Tierney, 2012). Both absolute and relative power were compared between groups at each time point.

Results: Preliminary analyses of relative power revealed lower high alpha power in HR-ASD infants at 9 and 18 months of age ($p=0.02$ and $p=0.01$, respectively). At 24 months of age, HR-ASD infants demonstrated lower levels of relative delta power ($p=0.04$) and greater relative theta power ($p=0.03$) than NR infants. Analyses of absolute power revealed greater low alpha power ($p=0.01$) and greater theta power ($p<0.01$) in HR-ASD infants at 24 months.

Conclusions: Preliminary results indicate both absolute and relative differences in spectral power bands between HR-ASD and NR infants. These findings expand upon prior work that has identified differences in delta, theta, and alpha power across development in infants at elevated risk for ASD. These results provide additional insight into typical and atypical neural development in the first two years of life. Ongoing analyses are examining spectral power differences among these developmental trajectories through the incorporation of phenotypic outcome data collected at 36 months of age.

70 **127.070** Diminished Neural Resources Allocation to Time Processing in Autism Spectrum Disorders

A. Lambrechts[1], *C. M. Falter-Wagner*[2,3] *and V. van Wassenhove*[4], *(1)City, University of London, London, United Kingdom of Great Britain and Northern Ireland, (2)LMU Munich, Munich, Germany, (3)Institute of Medical Psychology, Faculty of Medicine, LMU Munich, Munich, Germany, (4)Cognitive Neuroimaging Unit, CEA DRF/Joliot/NeuroSpin, INSERM, Université Paris-Sud, Université Paris-Saclay, Gif/Yvette, France*

Background: Interval timing, the ability to judge the duration of short events, has been shown to be compromised in Autism Spectrum Disorders (ASD). Timing abilities are ubiquitous and underlie behaviours as varied as sensory integration, motor coordination or communication. It has been suggested that atypical temporal processing in ASD could contribute to some of the disorder's symptoms, in particular motor clumsiness and difficulties in social interaction and communication. Recent behavioural investigations have suggested that interval timing in ASD was characterised by intact sensitivity but reduced precision in duration judgements.
Objectives: In this study we investigated the processing of duration as compared to pitch in a group of high-functioning individuals with ASD using magnetoencephalography (MEG).

Methods: 18 adolescents and adults with ASD and 18 age- and IQ-matched typically-developing control (TDC) individuals compared two consecutive tones according to their duration or pitch in separate experimental blocks. MEG activity was recorded throughout the task. The analysis was carried out exclusively on physically identical stimuli (500 Hz tones lasting 600 ms), which served, according to instruction, as standard or probe in a Duration or Pitch task respectively.

Results: Our results indicate that compared to TDC individuals, individuals with ASD are less able to predict the duration of the standard tone accurately, affecting the sensitivity of the comparison process. In addition, contrary to TDC individuals who allocate resources at different times depending on the nature of the task (pitch or duration discrimination), our data suggest that individuals with ASD engage less resources for the Duration task than for the Pitch task regardless of the context.

Conclusions: Although individuals with ASD showed top-down adaptation to the context of the task, this neuronal strategy reflects a bias in the readiness to perform different types of tasks, and in particular a diminished allocation of resources to duration processing which could have cascading effect on learning and development of other cognitive functions such as turn-taking and motor coordination.

71 **127.071** Dynamic fcMRI Reveals Transient Atypical Connectivity Patterns in Adolescents with Autism Spectrum Disorders

L. E. Mash[1,2], *A. C. Linke*[3], *C. H. Fong*[3], *M. Falahpour*[4], *T. T. Liu*[4] *and R. A. Mueller*[3], *(1)Brain Development Imaging Laboratories, Department of Psychology, San Diego State University, San Diego, CA, (2)Joint Doctoral Program in Clinical Psychology, SDSU / UC San Diego, San Diego, CA, (3)Brain Development Imaging Laboratories, San Diego State University, San Diego, CA, (4)Center for Functional MRI, Department of Radiology, UC San Diego, San Diego, CA*

Background: There is ample evidence of atypical static functional connectivity (FC) in autism spectrum disorders (ASDs). However, transient relationships between neural networks are not easily captured by conventional functional connectivity magnetic resonance imaging (fcMRI) methods. Dynamic FC approaches have been used to identify repeated, transient connectivity patterns ("brain states"), revealing spatiotemporal network properties that are not observable in static FC. Several recent studies using this method have found atypical dynamic FC in ASDs (Chen et al., 2017; de Lacy et al., 2017). However, the exact relationship between static and dynamic FC in ASDs remains unclear, as does the characterization of state-specific group differences.
Objectives: We aimed to (i) establish the relationship between static and dynamic FC in typical development (TD) and ASDs; (ii) describe group differences in transient states and compare these to static FC patterns; and (iii) examine temporal stability and flexibility between identified states.

Methods: Resting-state functional MRI data from 62 ASD and 57 TD participants were included, group-matched for motion, age, sex, handedness, and nonverbal cognitive ability. High-order group independent component analysis and dual-regression were used to generate maximally independent, functionally cohesive network regions of interest (ROIs) at the individual level. Static FC was calculated using entire time series.

Dynamic FC between ROI pairs was examined using tapered sliding windows, generating a temporally contiguous series of connectivity matrices. For each subject and ROI pairing, the standard deviation of FC (sd-FC) was calculated across all time windows. Windows underwent k-means clustering, generating four analogous brain states in each group.

Results: A one-sample t-test determined that across all ROI pairings, group differences in static FC primarily reflected hyperconnectivity in ASD (t(1080) = 12.06, p <.001); additionally, increased sd-FC in the ASD group predominated (t(1080) = 9.72, p < .001). There was a significant negative relationship between static FC and sd-FC in both the ASD (r = -.34, p <.001) and TD groups (r = -.29, p < .001). However, the strength of this association at the individual level was predicted by diagnosis in a general linear model, being weaker in individuals with ASD (β = .09, p =.04). While static FC group differences did not survive FDR correction, two dynamic states showed widespread significant group differences. In one of these states, relative within-network hypoconnectivity and between-network hyperconnectivity were observed for both default-mode and sensorimotor ROIs. This state was more likely to occur in participants with ASD (χ^2= 11.99, p < .001). No significant group differences were observed for time spent per state, mean dwell time, or state-switching frequency.

Conclusions: Higher static FC was associated with reduced variability over time, but this relationship was weaker in ASD participants. Group connectivity differences emerged in dynamic FC states that were not observed in the static FC analysis. Furthermore, findings in one state, which occurred more frequently in ASD participants, were consistent with previous evidence of reduced network integration and differentiation in ASDs. These results highlight the importance of dynamic approaches, and may explain discrepant findings in the static FC literature.

72 **127.072** Dysregulated Local Oscillatory Connectivity of the Visual System in Autism Spectrum Disorder

R. A. Seymour[1,2]*, G. Rippon*[2] *and K. Kessler*[2]*, (1)Department of Cognitive Science, Macquarie University, Sydney, Australia, (2)Aston Brain Centre, Aston University, Birmingham, United Kingdom*

Background:

Individuals diagnosed with Autism Spectrum Disorder (ASD) frequently report sensory overload (both hypo- and hyper-sensitivities), and display a distinct sensory processing style. However, the neurophysiological principles underlying this remain largely unknown. Recent non-invasive magnetoencephalography (MEG) autism research suggests one candidate mechanism may be disorganised local oscillations (neuronal rhythms) produced in response to sensory stimuli, combined with reduced top-down modulation.

Objectives:

We set out to investigate the oscillation-based connectivity within the visual system of ASD participants and matched controls. Specifically, we quantified local dysregulation through low-frequency alpha (7-13Hz) to high-frequency gamma (40-100Hz) phase-amplitude coupling (PAC); and feedforward versus feedback connectivity, using non-parametric granger causality.

Methods:

Whilst undergoing MEG, 17 participants (mean age = 16.63) diagnosed with ASD and 17 matched controls (mean age = 17.43, 15 analysed at present) performed an interactive visual paradigm, with embedded visual grating, designed to elicit non phase-locked high-frequency (40-70Hz) gamma oscillations. Both groups had movement less than 5mm and similar numbers of trials (mean ASD = 62.46, mean control = 62.33). All participants completed the Autism Quotient and Glasgow Sensory questionnaires, to asses the severity of ASD sensory symptoms.

Results:

As expected, presentation of the visual grating was accompanied by increases in gamma-band (40-70Hz) power and decreases in alpha-band (8-13Hz) power within the ventral occipital cortex. There were no statistical differences in power between groups at either frequency. However, there were differences between groups in the coupling (PAC) between the amplitude of gamma-band oscillations and the phase of alpha-band oscillations extracted from virtual electrode time courses in primary visual cortex (V1). The ASD group showed PAC between higher alpha (12-13Hz) and gamma frequencies (60-80Hz) than the control group (9-10Hz and 50-70Hz, respectively). We argue that this could be indicative of dysregulated oscillatory activity and an excitation-inhibition imbalance in autism. Next, virtual electrode time-courses were extracted from areas V1 and V4 to quantify directed functional connectivity from V1 to V4 (feedforward) and V4 to V1 (feedback), using Granger causality. Whilst feedforward connectivity was equivalent in both groups and elevated at gamma frequency (40-80Hz) in particular, V4 to V1 feedback connectivity was significantly reduced in the ASD group, especially at alpha frequency (~10Hz).

Interestingly, the strength of alpha-gamma PAC (9-10Hz; 50-70Hz) was correlated with the ratio between feedforward and feedback connectivity, for the control but not ASD group. Neurophysiologically, this suggests that processing within the visual system is locally segregated in autism, resulting in a stronger dissociation between peak gamma frequencies for PAC (~75Hz), power (~55Hz) and forward connectivity (~45Hz).

Finally, these MEG data will be regressed against self-report questionnaire data, to determine whether local connectivity is related to ASD sensory symptoms.

Conclusions:

Overall, our work suggests that the complex interplay of stimulus-related alpha and gamma oscillations within the human visual system could be dysregulated in autism. The ASD group showed typical patterns of oscillatory power and feedforward connectivity, but dysregulated oscillatory coupling between frequency bands (PAC) and reduced feedback alpha-band connectivity. These findings have implications for emerging neurocognitive theories of sensory processing in autism.

73 **127.073** Early Sensory Prediction Errors Are Less Modulated By Global Context in Autism Spectrum Disorder

J. Goris[1]*, S. Braem*[2]*, A. D. Nijhof*[3]*, D. Rigoni*[4]*, E. Deschrijver*[4]*, S. Van de Cruys*[5]*, J. R. Wiersema*[6] *and M. Brass*[1]*, (1)Department of Experimental Psychology, Ghent University, Ghent, Belgium, (2)Department of Psychology, Vrije Universiteit Brussel, Brussels, Belgium, (3)Institute of Psychiatry, King's College London, London, United Kingdom, (4)Ghent University, Ghent, Belgium, (5)Laboratory of Experimental Psychology, Brain & Cognition, KU Leuven, Leuven, Belgium, (6)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background: Recent theories of autism spectrum disorder (ASD) attempt to explain both social and sensory symptoms of ASD by using the predictive coding framework. Central to these domain general accounts is the hypothesis that individuals with ASD are less flexible in modulating local prediction errors as a function of global top-down expectations. Though some studies already provided preliminary support for these recent

theories, this main hypothesis remains to be tested.
Objectives: As a direct test of this central hypothesis, we used electroencephalography (EEG) to investigate whether local prediction error processing was less modulated by global context in ASD.

Methods: A group of 24 adults diagnosed with ASD was compared to a gender-, age- and IQ-matched group of 24 neurotypical adults on a well-validated hierarchical predictive coding paradigm. In this auditory oddball task, participants listened to short sequences of either five identical sounds or four identical sounds and a fifth deviant sound. The latter condition is known to generate the mismatch negativity (MMN) component, believed to reflect early sensory prediction error processing. Crucially, we manipulated the relative frequency of deviant sound sequences across blocks, as previous studies have shown that in blocks with frequent deviant sound sequences, top-down expectations seem to attenuate the MMN. We predicted that this modulation by global context would be less pronounced in the ASD group.

Results: Both groups showed a MMN that was modulated by global context. However, this effect was significantly smaller in the ASD group as compared to the neurotypical group. In contrast, the P3b, as an electroencephalographic marker of conscious expectation processes, did not differ across groups.

Conclusions: Our results demonstrate that the MMN was less modulated by global context in the ASD compared to the neurotypical group. These findings confirm the central hypothesis of contemporary predictive coding accounts of ASD, indicating that individuals with ASD are less flexible in modulating their low-level prediction errors according to more global contexts. Therefore, this study provides an important piece of evidence for these domain general theories of ASD.

74 **127.074** EEG DATA Processed By Advanced Machine Learning Systems ALLOW an Accurate Differential Diagnosis between ASD Children and Children with Other Neuro-Psychiatric Disorders.

E. Grossi[1], *M. Buscema*[2] *and R. J. Swatzyna*[3], *(1)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy, (2)Semeion Research Centre, Roma, Italy, (3)Tarnow Center for Self-Management, Huston, TX*

Background: In a previous study the authors have shown the ability of a novel kind of Machine Learning System(MLS) named MS-ROM/I-FAST developed by The Semeion Research Institute in Rome to extract interesting features in computerized EEG that allow an almost perfectly distinction of ASD children from typically developing ones. The proof of concept study, published in 2017 in Computer Method and Programs in Biomedicine showed accuracy values near to 100% using training-testing protocol and to 84% - 92.8% using Leave One Out protocol. The similarities among the MLS weight matrixes measured with apposite algorithms were not affected by the age of the subjects suggesting that the MLS do not read age-related EEG patterns, but rather invariant features related to the brain's underlying abnormalities.
Objectives: The aim of the study is to assess how effectively this methodology distinguishes ADS subjects from children affected with other neuro-psychiatric disorders .

Methods: Twenty definite ASD subjects and twenty subjects with neuropsychiatric disorders matched for age and gender distribution observed at Tarnow Center for Self-Management, Huston (US) were included in the study. The two groups had the same age range (4-14 yrs) and male/female ratio (14/6). ASD patients received independent Autism diagnoses according to DSM-V criteria, subsequently confirmed by a qualified psychiatrist using the ADOS scale. No autistic child was affected by genetic conditions and/or cerebral malformations documented by neuroimaging and epilepsy. In the comparison group the range of primary diagnoses was the following: Attention-Deficit Disorder (N= 13), Disorder of social functioning(N=3), Anxiety disorders(N= 2), Major depressive disorder(N= 1), Specific developmental disorders of scholastic skills(N=1). A continuous segment of artefact-free EEG data lasting 10 minutes in ASCCI format was used to compute multi-scale entropy values and for subsequent analyses. A Multi-scale ranked organizing map (MS-ROM), based on the self-organizing map (SOM) neural network, coupled with the TWIST system (an evolutionary system able to select predictive features) created an invariant features vector input of EEG on which supervised machine learning systems acted as blind classifiers.

Results: After MS-ROM/I-FAST preprocessing, twelve features were extracted representing the EEG signature. Acting on these features the overall predictive capability of different machine learning systems in deciphering autistic cases from other NP disorders ranged between 93% and 97.5% (Table 1). These results were obtained at different times in separate experiments performed on the same training and testing subsets. The similarities among the ANN weight matrixes measured with apposite algorithms were not affected by the age of the subjects.

Conclusions: This study demonstrates the value of EEG processing with advanced MLS in the differential diagnosis between ASD and other NP disorders confirming therefore the existence of a specific EEG signature in ASD.

75 **127.075** EEG Resting State Architecture Is Atypical in Children with ASD and Sleep Disturbances

T. Winkelman[1], *S. Hasselmo*[1], *K. A. McNaughton*[1], *T. C. Day*[1], *M. J. Rolison*[1], *K. S. Ellison*[1], *E. Jarzabek*[1], *B. Lewis*[1], *J. Wolf*[1], *S. Baddam*[2], *C. Canapari*[3], *T. McAllister*[1], *A. Naples*[1] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Yale University, New Haven, CT, (3)333 Cedar St PO Box 208064, Yale University, New Haven, CT*

Background: Sleep disturbance is common in Autism Spectrum Disorder (ASD), with between 40 and 80% of children with ASD reporting sleep difficulties, as compared to just 9 to 50% of typically developing (TD) children (Robinson-Shelton, 2016). Sleep disturbances and consequent sleep deprivation are reflected in increased absolute theta (4-8 Hz) power during resting state brain activity in both children and adults (Cajochen, 1995). While the resting EEG profile associated with sleep deprivation is established in the literature, relationships among resting state EEG profiles and sleep disturbances in children with ASD are poorly understood.
Objectives: To investigate relationships among sleep disturbances and resting state EEG power in children with ASD and TD. Study of sleep disturbances in the ASD population may provide important information about underlying neuropathology and potential subgroups of ASD.

Methods: Participants were children with ASD (n=31) and TD controls (n=16), aged 6-18. Parents and children completed measures of social functioning, anxiety, and problem behaviors. Parents additionally completed the Children's Sleep Habits Questionnaire (CSHQ), a validated 33-item measure of sleep problems; impaired sleep is defined as a CSHQ score ≥ 41. A resting EEG was collected from all participants. Participants sat for 60 seconds with their eyes open, followed by 60 seconds with their eyes closed. EEG data was filtered, segmented into 2-s epochs, and hand-edited for movement artifacts. Participants with less than 30 seconds of artifact-free data were excluded, resulting in a final sample of 13 children with ASD and 11 TD children.

Results: Consistent with the literature, 52% of children with ASD met CSHQ criteria for sleep impairment, as compared to 25% of children with TD, approaching a statistically significant difference in this small sample (p=0.08). CSHQ score did not correlate with measures of behavioral dysregulation from the Child Behavior Checklist. All children demonstrated global reduction of absolute theta power with increasing age (frontal: p=0.003, central: p=0.01, posterior: p=0.009; temporal p=0.01), consistent with the expected developmental trajectory. Children with TD showed a positive correlation between CSHQ score and theta power along the midline (r=0.9, p<0.001), frontal (r=0.87, p=0.001), and central (r=0.65, p<0.001) regions of the scalp, whereas children with ASD showed no correlation between theta power and CSHQ score.

Conclusions: Findings demonstrate that children with ASD had higher rates of sleep disturbances, however do not exhibit the expected relationship between sleep problems and EEG spectral power that was seen in TD children. This atypical presentation of sleep problems suggests a potentially distinct neural mechanism of sleep disturbance in ASD. An EEG correlate of the disruption of the sleep/wake cycle in children with ASD provides an important area for future study.

76 **127.076** EEG-IP: An International Infant EEG Data Integration Platform for the Study of Risk and Resilience in Autism and Related Conditions

J. Desjardins[1], *L. A-Abbas*[2], *M. Cichonski*[3], *S. Huberty*[4], *S. J. Segalowitz*[5], *M. H. Johnson*[6], *T. Gliga*[7], *S. J. Webb*[8], *C. A. Nelson*[9], *H. Tager-Flusberg*[10], *S. Jeste*[11], *A. C. Evans*[12] *and M. Elsabbagh*[13], *(1)SHARCNET, St Catharines, ON, Canada, (2)Research Institute - McGill University Health Centre, Montreal, QC, Canada, (3)Brock University, St Catharines, ON, Canada, (4)Mcgill University, Montreal, QC, Canada, (5)Psychology, Brock University, St Catharines, ON, Canada, (6)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom, (7)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (8)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (9)Boston Children's Hospital, Boston, MA, (10)Psychological and Brain Sciences, Boston University, Boston, MA, (11)University of California, Los Angeles, Los Angeles, CA, (12)Montreal Neurological Institute, McGill University, Montreal, QC, Canada, (13)McGill University, Montreal, PQ, Canada*

Background: EEG is a widely available, non-intrusive and powerful method for capturing aspects of brain behaviour. There has been an increased interest in using EEG to identify neurological markers of ASD that precede the onset of behavioral symptoms. However, EEG lacks standards in acquisition and processing, and is prone to noise contamination (Movement, EMG, EOG, ECG), particularly when working with populations with neurodevelopmental disorders and infants. Additionally, while infant samples are important in studying early risk markers of autism, most studies remain limited by small sample size.

Objectives: We established a new International infant EEG data-integration platform for the study of risk and resilience in autism (EEG-IP). The platform includes three components: (1) A data repository of >4,000 recordings on approximately 700 infants at risk and controls collected across four laboratories; (2) A generalizable and highly optimized signal extraction pipeline that maximizes the isolation of signal and noise in large-scale EEG data recordings; (3) A signal processing toolbox that optimizes the execution of analytic techniques for infant data.

Methods: Data integration of EEG recording is currently underway. In parallel, we validated the new analytic pipeline by exploring whether or not it can isolate the cortical signal to identify clearly event-related potentials (ERPs) and a reliable ICA decomposition at the individual infant level. 75 EEG recordings of 7-month old infants were drawn from EEG-IP. The visual stimulus procedure included a stimulus stream of human faces and non-face stimuli (phase scrambled version of the face stimuli). The recordings were preprocessed using the new Lossless pipeline that uses a sequence of robust measures to isolate spatially non-stationary channels and periods of time in the recording. This pipeline also performs the Adaptive Mixture Independent Component Analysis (AMICA) to isolate noise factors from cortical signal, as well as isolate the activation of specific cortical generators.

Results: Many of the procedures employed by the Lossless pipeline are computationally intensive and typical EEG pre-processing for ICA requires substantial manual interaction with the data. By optimizing this procedure for High Performance Computing (HPC) resources, and streamlining manual interaction to single annotation procedure, a sample of this size can be processed in days rather than weeks or months. From the output state of the processing pipeline we were able to extract pronounced ERPs emanating from various occipital regions of the cortex. Unlike more typical preprocessing pipelines, the output file contains all of the original data (nothing is removed that cannot be reinserted) so this signal isolation process does not restrict post-processing options.

Conclusions: Infants at risk for ASD are a traditionally difficult population to recruit, and the EEG-IP provides a sufficiently powered sample size for hypothesis testing at an unprecedented scale. However, this rests on our ability to extract valid individual-level data. The Lossless pipeline produces a state of EEG data with annotations regarding several fine-grained measures of signal quality and ICA decompositions, allowing researchers to perform complex analyses on the data, with the goal of identifying neurological differences between infants that do and don’t develop ASD.

77 **127.077** Effect of Cooperative and Non-Cooperative Social Interactions on Personal Space Regulation in Adults with Autism Spectrum Disorders: An fMRI Study

G. Silani[1], *C. Massaccesi*[1], *A. Grössing*[1], *M. Hubinger*[1], *L. Rosenberger*[1], *M. Candini*[2], *G. di Pellegrino*[2] *and F. Frassinetti*[2], *(1)University of Vienna, Vienna, Austria, (2)University of Bologna, Bologna, Italy*

Background: Personal Space (PS) is the space immediately surrounding an individual and it can be regulated during social interactions. Intrusion into this space by others can generate feelings of discomfort. Developmental and psychiatric disorders influence the regulation of PS. Importantly, in the case of autism spectrum disorder (ASD), characterized by deficits in interpersonal interaction, the regulation of PS is often altered compared to typically developing (TD) children [1] and/or not modulated by changes in the quality of experienced social interactions [2].

Objectives: This study aimed at extending the previous findings to the ASD adult population and to investigate the behavioral and neurophysiological underpinning of PS and its modulation by different types of social interactions.

Methods: Fifteen ASD and fifteen TD matched participants underwent fMRI investigation while performing a modified version of the stop-distance paradigm for measuring PS preferences. In particular, participants were presented with several prerecorded videos from a first person perspective: an actor moving a predetermined number of steps towards them. They were asked to specify how comfortable they felt in regard to the observed distance. In order to see the effect of social interaction on PS perception, participants and confederates played a repeated trust game session, in which cooperative and non-cooperative interactions were experimentally manipulated. After the game, participants were confronted a second time with the distance task, in order to measure PS preference variation due to the type of social interaction (cooperative or not) previously experienced.

Results: We observed a significant modulation of the trust game on the PS, as TD participants showed increased comfort toward the cooperative player and increased discomfort towards the non-cooperative one (Fig.1), associated with modulation of emotional brain areas (bilateral insula). Notably, we observed the same effect in the ASD population on the behavioral level, but reduced insular activity on the neural level, suggesting that the perception of a cooperative (or not) interaction is processed differently in the ASD population (Fig.2A,B). Moreover, ASD participants showed a general reduction of activity in the intraparietal sulcus, a region involved during the observation of approaching stimuli (Fig. 2C). Notably, a stronger approaching-bias observed in this region has been recently associated to higher sociability in healthy participants [3].

Conclusions: The findings suggest differences between ASD and TD individuals in processing the emotional saliency of an approaching person, as result of the type of social interaction previously experienced. A better understanding of the behavioral and the neuronal mechanisms behind PS perception and its modulation will improve our knowledge of the social deficits observed in ASD.

78 **127.078** Effect of Eye Contact and Anxiety Symptoms on ERPs in Autism Spectrum Disorder and Schizophrenia

D. Stahl[1], *A. Naples*[1], *J. Wolf*[1], *K. A. McNaughton*[1], *T. C. Day*[1], *B. Lewis*[1], *E. Jarzabek*[1], *K. S. Ellison*[1], *M. R. Altschuler*[1], *S. Hasselmo*[1], *T. Halligan*[1], *T. Winkelman*[1], *E. Hamo*[1], *J. Foss-Feig*[2], *V. Srihari*[3], *A. Anticevic*[3] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Individuals with Autism Spectrum Disorder (ASD) exhibit high levels of comorbid anxiety that can impede treatment, but the neural basis of this anxiety is under-characterized. Previous work studying early time course brain activity in anxiety and ASD has identified that the P100 and N170 ERP components are atypical in response to social stimuli. However, few have examined this brain activity transdiagnostically in interactive social contexts that better capture the reciprocal nature of social interactions.

Objectives: We examined brain responses to faces across diagnostic categories with vulnerabilities in social and anxious symptomologies. We assessed the relationship of categorical and continuous clinical characterization on brain activity.

Methods: 22 individuals with ASD, 23 with Schizophrenia (SCZ), and 31 TD adults (aged 18-48) participated. Eye tracking and EEG were used to measure brain response to reciprocal gaze. Participants looked at the mouth or eyes of a face; the mouth ("Mouth") or eyes ("Eye Contact") then opened. EEG data was recorded using an EGI 128 channel net at 500Hz. P100 and N170 components were recorded from temporal-parietal electrodes. Anxiety symptoms were measured using the State-Trait Anxiety Inventory (STAI) and Beck Anxiety Inventory (BAI). ASD symptoms were measured with the Autism Quotient (AQ), ADOS, and Social Communication Questionnaire (SCQ).

Results: ANOVAs were run with ERP component as dependent, and diagnosis, hemisphere, and condition as independent, variables. Main effects of condition for N170 amplitude, latency, and P100 amplitude were significant ($p<0.01$): Eye Contact increased N170 amplitude and decreased P100 amplitude and latency relative to the Mouth condition. There were no main effects of diagnosis. Across groups, increased STAI [$r(40)=-0.38$, $p<0.05$] and BAI total scores [$r(42)=-0.43$, $p<0.01$] correlated with faster P100 in the right hemisphere (RH) during Eye Contact. Greater anxiety correlated with smaller differences in P100 amplitude between Eye Contact and Mouth Movement [STAI $r(40)=-0.33$, $p<0.05$; BAI $r(42)=-0.32$, $p<0.05$]. Increased ASD traits on the AQ correlated with decreased P100 to Eye Contact [$r(71)=-0.32$, $p<0.01$]. Among individuals who did not show eye contact on the ADOS, BAI score was associated with decreased P100 latency [$r(5)=-0.93$, $p<0.05$]. On the SCQ, participants that looked at faces had slower N170s with increased STAI score [$r(10)=0.68$, $p=0.01$]. Those that did not had a marginally significant correlation between faster N170s and increased STAI score [$r(9)=-0.58$, $p=0.056$]. These correlations differed from each other ($p<0.01$).

Conclusions: Symptoms of ASD and anxiety modulate the P100 and N170. Consistent with previous research, greater anxiety related to faster P100 in the RH. Greater anxiety was also associated with smaller differences between P100 amplitudes in the Eye Contact and Mouth conditions. Previous research has found eye contact evokes stronger N170 responses than no eye contact. This indicates that individuals with greater anxiety ascribe similar amounts of attention to both Eye Contact and Mouth conditions. Increased symptoms of ASD correlated with slower P100 during Eye Contact. Lack of eye contact, an important social symptom in ASD, and anxiety significantly altered latency of both N170 and P100, suggesting that anxiety symptoms alter early processing of social information in this group.

79 **127.079** Effects of Autism on Emotional Sharing and Learning in the Anterior Cingulate

J. H. G. Williams[1], *L. Braadbaart*[2] *and G. Waiter*[2], *(1)Psychiatry, University of Aberdeen, Aberdeen, United Kingdom of Great Britain and Northern Ireland, (2)University of Aberdeen, Aberdeen, United Kingdom of Great Britain and Northern Ireland*

Background:

Impaired imitation in autism is well recognised but the developmental relationship between imitation and aspects of autism psychopathology, such as impaired empathy and shared emotion, is poorly understood. This is possibly because research has focussed on either manual imitation or emotional mimicry. We have created a task that blends facial stimuli expressing basic emotions, in which we systematically vary the relative quantity of each emotion being expressed. The task measures an individual's ability to evidence accurate discrimination between emotionally expressive stimuli of varying similarity by expression through imitation. Task performance shows good correlations with empathic traits.

Objectives:

To determine the neural correlates of facial imitation ability and to determine whether these are disrupted in autism.

Methods:

27 participants with autism (aged 9-20 yrs, 2 females, IQ 93-133; diagnosis confirmed using ADI-R; current severity assessed with Social Responsiveness Scale [SRS]), matched on age, sex and IQ to 25 control participants undertook the facial imitation task. Of the participants who

took part in the behavioural tasks, 17 participants with autism and 19 controls were able to complete the task during functional neuroimaging, in which they also completed a control task, viewing the same stimuli but instead enacting a previously learnt facial action in response to an instruction. In addition we utilised data from a previous study in which 20 adults undertook the same tasks during fMRI.

Results:

The ASD group should much lower levels of imitation accuracy on the behavioural task (ASD mean facial error=41.82, SD=5.97; control group error=36.07, SD=3.38; df=50; t=4.229; p< .001). Imitation accuracy across the whole group correlated with self-reported and parent-reported empathy quotient, as well as SRS score. In the fMRI study, using the whole group and conservative statistical thresholds (p<0.05 FWE corrected for cluster), facial imitation ability only correlated with activity in the genu of the anterior cingulate (ACCg) where activity was greater in the control task compared to imitation. Using this cluster as a region of interest we found significantly decreased activity in this area among the group with autism

Conclusions:

The ACCg serves to represent the value of actions to others and also signals differences between predicted and experienced action outcomes. We found that higher activity in this region when perception-action differences were greater predicted imitation accuracy and empathic traits. Low activity was associated with autism. We suggest that the ACCg plays a key role in the intentional control and learning of appropriate emotional responses to others' emotionally communicative actions. This is required for development of empathy, shared emotion and the cultural transmission of behaviour according to its emotional value. A number of studies have shown abnormal anatomy and neurochemistry in this region, suggesting that the reduced prediction error signal in ACCg (and easily measured facial imitation ability) may provide a practical target for therapeutic intervention.

80 **127.080** Effects of Oxytocin on Social Perception in Youth with ASD: A MEG Study

A. Korisky[1], *A. Goldstein*[2] *and I. Gordon*[3], *(1)Department of psychology, Bar-Ilan University, Ramat Gan, Israel, (2)Department of Psychology, Bar Ilan University, Ramat Gan, Israel, (3)Department of Psychology, Bar-Ilan University, Ramat-Gan, Israel*

Background: Autism spectrum disorders (ASD) are neurodevelopmental conditions characterized partly by core social dysfunction, impaired social motivation and interaction. Recent discoveries draw attention to the impact that intranasal administration of the neuropeptide Oxytocin (OT) may have on social behavior and perception in ASD. Several brain imaging studies in individuals with ASD highlighted OT's capacity to modulate "the social brain", however, there is a gap in the literature regarding the influences of OT on neural temporal dynamics. Thus, a comprehensive understanding of OT's influences on the brain in ASD requires the use of methods with superior temporal resolution, especially in children.

Objectives: This study aims to explore the impact of OT on temporal dynamics in ASD using magnetoencephalography (MEG) during a well-validated social perception paradigm. Extending on previous findings which pointed to OT modulation of ERP components in typically developed (TD) adults during a similar task, we focused on the P100, N170 and P250 components, which also tend to show atypical patterns in ASD. We hypothesize that OT will modulate the amplitude and latency of these components to resemble those of an age-matched TD group.

Methods: As a part of an ongoing study, we present initial data from seven youth with ASD (aged 12-18), who received a single dose of intranasal OT (24IUs) in a double-blind placebo-controlled study. Forty five minutes following administration, participants were scanned in the MEG. During each scan participants were presented with pictures of emotional eyes or vehicles and asked to identify the picture theme. An aged-matched TD group served as a baseline for comparison. For ethical reasons, TD participants did not receive OT/placebo.

Results: Preliminary results indicate that in our components of interest, OT indeed normalized brain activity in ASD to be more similar to that of the TD group (enhancing P100 and P250 amplitudes while reducing N170 amplitude). This effect was visible only for the amplitude but not for the latencies of the components. Interestingly, while this effect was present in all three components in the emotional identification condition, in the vehicles recognition condition, OT influenced only the P100 component.

Conclusions: These initial results provide the basis for essential understanding of the influences of OT on ASD neural activation from a new perspective. Being the first exploration of the impact of OT on the brain in youth with ASD using MEG, this study indicates that OT can modulate early stages of visual perception, especially during social stimuli. Our study addresses core issues regarding OT's impact on the social brain and social behavior in ASD and thus, in the future, may promote the development of more effective treatments for social deficits.

81 **127.081** Elevated Cortical Reactivity to Auditory Repetition Is Present at 8 but Not 14 Months in Infants with Later ASD

A. Kolesnik[1], *E. J. Jones*[2], *J. Begum Ali*[2], *T. Gliga*[3], *J. Guiraud*[4], *T. Charman*[5] *and M. H. Johnson*[6], *(1)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom of Great Britain and Northern Ireland, (2)Centre for Brain and Cognitive Development, Birkbeck, University of London, London, United Kingdom, (3)Centre for Brain and Cognitive Development, Birkbeck University of London, London, United Kingdom, (4)Brookside Family Consultation Clinic, Cambridge, United Kingdom, (5)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (6)Centre of Brain and Cognitive Development, Birkbeck College, University of London, London, United Kingdom*

Background: Autism Spectrum Disorders (ASDs) are characterised by difficulties in social communication, restricted interests and repetitive behaviours, as well as sensory perturbations (APA, 2013). Previous work from animal models and the mature adult brain suggests that abnormal cortical excitability could underlie ASD aetiology (Rubenstein & Merzenich, 2003; Lee et al., 2017). Potential atypicalities in regulation of excitation/inhibition balance in early development could alter homeostatic interplay between perceptual mechanisms and result in ASD-phenotype. This would feed into novel treatment approaches to be administered prior to symptom onset and within a stage of augmented plasticity. Recent studies have suggested gamma-band activity may be a candidate neural marker of e/i balance regulation (Rojas, 2008,2014).

Objectives: In this longitudinal study, we examine whether infant siblings with later ASD show a distinct pattern of oscillatory activity and phase-locking responses to auditory repetition relative to those with typical development. We aim to expand on previous reports of atypical gamma-band activity in individuals with ASD and their first-degree relatives.

Methods: Infants with and without family history of ASD were tested in an auditory oddball paradigm at 8 and 14 months. Wavelet analyses were used to examine change in evoked gamma amplitude and low-frequency phase-locking in response to repeated standard tones. Analysis was constrained to location and frequency band where low-risk controls showed habituation effect to repetition, and then the model was applied to high-risk siblings. Infants were followed up at 36 months with standardised assessments of current ASD symptoms.

Results: Relative to high-risk infants with typical development, those with later ASD showed reduced habituation of evoked gamma at 8 months (40-60Hz, 30-150ms; [p=.012, h^2=.105]) and greater phase-locking (10-20Hz, 100-180ms; [p = .036, h^2= .06]) to repeated tones. A combined index of cortical hyper-reactivity was dimensionally associated with levels of parent-rated social impairment (SRS™) at 3 years as well as with reduced growth in Receptive Language skills between 8 months and 3 years across the whole sample [p = .032]. However, preliminary analysis suggested that reduced habituation did not appear to be present in the ASD group at 14 months (within the same time and frequency bands, all p values are above .05).

Conclusions: We present the first evidence for cortical hyper-reactivity to be present in infants with later ASD, before the onset of behavioural symptoms. The data is consistent with the literature on E/I balance as a potential mechanism underlying neurodevelopmental disorders, further suggesting that an imbalance can be detected during early stages of brain development. This effect did not appear to be present during the 14-month-visit. This could be due to the differences in the nature of the E/I balance itself and possible compensation strategies used by the auditory cortex in response to repetition (Mottron et al., 2006).

82 **127.082** Frontal Interhemispheric Coherence of the Electroencephalogram after Dolphin-Assisted Therapy in Children with Autism Spectrum Disorder

***F. Mulas**[1], P. Ortiz[1], P. ROCA[2], R. Gandia[1] and L. Abad[3], (1)Child Neurology, INVANEP-Instituto Valenciano de Neurología Pediátrica, VALENCIA, Spain, (2)INVANEP- Instituto Valenciano de Neurologia Pediatrica, VALENCIA, Spain, (3)Centros de Desarrollo Cognitivo RED CENIT, VALENCIA, Spain*

Background: Interhemispheric coherence of the electroencephalogram (IHC) show differences between Autism Spectrum Disorder (ASD) and typical development children (TD). This fact is congruent with connectivity disorder models in ASD.
Objectives: The aim of this study was to explore the frontal IHC in children with diagnosis of ASD before and after an intervention with dolphin-assisted therapy.

Methods: Frontal IHC was determined in 42 subjects with ASD (4-6 years old) before randomly assigning them to two therapeutic groups, one with dolphins (DAT) and one without dolphins (TIWD). Furthermore, a TD group (20 children) was added to compare the differences with ASD children.

Results: Frontal IHC was significantly lower in TD than ASD children (p<0.001). Alpha frequency in frontal IHC showed a significant reduction in both ASD groups compared to basal measurement (p<0.05), whereas this reduction was higher in DAT group (without reaching statistical significance).

Conclusions: Frontal IHC was higher in ASD than in TD children. The dolphin-assisted intervention did not show significant differences between the treated groups.

83 **127.083** Functional Integration of the Neural Theory-of-Mind Network and Its Relations to Children's Social Communication and Functioning

***C. E. Mukerji**[1,2], S. H. Lincoln[3], C. I. Hooker[4] and C. A. Nelson[2], (1)Harvard University, Cambridge, MA, (2)Boston Children's Hospital, Boston, MA, (3)McLean Hospital/Harvard Medical School, Belmont, MA, (4)Psychiatry Department, Rush University Medical Center, Chicago, IL*

Background: Theory of Mind (ToM) impairments may contribute to social communication and interaction deficits in autism spectrum disorder (ASD). Individuals with ASD show atypical neural activity and connectivity in the ToM network. Despite its relevance to understanding functional integration, few studies have evaluated effective connectivity of ToM circuitry, i.e., how different neural regions interact to support ToM reasoning versus other inferential processes, during childhood. Moreover, associations between effective connectivity and variation in social communication and interaction across typical (TD) and atypical child development remain unclear.
Objectives: This study aimed to (a) evaluate effective connectivity between key nodes of the ToM network, i.e., the precuneus and bilateral temporoparietal junction (rTPJ and lTPJ), and other brain regions during ToM versus non-ToM reasoning and (b) explore relations between these neural measures of functional integration and children’s social communication skills and everyday social functioning. We predicted that (a) TD children would demonstrate greater connectivity between ToM regions and other neural circuitry implicated in social cognition during ToM reasoning and (b) the strength of this functional coupling would be associated with individual variation in children’s social communication and functioning.

Methods: Participants were 32 TD children, ages 9-13. In the MRI scanner, participants completed a false belief task. In the experimental (ToM) condition, children listened to vignettes describing social scenarios and evaluated characters’ beliefs. In the control condition, they listened to non-social scenarios and made inferences about physical causality. Children also completed the Social Language Development Test, and parents completed the Social Skills Improvement System questionnaire.

Results: Generalized psychophysiological interaction (gPPI) analyses seeded in the precuneus, lTPJ, and rTPJ revealed distinct patterns of effective connectivity during ToM versus control conditions. Results were significant at a peak threshold of p<.001 with a cluster-wise false discovery rate correction (p<.05). The precuneus demonstrated greater connectivity with the left middle temporal gyrus (MTG), while the lTPJ showed enhanced connectivity with the bilateral superior temporal sulcus (STS). The rTPJ showed increased connectivity with several brain regions associated with social cognition, including the left dorsomedial prefrontal cortex (DMPC), pSTS/MTG, pre-supplementary motor area, and right cerebellum. Brain-behavior analyses revealed that greater coupling between the rTPJ and DMPFC showed a trend-level association with better social functioning (r_s=0.33, p=.078); diminished coupling between the precuneus and MTG was associated with better social communication, specifically using mental state inferences to explain others’ behavior (r_s=-0.41, p=.027).

Conclusions: Children demonstrated greater coupling of the rTPJ, lTPJ, and precuneus with a distributed set of neural regions implicated in social cognition during ToM relative to control conditions. Findings elucidate how key nodes of the ToM network interact with other regions to support mental state reasoning. Results also suggest that measures of effective connectivity during ToM index individual variation in children’s social communication and functioning. This work has important translational implications for studying social deficits in children with ASD. Exploring effective connectivity in atypical neurodevelopment could yield insight into disruptions in functional integration of the social brain. Moreover, effective connectivity measures may serve as potential metrics of heterogeneity in social development.

84

127.084 Global and Local Scale Gamma-Band Activity within a Perceptual Organization Task in Individuals with and without Autism Spectrum Disorder

S. Naumann[1]*, U. Senftleben*[2] *and S. J. Webb*[3]*, (1)Humboldt-Universitaet zu Berlin, Berlin, Germany, (2)Technische Universitaet Dresden, Dresden, Germany, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA*

Background: In autism spectrum disorders (ASD), a bias to process local rather than global facial information (e.g., relations between face parts) has been proposed to be an underlying cause of impaired face processing. The temporal synchronization within and between cortical micro circuits, as measured by oscillatory gamma-band activity (GBA; > 25 Hz), offers an opportunity to examine how the brain integrates visual information into a coherent whole ("binding problem"). GBA findings are heterogeneous in ASD when compared to controls. Novel analytic approaches suggest coherence measures such as the inter-trial variability within subjects (inter-trial phase coherence; ITPC) and phase synchrony between electrodes (phase-locking value; PLV) to study processing efficiencies.

Objectives: We examined GBA amplitude, ITPC and PLVs in ASD individuals (n=20) and age- and IQ-matched neurotypical controls (N=25) during a perceptual organization task to investigate the hypothesis of an imbalance of local and global processing of faces.

Methods: Participants saw upright and inverted Mooney stimuli, which are degraded, two-tone pictures of human faces, and indicated face perception behaviorally (Face or No-Face). EEG was time-locked to the presentation of the stimuli.

Results: The pattern for Face and No-Face responses indicated significantly larger GBA for controls compared to individuals with ASD. ITPC analyses did not reveal any Group differences. Compared to ASD individuals, controls displayed larger phase synchrony for Face responses at posterior sites. For No-Face responses, synchrony pairs at frontal sites showed larger synchrony in controls compared to ASD individuals.

Conclusions: We detected lower levels of GBA for Face and No-Face responses in individuals with ASD, potentially indicative of a less effective activation of cortical micro circuits or impaired binding processes. Since ITPC did not differ between groups, ASD individuals do not seem to be inefficient in their local response to visual stimuli. Larger PLVs for controls (higher phase synchrony between electrodes) may suggest more elaborated communication on the global scale. In line with the framework provided by Kessler et al. (2016), our results suggest that local neural activity is similar in both ASD and neurotypical controls, but that the global, neural communication is less effective in ASD.

85

127.085 Infants at High Risk for ASD Show Altered Functional Connectivity in Auditory Networks at 9 Months of Age

J. Liu[1]*, T. Tsang*[1]*, L. P. Jackson*[2]*, C. Ponting*[1]*, S. Jeste*[1]*, S. Y. Bookheimer*[3] *and M. Dapretto*[3]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)UCLA, Los Angeles, CA, (3)Dept of Psychiatry and Biobehavioral Sciences, University of California, Los Angeles, Los Angeles, CA*

Background: Altered functional connectivity is characteristic of developmental disorders involving language impairments such as autism spectrum disorder (ASD). Children with ASD show altered connectivity in several resting state networks compared to neurotypical controls (Uddin et al., 2013, Hernandez et al., 2014), suggesting that functional connectivity may provide a reliable biomarker of the disorder. In particular, connectivity with the right anterior insula, the hub of the salience network, is altered in ASD. In addition to its role in modulating attention to salient elements of one's environment, the insula has also been shown to be specialized for sensory and auditory-related functions as an integration hub for auditory stimuli (Bamiou et al., 2003; Oh et al., 2014). As such, altered functional connectivity between auditory regions and the insula early in life may predict future language outcome and ASD diagnosis.

Objectives: Here we use resting-state fMRI (rsfMRI) to characterize the developing auditory network and its connectivity with the right anterior insula in 9-month-old infants at high (HR) and low risk (LR) for ASD. Early differences in functional connectivity may predict altered developmental trajectories prior to overt language delays and the onset of ASD symptomatology.

Methods: During natural sleep, 8-minute rsfMRI scans were collected in 9-month-old infants. Preprocessing was performed using FSL. To correct for effects of head motion, an advanced ICA-based strategy for automatic removal of motion artifacts (ICA-AROMA; Pruim et al., 2015) was used. Auditory network connectivity was examined using left and right hemisphere Heschl's gyrus (HG) and superior temporal gyrus (STG) seeds from an infant brain template (Shi et al., 2011). Time-series extracted from processed residuals in standard space were correlated with every other voxel to generate functional connectivity maps. We examined group differences for functional networks associated with each seed separately. Next, we investigated connectivity between primary auditory cortex (left and right HG) and right anterior insula, the hub of the salience network. Lastly, differences in auditory network connectivity were related to behavioral indices of language development and ASD symptom severity collected at 12 and 18 months of age.

Results: Whole-brain correlation maps generated from left and right HG and STG seeds demonstrated that the auditory network was detectable in all infants. Between-group comparisons yielded significant differences in functional connectivity with HR infants showing hyperconnectivity between left HG and supplementary motor area. By contrast, LR infants showed stronger intrahemispheric connectivity between right STG and right temporo-parietal areas when compared to the HR group. Furthermore, HR infants showed hyperconnectivity between both left and right HG with right anterior insula. Auditory network connectivity and auditory-insular hyperconnectivity were positively associated with better language outcome at both 12 and 18 months, and less severe ASD symptomatology at 18 months.

Conclusions: At 9 months of age, the auditory network is hyperconnected with various cortical and subcortical regions in infants at risk for developing ASD. Early evidence of increased connectivity between these regions may reflect a compensatory mechanism in ASD risk.

86

127.086 Interhemispheric Alpha-Band Hypoconnectivity in Children with Autism Spectrum Disorder (ASD)

A. H. Dickinson[1]*, C. DiStefano*[2]*, E. Lin*[3]*, A. W. Scheffler*[3]*, D. Senturk*[3] *and S. Jeste*[1]*, (1)University of California, Los Angeles, Los Angeles, CA, (2)University of California Los Angeles, Los Angeles, CA, (3)UCLA, Los Angeles, CA*

Background: Autism Spectrum Disorder (ASD) has been associated with, and likely results from, aberrant neural connectivity, with patterns of decreased short range and increased long range connectivity generally described (Wass, 2011). The dynamics of neural oscillations in the alpha range (6-12 Hz) are exquisitely sensitive to healthy development of (Varokin, 2012), and disruptions to (Hinkley, 2011), functional and structural connectivity. Here we used electroencephalography (EEG) to quantify alpha-band functional connectivity in children with ASD across a range of cognitive abilities. Employing a data driven approach to analyze all possible short and long range connections allowed for an unbiased examination of all possible atypical connectivity patterns.

Objectives: We asked: (1) whether alpha band coherence in both long and short-range networks distinguishes children with ASD from typically developing (TD) children, and (2) whether alpha band coherence relates to developmental level and cognitive function within the autism spectrum.

Methods: We studied 59 children with ASD (mean age 69 months; range: 25-126) with nonverbal IQ ranging from 10-145 (mean NVIQ: 75) and 39 age matched TD children (mean age: 72 months; range: 29-146; mean NVIQ: 113). Spontaneous EEG was recorded using a high density 128 channel hydrocel geodesic sensor net (EGI inc.), and extensively cleaned through both manual inspection, and independent component analysis (ICA). To mitigate the effects of volume conduction, EEG data were transformed into current source density (CSD) using a spherical spline Laplacian transform. CSD estimates were then decomposed into the time-frequency domain using fast Fourier transform. Phase coherence within the alpha range was calculated between every possible electrode pair. A permutation test with a false discovery rate (FDR) adjustment for multiple testing was used to identify electrode pairs which demonstrated significantly different phase coherence between ASD and TD participants.

Results: Using a conservative FDR correction of 0.05, one electrode pair between left and right temporal regions showed significantly decreased phase coherence in ASD compared to TD children ($t(96)=4.20$, $P=.000$). Alpha phase coherence for this electrode pair was not associated with either age or IQ in the ASD group (age: $P=.193$; non-verbal IQ: $P=.267$, verbal IQ: $P=.215$).

Conclusions: Long range alpha band coherence between left and right temporal regions distinguished TD children from a heterogeneous group of ASD children. No association was found between long range connectivity and cognitive ability. Our results are consistent with previous research, suggesting that interhemispheric temporal hypoconnectivity represents a fundamental brain difference in children with ASD across a wide cognitive range. The findings presented here may reflect structural factors causing decreased neural communication (such as white mater disturbances), or increased signal variability at one (or both) temporal sites in ASD (neural noise). Future research will address the earliest developmental origins of aberrant spontaneous functional connectivity in infants at risk for ASD and will examine the specific behavioral consequences of these connectivity patterns.

87 **127.087** Investigating Social Reward Circuitry during Real-Time Peer Interaction in ASD

L. A. Kirby[1], *E. Sadikova*[2], *K. R. Warnell*[3], *M. G. Pecukonis*[4], *D. Moraczewski*[5] *and E. Redcay*[5], *(1)Yale Child Study Center, New Haven, CT, (2)Children's National Health System, Washington, DC, (3)Department of Psychology, Texas State University, San Marcos, TX, (4)Psychological and Brain Sciences, Boston University, Boston, MA, (5)Department of Psychology, University of Maryland, College Park, MD*

Background: Difficulties with social communication and social interaction, including reduced interest in both approaching and sharing information with peers, are core features of autism spectrum disorder (ASD). Some hypothesize that reduced social motivation in ASD is one cause of these social communication deficits. However, functional magnetic resonance imaging (fMRI) studies investigating the neural correlates of social motivation in ASD reveal inconsistent findings. Critically, these past paradigms do not involve social *interactions*, which is a core area of dysfunction in ASD. Rather, participants are asked to passively and independently view images (e.g., static photos of smiling faces), which may not approximate real-world social communicative contexts. This lack of reciprocal social interaction and real-world applicability is troubling since individuals with ASD perform within normal limits on non-interactive laboratory tasks related to social cognition, but may have the most difficulty in interactive social communicative contexts (Schilbach et al., 2013; Senju et al., 2009).

Objectives: The purpose of this study was to utilize a real-world interactive fMRI paradigm to investigate neural circuitry supporting social reward during reciprocal social interaction in ASD and neurotypical (NT) children.

Methods: 21 children with ASD (ages 7-14, three females) and 19 NT children (ages 8-14, three females) were informed they would be chatting online with a peer and a computer. The chat was simulated, but all children believed that the peer was real. Participants shared information about themselves with the peer and the computer, then during the “Reply” period, received either engaged (Peer: “Me too!”, Computer: “Matched!”) or non-engaged (Peer: “Away”, Computer: “Disconnected”) responses. For the current analyses, we focused on differences in neural activation between ASD and NT to the peer versus the computer during this “Reply” period.

Results: There were no differences between ASD and NT in a whole brain analysis when participants believed they were chatting with a peer versus a computer (“Me too!” vs. “Matched!”; $p<0.005$, k=20). Consistent with whole brain analyses, ROI analyses within classic reward regions (amygdala, ventral striatum, and ventral medial prefrontal cortex) revealed no group by condition interactions. However, posthoc analyses showed greater activation during the peer response in these reward regions in NT ($ps<0.05$), but not ASD participants. Whole brain and ROI analyses revealed no differences between ASD and NT when they believed they were chatting with a peer versus when they believed the peer was busy (“Me too!” vs. “Away”*;* $p<0.005$, k=20).

Conclusions: In summary, preliminary results suggest no differences between ASD and NT in classic reward brain regions when receiving a response from a peer. These findings suggest that the neural circuitry supporting social reward may be intact in ASD, and that perhaps other brain regions underlie the difficulties with social communication and social interaction that define the disorder. The investigation of neural and behavioral correlates of social reward within real-time social interactive contexts will help us better understand the core social deficits in ASD as well as typically developing children’s drive to orient to and interact with the social world.

88 **127.088** Language Associated Neural Responses of Infants at High Risk for ASD and Nonsyndromic Craniosynostosis

R. Wu[1,2], ***T. Halligan***[3], *A. H. Sun*[4], *M. J. Rolison*[3], *R. Cabrejo*[2], *C. Chuang*[2], *J. Yang*[2], *A. Wilson*[2], *N. Landi*[5], *L. Mayes*[2], *J. Persing*[2] *and J. McPartland*[3], *(1)Yale School of Medicine, New Haven, CT, (2)Yale University School of Medicine, New Haven, CT, (3)Child Study Center, Yale University School of Medicine, New Haven, CT, (4)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (5)University of Connecticut, New Haven, CT*

Background: Literature suggests that infants at high risk for autism spectrum disorder (HR-ASD) and nonsyndromic craniosynostosis (NSC), early cranial suture fusion, have similar language acquisition profiles. Essential in language remediation for these cohorts is early detection and prevention. Auditory event-related potentials (ERPs) measure passive neurological responses to speech sounds, suggesting a promising avenue for studying infant speech development. In particular, the mismatch negativity (MMN) quantifies perceptual narrowing and can predict future language development. The MMN component has demonstrated attenuated responses in HR-ASD infants compared to typically-developing (TD) controls. Previous work has established differences between the auditory ERPs of HR-ASD and those of metopic synostosis (MSO) and sagittal synostosis (SSO) infants. However, comparisons have not been made with coronal synostosis (CSO) or across groups of NSC.

Objectives: To characterize specificity of language acquisition in HR-ASD by comparing MMN responses to speech sounds between HR-ASD, CSO, MSO, SSO, and TD controls.

Methods: HR-ASD, NSC, and TD infants were recruited from the Yale Autism Program and Yale Craniofacial Clinic. Participants were presented with a non-native phoneme discrimination paradigm involving the Hindi retroflex phoneme /da/ and the dental phoneme /da/ in random order. Auditory stimuli were set at 80 dB, and EEG was recorded at 250 Hz with a 128-channel HydroCel Geodesic Sensor Net. Analysis focused on four electrode clusters: left and right frontal, and left and right central electrodes. The MMN component was calculated as the largest negative amplitude in the difference wave between 80-300ms after stimulus presentation. Statistical comparisons were performed with ANOVA and studentized T-tests.

Results: 12 HR-ASD, 5 CSO, 14 SSO, 14 MSO, and 34 age-matched TD infants were included in analyses. The MMN amplitudes measured in left frontal clusters were statistically different between cohorts (*p=0.043*). HR-ASD, SSO, and MSO infants produced attenuated left frontal responses compared to TDs (*p*=0.025, *p*=0.001, *p*=0.003). Between NSC cohorts, SSO and MSO infants had attenuated MMN responses in the left frontal clusters compared to CSO (*p*=0.022, *p*=0.04). MMN amplitudes in the left central clusters were also significantly different between cohorts (*p*=0.006). SSO and MSO infants demonstrated attenuation in the left central clusters compared to TDs (*p*=0.015). In comparison to HR-ASD, SSO produced attenuated right frontal and central clusters (*p*=0.031, *p*=0.008), while MSO demonstrated attenuated right central clusters (*p*=0.005). There were not differences between CSO infants and TD or HR-ASD infants.

Conclusions: This represents the largest ERP comparison of ASD with different subtypes of NSC. Results replicate earlier findings that HR-ASD infants respond with lower MMN amplitudes than TD infants. In comparison with SSO and MSO infants, our findings suggest that HR-ASD infants may manifest cerebral attenuation focal to the left frontal brain, the hemisphere responsible for language production. Importantly, CSO infants may represent an intermediary phenotype between TD and HR-ASD infants. This study begins to develop the early language profile of HR-ASD infants within the clinical context of different suture fusion synostosis. Results warrant future studies comparing language acquisition in HR-ASD and NSC.

89 **127.089** Role of Anxiety in the Neural Response to Faces in Children with ASD: Results from the ABC-CT Feasibility Study

T. Halligan[1], *A. Naples*[1], *B. Lewis*[1], *K. Chawarska*[1], *R. Bernier*[2], *S. Jeste*[3], *C. A. Nelson*[4], *G. Dawson*[5], *S. J. Webb*[2], *M. Murias*[6], *F. Shic*[7], *C. Sugar*[3] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)University of California, Los Angeles, Los Angeles, CA, (4)Boston Children's Hospital, Boston, MA, (5)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (6)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (7)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background: Biomarkers of social-communication in autism spectrum disorder (ASD) are needed to obtain objective measures of social functioning. Furthermore, examining relationships among potential biomarkers and other measures of functioning within and across diagnostic groups is vital. There is high comorbidity of anxiety disorders in ASD; specifically, 40-84% of individuals with ASD have at least one co-morbid anxiety disorder. Exploring the role of anxiety on neural response to social stimuli measured with event related potentials (ERP) may provide insight into the complex relationship between anxiety and ASD and provide pertinent information regarding potential ERP biomarkers.
Objectives: Examine relationships between anxiety and neural response to faces in children with and without ASD.

Methods: Across five sites, ERPs were collected from 20 children with ASD [16 males; *M*=7.99±2.26 years] and 26 typically developing (TD) children [17 males; *M*=6.59±1.98 years] using a 128 electrode Geodesic Net. Children were presented with standardized photographs in two experiments: 1) 50 neutral and 50 fearful faces; 2) 72 upright faces, inverted faces, and upright houses. P100 and N170 ERP latencies were extracted from selected electrodes over the occipitotemporal cortex. Anxiety was measured with the *Childhood and Adolescent Symptom Inventory*, and analyses included *T*-scores from the General and Social Anxiety subscales. Group differences were examined using t-tests, and relationships between anxiety and neural responses were examined with correlational analyses.

Results: Participants were matched on sex, [$X^2(1,46)=1.19$, *p*=.34], but not IQ [*t*(44)=-4.59, *p*<.01], or age [*t*(44)=2.24, *p*=.03]. ASD children had higher symptoms of general anxiety [*M*=66.62±13.67] than TD children [*M*=42.95±3.95], [*t*(31)=7.34, *p*<.01] and higher symptoms of social anxiety [*M*=57.92±13.43] compared to TD children [*M*=45.05±4.40], [*t*(31)=3.40, *p*<.01]. Significant negative relationships were found between general anxiety and P100 and N170 latency to stimuli across hemispheres and conditions in Experiment 1 [all *r*'s(20)≥-.59, *p*'s<.01] and Experiment 2 [all *r*'s(20)≥-.47, *p*'s<.04] in TD children only. There were no significant relationships between general anxiety and neural response in ASD children in either experiment. For ASD children, social anxiety was negatively correlated with N170 latency to fearful faces in the right hemisphere [*r*(13)=-.59, *p*=.03], and upright faces in the left hemisphere [*r*(17)=-.50, *p*=.04]. There were no significant relationships between social anxiety and neural responses in TD children in either experiment.

Conclusions: Results indicate that general anxiety, but not social anxiety, affect TD neural response to stimuli regardless of content or emotional valence. Faster activation in individuals with heightened anxiety symptomology may reflect a neural index of hypervigilance. A different pattern was observed for ASD children; only social anxiety impacted neural response to condition-specific stimuli. These findings suggest that increased anxiety specific to core deficits in ASD (i.e. processing social information) relates to faster neural processing when presented with 1) fearful compared to neutral faces and 2) upright faces compared to inverted faces and upright houses. Results indicate that potential ERP biomarkers were sensitive to the effect of anxiety on neural processing, and specific in distinguishing differences between diagnostic groups.

90 **127.090** Language Perception in Infants at Risk for ASD：a Functional Near Infrared Spectroscopy Study

***F. Zhang**, P. Warreyn and H. Roeyers, Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium*

Background:
Researchers have gained interest in the early development of behaviour and brain functions in Autism Spectrum Disorder (ASD) over the past decade. In order to investigate such an early developmental issue, they started to study infants who have older sibling with ASD (HR) and thus have a high risk to develop ASD. The majority of individuals with ASD have difficulties in language processing, especially when they have to extract implicit social cues. There is increasing consensus that language impairments in ASD are linked to disturbances of brain functions. However, such

functional alterations related with language dysfunction in infants at risk of ASD have not yet been fully characterized.

Objectives:

In this study, we aimed to explore whether the brain response in HR infants differs from low risk (LR) controls by using functional near infrared spectroscopy (fNIRS). The developmental trajectory of brain functions related to language processing in HR infants was also observed through the comparison of different age groups.

Methods:

We recruited 5- and 10- month-old infants to participate in this language study. Infants were coming from two different groups including the HR group and LR group with no family history with ASD. All subjects underwent a 16-minute experiment with three sessions of fNIRS measurements. The first session was 5-min resting state, and the latter two sessions were 5.5-minutes speech tasks using forward and backward Dutch sentences respectively. Infants were held in the parent's arms or sat on the lap of the parent in a silent room with dim lighting. A NIRScout (NIRX, Germany/USA) device was used to measure the hemodynamic changes in bilateral neural activity of the brain. The probe holders were placed over the bilateral frontal, temporal and inferior parietal areas. To investigate possible patterns of brain response in HR infants in the process of language perception, changes in the hemodynamic response were recorded and compared between HR and LR infants in the language-related regions.

Results:

Our preliminary results suggested that 5-month-old infants with HR show less neural responses to speech stimuli in the left temporal areas than the LR group. During the non-speech task, there were no significant differences in the left temporal areas between these two groups. For 10-month-old infants, the changes in the oxygenated hemoglobin (Hb) showed a different pattern between speech and non-speech tasks in LR group but not in HR infants.

Conclusions:

Our initial results show a different neural response in the language brain regions in infants at high risk for ASD at 5 and 10 months. This suggests that language development may already be impaired in the first year of life in (some of the) infants in the HR group. A complete analysis on 40 participants in each group will be presented at the conference.

91 **127.091** Magnetoencephalographic (MEG) Gamma Oscillations and Sensory Sensitivity in People with and without Autism Spectrum Disorders (ASD)

E. V. Orekhova[1], *J. F. Schneiderman*[2,3], *S. Lundström*[4], *B. Riaz*[5], *N. Hadjikhani*[4,6], *O. V. Sysoeva*[1], *T. A. Stroganova*[1] *and C. Gillberg*[4], *(1)MEG-Center, Moscow University of Psychology and Education, Moscow, Russian Federation, (2)Department of Clinical Neurophysiology, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (3)MedTech West, Gothenburg, Sweden, (4)Gillberg Neuropsychiatry Centre, Department of Psychiatry and Neurochemistry, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (5)Department of Clinical Neuroscience, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, (6)MGH/ Martinos Center for Biomedical Imaging/ Harvard Medical School, Charlestown, MA*

Background: People with ASD often demonstrate hypo- and hypersensitivity to sensory stimuli of different modalities. Altered balance between neural excitation (E) and inhibition (I) has been suggested as one of the mechanisms underlying ASD and is likely to contribute to the sensory sensitivity problems through affecting gain control properties of the neurons in sensory cortex (Isaacson and Scanziani, Neuron, 2011, 72:231-43). Neural oscillations in high-frequency (30-100 Hz, i.e. 'gamma') range are generated by local E-I circuits and are highly sensitive to changes in the E/I balance. Therefore, variations in gain control properties of the cortical circuitry may be reflected in intensity-related changes of gamma oscillations.

Objectives: In this study we sought to find E/I–related neurophysiological underpinning of abnormal sensory sensitivity in people with ASD by investigating properties of magnetoencephalographic (MEG) gamma oscillations and their modulation by intensity of visual stimulation (excitatory drive).

Methods: MEG was recorded in 20+20 high-functioning adults with and without ASD. Subjects watched high-contrast concentric gratings moving at 1.2, 3.6 or 6.0 deg/sec that effectively induced visual gamma oscillations in our previous study in children. We also recorded pupillary constriction as an indirect measure of excitatory drive. Sensory sensitivity was assessed in all participants using the Adolescent/Adult Sensory Profile questionnaire.

Results: Participants with ASD had higher sensory sensitivity ($p<0.05$). Increasing stimulus velocity led to stronger pupillary constriction - reflecting an increase in excitatory drive to the cortex **–** both in individuals with ASD and those without. The increase in excitatory drive was accompanied by highly significant acceleration of gamma oscillations and suppression of gamma response magnitude. The ASD group demonstrated weaker intensity-related suppression of gamma response, while no significant group differences in either amplitude or frequency of gamma response were found. In both groups the weaker suppression of gamma response correlated with higher sensory sensitivity.

Conclusions: The intensity-related changes in MEG gamma oscillations may be useful for characterization of E/I balance in the visual cortex and may provide biomarkers for clinical trial studies targeting E/I balance in ASD.

92 **127.092** Modulation of Emotional Face Processing By Visual Attentional Flexibility and Attention Deficit Hyperactivity Disorder (ADHD) Symptoms in ASD: Results from the ABC-CT Feasibility Study

M. R. Altschuler[1], *A. Naples*[1], *B. Lewis*[1], *G. Dawson*[2], *R. Bernier*[3], *S. Jeste*[4], *C. A. Nelson*[5], *K. Chawarska*[1], *S. J. Webb*[3], *F. Shic*[6], *Q. Wang*[1], *M. Murias*[7], *C. Sugar*[4] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)University of California, Los Angeles, Los Angeles, CA, (5)Boston Children's Hospital, Boston, MA, (6)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (7)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC*

Background: Face processing difficulties are common in ASD. In addition to social deficits, children with ASD often show impaired executive function(EF). Atypical face processing and impaired EF are also evident in ADHD, which often co-occurs in ASD. It is not known whether ADHD and visual attentional flexibility(VAF)—a type of EF that involves shifting, engaging, and disengaging visual-spatial attention—modulate ERPs to emotional faces in ASD.

Objectives: To examine whether ADHD and VAF modulate ERPs to emotional faces in ASD versus TD.

Methods: EEG and eye-tracking(ET) data were collected from children (4-11 years-old and *DAS-2* IQ ≥ 50) with ASD (n=25) and TD (n=26). For EEG, participants viewed neutral and fearful faces, while EEG was recorded with a 128-channel Hydrocel Geodesic net at 1000Hz. ERPs (P100, N170) were extracted over left(LH) and right(RH) hemispheres. For ET, participants completed a gap-overlap task, while fixations were recorded via a SR Eyelink 1000+ binocular eye-tracker at 500Hz. A central stimulus(CS) was displayed, followed by a peripheral stimulus(PS). PS was displayed while CS was on screen (overlap), immediately after CS disappeared (baseline), or 200 ms after CS disappeared (gap). VAF effects were calculated from reaction time(RT) to PS: disengagement (overlap-baseline), facilitation (baseline-gap), and gap (overlap-gap). *Childhood and Adolescent Symptom Inventory-5* measured ADHD inattention and hyperactivity/impulsivity symptoms. To examine effects of group and condition, ANOVAs were used for ERPs, and trial-level linear mixed effects modeling(LMM) was used for gap-overlap, controlling for IQ.

Results: In ASD, greater inattention related to slower P100 to fearful faces (LH; r=.69, p=.01), and greater hyperactivity/impulsivity related to slower N170 to fearful (LH; r=.59, p=.04) and neutral (RH; r=.56, p=.049) faces. In TD, greater inattention related to faster N170 to fearful faces (LH; r=-.46, p=.04). In ASD, greater inattention related to slower P100 to fearful versus neutral faces (LH; r=-.56, p=.048), and greater hyperactivity/impulsivity related to slower N170 to fearful versus neutral faces (LH; r=-.64, p=.02). Greater facilitation effect related to slower N170 to fearful versus neutral faces (RH; r=-.60, p=.04) in ASD, whereas greater gap effect related to faster N170 to fearful versus neutral faces (RH; r=.47, p=.02) in TD. Main effects of group were identified for gap-overlap RTs (p=.048), but not ERPs (p>.05). RTs were faster in ASD. Main effects of condition were identified for N170 and P100 amplitudes (p<.03) and gap-overlap RTs (p<.001). P300 will be extracted for future analyses.

Conclusions: Variability in EF-related ADHD symptoms and VAF modulate neural response to faces differently in ASD versus TD. Children with ASD with more ADHD symptoms showed slower neural responses to faces, whereas TD children showed the opposite. When comparing emotional faces, children with ASD with more ADHD symptoms showed slower neural responses to fearful versus neutral faces. Greater facilitation predicted slower neural response to fearful versus neutral faces in ASD, while greater gap effect in TD predicted the reverse. Therefore, brain response to faces may be modulated by orienting efficiency in ASD but by processing efficiency in TD, suggesting distinct relationships among EF and social perception in ASD versus TD.

93 **127.093** Mu Suppression during Action Execution and Observation in Low-Functioning, Young Children with Autism Spectrum Disorder

A. Kylliainen[1]*, P. Warreyn*[2]*, M. Miettinen*[3]*, T. M. Helminen*[1]*, K. Eriksson*[4] *and J. M. Leppanen*[1]*, (1)Tampere University, Tampere, Finland, (2)Department of Experimental-Clinical and Health Psychology, Ghent University, Ghent, Belgium, (3)University of Tampere, Tampere, Finland, (4)Tampere University and Tampere University Hospital, Tampere, Finland*

Background: There has been a discrepancy in literature whether the dysfunctional mirror neuron system (MNS) underlies the imitation difficulties in autism spectrum disorder (ASD). The attenuation of the EEG mu rhythm is considered to reflect the activation of the MNS. The suppression of the mu rhythm occurs not only when individuals execute actions but also when they observe actions. It has been suggested that differences in age, developmental level and symptom severity of a sample with ASD might explain why some studies have found a lack of suppression during the action observation in individuals with ASD whereas other studies have not.

Objectives: The aim of the study was to investigate mu suppression during the execution and observation of hand actions in low-functioning, young children with severe ASD. In order to study the effects of developmental level, we also had an IQ-matched comparison group of children with intellectual disability who did not show marked autistic behaviour. In addition there was a normative comparison group of age-matched typically developing children.

Methods: The original sample consisted of 58 children aged 2.5-6.5 years. The final sample included 12 children with ASD, 11 children with intellectual disability (ID) and 14 typically developing children (TD) who had a sufficient number of artefact-free trials. The EEG mu rhythm (7-11Hz) was measured using The EGI Geodesic 128-channel dense-array system whilst the children were shown 6-second video clips of object-directed hand actions (e.g., pressing a button), meaningless, non-object-directed hand actions (e.g., tapping a table with fingers), a non-biological movement (a slightly bouncing ball), or a white screen. In the action execution conditions, the children imitated the preceding object-directed action. The suppression was calculated as a ratio of mu band power between three action conditions (execute, observation of object-directed and non-object-directed actions) and the baseline conditions (non-biological movement and white screen).

Results: The repeated-measures ANOVA showed a significant main effect of condition (F (2, 34) = 25.644, p < .001), reflecting greater mu suppression over central region in the action execution condition as compared to other conditions. There was no main effects of hemisphere, group or any interaction effects involving these factors on mu suppression. Separate analyses of condition effects within groups revealed, however, that mu suppression was significantly different from baseline in the observation condition of object-directed action in the TD group only. The execution condition differed significantly from baseline in all groups. None of the groups showed significant suppression in non-object-directed condition (Figure 1).

Conclusions: The findings of the study provided no evidence for an ASD-specific deficit in MNS function, as assessed by group by condition interaction effect on mu suppression. Separate within-group comparisons were consistent with prior results showing significant mu suppression during observation in typically developing children but not in young, low-functioning children with ASD. This result was not, however, specific to children with ASD as a similar pattern was also found in children with intellectual disability, raising the possibility that the lack of mu suppression during action observation could relate to more general developmental difficulties.

94 **127.094** Neonatal Electrophysiological Biomarkers for Neurodevelopmental Disorder Risk

L. C. Shuffrey[1]*, P. E. Springer*[2]*, M. Potter*[3]*, H. J. Odendaal*[4]*, J. D. Nugent*[1]*, N. H. Brito*[5] *and W. P. Fifer*[1]*, (1)Division of Developmental Neuroscience, Columbia University Medical Center, New York, NY, (2)Paediatrics & Child Health, Stellenbosch University, Cape Town, South Africa, (3)Obstetrics and Gynaecology, Stellenbosch University, Bellville, South Africa, (4)Obstetrics and Gynaecology, Stellenbosch University, Cape Town, South Africa,* *(5)Department of Applied Psychology, New York University, New York, NY*

Background: Presently, the factors leading to ASD are unknown, with no specific biological, genetic, or environmental marker. But, there is abundant evidence of structural, functional, and morphological brain abnormalities in individuals with ASD. Although ASD can be reliably diagnosed as early as 2, the median age of diagnosis is approximately 4 years of age. Prior research has demonstrated that early intervention services from birth to 36 months of age can drastically improve neurodevelopmental outcome. Therefore, the identification of an objective neonatal marker of ASD has the potential to aid in detecting at-risk children who may benefit from early intervention services.

Objectives: Prior research has demonstrated that neonatal electroencephalography (EEG) during sleep is predictive of neurodevelopmental outcome in clinical and neurotypical populations. Although abnormal EEG power and coherence has been demonstrated concurrently in both children and adults with ASD, to our knowledge this is the first study to examine EEG power in neonates and subsequent autism risk.

Methods: Neonatal EEG was collected from healthy term newborns enrolled in the Prenatal Alcohol and SIDS and Stillbirth Network in the Western Cape province of South Africa. Average power for 10 frequency bands were computed for multiple 30-second epochs for a 10-minute period prior to a physiological challenge. We examined neonatal EEG power in active sleep in the low-frequency theta (2-9Hz), mid-frequency Alpha (10-12Hz), and higher-frequencies Beta (13-21Hz) and Low Gamma (22-36Hz). Neurocognitive outcome and autism risk were assessed between 30 and 38 months of age by The Modified Checklist for Autism in Toddlers, Revised with Follow-Up (M-CHAT-R/F) (n=198), the Brief Infant-Toddler Social and Emotional Assessment (BITSEA) (n=253), and the Bayley Scales of Infant Development III Screener (Bayley)(n=117).

Results: When controlling for gestational age at birth, sex, chronological age in months at the time of assessment, and multiple comparisons (Benjamini & Hochberg 5% False Discovery Rate), significant associations were found between neonatal EEG power during active sleep, autism risk, and expressive language ability. BITSEA ASD Risk scores were correlated with EEG power in the Theta frequency in the right temporal region (r(86)=.279, p<.005) where lower EEG power was indicative of higher autism risk. Although there were no significant correlations between the receptive language, gross motor, fine motor, or the overall cognitive scores, there were moderate correlations between the Bayley expressive language subdomain and EEG power in the Alpha, Beta, and Low Gamma frequencies in the left central, occipital, and frontal polar regions (Alpha left-central: (r(86)=-.453, p<.001); Alpha left-occipital (r(86) = -.450, p<.001); Beta left-central: (r(43)=-.434, p< .001); Low gamma left-central (r(43)=-.483, p<.001); Low gamma left-frontalpolar (r(44)=-.457, p< .001)). Specifically, higher EEG power in these frequency bands was indicative of superior expressive language ability.

Conclusions: Our preliminary results demonstrate robust associations for expressive language ability and modest associations between early neural biomarkers for autism risk. Further research to examine neonatal neural oscillations and subsequent developmental trajectories may contribute to our comprehension of atypical neurodevelopment. Data collection is ongoing.

95 **127.095** Neural Response to Emotional Faces and Anxiety in Children with Autism Spectrum Disorder

***K. S. Ellison**, J. Wolf, A. Naples, K. A. McNaughton, T. C. Day, T. Winkelman, M. J. Rolison, E. Jarzabek, B. Lewis and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Anxiety is highly prevalent in children with Autism Spectrum Disorder (ASD; White et al., 2009). While it is well established that children with ASD have an atypical brain response to emotional faces (Dawson et al., 2004), there is less research examining anxiety dimensionally and how this comorbidity may affect a child's neural response to social stimuli. This study investigated electrophysiological (EEG) brain response during a gaze-contingent paradigm that simulated face-to-face interactions.

Objectives: To examine the relationship between anxiety symptoms and face-processing event related brain potential (ERP) components in children with ASD with varying levels of anxiety.

Methods: ERPs were recorded from 24 youth with ASD (18 males, 6 females) and 22 typically developing (TD) controls (13 males, 9 females) using a 128 channel Geodesic Sensor Net). The sample was matched on age (ASD; *M:* 14.38, *SD:* 2.36, TD; *M:* 12.93, *SD:* 3.00) and IQ (ASD; *M:* 109.10, *SD*: 20.35, TD; *M:* 109.01, *SD*: 11.55). Participants were presented with 80 distinct photorealistic, animated faces matched for low-level visual features. Utilizing gaze-contingent eye tracking technology, stimuli responded to a participant's direct fixation to the face by exhibiting happy or fearful emotions. P100 and N170 amplitudes and latencies were extracted from selected electrodes over the occipitotemporal scalp. Difference scores were calculated as Fear minus Happy condition. Anxious symptomology was measured using the following standardized child self-report measures: The Multidimensional Anxiety Scale for Children (MASC-C) and Social Anxiety Scale for Adolescence/Children (SAS-A/SASC-R). Correlations were conducted between the ERP difference scores and standard scores on the anxiety measures. Eye-tracking analyses (data collected using an EyeLink-1000 remote camera system) are ongoing.

Results: In children with ASD, greater left N170 Amplitude to Fear vs. Happy was associated social anxiety (SAS-A/SASC-R Fear of Negative Evaluation [*r*(24)=.428, *p*=.04], and MASC-C Humiliation/Rejection [*r*(23)=.380, *p*=.07]). Additionally, children with ASD had a shorter P100 Latency to Fear vs. Happy associated with physical symptoms of anxiety (MASC-C Tense/Restlessness [*r*(23)=-.616, *p* <.001], MASC-C Somatic/Automatic [*r*(23)=-.393, *p*=.06], MASC-C Physical Symptoms Total [*r*(23)=-.597, *p* <.001]), as well as overall anxiety (MASC-C Total [*r*(23)=-.406, *p*=.06]). Children in the TD group had a smaller right N170 Amplitude to Fear vs. Happy associated with social anxiety (MASC-C Humiliation/Rejection [*r*(22)=-.469, *p*=.03], MASC-C Performance Fears [*r*(22)=-.423, *p*=.05], MASC-C Social Anxiety Total [*r*(22)=-.479, *p*=.03]). Furthermore, the TD group had a smaller right P100 Amplitude to Fear vs. Happy associated with social anxiety (MASC-C Performance Fears [*r*(22)=-.427, *p*=.05], MASC-C Social Anxiety Total [*r*(22)=-.426, *p*=.05]). No other significant associations were found between the N170 or the P100 Amplitude or latencies and the other subscales of the SAS-A/SASC-R

Conclusions: Results demonstrate that anxiety influences brain response to emotional faces in ASD, providing information potentially useful for stratification in a heterogeneous population. Understanding the role of anxiety in relation to social-communicative biomarkers may lead to targeted, biologically informed treatments.

96 **127.096** Transdiagnostic Relationships Among Social Communication and Neural Response to Dynamic Social Stimuli

*K. Shulman[1], **K. S. Ellison**[1], J. Wolf[1], K. A. McNaughton[1], T. C. Day[1], T. Winkelman[1], M. J. Rolison[1], B. Lewis[1], E. Jarzabek[1], J. Foss-Feig[2], A. Naples[1], A. Anticevic[3], V. Srihari[3] and J. McPartland[1], (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Psychiatry, Icahn School of Medicine at Mount Sinai, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Individuals with Autism Spectrum Disorder (ASD) and individuals with Schizophrenia (SCZ) both experience deficits in social communication (Abdi & Sharma, 2004). Previous studies have found atypical brain response to faces in ASD at a facially sensitive event-related potential (ERP), the N170 (Bentin et al., 1996; McPartland et al., 2004). This study aimed to use an interactive social EEG paradigm to explore the relationships between social communication and brain response across diagnostic groups
Objectives: To explore the relationship between the N170 response to dynamic social stimuli and degree of social impairment across adults with diagnoses of ASD, SCZ and typically developing (TD) controls.

Methods: ERPs were recorded from 43 adults (16 with a diagnosis of ASD, 16 with a diagnosis of SCZ, and 11 TD controls) using a 128-electrode Geodesic Sensor Net. Utilizing gaze-contingent eye tracking technology, on-screen dynamic face stimuli responded to the participant's gaze by either directing or averting gaze. N170 amplitudes and latencies for both conditions were extracted from select electrodes. Social communication functioning was measured using standardized measures, the Autism Diagnostic Observation Schedule (ADOS-2) Module 4 (clinician-rated) and the Social Responsiveness Scale (SRS-2; self-report). Relationships were examined between ERP components and the ADOS-2 Module 4 total score and SRS-2 standard scores. Data collection is ongoing.

Results: A smaller N170 amplitude to averted gaze was associated with social communication impairment (SRS-2 Total T-score [$r(43)=-.310$, $p=.04$], SRS-2 Social Motivation T-score [$r(43)=-.319$, $p=.04$], SRS-2 Cognition T-score [$r(43)=-.287$, $p=.06$], SRS-2 Communication T-score [$r(43)=-.294$, $p=.06$], SRS-2 Awareness [$r(43)=-.146$, $p=.35$]). No significant associations were found between N170 amplitude to direct gaze and the SRS-2. Additionally, participants had a smaller N170 amplitude to direct gaze associated with the ADOS-2 Algorithm Total Score [$r(43)=-.291$, $p=.06$]. No significant associations were found between the N170 amplitude to averted gaze and the ADOS-2. Additionally, no significant associations were found between N170 latency and the SRS-2 or ADOS-2.

Conclusions: Results suggest that the ADOS-2 and SRS-2 measure distinct aspects of social communication associated with differential patterns of brain response to gaze-related stimuli, with the former being associated with direct gaze and the latter being associated with averted gaze. Response to averted gaze may reflect interpretation of the stimulus (e.g. as a sign of rejection or disinterest) and is thus more influenced by factors captured by the SRS-2, such as social motivation and cognition. In contrast, neural response to direct gaze may be more associated with observable gaze-related behaviors as measured by the ADOS-2. This suggests the importance of measuring social communication in a comprehensive fashion, utilizing multi-informant ratings across multiple measures.

97 **127.097** Neural Response to Eye Gaze Differentiates ASD Diagnostic Status Among Adults Meeting ADOS-2 Criteria

K. A. McNaughton[1], *A. Naples*[1], *T. C. Day*[1], *T. Winkelman*[1], *M. J. Rolison*[1], *T. McAllister*[1], *D. Stahl*[1], *S. Hasselmo*[1], *T. Halligan*[1], *B. Lewis*[1], *K. S. Ellison*[1], *E. Jarzabek*[1], *J. Wolf*[1], *J. Foss-Feig*[2], *A. Anticevic*[3], *V. Srihari*[3] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Individuals with autism spectrum disorders (ASD) process social information differently than individuals with typical development (TD), as indicated by a slower latency of face-specific processing components (McPartland et al., 2004). However, there has been little investigation of the relationship between neural processing of social stimuli in individuals who have social communication challenges but do not receive an ASD diagnosis from a clinician compared to individuals who receive an ASD diagnosis.
Objectives: To examine the relationship between EEG response to faces, social communication symptoms, and autism diagnosis in a clinically heterogeneous population.

Methods: The study included (a) adults who met criteria for autism or autism spectrum on the ADOS-2 Module 4 and received an ASD diagnosis (n=20; male=15); (b) adults who met criteria on the ADOS-2 but did not receive an ASD diagnosis (n=10; male=8; DX: n=9 schizophrenia spectrum, n=1 generalized anxiety disorder); and (c) adults who did not meet criteria on the ADOS-2 and did not receive an ASD diagnosis (n=40; male=26). Groups did not differ on age or IQ, and the two groups that met criteria on the ADOS did not differ in their communication and social interaction totals (ps>0.05). Each EEG trial began with a crosshair in the upper, middle, or lower portion of the screen directing gaze to specific regions of a subsequently appearing stimulus (eye/nose/mouth region of a face or upper/middle/lower region of a house). The N170 event-related potential, a component reflecting early face processing, was segmented to the appearance of the face or house.

Results: There was a significant main effect of diagnostic group on N170 latency ($F(2, 67)=8.16$, $p<0.01$). Adults who met criteria on the ADOS and received an ASD diagnosis had significantly longer N170 latencies to all stimuli than adults who met criteria but did not receive a diagnosis ($p<0.01$) and adults who did not meet criteria ($p<0.01$). Adults who met criteria but did not receive an ASD diagnosis did not have significantly different N170 latencies from adults who did not meet criteria on the ADOS ($p=0.72$). There was a significant main effect of condition on N170 latency ($F(3, 201)=5.30$, $p<0.01$) and amplitude ($F(3, 201)=54.18$, $p<0.01$), with faster N170 components to eyes than mouths, noses, or houses, and more negative N170 components to facial features than houses. Among adults who met criteria on the ADOS, those who did and did not receive an ASD diagnosis differed significantly in their N170 latency to eyes ($p=0.01$), noses ($p=0.03$), and houses ($p=0.03$), but not mouths ($p=0.11$), with only the latency difference to eyes remaining significant after post-hoc correction.

Conclusions: The presence of differences in N170 latency between groups that scored similarly on the ADOS but had different diagnostic outcomes underscores the utility of N170 latency as a biomarker to differentiate individuals with ASD from individuals without an ASD diagnosis. This finding further highlights the importance of considering brain-based measures of social functioning, as they provide practicable and complementary information to commonly used clinical instruments such as the ADOS.

98 **127.098** Ouch and Yucks: Anxiety, Alexithymia and Empathetic Reactions in Autism

A. Lassalle[1,2], *N. R. Zurcher*[2], *C. A. Porro*[3], *F. Benuzzi*[3], *L. Hippolyte*[4], *E. Lemonnier*[5], *J. Åsberg Johnels*[6] *and N. Hadjikhani*[2,7], *(1)Psychology (Brain & Cognition), University of Amsterdam, Amsterdam, Netherlands, (2)MGH/ Martinos Center for Biomedical Imaging/ Harvard Medical School, Charlestown, MA, (3)Biomedical, Metabolic and Neural Sciences, Università di Modena e Reggio Emilia, Modena, Italy, (4)Service de Genetique Medicale, University of Lausanne, Lausanne, Switzerland, (5)centre expert autisme du limousin, CHU de limoges, Limoges, France, (6)Gillberg Neuropsychiatry Center, University of Gothenburg, Göteborg, Sweden, (7)Gillberg Neuropsychiatry Center, Gothenburg University, Gothenburg, Sweden*

Background: The circumstances under which empathy is altered in Autism Spectrum Disorder (ASD) remain unclear, as previous studies did not systematically find differences in brain activation between people with and without ASD in empathy-eliciting paradigms. In addition, these studies did not always monitor whether the differences between ASD and controls were primarily due to ASD "per se", or to conditions overlapping with ASD, such as alexithymia and anxiety.
Objectives: The present study aimed at (1) clarifying the difference of activations in the empathy network between people with and without ASD viewing a particular kind of empathy eliciting stimulus, and (2) investigating the influence of alexithymia and anxiety on those activation differences.

Methods: Functional Magnetic Resonance Imaging (fMRI) data were collected from 47 participants (22 with ASD) viewing pictures depicting the hands and feet of unknown others in painful, disgusting, or neutral situations. We focused our analysis on two contrasts: painful vs. neutral and disgusting vs. neutral. For those contrasts, we extracted whole brain (WB) activity and activity in Regions Of Interests (ROIs) of the empathy network (frontal pole, supplementary motor area, thalamus, anterior cingulate cortex, posterior cingulate cortex, anterior insula, post central gyrus, and parietal operculum). We also explored the influence of alexithymia and anxiety on WB and ROI activity for those two contrasts, using regression and correlation analyses.

Results: We found that participants with ASD had decreased activation for both contrasts compared with control participants. However, these differences disappeared when either alexithymia or anxiety (both more elevated in the ASD group than in the control group) were controlled for. For ROIs, alexithymia (but not anxiety or autistic traits) was correlated with activation in the frontal pole for painful stimuli (after correction for multiple comparison).

Conclusions: Our results suggest that empathy is affected in ASD but that this association is complex and not necessarily attributable to ASD "per se".

99 **127.099** Reduced Neural Activity of Social and Motor Networks in Children and Adolescents with Autism Spectrum Disorder and Developmental Coordination Disorder during Observation and Imitation of Social and Motor Actions

E. Kilroy[1], *C. Butera*[1], *L. A. Harrison*[2], *L. Aziz-Zadeh*[3] *and S. A. Cermak*[1], *(1)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)California Institute of Technology, Pasadena, CA, (3)Occupational Science and Occupational Therapy; Psychology, University of Southern California, Los Angeles, CA*

Background: A growing body of literature suggests that children with ASD often have motor deficits and that these deficits may be related to social skills in ASD (Dziuk, 2007). Previous imaging work has shown that motor system networks (e.g., Action Observation Network [AON]) play a role in supporting intention understanding as well as imitation (Iacoboni, 2005). It is thus possible that mechanisms underlying motor impairments contribute to social deficits in ASD. To our knowledge, no study to date has investigated social and motor neural processing in ASD across a spectrum of social-motor stimuli nor has anyone compared such stimuli to clinical populations with motor impairments.
Objectives: (1) To assess how children and adolescents with ASD differ in social neural networks when observing and imitating social and motor stimuli compared to typically developing (TD) participants and individuals with developmental coordination disorder (DCD). (2) To assess how these differences may be related to group differences in social and motor skills assessed with the Social Responsiveness Scale (SRS; Constantino, 2003) and Movement Assessment Battery for Children (MABC-2; Henderson, 2007).

Methods: Data from thirteen high-functioning children and adolescents with ASD (mean age [years] 11.26±1.09), seven children and adolescents with DCD (mean age [years] 11.97±2.09), and sixteen TD participants (mean age [years] 11.25±1.41) were analyzed. Imaging data was collected on a 3-T Siemens MAGNETOM Prisma scanner. In the scanner, participants observed and imitated separately to three video stimuli conditions: 1) emotional expressions (i.e., Happy), 2) Non-Emotional expressions (i.e., wiggle nose) and 3) hand actions (i.e., cutting paper). Using a block design, each condition was randomly presented for 15-seconds followed by 15-seconds of rest. Standard preprocessing and motion scrubbing were performed. Direct whole brain comparisons between groups were made. The degree of social and motor skills were also analyzed to determine group differences in ability.

Results: During the observation task, the ASD group elicited less activation in social and motor regions (angular gyrus, amygdala) when observing emotional faces and increased activity when observing hand actions compared to TD participants. During the imitation task, TD participants showed increase activation in the left IFG when imitating emotional faces compared to the ASD group (p=.021), and when imitating hand condition compared to DCD (p=.022). Movement scores were significantly related to activity in motor regions (IFG) during the imitation task across groups (R=.405, p=.019). For children with ASD, activity in motor regions (inferior frontal gyrus) was also correlated with social ability (p<.05).

Conclusions: Our results indicate that motor regions are less active in ASD during observation and imitation. During imitation, activity in motor regions (inferior frontal gyrys) correlates with motor ability (MABC2 scores) across groups, and for social ability in the ASD group. These results may have implications for understanding heterogeneity within ASD along the axis of motor impairment, and in the long run, lead to individualized forms of treatment.

100 **127.100** Relating Measures of Sleep from Polysomnography Exams and Parent Questionnaires in Children with Autism

A. Arazi[1,2], *A. Tarasiuk*[3,4], *G. Meiri*[5] *and I. Dinstein*[6,7,8], *(1)Department of Cognitive and Brain Sciences, Ben Gurion University, Beer Sheba, Israel, (2)Zlotowski Center for Neuroscience, Ben Gurion University of the Negev, Beer Sheba, Israel, (3)Sleep-Wake Disorders Unit, Soroka University Medical Center, Beer Sheba, Israel, (4)Department of Physiology, Ben Gurion University of the Negev, Beer Sheba, Israel, (5)Soroka Medical Center, Beer Sheba, Israel, (6)Negev Autism Center, Ben Gurion University of the Negev, Beer Sheba, Israel, (7)Department of Psychology, Ben Gurion University of the Negev, Beer Sheba, Israel, (8)Department of Cognitive and Brain Sciences, Ben Gurion University of the Negev, Beer Sheba, Israel*

Background:
Numerous studies using parental questionnaires, such as the Children’s Sleep Habits Questionnaire (CSHQ), reported that sleep problems are highly prevalent in children with autism. In parallel, several polysomnography studies have reported that the proportion of rapid eye movement (REM) sleep is decreased and that low-frequency EEG power (Delta band: 0.5-4 Hz) is weaker in toddlers with autism. Are such polysomnography measures related to parental reports of sleep disturbances or to measures of autism severity (ADOS)? To examine these relationships, we performed prospective polysomnography recordings in children with autism and asked their parents to fill out the CSHQ. All participating children

were part of the regional autism database initiative at the Negev Autism Center in Israel (www.negevautism.org), which continues to grow at a rate of ~20 new children per month.

Objectives:

To explore the association between objective sleep measures by polysomnography recordings and subjective parental report measures from the CSHQ questionnaire.

Methods:

Twenty-two children with autism (mean age: 55±4 months) were prospectively recruited to the study. All children underwent overnight polysomnography recording at Soroka University Medical Center and completed the Autism Diagnostic Observation Schedule (ADOS) assessment. Parents of all children completed the CSHQ questionnaire. Sleep/wake activity was scored according to accepted guidelines and EEG power in the Delta (1-4Hz), Theta (4-8Hz), Alpha (8-13Hz) and Beta (13-20Hz) frequency bands were calculated for each sleep stage (I, II, III, and REM).

Results:

Parental report with the CSHQ revealed that 86% of participating children had a total sleep disturbance score of over 41 (mean score: 53±2.5), which is often used as a cutoff score for identifying sleep problems. No significant correlations were found between the total sleep disturbance score and EEG power in any of the examined bands, nor with the proportion of REM sleep/duration, or with ADOS scores. However, ADOS scores were positively correlated with Delta power ($r>0.51$, $p<0.05$) and negatively correlated with Alpha ($r<-0.41$, $p<0.05$) and Beta ($r<-0.49$, $p<0.05$) power.

Conclusions:

These results suggest that parental reports of sleep quality using the CSHQ were not associated with Polysomnography measures of sleep. Interestingly, children with more severe autism symptoms exhibited deeper sleep (i.e., larger Delta power during all sleep stages). We continue to expand the sample to determine the validity of these preliminary findings.

101 **127.101** Sex-Dependent Cerebellar Connectivity in Autism Spectrum Disorders

R. E. Smith[1,2]*, S. J. Gotts*[1]*, J. A. Avery*[1]*, G. L. Wallace*[3]*, L. Kenworthy*[4] *and A. Martin*[5]*, (1)Laboratory of Brain and Cognition, NIH/NIMH, Bethesda, MD, (2)Institute of Cognitive Neuroscience, University College London, London, United Kingdom, (3)The George Washington University, Washington, DC, (4)Children's National Health System, Washington, DC, (5)NIMH, Bethesda, MD*

Background: Human neuroimaging studies have documented sex-specific differences in the development, structure, and function of the cerebellum (Nguon et al., 2005). This part of the brain, in conjunction with the cortex, is involved in both sensorimotor and socio-affective processes. These two domains of function are both impaired in autism spectrum disorders (ASD), and not surprisingly, the cerebellum has been highlighted in neuroimaging studies of males with ASD. Behavioral studies have also found sex differences in ASD prevalence and phenotype.

Objectives: Given what we know about the relationship between ASD and the cerebellum, and the sex differences associated with each, we were interested in whether there may be sex-dependent changes in the cerebellum's functional architecture in ASD. The aim of the current study was to explore this using resting-state functional magnetic resonance imaging (fMRI).

Methods: We collected resting-state fMRI scans from 47 women (23 ASD, and 24 controls) and 120 men (56 ASD, and 64 controls), matched on age, head motion and IQ. Using a measure of global functional connectivity, we ran a linear mixed effects analysis across both groups to determine whether there was a sex-by-diagnosis interaction associated with resting state functional connectivity.

Results: Two clusters in the left and right cerebellum exhibited a diagnosis-by-sex interaction in global connectivity ($p< 0.005$ with small volume correction in the cerebellum). Compared to controls, females with ASD showed *hyper*connectivity between those cerebellar clusters and the cortex, whereas males with ASD showed the opposite pattern (*hypoco*nnectivity with the rest of the brain). Follow-up analyses of seed-based connectivity effects underlying these global connectivity differences (using a 6mm spherical region of interest centered on the peak voxel in each cerebellar cluster) revealed significant diagnosis-by-sex interactions between the cerebellum and several cortical regions including the right fusiform, right inferior frontal gyrus, right precentral gyrus, mid-cingulate, precuneus, middle temporal gyrus, and thalamus.

Conclusions: These results shed light on the sex-specific pathophysiology of ASD. This pattern of sex-dependent, aberrant cerebellar connectivity in ASD might explain some of the abnormalities in motor and socio-affective abilities seen in this population.

102 **127.102** Shared and Distinct Features of Dynamic Emotional Face Processing in Autism Spectrum Disorder and Schizophrenia As Measured By Neural and Behavioral Responses

T. C. Day[1]*, A. Naples*[1]*, B. Lewis*[1]*, K. A. McNaughton*[1]*, T. Halligan*[1]*, T. Winkelman*[1]*, M. J. Rolison*[1]*, T. McAllister*[1]*, S. A. A. Chang*[1]*, K. S. Ellison*[1]*, E. Jarzabek*[1]*, J. Wolf*[1]*, J. Foss-Feig*[2]*, V. Srihari*[3]*, A. Anticevic*[3] *and J. McPartland*[1]*, (1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Seaver Autism Center, Department of Psychiatry, Icahn School of Medicine at Mount Sinai Hospital, New York, NY, (3)Division of Neurocognition, Neurocomputation, and Neurogenetics (N3), Yale University School of Medicine, New Haven, CT*

Background: Social impairment is a shared feature of autism spectrum disorder (ASD) and schizophrenia (SCZ). Nonverbal communication, including emotional facial expression, is a central component in understanding the social world. Examinations of electroencephalography (EEG) and eye-tracking (ET) have revealed similar brain and behavior atypicalities in individuals with ASD and SCZ in response to emotional faces. Collecting EEG and ET simultaneously during changes in emotional expressions allows for the examination of brain-behavior relationships in more ecologically valid contexts.

Objectives: To contrast event-related potentials (ERPs) to dynamic emotional faces in adults with typical development (TD), ASD, and SCZ and examine their relation to behavior, eye-tracking, and affective expression.

Methods: The TD (n=21), ASD (n=18), and SCZ (n=15) groups were matched on age (range: 18-33 years). EEG was collected using a 128-channel Geodesic Sensor Net. Concurrently, ET was collected with an EyeLink-1000 remote camera system. Participants underwent an interactive paradigm during ET-EEG collection in which they viewed a neutral face, and, contingent upon participant gaze to the eyes, the expression changed to happy or fearful. The N170 ERP component was extracted at emotional expression onset. Behavior, time looking at facial features, and a measure of affective blunting, the Unchanging Facial Expression item from the Scale for the Assessment of Negative Symptoms, were collected.

Results: The TD, ASD, and SCZ groups did not differ on N170 amplitude or latency response to dynamic emotional faces. The ASD and SCZ groups were combined into a clinical group in which an interaction effect between N170 amplitude and group approached significance [*F*(1, 53)=3.66, *p*=.06]. A significant difference in time spent looking at the left eye emerged across the TD, ASD, and SCZ groups [*F*(1, 51)=3.80, *p*=.03]. The ASD group looked to the left eye significantly less than the SCZ group (*p*=.01) which survived Bonferroni correction. Time spent looking at eyes in the fearful condition was related to faster right N170 latency in the ASD group (r_s=-.52, *p*=.03), and a trend was present in the SCZ group (r_s=-.45, *p*=.09), but not the TD group (r_s=.21, *p*=.36). This relationship in the happy condition approached significance in the ASD group (r_s=-.45, *p*=.06) only. A marginally significant relationship between faster right N170 latency in the fear condition and affective expression, as measured by the Unchanging Facial Expression item, emerged in the ASD group (r_s=.557 *p*=.06) only.

Conclusions: Examination of individual diagnostic groups and a single clinical group compared to normative social function revealed both common and distinct elements of brain-behavior responses to emotional faces between clinical groups. Together, individuals with clinical levels of social dysfunction exhibited distinct neural response from TD individuals suggesting atypical emotional face processing may not be unique to ASD. Yet individuals with ASD and SCZ had distinct viewing patterns of emotional faces and showed distinct brain-behavior relationships from one another and the TD group. Furthermore, the association between observed affect and emotional face processing may serve as a bridge between clinical phenotype and underlying biological response, specifically, in ASD.

103 **127.103** Socio-Dramatic Affective-Relational Intervention (SDARI) Changes the N100 ERP to Prosodic Voices

C. M. Keifer[1]*, E. J. Libsack*[1] *and M. D. Lerner*[2]*, (1)Stony Brook University, Stony Brook, NY, (2)Psychology, Stony Brook University, Stony Brook, NY*

Background: Several group social skills interventions have been developed to target social communication skills, a core deficit in autism spectrum disorder (ASD; McMahon et al., 2013). One such intervention, Socio-Dramatic Affective-Relational Intervention (SDARI), uses naturalistic performance-based techniques to develop social skills (Lerner et al., 2011). While participation in SDARI is related to social gains on subjective measures and behavioral (including vocal) emotion identification tasks, it is difficult to objectively quantify social communication improvements. Event-related potentials (ERPs) recorded via electroencephalogram (EEG) can be used to index the neural correlates of social processing and thus may be a useful tool for quantifying social improvement. The N100 and N300 are two ERP components related to processing vocal prosody that are aberrant in amplitude in individuals with social deficits (Pinheiro et al., 2011). While the N100 reflects early perceptual coding of auditory stimuli and is modulated by attention, the N300 is related to cognitive evaluation of emotion (Paulmann et al., 2008). Auditory ERPs to emotional prosody may be a useful objective technique for quantifying treatment outcomes in ASD.

Objectives: Examine whether participation in SDARI versus an active control is related to changes in N100 and N300 ERPs.

Methods: Thirty-three children (25 male; M_{age}=12.77, SD_{age}=3.01) with ADOS-2 confirmed ASD diagnosis and IQ ≥ 70 (M_{IQ}=107.94, SD_{IQ}=15.20) were randomly assigned to participate in 10 weeks of SDARI or a recreational games control group. Pre- and post-intervention, participants completed a measure of vocal emotion recognition (DANVA-2; Nowicki, 2004) while EEG was recorded. N100 and N300 to auditory stimuli of neutral sentences with emotional prosody were extracted from EEG data. We used Generalized Estimating Equations (GEE) to examine change in ERP amplitude and intensity as a function of group membership. We modeled the ERP (N100 or N300) at post-test as the dependent variable, group membership (SDARI vs. CONTROL) as the nested between-subjects variable, and ERP at pre-test as a covariate.

Results: Participation in SDARI resulted in significantly larger (more negative) N100 amplitude at post test (*Wald's c2*=4.43, *B*=2.78, *p*<.05). To probe this effect we ran two additional GEE models examining N100 amplitude to low and high intensity emotional voices. No significant effects were found for low intensity voices but participation in SDARI was associated with increases in N100 amplitude to high intensity emotional prosody (*Wald's c2*=6.75, *B*=2.25, *p*<.01). GEE models of change in N100 latency, N300 amplitude, and N300 latency were non-significant (all *p*>.05).

Conclusions: Results indicate that participation in SDARI, a naturalistic social skills intervention, is associated with increased magnitude of N100 response to highly salient prosodic language in youth with ASD. This suggests that engagement in this performance-based intervention leads to greater attention to and engagement in perceptual coding of emotional voices in comparison to an attention-control intervention. Thus, performance-based interventions such as SDARI may improve sensitivity to salient social cues like prosody. Not only is the N100 malleable in response to intervention, but future intervention studies might consider implementing the N100 as an objective index of social gains resultant from participation in intervention tasks.

104 **127.104** Sustained Neural Processing of Personally Relevant Negative Emotional Stimuli in Youth with ASD: A Possible Mechanistic Explanation for Poor Emotion Regulation

J. Golt[1]*, G. J. Siegle*[2] *and C. A. Mazefsky*[2]*, (1)University of Pittsburgh Medical Center, Pittsburgh, PA, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: There is increasing evidence that individuals with autism spectrum disorder (ASD) have poor emotion regulation, but the underlying neural processes are not well understood. In depressed samples, functional neuroimaging has revealed sustained neural processing of emotional stimuli (Erk et al., 2010). This may also occur in ASD given observations that emotional reactions are often characterized by a perseverative quality and prolonged negative affect (Mazefsky, Pelphrey, & Dahl, 2012).

Objectives: This study investigated differences in blood oxygen level dependent (BOLD) signal activation in youth with ASD during an event-related task that alternated between emotional processing and non-emotional processing conditions. Using a priori criteria, the objective was to identify brain regions with sustained activity following the presentation of personally-relevant negatively valenced stimuli.

Methods: Youth (12-17 years old) with ADOS- and ADI-confirmed ASD without intellectual disability (n= 25) and an IQ-, age-, and gender-matched control sample (n= 23) completed a task in a Siemens Verio 3T Magnetic Resonance Imaging (MRI) Scanner with a 32-channel head coil. The participants, together with their parents, created a list of 12 words that had a negative connotation to them prior to the participant being scanned. Each of the imaging trials alternated between an emotional processing condition, which consisted either of the personally-relevant negative words or normed neutral words, and a non-emotional simple memory task. Analyses were conducted using the Analysis of Functional NeuroImages (AFNI). A feature conjunction analysis was conducted to identify regions that satisfied the following a priori criteria in support of the hypothesis: 1) ASD group had greater activity than controls during the emotional portion of the task; 2) ASD group had greater activity during the entire trial (into the memory task), following the presentation of negative words: 3) ASD group was more reactive to negative versus neutral words; 4) changes in activity represented an increase from baseline. All regions included were greater than 30 voxels and had an effect size that was medium or greater (d > .5) and *p* <.05.

Results: Regions satisfying all a priori criteria were the left insula (89 vox), right pulvinar (67 vox), left dorsolateral prefrontal cortex (62 vox), and right insula (45 vox) (Figure 1). Time course plots of activity in these brain regions provided further support for increased and sustained processing across the trial after the personally relevant negative words in the ASD group (Figure 2). In the ASD group, correlations between heightened and sustained activity in the identified regions and poorer cognitive control and greater irritability were moderate and approaching significance.

Conclusions: fMRI findings indicate a heightened and sustained response to negative stimuli in youth with ASD in brain regions related to salience evaluations and cognitive control. This may provide a potential neural mechanism to explain poor emotion regulation in ASD. Prolonged processing

105 **127.105** Whole Brain Patterns of Cross-Frequency Coupling in ASD

***J. I. Berman**, S. Liu, J. C. Edgar, L. Blaskey and T. P. Roberts, Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Phase amplitude coupling (PAC) has emerged as a fundamental resting-state mechanism by which low-frequency (4-12Hz) cortical oscillations modulate or gate higher frequency oscillations such as gamma-band activity (30-80Hz). PAC is thought to facilitate the input of long-range networks to local connections and subsequent processing. Abnormally high midline parietal-occipital resting-state alpha-gamma PAC has been previously observed in children with autism spectrum disorder (ASD). This study introduces a novel whole-brain mapping of PAC in order to elucidate the spatial pattern of resting-state cortical dysfunction in ASD.

Objectives: This study hypothesized that the PAC abnormalities in ASD are network-wide and pervasive.

Methods: Participants included 26 children with ASD (mean age = 9.5, SD = 2.2) and 22 typically developing (TD) children (mean age = 10.5, SD = 2.4). Five minutes of eyes-closed resting-state data were obtained using a 275-channel MEG system (VSM MedTech). Using BESA, a 15 regional source model assessed cortical activity across the entire brain at an approximately lobar level. At each cortical source, PAC was computed for each frequency pairing allowing whole-brain mapping of PAC (PAC-map) as a function of both space and frequency pairing. For this study, PAC between alpha (9 to 11 Hz) and gamma (30 to 40Hz) was examined.

Results: Across both ASD and controls, PAC decreased with age in midline frontal, left parietal and right parietal regions (p<0.05, each). In the ASD group, PAC was lower in midline frontal, left parietal, and right parietal regions (p<0.05 each) and elevated in the occipital-parietal midline region (p<0.05) compared to controls. In the midline frontal region, PAC decreased with age at a slower rate in ASD than controls (p<0.01).

Conclusions: PAC was visualized throughout the cerebral cortex to enable characterization of the development and heterogeneity of this vital neural network process. A primary finding was that PAC decreased in frontal and parietal regions as a function of age, with a slower frontal PAC decrease in ASD than controls. Whole brain PAC-map may form the foundation of future studies examining spatial patterns of cortical dysfunction in ASD.

Poster Session
128 - Diagnostic, Behavioral & Intellectual Assessment

5:30 PM - 7:00 PM - Hall Grote Zaal

106 **128.106** ASD Diagnosis within the Medical Home: Feasibility, Sustainability, and Satisfaction

***J. F. Hine**[1], A. Pasternak[2] and Z. Warren[1], (1)Vanderbilt University Medical Center, Nashville, TN, (2)Vanderbilt Kennedy Center/TRIAD, Nashville, TN*

Background:
Early accurate diagnosis of Autism Spectrum Disorder (ASD) currently represents a challenging public health and clinical practice issue. Despite the wide-scale availability of effective screening tools for young children, waits for diagnostic assessment are still often quite lengthy and impede access of appropriate early intervention services. Embedded processes for effective triage and diagnosis of children at-risk for ASD within the medical home may be a viable mechanism for reducing age of detection and initiation of services.

Objectives:
We examined (1) the feasibility and value of incorporating ASD-specific assessment and targeted treatment services in primary care settings, (2) analysis of sustainability and financial viability of services, and (3) physician satisfaction with services. We hypothesized that embedding a psychologist with specific skills and training related to ASD diagnostic consultation could help accurately and rapidly identify many cases of ASD and potentially represent a more realistic model for advancing ASD identification.

Methods:
We developed explicit ASD diagnostic consultation and support clinics embedded across two medical center affiliated pediatric primary care programs. A psychologist was physically embedded in the clinic one day per week and available solely for providing follow-up for ASD-related concerns (e.g., failed screenings, diagnostic referrals, behavioral consultation). Data about referral types, show rates, and latency to consultation and diagnosis were used to assess feasibility and impact. Specific data regarding time, cost, and resources associated with implementation were collected via electronic medical records. We also surveyed medical providers regarding the benefits and challenges of the embedded service. They were asked their level of agreement with statements about whether integration of behavioral-health services improves the quality/continuity of healthcare, reduces added healthcare costs, increases show rates, and increases their own ability to identify/manage behavioral health concerns.

Results:
The embedded psychologist saw over 400 children and adolescents over 24 months, 60% of the patients were referred due to concerns for ASD. Of those patients, 42% received formal diagnoses of ASD. It was possible to make a diagnosis within the initial consult session for 60% of the children; further testing was required for the remaining children. The latency to evaluation and diagnosis for referred children was less than two months, compared with a minimum of 7-8 months for other specialty clinic assessments. Similarly, the median age at diagnosis (32 months) was considerably lower than the national average of approximately 50 months. Provider feedback indicated significant improvements related to quality and continuity of care and decreased waits for service. Updated clinical data and data regarding financial viability of the program over

time will be provided in detail.

Conclusions:

This study extends support for the value of embedding behavioral health services for children with ASD within pediatric primary care settings. Such models of care may reduce waits, age of diagnosis, and reduce other service barriers encountered by individuals with ASD and their families seeking services through referrals to traditional tertiary care facilities.

107 **128.107** Assessment and Diagnostic Practices for School-Aged Children with Autism Spectrum Disorders: A Survey of Canadian Clinicians

A. M. Yaholkoski[1], *J. M. Montgomery*[2] *and B. M. Stoesz*[1], *(1)Psychology, University of Manitoba, Winnipeg, MB, Canada, (2)Psychology, University of Manitoba, Winnipeg, MB, CANADA*

Background: Timely assessment for Autism Spectrum Disorder (ASD) is essential to provide a comprehensive understanding of child functioning, advise diagnosis, and inform individualized treatment. Although early diagnosis is ideal, many children with ASD are not identified until school age. Information to guide early diagnostic practice is widely available; however, information specific to diagnosing ASD in school-aged populations is limited. Some evidence-based practice guidelines for school-aged ASD diagnosis have been developed, however, results from studies conducted outside of Canada suggest that disparities between these practice guidelines and clinical procedures exist. Various challenges to using these guidelines have also been identified. To date, no research has been conducted to examine school-aged ASD diagnostic practices in Canada.

Objectives: The primary objectives of this study were to: (a) understand clinicians' knowledge, practices, and challenges encountered in screening, assessment, and diagnosis of ASD in Canadian school-aged children (i.e., ages 4-21 years); (b) compare Canadian clinicians' reports of procedures and assessment tools used to existing practice guidelines; (c) identify training and professional development needs; and (d) determine whether policy changes may be required to alleviate challenges in the diagnostic process.

Methods: Clinicians (i.e., school and clinical psychologists, psychiatrists, and physicians) involved in diagnostic assessment of school-aged children suspected of having ASD were recruited via Canadian professional organizations to participate. A web-based survey (using Qualtrics Survey Software) was used to gather information about knowledge, practices, and challenges for screening, assessment, and diagnosis of ASD. The survey consisted of four sections to gather information about: (1) referral, screening, and assessment processes; (2) tools used for screening, assessing, and diagnosing ASD; (3) broad assessment approaches for ASD diagnosis; (4) and participant demographics.

Results: Findings suggest both similarities and differences in perceived knowledge and expertise for ASD diagnosis, processes implemented, inter-professional consultation practices, and frequencies in using specific tools across professional groups and across Canada. Clinicians indicated that assessing comorbidities, difficulties organizing assessment teams, identifying ASD in higher functioning individuals, and lack of training/knowledge specific to ASD assessment are significant challenges. Although clinicians' responses indicated that they are generally aware of and follow evidence-based practice guidelines, in some cases, procedures differed from specific practice guidelines. This may reflect context specific constraints (e.g., access to specific tools and/or other professionals for consultation) rather than an awareness or unwillingness to follow recommended practice.

Conclusions: This study provides a picture of the current Canadian context for school-aged ASD assessment and diagnosis. Specifically, the findings contribute to an understanding of the extent to which Canadian clinicians conduct assessments in accordance with evidence-based practice guidelines for ASD diagnosis, and highlights reasons why they may be unable to adhere to some recommendations. This information may be used to inform the development of additional training opportunities, and highlight where funding and policy changes are required to alleviate challenges in the diagnostic process to increase access to timely, accurate identification.

108 **128.108** Assessment of Patterns of Play in Children with and without ASD and Their Relations with Maternal Behavior in Collaborative Play Interactions

C. Shulman[1,2] *and S. Shmueli*[2], *(1)The School of Social Work, The Hebrew University of Jerusalem, Jerusalem, Israel, (2)The School of Education, The Hebrew University of Jerusalem, Jerusalem, Israel*

Background:

Specific deficits in play distinguish children with autism from typically developing children. These include differences in type, level and duration (Kasari & Chang, 2014). Although symbolic play is significantly associated with later social (Sigman & Ruskin, 1999) and cognitive (Stanley & Konstantareas, 2007) development, equivocal findings regarding levels of play in children with ASD make it particularly important to characterize play patterns and investigate variables associated with better developmental outcomes.

Objectives:

By investigating play between mothers and their children in their homes with their own familiar toys, play can be evaluated naturalistically. Specifically, this study investigates the relationships between maternal sensitivity, maternal initiations and children's level and duration of play in young children with and without ASD. The levels of children's play included sensory manipulation, simple object manipulation, relational play, functional play and symbolic play.

Methods:

Ninety mother-child dyads participated in this study. Forty-five mother-child dyads involved children with ASD and 45 children with typical development, matched for mental age {ASD: M = 53.9 (20.20); TD: M = 56 (15.32)}. Mothers were asked to play with their children "as they typically would" and their play interaction was videotaped for later analysis. Play levels were assessed according to the coding system of Marcu, Oppenheim, Koren-Karie, Dolev, and Yirmiya (2009), with adaptations for home play, and emotional sensitivity was assessed using the Emotional Availability Scales – 4th Edition (Biringen, 2008). Maternal initiations and play act duration were calculated from the videotaped sessions.

Results:

Children with ASD exhibited more play acts, (t[88]=1.92, *p*=0.05), of shorter duration (t[88]=-2.12, *p*=0.02). Their play was characterized by lower levels of play, including simple object manipulation (t[88]=2.39, *p*=0.02), relational play (t[88]=2.01, *p*=0.05), and functional play (t[88]=-1.82, *p*=0.035), than those with TD. Mothers of children with ASD initiated more frequently than mothers of children with TD (t[88]=2.71, *p*=0.008), and interestingly, in both groups when mothers initiated more, their children played on a lower level {ASD: (r=-0.33, *p*=0.04); TD: (r=-0.36, *p*=0.08)} and for a shorter time {ASD: (r=-0.42, *p*=0.007; TD: (r=-0.43, *p*=0.008)}. No differences in maternal sensitivity emerged between groups.

Conclusions:

By evaluating levels of play of young children with and without ASD, and studying the relationship between their play and maternal behavior, this study supports the importance of looking at both the child and the play partner when characterizing variables associated with better outcomes. In addition, the need to study play in familiar contexts with real-life partners is underscored. These findings can serve as a foundation for interventions with young children with ASD, which should focus on socially mediated play using naturalistic strategies.

109 **128.109** Childhood Autism Screening Test (CAST) As a Screening Tool for ASD: Utility in a Community Population in Lagos, Nigeria

***E. A. Campbell**[1], B. Fadipe[1], K. A. Ogunsola[1], Y. Oshodi[2] and A. E. Lamikanra[3], (1)Lagos University Teaching Hospital, Lagos, Nigeria, (2)University of Lagos College of Medicine, Lagos, Nigeria, (3)Blazing Trails International, Frisco, TX*

Background:

Autistic spectrum disorder (ASD) is routinely screened during childhood in developed countries but still missed in developing countries. With increasing awareness about ASD, it has become pertinent for us to use simple tool to assist in early identification due to scarcity of manpower especially in our rural communities.

Childhood Autism Screening Test (CAST) a screening instrument developed as a combination of behavioural symptom of ASD according to International Classification of Disease (ICD-10) and Diagnostic and Statistical Manual fourth edition (DSM-IV) has been widely used in western societies. A few studies have reported use among African-American but none among Africans.

Objectives: To determine the utility of CAST for screening for ASD among individuals with neuro-developmental disorders in Lagos state, Nigeria.

Methods:

Participant were recruited during an annual community screening for autism and other neuro-developmental disorders which is a collaboration between a bank, Blazing Trail International USA (a Non-Governmental Organization) and Centre for Autism and Neuro-developmental Disorders (CANDo) of the College of Medicine, University Lagos. Participants were reached via mails, radio jingles word of mouth and text messages. They were screened in stages using a sociodemographic questionnaire, CAST for those aged 4 and above and diagnosis was based on DSM V criteria for ASD.

Results:

A total of 268 participants attended the screening exercise. Two hundred and eighteen individuals were attending for the first time (81.3%). More than three quarters were eligible for CAST (76.9%) and majority of them (83%) completed CAST. Sensitivity is 70.8%, specificity 60.4% and positive predictive value 52.3%.

Conclusions:

CAST was found to be a user friendly instrument with high specificity and sensitivity in diagnosis of ASDs. It should be considered for larger validation study for autism in Africa.

110 **128.110** Comorbidities and Adaptive Behavior Using the Behavior Assessment System for Children – Version 3 in Children with Autism Spectrum Disorder: Results from the ABC-CT Feasibility Study

***E. Pompan**[1], E. Baker[2], P. Renno[1], S. J. Webb[3], F. Shic[4], A. Naples[5], C. Sugar[6], M. Murias[7], R. Bernier[3], G. Dawson[8], C. A. Nelson[9], J. McPartland[5] and S. Jeste[6], (1)University of California Los Angeles, Los Angeles, CA, (2)UCLA Center for Autism Research and Treatment, Los Angeles, CA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (5)Child Study Center, Yale University School of Medicine, New Haven, CT, (6)University of California, Los Angeles, Los Angeles, CA, (7)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (8)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (9)Boston Children's Hospital, Boston, MA*

Background: Approximately 70% of children with autism spectrum disorder (ASD) develop comorbid psychiatric conditions that contribute to greater functional impairment (Simonoff et al., 2008). Despite the high prevalence of psychiatric comorbidities, they are inherently difficult to diagnose in children with ASD, and valid and reliable measures are needed (Lecavalier et al., 2014). Broad-based parent report measures, such as the *Behavior Assessment System for Children-Version 3 (BASC-3)*, can be useful for identifying co-occurring conditions and related functional impairment.

Objectives: This study investigated group differences in psychiatric symptoms and adaptive functioning in children with ASD and typically developing children. In addition, it examined convergent validity of the *BASC-3* in children with ASD and explored the relation between psychiatric symptoms and greater adaptive impairment.

Methods: As part of the Autism Biomarker Consortium for Clinical Trials (ABC-CT) feasibility study, we examined psychiatric symptoms and adaptive behavior in participants with ASD (n=23) and typically developing controls (n=26), ages 4-11 years, with IQ>50. Caregivers completed the *BASC-3,* the *Child & Adolescent Symptom Inventory-5 (CASI-5)/Early Childhood Inventory-5 (ECI-5)* parent questionnaires and the *Vineland Adaptive Behavior Scales, Second Edition (VABS-II)* interview. ASD diagnosis was confirmed using the *Autism Diagnositc Observation Schedule-2* (Lord et al., 2012) and the *Autism Diagnositic Interview-Revised* (Rutter, LeCouteur & Lord, 2003).

Results: Results from independent sample t-tests, revealed children with ASD had significantly higher standard scores on the *BASC-3* Externalizing Problems Composite (*t*(30.834)=-5.567, *p*<.001), Internalizing Problems Composite (*t*(47)=-3.775, *p*<.001), and the Adaptive Skills Composite (*t*(47)=10.558, *p*<.001) than typically developing children.

The *BASC-3* scale scores converged with the *VABS-II* domain scores with the exception of the socialization domain. The *BASC-3* Activities of Daily Living scale correlated with the *VABS-II* Daily Living Skills domain, (*r*=.677, *p*<.001). The *BASC-3* Functional Communication scale correlated with the *VABS-II* Communication domain (*r*=.580, *p*=.004). The *BASC-3* Social Skills scale did not correlate with the *VABS-II* Socialization domain (*r*=.308,

p=.152).

Furthermore, Pearson correlations indicated convergence of *BASC-3* clinical symptom scales and *CASI-5/ECI-5* scales. The *BASC-3* Hyperactivity scale correlated with the *CASI-5/ECI-5* Hyperactive-Impulsive scale (r=.798, p<.001). The *BASC-3* Attention Problems scale correlated with the *CASI-5/ECI-5* Inattentive scale (r=.431, p=.045). The *BASC-3* Anxiety scale correlated with the *CASI-5/ECI-5* Generalized Anxiety scale (r=.878, p<.001). The *BASC-3* Depression scale correlated with *CASI-5/ECI-5* Dysthymic scale (r=.767, p<.001).

The *BASC-3* Internalizing Problems Composite negatively correlated with the *BASC-3* Adaptive Skills Composite (r=-.416, p=.048). There was not a significant correlation between the Externalizing Problems Composite and the Adaptive Skills Composite (r=-.1, p=.65).

Conclusions: Findings indicate the BASC-3 demonstrates adequate convergent validity with more targeted, commonly used measures of psychiatric comorbidity (*CASI-5/ECI-5*) and adaptive functioning (*VABS-II*) in ASD. This study contributes to the growing literature on accurate assessment in ASD and suggests the *BASC-3* may be a useful broad-based parent report measure for identifying psychiatric conditions and adaptive impairment in children with ASD. Furthermore, findings on the relation between greater internalizing problems and poorer adaptive functioning skills may inform intervention research, as adaptive functioning skills may be an important focus of treatment in children with ASD and co-occurring internalizing symptomatology.

111

128.111 Day-to-Day Variability in Behavior Via Smartphone Data Collection from Caregivers of Children with Autism

R. M. Jones[1], *T. Tarpey*[2], *A. Hamo*[1], *C. Carberry*[1] *and C. Lord*[3], *(1)Weill Cornell Medicine, New York, NY, (2)Wright State University, Dayton, OH, (3)University of California Los Angeles, Los Angeles, CA*

Background: Mobile phones are woven into the fabric of our daily lives and thus offer the versatility to gather robust daily variations in behavior in a variety of contexts. Recent evidence suggests that smartphones have the ability to supplement and perhaps even replace traditional caregiver-report paper questionnaires that are broadly utilized in developmental research. Whether smartphones offer such promise for autism is unknown.

Objectives: The goal of the present study was to validate single questions on a smartphone completed by a caregiver of a child with autism across 8-weeks, compared to gold-standard, paper questionnaires. The second goal was to determine a method to accurately capture day-to-day fluctuations in caregiver reports about their child's behavior on the smartphone.

Methods: 20 caregivers completed single questions about their child's mood, irritability, disruptive behavior and anxiety on an 8-point scale across 8-weeks with a modified version of the JAKE™ application. Children were diagnosed with autism and were 5-13 years of age. Consistency between caregiver report on a smartphone versus standardized paper questionnaires was analyzed with mixed ordinal logistic regression models. A total variance measure for each smartphone question was calculated by combining the probability of responses on each day, so that total variance values close to 1 reflected high variability of responses to each number on the 0-7 scale across 8-weeks, whereas values close to 0 reflected little variation in smartphone responses. Lastly, we re-calculated the total variance with N days at the beginning and end of the study to determine how many days of data was necessary to accurately capture variability.

Results: All smartphone questions addressing irritability, negative mood, disruptive behavior, and anxiety were significantly associated with the standard caregiver questionnaires and related subscales on the Aberrant Behavior Checklist (ABC), Child Behavior Checklist (CBCL) and the Positive and Negative Affect Schedule (PANAS) (p's < 0.05). Maternal education influenced caregiver reporting, such that the more educated the mother, the more severe children were rated on the smartphone, specifically irritability and disruptive behaviors. We found that greater variability on the smartphone questions that targeted mood, irritability and disruptive behavior across the eight weeks corresponded to more severity on the standard paper questionnaires listed above. Interestingly, increased variance on one smartphone question was associated with increased variance on another. Lastly, 7-10 days at the beginning and 7-10 days at the end of the study were able to capture similar amounts of variance as 8-weeks worth of data.

Conclusions: These findings suggest that the smartphone questions were consistent with standardized measures and thus in the future smartphone questions may be used to save time for studies in lieu of longer questionnaires. In addition, these findings suggest that it may be sufficient to deploy cell phones for a week at the beginning and end of an intervention study in order to reliably capture change. Together the data support the use of smartphones as a flexible method to gather data about a child with autism outside of a clinical setting.

112

128.112 Delay of Diagnosis in ASD

L. Verhoeven[1], *D. van Dijk*[2], *P. van Deurzen*[3] *and W. G. Staal*[4,5], *(1)Dr Leo Kannerhuis, Doorwerth, Netherlands, (2)Research, Development & Innovation, Dr Leo Kannerhuis, Doorwerth, Netherlands, (3)Karakter, NIjmegen, Netherlands, (4)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Department of Cognitive Neuroscience, Nijmegen, Netherlands, (5)Institute for Brain and Cognition, Leiden University, Leiden, Netherlands*

Background:

Timely diagnosis of autism spectrum disorders (ASD) is of major interest for public health, patients and caregivers. So far, the majority of studies have focused on age of ASD diagnosis. However, the diagnostic process is an important factor to consider when trying to establish an early age of diagnosis. The few studies on this subject indicate a rather long diagnostic process.

Objectives:

The present study emphasizes on the duration of the diagnostic process, the diagnostic delay. The studies aimed to assess the mean diagnostic delay as well as to identify factors associated with this potential delay (predictors).

Methods:

For this purpose a cohort study with retrospective data collection was conducted among a population of individuals with ASD who were referred for diagnosis or care to mental health care centers specialized in ASD in the Netherlands. A random sample of 814 individuals with ASD referred in the period between May 2013 – April 2014 was included.

Eight potential factors (predictors) that could influence the diagnostic process were assed: age at first contact with mental healthcare/welfare, age of ASD diagnosis, gender, intellectual disability, current psychiatric comorbidity, prior diagnosis, year of first contact with mental healthcare/welfare, and the amount of previous mental healthcare/welfare tracks.

Analysis regarding diagnostic delay included expression of the mean, median, and standard deviation and illustrated by a Kaplan Meier curve. Second, the relationships between diagnostic delay and the included predictors of delay were tested. Pearson correlation coefficients were conducted between diagnostic delay and our continuous predictors (number of mental healthcare/welfare tracks, age at first contact with mental healthcare/welfare, age of ASD diagnosis, and year of first contact with mental healthcare/welfare). Student's *t*-test were conducted to asses potential differences in delay regarding the categorical predictors (gender, intellectual disability, the presence of prior diagnosis, and the presence of comorbid diagnosis). As a final step, a linear multiple regression analysis was performed including all predictors.

Results:

Results showed that diagnostic delay ranged from 0 to 366 months with a median of 19 months and a mean of 35.7 months (three years). Of all individuals with ASD, 25% received the ASD diagnosis within 2 months and the last 25 % 'waited' for longer than 4.2 years. A longer diagnostic delay was associated with several factors including a higher number of previous mental healthcare/welfare tracks, an earlier year of first contact with mental healthcare/welfare, an older age of ASD diagnosis, more prior diagnosis, and more comorbidity. Gender and intellectual disability were not related to diagnostic delay.

Conclusions:

Although findings indicated that the diagnostic delay for ASD has been reduced for individuals encountering welfare/mental health care in more recent years, the majority of individuals still show a considerable diagnostic delay. This observed diagnostic delay shows spacious room for improvement in the diagnostic process.

113

128.113 Detection of Ignored Autism Spectrum Disorder By Simple External Observation in Kindergarten: A Proof of Concept Study

E. Castagna[1], *R. Pirovano*[2], *A. Castelnuovo*[1], *E. Alfiedi*[1], *G. Lanzi*[1], *F. Bernasconi*[1], *M. Norsi*[1] *and E. Grossi*[2], *(1)Autism Research Unit, Villa Santa Maria, Tavernerio, Italy, (2)Autism Research Unit, Villa Santa Maria Foundation, Tavernerio, Italy*

Background:

Kindergarten is a privileged opportunity to observe children's behavior in a natural context. This possibility allows for detecting signs of derangement in motor and neuropsychological development not otherwise previously observed.

Our group has developed a standardized protocol with a checklist containing over 284 items for carefully detecting delay in the acquisition of a given capacity according to age related international developmental nomograms.

Objectives:

The aim of this study is to assess the feasibility and effectiveness in the screening of ASD by simply observing child behavior while at Kindergarten.

Methods:

The protocol included two different tests:

- The Denver Developmental Screening Test (Denver test)is a 41 item test for screening development of infants and preschool-aged children; items cover four general functions: personal social (e.g. smiling), fine motor adaptive (e.g. grasping and drawing), language (e.g. combining words), and gross motor (e.g. walking). Test age range 0-6.
- The Adaptive Behavior Assessment System – Second edition (ABAS – II) containing 216 items is a global and normative assessment scale of behavior that measures daily life skills. The project protocol provides for teacher/caregivers questionnaires regarding subjects aged 2-5. It investigates 10 adaptive areas: Communication, Preschool/School skills, self-Control, Playing/leisure, Socializing, Self-Care, Home Care/School, Environmental Use, Health and Safety, Work.

Expert psychomotor and education therapists with the supervision of a senior neuro-pediatrician (MN), observed and interacted with 62 children, aged 36 - 65 months, attending the "Istituto Comprensivo Don Milani" in Tavernerio (Como, Italy) during two sessions and after obtaining written informed consent.

Seven out of 62 children were found to be affected by neuro-psychiatric disorders (ASD; Down syndrome; delay of psychomotor development; Cerebral Palsy; developmental disorder; hyperactivity)

Our staff was pleasantly accepted in the classroom and was able to collect all the information required. The school teachers learned basic skills to heighten their observation capabilities in child behavior as a result of interacting with our professional staff.

Results:

In the 55 children without previous diagnoses of neuro-psychiatric disorders, the application of the Denver test and ABAS scales pointed out the presence of 7 and 12 cases respectively with at least one (range 1 - 6) item not corresponding to chronological age. The integration of this information with the experience and skills of our staff resulted in the recognition of possible undetected developmental disorders and the subsequent invitation to parents to bring the children in question to a neurodevelopmental diagnostic unit.

In one of these cases, an Autism Spectrum Disorder (ASD) diagnosis was made.

In one of two other cases, parents did not continue with the diagnosis, in the other, a pediatric psychiatrist did not confirm the presence of language developmental delay (table 1).

Conclusions:

This experience shows that structured external observation in a kindergarten is a feasible and promising approach for the screening and the early detection of neurodevelopmental disorders. ABAS II seems to provide increased sensitivity in detecting suspicious cases.

114

128.114 Development and Validation of Objective, Eye Tracking-Based Risk and Symptom Measures for Autism

T. W. Frazier[1,2], *E. W. Klingemier*[3], *A. Y. Hardan*[4], *C. Eng*[5], *M. S. Strauss*[6], *L. Speer*[2], *S. Parikh*[2] *and E. Youngstrom*[7], *(1)Autism Speaks, New York, NY, (2)Cleveland Clinic, Cleveland, OH, (3)Cleveland Clinic Center for Autism, Cleveland, OH, (4)Psychiatry and Behavioral Sciences, Stanford University,* *Stanford, CA, (5)Genomic Medicine, Cleveland Clinic, Cleveland, OH, (6)Psychology, University of Pittsburgh, Pittsburgh, PA, (7)University of North Carolina at Chapel Hill, Chapel Hill, NC*

Background: At present, there are no validated, objective, quantitative, scalable assessment tools for autism spectrum disorder (ASD).
Objectives: To develop and validate eye tracking-based measures for estimating ASD risk and quantifying autism symptom levels.

Methods: Patients were recruited into this cross-sectional, case-control study from a tertiary care, multi-disciplinary, autism diagnostic evaluation clinic. Eye tracking data were collected during a single evaluation visit with administrators blinded to all clinical information. Participants included 201 children referred for evaluation of possible developmental disorder who completed a valid eye tracking assessment (ages 1.6-17.6; 80% male; ASD n=91, non-ASD n=110). Consensus clinical diagnoses were given by the multidisciplinary team based on Autism Diagnostic Observation Schedule-2 (ADOS-2) results, developmental history, physician evaluation, and additional clinical measures. Participants viewed a 5-minute video that included 44 dynamic stimuli from 7 distinct paradigms while gaze was recorded. Five gaze metrics (glances, fixation count, fixation duration percent, first fixation duration, and average fixation duration) were computed for temporally-defined regions-of-interest within each stimulus. Autism risk and symptom indices were created by aggregating across gaze measures showing significant bivariate relationships with ASD diagnosis and ADOS-2 symptom severity levels in a training sample (75%, n=150). Receiver operating characteristic curve analysis and non-parametric correlations were used to cross-validate identification of ASD diagnosis and autism symptom severity in a test sample (25%; n=51).

Results: The autism risk index had excellent accuracy for identifying ASD diagnosis in the training sample (AUC=.92, 95%CI=.88-.96) and maintained high accuracy in the test sub-sample (AUC=.86, 95%CIs=.75-.95; Figure 1). Autism symptom indices were strongly associated with ADOS-2 total, social affect, and restricted/repetitive behavior severity scores (smallest r=.26, p=.040). The autism risk index had high internal consistency reliability (α=.92) and wide quantitative range, with 95% of non-ASD cases falling from z=-2.3 to 1.6 and 95% of ASD cases falling from z=-0.1 to 5.0. The majority of missed cases (68%) fell within +/-0.75 SD of the optimal cut point z=0.74. Autism symptom indices had high internal consistency reliability (α>=.93). Validity of autism risk and symptom indices was not substantively attenuated after adjustment for language, non-verbal cognitive ability, or other psychopathology symptoms (r=.40-.67, p>.001), indicating that the eye-tracking based measures were highly specific to autism.

Conclusions: Eye tracking measures may be useful quantitative, objective measures of ASD risk and autism symptom levels. Future studies with large, multi-site samples are needed to replicate these findings and determine their generalizability, including resistance to sampling differences and minor procedural variations. If replicated and scaled for clinical use, eye tracking-based risk and symptom measures could be used to inform clinical judgment regarding ASD identification and to track autism symptom levels in clinical trials and longitudinal studies.

115 **128.115** Discriminant Validity of the Autism Spectrum Screening Questionnaire Parent Form to Preschool Children

M. Adachi[1], *M. Takahashi*[1], *N. Takayanagi*[2], *S. Yasuda*[3], *Y. Sakamoto*[4], *M. Tanaka*[5], *A. Osato*[4], *S. Kato*[6], *M. Saito*[4] *and K. Nakamura*[4], *(1)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Aichi Toho University, Nagoya, Japan, (3)Research Center for Child Mental Development Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (4)Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (5)Hokkai gakuen University, Sapporo, Japan, (6)Aomori Chuo Gakuin University, Aomori, Japan*

Background:The Autism Spectrum Screening Questionnaire(ASSQ;Ehlers et al.,1999) was developed to screen school children for HF-ASD. Although the ASSQ consists of only 27 items, it has shown both validity and reliability, with good sensitivity and specificity in clinical settings. Although the ASSQ has been psychometrically tested in only 7-16-year-old children, an application for younger children than 7-year-old is also expected to make early detection of HF-ASD and prevent secondary maladjustment of them. There have been reports of ASSQ being used for six-year-olds in other studies and earlier practical clinical usages(Kopp et al.,2011). As such, it is important to examine the scale's psychometric properties and discriminant validity, especially when considering the application of the instrument at an earlier age.
Objectives:This study examined the psychometric properties of applying the ASSQ for preschool children.

Methods:Two groups of children took part in the current study. The first "community" group(*N*=1390) who were recruited from a Hirosaki Five-year-old Child Developmental Health Check-up Study, which assessed the mental health of children in the city, from 2013 to 2016. The questionnaires were sent to the parents of five-year-old children after which those who agreed to participate in the study(through their informed consent) answered the questionnaires and sent them back to the municipal health center. The response rate was 74.6%. The second "clinical" group consisted of children from affiliated research centers with Graduate School of Medicine, Hirosaki University. This group consisted of 60 children diagnosed ASD and 94 children with Non-ASD neuropsychiatric diagnoses.

Results:There was a good internal consistency for the ASSQ in both the clinical and community group with Cronbach's alpha of .844-.881. The results from Kruskal-Wallis tests, only one item "Is old-fashioned or precocious" was not able to discriminate between ASD and Community group. Meanwhile, in 19 of 27 items, there was a difference in scores between the ASD and the Non-ASD group, so that certain discriminant validity was also shown within the clinical group. ROC analyses revealed the full extent of the scale's ability to distinguish children with ASD against community children with an area of 0.960 under the curve(95%CI: 0.939–0.981). A score of 6.5 on the ASSQ had a sensitivity of 0.933 and a specificity of 0.835 when it is used as a primary screening tool. On the other hand, discriminatory power within clinical groups was lower than discriminant power of the ASSQ in distinguishing the ASD from the Community children(AUC=0.749, 95%CI=0.671–0.826). A score of 6.5 had a sensitivity of 0.933 and a specificity of 0.319, while a score of 13.5 resulted in sensitivity reducing to 0.650 but specificity increasing to 0.734.

Conclusions:The results showed that, just like in the case of school-aged children, the ASSQ had reliability and validity as a screening instrument in both community and clinical settings for pre-school children. However, the analysis of the ASSQ subscale items showed that only for number 1, namely, "Is old-fashioned or precocious," the score of the community group was higher than that of the ASD group; this revealed the possibility that this decreased the discriminant validity.

116 **128.116** Does Intention Lead to Success? Social Camouflaging in Autistic Girls

L. Hull[1], *K. V. Petrides*[2] *and W. Mandy*[1], *(1)University College London, London, United Kingdom of Great Britain and Northern Ireland, (2)London Psychometric Laboratory, London, United Kingdom*

Background: Social camouflaging (the use of compensation or masking strategies to minimise autistic characteristics during social interactions) has recently come to attention as a behaviour common in autistic women and girls. Qualitative research has suggested that social camouflaging strategies may result in missed or late diagnosis for autistic girls, in addition to poor mental health outcomes resulting from the effort required to camouflage successfully. Previous research into camouflaging has focused on the observable strategies used mostly by adults; no research has yet compared autistic girls' intentions to camouflage with the success of their attempts.
Objectives: To test a recently developed measure of self-reported camouflaging and compare this to other measures of camouflaging, including a measure of camouflaging success, amongst autistic teenage girls. Questions of interest: Do autistic girls report camouflaging at similar levels to autistic women? Is self-reported camouflaging related to objective social skills?

Methods: Approximately 60 autistic girls aged 13-19 will be included in the final sample. Multiple measures of camouflaging are used, including the newly developed and validated Social Camouflaging in Autism Questionnaire, and the discrepancy between an individual's internal experience of autism and their external presentation. Success of camouflaging is measured through blinded observer ratings of autistic girls' sociability and likeability during a social interaction in which they camouflage.

Results: Data collection is ongoing; however, we expect to find that autistic girls report relatively high levels of camouflaging, and that their camouflaging is on the whole successful. In these preliminary results we also report on the relationship between different measures of camouflaging, and how age and cognitive abilities affect camouflaging extent and success

Conclusions: This is the first known study to examine the relationship between different measures of social camouflaging and its impact on the social skills of autistic girls. Reflections on the extent and success of camouflaging strategies in autistic girls will be discussed. Camouflaging is an important behaviour amongst autistic girls and should be considered during diagnosis and by other services when considering support requirements.

117 **128.117** DSM-5 Levels of Support and Autism Severity Ratings

T. Dawkins[1] *and M. Van Bourgondien*[2]*, (1)The University of North Carolina - Chapel Hill, Carrboro, NC, (2)University of North Carolina at Chapel Hill, Carrboro, NC*

Background: Given the variability in symptom severity within individuals with Autism Spectrum Disorder (ASD) and the need for quantifying the severity of symptoms for determining service provision needs, the authors of the DSM-5 ASD criterion included severity ratings in the areas of Social Communication(SC) and Restricted and Repetitive Behaviors (RRB). This severity marker is based on "Levels of Support" and classified in terms of Level 1 ("Requiring support), Level 2 ("Requiring substantial support") and Level 3 ("Requiring very substantial support"). The inclusion of these ratings were not based on any empirical data and to date, few studies in which the relationship between the severity ratings of established measures of autism symptoms and severity such as the Autism Diagnostic Observation Schedule-Second Edition (ADOS-2), the Childhood Autism Rating Scale-Second Edition (CARS2) and the Social Responsiveness Scale-Second Edition (SRS-2) have been published (Reszka, et al, 2014; Weitlauf, et al, 2014). Further, the studies published thus far were conducted prior to the publication of the finalized DSM-5 ASD criterion. Thus, there is a need to examine the relationship between existing measures of autism symptoms, cognitive ability and adaptive skills to better understand how these variables may influence the assignment of DSM-5 severity ratings at the time of diagnosis.
Objectives: The goal of the current study is to investigate the relationship between autism symptoms, associated features of autism (cognitive ability, adaptive skills and language level) and the assignment of DSM-5 levels of support.

Methods: The data included within this study was obtained through a secondary data set pulled from the University of North Carolina TEACCH Autism Program Research Registry. The database contains records of 11, 358 individuals, 754 of whom, were evaluated for autism at one of the 7 outpatient community-based centers of the UNC TEACCH Autism Program in North Carolina, by a local school, or other agency that provided evaluation for autism and a diagnostic report from which the data was pulled and added to the database. DSM-5 Severity ratings of SC as well as RRB were available for all 754 individuals included within the dataset of the present study. The dataset included scores from measures of cognitive development, adaptive skills, and severity of autism (as measured by the ADOS2, CARS2, and/or SRS-2 when available). The TEACCH Centers conduct diagnostic evaluations on all ages from toddlers through adults. Thus, the age range of participants with DSM-5 Severity Ratings was 1 through 68 years.

Results: Preliminary analyses indicate that clinical impression of autism severity (.000), as measured by clinician ratings of severity of autism on the CARS2, scores of adaptive skills (.000), and severity of symptoms as measured by the ADOS (.022) were positively correlated with DSM-5 SC level of severity rating. Clinical impression as rated on the CARS2 (.000), and adaptive scores (.005) were positively correlated with DSM-5 RRB severity rating.

Conclusions: In a community based sample, clinician impressions and direct assessment of autism symptom severity were associated with DSM-5 Level of severity assignment. Implications for clinical diagnosis will be discussed.

118 **128.118** Empathy in Adolescent Girls with Autism; Quantity and Quality of Their Reactions

C. Rieffe[1]*, D. Willems*[2]*, F. R. Sedgewick*[3]*, L. Hull*[4]*, E. M. Blijd-Hoogewys*[5] *and L. Stockmann*[6]*, (1)Leiden University, Leiden, Netherlands, (2)Developmental Psychology, Leiden University, Leiden, Netherlands, (3)Centre for Research in Autism and Education (CRAE), London, United Kingdom of Great Britain and Northern Ireland, (4)University College London, London, United Kingdom of Great Britain and Northern Ireland, (5)INTER-PSY, Groningen, Netherlands, (6)Centrum Autisme Rivierduinen, Leiden, Netherlands*

Background: Autism in girls is receiving increasing attention internationally, but it is still unclear where or how behavior with their male counterpart coincides or deviates. Better social skills in girls have frequently been noted as an possible feature that makes it more difficult to detect autism in females. Another issue that might disguise female autism is that girls without autism react differently to another person in distress than boys. Whereas girls more often offer emotional support, boys more often tend to solve the problem (Banerjee, Rieffe, Meerum Terwogt, Gerlein, & Voutsina, 2006). The question is to what extent this also applies to girls with autism.
Objectives: In this study we examined the extend to which girls with autism act in line with girls without autism, and react emotion-focused to pain in another person; or whether they show the more male oriented behavior and react more problem-focused.

Methods: We presented female and male adolescents (mean age 13 years old, range 110-161 months) with and without autism with an in-vivo empathy task. The experimenter pretended to hurt herself and participants' reactions were video-taped. Based on these recordings, we coded the extent to which the participants paid attention to the event/experimenter when she was showing a pain reaction. In addition, we coded the extent to which participants reacted to the experimenter's pain (emotion-focused), or tried to offer a solution for the problem (problem-focused).

Results: Most female adolescents reacted empathically, regardless their diagnoses of autism or not, and almost all reactions were emotion-focused. Yet, half of the male adolescents in both groups did not react to the distress in the experimenter. Moreover, many male adolescents also avoided to make eye contact with her. Within the group of male adolescents who did react to the event, many gave a problem-focused reaction. The remaining male adolescents gave emotion-focused reactions, but less often than the female adolescents.

Conclusions: The outcomes showed that empathic reactions to a pain episode differ quantitatively and qualitatively between female and male adolescents, in line with the literature on community populations. This finding also extends to adolescents with autism. These outcomes can shed more light on the different phenotype of girls with autism.

119 **128.119** Experiences of the Autism Spectrum Disorder Diagnostic Process from the Perspective of Individuals, Families and Practitioners: A Systematic Review

B. Afsharnejad[1,2,3]*, A. J. Whitehouse*[1,4,5]*, J. Wray*[6]*, V. Eapen*[7,8]*, M. R. Prior*[9] *and K. Evans*[1,4]*, (1)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (2)Autism Research Team, Telethon Kids Institute, Perth, Australia, (3)School of Occupational Therapy and Social Work, Curtin University, Perth, Australia, (4)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (5)University of Western Australia, Perth, Australia, (6)State Child Development Service, Western Australia Department of Health, Perth, Western Australia, Australia, (7)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (8)School of Psychiatry, University of New South Wales, Sydney, Australia, (9)The University of Melbourne, Melbourne, Australia*

Background: In recent years, an increasing number of individuals have been diagnosed as being on the autism spectrum. The diagnosis of autism spectrum disorder (ASD), along with the diagnostic process, can significantly affect these individuals and their families. However, there is not a consistent understanding of the experiences of these individuals and their families within the existing literature.
Objectives: This systematic review evaluated the extent and quality of the existing published literature regarding diagnostic experiences of individuals on the autism spectrum, their families and their practitioners.

Methods: The systematic review was conducted according to the PRISMA statement (Preferred Reporting Items for Systematic reviews and Meta-Analyses). A systematic database search was conducted of the academic literature describing the experiences of individuals on the autism spectrum and/or their families or practitioners during the ASD diagnostic process. The search was limited to journal articles and postgraduate theses published in English during the past decade. Search terms (title, abstract and key word) were establish synonyms for the three concepts of ASD, diagnosis and experience. CINAHL, Cochran Library, Embase, Medline, Proquest, PsychInfo, PubMed, Science Direct, Scopus and Web of Science were searched, resulting in a total of 11,940 documents (5,110 once duplicates were removed). This resulted in 54 articles for inclusion once the abstract and/or full text were reviewed for relevance. A data extraction form was used to summarise the articles, and a thematic data analysis approach was utilised to identify themes. Quality was evaluated by using the 'Kmet forms' for quantitative and qualitative studies or the AMSTAR form for systematic reviews.

Results: Three inter-related themes emerged from the literature: approach, support and process. In relation to approach, a strengths-focused and individual/family centered approach was advocated, where it was recommended the individual's and family's strengths, interests and goals be explored. This was perceived to promote optimism and hope, whilst keeping in perspective that ASD is a significant and lifelong disability. In terms of support, the provision of informational and emotional support during the ASD diagnostic process were appreciated. Providing a comfortable and private environment for sessions, using an empathetic communication style and making referrals for support groups was suggested to address this issue. This was identified as one of the most challenging aspect of diagnosing ASD by the practitioners. Finally, a coordinated, efficient and comprehensive process through-out the diagnostic process was considered important, where accurate and clear information is provided to the family.

Conclusions: The perspective of individuals, families and practitioners illustrated that an ASD diagnosis is often associated with a wide range of positive and negative emotions. The experiences of these key stakeholders suggested that it would be beneficial for an ASD diagnostic process to involve a strengths-focused and individual/family centered approach, provision of informational and emotional support, and a coordinated, efficient and comprehensive process.

120 **128.120** Exploration of Diagnostic Validity of Autism Diagnostic Observation Schedule (ADOS) in Korean Population

G. Bong[1]*, M. Oh*[2]*, I. H. Cho*[3]*, Y. S. Lee*[4]*, M. S. Kim*[5]*, D. W. Han*[6]*, C. Y. Shin*[7] *and H. J. Yoo*[8]*, (1)Psychiatry, Seoul National University Bundang Hospital, Seungnam, Korea, Republic of (South), (2)Psychiatry, Seoul National University Bundang Hospital, Sungnam, Korea, The Republic of, (3)Dr. Cho's Child & Adolescent Psychiatric Clinic, Seongnam, Korea, Republic of (South), (4)Department of Physiology, Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of (South), (5)Department Applied Chemistry, Kyung Hee University, Seoul, Korea, Republic of (South), (6)Dept. of Stem Cell Biology, School of Medicine, Konkuk University, Seoul, Korea, Republic of (South), (7)Department of Neuroscience, School of Medicine, Konkuk University, Seoul, Korea, Republic of (South), (8)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, The Republic of*

Background: Autism Diagnostic Observation Schedule (ADOS) has been widely used as one of the gold standard instruments for the diagnosis of ASD. However, research on the use of the ADOS and its applicability in individuals with ASD across non-English speaking populations is limited.
Objectives: ADOS has been widely used as one of the gold standard instruments for the diagnosis of ASD. However, research on the use of the ADOS and its applicability in individuals with ASD across non-English speaking populations is limited.

Methods: We used pooled data of ADOS from an ASD genetic study, clinical trials of social skills trainings, research on the development of early screening instruments, and clinical records of Seoul National University Bundang Hospital referred to diagnostic evaluation from 2008 to 2017. The subjects were composed of individuals with ASD, their unaffected siblings, children with other developmental delay referred for diagnostic evaluation, and typically developing children volunteered via community channels. Either ADOS or module-T of ADOS-2 were administered and scored by professionals whose research reliability had been established. Autism Diagnostic Interview–Revised (ADI-R) was also administrated.

Other measurements for ASD symptoms were administrated as well, including Social Responsiveness Scale (SRS), Social Communication Questionnaire (SCQ), and Korean version of the Childhood Autism Rating Scale (K-CARS). Clinical best estimate diagnosis was established by two board-certified psychiatrists based on DSM-IV-TR and DSM-5^{TM} criteria. We classified the *Best Estimate Clinical Diagnosis* into ASD (including pervasive developmental disorder and Asperger's syndrome) and non-ASD. *Autism* and *ASD* in ADOS classification and *mild-moderate concern* and *moderate-severe concern* in module-T of ADOS-2 were considered as ASD in the *ADOS Diagnosis*. Statistical analyses were performed to compare those two diagnoses using SPSS 22.0 and *t*-test and Cohen's kappa were used to compare the two groups.

Results: Data from total 1,248 subjects (age 90.29±62.04 months, 912 males, 336 females) were collected (Module-T, n=86; Module-1, n=385; Module-2 n=260; Module-3 n=285; Module-4, n=232). The sensitivity and specificity of ADOS showed sufficient degrees (Module-T=100%, 94.55%; Module-1=100%, 89.36%; Module-2=97.83%, 97.40%, Module-3=98.44%, 96.82%;, Module-4=99.29%, 92.39%) across all modules. Positive Predictive Value (PPV) was 97.37 (91.18 to 98.90) and Negative Predictive Value (NPV) was 98.31 (94.94 to 100), depending on modules. The agreement between all the modules of ADOS and clinical diagnosis were at excellent levels (*k*=.948; Module-T, *k*=.926; Module-1, *k*=.937; Module-2, *k*=.945; Module-3, *k*=.950; Module-4, *k*=.927) and other measurements' were at good to excellent levels (Cohen's kappa of ADI-R, K-CARS, SCQ and SRS with ADI-R =.844, .810, .625, .656, respectively). Individual item analyses showed significant differences in scores for all algorithm items on module 1 to 4 between ASD and non-ASD groups (*p*<.05). In module T, 'D2-Mannerism,' and 'D5-Repetitive Behavior' items were not statistically significant, falling between *two* groups.

Conclusions: The Korean version of ADOS showed high level of diagnostic validity in all modules. This study suggests that ADOS might be a valuable diagnostic instrument for individuals with ASD across countries with different languages and cultural backgrounds. Further analysis is required with larger samples to examine the validity of individual items of Module-T.

121 **128.121** Exploring Autism Symptoms in Individuals with Prader-Willi and Angelman Syndromes

E. K. Baker[1]*, D. E. Godler*[2]*, D. Amor*[3]*, M. Bui*[4]*, C. Rogers*[5]*, M. Field*[6] *and L. Bretherton*[1]*, (1)Murdoch Children's Research Institute, Melbourne, Australia, (2)Genetics, Murdoch Children's Research Institute, Melbourne, Australia, (3)Victorian Clinical Genetics Service, Melbourne, Australia, (4)Centre for Epidemiology and Biostatistics, University of Melbourne, Melbourne, Australia, (5)Hunter Genetics, GOLD Service, Newcastle, Australia, (6)Hunter Genetics, Newcastle, Australia*

Background: Prader-Willi syndrome (PWS) and Angelman syndrome (AS) are imprinting disorders that are caused by genetic or epigenetic changes at the same locus on chromosome 15. PWS results from the loss of paternal genes from chromosome 15q11.2-q13 while AS from the absence of the maternal genes in the same region. Overexpression of maternally imprinted genes in the 15q11-13 region is also a susceptibility factor for autism spectrum disorder (ASD), which is observed in both PWS and AS. Individuals with PWS are reported to have social withdrawal, compulsive behaviours and repetitive speech. In contrast, those with AS are more likely to be eager to communicate and engage socially. However most research to date has relied on parent-report rather than through objective assessment.

Objectives: (1) to explore symptoms of ASD in well-characterized samples of individuals with PWS and AS; (2) to compare rates of ASD between individuals with PWS and AS; and (3) to compare intellectual functioning between those meeting criteria for ASD compared to those classified as non-ASD.

Methods: Twenty-three individuals with PWS (47.8% male; age 1.5 – 32.2 years) and 14 individuals with AS (50.0% male; age 2.8 – 39.7 years) participated in the study. The Autism Diagnostic Observation Schedule-2nd Edition (ADOS-2) was used to assess ASD symptoms. The Mullen Scales of Early Learning was used to assess intellectual functioning in PWS children aged under 3 years and all individuals with AS. For the remaining PWS participants, the age appropriate Wechsler intelligence scale was used to assess intellectual functioning.

Results: The criteria for ASD were met by 16 (69.6%) PWS participants compared to five (35.7%) AS participants, however the difference was not significant ($\chi^2 = 2.801$, *p* = .094). The mean Calibrated Severity Score (CSS) for the total (PWS: Median [*Md*] = 7.00; AS: *Md* = 3.00) and the Social Affect (SA; PWS: *Md* = 6.00; AS: *Md* = 3.00) domains of the ADOS-2 were significantly higher in PWS participants (*p* = .003 and .001, respectively); however the two groups did not differ on Repetitive and Restricted Behaviour (RRB) CSS scores (PWS: *Md* = 6.00; AS: *Md* = 6.00; *p* = .408). Individuals with PWS meeting criteria for ASD on the ADOS-2 had significantly lower VIQ (*p* = .006) and FSIQ (*p* = .018) scores compared to PWS patients not meeting criteria for ASD. In the AS group, no significant differences were found between the two groups on the intellectual functioning domains (*p* > .05). Exploratory analyses revealed that SA behaviours tended to differentiate those meeting criteria for ASD compared to Non-Spectrum cases, rather than RRBs.

Conclusions: ASD symptoms, particularly SA deficits were more common in individuals with PWS compared to individuals with AS; though the rate of ASD did not significantly differ between the two groups. Meeting criteria for ASD was associated with lower intellectual functioning scores in individuals with PWS, but not those with AS; though effect sizes were moderate to large.

122 **128.122** Exploring the Experience of Seeking an Autism Diagnosis As an Adult: Findings from Online Submissions and Interviews

M. De Broize[1,2]*, K. Evans*[2,3]*, A. J. Whitehouse*[2,3,4]*, J. Wray*[5]*, V. Eapen*[6,7]*, M. R. Prior*[8] *and* ***A. Urbanowicz***[2,9]*, (1)Queensland Centre for Intellectual and Developmental Disability, MRI-UQ, The University of Queensland, South Brisbane, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (4)University of Western Australia, Perth, Australia, (5)State Child Development Service, Western Australia Department of Health, Perth, Western Australia, Australia, (6)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (7)School of Psychiatry, University of New South Wales, Sydney, Australia, (8)The University of Melbourne, Melbourne, Australia, (9)Queensland Centre for Intellectual and Developmental Disability, MRI-UQ, The University of Queensland, Brisbane, Australia*

Background: Ideally, diagnosis of Autism Spectrum Disorder (ASD) should occur by three years of age. However, due to a number of factors an accurate assessment often does not occur until between six and eight years old. People who are not diagnosed at early ages experience greater challenges to receiving an accurate diagnosis as time progresses. There is a limited body of research, particularly within the Australian context, describing the experiences of adults who seek an ASD diagnosis.

Objectives: This project aimed to explore the diagnostic experiences of adults who seek an ASD diagnosis as an adult.

Methods: This qualitative study used two unique data sets: online written submissions and interview transcripts. Australian adults who identified as being autistic were eligible to participate. A total of 36 participants were involved in this study, with a median age of 42 years (range = 27 – 80 years) and a gender distribution of 24 females and 12 males. Twenty-two completed an online submission answering the question "From your perspective, what are the most important considerations to address when developing a national guideline for the diagnosis of autism spectrum disorder in Australia?" Online submissions had to be written in English and had a limit of 100 words. Semi-structured interviews were conducted with 14 participants, where experiences before, during and after diagnosis were discussed. Online submissions and interview transcripts were imported into NVivo 11 and were analysed using thematic analysis.

Results: Three major themes emerged from the data describing experiences prior to, during and following an ASD diagnosis in adulthood.

Experiences prior to ASD diagnosis were focused primarily on the motivators that ultimately led to diagnosis, such as other family members having an ASD diagnosis and feelings of being "different" while growing up.

Experiences during the ASD diagnostic process were varied in terms of logistic factors, approaches and barriers. Logistic factors included who, where and how the assessment was conducted. Approaches that were valued included strengths focused assessments where rapport was built with a key contact person and tailored communication was utilised. Frequent barriers to diagnosis included the cost of assessment, availability of appropriately skilled assessors, masking strategies hindering symptom identification (particularly among women) and sensory distress associated with assessment locations.

Experiences following ASD diagnosis were typically positive, characterised by empowerment and self-realisation due to receiving the ASD diagnosis. However, negative experiences were also reported, such as stigma. Many of the participants reported unmet needs and difficulty in accessing important supports following diagnosis.

Conclusions: The online submissions and interviews revealed varied ASD diagnostic experiences of adults in Australia, and unmet needs in the current diagnostic system were highlighted. Participants reported the benefits of having an ASD diagnosis. Access to ASD diagnosis for Australian adults may be improved with the new nationwide diagnostic guideline.

123 **128.123** Gender Difference of Gaze Fixation Patterns in 5-Year -Old Children -the Usefulness of Early Detection of Girls with Autism Spectrum Disorder-

Y. Sakamoto[1]*, M. Saito*[1]*, K. J. Tsuchiya*[2]*, A. Osato*[1]*, S. Kato*[3]*, Y. Matsubara*[4]*, T. Mikami*[5]*, M. Adachi*[6]*, M. Takahashi*[6]*, S. Yasuda*[5] *and K. Nakamura*[1]*, (1)Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (2)Research Center for Child Mental Development, Hamamatsu University School of Medicine, Hamamatsu, Japan, (3)Aomori Chuo Gakuin University, Aomori, Japan, (4)Hirosaki University Graduate School of Medicine, Hirosaki, Japan, (5)Research Center for Child Mental Development Graduate School of Medicine, Hirosaki University, Hirosaki, Japan, (6)Research Center for Child Mental Development, Graduate School of Medicine, Hirosaki University, Hirosaki, Japan*

Background: It has been suggested that early intervention can improve developmental outcomes of Autism Spectrum disorder (ASD). Delay in the identification of ASD impedes early access to interventions and causes negative developmental outcomes. However, identifying children with ASD is difficult, especially in girls. We need biomarker considering gender difference. Recently, a lot of studies have identified unique gaze fixation patterns in individuals with ASD using eye-tracking systems. Such gaze fixation patterns in individuals with ASD are considered to be associated with social attention. Recently Gaze fixation patterns have attracted attention as the indicator of sociability.
Objectives: The purpose of this study is to clarify the gender difference of gaze fixation patterns in 5-year-old children and analyze these results statistically along with other existing tools, after then to examine the utility for early diagnosis of ASD.

Methods: In the community health check-up spanning three years (2013-2015, N=3804), the participants screened in the community health check-up were 2923 children. The local government officers invited 440 children (included 31 applicants) to additional assessments and an interview based on the results of the screening. We measured the percentage of gaze fixation time allocated to particular objects depicted in movies by 5-year-old children in a community health check-up (n=438) by the double-blind method. Subjects of analysis are ASD (n=64) who diagnosed by DSM-5 criteria and Typical development (TD, n=68) who had no abnormalities in all the experiment. We compared gaze fixation percentage between the two groups and determined the cut-off point by ROC analysis using all 200 girls. In addition, we compared the fitness and the Odds Ratio of using Gaze fixation patterns with other existing tools by logistic regression.

Results: Analyzed the gaze fixation percentage of 'People' by gender, there was a significant difference only in girls ($p < 0.05$, ES = 0.96). As a result of ROC analysis in girls, AUC was 0.762 ($p<0.001$). It indicates moderate predictive ability and diagnostic ability. When we set the cut-off point to gaze fixation percentage 50% (sensitivity 90%, specificity 59%) and combine it with Autism Spectrum Screening Questionnaire (ASSQ) and Strengths and Difficulties Questionnaire (SDQ), the fitness of logistic analysis and the Odds Ratio rose to 3.3 times. In girls, the combination of Parent-interview ASD Rating Scale - Text Revision (PARS-TR) short-version and gaze fixation percentage 50% showed sensitivity 71.5%, specificity 88.7%.

Conclusions: This study suggested the gender difference in the evaluation of sociability in 5-year-old children. We have to select images considering age and gender. Gazing fixation pattern is useful in objectively evaluating social development. There is the possibility to contribute to early identification of girls with ASD by adding gaze fixation patterns.

124 **128.124** Get It Right, Make It Easy, See It All: Autism Spectrum Disorder Diagnosis in Australia from the Perspective of Autistic Individuals and Their Caregivers

E. D'Arcy[1,2,3]*, M. Falkmer*[3,4,5]*, A. J. Whitehouse*[3,6,7]*, S. J. Girdler*[8,9]*, T. Falkmer*[3,10,11,12]*, J. Wray*[13]*, V. Eapen*[9,14]*, M. R. Prior*[15] *and K. Evans*[3,6]*, (1)Autism Research Team, Telethon Kids Institute, Subiaco, Australia, (2)School of Occupational Therapy and Social Work, Curtin University, Bentley, Australia, (3)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (4)School of Occupational Therapy and Social Work, Curtin University, Perth, Western Australia, Australia, (5)School of Education and Communication, CHILD programme, Institute of Disability Research, Jönköping University, Jönköping, Jönköping County, Sweden, (6)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (7)University of Western Australia, Perth, Australia, (8)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Western Australia, Australia, (9)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (10)School of Occupational Therapy, Social Work and Speech Pathology, Curtin University, Perth, Australia, (11)Pain and Rehabilitation Centre, and Department of Medical and Health Sciences, Linköping University, Linköping, Sweden, (12)Department for Rehabilitation, Jönköping University, Jönköping, Sweden, (13)State Child Development Service, Western Australia Department of Health, Perth, Western Australia, Australia, (14)School of*

Psychiatry, University of New South Wales, Sydney, Australia, (15)The University of Melbourne, Melbourne, Australia

Background: There is an emerging body of evidence in relation to the perspectives of autistic individuals and their caregivers in relation to the autism spectrum disorder (ASD) diagnostic process. However, these studies have focused on previous experiences that occurred before, during or after diagnosis. There is scarce information describing the future preferences or recommendations of these individuals.
Objectives: This viewpoint survey aimed to understand the relative importance of different aspects of an ASD assessment from the perspective of people with lived experience of autism.

Methods: Thirty-eight autistic adolescents / adults (>12 years, n=12) or caregivers of autistic individuals of any age (n=26) participated in the viewpoint survey. The median age of participants was 42 years (range=12-59), and most were females (n=29). This project employed a Q-methodology, where participants sorted 66 statements regarding the ASD diagnostic process from least important (-5) to most important (5). After extraction from the online Q sort software, the PQMethod software package was used to analyse the results according to the prescribed method. This supported the retention of three factors, hence results were generated through by-person varimax rotation factor analysis. The three-factor varimax solution accounted for 42% of the explained variance in the sample. Factor arrays were created to define the three factors. The factor arrays were interpreted to formulate viewpoints by a group of five researchers familiar with Q methodology research and the ASD diagnostic process.

Results: The first viewpoint, “Get it Right”, was defined by 18 participants (4 autistic individuals and 14 caregivers), and explained 18% of the variance. Individuals in this viewpoint valued trained and experienced diagnosticians, along with a comprehensive assessment process.

The second viewpoint, “Make it Easy”, was defined by 12 participants (5 autistic individuals and 7 caregivers), and accounted for 15% of the variance. This viewpoint was characterised by prioritisation of convenience, accessibility and support, while not compromising accuracy of assessment.

The third viewpoint, “See it All”, was defined by 5 participants (3 autistic individuals and 2 caregivers), and explained 9% of the variance. This viewpoint highlighted the importance of holistically evaluating the needs of the individual and their family, and tailoring the assessment to the unique circumstances.

Conclusions: The complexity of developing an ASD diagnostic process that is acceptable to all autistic individuals and caregivers was highlighted by this viewpoint survey, given the three contrasting perspectives identified. This emphasises the importance of the guideline allowing sufficient flexibility to meet the varied needs and wants of end-users.

125 **128.125** ICF Core Sets for Autism Spectrum Disorder, ADHD and Cerebral Palsy: Commonalities and Differences

S. Bolte[1], *S. Mahdi*[2] *and V. Schiariti*[3], *(1)Center for Neurodevelopmental Disorders (KIND), Center for Psychiatry Research, Department of Women’s and Children’s Health, Karolinska Institutet, Stockholm, Sweden, (2)Karolinska Institutet Center of Neurodevelopmental Disorders (KIND), Karolinska Institute Center of Neurodevelopmental Disorders, Stockholm, Sweden, (3)Division of Medical Sciences, University of Victoria, Victoria, BC, Canada*

Background: Capturing functional information is crucial in autism spectrum disorder. The International Classification of Functioning, Disability and Health (ICF) Core Sets promote a functional approach in day-to-day practice. Objectives: This study sought to identify content commonalities and differences among the ICF Core Sets for the newly developed Core Sets for Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD), as well as Cerebral Palsy (CP) Methods: Descriptive analyses were conducted to compare the content of the different ICF Core Sets. The categories within each ICF Core Set were aggregated at the component and chapter level prior to the analysis. Results: Activities and participation was the most covered component across all ICF Core Sets. Differences included: 1) overall representation of ICF components, and 2) coverage of chapters within each component. CP included all ICF components, while ADHD and ASD predominantly focused on activities and participation and environmental factors. Environmental factors were highly covered in the ADHD Core Set (40%), as opposed to ASD (28%) and CP (27%). Conclusions: ICF Core Sets for ASD ADHD, and CP capture both common, but also much unique information, showing the importance of creating condition specific ICF-based tools to build accurate functional profiles for each clinical population.

126 **128.126** Linking the Esdm Curriculum Checklist for Young Children with Autism to the ICF-CY Who Comprehensive Classification System

K. Strauss[1], *A. Delle Fratte*[2] *and L. Fava*[2], *(1)Umbrella Autism, Rome, Italy, (2)Association for Treatment and Research in Autism Spectrum Disorders "UmbrellAutism", Rome, Italy*

Background: Children with Autism Spectrum Disorders are characterized by divers patterns of behavior and level of performance. Such variability translate into different intervention needs that makes planning of individualized intervention programs challenging. Curriculum driven tools that guide decision-making process for intervention goals should rely on critical variables that promote a broad range of children's life skills, that are developmental appropriate and include information on the environmental support (Wilczynski et al., 2017). Approaches to evaluate the quality of curriculum based intervention tools in addressing developmental and educational process in children with autism are lacking. The International Classification of Functioning, Disability and Health version for Children and Youth (ICF-CY, WHO, 2007) may offer a framework by which to approach teaching goals of autism intervention curricula.
Objectives: The aim of the research is to document the utility of linking the Early Start Denver Model Curriculum Checklist (Rogers & Dawson, 2010) to the codes of the ICF-CY.

Methods: The ESDM curriculum checklist is a tool for designing teaching objectives for intervention in children with autism spectrum disorders until ages 4-5 and is divided into logical teaching sequences covering broadly nine developmental domains with a total of 446 items. The ICF-CY provides a classification of functioning and disability form both and individual and societal perspective on Body Functions, Activities and Participation, and Environmental Factors. Deductive content analysis was used to make inferences from textual data. The process of analysis has followed a set of sequential steps using the linking rules (Cieza et al., 2005) on the identification of meaningful concepts. Two independent researchers linked the ESDM curriculum items with the full ICF-CY set. Inter-rater agreement was calculated using Kappa Coefficient. Once final coding of ESDM items was achieved, the derived code set as compared for completeness to a code set of meaningful concepts specifically for autism (Castro & Pinto, 2012; Pinto et al., 2013; Boelte et al., 2016) and developmental core sets for 0-2 and 3-5 years (Ellingsen & Simonsson, 2011),

corresponding to the relative age range of the ESDM curriculum.

Results: The ESDM curriculum checklist is addressing mostly the Activities and Participation component of the ICF-CY, focussing essentially on directly observed performance of skills. The Environmental Factors component in which the child is embedded is not addressed, missing inferential characteristics that may be related with limited participation and performance. While the ESDM curriculum checklist covers broadly the developmental core sets, some aspects of meaningful concepts of code sets for children with autism are missing.

Conclusions: The present research document the ICF-CY Environmental Factors component as a supporting tool to improve the intervention goal-setting process in programs for young children with autism. Results may be suggestive of the difficulty in finding a balanced, feel-grounded approach on how to describe disability in pre-school children with autism from a developmental perspective and to address essential aspects of learning and participation for young children with autism in curriculum tools guiding intervention planning.

127 **128.127** Measuring Emotion Regulation in Children with Autism: A Novel Observational Tool

J. K. Lake, P. Tablon Modica, V. Chan (Ting) and J. A. Weiss, Psychology, York University, Toronto, ON, Canada

Background: Children with autism often experience difficulty regulating their emotions, and these difficulties have been associated with a range of emotional and behavioural problems (Mazefsky et al., 2013). While there are a number of self and parent-report questionnaires of emotion regulation (ER), few observational measures exist. To address this gap, we created an observational measure of child ER, adapted from a parent-report measure, the *Emotion Regulation Checklist* (Shields & Cicchetti, 1997). This adapted measure was used to assess child ER processes during a standardized 15-minute *Emotion Discussion Task* (EDT; Suveg, 2008), around situation(s) where the child felt anxious, angry and happy.
Objectives: 1) Examine the reliability and concurrent validity of an observational measure of ER; 2) investigate associations between an observational measure of child ER and parent co-regulation strategies, assessed during the same task; and 3) examine associations between an observational measure of child ER and child internalizing and externalizing problems.

Methods: Preliminary findings are based on 49 children with ASD (aged 8-12 years), however final results will be based on a total of 62 children. To examine the concurrent validity of our observational measure of ER, we correlated scores with scores on standardized, parent and self-report measures of ER. To examine associations between our observational measure and parent co-regulation strategies, we used a behavioural coding scheme (Gulsrud et al., 2010) to assess parent scaffolding and parent co-regulation strategies, during the same EDT task. Finally, to examine associations between our observational measure of child ER and child emotional and behaviour problems, we correlated scores on our observational ER measure with a standardized measure of internalizing and externalizing problems.

Results: Preliminary findings suggest that our observational ER measure has excellent reliability for both subscales: *lability/negativity* (ICC = .94) and *emotion regulation* (ICC = .88). The observational lability/negativity subscale score was associated with parent ratings of emotion lability/negativity (r_s = .31, p = .03), emotion regulation (r_s = -.40, p = .01), and behavioural symptoms (r_s = .31, p = .03). The observational emotion regulation subscale score was associated with parent global scaffolding ratings (emotional: r_s = .33, p = .02; motivational: r_s = .38, p = .02), suggesting that parents who provided higher quality scaffolding during the EDT had children who displayed higher levels of emotion regulation during that interaction. The observational emotion regulation subscale was also associated with child self-reported emotion management (dysregulation: r_s = -.35, p = .02; coping: r_s = .38, p = .01), and parent ratings of child emotion regulation (r_s = .32, p = .03). Finally, internalizing (r_s = -.32, p = .03) and externalizing (r_s = -.44, p = .001) symptoms were also related to our observational emotion regulation subscale, indicating that parents reported greater internalizing and externalizing problems among children observed to display more difficulty with emotion regulation.

Conclusions: Preliminary results support the concurrent validity of an observational measure of ER among children with ASD. Findings also highlight the importance of a multidimensional approach to assessing emotion regulation.

128 **128.128** Miss Asd; A New Screening Instrument for Girls and Women with ASD

*R. H. Grondhuis, M. L. Bezemer and **E. M. Blijd-Hoogewys**, INTER-PSY, Groningen, Netherlands*

Background: The diagnosis for ASD is mainly based on the male ASD phenotype. Consequently, women with ASD are often misdiagnosed or diagnosed much later in life. A screening instrument taking into account the female ASD phenotype could aid in the identification of women who may have undiagnosed ASD. The Autism-spectrum Quotient (AQ, Baron-Cohen et al., 2001), an often-used ASD screening instrument, does not take into account the female ASD phenotype. Typical for a female ASD phenotype is a higher social motivation, better camouflaging techniques, gender specific preoccupations, and vulnerability for emotional problems.
We developed the M-ASD (Miss-ASD), an ASD screening instrument taking into account this phenotype. It includes 120 items derived from extensive literature search on female ASD expressions, clinical impressions of the authors, and data analysis aimed at sex differences in adults with ASD on other questionnaires (N=200 AQ, N=90 SRS-A, N=250 BRIEF-A). The M-ASD has 6 subscales: 1) Social interaction and communication, 2) Rigidity, 3) Coping, compensation and camouflaging behavior, 4) Sensory issues, 5) Information processing, and 6) Miscellaneous.

Objectives: Development, validation and standardization of a new screening instrument, M-ASD, which takes into account the female ASD-phenotype.

Methods: There were 31 participants with ASD (14 men, 17 women; M = 33.31, SD = 12.56 year), diagnosed by trained clinicians. Their estimated intelligence, based on education, is average to superior. All participants completed the AQ and the M-ASD. A cut-off score of 26 is used for the AQ. There are yet no norm scores available for the M-ASD, therefore, in semi-accordance with the AQ, the cut-off is set at >60% of ASD confirmatory answers.

Results: Women have higher M-ASD mean scores (more reported problems) than men, on both total score and all sub-scores (6-14% higher), with the highest mean difference on the subscales 'Sensory issues' and 'Coping, compensation and camouflaging behavior'. T-tests showed a significant difference for 'Sensory issues' and a trend for 'Coping, compensation and camouflaging behavior': women report more problems than men (p = .04, p = 08, respectively). The correlation between AQ and M-ASD was high (r = .72, p = .010).

Conclusions: The M-ASD seems to be suitable in measuring ASD characteristics; the correlation with another ASD questionnaire (AQ) is high. Women diagnosed with ASD score higher on M-ASD subscales that seem to be more characteristic for women. Women have higher M-ASD scores than men, on both the total score and all sub-scores. This might be linked with a higher self-knowledge in women and/or the fact that this tool is more focused on the proposed female ASD phenotype. Coming months, we will continue to collect data. Our ultimate plan is to shorten the M-ASD and focus on validation and standardization of this new screening tool.

129 **128.129** New DSM-5 Severity Level Ratings for Autism Spectrum Disorder: Clinical Use and Associated Factors

M. O. Mazurek[1], *F. Lu*[2], *M. Eric*[3] *and B. Handen*[4], *(1)University of Virginia, Charlottesville, VA, (2)Massachusetts General Hospital, Boston, MA, (3)Harvard Medical School, Boston, MA, (4)University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background:

The newest edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) introduced substantial changes to the criteria for autism. The shift from separate diagnostic subcategories into a single category of autism spectrum disorder (ASD) resulted in considerable discussion and research. By contrast, the introduction of new severity level ratings for social communication and restricted and repetitive behavior (RRB) in DSM-5 has received little scientific attention. Although the ratings intended to capture domain-specific severity, clear-cut operational definitions are lacking. Thus, it is unclear how these rating will be used and whether they will reflect symptom severity alone or be influenced by other indices of impairment.

Objectives:

The study objectives were to evaluate the use of DSM-5 severity level ratings in a large sample of children with ASD and to examine their relation to standardized measures of ASD severity and other clinical features, particularly cognitive and behavioral functioning.

Methods:

Participants included 248 children and adolescents with ASD (ages 2-17, 82% male) who received comprehensive diagnostic evaluations for autism at one of six Autism Treatment Network sites. Each assessment included a review of records, diagnostic clinical interview, Autism Diagnostic Observation Schedule – 2nd Edition (ADOS-2), cognitive assessment, assessment of behavioral functioning (Child Behavior Checklist, CBCL, and Aberrant Behavior Checklist, ABC), and completion of a DSM-5 Checklist.

Results:

Twenty-six percent of the sample was rated as having the lowest severity (Level 1, "requiring support") in both domains, while 15% was rated as having the highest severity (Level 3, "requiring very substantial support") in both domains. Bivariate analyses (cumulative logistic regression for the three levels of severity, binary logistic regression for lowest severity, and linear regression) all indicated that higher severity ratings in both domains were significantly associated with younger age, lower IQ, and greater ADOS-2 domain-specific symptom severity ($p < .05$ for all). The strength of associations was moderate/large for age (Spearman's correlations of $r_s = -.51$ and -.43) and IQ ($r_s = -.61$ and -.47), and small for ADOS-2 domains ($r_s = .23$ and .29). Greater DSM-5 RRB severity was also associated with higher parent-reported stereotyped behaviors (measured by the ABC) in two of three bivariate models. Severity ratings were not associated with emotional or behavioral problems (measured by the CBCL). Multiple regression models indicated that age, IQ, and ADOS-2 social affect were significant independent predictors of social communication severity ($p < .05$ across all models), and that age, IQ, and ADOS-2 RRB were significant independent predictors of DSM-5 RRB severity ($p < .05$ across all models).

Conclusions:

These findings partially support the concurrent and discriminant validity of the new DSM-5 severity ratings. Clinician ratings of severity in both domains were significantly associated with behavioral observations of autism severity, but not with measures of other behavioral or emotional symptoms. However, the strong associations between IQ and DSM-5 severity ratings in both domains may suggest that clinicians are including cognitive functioning in their overall determination of symptom severity. Further research is needed to examine clinician decision-making and interpretation of these specifiers.

130 **128.130** Structural and Convergent Validity of the Autism Impact Measure (AIM)

M. O. Mazurek[1], *C. Carlson*[2], *M. Baker-Ericzén*[3], *E. Butter*[4], *M. Norris*[4] *and S. M. Kanne*[5], *(1)University of Virginia, Charlottesville, VA, (2)Department of Psychology, University of Houston, Houston, TX, (3)Rady Children's Hospital, San Diego, CA, (4)Nationwide Children's Hospital, Columbus, OH, (5)Thompson Center for Autism & Neurodevelopmental Disorders, Columbia, MO*

Background: Psychometrically sound outcome tools are needed to evaluate the effects of autism treatments in both clinical and research settings. The Autism Impact Measure (AIM) was designed to enable efficient measurement of incremental changes in both frequency and impact of core ASD symptoms. The initial psychometric study of the AIM indicated strong to moderate test-retest reliability and inter-rater reliability (Kanne et al., 2014). However, a larger sample was needed to further establish structural validity and scoring guidance. An extensive battery of domain-specific measures of communication, social functioning, and repetitive behaviors was also necessary to thoroughly examine convergent validity.
Objectives: The objective of the current study was to examine the structural and convergent validity of the AIM in a large sample of children with ASD.

Methods: Participants included 890 children and adolescents with ASD. The study included a primary sample ($n = 450$, 82% male) used in both convergent and structural validity analyses and a secondary sample ($n = 440$, 84% male) used only in structural validity analyses. The following convergent validity measures were administered (Sample 1): Repetitive Behavior Scale – Revised (RBS-R), Aberrant Behavior Checklist (ABC), Social Responsiveness Scale (SRS-2), Autism Diagnostic Observation Schedule – 2nd Edition (ADOS-2), Ohio Autism Clinical Global Impression Severity Scale (OACIS-S), Vineland Adaptive Behavior Scales (VABS-II), MacArthur Communicative Development Inventory (CDI), Pediatric Quality of Life Inventory (PedsQL).

Results:

A series of exploratory (EFA) and confirmatory (CFA) factor analyses was conducted to establish construct and structural validity of the AIM. AIM item scores were calculated by adding the Frequency and Impact scores for each item, yielding a single summative item metric representing overall severity. EFA was conducted first, followed by cross-validation using CFA with a hold-out sample of subjects. To accomplish this, the total sample was randomly assigned to one of two groups (each consisting of half the sample). EFA was conducted on the first randomly established sample, while the CFA was conducted on the second randomly established hold-out sample. The results yielded a final model with five theoretically and empirically meaningful subdomains: Repetitive Behavior, Atypical Behavior, Communication, Social Reciprocity, and Peer Interaction. The final model showed very good fit both overall and for each of the five factors (RMSEA <.06, CFI and TLI >.95), indicating excellent structural validity. Convergent validity analyses indicated that AIM subdomain scores were significantly correlated with measures of similar constructs across all five domains.

Conclusions: The current study examined the construct and structural validity of the AIM in a sample of 890 children with ASD. The study extended prior research on the AIM by including a larger sample and using a more comprehensive measurement battery to test convergent validity. The results indicate that the psychometric properties of the AIM are strong, including excellent structural validity and solid convergent validity. The results suggest that the AIM may be useful for efficient assessment of short-term improvements in core ASD symptoms across five empirically-derived and clinically meaningful symptom domains.

131 **128.131** Pilot Analyses of the Feasibility and Validity of Autism Spectrum Disorder Screening Instruments: Social Communication and Interaction Screening in Toddlers (SISO)

H. J. Yoo[1], *G. Bong*[2], *M. Oh*[3], *J. Kim*[4], *H. Sunwoo*[5], *J. Jeon*[6], *J. Jang*[7], *K. S. Lee*[8], *S. Jung*[9], *Y. S. Lee*[10], *M. S. Kim*[11], *D. W. Han*[12] *and C. Y. Shin*[13], *(1)Psychiatry, Seoul National University Bundang Hospital, Seongnam, Korea, The Republic of, (2)Psychiatry, Seoul National University Bundang Hospital, Seungnam, Korea, Republic of (South), (3)Psychiatry, Seoul National University Bundang Hospital, Sungnam, Korea, The Republic of, (4)Psychiatry, Seoul National University Bundang Hospital, Seoul, Korea, Republic of (South), (5)Psychiatry, Soonchunhyang University Hospital, Seoul, Seoul, Korea, Republic of (South), (6)Seoul National University Bundang Hospital, Seoul, Korea, Republic of (South), (7)Incheon Center for Developmental Disabilities, Incheon, Korea, Republic of (South), (8)Hanshin University, Osan-SI, Korea, The Republic of, (9)Sewon Infant Child Development Center, Seoul, Korea, Republic of (South), (10)Department of Physiology, Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of (South), (11)Department Applied Chemistry, Kyung Hee University, Seoul, Korea, Republic of (South), (12)Dept. of Stem Cell Biology, School of Medicine, Konkuk University, Seoul, Korea, Republic of (South), (13)Department of Neuroscience, School of Medicine, Konkuk University, Seoul, Korea, Republic of (South)*

Background: Early diagnosis is the critical first step for early intervention for autism spectrum disorders (ASD), which is crucial for prognosis. However, there have been limited early ASD screening instruments available in Korea.
Objectives: The objectives of this study are 1) to develop an early screening instrument of ASD for infants/toddlers in Korea, named "Social Communication and Interaction Screening in tOddlers (SISO)," and 2) to verify feasibility and validity of the instrument by comparing with clinical best estimate diagnosis.

Methods: 1) We primarily identified the lists of social and communication behaviors that might be manifested in infants/toddlers with ASD by age range, each of which is relevant to DSM-5^{TM} criteria. Behaviors in the lists were paralleled by those observed in typically developing infants/toddlers in each age range. We developed preliminary interview questions and play-based activities to detect such behaviors clearly. 2) Focus group interviews were conducted on 30 daycare center/kindergarten teachers and 11 professionals, in order to select the most relevant items, draw appropriate examples regarding children's play in everyday life, and refine item wordings and expressions for better understanding. 3) Finally, we developed SISO-P (Play-based observation of toddlers, 3~14 items) and SISO-I (Interview questions for caregivers/teachers, 11~19 items). Both instruments covers five age ranges: 9~11, 12~17, 18~23, 24~35, and 36~42 months. 4) Subjects included for validity analyses were toddlers at age 12 to 42 months with no significant physical/neurological/sensory problems interfering the diagnostic procedures. For all participants, SISO-P and SISO-I were conducted along with the diagnostic procedures using CARS, ADOS, and ADI-R. We analyzed sensitivity, specificity, positive predictive value, and negative predictive value of the SISO Classification in relation to the clinical best estimate diagnosis that provides ASD/non-ASD classification. χ^2-test and *t*-test were used to analyze validity of individual items.

Results: Total 251 infants/toddlers participated (9~11, n=3; 12~17, n=20; 18~23, n=30; 24~35, n=110; 36~42, n=88). 1) For overall subjects, sensitivity was 97.84% in SISO-P, and 95.00% in SISO-I. Specificity was 34.55% in SISO-P, and 56.25% in SISO-I. For SISO-P, PPV was 65.38 and NPV was 92.68. For SISO-I, PPV was 73.08 and NPV was 90.00. 2) For SISO-P, individual item analyses on 24~35 month-olds (ASD, n=61; non-ASD, n=48) and 36~42 month-olds (ASD, n=71; non-ASD, n=17) showed significant differences in scores for all items ($p<.05$) and significant differences in frequencies of screen-positive and -negative scores between ASD and non-ASD groups for all items ($p<.05$). The results showed that, for SISO-I, differences in scores for 'Social Interest to others' item in 24 months and 'Eye Contact', 'Social Smile', and 'Social interest to others' items in 36 months are not statistically significant across two groups, suggesting that the interview questions might need to be revised in a way that better differentiates toddlers' behaviors towards others and caregivers.
Conclusions:

The present study suggests that SISO might be feasible and highly sensitive but is a less specific screening instrument for ASD in toddlers. Further study is needed on a larger number of subjects to find out which items are adequately specific in screening ASD.

132 **128.132** Profiles of Autistic Symptoms in Individuals with 22q11.2 Duplication or Deletion Syndromes, Regardless of Autism Diagnosis

C. C. Clements[1], *J. R. Bertollo*[1], *A. Zoltowski*[2], *A. de Marchena*[3], *L. DePolo*[4], *E. Zackai*[5], *B. Emanuel*[5], *D. McDonald-McGinn*[5], *T. Wenger*[6], *R. T. Schultz*[1], *J. S. Miller*[7] *and O. Ousley*[8], *(1)Center for Autism Research, Children's Hospital of Philadelphia, Philadelphia, PA, (2)Vanderbilt University, Nashville, TN, (3)University of the Sciences, Philadelphia, PA, (4)Children's Hospital of Philadelphia, Philadelphia, PA, (5)Department of Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, (6)Department of Pediatrics, Seattle Children's Hospital, Seattle, WA, (7)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA, (8)Department of Psychiatry and Behavioral Sciences, Emory Autism Center, Emory University School of Medicine, Atlanta, GA*

Background: Genetic syndromes associated with Autism Spectrum Disorder (ASD) may hold promise for understanding its underlying biology, but such insights depend on a solid understanding of human phenotypes. Our groups recently reported increased prevalence of ASD among individuals with 22q11.2 Deletion (DS; Ousley et al., 2017) and Duplication Syndromes (DupS; Wenger et al, 2016). Many studies note pervasive autism-like symptoms in individuals with 22q11.2DS/DupS, *regardless* of ASD diagnosis, highlighting social communication impairments (SCI) such as reduced facial expression and difficulty initiating in 22q11.2DS, and high rates of restricted or repetitive behaviors and interests (RRBI) in 22q11.2DupS. Thus, possessing either one or three copies of the 22q11.2 region appears to yield at least some SCI or RRBI symptoms in most individuals. It remains unknown how or why autistic symptom profiles differ between deletions and duplications, which could inform clinical practice at 22q11.2 clinics as well as 22q11.2 animal models of ASD.

Objectives: To compare and describe the profile of autistic symptoms between individuals with 22q11.2 duplication and deletion.

Methods: We recruited participants with 22q11.2DupS (n=20; ages 4-14; 80% male) or DS (n=61; ages 4-29, 50.8% male) confirmed by SNP, MLPA, or FISH testing. We examined differences in RRBI and SCI between and within groups on the subsets that completed the ADI-R, ADOS, and DSM5 checklist. We computed the proportion of possible algorithm points (or possible symptom count for DSM5 checklist) endorsed in each domain to facilitate comparisons across domains and measures. We used MANOVA followed by Bonferroni-corrected (adjusted-p=0.004) nonparametric posthoc Wilcoxon within- and between-group tests to account for small, non-normal distributions and ordinal data. We report effect sizes to aid interpretation given our small sample.

Results: Results showed no significant differences in levels of SCI or RRBI between deletions or duplications of 22q11.2. Posthoc tests revealed small effect sizes for most comparisons (r's 0.006-0.23), and negligible effect sizes for the most powered between-group analysis, the ADI-R (SCI r=0.006, RRBI r=0.015; see figure). Preliminary ADOS results showed two large, non-significant effects driven by low RRBI scores for deletions (ADOS SCI vs. RRBI within deletions: r=0.72, p=0.042; ADOS RRBI between groups: r=0.58, p=0.35). Future analyses available by May 2018 will include clinically useful descriptions of item endorsement rates for each group.

Conclusions: Individuals with duplication or deletion of 22q11.2 appear to show similar ADI-R profiles of SCI and RRBI symptoms in the full sample. These surprising results open questions about 'dosage' effects of genes in the region, as both too many and too few copies yield similar autistic profiles. Animal models might be particularly suited to probe these questions; recent work with 22q11.2DS mouse models reported partial relief of schizophrenia phenotypes, and similar advances may be possible with ASD. Furthermore, Auerbach and colleagues (2012) studied such 'dosage' effects and relieved autistic phenotypes by cross-breeding two mouse models (TSC and FragX) with excessive or insufficient synaptic protein synthesis. Our study will provide nuanced information about the autistic phenotypes that can be expected in individuals with 22q11.2DS and DupS.

133 **128.133** Psychometric Properties of the Merrill-Palmer-Revised Scales of Development in Preschool-Aged Children with Autism Spectrum Disorder

E. E. Dempsey[1], *I. M. Smith*[2], *H. E. Flanagan*[3], *E. Duku*[4], *L. Zwaigenbaum*[5], *P. Szatmari*[6], *M. Elsabbagh*[7], *T. Bennett*[8], *J. Volden*[5], *S. Georgiades*[4], *W. J. Ungar*[9], *P. Mirenda*[10], *T. Vaillancourt*[11] *and C. Waddell*[12], *(1)Psychology and Neuroscience, Dalhousie University, Halifax, NS, Canada, (2)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (3)IWK Health Centre, Halifax, NS, Canada, (4)McMaster University, Hamilton, ON, Canada, (5)University of Alberta, Edmonton, AB, Canada, (6)Centre for Addiction and Mental Health, Toronto, ON, Canada, (7)McGill University, Montreal, PQ, Canada, (8)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (9)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (10)University of British Columbia, Vancouver, BC, Canada, (11)University of Ottawa, Ottawa, ON, Canada, (12)Simon Fraser University, Vancouver, BC, Canada*

Background:

Best practice diagnostic assessment of children suspected of having autism spectrum disorder (ASD) includes cognitive testing; psychometrically strong cognitive measures are also indispensable in longitudinal research. Assessment of cognition in ASD is complicated by variable skill levels and uneven profiles of strengths and weaknesses, as well as inherent social communication differences. Few tests have been validated for use with this population. The Merrill-Palmer-Revised Scales of Development (M-P-R) is a standardized cognitive assessment that is well-validated and reliable for use with typically developing preschoolers. However, the suitability of the M-P-R for assessing cognition in children with ASD has not been well-researched.

Objectives:

The current study's aim was to investigate the criterion validity of the M-P-R for assessing cognition in a large group of preschoolers with ASD whose abilities span a broad range of intellectual functioning.

Methods:

Participants (N = 391; 84% male; M_{age} = 41.25 months) were drawn from an ongoing multi-site longitudinal study examining the development of children with ASD (*Pathways in ASD* study, Szatmari et al., 2015). Bayesian analytic methods were used to assess the criterion validity of the M-P-R. Standard scores of all Domains and Indices of the M-P-R are reported. Concurrent validity was assessed by calculating the correlation between the Receptive Language domain of the M-P-R to the Auditory Comprehension subscale of the PLS-4. Predictive validity was assessed by calculating the correlation between M-P-R scores and later WISC-4 scores at age 8 or 9. Concurrent validity was further assessed by comparing profiles of cognitive strengths and weaknesses with those previously described (e.g., Coolican, Bryson, & Zwaigenbaum, 2008).

Results:

Children in our sample scored below norms on all Domains and the Developmental Index of the M-P-R (see Table 1). The M-P-R Receptive Language domain was strongly positively correlated with the PLS-4 Auditory Comprehension subscale (r = .73). The Cognitive domain of the M-P-R was weakly positively correlated with later WISC-4 scores (r = .37). Cognitive strengths and weaknesses assessed using the M-P-R mirrored those previously described, with children obtaining higher standard scores on the Cognitive (nonverbal): 64, $HDI_{95\%}$ [61 – 66] than the Receptive Language domain: 55, $HDI_{95\%}$ [52 – 59].

Conclusions:

The M-P-R showed good concurrent validity and acceptable predictive validity in a large, well-characterized sample of preschoolers with ASD whose cognitive functioning ranged from severely impaired to above average. The M-P-R shows promise for assessing cognitive abilities in the ASD population.

134 **128.134** Sex Differences in Clinical Presentation Among Children with ASD

E. A. DeLucia[1], *K. Pelphrey*[2], *A. Pomales*[1], *R. L. Gruen*[1], *C. C. Kautz*[1], *L. L. Booth*[1] *and P. E. Ventola*[3], *(1)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (2)Autism and Neurodevelopment Disorders Institute, George Washington University and Children's National Medical Center, Washington, DC, (3)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background:
The sex ratio in ASD is estimated to be 4:1 and as high as 8:1 in cognitively-able children (Fombonne, 2009; Werling & Geschwind, 2013); however, the literature is less clear regarding sex differences in clinical presentation of children with ASD. The existing literature suggests that girls with ASD have lower IQs and exhibit fewer restrictive and repetitive behaviors (RRBs) than boys (Volkmar, Szatmari & Sparrow, 1993; Hartley & Sikora, 2009). Findings on internalizing and externalizing symptoms have been mixed, and it is unclear whether boys and girls with ASD experience different developmental trajectories. It is important to understand differences between boys and girls with ASD across development in order to improve clinical care.

Objectives: The present study examines sex differences in clinical presentation of children with ASD between 3-17 years of age.

Methods:

The study sample included 396 children ages 3-17 who were diagnosed with ASD and had IQ scores in the average range. All study participants received an Autism Diagnostic Observation Schedule (ADOS) assessment. A subset of participants also received the Vineland Adaptive Behavior Scale (n=289), Child Behavior Checklist (CBCL; n=260), Differential Ability Scale (DAS; n=351), Social Responsiveness Scale (SRS; n=104), and Repetitive Behavior Scale – Revised (RBS; n=207). Sex differences on these measures were examined using independent samples t-tests.

Results:

Independent samples t-tests demonstrated markedly higher general conceptual ability scores on the DAS for boys compared to girls (male M=97.5, female M=91.4, t(351)=2.17, p=0.031), driven primarily by higher spatial ability scores (male M= 97.5, female M=90.9, t(347)=2.75, p=0.006). Boys exhibited more severe ASD symptoms, as assessed by the Calibrated Severity Scale (CSS) of the ADOS (male M=7.59, female M=7.05, t(365)=2.44, p=0.015). Additionally, males exhibited marginally higher scores on the restricted behavior subscale of the RBS (male M=3.46, female M=2.58, t(207)=1.94, p=0.053). On the CBCL, boys under 5 (preschool-aged children) scored significantly higher on the Oppositional Defiant subscale (male M=59.4, female M=52.8, t(26)=2.57, p=0.032) and the ADD/ADHD subscale (male M= 59.0, female M=53.6, t(26)=2.57, p= 0.018). In children ages 9:0-12:0 (school-aged children), girls received higher t-scores on the following subscales of the CBCL: Internalizing Symptoms (male M=59.5, female M=65.3, t(62)=-2.22, p=0.030), Externalizing Symptoms (male M= 53.9, female M= 60.9, t(62)=-2.27, p= 0.027), Anxiety Problems (male M=59.7, female M=65.9, t(61)=-2.61, p=0.012), Anxious/Depressed (male M=59.4, female M=65.4, t(61)=-2.12, p=0.038), and ADD/ADHD (male M=59.7, female M=65.3, t(60)=-2.21, p=0.031). There were no sex-based differences in children ages 13-17 (adolescents).

Conclusions:

Boys displayed more severe autism symptoms in a clinical setting, despite having higher IQs than girls. These more severe symptoms, coupled with increased dysregulation boys exhibited at young ages, may contribute to earlier diagnosis among boys with ASD (Chen, Marvin & Lipkin, 2015). Importantly, school-aged girls exhibited more externalizing and internalizing symptoms than boys. Clinically, these results suggest the importance of symptom monitoring over time, as pre-adolescent girls may experience a period of heightened risk for both internalizing and externalizing symptoms. Future studies should focus on developing effective screening and treatment methods for comorbid psychopathology, particularly for pre-adolescent girls with ASD.

135 **128.135** Temperament in Individuals with Autism Spectrum Disorder (ASD): A Systematic Review

L. Chetcuti[1], *K. Hudry*[1], *K. Ellis-Davies*[2], *S. Putnam*[3], *M. R. Prior*[4] *and M. Uljarevic*[5,6], *(1)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (2)Cambridge University, Cambridge, United Kingdom, (3)Department of Psychology, Bowdoin College, Brunswick, ME, (4)The University of Melbourne, Melbourne, Australia, (5)Department of Psychiatry and Behavioral Sciences, School of Medicine, Stanford University, Stanford, CA, (6)Stanford Autism Center, Department of Psychiatry and Behavioral Sciences, Stanford University, CA*

Background: Individuals with Autism Spectrum Disorder (ASD) vary considerably in the onset and course of their condition, for both core and co-morbid symptoms and, ultimately, in terms of life outcomes. Despite being well-recognized, heterogeneity in ASD is not fully captured by current diagnostic classification systems, nor adequately explained by disorder-specific features. Hence it remains difficult to predict longer-term outcomes on the basis of early presentation. A large body of research outside the context of ASD has demonstrated that particular dimensions of temperament can have both direct and indirect positive and negative influences on development across the lifespan, across a broad range of domains including social, emotional, and behavioural outcomes. Research on temperament in the context of ASD could therefore hold significant potential for furthering our understanding of heterogeneity inherent in this condition.
Objectives: We conducted a systematic review of the literature to integrate existing findings concerning temperament in the context of ASD within a proposed unified taxonomy of overarching temperament traits in order to identify consistencies in the evidence base and gaps which still require attention.

Methods: Medline, PsychInfo and Scopus databases were searched for published articles available through July 2017. Forty studies were identified, including 30 cross-sectional and 10 prospective longitudinal studies.

Results: Current research is complicated by different conceptualisations and measures of temperament across studies. However, when integrated within the proposed unified taxonomy, findings converge to suggest that individuals with ASD may be temperamentally different from both typically developing and other clinical non-ASD groups at a higher-order level. Consistent with research on typically developing children, correlational findings suggest that lower self-regulation and higher negative emotionality are associated with increased internalizing and externalizing problems in ASD samples. Longitudinal studies suggest the possibility that, from as early as 6-months, certain temperament traits can be useful in discriminating among infants who do and do not develop ASD.

Despite promising findings, current research is limited in that it remains largely descriptive, and the nature of the relationship between temperament and core ASD symptoms needs to be explored further. Methodological considerations and directions for future research are highlighted, including the need for more longitudinal investigations into temperament in ASD and the use of more refined statistical techniques. We also suggest that researchers exploring temperament in ASD adopt the proposed overarching temperament dimensions of negative emotionality, surgency and self-regulation in their work to enable generalization of findings across studies.

Conclusions: This field is still in its relative infancy, with many methodological issues to be considered and research gaps to be filled. Nonetheless, work in this area holds promise to further our knowledge of the early developmental pathway/s toward ASD diagnosis, and predictors of outcomes beyond this point.

136 **128.136** The Development and Validation of the Dutch Contextual Assessment of Social Skills (CASS): An Independent Observational Outcome Measure of Social Skills in Adolescents with Autism Spectrum Disorder

***S. Idris**[1,2], F. ten Hoeve[3], A. B. Ratto[4], S. W. White[5] and K. Greaves-Lord[1], (1)Erasmus MC, Rotterdam, Netherlands, (2)Discipline of Psychological and Behavioral Medicine, Faculty of Medicine, Universiti Teknologi MARA, Selangor, Malaysia, (3)Faculty of Social Sciences, Erasmus University, Rotterdam, Netherlands, (4)Children's National Health System, Washington, DC, (5)Psychology, The University of Alabama, Tuscaloosa, AL*

Background: Social skills interventions are considered to be efficacious if social skills are improved as a result of an intervention. Nevertheless, the objective assessment of social skills is hindered by a lack of sensitive and validated measures. To measure the change in social skills after an intervention, questionnaires reported by parents, clinicians and/ or teachers are commonly used. Yet, observations are the most ecologically valid method of assessing improvements of social skills after an intervention. For this purpose, The Program for the Educational and Enrichment of Relational Skills (PEERS) was developed for adolescents, in order to teach them the age-appropriate skills needed to participate in society (Laugeson, Frankel, Mogil, & Dillon, 2009). It is an evidence-based intervention for adolescents with ASD that taught ecologically valid social skills techniques.

Objectives: The current study aims to describe the development and psychometric evaluation of the Dutch Contextual Assessment of Social Skills (CASS), an observational outcome measure of social skills for adolescents with Autism Spectrum Disorder (ASD) (Ratto et al., 2011).

Methods: 34 adolescents (M = 14.68, SD = 1.41, 71% boys) with ASD performed the CASS before and after a social skills intervention (i.e. PEERS *or* the active control condition). Each adolescent completed a 3-minutes conversation with a confederate. The conversation was prompt as a natural introduction between two-unfamiliar, similarly ages, and opposite sex peers who meet for the first time. The adolescent and the confederate completed a brief questionnaire about the conversation (Conversation Rating Scale).

Results: Results indicated sufficient psychometric properties. The Dutch CASS has a high level of internal consistency (Cronbach's α coefficients = 0.84). Data supported the convergent validity (i.e. significant correlated with the Social Skills Improvement System (SSiS). The Dutch CASS did not significantly correlate with the autistic mannerism subscale from Social Responsiveness Scale (SRS), thus proved the divergent validity. Based on scorings made by raters who were kept blind to the time points, reliable change index were computed to assess the change in social skills. With regard to the content validity, only the learning objectives of the first two meetings of PEERS about conversational skills relatively matched with rating domains of the CASS. Due to this underrepresentation, we found an existing observational measure (TOPICC) that covers some of the other learning objectives of PEERS. TOPICC covers 22% of the learning objectives of PEERS about conversational skills, meanwhile CASS is 45%. Unfortunately, 33% of the learning objectives of PEERS was not covered by CASS or TOPICC.

Conclusions: Recommendations are made to improve the psychometric properties and content validity of the Dutch CASS.

137 **128.137** The Effect of Comorbidity on Cognitive Efficiency in ASD

***B. Lewis**, K. A. McNaughton, A. Naples and J. McPartland, Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Previous studies have found intact working memory in individuals with autism spectrum disorder (ASD), but deficits in processing speed and mixed impairments in executive functioning. Psychiatric comorbidity has negative consequences on cognitive functioning. Understanding whether comorbidity has unique or shared impact on ASD compared to other diagnostic groups has important implications for assessment and treatment.

Objectives: To study the effect of comorbidity on cognitive efficiency in individuals with ASD compared to individuals with diagnoses other than autism.

Methods: Retrospective analyses were conducted on a clinical pediatric sample of 421 individuals (73% Male; Caucasian: 37%, Asian: 2%, African American: <2%, Indian: <1%, Multi-racial: 2%) who presented to a developmental disabilities clinic. Cognitive assessments were conducted by licensed psychologists, and final consensus diagnosis was determined by a multidisciplinary team consisting of psychology, psychiatry, and speech/language specialists following comprehensive evaluation. Analyses consisted of group comparisons of individuals diagnosed with ASD (*n*=307) and individuals receiving another diagnosis (non-ASD group, *n*=110; Learning Disability 28%; ADHD 15%; Anxiety Disorder 15%; Language Disorder 14%; Mood Disorder 5%; and behavior disorders, tic disorders, OCD, and thought disorders, each <4%). Those given no diagnosis or those with Intellectual Disability as a primary or comorbid condition were excluded. Cognitive functioning was measured using standardized scores across *WISC-III, WISC-IV, and WAIS-III*, with the Working Memory Index and Freedom from Distractibility Index combined to create a composite score. The *Behavior Rating Inventory of Executive Function (BRIEF)* was also analyzed.

Results: Comorbid conditions were diagnosed in 8% (*n*=26) of individuals with ASD, and 20% (*n*=22) of individuals in the non-ASD group (χ^2=10.57, *p*<.01). Individuals with ASD were younger than the non-ASD group [ASD: *M*=9.76±3.75; non-ASD: *M*=10.82±3.83; *t*(402)=-2.49, *p*=.02]. There was a significant difference in Full Scale IQ (FSIQ) across diagnostic groups [ASD: *M*=94, *SD*=22; non-ASD: *M*=101, *SD*=20; *t*(397)=-2.93, *p*<.01). This difference remained true when factoring in comorbidity; only diagnostic groups without comorbidity had significantly different FSIQ [*F*(3,396)=3.24, *p*=.02]. FSIQ differences were driven by lower verbal and nonverbal reasoning index scores.

Within the ASD group, working memory index scores did not differ with comorbidity [non-comorbid: *M*=97, *SD*=21; comorbid: *M*=90, *SD*=18; *t*(214)=1.33, *p*=.19), nor did processing speed index scores [non-comorbid: *M*=88, *SD*=17; comorbid: *M*=87, *SD*=18; *t*(210)=0.30, *p*=.77]. The same was found within the non-ASD group for working memory [non-comorbid: *M*=100, *SD*=20; comorbid: *M*=95, *SD*=19; *t*(78)=1.05, *p*=.30] and processing speed [non-comorbid: *M*=91, *SD*=17; comorbid: *M*=88, *SD*=17; *t*(76)=0.61, *p*=.54]. Detailed evaluation of executive functioning from the *BRIEF* indicated more pronounced deficits in self-monitoring for individuals who received a diagnosis other than ASD [non-ASD: *M*=68, *SD*=9; ASD: *M*=63, *SD*=11; *t*(107)=-2.36, *p*=.02]. There were no other significant differences in executive functioning between diagnostic groups or within groups based on comorbidity.

Conclusions: Overall, individuals with ASD and other psychiatric diagnoses demonstrated similar cognitive efficiency profiles as measured by working memory and processing speed. Executive functioning across ASD and other diagnostic groups was also similar with the exception of self-monitoring which was more impaired in the non-ASD group. Comorbidity did not further impair one’s cognitive efficiency or executive functioning.

138 **128.138** The Utility of a Parent and Teacher-Rated ASD Self-Awareness Scale

***T. Warren**[1], S. Bent[1], F. Widjaja[1], K. Delucchi[1], E. Johnson[2] and R. Hendren[1], (1)Psychiatry, University of California, San Francisco, San Francisco, CA,* *(2)Meristem, Fair Oaks, CA*

Background: Research has linked self-awareness about mental health and capabilities to better social and functional outcomes, possibly because awareness may result in increased motivation to improve or compensate for mental difficulties. However, scales that measure this self-awareness in people with developmental disabilities are lacking in the literature. Instead, autism spectrum disorder (ASD) outcomes have traditionally been measured through concretely operationalized aspects of behavior, communication, and functional abilities.
Objectives: The objective of this study was to examine the utility of a novel scale given to parents and teachers to separately measure capability and awareness in several domains for young adults with ASD and related developmental disorders.

Methods: This was an 8-month observational study from October 2016 to May 2017 done at Meristem, a program for young adults with ASD and related neurodevelopmental disabilities in Fair Oaks, California. The Meristem staff and study team developed a 10-item measure, the Meristem Capability and Awareness Scale (MCAS), to assess outcomes in five domains (Practical Work Skills, Spatial Integration, Independent Living Skills, Wellbeing, and Social & Communication Skills), on two subscales (Capability, rated 1-5, and Independence/Awareness, rated 1-10) (Table 1). All students at the school were invited to participate, and all chose to participate (n=29, mean age=21.7). Parents and teachers rated students at baseline (October 2016) and at the end of the study (May 2017). Teachers additionally rated students midway through the school year (January 2016). Parent and teacher MCAS ratings were tested for significant change over time using a linear regression model. Additionally, Pearson's correlations were calculated for each MCAS domain's Capability score and Independence/Awareness score.

Results: Parent MCAS ratings showed trending improved scores on the Independence/Awareness subscale in the Practical Work Skills domain (0.13 points/month, p=0.15) and Social & Communication Skills domain (0.16 points/month, p=0.09), as well as on the overall Independence/Awareness subscale (average of Independence/Awareness scores) (0.13 points/month, p=0.15). Teacher MCAS ratings showed trending improved scores on the overall Independence/Awareness subscale (0.10 points/month, p=0.13) and significant improvement on the Independence/Awareness subscale in the Social & Communication Skills domain (0.41 points/month, p=0.04). No other subscales or domains showed significant or trending change. Pearson's correlations between the Capability and Independence/Awareness scores for each subscale ranged from r=0.37 to r=0.57, and p-values ranged from p=0.02 to p=0.0002 (Table 2).

Conclusions: Despite limitations including a small sample size, short time frame, and lack of comparison with standardized measures, greater improvement on Independence/Awareness than on Capability may indicate that self-awareness of challenges precedes the ability to work on them. Additionally, strong correlations between Independence/Awareness and Capability are an indication of good internal validity and show that scores on the two subscales may move together. However, correlations show enough difference between the subscales to provide evidence that the concepts of capability and awareness are distinct and may merit individual measurement. These findings support the use of a specialized awareness scale in outcome measurement for people with developmental disabilities. Such a scale may capture important change and should be considered in the development of future outcome measures.

139 **128.139** Validation of a Broader Autism Phenotype Interview in Families of Individuals with High-Functioning Autism Spectrum Disorder

C. C. Green[1], *A. E. Richard*[2], *S. J. Wilson*[3] *and I. E. Scheffer*[4], *(1)Olga Tennison Autism Research Centre, La Trobe University, Bundoora, VIC, Australia, (2)Autism Research Centre, IWK, Halifax, NS, Canada, (3)Florey Institute of Neuroscience and Mental Health, Melbourne, VIC, Australia, (4)Department of Medicine, The University of Melbourne, Melbourne, Australia*

Background:
The Broader Autism Phenotype (BAP) is characterised by sub-clinical traits of Autism Spectrum Disorder (ASD), however there is no gold standard assessment for the BAP. The BAP is commonly found in relatives of individuals with ASD, and is most often measured using self- and informant-ratings of ASD traits, and occasionally using a lengthy family history interview as well.

Objectives:

We aimed to 1) validate a brief interview of BAP traits; and 2) elucidate the BAP profile in first-degree relatives of individuals with ASD with at least average cognitive abilities, where genetic factors may more likely be involved in its aetiology.

Methods:

Parents and siblings from 30 families of individuals with high-functioning ASD (HFA) were assessed for the BAP and associated traits using a 2.5 hour protocol. Clinical best estimate of BAP status was determined using a 30-45 minute interview of BAP traits rated on the Broader Autism Phenotype Rating Scale (BAPRS). To validate the interview, ASD and BAP traits were also measured using self- and informant- ratings on the Social Responsiveness Scale, 2nd ed. (SRS-2) and through self-ratings on the Broad Autism Phenotype Questionnaire (BAP-Q). Psychiatric symptoms and adaptive functioning were measured through self- and informant-ratings using the Achenbach System of Empirically Based Assessment, including the Adult Behaviour Checklist (ABCL). General cognitive abilities were measured using the Wechsler Abbreviated Scale of Intelligence, 2nd ed. (WASI-II).

Results: Clinical ratings of BAP traits significantly correlated with self- and informant-ratings of BAP traits. Individuals with the BAP exhibited similar but fewer ASD traits than individuals with ASD. A graded expression of psychiatric symptoms was also observed between the groups, with individuals with ASD having significantly more traits than those with the BAP, who in turn had significantly more traits than unaffected individuals. Participants with the BAP exhibited an uneven cognitive profile, similar to participants with ASD. Individuals with the BAP showed significant differences between their verbal and perceptual abilities, in contrast to unaffected participants who had an even cognitive profile.

Conclusions: A brief BAP interview was validated in a sample of families of individuals with HFA. Using this classification of the BAP, it was evident that individuals with the BAP exhibited similar but fewer ASD traits than their relatives with ASD, and had an intermediate expression of psychiatric symptoms including internalising and externalising behaviour, and a similar cognitive profile to individuals with ASD.

140 **128.140** What Australian Medical, Allied Health and Educational Experts Want from an Autism Spectrum Disorder Diagnostic Process

K. Evans[1,2], *J. Wray*[3], *V. Eapen*[4,5], *M. R. Prior*[6] *and A. J. Whitehouse*[1,2,7], *(1)Telethon Kids Institute, University of Western Australia, Perth, Western Australia, Australia, (2)Cooperative Research Centre for Living with Autism (Autism CRC), Brisbane, Australia, (3)State Child Development Service,* *Western Australia Department of Health, Perth, Western Australia, Australia, (4)Cooperative Research Centre for Living with Autism (Autism CRC), Long Pocket, Brisbane, Australia, (5)School of Psychiatry, University of New South Wales, Sydney, Australia, (6)The University of Melbourne, Melbourne, Australia, (7)University of Western Australia, Perth, Australia*

Background: In the absence of empirical evidence regarding the accuracy of various autism spectrum disorder (ASD) diagnostic practices, numerous clinical guidelines on the topic rely on expert consensus. However, the process for attaining this consensus is not often articulated.
Objectives: This Delphi survey sought to generate consensus recommendations regarding assessment and diagnosis from medical, allied health and educational experts in Australia.

Methods: Steering committee members from medical, allied health, education and ASD specific backgrounds were invited to nominate up to 20 experts in the ASD assessment field. This resulted in 118 professionals being invited to participate, with a total of 77 participants from a wide variety of disciplines completing (n = 66) or partially completing (n = 11) the first round of the Delphi survey. The majority of participants were diagnosticians (n=48), with other participants reporting their involvement in other aspects of the clinical or educational management of autistic children or adults. Participants had been involved in the assessment process for ASD for a median of 15 years (range = <1–40 years). Participants practiced within public and private settings, including community, hospital and university environments. The participants worked with individuals on the autism spectrum with a wide age range, from babies to older adults. A total of 42 participants provided responses on the Round 2 survey.

The questions contained within Round 1 of the Delphi Survey were developed on the basis of a scoping review. A range of potential assessment components were provided with a five point scale to allow participants to indicate their agreement regarding if each component should be part of an ASD assessment. Participants were provided with an opportunity to make comments after each question, each section and at the end of the survey. The questions contained within Round 2 of the Delphi Survey were developed on the basis of Round 1 quantitative and qualitative results, with a focus on items where agreement had not been achieved.

Two methods were utilised to determine if consensus had been achieved for a recommendation, based on the median / interquartile range and proportion of agreement. Agreement was considered to exist if both criteria were met and partial agreement was achieved if only one of the two criteria was met.

Results: Agreement was obtained for many recommendations regarding who, where and how an ASD assessment should be conducted. The strongest agreement was obtained for recommendations addressing the prerequisite knowledge and experience of professionals conducting ASD assessments, topics to be addressed during an ASD assessment (in particular history and symptoms), and assessment approaches (observation and interview).

Conclusions: Results of the Delphi survey provide clear support for guideline recommendations that are considered acceptable by medical, allied health and educational professionals.

141 **128.141** Variables at the Time of ASD Diagnosis in Toddler Years Predict Outcome in Adaptive Functioning and ADHD Co-Morbidity in Adolescence: A Long-Term Follow-up Study

E. Ben-Itzchak[1] *and D. A. Zachor*[2]*, (1)Bruckner Center for Research in Autism, Communication Disorder, Ariel University, Ariel, Israel, (2)The Autism Center/Pediatrics, Tel Aviv University / Assaf Harofeh Medical Center, Zerifin, Israel*

Background:
Some children with autism spectrum disorder (ASD), show limited progress, while others make rapid, remarkable gains. Short-term follow-up studies in ASD reported that higher cognitive ability, less severe autism symptoms, better adaptive functioning, and younger diagnosis age predicted better outcome in different domains. Adolescents with ASD have shown high rates of attention deficit/hyperactivity disorder (ADHD) co-morbidity.

Objectives:

To examine how measures of age of diagnosis, cognitive ability, autism severity and adaptive skills at diagnosis can predict long-term outcomes in adaptive skills and ADHD symptoms.

Methods:

The study included 61 participants, 55 males and 6 females, with an age range of 10:5 – 17:10 years (M=13:6±1:10y). All the participants were diagnosed with ASD (T1) in the age range of 1:3-3:1 years (M=2:2±0:5y) and were reassessed (T2) after 8:7-15:7 years (M=11:5±1:10y). ASD diagnosis at baseline employed two standardized tests, the Autism Diagnosis Interview-Revised (ADI) and the Autism Diagnosis Observation Schedule (ADOS), including the calibrated severity scale (CSS). Outcome measures included: Vineland adaptive behavior scales (VABS) composite score for adaptive skills; ADOS social-affect calibrated severity scale (SA-CSS) and restrictive and repetitive behaviors CSS (RRB-CSS) (≥4-ASD) at T1 and T2 to measure autism severity; Inattention and Hyperactivity/Impulsivity scores from the Conners' Rating Scales–Revised (CRS-R***)*** (score>60 is considered significant) at T2.

Results:

At T2, four participants (6.7%) received a score of <3 for the ADOS-SCC. Seventy percent received a score >60 for the Conners Inattention scale and 58.3% a score >60 for the Conners Hyperactivity/Impulsivity scale. To explore which variables at T1 predicted outcome in functioning (VABS composite scores) and ADHD symptoms (Inattention and Hyperactivity/Impulsivity scores) at T2, we performed three hierarchical regression models for these dependent variables.

Independent variables in each model included: T1 DQ in the first step, T1 VABS score in the second step, ADOS-SA-CSS and ADOS-RRB-CSS scores in the third step and age of diagnosis in the fourth step.

The first model, where the VABS score served as the dependent variable, explained 19.7% of the variance. ADOS-SA-SCC score ($\beta=-.36$, $p<.01$) and age of diagnosis ($\beta=-.23$, $p<.05$) correlated negatively and significantly with VABS score at T2. The second model, where the Conners Hyperactivity/Impulsivity score served as the dependent variable, explained 27.5% of the variance. DQ score at T1 ($\beta=.33$, $p<.05$) correlated significantly and positively and VABS score at T1 ($\beta=-.33$, $p<.05$) correlated significantly and negatively with the Conners Hyperactivity/Impulsivity score. The third model, where the Conners Inattention score served as the dependent variable, explained 17.7% of the variance. DQ score at T1 ($\beta=.27$, $p<.05$) and ADOS-RRB-CSS at T1 ($\beta=.36$, $p<.05$) correlated significantly and positively with the Conners inattention score.

Conclusions:

Less severe social-communication symptoms and younger ASD diagnosis age predicted better functioning in adolescence. Baseline lower adaptive skills and higher cognitive abilities predicted more severe symptoms of hyperactivity/impulsivity in adolescence. More severe RRB symptoms and higher cognitive abilities at the time of ASD diagnosis predicted more severe inattention symptoms in adolescence. Autism severity and level of functioning in early diagnosis of ASD predicted adaptive skills and ADHD co-morbidity.

142 **128.142** Measurement Invariance of the Child Behavior Checklist in a Large Sample of Children with Autism Spectrum Disorder with and without Intellectual Disability

***K. N. Medeiros**, Health Psychology, University of Missouri, Columbia, MO*

Background: Autism spectrum disorder (ASD) is characterized by core impairments in social communication and restricted and repetitive behaviors, with high rates of co-occurring emotional and behavioral problems. The Child Behavior Checklist (CBCL) is one of the most widely accepted rating scales used to assess childhood emotional and behavioral problems, and it has been used in many large-scale studies of children with ASD. Recently, conflicting research assessed whether the previously established factor model sufficiently accounts for symptom patterns in children with ASD. However, these samples have included a mix of children with and without concurrent intellectual disability (ID).
Objectives: The aim of this study was to determine whether the CBCL has the same validity in a sample of children with ASD who had ID compared to a sample of children with ASD who did not have ID. I aimed to decipher which elements of the factor models could confirm measurement invariance.

Methods: I used a multi-group confirmatory factor analysis of the CBCL subscales for young children (ages 1.5-5) and older children (ages 6-18) across those with (n=107) and without (n=301) ID. I used nested models to set progressively more constraints to test for various types of invariance across the two groups. The configural model had no constraints, and the groups were free to vary. The metric model constrained factor loadings to be equal across groups. The scalar model added that item intercepts were equal across groups. The residual model added that error variances were equal across groups. The structural model set factor variances equal across groups. Nested chi square tests assessed the null hypothesis that the more constrained model is correct under the assumption that the less constrained model is correct. I examined the seven CBCL subscales for young children: Emotionally Reactive, Anxious/Depressed, Somatic Complaints, Withdrawn, Sleep Problems, Attention Problems, and Aggressive Behavior. I examined the eight CBCL subscales for older children: Anxious/Depressed, Withdrawn/Depressed, Somatic Complaints, Social Problems, Thought Problems, Attention Problems, Rule-Breaking Behavior, and Aggressive Behavior.

Results: For young children, the configural model was the best fit for the emotional reactivity, anxiety/depression, and somatic complaints subscales. Sleep problems held metric invariance, and withdrawn behavior held residual invariance. The structural model was the best fit for both attention problems and aggression. For older children with ASD, the configural model was the best fit for the anxiety/depression, somatic complaints, social problems, attention problems, and rule-breaking behavior subscales. Whereas, withdrawn/depression, thought problems, and aggression held metric invariance.

Conclusions: The equality of factor loadings held for sleep problems in younger children, and for conduct/behavior regulation problems in older children (i.e., withdrawn, thought problems, aggression), suggesting that the CBCL measures the same latent traits in both groups, but with a bias in the manner in which trait levels are estimated. However, for young children with ASD, the CBCL measured attention and aggression problems equally across ID groups. Results of the current study suggest that cross-group comparisons of CBCL scores between children with ASD with and without ID may not always be appropriate.

143 **128.143** Tablet-Based Mobile Eye Tracking for Studying Visual Preference in Children with ASD: Proof-of-Concept and Feasibility Study

***A. Atyabi**[1], Q. Wang[2], C. Foster[2], E. Barney[3], Y. A. Ahn[4], M. Kim[4], B. Li[4,5], C. A. Paisley[6], S. M. Abdullahi[7], M. L. Braconnier[7], J. Lei[7], C. C. Kautz[8], L. L. Booth[8], M. Lyons[2], P. E. Ventola[9] and F. Shic[3], (1)Seattle Children's Research institute University of Washington, Seattle, WA, (2)Child Study Center, Yale University School of Medicine, New Haven, CT, (3)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA, (4)Seattle Children's Research Institute, Seattle, WA, (5)Computer Science and Engineering, University of Washington, Seattle, WA, (6)The University of Alabama, Tuscaloosa, AL, (7)Yale Child Study Center, New Haven, CT, (8)Yale Child Study Center, Yale School of Medicine, New Haven, CT, (9)Yale Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Eye-tracking has been used for over 15 years to study atypical visual social cognition in ASD. Current access to eye-tracking technologies is limited due to the expense of eye-tracking devices, the need for highly controlled laboratory settings, and the necessity of trained personnel. This study reports on the development of a tablet-based eye-tracking platform designed to examine the feasibility of mobile eye tracking, a step towards significantly increasing the accessibility of eye tracking for clinical applications.
Objectives: To (1) examine the feasibility of tablet-based (iPad) eye-tracking; (2) provide preliminary results regarding differences between children with and without ASD; (3) conduct a machine learning investigation of diagnostic prediction using acquired data.

Methods: Three 6-minute sessions comprising side-by-side presentations of age-appropriate social target movies with distractor movies (moving machinery, sporting events, animals, or random clips from another movie) were administered to 6-12-year-old children (ASD n=29 , non-ASD n=33). Each session included five calibration sets (three 5-point calibrations and two smooth-pursuit-trajectories with animations). Sessions paused automatically when participants' faces were not detected for more than 5 seconds.

Results: Data Quality: 92% of sessions had <2.5 degrees of calibration error. >80% valid tracking data was recorded in 83% of sessions. Across groups, valid-looking-time was 86% (SD=7%), and calibration-error 1.49° (SD=1.19°). These results indicated robust recording and participant attention. Data Quality Group Differences: Univariate ANOVAs on calibration quality indicated group differences in smooth-pursuit calibration, with the non-ASD group following both the left-half (p<.01) and the right-half (p=.056) of the pursuit better than the ASD group. No 5-point calibrations differences emerged. Looking Pattern Group/Condition Effects: A main effect of distractor condition on %Distractor (p<.001) was found with a trend toward a diagnosis*condition interaction (p=.063). Pairwise comparisons indicated children looked more at machine distractors, compared to animals (p<.001) and dynamic-naturalistic-scenes (p<.01); and more at sports compared to animals (p<.001). Participants with ASD looked more at the animal distractors than the non-ASD group (p<.05). A main effect of condition on GazeOffscreen% (p<.01) and a diagnosis*condition interaction (p<.05) was also observed. Pairwise comparisons showed that children looked offscreen more during animal distractor videos than machines (p<.001) and sports (p<.01). Participants with ASD looked offscreen less during animal distractors than the non-ASD group (p<.05). Machine Learning: Using linear support-vector-machines (SVM) on predictors (GazeOffscreen%, Distractor%, %Target, and associated timings) in a repeated (n=5) leave-one-out cross-validation with nested-bootstraps (n=10, group balancing), we achieved 79% average group-membership-prediction accuracy.

Conclusions: These analyses provide evidence for tablet-based eye tracking as a viable option for remotely quantifying eye movements in children with and without ASD. We piloted a preferential looking task to social videos and smooth-pursuit trajectories. The results revealed that children with ASD showed smooth-pursuit tracking difficulties, with nuanced differences in scanning patterns potentially relating to attentional biases relative to controls towards animal distractors. Results will be presented in the context of design choices and challenges of tablet-based eye tracking.

144 **128.144** Utility of Heart Rate Increase for Prediction of Challenging Behavior Episodes in Preschoolers with Autism

***H. J. Nuske**[1], E. Finkel[2], L. Tomczuk[3], D. Hedley[4], V. Parma[5], M. Pellecchia[6], J. D. Herrington[7], D. S. Mandell[1] and C. Dissanayake[4], (1)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (2)Department of Psychology, University of Pennsylvania, Philadelphia, PA, (3)Neuroscience Department, Dickinson College, Carlisle, USA, Carlisle, PA, (4)Olga Tennison Autism Research Centre, La Trobe University, Melbourne, Australia, (5)William James Center for Research, ISPA - Instituto Universitário, Lisbon, Portugal, (6)University of Pennsylvania, Philadelphia, PA, (7)Center for Autism Research, The Children's Hospital of Philadelphia, Philadelphia, PA*

Background: Understanding the triggers to challenging behavior is difficult in some children with autism due, in large part, to their limited communication abilities generally, and communicating emotions in particular. Physiological indicators such as increase in heart rate are well-established, fine-grained measures of emotional stress; they may provide important insights on the triggers to challenging behavior.
Objectives: The study aim was to determine the predictive utility of increase in heart rate to indicate a challenging behaviour episode in children with autism with frequent challenging behaviors.

Methods: Whilst wearing a ECG monitor, 41 children with autism recruited as part of a larger study aged 2-4 years participated in tasks from the Laboratory Temperament Assessment Battery, which mimic everyday life experiences requiring emotional regulation in low-level stress situations (e.g., waiting for a snack). Coders blind to diagnostic group coded challenging behaviors during the 1-1.5 hour-long sessions (i.e., aggression, self-injury, property destruction, loud noises and non-compliance, n=212) and random non-challenging behaviors (n=106). Only 13/41 participants exhibited challenging behaviors. Baseline-corrected heart rate (HR) was computed for each behaviour. The predictive utility of HR in challenging vs. non-challenging behaviors was examined via Receiver Operating Curve (ROC) analysis and a binary logistic regression model was run to examine the contribution of participant characteristics on the association between HR and challenging vs. non-challenging behaviors.

Results: On average, children with autism showed a 21±10% HR increase from baseline, 58±22 s before the onset of a challenging behaviour. The ROC analysis indicated that the peak HR change predicts fairly well the onset of a challenging behaviour vs. non-challenging behaviors (area under the curve= .71, p< .001, 95% CI= .66 - .77), see Figure 1. However, across children there was considerable variation in area under the curve coefficients (.28, p= .20; - .95, p= 04). Binary logistic regression results indicated that the behavioral outcome (challenging vs. non-challenging behavior) was explained by peak HR change (*Nagelkerke* R^2= .21, p< .001), and additionally by participants' gender [female] and age [older] (*Nagelkerke* $R^{2\ \mathrm{change}}$= .06, p= .002). Autism severity and developmental ability did not significantly contribute variance to the model (see Table 1).

Conclusions: Results indicate that physiological stress predicts challenging behaviour episodes in preschoolers with autism, particularly for girls and older preschoolers. Given the recent technological advances in wearable biosensing, our results indicate that incorporating HR monitoring in intervention for autism may be helpful for some children. By signalling children's stress, such wearables may allow parents and teachers to intervene and create learning opportunities for emotional expression and regulation. However, given the strength of the prediction and likelihood of false positives, individualised human-computer interaction and machine learning algorithms may be needed to increase the utility of including such information in moment-to-moment treatment planning.

145 **128.145** A Diagnostic Tool for Reciprocal Behavior in Children, Adolescents and Adults with ASD

***S. Begeer**[1], T. Backer van Ommeren[2], H. M. Koot[3], M. Vreugdenhil[4] and A. Scheeren[5], (1)VU University Amsterdam, Amsterdam, Netherlands, (2)Clinical Developmental Psychology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, (3)Clinical, Neuro and Developmental Psychology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, (4)Clinical Developmental Psychology, Vrije Universiteit Amsterdam, Amsterdam, New Caledonia, (5)Psychology, University of Tilburg, TIlburt, Netherlands*

Background: Individuals with Autism Spectrum Disorder (ASD) are characterized by a poor understanding of the social norms for reciprocal behavior. The DSM-5 now includes deficits in reciprocity as a *necessary* criterion for an ASD diagnosis, whereas the DSM-IV included it as a possible criterion (APA 2000, 2013). Qualitative differences in social reciprocal skills of individual with Autism Spectrum Disorder (ASD) across gender, IQ levels and ages have not been studied to date. A new test for reciprocity, the Interactive Drawing Test (IDT; Backer van Ommeren, et al,. 2012; 2015; 2017[a], 2017[b]), was shown to be a valid measure of the quality of reciprocal behavior, and highly sensitive to differences between individuals with and without ASD.
Objectives: To measure the sensitivity of the IDT for differences in reciprocal behavior in participants with or without ASD, across age and intelligence levels.

Methods: Reciprocal behaviors of individuals with autism were analyzed using the Interactive Drawing Test (IDT), a valid instrument to assess reciprocal behavior. In 5 studies, we analyzed over 500 individuals with or without ASD, including children, adolescents, and adults, intellectually disabled or normally intelligent, male and female. In addition to the paper version, we also tested a digital touch table version of the test.

Results: The IDT showed a high sensitivity to ASD. Large effect sizes indicated strong differences between ASD and TD participants in the quality of reciprocal behavior. These differences were independent of gender, IQ and age. ASD girls performed better than ASD boys, but both groups showed more limitations compared to TD children. Specific response patterns will be discussed, including comparisons to ADOS. The digital version of the IDT showed equal sensitivity to ASD.

Conclusions: The IDT seems highly suitable to assess impairments in reciprocal behavior and to differentiate between performances of ASD and TD children and adolescents with and without MID. The administration is short and cheap, participants appreciate the procedure (making a mutual drawing), and the IDT will be a welcome addition to standardized test batteries for ASD.

Poster Session
129 - Medical and Psychiatric Comorbidity
5:30 PM - 7:00 PM - Hall Grote Zaal

146 **129.146** A Dimensional Relationship between Autistic and Paraphilic Traits

*E. Deakins[1], W. Simpson[2] and **M. Belmonte**[3], (1)Division of Psyhcology, Nottingham Trent University, Nottingham, United Kingdom, (2)Division of Psychology, Nottingham Trent University, Nottingham, United Kingdom, (3)Com DEALL Trust, Bangalore, India*

Background: Autism spectrum conditions (ASC) are typified by visual thinking, that is, by the attachment of meaning and significance to concrete visual representations, and by an aversion to the unpredictable and unscripted nature of conventional social interaction. Also typified by attachment of undue significance to sensory (usually visual) stimuli and a tendency to scripted behaviour is paraphilia, in which a stimulus or situation that is not conventionally sexual becomes an occasion for sexual arousal. Most paraphilias are innocuous (e.g. involving specific clothing, or scripted roleplay) except insofar as compulsive interest in the paraphilic sexual outlet may displace interest in the human partner, interfering with formation and maintenance of healthy relationships. Our own case data suggest heightened incidence of such effects in ASC and the broader autism phenotype (BAP). Paraphilic traits, like autistic traits, may vary dimensionally and in subclinical cases may simply constitute unusual object-centred and/or scripted interests integrated into healthy sexual relationships.

Objectives: We queried whether paraphilic traits extend transdiagnostically, and whether scripted and sensory aspects of such dimensional paraphilic traits correlate with dimensional autistic traits.

Methods: Qualitative interviews with 16 young adults (7 male) generated common paraphilic themes within the bounds of typical sexual outlet. The resulting items were included in a 220-item questionnaire administered to 300 typical individuals (107 men, 187 women, 6 unspecified gender, age 23.72±8.26, range 18-56), 161 of whom (62 men, 99 women) thereafter consented also to complete the Autism Spectrum Quotient (AQ) and the Broader Autism Phenotype Questionnaire (BAPQ). Principal components analysis was conducted on the paraphilia questionnaire, resulting factors were labelled, and items not loading strongly (>0.4) on any single factor were dropped, yielding a 190-item scale. Loadings were used to compute factor scores for each individual. Each of the three BAPQ subscales and the AQ was entered alongside gender as a predictor in an analysis of covariance with each of these factor scores, using Type III sums of squares. Holm-Bonferroni correction was applied to tail probabilities.

Results: Principal components analysis generated fourteen factors accounting for 51.13% of variance in reported paraphilic interest, all but one of which were significantly greater in males. Nine of these fourteen paraphilic trait factors correlated significantly with measures of autistic traits. The AQ captured a subset of the relationships captured by BAPQ subscales. BAPQ Aloof predicted a cluster of factors relating to desire to be violated (*e.g.* wet-and-messy fetishes, submission, desire to be victimised). Similarly BAPQ Aloof, and in males also BAPQ Rigid, predicted a cluster relating to desire to replay a defeat as a victory (*e.g.* transvestism, frotteurism, voyeurism). BAPQ Rigid predicted a cluster relating to desire to be disempowered (positive effect on desire to be mothered, negative effect on desire to dominate).

Conclusions: Autistic traits correlate with paraphilic traits in the general population. Paraphilic interests thus are likely to be of high incidence in autism and in its broader phenotype. Knowledge of this association can inform relationship counselling for couples affected by ASC/BAP, dispelling stigma and aiding integration of paraphilic interests into healthy relationships.

147 **129.147** A Longitudinal Study of Sleep Disturbance and Parent Stress in Children with ASD at 4 and 6 Years of Age: A Mediational Model

***A. Estes**[1], T. Ward[2], J. N. Collett[1], K. E. MacDuffie[3] and J. Munson[4], (1)University of Washington, Seattle, WA, (2)School of Nursing, University of Washington, Seattle, WA, (3)Speech and Hearing Sciences, University of Washington, Seattle, WA, (4)UW Autism Center, University of Washington, Seattle, WA*

Background: It is estimated that 70% of 2-6 year olds with ASD experience sleep disturbances, a rate two to three times that of typically developing 2-6 year olds (15-40%). Emerging evidence suggests young children with ASD may suffer from sleep-onset difficulties, frequent night awakenings, irregular sleep patterns, and reduced sleep duration in comparison to children with developmental delays and typical development. Early childhood is particularly important for establishing healthy sleep patterns to support rapid physical growth, cognitive development, and self-regulation skills. Untreated sleep disturbances are known to pose significant adverse consequences including cognitive deficits and daytime sleepiness in typically developing children, and may exacerbate symptoms and negatively affect social interactions in children with medical problems. Parents may also be negatively impacted by child sleep disturbances. Little is known about the impact of sleep disturbances on cognitive and behavioral functioning in children with ASD or the impact of child sleep disturbances on stress in parents of children with ASD.

Objectives: To examine 1) the nature and extent of parent-reported sleep disturbances in children with ASD longitudinally at ages 4 and 6, 2) the association of sleep disturbances with child cognitive abilities and problem behaviors, and 3) whether the association between child sleep disturbances and parenting-related stress is mediated by increased problem behaviors.

Methods: Participants were a sample of children (n = 38 at age 4; n = 36 at age 6) who met DSM-IV criteria for a Pervasive Developmental Disorder based on direct assessment (ADI-R, ADOS) by research reliable examiners using all available information. All participants had data from the Child Sleep Habits Questionnaire (CSHQ), a parent-report of a child's sleep behavior over the previous week. Child cognitive ability (Mullen Scales of Early Learning age 4; Differential Abilities Scale age 6), child problem behavior (Aberrant Behavior Checklist), and parenting-related stress (Questionnaire on Resources and Stress) were assessed when children were age 4 and 6.

Results: Over 73% of children met criteria for sleep disturbance at age 4 (28/38) and over 83% at age 6 (30/36). Longitudinally, 22/30 children (73%) showed sleep disturbances at both time points. Cognitive ability was not significantly related to sleep at either age. At age 4, sleep was not related to problem behavior or parenting stress. However, at age 6, sleep disturbance was related to both increased problem behavior and parenting stress. Mediation was not testable at age 4, as child sleep was not related to parenting stress. However, at age 6, problem behaviors completely mediated the effect of sleep disturbance on parent stress (Sobel test: $Z = 2.79$, $p = .005$).

Conclusions: Sleep disturbances in children with ASD appear highly stable from age 4 to 6. By age 6, sleep disturbances are related to problem behavior and parent stress. The preschool years may be well-suited for implementing parent-delivered sleep interventions to support the development of adequate, well regulated sleep in young children with ASD and could reduce caregiver stress associated with child sleep disturbances and related problem behaviors.

148 **129.148** Anxiety and Sleep Disturbance in Youth with Autism Spectrum Disorder

***P. Renno**[1], L. Sterling[2], J. Yang[3] and J. J. Wood[4], (1)University of California Los Angeles, Los Angeles, CA, (2)California State University Long Beach, Long Beach, CA, (3)Department of Psychiatry and Biobehavioral Sciences, UCLA, Los Angeles, CA, (4)Human Development & Psychology, University of California, Los Angeles, Los Angeles, CA*

Background: Sleep problems are prevalent in individuals with ASD, with up to 50-80% of children with ASD experiencing sleep disturbance (Williams, Sears & Allard, 2004). There are many factors that may contribute to insomnia in children with ASD. In the typically developing literature, anxiety symptoms are related to sleep disturbance (Alfano, Beidel, Tuner, & Lewin, 2006). In ASD, greater anxiety has also been related to sleep problems in broad samples of children and adolescents with ASD using parent-report questionnaires (Mazurek & Petroski, 2015). However, little is known about specific anxiety subtypes that may be related to greater sleep disturbance in youth with ASD.
Objectives: This study aimed to investigate the relation between specific anxiety subtypes and sleep disturbance in a well-characterized sample of youth with ASD.

Methods: Participants were 43 youth with ASD (aged: 7-14; IQ > 70). Sleep diaries were completed by parents at home for three nights. Parent (*i.e., Multidimensional Anxiety Scale for Children-parent version; MASC-P*), child (i,e., *Multidimensional Anxiety Scale for Children-child version; MASC-C*) and diagnostician (i.e., *Pediatric Anxiety Rating Scale; PARS*) reports of anxiety symptoms were collected.

Results: Preliminary results from correlational analyses suggest sleep disturbance is related to parent, child, and clinician-reports of anxiety. More nighttime awakenings were significantly related to greater total anxiety reported on the *MASC-P* (*r*=.657, *p*=.001), *MASC-C* (*r*=.438, *p*=.041), and P*ARS* (*r*=.434, *p*=.038). Sleep quality was also significantly related to anxiety symptoms. Poorer sleep quality was related to greater overall anxiety on the *MASC-P* (*r*=-.513, *p*=.009). In regard to specific anxiety types, greater separation anxiety reported on the *PARS* and *MASC-P* was related to poorer sleep quality (*r*=-.466, *p*=.033; *r*=-.513, *p*=.009, respectively). Additionally, more nighttime awakenings were related to social anxiety symptoms reported on the *MASC-P* (*r*=.514, *p*=.014).

Conclusions: Findings from this study suggest anxiety may contribute to sleep disturbance in youth with ASD and no intellectual disability. In particular, sleep problems may be especially prevalent in children with separation anxiety and social anxiety. These results indicate that sleep is an important treatment target for anxious youth with ASD. Future research should continue to investigate insomnia as a determinant and/or consequence of anxiety in youth with ASD and examine other factors that may contribute to insomnia and anxiety in these youth.

149 **129.149** Autistic Characteristics in Anorexia Nervosa and Its Relationship with Anxiety, Depression and Eating Habits

*J. Lugo-Marín[1], M. P. López[2], M. Alviani Rodríguez-Franco[3], E. Diez Villoria[4] and **R. Canal-Bedia**[5], (1)Hospital Universitario Nuestra Señora de Candelaria, Tenerife., Spain, (2)Unidad de Trastornos de la Conducta Alimentaria, Hospital Universitario de Canarias, Tenerife, Spain, (3)Servicio de Psiquiatría, Hospital Universitario Nuestra Señora de Candelaria, Tenerife, Spain, (4)Universidad de Salamanca, Salamanca, Spain, (5)University of Salamanca, Salamanca, Spain*

Background: The Autism Quotient (AQ) (Baron-Cohen et al., 2001) is a 50-item screening questionnaire that is broadly used in clinical practice regarding the identification of autistic characteristics in adult population. The participant must choose the most suitable out of four alternatives ('Strongly agree', 'Slightly agree', 'Slightly disagree', 'Strongly disagree'). This tool has been shown to be useful in the detection of autistic characteristics in different psychiatric populations (Sizoo et al., 2009; Lugnegård, 2015). A special case is that of anorexia nervosa (AN). In a meta-analysis on the use of AQ in population with AN (Westwood et al., 2016), it was found that patients with AN presented higher scores in AQ compared to healthy controls. This suggests a possible relationship between autistic traits and the development of eating disorders.
Objectives: The aim of this study is to explore the relation of autistic characteristics with eating behaviors in a sample of young people with AN, as well as their relation with anxiety and depression symptoms.

Methods: Thirty adolescents and young adults (27 women and 3 men; mean age 16.43 years, sd 2.5) were asked to complete the AQ, as well as the Beck Anxiety Inventory (BAI) (Beck & Steer, 1988), the Beck Depression Inventory (BDI-II) (Beck, Steer & Brown, 1996), and the Eating Disorder Inventory (EDI-3) (Garner, 2002). The sample was divided by taking the median in the AQ score as the cutoff point and comparing the scores in the BAI, BDI-II and EDI-3. Finally, correlations between autism scores and measures of anxiety and depression, as well as eating behaviors were explored.

Results: The results suggest that there are no differences between both, above- and below-AQ median groups, in the three clinical measures (p <.05). Scores on anxiety, depression and eating behaviors do not present significant correlations with the AQ total score. One of the five subscale of the AQ (Communication) shows significantly correlations with anxiety (r=0.63), depression (r=0.67), and eating behaviors (r=0.61), but only in the above-AQ median sample.

Conclusions: These findings shed light on the role of autistic traits in young population suffering from AN. The results found here suggest that eating disorders are not directly related with the presence of autistic traits. Also, it seems that autistic characteristics do not play a main role in the emergence of anxious or depressive symptoms among these population. A lack of communication skills seems to be related to the psychiatric symptoms described above. Some limitations of this study are the reduced number of participants, as well as the lack of a comparison non-clinical group. Further investigation of autistic traits in this population, as well as their first-degree relatives, could be of interest.

150 **129.150** Autistic Traits and Further Clinical Manifestations in Phelan-Mcdermid Syndrome (22q13 deletion syndrome)

***M. Burdeus**, Instituto de Investigación Biomédica Gregorio Marañon , CIBERSAM, IISGM, Madrid, Spain*

Background: Phelan-McDermid syndrome (22q13.3 deletion syndrome or PMS), is a genetic disorder characterized by global developmental delay, severe speech impairments, intellectual disability, hypotonia and autism spectrum disorder to a variable degree. The loss of a functional copy of the SHANK3 gene, responsible for the codification of a scaffolding protein in the postsynaptic density, causes the clinical phenotype of PMS. Recent studies suggest that deletions or mutations compromising SHANK3 can cause a monogenic form of both ASD and intellectual disability, accounting for around 1% of the overall ASD cases [Guilmatre et al 2012; Durand et al 2007; Moessner et al 2007] and 0.3-1% of the ID [Cooper et al 2011; Gong et al 2012]. Literature also reports a higher prevalence of medical and psychiatric comorbidities and developmental regression in patients with 22q13.3 deletions [Scoorya et al 2013; Denayer et al 2012].
Objectives: To describe the clinical phenotype of a sample of participants with PMS, using standardized tools for the assessment of repetitive or otherwise altered behaviors, global adaptive functioning and ASD. Furthermore, we seek correlations between the clinical phenotype and the information provided by previous genetic reports regarding length of deletion and other abnormalities, such as ring chromosomes, deletions or duplications in multiple regions or mosaicisms, among others.

Methods: Forty-four participants were recruited in coordination with the PMS Association in Spain or through direct contact with their clinicians at the HGUGM in Madrid. Mean age is 10.41 and the sample shows an equal gender distribution.

Clinical assessment was conducted through a variety of questionnaires and scales measuring altered behavior (CBCL, ABC-C, RBS-R), adaptive behavior (Vineland-3) and social responsiveness (SRS). We assessed ASD –related development and symptoms by means of gold-standard diagnostic instruments, ADI-R and ADOS-2.

Results: Preliminary results of 30 participants are available, showing great variability in their clinical symptoms. Despite all patients showing mild to severe intellectual disability and deficiencies in language acquisition, the severity of the difficulties in social communication and restrictive, stereotyped or altered behavior appears to be variable, with some individuals presenting behavioral abnormalities (self-injuries, sleep disturbances, attention deficit or hyperactivity, among others). A majority of participants showed impaired development with autistic traits during early childhood; however, only some of them meet criteria for ASD at present evaluation, according to DSM-5 . Developmental regression or stark developmental standstill affecting language, motor or daily living skills is possibly present in 6 to 10 cases, with an age of onset ranging from two years to adolescence.

Evaluations are still taking place; these results may therefore suffer modifications.

Conclusions: Clinical manifestations of the Phelan-McDermid syndrome are heterogeneous, showing a wide range of symptom severity. We observe differences between present moment and early years in relation to autistic-like behaviors. Neuropsychiatric disturbances and aberrant behaviors are also reported. Developmental regression may begin at a later age (early adolescence) and occur in combination with a period of psychiatric distress. Further investigation is required to ascertain possible associations between clinical features and genotype-phenotype correlations.

151 **129.151** Differences in the Anxiety Profiles of Middle Childhood Boys and Girls with ASD

L. Libero[1]*, B. Winder-Patel*[2]*, M. Solomon*[3]*, C. W. Nordahl*[1] *and D. G. Amaral*[1]*, (1)Department of Psychiatry and Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, UC Davis School of Medicine, University of California Davis, Sacramento, CA, (2)MIND Institute, University of California, Davis, Sacramento, CA, (3)Department of Psychiatry & Behavioral Sciences, The Medical Investigation of Neurodevelopmental Disorders (MIND) Institute, University of California, Davis, Sacramento, CA*

Background: Symptoms of anxiety are reported commonly in ASD, with approximately 30-50% of individuals with ASD meeting criteria for an anxiety disorder. In typical development, anxiety disorders affect boys and girls at similar rates during early childhood, but at higher rates in females by adolescence. It is unclear whether these sex differences exist in the context of ASD. The current study evaluates a longitudinal dataset of children with ASD to examine potential predictors of the development of clinically significant anxiety in children with ASD.
Objectives: To examine anxiety prevalence and severity in boys and girls with ASD. To define early childhood predictors of the development of clinically significant anxiety at middle childhood.

Methods: Participants studied to date include 30 children with ASD (20 male/10 female; IQ range 39-123; ADOS-2 composite score range 5-10) enrolled in the ongoing Autism Phenome Project. Early childhood behavioral measures (Autism Diagnostic Observation Schedule-Generic [ADOS-G], Childhood Behavior Checklist for Ages 1½-5 [CBCL], Short Sensory Profile [SSP], and Vineland Adaptive Behavior Scales-II [VABS-II]) were collected at approximately 3 years-of-age. The children are currently between 9 and 13 years of age and clinically significant anxiety was evaluated using the clinician administered Anxiety Disorders Interview Schedule (ADIS-IV) parent version with the Autism Spectrum Addendum. Children with a clinical severity rating of 4 or greater were classified as having an anxiety disorder.

Results: In middle childhood, there is a trend towards a greater proportion of girls with ASD who have clinically significant anxiety than boys with ASD (80% of girls vs. 65% of boys, X^2=0.71, p=0.39). Girls with ASD also have more severe anxiety than boys as measured by the ADIS-IV clinical severity rating (girls=5.20, boys=3.70, F=5.6, p=0.024). Interestingly, for girls with ASD, but not for boys, parent-ratings of behavior on the CBCL at 3 years-of-age predicts anxiety severity in middle childhood for three subscale scores: Internalizing t-score (F=17.62, p=0.002, R^2=0.716), Withdrawn t-score (F=10.01, p=0.016, R^2=0.539) and Emotionally Reactive t-score (F=12.96, p=0.009, R^2=0.649). Scores on the ADOS-G, SSP, and VABS-II were not predictive of anxiety for boys or girls.

Conclusions: By middle childhood, a greater proportion of girls with ASD develop anxiety disorders and with greater severity, compared to boys with ASD. In typical development, sex differences in the prevalence of significant anxiety are present around this age (approximately 12% of girls versus 8% of boys have an anxiety disorder). It should be noted that both girls and boys with ASD are presenting with anxiety at rates much higher than their typically developing peers. In girls, the CBCL also may provide an early predictor for the future development of anxiety, which holds clinical implications for specific early intervention of anxiety symptoms. This study provides evidence for sex differences in the anxiety profiles of girls and boys with ASD.

152 **129.152** Discharge from Children's Services: Experiences and Predictors of Mental Health Outcomes

H. Merrick[1]*, C. King*[2]*, H. McConachie*[1]*, J. R. Parr*[3] *and A. LeCouteur*[1]*, (1)Institute of Health and Society, Newcastle University, Newcastle upon Tyne, United Kingdom, (2)Northumberland, Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, (3)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background:

Young people (YP) with mental health problems can get 'lost' following discharge from child and adolescent mental health services. Adult services may have different referral criteria or there may not be an appropriate service for young people to be referred to. This disruption of care may especially adversely affect the health, wellbeing and longer-term outcomes of YP on the autism spectrum. Mental healthcare transition occurs at approximately the same time as other developmentally appropriate transitions such as leaving school, moving to further education or employment, or seeking some degree of independence. For YP with ASD these transitions may be further complicated with a lack of support and post-education options.

Objectives:

The overall aim of this study was to describe the lived experience and outcomes for YP with ASD and an additional mental health problem leaving child and adolescent mental health services (CAMHS) and how this relates to their mental health and wellbeing.

Methods:

Participants were YP aged 14-18 years, with a diagnosis of ASD without additional intellectual impairment who were accessing CAMHS, from a 3-year longitudinal study. YP completed measures on their mental health (Hospital Anxiety and Depression Scale; HADS), wellbeing (Warwick and Edinburgh Mental Wellbeing Scale), and frequency of social participation. Additional qualitative contextual (clinical, family, social and education) information about the YP and their families was recorded by the research assistant. Qualitative and quantitative data were used to identify mental health outcomes and potential predictors of transfer locations (general practitioner or adult mental health services). Framework analysis was used to identify themes in the YP's lived experiences over the course of the longitudinal study.

Results:

In total, 118 YP with ASD and additional mental health problems completed baseline measures (mean age= 16.1 yrs). 88 (74.6%) YP completed a final visit (either 3 or all four visits). By the final visit, 60 YP were in full time education, 5 YP were in full time employment, 1 in part time, 3 doing volunteer work, 3 in vocational training, 6 were looking for work, and 7 were unemployed and not looking for work (3 missing data). Only 24 YP (27.3%) transferred to adult mental health services, 44 (50%) were under general practitioner care and 20 (22.7%) remained in children's mental health services. Predictors of transfer location will be reported.

Wellbeing was consistently below general population norms and the proportion of YP with an 'abnormal' HADS score on the 'anxiety' and 'depression' domains remained the same over the 4 visits. The qualitative themes allowed us to understand in more detail the YP lived experiences of transition and identify variables associated with ongoing problems or with positive outcomes.

Conclusions:

This study has identified the health and social factors that are relevant for young people with ASD as they are discharged from children's services. For some young people adulthood is a new beginning. For others ongoing mental health difficulties, social needs and lack of access to adult services remain key risk factors for outcome in adulthood.

153

129.153 Does Autism Risk Confer a Greater Risk for Sleep Problems?

A. J. Schwichtenberg[1]*, E. A. Abel*[1]*, A. M. Kellerman*[1]*, P. L. H. Chong*[1]*, M. Miller*[2] *and S. Ozonoff*[3]*, (1)Purdue University, West Lafayette, IN, (2)University of California, Davis, MIND Institute, Sacramento, CA, (3)Psychiatry and Behavioral Sciences, University of California at Davis, MIND Institute, Sacramento, CA*

Background: Elevated rates of sleep problems have been reported in children with autism spectrum disorder (ASD), their parents, and their younger siblings. In families raising children with ASD the mechanisms for familial sleep problems are unclear. Sleep problems may align with ASD risk and simply reflect an element of the broader autism phenotype. Conversely, sleep (particularly in young children) implicates parents; therefore, sleep disruption in families could evolve from one child having a sleep problem. The proposed study explores these hypotheses by assessing maternal and sibling sleep in families raising children with ASD (and a comparison group).

Objectives: The overall goals of this study were to: (1) assess if elevated autism risk is associated with elevated maternal and sibling sleep problems, (2) assess whether sleep problems align with developmental functioning/concerns, and (3) assess whether maternal sleep problems are associated with child sleep problems.

Methods: Participants included families raising children with ASD (high-risk group; *n*=45) and families with no history of ASD (low-risk group, *n*=55) who were part of a prospective, longitudinal study. When children were 30 or 36 months of age, mothers completed the Children's Sleep Habits Questionnaire (CSHQ), the Child Behavior Checklist (CBCL), and the Pittsburgh Sleep Quality Index (PSQI). At 30 or 36 months children also completed a detailed developmental battery and were classified as having developmental concerns (DC group, *n*=36) or typical development (TYP group, *n*=36). Additionally, between 18 and 24 months of age a subgroup of children (*n*=72) wore an actigraph to objectively record their sleep for 7 consecutive 24-hour periods.

Results: General linear models were employed with terms for infant sex and family income where appropriate. Risk group status was not associated with sleep problems reported on the CSHQ or CBCL. Similarly, actigraphy indexed sleep patterns were not significantly different across the risk groups. When comparing children in the DC and TYP groups, sleep problems on the CSHQ were elevated for children in the DC group for sleep onset delay ($p<.05$), sleep anxiety ($p<.05$), and were slightly elevated for bedtime resistance ($p=.05$). On the CBCL, general sleep problem reports were also elevated for children in the DC group ($p<.01$). Additionally, children in the DC group slept less at night ($p<.05$) and had more variable nighttime sleep ($p<.01$). Maternal reports of their own sleep did not differ across risk groups or DC and TYP groups. However, mothers were more likely to endorse problems with their own sleep if their child had high nighttime sleep variability (measured via actigraphy), short sleep duration, sleep distress, and general sleep problems (all $p<.05$).

Conclusions: Sleep problems in families raising children with autism do not appear to align with general ASD risk. Rather sleep problems in this study were associated with developmental concerns. For parents, having a child with a sleep problem, not simply a child with ASD, was associated with elevated problems with their sleep. This study demonstrates the strong interconnectedness of family sleep in families with and without a history of ASD.

154

129.154 Early Life Developmental Deviances and Prediction of Psychosis in 22q11.2 Syndrome

D. Fraguas[1] *and M. Bravo*[2]*, (1)Child and Adolescent Psychiatry, Hospital Gregorio Marañon, CIBERSAM, IISGM, Madrid, Spain, (2)Hospital Gregorio Marañon, Madrid, Spain*

Background: The chromosomal region 22q11.2 is particularly vulnerable to aberrant rearrangements, generating deletions or duplications, and producing a set of developmental anomalies. The 22q11 deletion syndrome (22q11.2DS) occurs at a frequency of around 1 in every 2,000-4,000 live births, making it the most common known interstitial deletion in humans.

This syndrome is one of the most common genetic causes of neurodevelopmental disorders, such as attention deficit hyperactivity disorder (ADHD) or autism spectrum disorders (ASD). It has also become one of the better known risk factors for developing psychotic symptoms. It has been estimated that the risk of developing schizophrenia for an individual with 22q11DS approaches 20 times the risk in the general population.

Objectives: The objective of this analysis was to evaluate the predictive value of the presence of developmental alterations in early childhood (retrospective assessment at age 4) on the risk of psychosis in late childhood and adolescence (current assessment).

Methods: 55 individuals with 22q11.2DS were recruited consecutively from the outpatient unit "Genetics and Mental Health Program" in the Child and Adolescent Psychiatry Service of the University Hospital Gregorio Marañón, Madrid.

We collected data on sociodemographic characteristics, retrospective neurodevelopment and social functioning in early childhood (by means of the social communication questionnaire, SCQ), and current psychotic symptoms and diagnosis (by means of diagnostic interviews, K-SADS or SCID, according to the age of participants, and the clinical scales PANSS and SIPS).

The objective of this analysis was to evaluate the predictive value of the presence of developmental alterations in early childhood (retrospective assessment at age 4) on the risk of psychosis in late childhood and adolescence (current assessment).

Results: The presence of aberrant neurodevelopmental processes in early childhood, measured by the SCQ, was associated with an increased risk of psychosis in late childhood and adolescence, Odds Ratio=1.16, Cohen's D=1.08, p<0.001.

Conclusions: To the best of our knowledge, this is the first report describing an excess risk of psychosis in a sample of patients with 22q11.2DS with abnormal neurodevelopmental indicators during early childhood. These data support the importance of the so-called "personalized medicine" to develop strategies to get early detection and early intervention in specific populations such as subjects with 22q11.2DS.

155 **129.155** Emotion Dysregulation in Youth Presenting for Evaluation to a Specialized Autism Clinic

R. A. Vasa[1,2]*, A. Keefer*[2]*, V. Singh*[2]*, L. Kalb*[2]*, J. S. Hong*[2] *and C. A. Mazefsky*[3]*, (1)Kennedy Krieger Institute, Baltimore, MD, (2)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (3)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Research suggests that emotion dysregulation (ED) is an associated feature of autism spectrum disorder (ASD) and may contribute to the high rates of psychopathology in this population (Mazefsky and White, 2014). Few studies, however, have attempted to identify clinical features that distinguish ED in youth with and without ASD. This information could be helpful in recognizing ED, and developing customized treatments for each group.

Objectives: To compare (1) the prevalence of ED among youth with and without ASD and (2) whether youth with and without ASD differ in ED symptom profiles, parenting stress and treatment utilization.

Methods: Data were from 1099 youth (n=727 with ASD; n =372 without ASD), ages 6 to 18 years (M=10.2, SD=3.0), who were seen by a clinician for evaluation at a specialized ASD clinic between 2014-2017. ASD diagnosis was confirmed via clinical evaluation. Parents completed the Child Behavior Checklist (CBCL), the Parenting Stress Index-4th Edition, and customized clinic forms that asked about current mental health treatments. ED was assessed using the Dysregulation Profile from the CBCL, which is a composite T score of the aggression, anxious/depressed, and attention problems subscales (Achenbach, 1991). Moderate and severe ED were defined as T scores between 180-210 and above 210, respectively. Bivariate (Chi-square and t-tests) and multivariate (logistic, multinomial and linear regressions) analyses were employed to examine the associations between ED, ASD, parental stress, recipient of treatment, and demographics (age, gender, race, and insurance status).

Results: Overall, 55% of youth with ASD and 67% of youth without ASD met the cutoff for ED. Youth without ASD were more likely to have severe ED (27% vs. 15%), however, the proportion of youth with moderate ED was comparable across the groups (40% for both groups). After adjusting for demographics, youth with ASD had a significantly lower probability of having moderate/severe ED (OR = 0.62; p < 0.001), specifically severe ED (0.41; p < .001). When examining symptom profiles, all three Dysregulation Profile subscales were significantly lower in the ASD group (all p < .05). Parenting stress levels were significantly related to increasing levels of ED, regardless of ASD diagnosis, (p < 0.001). Overall, 37% of youth with ED were receiving no treatment and 21% were receiving both pharmacotherapy and behavioral therapy.

Conclusions: The majority of youth presenting to an ASD clinic had moderate or severe ED. Severe ED was more common in youth who did not end up with an ASD diagnosis. This finding likely reflects the complex mental health issues of youth who present for ASD evaluations but do not have ASD. It is therefore critical that clinicians not rely on ED as a specific feature of ASD, but rather maintain focus on obtaining a thorough developmental history of core ASD features. The high levels of parenting stress and alarmingly limited number of youth with ED engaged in treatment demonstrates the importance of early detection and facilitating access to care for all youth with ED.

156 **129.156** Enhancing Health, Well-Being and Physical Activity Among Adolescents with Autism Spectrum Disorder

P. Jachyra[1]*, E. Anagnostou*[2]*, B. Gladstone*[3]*, R. Renwick*[4] *and B. Gibson*[5]*, (1)University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada, (4)Occupational Therapy, University of Toronto, Toronto, ON, Canada, (5)Physical Therapy and Bloorview Research Institute, University of Toronto and Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Despite the numerous health/social benefits of regular physical activity participation (PAP), adolescents with Autism Spectrum Disorder (ASD) are less likely to be physically active compared to their age-related peers. Research suggests that they become even less active during adolescence in both school/community settings. With declining PAP during adolescence, side effects of psychotropic medication treating core symptoms often resulting in weight gain, and high levels of sedentary activity participation, they are at significantly higher risk to develop complex acute/chronic health conditions such as cardiovascular disease, psychological disorders, and musculoskeletal disorders. Given these

health complications, there is a need then to examine how to potentially increase PAP in an attempt to mitigate some of these preventable health complications. To date, much of the research examining PAP has drawn from the somato-motor performance (issues with balance, gait and joint flexibility) deficits associated with ASD. As such there is a paucity of research, and no research in Canada that has examined how non-bio-physical factors influence PAP.
Objectives: The purpose of this study was to examine the social, psychological, and behavioural, factors which influence PAP.

Methods: A qualitative study was conducted to elicit an in-depth examination and understanding of the factors which facilitate/constrain PAP. Ten adolescents with ASD (aged 11-18 years) and ten caregivers were interviewed from Ontario, Canada to maximize the depth/breadth of perspectives. Data was analyzed thematically where interview transcripts were coded to develop a preliminary understanding of the data. Codes with common patterns were then clustered and themes were generated. Negative cases within the data were used to test the rigour of the interpretations. Analytic memo writing and final integrative writing about PAP were employed to ensure findings were grounded in participant data. Participant quotes were drawn out to support research findings.

Results: Among adolescents, little exposure to PAP during childhood, bullying/traumatic experiences, and feeling an incessant pressure to camouflage in order to act ‘normal to fit in’ functioned to dissuade participation. Caregivers outlined that they prioritized behavioural/communication interventions over PAP throughout their child’s life, and the lack of participation during formative childhood years shaped physical activity interests during adolescence. Caregivers also described experiencing systemic challenges when accessing physical activity programs, including a lack of awareness about ASD among service providers, funding challenges, and limited/few program options. The lack of PAP individualization and competing commitments contributed to tremendous strain on families where caregivers expressed a need for guidance to help them balance family life, schooling, and therapies with PAP.

Conclusions: Study findings demonstrate that the lack of PAP among adolescents with ASD is not merely influenced by bio-physical deficits. Rather, findings suggest that inactivity is tied within complex psycho-social/behavioural mechanisms which intersect at individual, community, and policy levels. Findings suggest that there is a need to work collaboratively with policy makers and service providers in the community in an effort to create optimal physical, social, cultural, sensory, and behavioural conditions that could facilitate PAP. Solutions on how to potentially achieve such conditions of possibility will be discussed.

157 **129.157** How Should We Talk about Obesity and Weight-Related Topics with Children with Autism Spectrum Disorders and Their Families?

*A. C. McPherson[1], **P. Jachyra**[2], C. Petta[1], S. Cosgrove[1], L. Chen[1], L. Capano[3], L. Moltisanti[4], T. J. Knibbe[5] and E. Anagnostou[4], (1)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Autism Research Centre, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (5)Research, Abilities Centre, Whitby, ON, Canada*

Background: Obesity is a global health concern and can significantly impact the physical and psycho-social health of children. Children with Autism Spectrum Disorder (ASD) appear to be at a higher risk of having obesity than their typically developing peers. One particular risk factor is the use of psychotropic medications to help control mood and impulsivity, which frequently can contribute to significant weight gain. Although it has been recommended that health care providers (HCPs) speak to families about the potential health risks of unhealthy weight in ASD, no previous research has explored exactly how HCPs communicate with children with ASD and their families about this topic.
Objectives: To explore the experiences of children with ASD, their families and HCPs when discussing weight-related topics in healthcare consultations.

Methods: Individual, in-depth qualitative interviews were conducted with children with ASD aged 10-18 years with verbal fluency who were attending a tertiary psycho-pharmacology clinic and whose Body Mass Index was greater than the 85th percentile. Their parents were also invited to take part in a separate interview, as were all HCPs who worked in the clinic. Thematic analysis using an interpretive phenomenological approach was used to analyze the verbatim transcripts. Emerging themes were analyzed and discussed by the whole team comprising multi-disciplinary HCPs, researchers and a parent of two children with ASD.

Results: Eight children with ASD, eight parents, and five HCPs were interviewed. Three main themes were identified: 1) Layers of complexity: Weight and health issues were complicated by a combination of medication side-effects, social dynamics within the home, and overall quality of life considerations. Narratives of ‘the lazy child’ and ‘non-compliant parent’ were strongly rejected; 2) Uncertainties of communication: Clinicians were often hesitant to start weight-related conversations when families came to see them for other issues. Others worried what impact such a discussion would have on the therapeutic relationship with the families. Parents wanted HCPs to raise the topic early, but were frustrated when realistic solutions were not offered; 3) Wellness over weight: Parents, children and HCPs all identified a need to move from predominantly focusing on a child’s weight, and instead promoting overall wellness throughout the life course. Overall recommendations included: Acknowledging the complexity of the situation; Engaging child in the discussion where possible; Using clear visuals and examples; Establishing a trusting relationship with the family; Using a strengths-based approach.

Conclusions: Children, caregivers and HCPs all recognized the potential short and long term health risks of overweight/obesity, and identified a need to work collaborative to positively impact the health status of children. Tools are needed to help HCPs foster positive conversations about weight-related topics and lifelong wellness.

158 **129.158** Exome Sequencing and Clinical Correlates in 250 ASD Trios

***J. Gonzalez-Peñas**, Child and Adolescent Psychiatry, Fundación investigación Biomedica Gregorio Marañón, CIBERSAM, Madrid, Spain*

Background: The diagnoses of ASD is mainly based on i) defficiencies in social interaction and communication and ii) restrictive and repetitive behavioral patters, interests or activities, including sensorial alterations. The behavioral assessment sufficient for a clinical diagnosis has limited use in research field and it is also likely that it will also have limited use for personalized medicine approaches, where trying to identify different biological subtypes seems the appropriate move forward .
In addition to important polygenic component, a great variety of single-gene disorders and chromosomal abnormalities have been described across latest genetic studies. Proper biological pathways and/or specific physiopathological mechanisms involved such as chromatin remodeling,

redox system regulation or transcriptional regulation processes have been identified as candidate gene sets enriched in deleterious rare, inherited and *de novo* variation [Lai et al. 2013; de Rubeis et al 2014; Kosmicki 2017].

Objectives: In this study, we aimed to differentiate ASD patients based on rare disrupting and common genetic predisposing variation found to be enriched in main gene networks previously reported in ASD, as synapse, chromatin remodelling or transcription regulation. We extensively phenotipically characterize each group based on clinical manifestations, including restricted and repetitive behaviors, unusual interests, developmental regression, epilepsy or gastrointestinal disease.

Methods: 250 Spanish ASD trios were recruited at Hospital Universitario Gregorio Marañón. Demographic, clinical and neuropsychological variables were collected from trios samples to perform cluster analysis with a combination of hierarchical and k-mean methodology. Exome from blood DNA was sequenced as part of the Autism Sequencing Consortium (ASC) dataset. Bioinformatic pipeline was constructed based on Broad Institute recommendations from alignment, base Quality Control or variant calling, and ANNOVAR was used for variant annotation from vcf files. For rare variant analysisi, we filtered rare (MAF < 0.1) and deleterous variation, making use of a myriad of existent and recently published algorithms to described funtional, brain-expressed and intolerant variation. To analyze common polygenic variation, we imputed whole genome variants using Michigan Imputation Server, utilized PGC available data as discovery sample and used PRSice to poligenic risk score calculations in our target sample. General linear model was used to statistically analyze associations between genetic and phenotypic variables collected.

Results: ASD sample was biologically characterized based on both rare and common predisposing genetic variation. We found disctintive patterns of common varaition and de novo rare disrupting variation affecting intolerant genes (pLI > 0.9) across identified groups. Biological groups were exhaustively characterized, according to several clinical variables as intelectual disability (ID), developmental regression, psychiatric comorbility, gastrointestinal pathology or pro-inflamatory status. We also report suggestive results in specific traits with several types of variation, as epilepsy and disrupting mutations within astrocyte related genes ($p = 4.5 \times 10^{-4}$) or post-zygotic mutations dependence with diagnostic categories ($P = 5 \times 10^{-5}$).

Conclusions: We claim the usefulness of differentiating biological clusters with diagnosable atributes not only to allow the establishment of stratification criteria for clinical purposes, but also to improve decision making about clinical trials designs to improve pharmacological treatment choice.

159 **129.159** Experience of Mental Health Diagnosis and Medication in Autistic and Non-Autistic Individuals: An Online Study.

S. Au-Yeung[1]*, S. A. Cassidy*[2]*, L. Bradley*[3] *and R. Shaw*[4]*, (1)Coventry University, Coventry, United Kingdom of Great Britain and Northern Ireland, (2)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (3)Coventry University, Coventry, United Kingdom, (4)NHS Coventry and Warwickshire Partnership Trust, Warwickshire, United Kingdom*

Background: Although previous research showed high levels of psychiatric co-morbidities among individuals with autism spectrum conditions and psychotropic medication are frequently prescribed for these individuals (Buck et al., 2014), little is known about autistic people's agreement with their mental health diagnoses and their experience of medication prescribed for their mental health conditions.
Objectives: The purpose of this study is to investigate and compare the experience of mental health diagnoses and medication between autistic and non-autistic adults.

Methods: Participants with or without a diagnosis of Autism Spectrum Conditions (ASC) completed an online survey collecting both qualitative and quantitative data regarding mental health or other diagnoses they received, and whether they agree with their diagnoses and why. Participants were also asked to report any current medication for their mental health condition, duration they have been taking them and any side effects. In addition, they were asked to rate the helpfulness and satisfaction of their medication and to report their experience of taking medication for their mental health condition.

Results: Preliminary analyses revealed that autistic individuals were more likely to receive diagnosis for mental health or other conditions, were less likely to agree with their diagnoses, were more likely to be on medication for their mental health condition, and were less satisfied with their medication than non-autistic individuals. There were no significant between-group differences in helpfulness rating and likelihood of experiencing side effects of their medication. Further qualitative findings will be reported in this presentation.

Conclusions: The current study revealed higher rate of diagnosis for mental health problems in autistic people, although they were less likely to agree with these diagnoses and were more likely to be prescribed medication which they may not necessarily be satisfied with. Autism awareness training as well as training staff to provide modified therapy in clinical practice could potential improve these experiences for autistic individuals

160 **129.160** Experiences of Suicide and Suicidal Thoughts Amongst Adults with an Autism Spectrum Condition.

L. Bradley[1]*, S. A. Cassidy*[2,3] *and J. Rodgers*[3]*, (1)Coventry University, Coventry, United Kingdom, (2)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (3)Institute of Neuroscience, Newcastle University, Newcastle Upon Tyne, United Kingdom*

Background: Currently, depression and suicide risk assessment tools are a 'one size fits all' design. However, they may need to be adapted for adults with an Autism Spectrum Condition (ASC), due to difficulties such as literal interpretation, identifying and communicating internal emotional states. The clinical implication being that these questionnaires may not accurately measure depression or suicide risk in adults with an ASC. This is worrying given high rates of depression and suicidal ideation in this group.
Objectives: To explore how adults with an ASC interpret questions in current clinical measures of depression and suicide risk, in order to inform development of new tools adapted for this group.

Methods: 15 adults with ASC took part in cognitive interviews while completing the Suicide Behaviour Questionnaire-Revised (SBQ-R), and Patient Health Questionnaire-9 item (PHQ-9). During the cognitive interviews, participants described what they were thinking and reading about when completing these questionnaires. Interviewers subsequently probed participants' responses to further explore how participants interpreted the questions.

Results: A conversational analysis approach was used to analyse the data. The extracts presented focus on key moments within the interaction when the participants talk about suicide and the future, their ongoing thoughts of suicide, and how they believe these to be autism specific and different from those without autism. These indicate that adults with ASC: 1) interpret the questions literally and in turn provide literal answers which do not always fit the question being asked; 2) find some questions unclear in terms of what information is required to ensure they provide an appropriate answer; and 3) report some questions are describing traits or behaviours typically associated with autism and therefore not appropriate markers of a mental health difficulty for them.

Conclusions: Results suggest that current measures of depression and suicide risk need to be adapted for adults with ASC, in order to accurately identify these difficulties in this group. Results will be used to inform adaptations to these measures, and guidelines for clinicians assessing depression and suicide risk in adults with ASC.

161

129.161 Inflammatory Profile in ASD Children with and without Functional Gastrointestinal Disorders

M. J. Penzol Alonso[1], *B. García-Bueno*[2], *K. S. MacDowell*[3], *J. C. Leza*[4], *A. Alcón*[5] *and M. Parellada*[6], *(1)HOSPITAL UNIVERSITARIO GREGORIO MARAÑON, MADRID, Spain, (2)Pharmacology,, Universidad Complutense, CIBERSAM, Madrid, Spain, Madrid, Spain, (3)Pharmacology, School of Medicine, UCM, Madrid, Spain, (4)Pharmacology, School of Medicine, UCM, CIBERSAM, Madrid, Spain, (5)Hospital Universitario Gregorio Marañón. Child and Adolescent Psychiatry. IISGM. CIBERSAM, Madrid, Spain, (6)Fundación Investigación Biomedica Gregorio Marañon, Madrid, Spain*

Background: There is considerable evidence that the gut-brain axis is involved in the physiopathology of some subjects with autism spectrum disorders (ASD). A number of studies point out towards a high prevalence of functional gastrointestinal disorders in children suffering from autism and a correlation between this symptoms and the severity of psychopathology. Published research suggests that part of the symptomatology in ASD could be mediated by systemic pro-inflammatory processes. Authors have described a neuroinflammatory status up to 65% of patients with ASD (Kern et al. 2015). This inflammatory status became detectable through blood markers, such as chemokines TNFα, IL-1β e IL-12, TLR-4, etc. Chemokines and their receptors might provide unique targets for the development of innovative therapies for these disorders. Functional Gastrointestinal Disorders (fGID), very prevalent in ASD, has been lucubrated to be a reflection of a systemic pro-inflammatory status.
Objectives: The main objective of this project is the identification of immunological markers involved in the pathogenesis of a subgroup of children with ASD. We hypothesized that children with ASD and gastrointestinal symptoms will also have markers of a systemic pro-inflammatory status.

Methods: We recruited 4 groups of participants (3 to 10 years old), selected for by the presence or absence of ASD diagnosis and the presence/absence of gastrointestinal (GI) functional symptoms: 1) ASD + fGID , group 2) ASD no fGID, group 3) healthy controls (HC) + fGID, group 4) HC; mean age was 6.67 (±1.9). 90% were male. ASD was diagnosed following the AACAP recommendations (Volkmar, 2014) and fGID were assessed with the ROMA-III. Plasma and peripheral blood mononuclear cell (PBMC) inflammatory biomarkers were analyzed: plasma TNFa, IL-1b, IL-6, , IFNg, LPS, LBP, IL-10, CD26act, CD26 exp; PBMC levels of Tool-Like receptor-4 (TLR-4), TLR-2, Myeloid differentiation primary response gene 88 (MyD88), TIR-domain containing protein TRIF, NFKb and TLR-3.

Results: One way-analysis of variance (ANOVA) analyses were conducted to determine statistically significant differences between groups for each biomarker; post hoc Dunn's Multiple Comparison Test was used to identify group pairs differences. The following markers differed between groups: LBP ($\chi 2=10.74$; $p=0.09$), IL-10, CD26act ($\chi 2=10.77$; $p=0.09$), Tool-Like receptor-4 (TLR-4) ($\chi 2=23.13$; $p=0.001$), Myeloid differentiation primary response gene 88 (MyD88) ($\chi 2=13.67$; $p=0.00$), TRIF ($\chi 2=16.15$; $p=0.00$), TLR3 ($\chi 2=8.76$; $p=0.03$), NFKb ($\chi 2=12.45$; $p=0.01$). Post-hoc analysis showed that ASD+fGID and HC+fGID groups did not differ in any of the markers analyzed. Significant differences were detected in all other comparisons between groups for several inflammatory markers. Bivariate analyses were conducted in order to compare the levels of the different markers between subjects with ASD and without ASD and patients with and without fGID. Specific differences will be fully reported together with clinical correlates.

Conclusions: Very early markers of activation of the innate immune system is seen in patients with ASD irrespective of the presence of fGID. This may reflect a that may indicate a systemic pro-inflammatory status in these patients. The study of the immunological pathophysiology in warranted in ASD, in order to identify a subgroup within ASD that may benefit from specific interventions.

162

129.162 Intellectual Disability in ASD. Paternal and Obstetric Factors in Relation with Cognitive LEVEL Outcome

A. Alcón[1] *and D. Gerez*[2], *(1)Hospital Universitario Gregorio Marañón. Child and Adolescent Psychiatry. IISGM. CIBERSAM, Madrid, Spain, (2)Child and Adolescent Psychiatry, Hospital Gregorio Marañon, CIBERSAM, IISGM, 28035, Spain*

Background: Different environmental and family factors have been associated with increased risk of Autism Spectrum Disorders (ASD) and/or its severity. Among these, advanced parental age (APA) is associated with increased risk of ASD [Janecka et al 2017; McGrath et al 2014] and one of the mechanisms proposed is that autistic traits in the parents may lead to delay age at conception [Gratten et al 2016]. Perinatal factors such as the use of oxytocin in labour have been associated with the severity of ASD [Smallwood 2016].
Objectives: In this presentation we aim to report on the effect of some parental and perinatal factors on the severity of ASD, as indicated by cognitive development [8].

Methods: Eighty patients with ASD (DSM-IV-TR diagnosis), mean age 13.25 ±7.7SD, 87.5% male, 92.5% Caucasian) were recruited at Hospital General Universitario Gregorio Marañón. Intelligence quotient (IQ) was assessed with the Wechsler Intelligence Scales for Children or Adults, as appropriate. Parental autism traits were evaluated with the Autism Spectrum Quotient (AQ). The presence of obstetric complications was evaluated with the Lewis-Murray Obstetric Complications Scale. After confirming the normality of data, Pearson correlation analyses were used to assess the relationship between parental autism traits and age at conception, and between and multiple linear regression were used to assess the potential association of patients IQ with the parental (APA, psychiatric history and autism traits), and obstetric predictors (birthweight, obstetric complications or labour oxytocin use). Statistical analyses were performed with SPSS 18. Statistically significance threshold $p<0.05$.

Results: 66.3% of the sample had fluent language and 31.3% only words/simple phrases (as per ADOS criteria). Mothers aged from 23 to 41 years old, mean age 31.99 SD=4.072 and fathers aged from 22 to 47, mean age 34.23 SD=5.31. 23.75% of parents had a positive psychiatric history. ASD birthweight was 3260.5±497.04SD [1950-4300] g; 62.5% of the cases had a positive history of obstetric complications.

Fathers of ASD probands had a mean AQ of 16.6 ±6 and mothers had a mean AQ of 14.8 ±6.7. Paternal or maternal autistic traits did not correlate with their age at ASD birth ($r=.209$, $p=.145$ and $r=.035$, $p=.798$ respectively). The use of oxytocin during labour was significantly associated with proband IQ (IQ mean 84.251 ±25SD [40-133], association with oxytocin use $t=2469$, $p=.016$). With regard to associations among risk variables, the presence of obstetric complications significantly correlated with birthweight ($t=2.155$, $s=.034$), maternal age at birth ($t=-2.256$, $s=.027$) and parental autism traits (t=-2.004, s=.051). Labour oxytocin was associated with the presence of ASD diagnosis before 1 year of age (s=.010). Multiple regression analysis showed that oxytocin use predicts IQ (B=-13.673, s=.016) , after controlling for age, sex and ethnicity (R2=.073).

Conclusions: Labour oxytocin use does partially predict IQ in ASD patients. Contrary to our hypothesis, parental autism traits does not predict IQ outcome. The direction of the relationship oxytocin use-IQ in ASD patients is, hitherto, unknown and needs further investigation.

163 **129.163** Investigating the Factor-Structure of the Child Behavior Checklist Dysregulation Profile in Youth with ASD

A. Keefer[1,2]*, V. Singh*[1]*, L. Kalb*[1,3]*, C. A. Mazefsky*[4]*, J. S. Hong*[1] *and R. A. Vasa*[1,2]*, (1)Center for Autism and Related Disorders, Kennedy Krieger Institute, Baltimore, MD, (2)Johns Hopkins School of Medicine, Baltimore, MD, (3)Department of Mental Health, Johns Hopkins University, Baltimore, MD, (4)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background: Emotion dysregulation (ED) is a common feature of autism spectrum disorder (ASD). Few studies have assessed the factor structure or established the internal construct validity of measures used to assess ED in the ASD population. Examining the factor structure of one such measure, the Child Behavior Checklist Dysregulation Profile, which combines the Anxious/Depressed (AD), Aggressive Behavior (AGG), and Attention Problems (AP) subscales of the CBCL (Achenbach, 2001), can guide understanding of the latent relationships that exist between ED and associated symptoms.

Objectives: To explore the factor structure of the CBCL Dysregulation Profile in a large clinical sample of youth with ASD.

Methods: Parents of 727 youth aged 6 through 18 years (Mean=10.28, SD=2.99) completed the CBCL prior to their initial appointment at an ASD clinic within a university-based medical center. ASD diagnostic status was determined by an expert physician or psychologist. A series of four confirmatory factor analytic (CFA) models were employed to explore the latent structure of the ED construct and its interrelations with the AD, AGG, and AP subscales: a uni-dimensional model in which there is only an ED factor, a second order model in which ED is an overarching factor that explains each of the subscales, a three specific factors model in which each of the subscales exist independently with no relationship to ED, and a bi-factor model in which ED is measured as a general factor capturing the majority of the variance alongside separate subscales. The best fitting model was then used to conduct an EFA in which the factors were allowed to load freely.

Results: Results of the CFA indicated that a bi-factor model which includes a general factor of ED and three specific factors of AD, AGG, and AP provided the best overall fit (RMSEA=0.06; SRMR=0.06; CFI=0.08). Results of the EFA revealed that most items loaded onto the ED factor. However, most items from the AD subscale loaded only on the ED factor, while items from the AGG subscale loaded on both the AGG and the ED factors. Although two items from the AP subscale loaded on the ED factor, most items loaded only on the AP factor. One AP item did not load on any factor.

Conclusions: The bi-factor structure of the Dysregulation Profile mirrors findings in non-ASD youth, supporting the validity of this measure in the assessment of ED in ASD youth. Per the results of the EFA, anxiety/depression items were explained almost completely by ED, suggesting that these symptoms may be ubiquitous to ED in the ASD population. Aggressive behaviors appear related to ED but also have independent associations apart from this construct. Although some attention problems are related to ED, many appear to exist independently from ED. These findings support current understanding of ED as a common factor underlying both internalizing and externalizing symptoms but suggest that ED does not contribute to some aspects of attention dysregulation.

164 **129.164** Molecular Characterization of Right-Sided Colonic Hypomotility in GI Symptomatic Children with ASD

S. J. Walker[1]*, C. D. Langefeld*[2]*, K. D. Zimmerman*[2] *and A. Krigsman*[3]*, (1)Wake Forest University Health Sciences, Winston Salem, NC, (2)Department of Biostatistical Sciences, Division of Public Health Sciences, Wake Forest University Health Sciences, Winston Salem, NC, (3)Pediatric Gastroenterology Resources of New York and Texas, Austin, TX*

Background: Constipation is a common and clinically heterogeneous finding in GI-symptomatic children with autistic spectrum disorder (ASD). One recurrent pattern we have observed in children with constipation as their primary gastrointestinal (GI) symptom is fecal loading ("soft stool constipation"), most prominent in the cecum and ascending colon. Regarding this pattern, a divergent clinical course suggests two distinct clinical subtypes characterized as: (1) following the initial colonic cleanout, a continued state of symptomatic remission while on maintenance anti-inflammatory therapy [*acute*] or, (2) recurrent right-sided fecal loading requiring regular colon cleanouts [*chronic*]. These observations raise the possibility of a localized dysmotility within the cecum and ascending colon which may contribute to the underlying etiology of constipation in children with ASD.

Objectives: The goal of this study was to compare gene expression in the right (ascending) colon from two groups of GI-symptomatic children with ASD and constipation (acute versus chronic fecal loading). We hypothesize that molecular examination of mucosal biopsy tissue from affected regions of the colon can provide mechanistic insights regarding transient versus chronic right-sided colonic hypomotility in the setting of enterocolitis in children with ASD.

Methods: RNASeq was used to measure the transcriptome in mucosal biopsy samples that had been collected from the ascending colon during elective colonoscopy in GI-symptomatic children with ASD. The children were all diagnosed with enterocolitis and had, as one of their presenting symptoms, constipation with right sided fecal loading (confirmed by abdominal x-ray). Gene expression in tissue from patients who, following an initial colon clean out, continued in a state of remission (acute; "controls") was compared to gene expression in the second group who continued to require regular colon clean outs (chronic; "cases").

Results: Hierarchical clustering of colonic gene expression profiles from all cases and controls initially revealed three clusters consisting of: 12 cases (cluster 1), 9 cases + 1 control (cluster 2) and, a mixture of the other 13 cases and controls (cluster 3). Analysis of differential gene expression between *all* cases (20) versus *all* controls (15) resulted in no transcripts that reached statistical significance. Gene expression profiles comparing only cases in the first cluster (N=12) and controls in the second cluster (N=9), 441 transcripts found to be significantly differentially expressed. The molecular pathways that were over-represented in this gene set are involved in host inflammatory response (e.g. granulocyte adhesion and diapedesis, T and B cell signaling, and communication between innate and adaptive immune cells). The top molecular and cellular functions that were found to differ between those with acute versus chronic dysmotility relate cell-to-cell signaling and interaction, cellular movement, and cellular growth and proliferation.

Conclusions: This initial comparison of gene expression profiles in the ascending colon from a subset of patients with ASD and chronic versus acute constipation (right-sided colonic hypomotility) revealed a down regulation of hundreds of transcripts that are involved in cell-to-cell communication and cellular growth and proliferation. These findings are suggestive of a coordinate down regulation of genes that may be necessary for normal cellular function in the lower gastrointestinal tract.

165 **129.165** Monitoring the Safety of Second Generation Antipsychotics in Children and Adolescents with Autism Spectrum Disorder

J. H. Filliter[1], *M. Kerr*[2], *S. Shea*[1], *I. M. Smith*[1], *J. MacCuspie*[1], *A. Hawkins*[1] *and T. Fraboni*[1], *(1)IWK Health Centre / Dalhousie University, Halifax, NS, Canada, (2)Dalhousie University, Halifax, NS, Canada*

Background: Approximately 17.5% of youth with autism spectrum disorder (ASD) are being treated with second-generation antipsychotics (SGAs; Park et al., 2016). While SGAs have been found to reduce irritability and associated behaviours (e.g., aggression and self-injury) in youth with ASD, a range of side effects (e.g., sedation, weight gain, extrapyramidal symptoms, and metabolic changes) has been reported. Therefore, careful monitoring of youth taking these medications is imperative. However, as the core and associated symptoms of ASD can make medical procedures challenging, monitoring the safety of SGAs may be particularly difficult in this population. The potential for undetected SGA side effects is a significant concern, given rates of SGA prescription to youth with ASD. To date, no investigations have been published describing how closely physicians monitor SGA side effects in youth with ASD or the barriers that they face in doing so.
Objectives: To begin to understand physicians' current practices in SGA monitoring and the challenges of monitoring SGAs in youth with ASD.

Methods: We designed an online questionnaire that was completed by 31 specialist physicians (General Pediatricians, Developmental Pediatricians, Psychiatrists, and Neurologists) serving children and adolescents with ASD in one region of Canada. Our survey examined physicians' reports of ordering vs. completion of monitoring tasks recommended by the Canadian Alliance for Monitoring Effectiveness and Safety of Antipsychotic Medications in Children, as well as their perceptions of factors relevant to SGA safety monitoring in youth with ASD.

Results: Of the monitoring tasks queried, physicians were most likely to measure height, weight, and blood pressure at baseline and as part of ongoing follow-up (>75% attempted these tasks 76-100% of the time). Waist circumference measurements and electrocardiograms (ECGs) were the monitoring tasks least often carried out at both time points (>50% attempted/ordered these tasks 0-25% of the time). Fasting and non-fasting bloodwork were frequently not ordered at baseline (>45% ordered these tasks 0-25% of the time), but were somewhat more likely to be ordered at follow-up. Neurological exams were attempted 76-100% of the time by 68% of physicians at baseline and 48% of physicians at follow-up. As expected, physicians indicated that ECG and fasting and non-fasting bloodwork were the procedures that youth with ASD have the most difficulty completing successfully. When asked their perspectives on child, family, physician, and other/system factors that impede completion of these procedures, physicians identified youth distress, activity level, and refusal, as well as family anticipatory anxiety, previous failed attempts, and competing commitments, as the most significant barriers.

Conclusions: Given rates of prescription of SGAs to youth with ASD and the side effects associated with these medications, careful monitoring is necessary. However, our results indicate inconsistent physician practices in ordering/completing various monitoring tasks at baseline and follow-up. Further, our findings suggest that many youth with ASD struggle to complete successfully the medical procedures required for thorough SGA monitoring. Additional research is indicated aimed at supporting physicians in their monitoring of SGAs and youth with ASD and their families in successfully completing associated monitoring tasks.

166 **129.166** Parent-Rated Anxiety Symptoms in Youth with ASD and Their Association with Problem Behaviors in an Inpatient Setting

R. Mahajan[1], *H. Nichols*[1], *B. Troen*[1] *and C. A. Mazefsky*[2], *(1)Sheppard Pratt Health System, Towson, MD, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA*

Background:
Youth with autism spectrum disorder (ASD) are frequently diagnosed with anxiety disorders, which may have a significant negative impact on their functioning; these symptoms may also impede their development and learning. Furthermore, severe problem behaviors (PB; aggression, disruptive and self-injurious behaviors, SIB) in these youth, may require inpatient hospitalization for safety and stabilization. Due to their internalizing nature, anxiety symptoms may be overlooked by clinicians in contrast to externalizing behaviors. Even though anxiety disorders are among the most prevalent co-occurring psychiatric conditions in these youth, little is known about anxiety symptoms' potential impact upon PB, in youth with ASD needing inpatient treatment.

Objectives:

This study aims to characterize parent-rated anxiety symptoms in youth with ASD in an inpatient setting, by examining the relationship between parent-rated anxiety symptoms, externalizing behaviors, and SIB.

Methods:

Participants were 282 youth (78% male) ages 5-20 years (mean age 12.9 years; SD ±3.2), with ADOS-confirmed ASD, enrolled through the Autism Inpatient Collection (AIC), a multisite study of youth with ASD hospitalized on 6 specialized inpatient psychiatric units across the U. S. Data were collected from parents on the youth's, communication, externalizing behaviors, emotion regulation, and SIB. Child and Adolescent Symptom Inventory (CASI-5) was used for parent-reported psychiatric symptoms including anxiety. Using previous research, 20 items from the original CASI-5 anxiety items were selected for analyses. Hierarchical linear regression and independent samples t-tests were used to determine the relationship between anxiety symptoms, externalizing behaviors, and self-injurious behaviors.

Results:

Prevalence of anxiety disorders was as follows: simple phobia (65%), generalized anxiety disorder (38%), somatization disorder (30%), panic disorder (28%), separation anxiety (21%), and social phobia (18%). Mean scores for externalizing behaviors were significantly higher for youth who met criteria for panic disorder ($p < .001$) and somatization disorder ($p = .003$). Mean scores for SIB were significantly higher for youth who met criteria for simple phobia ($p = .005$), social phobia ($p = .031$), and separation anxiety ($p = .005$). Separate regression models for each type of anxiety were conducted based on significant bivariate results and controlled for age, gender, race, income, and verbal ability. Both panic and somatization disorders were no longer significantly related to externalizing behaviors, after control variables were added. Simple phobia (b = .98, $t(233) = 2.85$, $p = .005$), social phobia (b = .40, $t(240) = 2.08$, $p = .039$), and separation anxiety (b = .30, $t(240) = 3.96$, $p < .001$), remained significant in their respective models predicting SIB.

Conclusions:

Youth with ASD requiring inpatient stabilization for problem behavior may also experience significant anxiety symptoms. Presence of externalizing behaviors or SIB should prompt an assessment of specific anxiety disorders. Future research should explore whether anxiety is driving or maintaining problem behaviors.

167 **129.167** Parental Anxiety and Family Functioning: A Comparison between Children with ASD and Comorbid Anxiety Disorders, Children with Anxiety Disorders, and Typically Developing Children

F. van Steensel[1] *and S. M. Bögels*[2]*, (1)University of Amsterdam, Amsterdam, Netherlands, (2)Research Institute of Child Development and Education, University of Amsterdam, Amsterdam, Netherlands*

Background: Anxiety disorders in children with ASD are commonly observed. It is however less clear which factors are related to the anxiety presentation in children with ASD. To date, little consideration is given to the association between anxiety and family factors (like parental anxiety and family functioning – which have found to be associated with child anxiety in typically developing and clinical samples using children with anxiety disorders).

Objectives: This study's aim was to examine parents' anxiety and the family functioning.

Methods: Families of children with (1) Autism Spectrum Disorder and anxiety disorders (ASD+AD; N = 80), (2) anxiety disorders (AD; N = 108) and (3) typically developing children (controls; N = 90) completed questionnaires.

Results: Parents' odds of having clinical anxiety levels was 3.5 times higher when their child had AD, and fathers' risk was further increased when their child also had ASD. AD was associated with lower family relationship scores and ASD further lowered this score, while only ASD was associated with elevated family system maintenance scores.

Conclusions: The findings suggest that having a child with (ASD+)AD co-occurs with parental health and family functioning problems, but the direction of this relationship remains to be examined.

168 **129.168** Possible Factors Associated with High Prevalence of Overweight and Obesity in Toddlers with Autistic Spectrum Disorder

O. E. Stolar[1]*, R. Ben-Zeev*[2]*, E. Gal*[3] *and T. Sinai*[4]*, (1)Autism Center, Assaf Harofeh Medical Center, zerifin, Israel, (2)School of Nutritional Sciences, The Hebrew University, Jerusalem., Israel, (3)Department of Occupational Therapy, University of Haifa, Haifa, Israel, (4)School of Nutritional Sciences, The Hebrew University, Jerusalem, Israel*

Background:

Autism spectrum disorder (ASD) is characterized by persistent deficits in social communication and social interaction along with restricted and repetitive behaviors. In addition, abnormal sensory processing and difficulties with oral motor skills are more common in children with ASD. These challenges, play an important role in eating patterns and dietary consumption. Food aversion/refusal or food selectivity is common. These feeding difficulties, may lead to inadequate nutritional intake and impaired growth parameters in children.

Objectives:

This study examined the incidence of overweight and obesity among toddlers diagnosed with ASD, and its relation to demographic and clinical parameters, as well as the severity of the core symptoms.

Methods:

Toddlers 1-3 years of age, with ASD who were enrolled in the 2015 or 2016 school year –in one of 11 different Early Intervention Day Care Centers (EIDCC) participated in the study. All of the toddlers were diagnosed with ASD based on DSM - 5 criteria. Demographic, parental and clinical data were collected. Weight and Height were measured and age and gender specific z-scores were determined according to the World Health Organization (WHO) child growth standards. Social and communication performance was evaluated using the Social Communication Questionnaire (SCQ). Exclusion criteria included genetic syndromes, chronic diseases and endocrine abnormalities. Statistical analyses were performed utilizing SPSS.

Results:

The study participants (n=142) included 98 males (69%), and 44 females (31%), aged 2.5±0.4 years. Of prenatal data that were available from 118-122 participants, 18 (15.3%) were born after IVF treatment and 51 (42.9%%) by Caesarean section, 15 (12.7%) are one of twins. Higher incidence of birth weight classified as large for gestational age (LGA) was noted (n=27): 22.3% versus 10%, as expected when compared to the general population ($p<0.05$). Total SCQ score ranged from 5 to 32 (n=133). Height – z scores corresponded to international averages with mean of -0.06±1.34 versus 0, $p>0.05$. In contrast, significantly increased BMI-z scores were found : 0.65±1.21 versus 0, $p<0.05$. Fifty- two participants had BMI z sore >1 SD and classified as overweight (13.4%) or obese (23.2%), while only one toddler presented underweight. In order to find which parameters may be related to overweight/obesity, comparisons were made between those with high z-scores versus those with normal BMI (n=89). No statistical differences were noted in age, gender distribution, height-z scores, parent's age and education, any of the prenatal and perinatal factors, nor SCQ scores ($p>0.05$).

Conclusions:

Our results from a multi-center sample of toddlers with ASD, suggest that there is an elevated risk for unhealthy weight status, which presents at a very young age. Since no associations were found with ASD symptoms severity, perinatal history or demographic parameters, it may be concluded that the tendency to obesity is related to eating habits and possibly low physical activity. This study emphasizes the importance of increasing awareness and providing education for caregivers and developing intervention strategies to prevent early – onset obesity that has known deleterious consequences on health over the lifespan.

169 **129.169** Predicting Aggression Onset in Minimally-Verbal Youth with Autism Spectrum Disorder Using Preceding Physiological Signals

***M. S. Goodwin**[1], C. Cumpanasoiu[1], A. Stedman[2], C. Peura[2], O. Ozdenizci[1], P. Tian[1], Y. Guo[1], S. Ioannidis[1], D. Erdogmus[1], C. A. Mazefsky[3] and M. Siegel[4], (1)Northeastern University, Boston, MA, (2)Spring Harbor Hospital, Westbrook, ME, (3)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (4)Maine Medical Center - Tufts School of Medicine, Westbrook, ME*

Background: Unpredictable and potentially dangerous aggressive behavior by youth with autism spectrum disorder (ASD) isolates them from foundational educational, social, and familial activities, thereby markedly exacerbating the morbidity and costs associated with the condition. As many as 2/3 of youth with ASD display aggression, which is one of the primary reasons they use behavioral healthcare services. Aggression presents imminent safety risks for the individual and others in the environment. Families report that aggression increases their stress, isolation, and financial burden, and decreases available support options. Aggression to others is particularly impairing and treatment refractory in the 30-40% of youth with ASD who are minimally verbal (MV-ASD). Their inability to self-report distress can lead to behaviors that seem to occur without warning, sometimes long after any observable trigger.

Objectives: Aggression to others may represent a maladaptive attempt to express or modulate physiological arousal arising from distress. Thus, we hypothesize that physiological arousal precedes aggressive behavior. Our objective is to test whether the proximal onset of aggression can be predicted from preceding physiological signals.

Methods: In this IRB approved study, we collected physiological data from the wrist using the commercially available E4 by Empatica, Inc. that wirelessly measures heart rate, heart rate variability, electrodermal activity, skin temperature, and physical motion from 20 MV-ASD inpatient youth. E4 signal parameters were derived using time-series statistics in a past interval of time (t_p). Ridge-regularized logistic regression models were used for binary decision making for aggression onset in an upcoming time interval (t_f) using temporal (time elapsed since last observed aggression) and E4 signals. Model prediction performance was calculated using 5-fold cross-validation. For all binary prediction models, receiver operator characteristic (ROC) curves and their corresponding area under the curve (AUC) values were calculated to represent accuracy based on true (sensitivity)/false (1-specificity) positive rates. Classification of varying values of t_p and t_f was assessed using both global (a single classifier consisting of concatenated time-series data across all sessions and participants) and person-dependent (data only pooled across sessions within person) models.

Results: All participants tolerated the E4 after desensitization and usable data was obtained in all cases. Sixty-nine independent naturalistic observational sessions were collected, totaling 87hrs. Out of 548 total aggressions observed with concurrent E4 data, our results [Fig 1] demonstrate that, on average, models with all signals included (i.e., time since last aggression and E4 signals) predict the onset of aggression 1min before it occurs using 3min of prior data with 0.71 AUC for global and 0.84 AUC for person-dependent models.

Conclusions: By linking observable aggressive behavior to preceding physiological signals in MV-ASD, we move the field of problem behavior assessment towards a new biologically-based, data-informed approach that is focused on prospective monitoring, prevention, and eventually real-time intervention, addressing a historically intractable problem for a segment of the ASD population who is arguably the most in need of innovative approaches.

170 **129.170** Relations between Executive Function and Sleep in ASD Children with Comorbid ADHD Symptoms

***A. M. Cremone-Caira**[1], J. Buirkle[2], K. Trier[2], R. Gilbert[2] and S. Faja[2], (1)Boston Children's Hospital Labs of Cognitive Neuroscience, Boston, MA, (2)Boston Children's Hospital, Boston, MA*

Background: Approximately 50% of children with ASD have concurrent symptoms of ADHD (Rommelse et al., 2010). Alongside the hallmark symptoms of these disorders, children with ASD and ADHD commonly have executive function (EF) deficits and sleep disturbances (Corbett et al., 2009; Thomas et al., 2015). Whether sleep or EF predict comorbidity of ADHD symptoms in ASD is unknown. Understanding factors that contribute to, or exacerbate, comorbidity may improve interventions and clinical outcomes in these populations.

Objectives: To determine whether EF and sleep disturbances predict comorbid ADHD symptoms in children with ASD.

Methods: Caregivers of 108 children with ASD (17 females; M_{age}=9.13±1.38 years) completed the BRIEF (*n*=103) and Children's Sleep Habits Questionnaire (CSHQ; *n*=99) to gauge EF and sleep. The Total CSHQ Score was used to index global sleep disturbance and differentiate children with (*n*=64) and without (*n*=35) clinically significant levels of sleep problems (Total CSHQ Score >41; Owens, Spirito, & McGuinn, 2000). The ADHD subscale of the CBCL was used to assess comorbid ADHD symptoms (*n*=103). Higher scores on these measures reflect greater impairment in functioning.

Results: BRIEF Index Scores and ADHD symptoms did not differ between children with and without clinically significant sleep problems (*p's*^{3}0.210). BRIEF outcomes were positively correlated with ADHD symptoms in both groups (*r's*^{3}0.270, *p's*£0.046). In a linear regression model, greater deficits on the BRIEF Metacognitive Index (*β*=0.419, *p*=0.001) and greater Total CSHQ Scores (*β*=0.214, *p*=0.060) were independently associated with increased ADHD symptoms among children with clinical sleep problems. Total CSHQ Scores did not predict ADHD symptoms in the group of children without clinical sleep problems (*β*=-0.024, *p*=0.881). Among children with clinical sleep problems, follow-up analysis of subscales included in the Metacognitive Index indicated that more problems with Working Memory (WM) were associated with increased ADHD symptoms (*β*=0.550, *p*£0.001). Total CSHQ Score was also significantly related to increased ADHD symptoms (*β*=0.228, *p*=0.028) in this model. However, WM and Total CSHQ did not interact to predict additional variance in ADHD symptoms (*β*=0.096, *p*=0.437).

Conclusions: Preliminary analyses indicate that children with ASD who have EF deficits and clinically significant sleep problems are more likely to have ADHD symptoms than children without sleep problems. These findings are consistent with work suggesting that both EF deficits and poor sleep contribute to comorbid neurodevelopmental disorders. Previous literature indicates that poor sleep is related to WM deficits in typically developing children (Steenari et al., 2003). As WM is impaired in ASD and ADHD (Andersen et al., 2015), the results of the current study suggest that targeting sleep may improve WM and, consequently, improve clinical outcomes in children with comorbid diagnoses. Importantly, however, WM and Total CSHQ Score did not interact to predict comorbid ADHD symptoms in this sample, suggesting that EF and sleep act through independent mechanisms to increase vulnerability for comorbidity. Future analyses will evaluate the role of specific sleep deficits (CSHQ subscales) and objective measures of EF in predicting comorbid outcomes.

171 **129.171** Repetitive Behaviors in Autism Spectrum Disorder: Associations with Internalizing Symptoms

***D. Swain**[1], A. Muskett[1], N. N. Capriola[2], A. Scarpa[3] and A. V. Dahiya-Singh[4], (1)Virginia Polytechnic Institute and State University, Blacksburg, VA, (2)Psychology, The University of Alabama, Tuscaloosa, AL, (3)Virginia Polytechnic Institute & State University, Blacksburg, VA, (4)Virginia Tech,* *Blacksburg, VA*

Background: Youth with Autism Spectrum Disorder (ASD) receive diagnoses of depression and anxiety at higher rates than typically developing children (Kim et al., 2000). Despite the high prevalence of internalizing problems among youth with ASD, little research has examined how depression and anxiety might be associated with core ASD features, such as Restricted and Repetitive Behaviors (RRBs). Although many theories have been posited, it is unclear exactly why children with ASD engage in RRBs. One common theory suggests that RRBs serve the purpose of assisting children with ASD in emotion regulation (Samson, Phillips, Parker, Gross, & Hardan, 2014). Within the context of this theory, it would be expected that RRBs would increase during intense emotional experiences such as depression and anxiety.

Objectives: The goal of the current study was to examine potential behavioral markers of depression and anxiety in terms of RRBs. We hypothesized that youth with clinically significant depressive and anxiety symptoms would be demonstrate greater RRBs relative to youth with sub-clinical levels of internalizing symptoms.

Methods: Participants included children ages three to seventeen years ($M = 7.25$, $SD = 3.85$). The children and adolescents were predominantly male (82.46%) and Caucasian (87.72%). Parents completed a series of measures including the Child Behavior Checklist (CBCL; Achenbach, 1991) and Repetitive Behavior Scale-Revised (RBS-R; Bodfish, Symons, & Lewis, 1999). The affective and anxiety subscales of the CBCL and all subscales of the RBS-R were used for the current analyses.

The institutional review board for human subject research approved the larger study (i.e. assessment database). Two Multivariate Analysis of Variances (MANOVA) were conducted to examine group status (i.e., ASD+/-Depression and ASD+/-Anxiety) as the independent variable and the six RBS-R sub-scale scores as dependent variables.

Results: The multivariate results demonstrated significant findings for group status comparing ASD+D to ASD-D as well as ASD+A to ASD-A. For comparisons in co-morbid depression, Univariate *F*-tests indicated a significant difference between the groups for Self-Injurious Behavior, $F(1,43) = 19.56$, $p = .001$, Compulsive Behavior, $F(1,43) = 9.71$, $p = .003$, and Sameness Behavior, $F(1,43) = 5.91$, $p = .02$. Additionally, for anxiety groups, significant difference between the ASD plus high anxiety and ASD low anxiety groups for Self-Injurious Behavior, $F(1,43) = 8.7$, $p = .01$, Compulsive Behavior, $F(1,43) = 16.43$, $p < .01$, Ritualistic Behavior $F(1,43) = 8.79$, $p = .01$, and Sameness Behavior, $F(1,43) = 12.88$, $p < .01$.

Conclusions: The presence of clinically elevated levels of co-occurring depression and anxiety in youth with ASD, when compared to individuals with ASD and sub-clinical internalizing symptoms, reveals significant differences in parent report of observable core ASD symptomology. It is unclear, however, whether depression and anxiety lead to increases in RRBs or more severe ASD symptomology leads to increased anxiety and depression.

172 **129.172** Similarity of Citizen-Science American Gut Project to Published ASD Studies on Gut Microbiota

C. Holingue[1], *N. Nueller*[2] *and M. D. Fallin*[1], *(1)Wendy Klag Center for Autism and Developmental Disabilities, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, (2)Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD*

Background:

The gut microbiome has been hypothesized to play a role in gastrointestinal and behavioral symptoms in autism spectrum disorder (ASD). Existing studies have sought to identify differentially methylated taxa between ASD and non-ASD samples, but are limited in sample size. The recently established “American Gut Project” (AGP) is a “citizen science” approach that invites participation from the general public, and includes some individuals with self-reported ASD.

Objectives:

In this study we analyzed publically available microbiota data among participants of the AGP who self-reported ASD, and pursued a descriptive comparison of these profiles to published microbiome profiles from non-crowd sourced ASD-specific studies. This provides important information about the potential utility of AGP for gut studies of ASD.

Methods:

We included 33 AGP participants who completed a fecal sample as well as reported having ASD [diagnosed by a medical professional, by an alternative medicine practitioner, or being self-diagnosed]. Fecal samples were collected at home using a swab. Samples were processed according to the 16s Illumina Amplicon Protocol, targeting the V4 region of the 16s small ribosomal subunits rRNA. Closed-reference OTU picking was used, according to 97% similarity with the Greengenes database. The top 10 phyla, classes, orders, families, genera, and species were summarized across the ASD sample. We descriptively compared AGP taxa to taxa from a sample of 20 children with ASD published by Son et al., PLoS One 2015, and to a sample of 66 children with ASD from the Simons Simplex Community, published by Kang et al., PLoS One 2013.

Results:

All taxa identified in the AGP ASD sample belonged to the Bacteria or Archaea kingdom. The top 10 phyla were Firmicutes, Bacteroidetes, Proteobacteria, Actinobacteria, Verrucomicrobia, Tenericutes, Euryarchaeota, Synergistetes, Cyanobacteria, and Fusobacteria. The top 10 genera were Bacteroides, Prevotella, Faecalibacterium, Ruminococcus, Blautia, Coprococcus, Parabacteroides, Akkermansia, Roseburia, and Dialister. The top 10 species were copri, prausnitzii, muciniphila, fragilis, bromii, distasonis, faecis, adolescentis, oxytoca, and uniformis. These findings are consistent with existing published studies that found that Firmicutes, Bacteroidetes, Actinobacteria, Proteobacteria, and Verrucomicrobia tend to be the top 5 phyla in ASD samples. The top genera were also consistent with published studies, with the exception of genera Subdoligranulum, which has previously been reported as a top 5 genera in ASD, but was not observed in the AGP sample.

Conclusions:

The top phyla and genera from the citizen science-based American Gut Project ASD samples are largely consistent with published rankings based on ASD-specific datasets. This suggests that crowdsourcing may be a useful approach to sampling gut microbiome data that is representative of ASD populations, although larger samples are still needed to confirm this.

173 **129.173** Sleep As a Predictor of Emotional and Behavioral Presentation in Children with Autism Spectrum Disorder (ASD) at Discharge from Specialized Psychiatric Inpatient Units

B. J. Taylor[1], *C. A. Mazefsky*[2], *K. Pedersen*[3] *and M. Siegel*[4], *(1)Psychiatry, Maine Medical Center Research Institute, Portland, ME, (2)Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA, (3)Department of Psychiatry, Maine Medical Center, Portland, ME, (4)Maine*

Medical Center - Tufts School of Medicine, Westbrook, ME

Background:

Children with Autism Spectrum Disorder (ASD) are disproportionately hospitalized for psychiatric treatment. Converging evidence suggests that sleep disturbances are associated with compromised emotional and behavioral health in children with ASD; however, the role of sleep in psychiatric inpatient treatment is largely unknown. Moreover, published studies examining sleep in relation to externalizing symptoms in children with ASD have relied on parent-report questionnaires of sleep which may be biased by the extent to which parent sleep is disturbed. Finally, inpatient psychiatric hospital settings, characterized by stimulus control, highly structured daily routines and low-distraction sleep environments, provide a unique opportunity to examine sleep in relation to clinical outcomes in the context of good sleep hygiene.

Objectives:

The goal of the current study was to examine observed sleep during psychiatric hospitalization as a predictor of parent-reported improvement in irritability, hyperactivity, and emotion regulation in children with ASD at discharge.

Methods:

Total Sleep Time (TST), number of arousals from sleep (NUMA), and minutes of wakefulness after sleep onset (WASO) were observed in 158 children with ASD (confirmed by research-reliable ADOS-2) between the ages of 4 and 20 (mean = 12.7 ± 3.3) across six inpatient units, drawn from the Autism Inpatient Collection (AIC). Nightly TST, NUMA, and WASO were measured observationally by hospital staff in 15 minute increments. Multiple regression models tested average TST, NUMA, and WASO as predictors of parent-reported irritability, hyperactivity, and emotion dysregulation at discharge, controlling for parent-reports at admission. All analyses were further adjusted for study site, length of hospital stay, and use of medications for sleep, antidepressants/anxiolytics, antipsychotics, and stimulants. Exploratory analyses examined if relationships between sleep and clinical improvement varied by psychiatric co-morbidity.

Results:

Irritability, hyperactivity, and emotion dysregulation all significantly improved from admission to discharge (t-statistics were 13.60, 11.09, and 14.47, respectively, p-values <.001). Average TST was 9 hours and 24 minutes ± 63.3 minutes, average NUMA was 0.39 ± 0.37, and average WASO was 19.51 ± 20.39 minutes. Indices of sleep did not vary by co-morbid psychiatric diagnosis. Greater average WASO during hospital stay predicted higher hyperactivity at discharge, controlling for hyperactivity at admission and covariates (β = .161, p = .034). Greater average NUMA predicted greater emotion dysregulation at discharge controlling for emotion dysregulation at admission and covariates (β = .196, p = .014). There were no main effects of TST on clinical outcomes; however, for those with a co-morbid anxiety disorder, shorter TST predicted greater emotion dysregulation at discharge in fully adjusted models (β = .462, p = .003). No index of sleep predicted irritability at discharge.

Conclusions:

Results of the current study suggest that sleep may be an under-examined predictor of clinical improvement in children with ASD hospitalized for psychiatric treatment. Given that the inpatient environment is consistent with many sleep hygiene recommendations, underlying mechanisms, such as autonomic dysregulation, may account for the relationship between nocturnal arousals, hyperactivity, emotion dysregulation, and anxiety. Future studies using objective measures of sleep (e.g., actigraphy) are needed to further examine the interrelationships of sleep and externalizing symptoms.

174 **129.174** Social Communication and Repetitive Behaviours in Gender Dysphoric Children: Exploring the Specificity of Autistic Traits

J. H. Leef[1,2]*, J. A. Brian*[3]*, D. P. VanderLaan*[4]*, H. Wood*[5] *and K. J. Zucker*[6]*, (1)Autism Research Centre, Bloorview Research Institute, Toronto, ON, Canada, (2)Department of Applied Psychology and Human Development, University of Toronto & Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (4)Department of Psychology, University of Toronto at Mississauga, Mississauga, ON, Canada, (5)Toronto District School Board, Toronto, ON, Canada, (6)Department of Psychiatry, University of Toronto, Toronto, ON, Canada*

Background: Gender dysphoria (GD) is characterized by distress due to incongruence between assigned gender and experienced/expressed gender (APA, 2013). Evidence suggests a higher-than-expected co-occurrence of GD and autism spectrum disorder (ASD) in children, adolescents and adults (vanderMiesen, et al., 2015). The GD-ASD link has been explored in samples of children with GD (de Vries, et al., 2010; VanderLaan, et al., 2015) and in those with ASD (Strang, et al., 2014). However, studies of GD children have not explored whether ASD traits found in these samples are specific to GD, or whether these traits are also found in children referred for other psychiatric/psychological concerns.

Objectives: To explore whether traits of ASD are elevated in gender dysphoric children relative to children clinically referred for other concerns.

Methods: Data collected from two groups were analyzed. The GD group included 51 children (aged 4-12 years) referred to a specialized Gender Identity Service (males=38). The comparison (clinical control; CC) group included 39 age- and sex-matched children (males=27) referred to the same psychiatric hospital as the GD group for concerns *other* than GD or ASD (e.g., mood/anxiety).

The study analyzed parent reports on two ASD-specific measures—the Social Communication Questionnaire (SCQ) and the Social Responsiveness Scale (SRS).

Results: ANOVA (controlling for age) revealed a significant group effect for SCQ total score (*F*=7.97, *p*=.006, η_p^2=.084), with significantly higher scores in the GD (mean=6.71, SD=4.85) than the CC group (mean=4.72, *SD*=3.25). Based on the a priori hypothesis of an association between GD and perseverative/intense interests, we explored SCQ item #24 specifically. Chi^2 analysis revealed a significant association (X^2=5.73, p=.026), with 30.4% of the GD group endorsing this symptom (versus 8.6% of the CC group). ANOVA failed to find a group effect for SRS Total T-scores (p=.38). Further examination of SRS domains revealed a group by sex interaction for Social Cognition T-Score (F=4.89, p=.03, η_p^2=.045), and sex main effects for Social Awareness, Social Communication, Social Motivation, and Autistic Mannerisms (all p's ≤ .002). In all domains natal females' mean T-scores were above 60.

Conclusions: Preliminary findings corroborate our hypothesis that symptoms of ASD are more common in children with GD than those referred for other concerns, with a medium effect size (SCQ; Field, 2013). Furthermore, the symptom of perseverative/intense interests was endorsed more frequently (30.4%) for GD children than CC children (8.6%)—consistent with recent findings of intense/obsessional interests in GD children (Zucker, et al., 2017). Further exploration of similar items on the SCQ and SRS will be conducted. The failure to find significant group differences on the SRS Total Score may be due to low power, given our sample size. Natal females tended to have SRS T-scores in the Mild-to-Moderate range (T-score ≥

60), suggesting they have more severe social-communication deficits than natal males seeking psychiatric/psychological services. Perhaps this parallels the emerging shifts in the male:female ratios reported in both GD (Aiken, et al., 2015) and ASD literatures (Lai, et al., 2015). Further analyses will account for other demographic characteristics, referral questions and degree of gender nonconformity.

175 **129.175** Stability and Persistence of Emotional and Behavioural Problems in Children with ASD

S. Chandler[1]*, G. Baird*[2]*, T. Charman*[3] *and E. Simonoff*[1]*, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:

High rates of co-occurring psychiatric disorders have been reported in older children, adolescents and adults with autism spectrum disorder (ASD). Recent studies have also shown high rates of emotional and behavioural problems (EBPs) in younger children with ASD. Early identification of comorbid problems is crucial in the management of ASD, especially given that the impact of many of these problems can often be reduced using evidence-based interventions. Psychiatric problems have been shown to persist in older children with ASD, but far less is known about the stability of EBPs in young children with ASD.

Objectives:

To assess the stability of IQ, ASD symptoms, and EBPs across approximately seven years, from early childhood to late childhood/adolescence in a community sample of children with ASD.

Methods:

All children born between 01/09/2000 and 01/09/2004, with a diagnosis of ASD, living in two London boroughs (n=447) were invited into the study. Parents were asked to complete the Developmental Behaviour Checklist (DBC) and the Social Communication Questionnaire (SCQ) at two time-points: when the children were aged 4- to 9-years-old (time 1); and again when the children were aged 11- to 15-years-old (time 2). IQ was assessed for all participating children at time 1, and for a subset at time 2. Paired t-tests were used to examine differences between scores at times 1 and 2. Children with persisting EBPs were defined as those who met the DBC clinical cut-off at times 1 and 2. Logistic regression was used to test whether any individual or background factors were associated with persisting EBPs. Individual factors examined were: IQ, autism severity (as measured by the SCQ) and EBPs (as measured by DBC total) at time 1; age; and sex. Background factors included: parental education and employment.

Results:

277 families participated at time 1 (child mean age = 6.8 years). Of these, 211 (76%) participated in the follow-up at time 2 (child mean age = 13.5 years). While there was no significant difference in IQ scores at time 1 and time 2 (p=.240), there was a significant decrease over time in both SCQ and DBC totals (p<.001 for both); the same was true for each of the DBC subscales (all p<. 05).

Despite an overall reduction in total scores, almost two thirds (62%) of children who reached the DBC cut-off at time 1 remained above cut-off at time 2. Persisting EBPs were associated with higher SCQ scores at time 1 (p=.032), but not with IQ or DBC totals at time 1, age, gender, or parent education or employment (all p>.15).

Conclusions:

Within this community sample of children with ASD, levels of ASD symptomatology and EBPs were less stable than IQ, and showed an overall reduction in parent-reported symptoms over time. However, for many of those with marked EBPs, these problems persisted over time. Higher autism severity at time 1 was associated with persisting EBPs. The study findings highlight the need for early identification of co-existing EBPs in children with ASD, in order to enable timely intervention.

176 **129.176** The Association between Additional Emotional and Behavioural Problems in Children with ASD and Their Parents' Stress and Mental Health Problems: A Systematic Review and Meta-Analysis.

I. Yorke[1]*, P. White*[1]*, A. Weston*[2]*, M. Rafla*[3]*, T. Charman*[4] *and E. Simonoff*[1]*, (1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)University of Bath, Bath, United Kingdom, (3)King's College London, London, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Children with Autism Spectrum Disorder (ASD) and their parents are at heightened risk for mental health difficulties. According to research in the general population, parents' and children's psychological health are reciprocally related, with parent mental health problems (MHP) being well-established risk factors for psychopathology in their children. Investigating this relationship in families of children with ASD may have important implications for the development of therapeutic interventions. Existing findings are variable, which may be due to differences in sampling, measurement, and the variety of other child and parent factors that are included as covariates. Despite progressing research, most studies are based on data collected at single time-points from parents reporting on both themselves and their child.

Objectives: The current research aimed to systematically identify, organise and summarise the existing research on the relationship between additional emotional and behavioural problems (EBPs) in children with ASD, and parenting stress (PS) and MHP in their parents.

Methods: We conducted a systematic search to identify published studies analysing the relationship between additional EBPs in children with ASD and either PS or MHP in their parents. Zero-order correlation coefficients, quantifying the magnitude of the associations at single time-points, were entered into a series of meta-analyses. Multiple regression-based analyses involving other factors at both single and multiple time points were reviewed and summarised narratively.

Results: Seventy-one studies met criteria for inclusion in the review and 53 of these provided correlation coefficients. Twelve studies included an analysis of the relationships of interest across time. Meta-analyses showed significant pooled correlation coefficients of moderate magnitude for the associations of child total EBPs, externalising and internalising with both parent PS and MHP (pooled r=.25-.43; see Table 1, Figure 1). Low to moderate between-study heterogeneity was also found in each analysis, except the EBP-PS analysis which showed high heterogeneity (I^2=70.84%). Sample characteristics, e.g. child age, did not significantly explain heterogeneity in any analysis. However, differences in PS measurement properties were found to account for 19.22% of between-study differences in the EBP-PS analysis (p=.03). In a separate planned analysis using data from studies which included an alternative informant for the child EBPs, the relationship between this and parent MHP was reduced but remained significant (pooled r=.21; p<.02). Narrative review of single time-point studies showed mixed evidence for unique associations between the child and parent factors of interest, depending on other factors accounted for. Longitudinal studies showed consistent evidence of earlier parent PS and MHP predicting later child EBP. Evidence for the reverse was less consistent, though more apparent in better-powered studies.

Conclusions: The literature to date shows robust association between additional EBPs in children with ASD and the PS and MHP of their parents. Although reduced when child EBPs are assessed by an alternative rater, the association remains significant, suggesting that the relationship cannot be entirely accounted for by shared rater effects. The association also maintains once certain other factors are accounted for. There is some evidence for bidirectional association between child and parent mental health over time.

177 **129.177** The Role of Anxiety in Looking Patterns Among Children with ASD: Results from the ABC-CT Feasibility Study

E. Hamo[1], *A. Naples*[1], *B. Lewis*[1], *K. Chawarska*[1], *R. Bernier*[2], *S. Jeste*[3], *C. A. Nelson*[4], *G. Dawson*[5], *S. J. Webb*[2], *M. Murias*[6], *F. Shic*[7], *C. Sugar*[3] *and J. McPartland*[1], *(1)Child Study Center, Yale University School of Medicine, New Haven, CT, (2)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (3)University of California, Los Angeles, Los Angeles, CA, (4)Boston Children's Hospital, Boston, MA, (5)Department of Psychiatry and Behavioral Sciences, Duke Center for Autism and Brain Development, Durham, NC, (6)Duke Center for Autism and Brain Development, Department of Psychiatry and Behavioral Sciences, Duke University, Durham, NC, (7)Center for Child Health, Behavior and Development, Seattle Children's Research Institute, Seattle, WA*

Background:
Background: Previous literature reports high comorbidity rates of anxiety disorders in individuals with autism spectrum disorder (ASD). Up to 39.6% of those with ASD have at least one co-morbid anxiety disorder. Therefore, it is important to understand whether anxiety impacts responses to social stimuli, and whether this effect is different in clinical populations. Overall, exploring these relationships can help understand the influence of anxiety on ASD symptoms to inform research and intervention.

Objectives: To examine the relationship between anxiety and attention to social stimuli among children with and without ASD.

Methods: Data was collected across five sites from 26 typically developing (TD) children and 23 children with ASD between ages 4-11 (M=7.22, SD=2.20; 71% male) and their caregivers. Binocular eye-tracking data was collected at 500Hz using a SR Eyelink 1000 Plus. Participants were presented with six trials, each consisting of five images (face, phone, bird, car, scrambled face; matched in color and luminosity) presented in an array such that each was equidistant from the center of the screen. Percent looking at specific images was calculated as the number of valid gaze samples in a pre-defined region around the image content divided by the total number of onscreen gaze samples. Caregivers were asked to complete the *Behavior Assessment for Children, Third Edition (BASC-3)* and *Childhood and Adolescent Symptom Inventory, 5th Edition* (*CASI-5*). T-tests were conducted to identify differences between groups. Correlations were used to determine associations between anxiety symptoms, as measured by *T*-scores from the *BASC-3* Anxiety subscale and *CASI-5* Social Anxiety subscale, and percent of time attending to social information during the eye-tracking task.

Results: Children with ASD spent significantly less time looking at faces (M=.17, SD=.02) than TD children (M=.24, SD=.02) [$t(45)$=2.53, p=.02)]. Anxiety scores were significantly higher in children with ASD (M=52, SD=2.72) than in the TD group (M=44.08, SD=1.39) [$t(46)$=-2.72, p=.01)]. Higher anxiety symptoms in children with ASD was positively correlated with percent of time looking at non-social objects (r_s=.426, p=.048). In particular, a higher anxiety score was significantly associated with more time spent looking at the technical objects (r_s=.477, p=.02) among children with ASD. Social anxiety was not significantly related to time looking at social or non-social images among children with ASD. No significant relationships between anxiety and looking patterns were found among TD children.

Conclusions: Results reveal a relationship between anxiety symptomology in children with ASD and preferential looking patterns toward non-social stimuli. Social anxiety was not associated with looking patterns, suggesting that the results are not attributed to specific anxiety toward social stimuli. Neither relationship was found in the TD group; however, clinically significant levels of anxiety were exclusionary for the TD group in the larger study. Overall, these findings suggest that anxiety may be a significant factor in existing ASD symptomology by contributing to the preferential looking patterns towards non-social information. In other words, children with ASD may be more likely to avoid looking at faces due to the anxiety-producing social stimuli.

178 **129.178** The Role of Medical (including Psychiatric) Evaluations in the Diagnosis of ASD:from Gold-Standard Instruments to Full Diagnosis

M. Parellada, *Fundación Investigación Biomedica Gregorio Marañon, Madrid, Spain*

Background: The diagnosis of ASD is based on observable behaviors. Best–estimate clinical diagnosis of ASD refers to a diagnosis of the clinical symptoms and development compatible with an ASD diagnosis with all available information including developmental history, assessment of ASD-behaviors, medical and school reports, with or without instruments developed for the assessment of parts of the diagnostic procedure (i.e. developmental history, ASD symptoms). Differential diagnosis of other psychiatric conditions that may better explain the observed behaviors should always be part of the diagnostic procedure.
Objectives: To present data from an "ASD Complex Diagnosis Program" where a full psychiatric evaluation is conducted in addition to a full ASD-related evaluation in cases in diagnostic doubt after a general Child Psychiatrist and/or Neuropaediatrician evaluation.

Methods: 180 patients consecutively attended in a Specialized consultative care (Tertiary Tier) Child Psychiatry Program for the assessment of children and adolescents with the suspicion of having an ASD diagnosis, underwent a full psychiatric and developmental evaluation. Final best-estimate diagnosis following DSM/ICD criteria was reached after i) evaluation of all life-time medical, educational and psychological reports ii) full psychiatric history with the patient and primary carer iii) full developmental history with the primary carer (roughly 50 % of the times with the ADI-R) iv) ADOS-2 evaluation v) psychopathological assessment including mental state vi) cognitive/language assessment if not available vii) family and teacher questionnaires for the assessment of ASD-behaviors, particularly in relation with peer-relationships vii) other questionnaires as appropriate viii) medical specialists consultation when indicated.

Results: main reasons for referral were: young children referred for a differential diagnosis with Specific Language Disorder, Intelligence

Developmental Disorder or emotional and/or behavioral disorders; children/adolescents with multiple previous diagnoses; adolescents for differential diagnosis with psychotic disorders or personality disorders. 85 % of the patients were male; 78 % were up to 9 years of age and 22 % were 10-18 years old. Roughly 50 % were elegible for module 3 of the ADOS-2 (complex language level and up to early adolescence). There was a deviation to the left in the distribution of IQ, with 51 % of the patients having a below average IQ (<70). 80 % of the full sample was given an ASD diagnosis. However, among children/adolescents 8-15 years of age only 58% were given a diagnosis of ASD; behavioural disorder (including severe ADHD), social communication disorder and specific language disorders followed in frequency. Among adolescents 16-18 years of age, 62 % were diagnosed with an ASD, followed by other psychiatric disorders (high-risk of psychosis, personality disorders) and specific language disorders.

Conclusions: a full psychiatric evaluation seems to be an important add-on for the proper diagnosis of children and adolescents with complex developmental/behavioral difficulties.

179 **129.179** Title: Do Motor Abilities Predict ADHD Symptoms in Preschoolers with FXS?

S. L. O'Connor[1], *E. A. Will*[2] *and J. E. Roberts*[2], *(1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Psychology, University of South Carolina, Columbia, SC*

Background: Attention Deficit/Hyperactivity Disorder (ADHD) is the most commonly diagnosed behavioral disorder in children with approximately 11% of the general population diagnosed with ADHD. Children with FXS and ASD experience higher rates of ADHD symptomatology, with rates in the literature ranging from 40-80%. Motor skills have been identified as a predictor of ADHD outcomes within the general population and have also been found to distinguish between clinical groups such as FXS and FXS+ASD. Thus, motor scores may be a viable predictor for ADHD in high risk populations such as FXS. Additionally, the presence of autism symptoms in FXS have been shown to moderate the severity and presence of ADHD in individuals with FXS. However, the relationship between autism symptoms and motor skills has not been investigated in ADHD and FXS.

Objectives: In the present study, we examined whether motor abilities, moderated by ADOS severity scores, were predictive of ADHD symptomatology in a group of preschoolers with FXS. We then examined whether fine motor and gross motor abilities, also moderated by ADOS severity scores, were predictive of ADHD symptomatology in preschoolers with FXS.

Methods: Participants included 36 preschool aged children with FXS. The Child Behavior Checklist 1½-5 ADHD-DSM subscale raw scores (CBCL) were used to assess the presence ADHD symptoms between 36-60 months of age. Both measures were collected at the same time. Broad motor abilities were measured by the Motor scale standard scores from the Vineland Adaptive Behavior Scale (VABS). Fine Motor and Gross Motor Scales raw scores were also used from the VABS.

Results: Results for the regression model testing broad motor skills predicting ADHD indicated that there were no significant associations between motor and ADHD, and that autism symptom severity did not moderate this association, though the overall model approached significance (p = .105; R^2 = .172). We followed up with two subsequent models to detect whether fine and gross motor skills individually predicted ADHD outcomes, however, no significant associations were found (p's > .05).

Conclusions: Study findings suggest that motor abilities may lead to developmental outcomes other than ADHD for preschoolers with FXS. Although neither fine motor nor gross motor was significantly associated with concurrent ADHD outcomes in preschool (i.e., 36 to 60 months), motor development in infancy may contribute to later ADHD outcomes for children with FXS. Future work should delineate early developmental pathways to ADHD and identify developmental outcomes related to early motor abilities in children with FXS.

180 **129.180** Vagal Tone As a Predictor of Separation Anxiety in Preschoolers at Elevated Risk for ASD

A. M. Brewe[1], *A. L. Hogan*[1], *C. E. Knott*[2] *and J. E. Roberts*[2], *(1)Department of Psychology, University of South Carolina, Columbia, SC, (2)Psychology, University of South Carolina, Columbia, SC*

Background: Separation anxiety disorder (SAD) affects about 4% of typically-developing (TD) children. However, rates of SAD are twice as high for children with autism spectrum disorder (ASD). While traditional screening and diagnostic measures help define behavioral expressions of SAD, physiological indices may serve as valuable biomarkers given subtle signs and limited verbal skills that could preclude accurate recognition of early features. Vagal tone indexes parasympathetic/vagal regulation and atypical vagal tone has been tied to anxiety in TD children and adults. It is unclear if children with ASD have atypical vagal tone because their ASD symptoms interact with anxiety symptoms in a complex manner.

Objectives: The current study aims to characterize differences in vagal tone in groups at high risk for SAD, including children with fragile X syndrome (FXS) and younger siblings of children diagnosed with ASD (ASIBs), compared to TD peers. The study also aims to determine if ASD symptom severity correlates with vagal tone during a socially stressful task and if vagal tone predicts SAD in the high-risk groups.

Methods: Participants included TD males (CA=52.41 months; n=17), ASIBs (CA=60.12 months; n=19) and children with FXS (CA=60.53 months; n=21). Vagal tone was measured during a maternal separation task. Respiratory sinus arrhythmia (RSA), an index of vagal tone, was measured during baseline, maternal separation, and recovery periods. RSA in each period and RSA reactivity between periods was computed. The Spence Children's Anxiety Scale (Spence & Rapee, 1999) was used as a measure of parent-reported SAD. The Autism Diagnostic Observation Schedule – Second Edition (ADOS-2; Lord, Rutter, DiLavore, & Risi, 2001) was used to measure ASD symptom severity.

Results: One-way ANOVAs indicated that groups did not differ on Spence SAD subscale scores, $F(2,52)=0.303$, $p=.740$ or on baseline RSA, $F(2,56)=1.028$, $p=.364$. However, children with FXS exhibited lower RSA than ASIBs during the separation period $F(2,56)=3.823$, $p=.028$ and lower RSA than both ASIB and TD groups during the recovery periods, $F(2,56)=3.743$, $p=.030$. Regression analyses indicated ASD severity did not predict RSA in any groups; however, RSA reactivity from baseline to separation periods predicted SAD for ASIBs $R^2=.505$, $F(1,9)=9.188$, $p=.014$ and approached significance for the FXS group $R^2=.201$, $F(1,17)=4.288$, $p=.054$.

Conclusions: Regulation of vagal tone during stressful situations serves an adaptive function; therefore, the FXS group's lower vagal tone during separation and recovery provides evidence of physiological dysregulation. SAD has been shown to exacerbate impairments in children with ASD; therefore, analyzing how biological measurements of SAD correspond with behavioral features in high-risk groups is essential to understanding the expression of SAD in these groups. Severity of ASD does not appear to influence vagal tone, suggesting vagal tone in high-risk groups may be influenced by other factors. However, vagal reactivity did predict SAD symptoms in the ASIB group and marginally in the FXS group, indicating vagal tone may serve as a biomarker of SAD in at-risk populations.

181 **129.181** Why Is Quality of Life Reduced in Individuals with Autism Spectrum Conditions? Investigating the Impact of Core Symptoms and Psychiatric Comorbidities on Quality of Life in the EU-AIMS LEAP Cohort.

B. Oakley[1]*, J. Tillmann*[2]*, D. V. Crawley*[1]*, A. San Jose Caceres*[1]*, R. Holt*[3]*, T. Charman*[4]*, J. K. Buitelaar*[5]*, T. Banaschewski*[6]*, E. Simonoff*[7]*, D. G. Murphy*[8] *and E. Loth*[1]*, (1)Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)King's College London, London, United Kingdom of Great Britain and Northern Ireland, (3)University of Cambridge, Cambridge, United Kingdom, (4)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (5)Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands, (6)Child and Adolescent Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany, (7)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (8)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background: Individuals with Autism Spectrum Conditions (ASCs) generally report lower quality of life (QoL) than the neurotypical population. There is often an implicit assumption that ASC per se (i.e. the defining core symptoms) is the central factor resulting in reduced QoL. However, the relative impact of psychiatric comorbidities (e.g. anxiety, depression, ADHD) vs. core ASC symptoms on different facets of QoL, at different stages of development, remains poorly understood, despite up to 71% of individuals with ASCs having one or more comorbidities.

Objectives: Thus, this study aimed to investigate the role of ASC core symptoms and psychiatric comorbidities in QoL across multiple domains, in a large and diverse sample of individuals with ASCs.

Methods: 445 individuals with ASCs and 302 individuals without ASC (with/without mild intellectual disabilities), aged 6-30 years, were recruited to EU-AIMS LEAP (Charman et al., 2017; Loth et al., 2017). ASC core symptoms were assessed using the Social Responsiveness Scale-2nd Edition (SRS-2) and Repetitive Behaviour Scale-Revised (RBS-R); co-occurring psychiatric symptoms were assessed using the Development and Well Being Assesesement. To measure QoL; 1) Across all participants, parent-report Columbia Impairment Scale (CIS) was administered; 2) In children (6-11 years), we also administered parent-report Child Health and Illness Profile (CHIP-CE), which indexes Satisfaction, Comfort, Resilience, Risk Avoidance & Achievement; 3) Participants 12-30 years completed self-report CIS and/or WHOQOL-BREF. The latter measure indexes Overall QoL, Physical Health, Psychological Health, Social Relationships & Environment. Within the ASC group we performed stepwise multiple regression for each domain of QoL as the dependent variable, and the following independent variables; demographics (age, IQ, sex, testing site), core symptomatology (SRS-2, RBS-R), and comorbid symptomatology (anxiety, depression, ADHD).

Results: In accordance with previous research, the ASC group scored significantly lower on QoL measures than Controls, with effect sizes from r=0.17-0.61. See Figure 1 for correlations.

CIS-Parent. Social-communication deficits accounted for 31.1% unique variance, with depression contributing a further 6.1%, and repetitive behaviours 1.8%.

CIS-Self. Social-communication deficits explained 29.1% variance, and anxiety explained a further 2.5%.

WHOQOL-BREF. Depression was the only variable significantly accounting for variance in; Overall QoL (29.1%), Physical Health (23.1%), and Social Relationships (47.2%). Social-communication deficits were the only symptom significantly explaining variance on Psychological (36.5%) and Environment (26.9%) domains.

CHIP-CE. For the Satisfaction domain, the best-fitting model included social-communication deficits (11.4% unique variance) and anxiety (5.1% unique variance). The same was true for the Comfort domain, however this time anxiety (20.1%) explained more variance than social-communication deficits (4.1%). Depression alone significantly accounted for 7.1% unique variance on the Resilience domain. Finally, the best-fitting model for Risk Avoidance included ADHD (17.5% unique variance) and sex (6.1%). The model for Achievement also featured ADHD (20.4% unique variance), as well as IQ (12.7%) and depression (5.8%).

Conclusions: These findings emphasise how QoL in ASCs is a multi-faceted construct, with diverse underpinnings, influenced by core and comorbid symptoms. Through better understanding the contributions of diverse symptoms on various domains of QoL, in different individuals with ASCs, we may identify how interventions can be targeted to improve QoL.

182 **129.182** The Effect of Nutrition and Exercise on Bone Density in Boys with Autism Spectrum Disorder

A. Neumeyer[1]*, N. Cano Sokoloff*[2]*, E. I. McDonnell*[3]*, E. Macklin*[2]*, T. M. Holmes*[4]*, J. L. Hubbard*[4]*, C. McDougle*[5] *and M. Misra*[6]*, (1)Lurie Center for Autism Massachusetts General Hospital, Lexington, MA, (2)Massachusetts General Hospital, Boston, MA, (3)Biostatistics Center, Massachusetts General Hospital, Boston, MA, (4)Translational & Clinical Research Center, Massachusetts General Hospital, Boston, MA, (5)Lurie Center for Autism,, Massachusetts General Hospital,, Lexington, MA, (6)Pediatrics, Massachusetts General Hospital and Harvard Medical School, Boston, MA*

Background:

Peak bone mass is an important determinant of future bone health. The childhood years are critical for development of bone mass, which depends upon many factors including genetics, nutrition, weight bearing activity, hormonal status, medication use and medical disease. Boys with autism spectrum disorder (ASD) have lower bone mineral density (BMD) than typically developing controls (TDC). Differences in nutrition and exercise may contribute to low BMD. Nutrition management of children with ASD is a challenge because children frequently have a restricted diet, either self-imposed and limited by taste or texture or imposed by parents to avoid potential allergens. Concurrent gastrointestinal diseases in children with ASD may affect absorption of nutrients. Children with ASD are also often less active physically and have a higher prevalence of hypotonia.

Objectives:

To examine macro- and micro-nutrient intake, serum levels of vitamin D and calcium, and self-reported physical activity in boys with ASD compared to TDC and the relationship of these variables with BMD**.**

Methods:

Participants included 49 prepubertal and pubertal boys (25 ASD, 24 TDC), ages 8-17 years, recruited from a clinic population (ASD) or community advertisements (ASD and TDC) matched for age. In this cross-sectional study, we assessed BMD of the lumbar spine, femoral neck, total hip and whole body less head using dual energy X-ray absorptiometry, and three-day diet/supplement and physical activity records. Fasting levels of 25(OH) vitamin D and calcium were obtained.

Results:

ASD participants were approximately 9 months younger than TDC participants on average. Age adjusted BMI z-scores were similar. Body mass index and serum vitamin D and calcium levels were similar. BMD Z-scores were 0.7 to 1.2 standard deviations lower in ASD than TDC at all locations. Fewer boys with ASD were categorized as “very physically active” (27% vs. 79%, p<0.001). Boys with ASD consumed significantly less calcium, iron, phosphorous, selenium, vitamins A, riboflavin, niacin, B6, B12 and dietary folate equivalents, with deficiencies ranging from 19 to 35%. Boys with ASD consumed 16% fewer calories, 37% less animal protein, and 20% less fat than TDC, with a larger percentage of calories obtained from carbohydrates. Higher animal protein, calcium and phosphorus intake was associated positively with bone density measures in boys with ASD. Our data confirm reports of micronutrient inadequacies in the diets (food alone) of boys with ASD and that vitamin supplementation does not correct several of these inadequacies.

Conclusions:

Boys with ASD were less active and had lower BMD Z-scores at the lumbar spine, femoral neck, total hip and whole body less head than TDC. Protein, calcium and phosphorus intake were lower in ASD than TDC and were associated positively with BMD. This suggests that encouraging diets higher in fortified dairy and animal protein as well as increased high-level exercise may improve bone health. It is important for practitioners to assess dietary intake of dairy and animal protein

183 **129.183** Heart Activity during Startle Paradym in Children with Fragile X Syndrome and Autism Spectrum Disorder Compared to Typically Developing Children

J. A. Ezell[1], *E. A. Will*[2], *S. McQuillin*[1] *and J. E. Roberts*[2], *(1)University of South Carolina, Columbia, SC, (2)Psychology, University of South Carolina, Columbia, SC*

Background: Fragile X syndrome (FXS) is a monogenetic disorder characterized by abnormal social behavior and intellectual disability. FXS is also the most frequent known heritable genetic cause of autism spectrum disorder (ASD), which makes it an ideal model for studying ASD. High rates of anxiety have been reported in both FXS and ASD with features of anxiety overlapping with ASD symptomatology in both clinical groups. Capturing anxiety in young children with FXS or ASD is challenging as verbal deficits can limit self-report and most measures are normed for older children or adults in these populations (Spence et al 2001). Behavioral and physiological measures of anxiety can provide important insight into early features of anxiety in children with FXS or ASD. Elevated heart rate and reduced modulation in response to threat can be indicative of anxiety (Whalen et al, 2017). Physiological reactivity to an auditory startle captures reflexive responses linked to underlying physiological mechanisms associated with anxiety. Given that children with FXS and ASD demonstrate dysregulated autonomic activity and related challenges modulating heart activity compared to typically developing (TD) children (Klusek et al, 2015; Roberts et al, 2012), heart activity in auditory startle response can provide insight into anxiety features in these high-risk groups.

Objectives: The purpose of this study is to characterize heart activity in response to an auditory startle in children with FXS and in children with ASD contrasted to low-risk controls. We predict that children with FXS or ASD will react with elevated heart activity to the auditory startle task compared to TD children.

Methods: Participants included 25 children with FXS, 21 TD children, and 11 children with idiopathic ASD (*n* =20 by INSAR) between the ages of 3-6 years old who are participating in an ongoing study. The auditory startle task takes place in the context of a silent children’s movie and is comprised of a three phases, 1). The pre-startle (30 seconds), 2) startle (1 second), and 3) post-startle (60 seconds).

Results: We examined patterns in heart activity during auditory startle response across FXS, ASD, and TD groups using a multi-level model, wherein 1s epochs were nested within children. The FXS and TD groups differed in startle response heart activity B=.50(.19), t=2.51, however, FXS and ASD groups did not B=.27(.19),t=1.39. Model results indicate that the FXS and ASD groups showed increased startle response heart rate, whereas the TD group showed a decrease (see figures).

Conclusions: These preliminary findings are consistent with previous research showing altered physiological reactivity in clinical samples with FXS and ASD compared to TD children. Results suggest that autonomic reactivity, indexed by heart rate, may represent a shared mechanistic vulnerability with anxiety in FXS and ASD. Elevated heart rate following startle response might be an early feature of anxiety in young children with FXS or ASD. Behavioral data are being coded during the startle experiment, and these data will be integrated with heart activity for presentation at the conference.

Poster Session
130 - Service Delivery/Systems of Care
5:30 PM - 7:00 PM - Hall Grote Zaal

184 **130.184** - Identifying Previous Service Experience and Needs Among Individuals with Autism Waiting for Services

L. Shea[1], *P. F. Turcotte*[2] *and S. Nonnemacher*[3], *(1)A.J. Drexel Autism Institute, Philadelphia, PA, (2)Drexel University, Philadelphia, PA, (3)Pennsylvania Bureau of Autism Services, Harrisburg, PA*

Background: Pennsylvania is home to two of the first programs for adults with autism in US, the Adult Autism Waiver and the Adult Community Autism Program, both administered by the Pennsylvania Bureau of Autism Services. In 2015, 1,648 individuals were waiting for services through these two programs. Understanding the service experiences and needs of individuals with autism waiting for services and their caregivers provides critical insight to help states plan for the services (and associated cost) individuals will need. Individuals waiting for services are also at risk of adverse outcomes such as hospitalization and police contact since they are less likely to be receiving behavioral supports that would help prevent these crises. To understand the needs of this group, the Pennsylvania Autism Needs Assessment was distributed to individuals with autism waiting for services and their caregivers.

Objectives: Demographic characteristics, service experiences, and service needs of individuals with autism waiting for services and their caregivers will be reported and compared to Autism Needs Assessment results from the rest of Pennsylvania who are not waiting for services.

Methods: The Pennsylvania Autism Needs Assessment was distributed to all individuals waiting for services for the Pennsylvania Bureau of Autism

Services programs over the age of 18 and their caregivers in 2015. Individuals and their caregivers could complete the Needs Assessment in paper copy or online. Paper copies were double data entered and data were analyzed using crosstabs for descriptive comparisons in SAS. Ongoing analyses to compare individuals waiting for services to those receiving services are underway.

Results: A total of 638 responses were gathered from individuals waiting for services and their caregivers. Most (410) responses were from caregivers and 228 individuals with autism over the age of 18 responded to the Needs Assessment for themselves. The majority of respondents (84%) were white. Most individuals indicated needing more support in social skills training (46%), supported employment (39%), and support groups (38%). One in five caregivers indicated a need for respite care. Additional analyses, including comparisons to responses to the Needs Assessment from statewide individuals not waiting for services are underway.

Conclusions: Limited available resources across states in the US for the foreseeable future indicate individuals with autism may wait for services especially during the transition into adulthood. Identifying the needs of this group helps to characterize the individuals who need services the most and provides valuable information to help states plan for their services and budget. With one-third of respondents indicating needing employment support services, and 24% indicating five or more co-occurring diagnoses, these results provide priorities for the services that can support individuals in obtaining and maintaining employment and seeking mental health support services. The low response rate from minority populations (< 20%) warrants a top priority for continued research, and more effort is needed to catalogue the needs of underserved and underrepresented populations.

185 **130.185** A Mixed Methods Approach to Understanding Community Providers' Implementation of an Evidence-Based, Parent-Mediated Intervention

__K. Casagrande__ and B. R. Ingersoll, Psychology, Michigan State University, East Lansing, MI

Background: Despite best practice recommendations for parent involvement in intervention for young children with ASD, parent-mediated interventions (PMIs) are highly under-utilized in community settings. A better understanding of factors that influence providers' implementation of PMIs is important for the development of successful training models. Research in other fields suggests a number of factors that influence implementation of evidence-based practices for young children, including provider self-efficacy, attitudes, and perceived barriers.
Objectives: The aim of the current study is to better understand factors that influence community providers' implementation of Project ImPACT, an evidence based PMI, using a mixed methods approach.

Methods: Ninety-two providers completed a follow-up 6 to 24 months after attending multi-day Project ImPACT workshops (response rate=24%). Providers reported whether or not they implemented Project ImPACT and rated their self-efficacy in using the program as a PMI. They completed questionnaires about attitudes towards and perceived barriers in their use of Project ImPACT. Finally, providers responded to open-ended questions about how they implemented the program, any modifications they had made, and characteristics of families for whom it was most and least helpful.

Results: Forty-four providers (48%) reported that they had implemented Project ImPACT as a PMI (group=5, individual=26, both=13). Of the 48 providers who did not implement Project ImPACT as a PMI, 31 reported implementing in other ways (direct intervention=17, used some components=8, telehealth=1). Implementers did not differ from non-implementers on demographic characteristics other than profession (χ^2=15.40, p=.017); SLPs were more likely to implement the intervention (p<.05), while social workers were less likely (p<.05).

Point-biserial correlations examined the relationship between implementation and provider self-efficacy, attitudes, and perceived barriers. Self-efficacy (r=.396, p<.001) and positive attitudes towards Project ImPACT (r=.271, p=.013) were positively correlated with implementation; perceived barriers (r=-.329, p=.004) were negatively correlated with implementation. Correlations also examined the relationship between individual barriers and implementation. Of the 18 potential barriers, 7 were significantly associated with program implementation (see Table 1).

An analysis of open-ended responses suggested that providers who implemented the program made a number of modifications, including alterations to intervention content (n=7), length of the program (n=24), and session format (n=4). Providers also reported making changes to core components, including collaborative goal setting (n=5) and homework (n=8). Two providers indicated they did not provide coaching. Providers thought the intervention was most helpful for parents with who were motivated (n=19), had adequate time to devote to the program (n=14), and have children with low attention and engagement (n=8); they indicated it was least helpful for parents with limited time (n=15), high stress (n=11), and other children (n=8).

Conclusions: Self-efficacy, barriers to program use, and provider perceptions of Project ImPACT were all significantly related to implementation as expected. There were also family characteristics, such as time, motivation, and stress, which influenced the successful use of the program. We can modify the development of EBPs and alter trainings to best support providers going forward by creating more intensive trainings, planning for common barriers to program use, and improving strategies for engaging and supporting parents.

186 **130.186** Accuracy of Community General Pediatrician Diagnosis of Autism Spectrum Disorder (ASD) Compared to Multi-Disciplinary Team Assessment

__L. Andoni__[1], J. A. Brian[2] and M. Penner[2], (1)University of Massachusetts, Boston, MA, (2)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada

Background: The prevalence of ASD has increased dramatically in recent years, placing a strain on access to diagnostic assessment. Early diagnosis is of significant importance to obtaining early intervention and optimizing outcomes. Encouraging community-based clinicians, such as general pediatricians (GPs), to make the diagnosis may increase diagnostic capacity and decrease wait times. If pediatricians are to be used as a diagnostic resource for ASD, it is important to evaluate whether they provide accurate diagnostic assessments compared to a multi-disciplinary team (MDT) assessment.
Objectives: The objective of this study is to determine agreement in ASD diagnosis between GPs and a subspecialist MDT assessment.

Methods: This study follows a prospective, cross-sectional design. There are two target populations for recruitment: 1) GPs in Ontario (projected n = 20), and 2) their patients under 5.5 years referred for developmental concerns (n = 200 total; 10/pediatrician). Participants are randomized 1:1 to have their MDT visits scheduled either before or after the pediatrician visit. MDT and general pediatrician assessments are conducted blinded to each other's impressions. The MDT visits consist of clinical assessments by a developmental pediatrician and a psychologist. The MDT and GP independently record a forced decision on whether the child has ASD, and the GP indicates the actions they would have taken had the child not been enrolled in the study. The MDT team provides feedback on their assessment results to the family. Agreement between the two assessments is measured with a simple kappa statistic. Descriptive data around the breakdown of true and false positive and negative cases is provided.

Results: To date, 36 assessments have been completed (24 males, 12 females; mean age 40 months, range 17-63). Thirty of the children had an ASD diagnosis as determined by the MDT. GPs agreed with the MDT team on 66.7% of cases (24/36 cases), corresponding to a kappa of 0.2 (poor agreement). In 20 true positive cases, GPs indicated that they would have given the ASD diagnosis in 12 cases, referred to a specialist in 7 cases, and 'watched and waited' in 1 case. In 2 false positive cases, GPs indicated they would have referred to a specialist. In 4 true negative cases, the GPs indicated they would have given the non-ASD diagnosis in 3 cases, and referred to a specialist in 1 case. In 10 false negative cases, the GP would have incorrectly give a non-ASD diagnosis in 4 cases, 'watched and waited' in 2 cases, and referred to a specialist in 4 cases.

Conclusions: These results are preliminary but are illustrative of the importance of this work. GP participants are willing to diagnose ASD in their practices. The incidence of several false negative cases, some of which may have been missed diagnoses as the pediatricians would not have referred for further assessment, suggests that further GP education is needed on the varied clinical presentations of ASD. Further analysis with a larger sample size will permit identification of child features associated with 'accurate' ASD diagnostic determination by GPs.

187 **130.187** Allies and Adversaries: The Experience of Healthcare and Healthcare Relationships for Adults with 'High-Functioning' Autism Spectrum Disorder

M. Wright[1], *M. Medved*[2], *J. M. Montgomery*[3] *and K. Roger*[1], *(1)University of Manitoba, Winnipeg, MB, Canada, (2)American University of Paris, Paris, France, (3)Psychology, University of Manitoba, Winnipeg, MB, CANADA*

Background: 'High-Functioning' forms of Autism Spectrum Disorder (HFASD) are characterized by a lack of what has been called 'social competence,' in the context of on-track language development and intact cognitive abilities. The hallmark social difficulties of HFASD often impact interpersonal relationships, and many individuals with HFASD report feeling dismissed and fundamentally misunderstood as persons. Within healthcare, the Patient-Centred Care (PCC) framework – which promotes understanding the patient as a person and developing positive healthcare relationships - has received much attention in the literature and is widely accepted as beneficial to patients. Despite this focus, little is known about how adults with HFASD experience their healthcare or healthcare relationships. Many physicians report feeling ill-equipped to treat and interact with adult patients with HFASD, yet healthcare research has rarely consulted adults with HFASD, missing the opportunity to understand the unique perspectives of adults with HFASD to inform practice. Given that being understood and having positive relationships is known to contribute to better healthcare experiences and health outcomes, it is essential that we understand what adults with HFASD value and want in their healthcare and healthcare relationships to improve practice.

Objectives: The purpose of this study was to better understand how adults with HFASD experience their healthcare and healthcare relationships by asking them about their experiences directly and exclusively. More specifically, this study aimed to understand perceived strengths and challenges experienced by adults with HFASD, and identify both positive and negative aspects of healthcare and healthcare relationships from their unique perspective.

Methods: Twenty-eight North-American adults with HFASD who could navigate healthcare independently answered four online long-answer open-response questions about their experiences of their healthcare and healthcare providers. Responses were analysed using constant comparison analysis within the Grounded Theory framework. Participants were provided with preliminary findings and given the opportunity to comment, agree or disagree, or clarify their responses to ensure that the researcher had accurately captured their intended meaning.

Results: Participants identified several strengths (e.g., written communication and high intelligence) and challenges (e.g. in-person communication and feeling condescended towards) in navigating their healthcare. Overall, participants reported that their experiences in healthcare were determined by their healthcare relationships, irrespective of their own personal strengths and challenges. Positive experiences occurred with healthcare providers described as 'allies' who were caring, knowledgeable and empowering. At times, these 'allies' were perceived as lacking knowledge about HFASD, but still fostered an overall positive relationship and healthcare experience by conveying care and understanding of the patient. Negative experiences – which were more commonly reported - occurred with healthcare providers described as unknowledgeable and overpowering 'adversaries', and who dismissed patient's strengths.

Conclusions: For these adults with HFASD, positive and negative experiences of healthcare were largely determined by their experience of their healthcare relationships. Furthermore, healthcare providers who were perceived as knowledgeable and caring were described as forming positive healthcare relationships. This highlights the importance of increased awareness about HFASD - in terms of understanding both the disorder itself and the person with it - among healthcare providers.

188 **130.188** An Examination of Disparities in Patterns of Use of State-Funded Disability Services

S. R. Rieth[1,2], *L. Brookman-Frazee*[2,3], *K. S. Dickson*[2,4], *R. Plotkin*[5], *T. Cook-Clark*[5] *and C. M. Corsello*[6], *(1)San Diego State University, San Diego, CA, (2)Child and Adolescent Services Research Center, San Diego, CA, (3)Psychiatry, University of California, San Diego, San Diego, CA, (4)University of California, San Diego, La Jolla, CA, (5)San Diego Regional Center, San Diego, CA, (6)Psychiatry, UNC TEACCH Autism Program, Raleigh, NC*

Background: Access to effective, evidence-based services for youth with developmental disabilities in the community is limited, especially for ethnic minorities populations where significant disparities in identification, service entry and utilization are documented (Mandell et al., 2002, 2005, 2007). There are a growing number of large-scale, system-driven efforts to address service disparities but little is known about the specific patterns and influences of service usage disparities among minorities, which are key to informing efforts to address service disparities. In 2016, the State of California Department of Developmental Services launched a large-scale initiative to address disparities in care for Latino clients statewide. To best inform this effort, the San Diego Regional Center (SDRC) prioritized the identification and tracking of disparities in current service expenditures and authorizations by ethnicity and race.

Objectives: The aim of the current study is to examine patterns of service use and expenditures for individuals with developmental disabilities receiving state-funded disability services to identify service disparities by ethnicity and specific disability. Service use patterns from birth to adulthood were also examined to identify age groups in which such disparities emerge.

Methods: SDRC administrative claims data from fiscal years 2014-2015 were extracted. Purchase of service (POS) data for 27,343 SDRC clients were used to characterize service utilization patterns, including differences in service use by ethnicity as well as disability group from birth to adulthood. Specific disability categories include intellectual disability (ID), autism spectrum disorder (ASD), and comorbid medical issues.

Results: Analyses indicate significant differences in POS for Latino and Non-Latino/White clients ($F(3,27,332)=107.47$, $p<.01$), with smaller POS for Latino clients. Follow-up analyses aimed to understand patterns to these disparities revealed a significant 3-way interaction between ethnicity, age, and disability types. Post-hoc analyses revealed significant differences in POS between Non-Latino/White clients and Latino clients with ID that emerge between the ages of 14-18:11 and for clients with ASD that emerge between 16-18:11 years of age, with lower POS for Latino individuals. A similar pattern was observed for individuals with comorbid ASD and ID, ID and medical issues and ASD and medical issues beginning at ages 19-21:11. Further analyses examining these disparities by service type will be discussed.

Conclusions: These results provide relevant information for targeted disparity reduction efforts, including identification of strategies targeting these age ranges.

189

130.189 An Overview of a Community-Based Treatment in Singapore for Children and Adolescents with Social Interaction and Communication Difficulties.

***Y. Heng*[1]** *and J. Wong[2], (1)National University Health System/ National University of Singapore, Singapore, Singapore, (2)Department of Psychological Medicine, National University Hospital of Singapore, Singapore, Singapore*

Background:

REACH (Response, Early intervention and Assessment in Community mental Health) is a community-based service in Singapore that provides mental health assessments and intervention of school-going children and adolescents (7-18 years old).

In Singapore, there is an estimated prevalence of 50, 000 individuals with Autism Spectrum Disorder (ASD), of which, 11, 500 are under the age of 19 years. With awareness, there has been a parallel increase in the number of individuals diagnosed with ASD, or identified to have social challenges since 2000 (Autism Resource Centre, 2017). These children can opt for education in a mainstream school where emphasis is placed more on academic learning. However, the children often require more intensive practice in social interaction and communication.

Objectives:

This poster aims to introduce REACH's intervention program for children and adolescents with ASD or social challenges, and explores its improvement outcomes based on pre and post parents' ratings.

Methods:

REACH's social skills lesson plans adopts Michelle Garcia's Social Thinking's strength-based treatment approach, focusing on building upon the key concepts of Central Coherence Theory (Happe and Frith, 2006), Theory of Mind (Flavell, 2004), and Executive Functioning (Hill, 2004).

Referrals to REACH are directed from health care professionals or school counsellors. Students underwent a compulsory screening session prior to commencement of social skills sessions. Parents completed a questionnaire during the screening process to identify key areas of social needs, namely, Self-Awareness and Self-Esteem, Non-Verbal Communication, Conversational Skills, Friendship Skills, and Assertiveness. For each skill, the students were rated on a scale of 1 to 3, where 1 was 'No Concern', 2 was 'Emerging Skill', and 3 was 'Needs Work'.

Based on the screening, students proceeded with either individual or group social skills sessions. Individual sessions were conducted in the respective schools of the participants, and an average of 8 hourly sessions was required to complete the individual sessions. Group sessions were scheduled at 1.5 hour for primary school-aged children, and 2 hours for secondary school students, for 5 weekly sessions. Upon completion of the therapy sessions, parents rated the students again to explore improvement outcome.

Results:

Since 2016, 3 primary school students and 11 secondary school students completed individual social skills session. 18 primary school students and 20 secondary students completed group social skills sessions. Preliminary findings showed overall improvements in the areas of Self-Awareness and Self-Esteem, Non-Verbal Communication, and Conversational Skills. (Actual results and analysis will be presented in the poster)

Conclusions:

REACH is the first community-based mental health team in Singapore that offers a tailored social skills therapy program for students with social challenges. Exploration of parents' ratings showed overall improvement in key areas of social skills. Future research could include teachers' ratings and students' self-ratings for more holistic evaluation of the program.

190

130.190 Autism Alertness and Psychiatric Stigma in Dutch Physicians Screening in the Child General Population

***M. van 't Hof*[1,2]**, *I. A. van Berckelaer-Onnes[3], M. C. Neukerk[4], A. Daniels[5], H. W. Hoek[6,7,8] and W. A. Ester[2,9], (1)Sarr Expert Centre for Autism, Lucertis Child- & Adolecent Psychiatry, Rotterdam, Netherlands, (2)Parnassia Psychiatric Institute, The Hague, Netherlands, (3)Faculty of Social Sciences, Clinical Child and Adolescent Studies, Leiden University, Leiden, Netherlands, (4)Sarr Expert Centre for Autism, Lucertis Child and Adolescence Psychiatry, Rotterdam, Netherlands, (5)Simons Foundation, New York, NY, (6)Parnassia Academy, Parnassia Psychiatric Institute, Den Haag, Netherlands, (7)Department of Psychiatry, University of Groningen - University Medical Center Groningen, Groningen, Netherlands, (8)Department of Epidemiology, Columbia University - Mailman School of Public Health, New York, NY, (9)Sarr Expert Centre for Autism, Lucertis Child- & Adolecent Psychiatry, Rotterdam, Netherlands, Rotterdam, Netherlands*

Background: Stigmatizing beliefs and lacking mental health knowledge can delay the diagnostic process of autism by health professionals.
Objectives: The aim of the study is to evaluate the level of ASD alertness in Dutch physicians screening for autism in the child general population.

Methods: In a cohort of 93 Dutch Youth and Family Centre (YFC) physicians, we administered the Community Attitudes to Mental Illness (CAMI) questionnaire, an ASD knowledge test and demographic questionnaires.

Results: Results show that Dutch YFC physicians have a positive attitude towards persons with mental illness (CAMI 1-5 Likert scale, mean ranging from 2.18-2.22), sufficient general autism and low levels of specific autism knowledge (ASD knowledge test, scores 1(low)-10 (high): general: 7.1; specific 5.7). The level of psychiatric stigma was unrelated to the level of autism knowledge and other demographic variables.

Conclusions: Psychiatric stigma and autism knowledge are points of concern in physicians screening for autism in the general population. Research elucidating the relation between psychiatric stigma, ASD knowledge and the early detection of autism in health professionals is needed.

191 **130.191** Autism Spectrum Disorder and Challenging Behaviours Demonstrated in a Paediatric Hospital Environment

M. J. Mitchell[1], *K. Williams*[2] *and F. Newall*[3], *(1)Department of Paediatrics, The University of Melbourne; Royal Children's Hospital, Melbourne, Australia, (2)University of Melbourne and Royal Children's Hospital, Melbourne, Australia, (3)Royal Children's Hospital; The University of Melbourne, Melbourne, Australia*

Background: Children and young people (referred to as children) with autism spectrum disorder (ASD) often exhibit challenging behaviours which can be magnified in the hospital environment (Johnson, Bekhet, Robinson, & Rodriguez, 2014; Lecavalier, 2006). Challenging behaviours, whether self-directed or directed at parents/ caregivers or staff result in injury and distress for the child (Carroll et al., 2014).
The Code Grey/ Black procedures are two of a series of Emergency Response Codes used in Australian hospitals to provide guidance to staff, patients and their carers with regard to the provision of health care services. A Code Grey will be called "when an individual fails to respond to initial defusing mechanisms undertaken by staff" (Royal Children's Hospital, 2017).

Objectives: The objective of this study is to review data from an Australian tertiary paediatric hospital to understand the proportion of Code Grey/ Black activations that are for children with ASD and the accompanying circumstances.

Methods: The total number of Code Grey/Black activations from 1 July 2016- 30 June 2017 were identified through the Victorian Hospitals Incident Management System (VHIMS). Incidents caused by parents, carers or visitors were removed from the data set. Each remaining incident was reviewed to identify the context, response and outcomes. Patient medical records were reviewed for each incident to describe if the child had a diagnosis of ASD, Intellectual Disability (ID) or both. The Electronic Medical Record (EMR) was also reviewed to decide if the child had an identified behaviour of concern. Descriptive statistics were used to analyse the data.

Results: In one year 675 Code Grey/Black activations occurred with 622 (92%) of these initiated due to the behaviour of a hospitalised child. Aggressive incidents occurred in paediatric mental health units, paediatric wards, emergency department and outpatient clinics and were triggered by 165 patients. Twelve patients triggered more than ten incidents each and contributed to 309 (50%) of all Code Grey activations. Behaviours of concern were known in 85 of the 165 (50%) children who triggered code grey activations.

Children with ASD with or without ID triggered 223 (36%) code greys. Of these, 54 were triggered by children with ASD only and 169 by children with ASD and ID. One patient with ASD and ID accounted for 102 Code Grey activations in the 12 month period. Of all patients with ASD who triggered code greys, 85% had known behaviours of concern.

Conclusions: Children with ASD account for 36% of all clinical aggressive incidents at an Australian tertiary paediatric hospital. Challenging behaviours when exhibited in hospital and the resulting staff response, can cause distress or injury to the child and their family and influence future health care use. Understanding the profile of children who trigger Code Grey/ Black incidents will enable targeted clinical strategies and staff training approaches to be developed to reduce the triggers for stress, distress and aggression from patients with ASD & ID. This in turn may result in short and long term benefits for staff, children and their families.

192 **130.192** Beyond Sick and Well Visits: Pediatricians Knowledge and Beliefs about the Diagnosis of ASD

C. Montiel-Nava[1], *Z. Gonzalez*[2] *and J. A. Chacin*[3], *(1)Universidad Latina de Panama, Panama, Panama, (2)Universidad del Zulia, Maracaibo, Venezuela (Bolivarian Republic of), (3)Instituto de Genetica Medina, Universidad del Zulia, Maracaibo, Venezuela (Bolivarian Republic of)*

Background: Pediatricians play a central and crucial role in the evaluation and management of ASD. In average, they see a child for 11 well visits by age 36 months; which provides a venue for screening and surveillance of ASD. Even though, professional associations have been urging physicians to screen for ASD at 18 and 24 months; studies report mean ages of ASD diagnosis ranging from 38 to 120 months. Early identification is desirable because it is linked to better outcomes, and might improve the likelihood of referral to early intervention. Early diagnosis and timely referral have been related to the pediatricians' knowledge about ASD' symptoms. Latin American countries, in general, have limited access to diagnostic and treatment services; highlighting the pivotal role of pediatricians as diagnosticians of ASD. Studies on diagnostic practices of pediatricians and other physicians in Latin American countries are scarce, thus limiting information about health policies or capacity and training needs for these professionals.
Objectives: the primary goal of this study was to explore Venezuelan pediatricians knowledge and beliefs about the diagnosis of ASD.

Methods: Diagnostic criteria for autism spectrum disorders used by 75 Venezuelan pediatricians were examined using a 30 item- survey developed by Daley y Sigman (2002). The survey was translated into Spanish and back-translated to English, and later was validated by experts. The survey comprised three parts: 1.) pediatricians background and experiences with autism, 2.) a list of 18 characteristics or behaviors which included those required by the DSM-IV and some associated with other disorders, 3.) 2 open questions: "What other comments do you have about your experiences with autism in Venezuela?" and "What other behaviors or characteristics do you use in guiding your diagnosis?" (Daley & Sigman, 2002).

Results: The majority of the sample (92%) was working in urban health facilities. Participants had a range of professional and educational experiences; with a mean number of years of practice of 12.3 years (SD 6.2). Pediatricians in the sample reported a mean number of ASD cases during their career of 26.3 (SD 15.7). More than half of the Venezuelan pediatricians (54.7%, n=41) endorsed the necessary characteristics for ASD diagnosis. When asked about ASD etiology, 77.3% (n=58) exhibited average knowledge regarding the currently accepted ASD etiology (neurobiological and no caused by parents). In the comments section, common themes revolved around lack of awareness, underdiagnosis, and lack of enough trained professionals to handle ASD population in the country.

Conclusions: Venezuelan pediatricians consider the core features of autism as necessary for the diagnosis. They report seeing in their daily practice an increasing number of cases of ASD. These results provide a relevant analysis about knowledge, skills, and procedures that Venezuelan pediatricians used during the diagnosis process of children with ASD. Furthermore, it emphasizes Pediatricians' role as a partner of the parents of children with ASD to offer early diagnosis and referrals according to the current professional's guidelines.

193 **130.193** Broken Bridges: New School Transitions for Students with Autism Spectrum Disorder: A Review on Difficulties and

Strategies for Success

B. Bronstein[1], *H. J. Nuske*[2], *E. McGhee Hassrick*[3], *L. Hauptman*[4], *C. A. Aponte*[5], *L. Levato*[5], *A. C. Stahmer*[6], *D. S. Mandell*[2], *P. Mundy*[7], *C. Kasari*[4] *and T. Smith*[8], *(1)University of Pennsylvania, Philadelphia, PA, (2)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (3)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (4)University of California, Los Angeles, Los Angeles, CA, (5)University of Rochester Medical Center, Rochester, NY, (6)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA, (7)University of California at Davis, Sacramento, CA, (8)University of Rochester, Rochester, NY*

Background: School transitions place enormous pressure on students to adapt quickly to new settings, which can strain their physical and mental health, and stress the family (Blair, 2002; Cairns and Harsh, 2014; Cauley and Jovanovich, 2006). Difficulties with social communication, peer relationships, resistance to change (Cuccaro et al., 2003) and intolerance of uncertainty (Boulter et al., 2014) may make new school transitions particularly difficult for students with autism spectrum disorder (ASD) and their parents. Therefore, usual transition procedures may not adequately address the needs of these students. Studies have hypothesized and measured different potential barriers to successful transition but few synthesize the transition needs of students with ASD or the benefits of specific supports.
Objectives: To review the literature on (1) transition difficulties faced by students with ASD, their families and school providers, (2) the strategies currently available to support them, and (3) inform future research about school transitions and the development of transition interventions for students with ASD, their families and school staff.

Methods: The review included 23 studies (10 primary school transition, 13 secondary school transition), with data from 394 students with ASD, 423 parents and 528 teachers, across 4 continents (North America, Europe, Africa, Australia). Authors assessed inclusion eligibility based on agreed upon criteria and reached high inter-rater reliability (Cronbach's α= .92). Coding was conducted in two stages (Boyatzis, 1998; Bradley et al., 2007). After establishing inter-rater agreement (>80%) with the lead coder on extracting transition difficulties and strategies of two articles, each article was independently coded by two coders and consensus coded in pairs. Second, themes and subthemes of transition difficulties and strategies were constructed through consensus using constant comparative method (Glaser and Strauss, 1967). For articles reporting on transition strategies (17 of 23), two authors independently rated level of evidence on a scale outlined in Harbour and Miller (2001), from 1++ (highest quality, (systematic reviews of RCTs) to 4 (expert opinion).

Results: Results confirmed that children with ASD, their families, and school staff experienced difficulties transitioning to kindergarten and secondary school. Main student difficulties were anxiety and increased social pressure; their parents felt overwhelmed with complex placement decisions and worried about the wellbeing of their children; and teachers strove to provide appropriate supports to their students with ASD, often with inadequate resources. Preliminary findings indicated that the most useful strategies involved clarifying the transition process for parents, helping the student adjust to the new school setting, fostering communication both between the sending and receiving schools and between school and home.

Conclusions: Current research highlights the concern that children with ASD, along with their parents and teachers, struggle with transitions and additional supports could be beneficial. However, intervention development has only recently begun. Strategies that clarify the transition process for parents, adjust the student to the new setting and foster communication among the sending and receiving schools and school and home may be particularly useful. There is a pressing need for community-based rigorously-tested interventions to test the effectiveness of different school transition strategies to ensure the success of students with ASD.

194 **130.194** Characterizing Disparities in Special Education Classroom Quality for Students with Autism

S. F. Vejnoska[1], *K. S. Dickson*[2], *S. R. Rieth*[2,3], *J. Suhrheinrich*[3] *and A. C. Stahmer*[4], *(1)University of California, Davis, Sacramento, CA, (2)Child and Adolescent Services Research Center, San Diego, CA, (3)San Diego State University, San Diego, CA, (4)Psychiatry and Behavioral Sciences, University of California at Davis MIND Institute, Sacramento, CA*

Background: Schools provide the majority of services for children with ASD (Brookman-Frazee et al., 2009). Despite known special education disparities in identification and placement for minority and low-resource students with autism (Hibel et al., 2010; Travers et al., 2014), very few studies have looked at the quality of special education program that children receive. Some data suggest that students with autism from racial/ethnic minority and low-resource backgrounds may not be receiving high quality programs or recommended evidence-based practices due to teacher training constraints (McLeskey & Billingsley, 2008; Odom, Cox, & Brock, 2013). However, few studies have examined the impact of district and school level factors (e.g., racial/ethnic minority enrollment, percentage of students receiving free and reduced lunch) on special education classroom quality, which may affect implementation of effective practices. Additional research is needed to understand potential disparities in classroom quality in order to best direct resources and professional development efforts.
Objectives: To characterize differences in classroom quality for students with autism in a large urban sample based on school and district level factors (enrollment, % White, % Hispanic/Latino).

Methods: Data from a four-year study of 113 teachers from 17 school districts serving children under the educational classification of autism in public schools were examined. An expert assessor conducted an observational assessment of classroom quality (based on the Professional Development Assessment; Hume et al., 2009) in each student's classroom at intake to the larger study (Fall of the school year). The PDA includes 54 individual items across 7 domains. Student race/ethnicity and other demographics were collected via parents report upon intake. School and district level factors were collected from data from the California Department of Education, retrieved from Ed-Data.org in August 2017. Factors examined included school overall enrollment, district and school percent enrollment of White students, district and school percent enrollment of Hispanic/Latino students, percent of students at the school receiving free and reduced-price lunch, and school Title 1 status.

Results: Analyses indicate that both district and school level factors are significantly related to aspects of classroom quality. Specifically, a higher percentage of Non-Hispanic/Latino-White students at the district level (B=.01, *p*=.06), lower percentage of Hispanic/Latino students at both the district (B=-.01, *p*<.05) and school level (B=-.01, *p*=.06), and lower percentage of students receiving free or reduced lunch within the district (B=-.01, *p*<.05) were associated with higher quality ratings related to opportunities for peer interaction. Higher school enrollment was also associated with decreased use of strategies to promote peer relationships (*p*'s<.05). Additionally, a higher percentage of Non-Hispanic/Latino-White students at the district (B=.01, *p*=.085) and school (B=.01, *p*<.05) levels as well as a smaller proportion of schools classified as Title 1 (B=-.47, *p*=.08) were associated with higher quality ratings of teachers' instructional planning.

Conclusions: Disparities in the promotion of peer relationships and teachers' instructional planning exist in special education classrooms based on school and district level factors. Targeting these areas with professional development and additional resources may help address disparities in classroom quality.

195 **130.195** Child and Parental Correlates of Participation in Sports and Recreational Activities in School-Aged Children with Autism Spectrum Disorder

V. Lee[1]*, T. Bennett*[2]*, A. Zaidman-Zait*[3]*, E. Duku*[4]*, S. Georgiades*[4]*, P. Szatmari*[5]*, M. Elsabbagh*[6]*, P. Mirenda*[7]*, I. M. Smith*[8]*, W. J. Ungar*[9]*, T. Vaillancourt*[10]*, J. Volden*[11]*, C. Waddell*[12]*, L. Zwaigenbaum*[11] *and A. Thompson*[4]*, (1)McMaster Universtiy-Offord Centre, Hamilton, ON, Canada, (2)Offord Centre for Child Studies, McMaster University, Hamilton, ON, CANADA, (3)Tel-Aviv University, Tel-Aviv, Israel, (4)McMaster University, Hamilton, ON, Canada, (5)The Hospital for Sick Children, Toronto, ON, Canada, (6)McGill University, Montreal, PQ, Canada, (7)University of British Columbia, Vancouver, BC, Canada, (8)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (9)University of Toronto / The Hospital for Sick Children, Toronto, ON, Canada, (10)University of Ottawa, Ottawa, ON, Canada, (11)University of Alberta, Edmonton, AB, Canada, (12)Simon Fraser University, Vancouver, BC, Canada*

Background: Participation in sports and recreational programs (SRP) by children and adolescents is an essential component to healthy development; benefits for developmental outcomes (e.g. physical and mental health) have been well documented (Anderson et al, 2006). Yet the literature consistently indicates that children and youth with ASD are less likely than their same-aged peers to participate actively in community-based programs (Orsmond, Krauss, & Seltzer, 2004). While previous studies have noted individual, parental, contextual characteristics that may act as barriers and facilitators to participation, our understanding of factors related to longitudinal participation in these programs is limited.

Objectives: The primary objective of this study was to identify differences between child and parental characteristics of school-aged children with ASD whose parents reported consistent participation or no participation in organized SRP over a 4-year period between the ages of 7 and 12 years. A secondary objective was to examine whether these child and parental characteristics were correlated with participation over time.

Methods: Data came from the Pathways in ASD study, a large Canadian longitudinal prospective study of children with ASD. The sample was composed of 189 school-aged children with ASD at T_1 (mean age: 12.7 years, 83% male). Participation in organized community-based sports and recreational programs was indexed using the Community Programs and Services Assessment (CPSA) over a 4-year period (T_1-T_4, with T_1 as the first assessment between age 8-9 years and one assessment every 12 months for 3 consecutive years). ANOVAs were used to explore group differences based on consistent participation across the 4-year period and on variables of interest including child characteristics: T_1 autism severity scores (Autism Diagnostic Observation Scale; ADOS), T_2 and T_4 adaptive functioning (Vineland Adaptive Behavior Scale; VABS II); and T_1-T_4 externalizing and internalizing behaviour (Child Behavior Checklist; CBCL 6-18), and parent characteristics across T_1-T_4 including: estimated household income, parental stress (Parental Stress Index; PSI), and T_1-T_4 parental anxiety and depression self-reported symptoms (Symptoms Checklist-Revised; SCL-90-R).

Results: Of the sample, 21% of the families indicated consistent participation in SRPs over the 4 years and 23% of families indicated no participation. Groups did not differ significantly in gender, autism severity score, or internalizing behaviour. However, compared to children who consistently participated, those who did not participate had significantly lower adaptive functioning skills at T_2 and T_4 and more externalizing behaviours across T_1-T_4 ($p < 0.001$, for all). On parental characteristics, the group who participated consistently had significantly higher household income across time than those who did not participate at all ($p < 0.001$). Adaptive functioning, externalizing behaviour, and household income were significantly correlated with participation ($p < 0.01$).

Conclusions: Study findings show that school-aged children with ASD who regularly participate in SRPs have higher adaptive functioning, fewer externalizing behaviour problems, and higher parental income. These findings are consistent with previous literature indicating child and parental factors that limit or facilitate participation in SRPs. They also underline the importance of implementing and evaluating proactive, multifaceted strategies aimed at reducing child- and family-level barriers to inclusion in SRPs.

196 **130.196** Child Characteristics Associated with Educational Placement in Children with Autism Spectrum Disorders

J. Christiansen[1]*, S. Parlar*[2] *and L. Pedersen*[1]*, (1)Centre for Autism, Herlev, Denmark, (2)Nexus, Copenhagen, Denmark*

Background: With the Danish "Inclusion Law" of 2012 school type placement for Danish children with disabilities has been dictated by a quota: 96% of all children should be in regular classes. Prior to the introduction of the law the question of school type placement for children with disabilities was based on individual needs.

Objectives: To examine child characteristics associated with educational placement of Danish children with ASD, prior to 2012, where individual needs were considered.

Methods: Our sample consisted of 44 low functioning (IQ<70) and 95 high functioning (IQ≥70) children with ASD (all assessed at the same site between 1996-2012). 41/44 low functioning children were in special education. Child characteristics for the remaining 95 high functioning children were analyzed with multiple binary logistic regression to determine predictors of school placement. School placement was either regular classes (n=53; mean age 11.5) or special education (special school/class (n=35) or "other" (n=7))(n=42; mean age 11.4). For all 95 children we had information on: gender, IQ, ADOS, ADI-R, co-morbidity, somatic problems, medication and behavioral problems and for 74 children we had information on Vineland (regular classes n=39; special education: n=35). A variable only entered the logistic regression if it differed significantly (t-test or Chi-square test) between the two school type placements.

Results: The logistic model was at chance when predicting whether or not a child was in special education. Nevertheless, knowing that a child had poor reciprocal social interaction (high scores on ADI-R algorithm scale: "reciprocal social interaction") and the co-morbidity ADHD allowed the logistic model to predict, well above chance, that a child was not in regular class. With these two variables the overall percent correct predictions rose from 56% (percent correct prediction when guessing that all 95 children are in a regular class) to around 70%.

Conclusions: When individual needs are considered almost all low functioning children are in special education. Furthermore, for high functioning children, child characteristics such as ADHD and poor reciprocal social interaction are part of the factors that lead to special education.

197 **130.197** Community Based Autism Liaison & Treatment Project (CoBALT): Decreasing Wait Time and Increasing Access to Services

J. Bellando[1]*, E. Schulz*[2]*, J. J. Fussell*[3]*, D. Chang*[4]*, K. Pearson*[5]*, S. Jernigan*[3]*, J. Oswalt*[5]*, K. Oswalt*[5]*, T. Reid*[3]*, B. Whitaker*[3]*, R. Carey*[5]*, M. Lopez*[6]*, A. Goudie*[3]*,* *M. Campbell[3] and E. Corley[3], (1)University of Arkansas for Medical Sciences, Little Rock, AR, (2)Pediatrics, University of Akansas for Medical Sciences, Little Rock, AR, (3)Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR, (4)Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR, (5)James L. Dennis Developmental Center, Little Rock, AR, (6)Dennis Development Center, Little Rock, AR*

Background:

Families can face barriers in obtaining an evaluation for their child for suspected Autism Spectrum Disorder (ASD). If medical professionals are not comfortable in identifying developmental delays (DD) or ASD, they refer to the primary developmental center in the state, UAMS J. Dennis Developmental Center (DDC). This creates longer wait times for evaluations. Children from medically underserved populations often have additional difficulties in accessing services (i.e. transportation, financial constraints).

CoBALT is a capacity-building program that trains teams of physicians, speech pathologists, or behavioral health professionals to conduct Tier II screenings for possible DD/ASD diagnoses. Teams are located throughout the state of Arkansas in order to screen/diagnose and refer for appropriate treatment in their home community. Tier II screening closer to the child's home can may make it easier for families to begin the evaluation process in order to obtain needed services.

Objectives:

To determine 1) referral concerns from PCPs; 2) if the CoBALT model allows quicker access to screening; and 3) diagnostic outcomes of CoBALT screenings. For children who were additionally referred to the DDC, agreement in CoBALT and subspecialty team's diagnoses was assessed.

Methods:

CoBALT teams completed QI outcome data for a 12 months period on all children referred. For children also referred to the DDC by CoBALT teams, QI data was also completed by the DDC team to check for agreement of diagnoses rendered by the subspecialty team vs. CoBALT teams. Frequency data was calculated for all outcome measures.

Results:

In the one year period, 96 children were evaluated in CoBALT clinics (mean age = 3.2 years, 80% male). PCP primary presenting problems were Speech concerns (74%), ASD (43.8%), and DD (33.3%). Primary diagnoses given by CoBALT teams were DD (31.3 %), suspected ASD (20.8%), and Speech Delay (16.7%).

Families were seen within 65.3 days on average and drove approximately 14.3 miles to their local CoBALT clinic. This is compared to an average wait of 171 days for an ASD full team evaluation through the state primary diagnostic center and an average of 54.5 miles traveled by families for that evaluation.

Of the 96 CoBALT children, 37 (38%) were deemed in need of a comprehensive developmental evaluation. Currently, 21 of referred children have been evaluated at the state diagnostic center. The agreement between CoBALT and developmental center diagnoses are high (80%).

Conclusions:

The CoBALT model is promising for a rural, medically underserved state in achieving the mission of ASD screening and helping "whittle down the wait time" for access to services. However, more needs to be done to educate and train medical professionals. Additional educational supports are being created in the state of Arkansas for this purpose.

198 **130.198** Content Analysis of Psycho-Educational Intervention Goal for Young Children with Autism within the ICF-CY Framework.

*K. Strauss[1], A. Delle Fratte[2] and **L. Fava**[2], (1)Umbrella Autism, Rome, Italy, (2)Association for Treatment and Research in Autism Spectrum Disorders "UmbrellAutism", Rome, Italy*

Background:

Effort has been made to use the ICF taxonomy as a way to improve service delivery in health and education (WHO, 2001, 2007), in line with recent advances in research concerning neuro-developmental disabilities demonstrating the usefulness of a functional approach to ASD (Gillberg, 2010). The fact that children with Autism Spectrum Disorders manifest divers pattern of behaviors and level of performance. Such variability with in a broad spectrum challenges the decision-making process of individualized intervention goals, that should include the promotion of a broad range of children's life skills, that are developmentally appropriate and include information on the environmental support (Wilczynski et al., 2007). The ICF-CY based Matrix for Assessment of Activities and Participation (MAAP, Castro & Pinto, 2013) was designed to capture the nature and severity of the limitations of functioning in children with autism spectrum disorders, allows for a developmental norm-referenced rating of each specific skill performance and assesses environmental factors that are scene-setters for the occurrence of forms of participation. Thus, the instrument elicits teaching goals to be included in intervention curricula.

Objectives:

Mapping learning objectives of early intensive behavioral intervention onto the MAAP assessment tool within the ICF-CY framework, to document the extent individual functional domains documented in the assessment process are included in the individualized intervention goals and thus frame the child's current developmental status.

Methods:

This study analyzed the learning objectives of 24 psycho-educational intervention programs developed for pre-schoolers aged 2-6 years with autism, enrolled in early intensive behavioral intervention services in Italy. Individual functioning patterns and aspects of the environment relevant to the child's engagement in daily routines were identified utilizing the MAAP tool. The MAAP comprises 45 items corresponding each to a ICF-CY dimension that was regarded as essential for the assessment-intervention process of children with autism from birth to 6 years of age (ASD core set; Castro & Pinto, 2012, Pinto et al., 2013). Analysis of the overlap of functional dimensions from assessment to intervention goals were carried out through deductive content analysis. The process of analysis has followed a set of sequential steps using the ICF-CY linking rules (Cieza et al., 2005) on the identification of meaningful concepts. Coding was conducted by two independent researchers. Inter-rater reliability was calculated using Kappa Coefficients.

Results:

Results illustrate the majority of functional domains addressed in intervention goals mapped to the Activities and Participation component of the ICY-CY, representing the execution of tasks and forms of involvement in life situations. Nearly all functionality domains identified as essential for children with autism were included both in assessment data and in the intervention goals. Nevertheless, very few Environmental factors were addressed.

Conclusions:

The results suggests that interventions for young children with autism are focused essentially on children's skills and on directly observed performance. Missing consideration of environmental characteristics in which the child is embedded, underrate the multidimensional nature of child development, specifically in program promoting parent, peer and classroom inclusion.

199

130.199 Disparities in Service Utilization Among Children with Autism Spectrum Disorder: A Review of the Literature

K. Smith[1]*, J. G. Gehricke*[2]*, S. Iadarola*[3]*, A. Wolfe*[4] *and K. Kuhlthau*[5]*, (1)Children's Hospital Los Angeles, Los Angeles, CA, (2)The Center for Autism & Neurodevelopmental Disorders, University of California, Irvine, Santa Ana, CA, (3)University of Rochester Medical Center, Rochester, NY, (4)Academic Pediatrics, Massachusetts General Hospital for Children, Boston, MA, (5)Massachusetts General Hospital, Boston, MA*

Background:

Previous research has demonstrated racial, ethnic, and socioeconomic disparities in autism spectrum disorder (ASD) diagnosis. However research related to disparities in service access and utilization in ASD is limited.

Objectives:

This literature review identified evidence related to the following key questions (KQ): 1) what are the disparities in service utilization among children with ASD by race/ethnicity and/or socioeconomic status, 2) are there differences in effectiveness of interventions for children with ASD by race/ethnicity and/or socioeconomic status and 3) are there differences in the quality of care provided to children with ASD by race/ethnicity and/or socioeconomic status?

Methods: On September 1, 2016, MEDLINE, PsycINFO, ERIC, and CINAHL databases were searched using a combination of MeSH terms and keywords related to ASD, disparities, treatment, and services; there was no limit to the date range. This search was supplemented by a review of relevant citations. The search identified 175 articles containing relevant keywords and addressing pediatric populations. At least two authors reviewed the titles and abstracts of all articles with full text of potentially relevant articles further reviewed. Authors abstracted articles that address at least one key question and met eligibility criteria.

Results:

Ten articles were identified, of which eight reported findings on service access and utilization (KQ1) with treatment disparities reported along several dimensions including access to care, referral frequency, number of service hours, and the proportion of unmet service needs. Groups with relatively low access to care include African American and Hispanic/Latino children, as well as children from low-income households. Findings from the papers reviewed indicate that these populations were shown to have higher odds of not having a primary care provider, are less likely to receive specialty and subspecialty care, and have less access to special education services as compared to their white, non-Hispanic, higher-resourced counterparts. None of the identified studies examined differences in intervention effectiveness (KQ2). Four studies addressed KQ3 by showing that parents of African American and Latino children reported worse quality of care (e.g. higher reports that doctor did not spend enough time with the family and not being sensitive to the family values), which may indirectly affect treatment effectiveness.

Conclusions:

This systematic review found evidence of disparities in service utilization and service quality among children with ASD by race/ethnicity and socioeconomic status. Evaluation of disparities in access as well as quality of care and effectiveness of intervention may further identify groups in need of outreach, care coordination and/or other interventions.

200

130.200 Echo Autism Model for Training School Psychologists and Applied Behavior Analysts

K. O'Connor[1] *and J. Randolph*[2]*, (1)MU Thompson Center, Columbia, MO, (2)University of Missouri, Thompson Center for Autism and Neurodevelopmental Disorders, Columbia, MO*

Background:

Given the heterogeneity of individuals with autism and the complex assessment and programming needs for this population, professionals working with individuals with autism are required to continue their education in order to advance their craft and stay current on evidence-based practices. Yet, there is limited research on the methods, social validity and efficacy of continuing education (CE) opportunities provided to professionals.

Additionally, access to high quality CE opportunities are limited for professionals working in rural areas and regions with limited local expertise available. The Extension for Community Healthcare Outcomes (ECHO) model has been utilized and researched across multiple healthcare conditions as an effective tool for providing professional training using case based teaching and an online community of practice to areas with limited local expertise. (Arora, et al., 2011; Katzman, et al., 2014; Mazurek, 2017; Scott, et al., 2012).

This presentation will provide data from two cohorts of professionals participating in a 9-month ECHO program specifically designed as CE for their professional role: 1) A cohort of behavior analysts participated in ECHO Autism: Applied Behavior Analysis (ABA), 2) A cohort of school psychologists participated in ECHO Autism: School Psychology.

Objectives:

The objectives of this study were to examine the efficacy and acceptability of the ECHO model for School Psychologists and Behavior Analysts. Efficacy data was obtained through pre/post content assessments and pre/post reported use of and confidence with principles/interventions in their respective fields. Social validity data was collected on the acceptability of the ECHO model for CE.

Methods:

Participants included practicing school psychologists, educational diagnosticians and special education administrators (n=15) in ECHO School Psychology and practicing Board Certified Behavior Analysts (BCBAs) and assistants (BCaBAs; n=16) in ECHO ABA.

This study utilized a quasi-experimental design to evaluate the acceptability and efficacy of ECHO for CE. Through the ECHO framework, each of the cohorts participated in a one-hour, monthly online meeting for 9 months. The host panel of experts (in each respective field) facilitated a discussion based on a presented case and provided a content presentation on advanced professional principles.

Measures:

- Pre/post self-efficacy and confidence surveys: comprehensive survey regarding confidence and frequency of use principles/interventions in their respective field
- Pre/post content assessments for each session
- Social validity survey for each session
- Social validity survey upon completion of program with an emphasis on acceptability of CE opportunities

Results:

The data collection is ongoing and will be completed in early spring 2018. Participant pre/post outcomes on the content assessment and confidence/frequency survey will be analyzed. Analyses will also be conducted to examine the relationship between participant characteristics (e.g., years of experience, self-efficacy, attendance) in relation to intervention use and content assessment outcomes.

Conclusions:

The preliminary results of ECHO for CE for special education professionals. The results of this study may provide support for the use of case based learning and an online community of practice to advance professional knowledge. These results may inform the field to evaluate CE opportunities and refine how to determine the efficacy and social validity of professional development.

201 **130.201** Educating Students with Autism Spectrum Disorder in Mainstream Classes: Teacher Knowledge and Use of Empirically Supported Treatments.

R. P. Sulek[1]*, D. Trembath*[2]*, J. M. Paynter*[3] *and D. Keen*[4]*, (1)Griffith University, Australia, Gold Coast, Australia, (2)Menzies Health Institute, Griffith University, Australia, (3)School of Applied Psychology, Griffith University, Southport, Australia, (4)Autism Centre of Excellence, Griffith University, Mt Gravatt, Australia*

Background: Providing equal educational opportunities for children with autism spectrum disorder (ASD) goes beyond providing a place in mainstream classrooms. Children with ASD might experience delays in their development of critical skills that otherwise prepare children for school (e.g., ability to work independently, follow teacher directions). It is therefore crucial that teachers are both aware of these differences, and well equipped to support the development of these skills in the early years of school. Although several empirically supported treatments (ESTs) exist which can target these skills in children with ASD, there has been minimal investigation into the extent to which teachers are aware of, and use ESTs in mainstream settings. Additionally, factors such as the social validity of ESTs and sources of information teachers are accessing must be considered.

Objectives: The aim of our study was to investigate knowledge and use of these ESTs in Australian teachers of the foundation year (commonly referred to as kindergarten or ‘prep’). Additionally, we examined factors that contribute to the uptake of treatments in mainstream settings.

Methods: We used a mixed methods approach, with the research conducted over two phases. Participants in both phases were Australian foundation year teachers working with at least one child with ASD. In phase one, 155 participants completed an online survey which included measures of knowledge, use, and social validity of 20 ESTs and two non-ESTs outlined in Fleury, Thompson, and Wong (2015). Additionally, demographic information and sources of information commonly accessed by participants were collected. In phase two, 13 teachers were interviewed to gain a richer understanding of the factors that contribute to the uptake of ESTs in the classroom.

Results: Participants reported using all 20 treatments at least sometimes, with ESTs used more frequently than non-ESTs. Participant knowledge and perceived social validity of interventions was also significantly positively associated with use (*p’s* $< .001$). Participants interviewed identified several factors that influenced their decisions to use treatments, including the needs of the child, their knowledge and previous experience working with a child with ASD, their access to other professionals, and training received. Reliance on research evidence (i.e., accessing available literature) was found to be infrequently accessed across both phases of the study, with participants more commonly accessing within-school supports.

Conclusions: The strong association between social validity of ESTs and their use highlights the importance of developing, evaluating, and recommending to teachers treatments that are appropriate for use in mainstream settings, in order to close the research to practice gap that exists in autism and education. Taken together with the teacher-identified factors that influence decision making, the findings provide tangible avenues for further clinical-research efforts in collaboration with teachers to improve transition outcomes for children with ASD.

202 **130.202** Effects of Medicaid Waivers for Autism Spectrum Disorder on State Medicaid Expenditures

Z. Cidav[1]*, A. Dick*[2]*, G. Liu*[3]*, M. Sorbero*[4]*,* ***D. S. Mandell***[5]*, B. Stein*[4] *and D. Leslie*[6]*, (1)University of Pennsylvania, Philadelphia, PA, (2)The RAND Corporation, Boston, MA, (3)Penn State College of Medicine, Hershey, PA, (4)RAND, Pittsburgh, PA, (5)Center for Mental Health, University of Pennsylvania, Philadelphia, PA, (6)Penn State Milton S. Hershey Medical Center, Penn State College of Medicine, Hershey, PA*

Background: In the United States, Medicaid is the largest source of funding for healthcare services for individuals with autism spectrum disorder (ASD). Several states have passed Medicaid Home and Community-based Services (HCBS) waivers that expand eligibility criteria and available services for children with ASD. Previous research has shown considerable variation in these waivers, but little is known about their effects on Medicaid expenditures.

Objectives: To estimate the impact of state Medicaid waiver programs targeting children with ASD on state Medicaid expenditures, both for institutional and community-based care.

Methods: We use Medicaid claims data from 2001-2013 to estimate state-level expenditures. A fixed effects model will be used to estimate the effects of specific waiver characteristics on Medicaid expenditures among states and over time. We hypothesize that the waivers will result in substitution from institutional care to community-based care and associated cost savings for the states. The effects of waivers on expenditures for children with ASD will be compared with their effects on children without ASD as way to isolate the effects of waiver characteristics from

states' overall Medicaid generosity.

Results: Analyses are ongoing.

Conclusions: The results will identify waiver characteristics that are associated with cost containment and increased use of community care. These results will be the first step towards helping states develop efficient and effective waivers to support children with ASD and their families.

203 **130.203** Embodied Empowerment Design: Reframing the Problem through Co-Design

***J. van Dijk**, Twente University, Enschede, Netherlands*

Background: As health-care policy increasingly focuses on 'empowerment', assistive technologies are developed to help persons with Autism Spectrum Condition (ASC) in independent living. Most technologies quite straightforwardly provide 'solutions' to aid with daily tasks, or to train certain skills.

Objectives: Given the poor success-rates of assistive technologies in general, our co-design approach aims first to explore instead in more detail what the actual problems are, as seen from the lived, embodied and situated experiences of the people involved.

Methods: We work closely together with a small number of people on the spectrum, over a longer period of time. Through a series of design cycles involving contextual interview, role-play, collaborative brainstorming, prototyping, and evaluation of experience prototypes, we develop a designerly understanding of the details of their lifeworlds, along with a final product proposal. Reflecting on this process and the design outcome with stakeholders (people with ASC, family, care-professionals), we uncover implicit assumptions that may actually get in the way of designing truly empowering technologies, and we envision what alternative conceptualizations may look like.

Results: In this talk I present two cases. The first concerns a system of wireless lamp-bodies that provide situated hints to help structure the day. The second is a smartwatch allowing users to record their own relaxing messages to be played in response to situations of stress. Using these cases I develop the vision of Embodied Empowerment. This vision on empowering technologies critically reframes several conventional interpretations of assistive technology. First: our designs never directly address 'the disorder'. Straightforward attempts at 'solving problems caused by autism', I claim, are always potentially misguided. Instead, Embodied Empowerment calls for technology that enables people first and foremost to be and become most fully themselves. Second, our systems do not 'take over': they provide scaffolds with which people may regain control over their lives, recruiting their skills and available resources in the environment. Third, our technologies are not 'monitoring' or 'training' tools used by care-givers, nor are they replacing real people: instead they mediate in social relations with significant others, towards more empowered interactions. Fourth: while we use information technology, we do not use it to 'remind', 'instruct' or 'inform' the user about what to do. Rather, we design objects and spaces with interactive properties to catalyze and transform sensorimotor routines, such that the user can find (his own) information, by taking action. Finally, we envision not finished solutions, but open platforms. which can be tailored by people in use to their individual needs, interests and talents.

Conclusions: To conclude, we used a co-design research approach as a method to critically reframe some implicit assumptions in present-day assistive technology. The resulting vision of Embodied Empowerment opens up a large, unexplored design potential, promising new personally meaningful devices, to empower persons with ASD in living their everyday lives, on their own terms, in their own unique ways.

204 **130.204** Examining the Relationship between Educator Knowledge, Implementation Frequency, and Perceived Feasibility of Utility of Evidence-Based Practices Following a Training Paradigm of in-Person and Teleconferenced Training, Coaching, and Mentorship

***W. Loring**[1], C. McQueen[1], T. E. Foster[2], A. Dubin[2] and P. Juárez[1], (1)Vanderbilt University Medical Center, Nashville, TN, (2)Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE*

Background: Federal legislation calls for educators serving students with autism spectrum disorder (ASD) to use evidence-based practices (EBPs). Educator feedback indicates that correctly identifying and implementing EBPs has become increasingly challenging, and the amount of pre-service information regarding EBP's and ASD varies greatly. Therefore, training in EBPs for educators is a pressing national need. In response, we partnered with our state's Department of Education in which collaborative planning of systems of professional development and program evaluation result in opportunities for students and educators to receive best-practice support and training. Through this, three-day workshops are provided in a fixed-model, experiential training paradigm designed for the unique support needs for staff educating students with ASD and provides in-person and teleconferenced training, coaching, and mentorship. During the year examined for this poster, 6 workshops were conducted in 3 versions for early childhood, elementary/middle, or high school educators. These workshops focus on the impact of ASD on learning and strategies to implement EBPs feasibly and successfully in optimizing learning.

Objectives: 1. To assist school districts statewide in moving towards more inclusive and evidence-based practices, 2. To develop nationally replicable models of high-quality educator professional development, 3. To advance policies and practices related to successfully building capacity and sustainability in educating students with ASD

Methods: Data collected evaluates: 1. Increased knowledge of targeted EBPs, 2. Implementation frequency and fidelity of targeted EBPs and 3. Perceived satisfaction, feasibility, and utility in optimizing student outcomes post-workshop. Knowledge and satisfaction data are collected immediately post-workshop. Reported implementation, feasibility, and utility are collected immediately post-workshop, during a classroom consultation 2 months post-workshop, and via survey 6 and 12 months post-workshop. Implementation fidelity is coded by consultants during the classroom consultation. The focus on this poster is examining the correlation between EBP knowledge and reported implementation, feasibility, and utility 2 months post-workshop.

Results: Across all workshop versions, there was a significant increase in EBP knowledge post-workshop. There was a significant correlation between EBP knowledge and reported implementation in one EBP in the High School version. There were no significant correlations between EBP knowledge and reported feasibility, utility, or implementation for any other EBPs across workshops. Reported implementation and perceived feasibility and utility were high 2 months post-workshop and implementation fidelity was moderate. There were significant correlations between feasibility and utility for all EBPs and between both feasibility and implementation and implementation and utility for 86% of targeted EBPs (see table).

Conclusions: This training paradigm results in increased EBP knowledge with moderate levels of implementation fidelity 2 months post-workshop.

EBP's were perceived as feasible to implement and useful in optimizing student outcomes. While minimal correlations were seen between EBP knowledge and implementation, feasibility, and utility, these 3 factors were highly correlated post-workshop, indicating that perceived feasibility and utility are directly related to the frequency of EBP implementation. These data are of great value in developing effective and efficient forms of professional development to support the critical need for educator training in the provision of EBP's in working with students with ASD.

205 **130.205** Experiences of Treatment and Support for Mental Health Problems, Self-Injury and Suicidality in Adults with Autism Spectrum Conditions.

L. Camm-Crosbie[1]*, S. A. Cassidy*[2]*, L. Bradley*[1] *and R. Shaw*[3]*, (1)Coventry University, Coventry, United Kingdom, (2)School of Psychology, University of Nottingham, Nottingham, United Kingdom, (3)NHS Coventry and Warwickshire Partnership Trust, Warwickshire, United Kingdom*

Background: Recent research has shown that adults with Autism Spectrum Conditions (ASC) are at high risk of co-morbid psychiatric disorders, non-suicidal self-injury and suicidality. However, anecdotal evidence suggests that adults with ASC may have difficulty accessing appropriate support and treatment for these difficulties. This is particularly worrying considering that adults with ASC are significantly more likely to die by suicide than the general population.

Objectives: To explore experiences of support and treatment for mental health difficulties, self-injury and suicidality amongst adults with ASC.

Methods: An online survey exploring mental health, non-suicidal self-injury and suicidality was designed with the help of a steering group of eight adults diagnosed with ASC. Data from the section of the survey including qualitative questions on experiences of support and treatment for these difficulties are presented. Open ended questions explored experiences of trying to obtain, and receiving treatment and support for mental health problems, self-injury and/or suicidality.

Results: The ASC group comprised 200 adults (122 females, 77 males, 1 unreported) aged 18 to 67 (M = 38.9, SD = 11.5). Thematic analysis was used to analyse these qualitative data. An overarching theme was identified that tied together participants' diverse experiences: that individually tailored treatment and support was both beneficial and desirable. Participants described lack of available services for adults with ASC with mental health problems, lack of professionals understanding and knowledge of ASC, and the importance of effective adapted treatment and support for their wellbeing. For many, positive experiences of tailored treatment and support meant that suicide was no longer seen as part of their future.

Conclusions: Findings demonstrate an urgent need for professionals' to improve their awareness of ASC and adopt a more flexible approach, suited to individual needs. Participants' experiences clearly indicated that this is essential for improving their wellbeing, reducing mental health problems, self-harm and suicidality. Results will be used to inform mental health service provision for adults with ASC.

206 **130.206** Exploring the Relationship between Social Skills Knowledge and Reported Family Quality of Life through PEERS

J. Mueller[1] *and L. Dewey*[2]*, (1)Nemours/Alfred I duPont Hospital for Children, Wilmington, DE, (2)Nemours/AIDHC, Wilmington , DE*

Background: The Program for the Education and Enrichment of Relational Skills (PEERS), a social skills group program developed at UCLA (Laugeson and Frankel, 2010), teaches social skills to adolescents with ASD using simultaneous adolescent and parent groups. Research suggests that engagement in social skills groups for teens with ASD can not only improve peer relationships, but also their family's quality of life (Rankin et al., 2016; Laugeson et al., 2012; Haddad, 2013). Additionally, it is understood that parents highly value the acquisition of social skills in their teen with ASD (Rankin et al., 2016). Consequently, many of the factors impeding a high family quality of life for families with a child with ASD stem from social skills deficits (Lee, L., Harrington, R., Louie, B., and Newschaffer, C., 2008; Rao, R. & Beidel, D., 2009).

Objectives: This research project aims to better understand the impact of PEERS on family quality of life and social skills knowledge. Aim 1: Better understand possible reported change in family quality of life and social skills knowledge after participation in PEERS; Aim 2: Assess a possible relationship to between family quality of life and social skill knowledge.

Methods: The adolescent completed the Test of Adolescent Social Skills Knowledge (TASSK) and the parent completed the Family Quality of Life Scale (FQOL) pre and post completion of the PEERS group. Pre and post scores on the TASSK and the FQOL were assessed using repeated measures t-tests, and regression analysis was used to determine if changes in the TAASK scores were related to changes in FQOL scores

Results: Thirty families enrolled in PEERS across Delaware (age range of child: 7-17; M=13 years; Males=23, Females=7), and 14 families were considered to have completed PEERS (attended 10 or more sessions and completed both pre and post measures). No difference was reported regarding family quality of life (FQOL: $t(13)=-.737$, $p=.474$) following PEERS. However, there was a significant improvement in the scores on the TASSK after PEERS intervention (TASSK: $t(9)=-7.592$, $p=.000$). Nevertheless, there was no significant effect of social skills knowledge on family quality of life ($F(5, 1)=.148$, $p=.972$).

Conclusions: This study shows that adolescents gained social skills knowledge after completion of PEERS. However, increase in social skills knowledge did not seem to impact family quality of life. It is possible that other factors of social skills interactions might contribute to family quality of life, and future research is needed to understand the impact of social skills group interventions on families. This information can help guide future research in understanding the need for other social interventions and family focused treatment to improve quality of life for families with an adolescent with ASD.

207 **130.207** Exploring Unconscious Bias of Health Care Professionals Caring for Children with Autism

L. I. Florindez[1]*, D. H. Como*[1]*, J. Polido*[2]*, S. A. Cermak*[3] *and L. I. Duker (Stein)*[1]*, (1)Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA, (2)Children's Hospital, Los Angeles, Los Angeles, CA, (3)USC Mrs. T.H. Chan Division of Occupational Science and Occupational Therapy, University of Southern California, Los Angeles, CA*

Background:
Some patient populations experience marginalization in health care settings. Children with autism spectrum disorders (cASD) often experience challenges when receiving medical care due to their sensory sensitivities. Health care providers (HCPs) have direct contact with cASD and their families and rely on communication to build relationships and create rapport. Language used by HCPs can influence provider-patient encounters,

impact the stigma associated with being diagnosed with a disability, and change the way cASD experience health.

Objectives:

This paper will explore hidden assumptions held by some HCPs toward their patients with ASD, and how those beliefs are expressed in their language and actions.

Methods:

Two focus groups of 9 dental practitioners treating cASD were conducted to describe oral care related challenges experienced by cASD and identify strategies to address them. Each session lasted 2.5-3 hours and was transcribed verbatim. Thematic analysis was used to describe strategies to improve care, with codes developed inductively from the data and informed by sensitizing concepts from the literature. Having completed the analysis focused on strategies, it was clear that there were important aspects of the data that were not accounted for by the initial coding scheme. Additional codes driven by the data emerged related to the hidden biases of dentists when discussing children with ASD and their families.

Results:

Three themes were identified. The first, *Healthcare Microaggressions,* described instances when HCPs described their patients in a manner that communicated subtle negative opinions. This included implying that some parents could not be bothered to make appropriate oral care related decisions for their children. The second theme, *Marginalization,* denoted the use of exclusionary language, such as "those kids," which created a sense of otherness, specifically identifying children with ASD as different from "normal" patients. The last theme, *Preconceptions,* focused on HCP comments that illuminated subtle biases and opinions they had about their patients. Statements included their perception that some parents of children with ASD did not value their child's oral health enough to conduct routine oral care between visits, and assumptions about their patients' cultural backgrounds.

Conclusions:

Focus group findings provide insight into the implicit biases held by HCPs and how they manifest in their language and interactions with patients. The lives of cASD and their caregivers are affected by the stigma they experience in health care settings. In presenting examples of assumptions embedded in HCP language, we aim to raise awareness about the significance and consequences of biased communication in the patient-provider relationship and how to decrease stigma in marginalized populations. Further research is necessary to understand how these assumptions relate to quality of care.

208 **130.208** Feasibility and Potential Impact of the Building Alliances to Meet Autism Needs in Clinical Encounters (BALANCE) Program

S. L. Snow[1,2]*, J. M. Chorney*[3] *and I. M. Smith*[4]*, (1)Psychology and Neuroscience, Dalhousie University, Halifax, NS, Canada, (2)University of Manitoba, Winnipeg, MB, Canada, (3)Dalhousie University, Halifax, NS, Canada, (4)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA*

Background: Youth with autism spectrum disorder (ASD) have a high need for healthcare services but tend to have difficult experiences. Recommendations for improving care experiences emphasize family-centered approaches (FCC; partnering with families, assessing needs of each child, coordinating care, expressing empathy).Working collaboratively with HCPs and families, we developed an intervention (BALANCE: Building ALliances to meet Autism Needs in Clinical Encounters) to address barriers and improve the delivery of FCC for children with ASD. BALANCE consists of seven online modules for HCPs, and a toolkit of resources designed for the day surgery unit.

Objectives: This study explored the feasibility and potential impact of BALANCE.

Methods: BALANCE was implemented in the day surgery unit of a Canadian pediatric tertiary care hospital. All HCPs were shown the toolkit and invited to complete BALANCE. HCPs self-reported on barriers to and the delivery of FCC at baseline, post-intervention, and three-month follow-up. Linear mixed-effect models were used for analysis. HCPs also rated the feasibility of BALANCE and provided suggestions for improvement.

Results: Of the 106 interdisciplinary healthcare providers on the unit, 70 consented to participate. Of these, 62 started BALANCE, 53 completed all modules. HCPs reported significant reductions in barriers from baseline to post-intervention that were sustained at follow-up, and significant increases in delivery of FCC from baseline to follow-up. More than 95% of HCPs rated modules as usable, acceptable, and feasible. The most common theme regarding improvement was to equalize sound levels across modules.

Conclusions: The implementation of BALANCE was successful, indicating feasibility. BALANCE has the potential to address barriers to care and improve the delivery of FCC to children with ASD. Challenges with the delivery of FCC to children with ASD occur across healthcare contexts; BALANCE could be adapted for other care settings.

209 **130.209** Higher Levels of Autistic Traits Are Associated with Lower Wellbeing in Performing Arts Professionals and Students

E. Buckley[1]*, E. Pellicano*[2] *and A. Remington*[3]*, (1)UCL Centre for Research in Autism & Education, London, United Kingdom, (2)Macquarie University, Sydney, Australia, (3)UCL Centre for Research in Autism and Education, London, United Kingdom*

Background:

Researchers and clinicians have long held that imagination is limited in autism. Yet it is increasingly recognised that creativity might be an area of strength in autistic people (Best *et al.*, 2015). Although creative practice has not traditionally been thought of as an occupation in which autistic people would engage, anecdotal reports suggest that there might be a group of individuals with high levels of autistic traits pursuing careers in creative fields such as the performing arts. The performing arts is a varied profession, but usually artists are self-employed and need to possess skills including networking, administration, self-promotion, and time management – skills that are well known to be challenging for autistic people. Performing artists with high levels of autistic traits may therefore be experiencing difficulties in these areas and may benefit from support.

Objectives:

This study sought for the first time to identify the extent to which autistic people, or those with high levels of autistic traits, are pursuing careers in the performing arts, and to determine the nature of the relationship between individuals' autistic traits and their reported wellbeing, including perceived self-efficacy (during training and in the workplace), quality of life, mental health and perceived level of support required.

Methods:

To address these aims, we recruited a self-selecting, community-based sample of individuals working or studying in the performing arts, and invited them to complete an online survey. 1729 respondents took part: 1447 professionals and 282 students. The survey collected responses on participants' backgrounds, including diagnostic history as well as measures assessing their level of autistic traits (Subthreshold Autistic Traits Questionnaire (SATQ)), perceived self-efficacy (related either to their workplace or education, indexed by bespoke measures), quality of life (WHOQOL-BREF) and mental health (PHQ-8, GAD-7). There were also asked open-ended questions about support needed, received, or desired in their workplace or educational institution.

Results:

16 professionals (1%) and 8 students (3%) reported a clinical diagnosis of autism, and 50 professionals (3%) and 8 students (3%) scored more than 2 SD above the mean score on the SATQ. Correlational analyses between SATQ scores and scores on wellbeing measures demonstrated significant relationships for quality of life ($r=-0.34$, $p<0.001$), self-efficacy (workplace: $r=-0.41$, $p<0.001$; educational: $r=-0.44$, $p=<0.001$) and mental health (depression: $r=0.405$, $p<0.001$; anxiety: $r=0.360$, $p<0.001$): higher levels of autistic traits were associated with lower levels of quality of life, lower levels of self-efficacy and greater severity of mental health conditions. 631 (44%) professionals and 94 (33%) students reported a desire for more support, and autistic traits were significantly higher in participants who wanted support ($p<0.001$).

Conclusions:

Within the community of performing artists, there are a minority of individuals who are autistic or who have high levels of autistic traits. This study has demonstrated for the first time that these individuals may be especially vulnerable to lower wellbeing. More research is needed to understand how best to support these individuals.

210 **130.210** Identifying and Combating Intervention Misinformation in Autism

J. M. Paynter[1], *S. Luskin-Saxby*[2], *A. DeBlasio*[3], *G. Frost*[4], *K. Fordyce*[5], *C. Imms*[6], *D. Keen*[7], *S. Miller*[8], *D. Trembath*[9], *M. Tucker*[10] *and U. Ecker*[11], *(1)School of Applied Psychology, Griffith University, Southport, Australia, (2)Griffith University, Southport, Australia, (3)Anglicare SA ASELCC, Adelaide, Australia, (4)Anglicare SA Daphne St Autism Specific Early Learning and Care Centre, Prospect, Australia, (5)North West Tasmania Autism Specific Early Learning and Care Centre, St Giles Society, Burnie, Australia, (6)Australian Catholic University, Melbourne, Australia, (7)Autism Centre of Excellence, Griffith University, Mt Gravatt, Australia, (8)Autism Association of Western Australia, Perth, Australia, (9)Menzies Health Institute, Griffith University, Australia, (10)Queensland Autism Specific Early Learning and Care Centre, AEIOU Foundation, Nathan, Australia, (11)University of Western Australia, Perth, Australia*

Background: Autism has been described as a “fad magnet” (Metz et al., 2005) with an array of interventions of varying quality and safety available. Many of these are aggressively marketed using anecdotes, appeals to emotions, and celebrity endorsements. This occurs in the absence of empirical evidence, or even in the presence of refuting empirical evidence. Surveys of parents (Carlon et al., 2014) and professionals (Paynter et al., 2017) have shown that practices rejected by research continue to be used despite widely available reviews documenting effective (and ineffective) interventions (e.g., Wong et al., 2015). This may be due to the presence of misinformation regarding the evidence-base of interventions, which poses a potential challenge to providing the best possible support to individuals with autism and the wider community. For example, the harmful effects of misinformation are evident in declining vaccination rates linked to the myth that vaccines cause autism. Ironically, poorly designed refutations, or “debunkings” of such misinformation may further exacerbate the problem. For instance, attempts to debunk the vaccine-autism myth have led to a reduction in intention to vaccinate (Nyhan et al., 2014). However, the cognitive science literature provides guidelines for more effective strategies to debunk myths, and emerging research supports the efficacy of these techniques to addressing the vaccine-autism myth (e.g., using visuals; Dixon et al., 2015). To date, these guidelines have not been applied to autism interventions.

Objectives: We aimed to test the application of debunking principles (e.g., visualizing evidence, demonstrating consensus, see Lewandowski et al, 2012 review) to debunking autism intervention myths. We hypothesized that optimized materials using these principles would be more effective in changing knowledge and intentions to use and recommend ineffective strategies, than currently available materials that did not use these principles in their design.

Methods: In Phase 1, 71 early intervention staff completed questionnaires measuring knowledge and use of autism intervention strategies, attitudes towards evidence-based practice and towards researchers generally. In Phase 2, participants were randomly assigned to two groups for training: control (treatment as usual) and optimized debunking (specifically targeting three ineffective strategies to address misinformation about intervention effectiveness observed in Phase 1). In Phase 3, a follow-up assessment will be conducted in November 2017. Information regarding perceived evidence, use, and intended use, of strategies will be collected using measures adapted from Paynter et al (2017).

Results: Phase 1 results indicate the presence of misinformation regarding the evidence-base of both effective and ineffective interventions. Further, perception of an intervention as evidence-based was linked to greater reported use, irrespective of accuracy of this belief. The impact of optimized debunking compared to treatment as usual, follow-up outcomes, and predictors of response to the training will be presented.

Conclusions: Effective knowledge translation mechanisms are essential for improving access to evidence-based interventions for children with autism and for minimizing the risk of exposure to ineffective and potentially harmful interventions. Increasing the awareness of the evidence base of effective interventions along with debunking misinformation regarding ineffective interventions is vital to improve real-world implementation and sustained change in practice.

211 **130.211** Identifying Clinician Barriers to Quality Mental Health Treatment for Adults with Autism

S. R. Crabbe[1], *B. B. Maddox*[1] *and D. S. Mandell*[2], *(1)University of Pennsylvania, Philadelphia, PA, (2)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: The number of adults diagnosed with autism is growing. More than half have a co-occurring psychiatric disorder, with anxiety and depression being the most common (Buck et al., 2014). In the general population, especially for those with public insurance, these disorders are typically treated at local community mental health centers (CMHCs). Many adults with autism would benefit from mental health treatment, but do not access these services, often because there are few clinicians trained to work with them. There is limited literature exploring this topic, and examining clinician perspectives on training needs would shed light on specific strategies to increase the quality services available to adults with autism. This study is the first to directly interview mental health clinicians on their experiences and needs in regards to treating adults with

autism.
Objectives: This community partnered study aims to identify the barriers clinicians in CMHCs face in providing quality services to adults with autism. These results will directly inform the development of a training program for CMHC clinicians.

Methods: To date, 28 clinicians (86% female, 76% white) from six CMHCs have completed a semi-structured interview. Participants were psychotherapists, case managers and intake coordinators. The interview contained questions about their knowledge of autism symptoms in adults, experience with and confidence in treating adults with autism, prior education and training related to adults with autism, and recommendations for topics that related training should address. All interviews were audio recorded and transcribed professionally for analysis. The analysis will be guided by grounded theory.

Results: Data collection and analyses are ongoing and will be completed by February 2018. While some clinicians noted that they had provided services to a handful of adults with autism, many did not have any experience treating this population. Most participants had no training or education in treating adults with autism and could only describe a few autism symptoms. Many clinicians were open to working with adults with autism, but lacked confidence to provide proper treatment due to inadequate knowledge about effective strategies for this population. For example, one clinician noted during her experience providing therapy to an adult with autism, "I was asking him the wrong questions or I was saying things in a way that I wasn't communicating or getting through to him. So it was challenging for me and…probably frustrating for the client."

Conclusions: Many CMHC clinicians do not have the confidence or skills to effectively address the needs of adults with autism. Clinicians could be better equipped to do so with the right training. From their perspective, priority training needs include a deeper understanding of core autism symptoms and how those affect the therapeutic relationship, along with direction on modifying treatment strategies for adults with autism. Clinicians would be interested in participating in an interactive training program, preferably with involvement from adults with autism, role-play exercises, discussion of actual cases, and ongoing consultation. Clinician training would increase their competence and confidence to provide needed services that will enhance the quality of life of adults with autism.

212 **130.212** Identifying Services That Provide Assistance to Individuals with Autism Spectrum Disorder in Brazil

J. Portolese[1]*, D. Bordini*[2]*, R. Lowenthal*[3]*, E. C. Zachi*[4] *and C. S. de Paula*[5]*, (1)Clinical Hospital, Sao Paulo, Brazil, (2)Departament of Psychiatry, Federal University of São Paulo, Sao Paulo, Brazil, (3)Santa Casa Hospital, Sao Paulo, Brazil, (4)Clinical Hospital, São Paulo, Brazil, (5)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil*

Background: In Brazil, the Unified Health SystemSUS should cover the majority of assistance services for individuals with Autism Spectrum Disorder-ASD, but there is no data on this field.
Objectives: To identify Brazilian institutions that provide assistance to individuals with ASD.

Methods: Information were collected through registries of the State Department of Health, Autistic Friends Associations-AMAs and searches on the internet. The institutions were contacted in order to gather information concerning target public and characteristics of the service.

Results: 650 institutions were identified, most of them concentrating in the Southeast and South regions of the country. Most of the institutions are the Association of Parents and Friends of Exceptional Children-APAEs, Centers for Child and Youth Psychosocial Care-CAPSIs and AMAs. There is a predominance of assistance to children and adolescents. Multiprofessional services were more frequent and intervention approaches include TEACCH, Psychoeducation and ABA.

Conclusions: The amount of institutions that assist individuals with ASD is insufficient and distributed irregularly in the country besides lacking to provide assistance to youngers and adults. The variability of the characteristics of the services reveals a lack of standardization regarding the procedures adopted. Knowledge of this information may help to promote the development of new evidence-based intervention proposals.

213 **130.213** Impact of Training Program to Treat Children with Autism in the Brazilian Public Health System

C. S. de Paula[1]*, L. C. Silva*[1]*, E. L. Ribeiro*[2] *and M. C. Teixeira*[1]*, (1)Developmental Disorder Program, Universidade Presbiteriana Mackenzie, São Paulo, Brazil, (2)Secretaria Municipal de Saúde de São Paulo, Secretaria Municipal de Saúde de São Paulo, São Paulo, Brazil*

Background: Autism Spectrum Disorder (ASD) affects different areas of the global development of the individual, primarily socialization, behavior, sensory functions and language. Due to the complexity and variability of clinical settings, professionals working with children with ASD need to receive specialized training.
In Brazil, the Unified National Health System provides universal access to health services for the entire Brazilian population. According to the Brazilian public policy, some services are considered strategic for the identification and treatment of children/adolescents with ASD, mainly the Psychosocial Community Care Center for Children and Adolescents (CAPSi) which are day treatment facilities with multidisciplinary teams. However, recent research has indicated the lack of specialized training for the treatment of autism even in the CAPSI units.

Objectives: to develop, implement and to verify the impact of a training program aimed at professionals working with children with ASD in CAPSis, focused primarily on managing problems of behavior, communication and social interaction.

Methods: Design: quasi-experimental. Site: The public health system of the São Paulo city is organized in five regionals. This study was conducted in four out of five existing CAPSI in the northern regional of São Paulo city. Participants: 14 professionals nominated by the four CAPSis. Training program was composed of six stages (total of 16 hours divide in four meetings): (1) pre-intervention observation; (2) meetings with professionals to assess the topics/main needs to the training program; (3) development of materials for training and evaluation; (4) meetings for the implementation of training; (5) Final meeting for discussion of cases (6) distance supervision. Instruments to evaluate the training program: (1) Knowledge, Attitudes and Practices-KAP questionnaire; (2) Videos and questions; (3) Satisfaction Questionnaire.

Results: In general, this work fulfilled the objective of developing and implementing a feasible training program for CAPSI professionals. About the video evaluation, there were increases in the percentage of correct answers in 11 of the 13 videos used in the evaluation of the training. Regarding the three subscales of the KAP survey, there was an improvement in knowledge questions ($p = 0.003$) and attitudes ($p = 0.050$), but this difference was not confirmed in the practice category ($p = 0.186$). Furthermore, the study participants had a positive reaction to the training, since 100% of them evaluated the training program as excellent or good.

Conclusions: this brief and low-cost training program for the care of children with ASD was shown to be feasible with positive results, taking into account the challenges of the reality of the public health system. Two out of the 13 evaluative videos did not show an increase in the mean score after training and some hypothesis have been raised. Upcoming studies should review them, and make necessary changes for better evaluation.

214 **130.214** Improvements in Patient Access Result in Earlier Age of Diagnosis in a Clinical Setting

C. Hall[1]*, J. Hamel*[2] *and S. Miller*[2]*, (1)Emory University, Marcus Autism Center, Atlanta, GA, (2)Marcus Autism Center, Atlanta, GA*

Background: Recent CDC findings report a median age of autism diagnosis of 50 months (Christensen et al., 2016), though autism can be reliably diagnosed by 24 months. As one of the only specialty clinics in our state and one that serves a diverse and often economically disadvantaged population, children tend to receive a diagnosis even later, with a median age of diagnosis of 63 months in 2012. Many factors likely contribute to this later age of diagnosis including limited access to diagnostic services throughout the state as well as long wait times for appointments. In response to these concerns, several clinical initiatives were undertaken with the aim of improving patient access to diagnostic services.

Objectives: The purpose of this study was to determine whether initiatives to improve patient access and to reduce wait times were associated with clinically significant changes in age of diagnosis of ASD.

Methods: A patient access steering committee was formed in 2016 with the goal of reducing the waitlist and improving access to diagnostic assessments. Several procedural changes were made including requiring a PCP referral, clinical review of records prior to scheduling, and fast-tracking children younger than three into diagnostic appointments within two months of referral. Additionally, 26 clinicians participated together in an intensive diagnostic campaign to complete 170 assessments within 2 weeks. To determine whether these collective efforts resulted in lower age of diagnosis, records were reviewed for all children receiving diagnostic evaluations between November 2016 and June 2017. Information including child's age, diagnosis, race, ethnicity, and gender were included in the review.

Results: 861 children received diagnostic evaluations between November 2016 and June 2017, and 619 (72%) of these received a diagnosis of ASD. The demographic characteristics of the children with ASD were as follows: 38% African American, 45% White, 3% Asian, and 14% other. Twelve percent of the families served were non-English speaking and 70% had Medicaid as their primary insurance. Of those children diagnosed with ASD, 523 (84%) had never been identified as having ASD before. The median age of first time diagnosis was 42 months (SD = 28 months) as compared to the median age of 63 months (SD = 31 months) in 2012. One hundred seventy-five (33%) of the children were younger than 3 years old at time of first diagnosis. There were no differences in age of diagnosis based on gender, race or ethnicity.

Conclusions: A multi-faceted approach to improving access to diagnostic services resulted in 21-month difference in median age of autism diagnosis (3 years, 6 months old in 2017 as compared to 5 years, 3 months in 2012). This change highlights the importance of access and the impact it can make on early identification of ASD, particularly in diverse communities. Given that early intervention is associated with better long-term outcomes for children with ASD (Dawson et al., 2009; MacDonald et al., 2014), such clinical undertakings are a priority for the field and continued work is needed to identify more children at earlier ages.

215 **130.215** Increasing Access to Empirically-Validated Interventions for Autism Spectrum Disorder: Dissemination of PEERS into Community Mental Health Settings

L. Dewey*, Nemours/AIDHC, Wilmington , DE*

Background: Autism spectrum disorder (ASD) is a lifelong neurodevelopmental disorder marked by significant impairment in social communication and interaction and presence of restricted, repetitive patterns of behaviors and interests. A recent needs-assessment of families affected by ASD in the state of Delaware identified a critical need for social skills interventions among parents of children with ASD (Rhoton & Ekbladh, 2012; University of Delaware, 2013).

Objectives: This research project aims to build capacity for social skills interventions for ASD for adolescents in community mental health settings in Delaware, using The Program for the Education and Enrichment of Relational Skills (PEERS), a social skills group program developed at UCLA (Laugeson and Frankel, 2010). Aim 1: Build capacity for ASD interventions by providing formal education to community clinicians in PEERS; Aim 2: Assess family outcomes following participation in PEERS regarding social skill symptoms, parenting stress, and family quality of life.

Methods: Aim 1: A two-day education on PEERS was provided to community clinicians (n=15). Clinicians completed a survey developed by the researchers assessing their perception of implementing a social skills group intervention for families affected by ASD prior to the two-day education, after the two-day education, and following PEERS group completion. Aim 2: Five PEERS groups were held at three community mental health locations across the state of Delaware. Caregivers (n=14) completed 1) Social Responsiveness Scale, Second Edition (SRS-2) 2) Stress Index of Parents of Adolescents (SIPA) and 3) Beach Center Family Quality of Life Scale (FQOL).

Results: Clinicians reported increased confidence in their ability to deliver social skills intervention following two-day education on PEERS, as rated on a Likert Scale with 0 being no confidence and 5 being most confidence (pre: M=3.2, SD=1.3; post: M=4.1, SD=.9; $t(14)=-2.82$, $p=.014$). Furthermore, the clinicians who facilitated a PEERS group (n=9) reported a clinically significant increase in confidence ($t(8)=-2.309$, $p=.05$). Thirty families enrolled in PEERS across Delaware (age range of child: 7-17; M=13 years; Males=23, Females=7), and 14 families were considered to have completed PEERS (attended 10 or more sessions and completed both pre and post measures). No difference was reported regarding family quality of life (FQOL: $t(13)=-.737$, $p=.474$), social skills (SRS-2: $t(11)=-1.183$, $p=.261$), or parenting stress (SIPA: $t(11)=.549$, $p=.594$).

Conclusions: This study shows the feasibility of expanding social skills interventions for children and families affected by ASD into community mental health settings, as 15 clinicians received additional education regarding social skills interventions and five more group opportunities using the PEERS program were made available in the community. Although the PEERS program did not show changes in family quality of life, adolescent's social skills, or parenting stress, the study was limited by a small sample size of 14 families completing the intervention. Future research is needed to understand family characteristics and barriers that may impact completion of social skills programs in the community.

216 **130.216** Integrating Clinic-Based and Parent-Mediated Intervention for Autism in India

S. H. Dalwai*, Developmental Pediatrics, New Horizons Health and Research Foundation, Goregaon East,, India; Indian Academy of Pediatrics Mumbai, Mumbai, India*

Background: India contributes to most of the five million children with Autism Spectrum Disorder (ASD) in South Asia. However, studies have mainly reviewed solitary therapies or exclusive parent-mediated interventions. The clinical complexity of ASD demands a comprehensive approach. Few studies have evaluated clinical interventions aligned with intensive caregiver-engagement, partly due to the scarce treatment documentation and limited patient compliance for a sustained duration due to low insurance coverage.
Objectives: This study aims to describe the framework and outcomes of an interdisciplinary intervention program for children with ASD in Mumbai, India.

Methods: Founded in 2003, the aforesaid program headed by a developmental pediatrician includes an audiologist, psychologists, occupational and physical therapists, remedial educators, speech therapists and other visiting specialists (ophthalmologist, neurologist, orthopedic, psychiatrist, and nutritionist). Each child receives a trans-departmental evaluation and an interdisciplinary, goal-oriented, individualized and measurable program for a defined time-period (e.g. six months). Thereafter, the child is re-evaluated for the attainment of therapeutic goals. Individual sessions span 45 minutes with a 1:1 child-therapist ratio. On average, children receive 48-72 sessions of occupational therapy (2-3/week), 24-48 sessions of speech therapy (1-2/week) and 5-6 sessions of caregiver counseling. In addition to monthly counseling, a 'home-program' encourages caregivers to adhere to proven practices for mitigating routine behavioral concerns in ASD (adequate sleep, outdoor physical play, minimum gadget and animation exposure and home-cooked ASD-customized diet); and monthly group meetings help them to co-learn ways to interpret and respond to the child's needs. Retrospective quantitative (Stata-12) and qualitative sub-analyses at different time-points with varying sample sizes (due to the degree of patient compliance and documentation of outcomes) revealed key results.

Results: Out of 4265 children evaluated during 2009-2016, 625 were diagnosed with ASD (14.6%; mean chronological age [CA]:49 months) using the Diagnostic and Statistical Manual of Mental Disorders. Data reflect the public health burden of delayed care-seeking. Paired t-test analysis (n=19) of Receptive-Expressive Emergent Language Scale assessments revealed significant differences between mean receptive language age (RLA in months) at evaluation-1 (mean:20.7) and evaluation-2 (mean:30.6) [p=0.003,95% CI:3.6-16.1]; and mean expressive language age (ELA in months) at evaluation-1 (mean:16.1) and evaluation-2 (mean:24.9) [p=0.006,95% CI:2.6-14.9]. Difference in mean total scores on Childhood Autism Rating Scale (n=38) was 4.2 (p=0.0001,95%CI:3.2-5.1); and in mean social age on Vineland Social Maturity Scale was 0.8 years (p=0.0001,95%CI:0.6-1.1). Thus, the six-month intervention substantially impacted receptive and expressive communication and social behavior. The gap between CA and RLA (not ELA) at evaluation-1, inversely correlated with therapeutic outcomes. These results are supported by studies citing greater receptive language difficulties in ASD (viz. echolalia, scripted speech, and unusual prosody) compared to expressive language. Caregiver interviews (n=10) revealed that parents developed a greater acceptance of their child's condition under the guidance of an interdisciplinary team employing a goal-oriented treatment plan; adherence to the home-program and counseling that periodically addressed their concerns.

Conclusions:

The author organized a consortium for drafting national guidelines on the management of ASD in India, which were published in 2017. Prospective studies should evaluate such an integrated intervention model in India.

217 **130.217** Internet Misinformation on Autism Spectrum Disorders in Vietnam

C. V. Tran[1] *and B. Weiss*[2]*, (1)Vietnam National University, Hanoi, Viet Nam, (2)Vanderbilt University, Nashville, TN*

Background: The internet is increasingly being used as a source for information for virtually all topics, including Autism Spectrum Disorders (ASD). There is a vast amount of information available on the internet regarding ASD, but the accuracy of the information is unclear, particularly for developing countries. The possibility of misinformation provides a significant risk particularly for non-professionals, who lack the ability to evaluate the quality of the evidence found on the internet. The current article aims to explore the status of internet misinformation on ASD in Vietnam.
Objectives: This study had three main purposes. First, it evaluated the quality and accuracy of information regarding ASD on Vietnamese language websites. Second, it proposed solutions for managing and controlling the quality of information about ASD on Vietnamese language websites. Third, it provides a reference of for professionals, teachers and especially families of children with autism regarding the quality of information regarding ASD on Vietnamese websites.

Methods: Data was collected using on popular Vietnamese search engines such as Google (google.com.vn), Yahoo search (search.yahoo.com), Bing (www.bing.com), and a popular Vietnamese search engine namely Cốc Cốc (coccoc.com) using all variations of the word «autism» in Vietnamese and related disorders such as *tu ky, tu ki, tu be, roi loan phat trien lan toa, Asperger, Rett*. Five hundreds articles/posts in Vietnamese from various resources on the internet such as electronic journals, corporate web sites, personal blogs and forums were collected, coded for accuracy, type of information, etc. and analyzed by Atlas.Ti qualitative software.

Results: The amount of information posted about autism on the internet is quite large and frequently visited for many websites. Results showed that, in 500 posts, the majority of information was reasonably valid in regards to, for instance, the cause, diagnosis, treatment, prognosis, etc. However, websites with correct information were not the most frequently visited websites, and about 30% of the information was misleading or, even invalid, with statments made with no backing evidence such as the effects of parental care, watching TV, or sad music causing ASD. There is confusion between ASD and attention deficit hyperactivity disorder or speech delay, depression and other mental disorders. Currently, there are many interventions and treatment methods for children with ASD promoted on the internet. The most common methods are behavioral and psychological interventions but are not specifically and clearly defined. Some treatment methods without scientific evidence are still being published widely online, such as stem-cell therapy, hyperbaric oxygen therapy, acupuncture, meditation, and nutrition.

Conclusions: Wrong information, once it is accessed by parents, caretakers and teachers of children with ASD, may harm the children and their families in many ways. Not only wasting time using ineffective treatment methods, the treatment may make the children worsen. Incorrect understanding of the cause and prognosis of ASD may make parents guilty, having unreasonable expectations of their children, and result in iatrogenic effects (e.g., avoiding vaccinating children). This may cause significant negative consequences and require serious attention from researchers, clinicians and policy makers in Vietnam.

218 **130.218** Is Parent Mediated Telehealth Interventions for Children with ASD a Viable Option?

G. M. Kuravackel[1] *and L. A. Ruble*[2]*, (1)University of Louisville, Louisville, KY, (2)University of Kentucky, Lexington, KY*

Background:

Many parents of children with ASD find it difficult to access quality services, and greater challenges are often experienced by families in rural areas (Chen, et al., 2007). Rural settings are characterized by lessened availability of services per capita, and a lack of evidence-based practices for identifying and providing services for individuals with ASD (Rhoades et al., 2007) which can lead to comparatively worse educational and functional outcomes (Scarpa et al., 2013). One possible solution is the use of telehealth technology (Dudding, 2009; Turner, 2003) to address families' unmet needs for intervention (Hetizman-Powell, et al., 2014). Telehealth technology allows for specialized services, in real time, over a geographical distance and permits interactive and individualized learning (Baggett et al., 2009). Parent training programs have also been found to be cost effective and ecologically valid way to increase access to evidence based intervention (Wainer et al., 2015).

Objectives:

The current literature review examined the reach, efficacy and feasibility of parent mediated telehealth interventions for children with ASD. More specifically this review answers questions of intervention effectiveness, parent satisfaction, fidelity of implementation, acceptability of telehealth mediated interventions, and dropout rates. Differences between self-directed (parent learns and implements interventions independent of a therapist)versus therapist supported approaches and existing barriers in telehealth-mediated interventions are also identified.

Methods:

Computer based database searches of peer-reviewed articles were used to identify studies that met inclusion criteria. Studies were included if they (a) utilized self-directed or therapist-assisted telehealth technology to treatment and assessed outcomes, (b) described an intervention that was delivered by a parent or caregiver, (c) report original data, (d) examined and discussed parent satisfaction and implementation fidelity, and (e) were published in English.

Results:

The review of literature produced ten studies that examined parent-mediated telehealth interventions that also examined parent satisfaction and fidelity of implementation. Five of the ten studies were part of two larger studies so original data could only be obtained from two of the five resulting in seven independent studies. All studies showed improvement in outcomes with the parent-mediated interventions. Effect sizes when available from data ranged from 0.35 to 2.41. Fidelity of implementation whether therapist or parent rated ranged from 72 to 97%. Parent satisfaction and acceptance ranged from 72 to 98.7%. Attrition ranged from 0 to 14.2%. Lower satisfaction and higher attrition occurred when the intervention was self-directed versus therapist assisted.

Conclusions:

All seven studies report greater access and reach with parent-mediated telehealth technology without compromising the fidelity and quality of the intervention. Parents also reported satisfaction and acceptance of telehealth approaches specifically with regard to access and availability of intervention in their community or home. On the other hand almost all studies were supported by research grants and families were provided with technology (when not available) and intervention at no cost. Service reimbursement could vary depending on state and location. Technological problems arising from internet speed or other malfunctions also posed occasional problems in access, despite these problems, satisfaction and fidelity were rated high.

219 **130.219** Longitudinal Trends in the Early Work Experiences of Youth with Autism in the U.S.

A. Roux[1], *P. Shattuck*[2], *J. Rast*[2] *and K. Anderson*[3], *(1)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (2)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (3)Life Course Outcomes Research Program, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Paid work experiences during high school are strongly associated with positive post-secondary employment outcomes for young adults with intellectual and developmental disabilities. In one study, only 11% of special education students with autism (with significant functional deficits) had paid work experience during high school, compared to 31% of students with intellectual disability (ID). Yet few studies have focused on early work experiences of students with autism and whether prevalence of early work is improving over time.

Objectives: Describe the paid work experiences of special education students with autism during high school, and determine how the prevalence of early work has changed across time relative to students with other types of disabilities.

Methods: We used secondary data from two related studies: the National Longitudinal Transition Study-2 (NLTS2) and the National Longitudinal Transition Study-2012 (NLTS2012). Both studies were designed to yield nationally representative estimates of the characteristics and experiences of youth who received special education services. Wave 2 of the NLTS2 (2002-2003) surveyed 600 students with autism ages 15-19 years who were in 9th grade or higher, and NLTS2012 (2012) surveyed 500. Both surveys asked students whether they did any work for and/or a school-sponsored job for pay within the past 12 months. Parents answered survey questions if youth were unable to respond. We report proportions and 95% confidence intervals for key variables. We tested for significant changes in early work experiences between cohorts.

Results: The 2012 cohort of adolescents in the special education autism category was less diverse (79% White), less impaired and had higher functional skills then the earlier cohort of students with autism. Approximately 34% of the recent autism cohort were reportedly unable to carry on a conversation, or had "a lot of trouble" with conversation compared to 54% of the previous cohort. Nearly 60% of recent autism cohort were able to get to places outside the home "pretty well" or "very well", compared to 46% of the earlier cohort. However, the autism group was generally more impaired than students with ID, emotional disturbance, other health impairments, and those who did not have disabilities that impacted their education.

Students with autism had the lowest rate of paid work experiences (27%) during high school compared to students with ID (35%), emotional disturbance (47%), other health impairments (48%), and those who did not receive special education or accommodations (56%). Rates of early work experiences were not significantly different for students with autism between the two cohorts, compared to a significant decrease in early work for those with ID, emotional disturbance, or other health impairments.

Conclusions: Although exposure to early paid work is a key policy target in the US and internationally, rates of early work experiences for high school students with autism have not improved across the last decade. Students with autism had the lowest employment rate across disability comparison groups in this study. Providing early work experiences, and the supports to make them successful, are critically important because of their strong association with post-secondary employment.

220 **130.220** Measuring Perioperative Distress in Children with Autism Spectrum Disorder

E. S. Cameron[1]*, J. M. Chorney*[2]*, I. M. Smith*[3] *and S. L. Snow*[4]*, (1)IWK Health Centre, Halifax, NS, Canada, (2)Dalhousie University, Halifax, NS, Canada, (3)Dalhousie University / IWK Health Centre, Halifax, NS, CANADA, (4)Psychology and Neuroscience, Dalhousie University, Halifax, NS, Canada*

Background: The surgical experience can be distressing for children. Between 40% and 50% of typically developing children experience distress during the induction of anesthesia. The characteristics of children with ASD may make them especially vulnerable to the demands of surgery. Deviation from routine (e.g., lengthy wait times, unfamiliar environments), hyper- or hypo-reactivity to sensory stimulation, and limitations in verbal and non-verbal communication may all result in heightened levels of distress for these children. Whereas the behavioural manifestations of distress and the frequency of perioperative distress has been well characterized in typically developing children, similar systematic descriptions have not been made in children with autism spectrum disorder (ASD). This study aimed to describe the behavioural manifestation of perioperative distress and the frequency of perioperative distress in children with ASD.

Objectives: The specific aims of this paper are to: 1) describe the frequency of parent-reported child distress across the perioperative course for a sample of children with autism, and 2) describe the behaviours parents use to judge children's level of distress.

Methods: Participants in this study were 55 parents and their children with ASD undergoing outpatient surgery with general anesthesia. Parents completed the Autism Perioperative Stoplight Distress Scale—a novel, theory-driven measure—to assess their children's distress at four time points (in the preoperative holding area, when the child was taken to the operating room, at induction, and in recovery) two to eight days after their child's surgery. This measure asked parents to rank their child's distress from 'green' ("good to go"), to 'yellow' ("a little bit on edge"), to 'orange' ("increasingly distressed or aroused") to 'red' ("experienced full-on distress") and to describe the behaviours they witnessed at each of the four time points.

Results: Results indicated that 89.1% percent of children with ASD experienced perioperative distress, with 38.2% of children experiencing extreme distress at one or more time points. Children experienced the most distress at the induction of anesthesia (84.6%, n = 13), and in the recovery unit (78.2%, n = 55). Parent reported behaviours were coded into 20 categories. The most common distress behaviours reported by parents included: fearful, distressed vocalizations, resistant, and uncomfortable.

Conclusions: Nearly 90% of children with ASD experienced perioperative distress, with a large portion of children experiencing extreme distress. Parents reported several novel behaviours that have not been included in assessment scales for typically developing children (e.g., repetitive behaviours, self-injurious behaviours, repetitive questioning). Many behaviours were reported across all four levels of distress, suggesting that parental input or individualization will be needed to interpret behavioural observations if they are to be used in future studies. This study provides a unique contribution to the fields of autism and anesthesiology in that it is the first to empirically describe the unique set of behaviours that children with ASD may display perioperatively and outlines the large frequency of children experiencing perioperative distress.

221 **130.221** Needs and Priorities of Providers Serving Children and Youth with Autism Spectrum Disorders in Rural Areas

S. Vanegas[1]*, Y. Xu*[2]*, S. Magaña*[3,4] *and T. Heller*[2]*, (1)School of Social Work, Texas State University, San Marcos, TX, (2)Disability and Human Development, University of Illinois at Chicago, Chicago, IL, (3)Steve Hicks School of Social Work, University of Texas at Austin, Austin, TX, (4)University of Texas at Austin, Austin, TX*

Background: Research on Autism Spectrum Disorders (ASD) has found significant disparities in access to services and outcomes in rural communities. Screening instruments used to identify children with ASD are less valid and reliable when used among low-income and ethnic minority families in rural areas (Scarpa et al., 2013). Rates of diagnosis are also much lower in rural areas when compared to urban areas (Dickerson et al., 2016), and when children from rural areas are diagnosed, they are typically diagnosed much later than children from urban areas (Kalkbrenner et al., 2011). These disparities have been associated with a lack of primary and specialty care providers (Mandell et al., 2010). With more information about the needs, barriers, and priorities of providers in rural areas, we can increase the professional capacity to address the specific needs of children with ASD and their families within rural communities.

Objectives: The objective of the current study is to identify the unmet needs and priorities providers face in rural areas.

Methods: We focused on two rural counties in Illinois (USA). These counties were identified as rural by the Office of Rural Health Policy (2016) and were comprised of predominantly low-income households, with over 55% of children enrolled in school, considered eligible to receive free or reduced lunch. Educators, service providers, and other professionals who provided services to children/youth with ASD under 22 years of age were eligible to participate. Providers were recruited from schools, clinics, and community organizations. Two experienced investigators led the focus group discussions and followed a script on topics and prompts. The topics included sources of information, services provided/barriers to providing services, transition/future planning, impact of ASD on families and unwanted outcomes. The focus groups included a total of 8 participants and each lasted approximately 90 minutes. The focus groups were audio-recorded and transcribed to identify common themes.

Results: The focus group participants were special education teachers (*n* = 2), case managers/resource specialists (*n* = 2), early childhood administrators (*n* = 2), and speech-language pathologists (*n* = 2). All participants were currently active in their professions, providing direct services and supports to children with ASD and their families. The most prominent themes across both focus groups included limited opportunities for interprofessional collaborations and consultation as a barrier in providing consistent recommendations to families, and insufficient support for staff salaries and professional development on ASD. Themes within each topic (sources of information, service provision and barriers to providing services, transition/future planning, impact of ASD on families, and unwanted outcomes) will be presented along with recommendations to address high priority needs.

Conclusions: Little is known about the experiences of ASD service providers in rural areas. As many disparities in access to and receipt of services have been identified for children with ASD and their families in these areas, it is critical to identify ways to adequately address these disparities. By identifying the critical needs and priorities service providers experience in rural areas in the United States, greater efforts can be made to ameliorate these disparities.

222 **130.222** Online but Live and Interactive Social Skills Intervention

T. P. Gabrielsen*, Counseling & Special Education, Brigham Young University, Provo, UT*

Background:

Addressing core social communication deficits of autism is a universally recommended intervention, but group social skills interventions have not been universally available, particularly in rural or otherwise underserved areas. With increasing availability of Internet service, delivery of telehealth and online services for autism is also increasing. Using an electronic format for social skills instruction has been available in static (learning module) formats, but has not yet been studied in a live, interactive format using a manualized curriculum for in-person group intervention.

Objectives:

This study developed feasible methods for adapting an evidence-based, in-person curriculum to an online, live, interactive format. Once developed, online and in-person delivery of the curriculum were compared in terms of ease, generalization effects, participation rates, and spontaneous conversation generated during sessions.

Methods:

Participants included some typical peers and adolescents (n=17, with n=35 projected), ages 12-16, with existing or pending autism diagnoses. Some parents (n=4) had immigrated to the USA, meaning participants lived in bilingual homes. Inclusionary criteria were language and cognitive abilities consistent with <3 years delay in academics and ability to function independently in group environments. Autism symptoms were verified by Autism Diagnostic Observation Schedule (ADOS-2), Social Communication Questionnaire, and Social Responsiveness Scales (SRS-2). Cognitive and verbal abilities were verified using standardized IQ measures. In-person participants required weekly transportation to the university. Online participants required Internet access and computers with videocameras and microphones. Settings were a large private university (in-person group and generalization probes for both groups) and online (HIPAA-compliant Zoom platform). Protocols for navigating the online environment and rules specific to that environment were developed and distributed. A tech demo teleconference visit was held with families prior to starting online sessions. Curriculum in both delivery models (in-person and online) was the PEERS® Treatment Manual (Laugeson & Frankel, 2010), delivered for 14 weeks, then in-person participants attended 3 generalization probes in age-appropriate activity settings (e.g., going to a museum, out for fast food, and bowling) on campus. Online participants met together on campus on two occasions for generalization probe activities. Parent sessions were held simultaneously for in-person groups, successively for online groups. Measures of effectiveness included direct observation of social engagement during group sessions, pre- and post-intervention parent social skills questionnaires (SRS-2 and Autism Social Skills Profile), and direct observation of social engagement during generalization probes.

Results:

Participants were able to effectively access the online or in-person sessions with only occasional disruption. All elements of the PEERS® curriculum were adapted for online participation, including some games (e.g., Jeopardy!, Battleship, Pictionary, etc.) and token systems for participation were rewarded in both environments. Social engagement in both groups increased over time, with the online group showing increased participation in breakout rooms versus the larger group. Generalization probes showed spontaneous conversation rates maintained in activities outside of group sessions, consistent with parent report of increased conversation skills.

Conclusions:

Online delivery of a manualized social skills intervention may not be ideal, but can be effective for families who cannot otherwise access groups because of geographical isolation or other barriers.

223 **130.223** Parents of Preschool Children Newly Diagnosed with Autism Spectrum Disorder: The Effectiveness of a Self-Directed on-Line Parent Training and Support Program on Parent and Child Outcomes

***A. T. Robson**, Applied Health Sciences, University of Manitoba, Winnipeg, MB, Canada*

Background: In community funded systems there is often a critical gap in service from diagnosis to the start of formalized autism treatment services. During this stressful gap in service, parents could be supported with an affordable, easily accessible, on-line training and support program.

Objectives: The primary purpose of this study was to address the gap in service between diagnosis and access to formal services, by developing and evaluating the effectiveness of a self-directed on-line ASD training and support program. The secondary purpose was to assess how parent stress interacts with participation in training, as well as parent and child outcomes.

Methods: A set of six multi-media on-line modules were developed based on the existing literature, with content specific to: Understanding ASD; Dealing with the diagnosis; Accessing community services; and Parent implemented, naturalistic, early intervention practices. An on-line support forum for parents in the treatment group was also included. The present study used a randomized, masked, waitlist control design, comparing an intervention treatment group to a waitlist control group. A prospective consecutive sample of participants was recruited from the local children's hospital (n = 10; child mean age 50 months). Parents were initially assessed using the Parenting Stress Index –Short Form, an ASD knowledge measure, and an early intervention treatment fidelity measure. Child outcome measures included observational measures of child engagement and expressive communication. After initial assessment, half the parents were given access to the on-line learning modules (treatment group). Four months later, all parents and children were re-assessed and then the parents in the waitlist control group received access to the on-line learning modules. Data was analysed to determine: i) if children in the treatment group had significant gains in engagement and expressive communication when compared to the waitlist control group; ii) if parents in the treatment group had significant increases in ASD knowledge and early intervention skills compared to the waitlist control group; and iii) if there was an interaction effect between parent stress and parent gains.

Results: Preliminary results (n=10) indicate children in the treatment group increased joint engagement (71% to 85%) and expressive communication scores (33% to 47%), while children in the waitlist control group stayed relatively the same (65% to 61% and 37% to 43% respectively). Parents in the treatment group had increased ASD knowledge scores (64% to 83%) and early intervention skills (82% to 96%) while parents in the waitlist control group stayed relatively the same (64% to 70% and 90% to 89% respectively), while parent stress scores decreased in the treatment group (78% to 69%) and increased in the waitlist control group (85% to 92%). An interaction effect between stress and parent knowledge and early intervention skills was not evident.

Conclusions: Preliminary results indicate that parents are able to gain ASD knowledge and early intervention skills from on-line multi-media autism learning modules and that participation in the learning modules and the on-line parent support forum helps to reduce parent stress.

Parent gains also had a positive effect on their child's engagement and expressive communication.

224 **130.224** Passport to Life: Investigating the Need for Life Skills Training Among High Functioning Young People with Autism and Their Parents"

S. Chantziara[1]*, J. Krska*[1]*, P. McGill*[2] *and A. Bratt*[1]*, (1)Medway School of Pharmacy, Universities of Kent and Greenwich, Chatham, United Kingdom, (2)Tizard Centre, University of Kent, Canterbury, United Kingdom*

Background:

In the area of autism interventions further research is needed to identify effective strategies to promote independence (Hendricks & Wehman, 2009). It is recommended that life skills should be addressed before adulthood and school could be an ideal place to target those skills and set individualised goals during transition planning (Duncan and Bishop, 2015). Furthermore there is a need to establish which outcomes are most meaningful for individuals and their families and they should be consulted in the development of future interventions and supports (Ratto and Mesibov, 2015).

Objectives:

This was a qualitative study with the aim to investigate: **a)** Views and needs in relation to adulthood transition as expressed by young people with Autism Spectrum Disorders (ASDs) and their parents **b)** Their experiences of previously accessed training and support with an emphasis on school provision **c)** What type(s) of future life skills support they may consider beneficial and would wish to access.

Methods:

Data were collected through 20 semi-structured interviews with ten young people in the age groups 11-17 years and ten mothers. Data were analysed using Thematic Analysis

Results:

Three overreaching themes were identified: Building the Foundations for the Future (*Sub theme 1a: Focusing on strengths and interests and encouraging participation in new activities; Sub theme 1b: Trying to identify available support but faced with confusion and lack of clarity*); Theme 2: Caught in between: Negotiating two parallel but different realities (*Sub theme 2a: Experiencing the common challenges of adolescence; Sub theme 2b: Facing additional challenges related to autism; Sub theme 2c: Young people with ASDs and their families share common aspirations with their neuroypical peers while recognising that achieving those is not going to be straightforward*); Theme 3: The need for personalisation of the support (*Sub theme 3a: Mixed acceptability and efficiency of previously accessed support; Sub theme 3b*: Shifting the *focus to the individual-The requirement for mentoring and ASD specific support; Sub theme 3c: Prioritising the Young Person*). Participants expressed the desire for personalised support and mentoring was considered to best meet this requirement. Mothers wanted the focus of interventions to shift on the young people and did not want to get involved in the training designed for their children. Perceived inability from schools and services to recognise and manage individual needs was the main cause for dissatisfaction among participants and only few of them described receiving ongoing support around life skills from their school. Furthermore, mothers were not always aware of what support is available and how to access it.

Conclusions:

The study highlights possible issues in the current provision of support for young people with ASDs and offers new insights into the existing literature of autism interventions, particularly regarding the types of support and levels of parental involvement that parents and young people consider desirable.

225 **130.225** Perspectives of Non-Urban General Pediatricians on Diagnosing Autism Spectrum Disorders

J. Das[1]*, L. Hartman*[2]*, G. King*[2]*, N. Jones-Stokreef*[3]*, C. Moore Hepburn*[4] *and* ***M. Penner***[1,5]*, (1)Developmental Pediatrics, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (2)Bloorview Research Institute, Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada, (3)Developmental Pediatrics, Orillia Soldiers Memorial Hospital, Orillia, ON, Canada, (4)Department of Paediatrics, The Hospital for Sick Children, Toronto, ON, Canada, (5)Holland Bloorview Kids Rehabilitation Hospital, Toronto, ON, Canada*

Background: Long wait times for autism spectrum disorder (ASD) diagnosis contribute to delayed access to ASD interventions, which are most effective at young ages. General pediatricians (GPs) represent a potential resource for increasing diagnostic capacity and decreasing wait times for ASD diagnostic assessments. Previous work has described urban GPs' opinions about their role in ASD diagnosis; however, no current research has solicited perspectives of non-urban GPs, whose practice realities may differ significantly.

Objectives: The objective of this project was to explore the perspectives of GPs practicing in smaller Ontario communities regarding their diagnostic processes and their role in ASD diagnostic assessment.

Methods: We performed a qualitative study using thematic analysis of GP's experiences with cases of suspected ASD. GPs from three small/medium-sized Ontario communities (population range: 14,000-64,000) were recruited to provide variation in perspectives. Semi-structured interviews were conducted, transcribed, and coded. A preliminary theoretical framework was developed and sent to participants with a request for feedback (member checking). Feedback did not necessitate any significant changes to the framework.

Results: 14 GPs participated in interviews (7 from Community A, 4 from Community B, 3 from Community C). All participants considered ASD diagnosis to be in the GP's scope of practice and many considered it part of their service to their community. Many sought out and self-funded additional ASD training as necessitated by their practices. Our framework identified three stages in the diagnosis of ASD: pre-assessment (gathering information prior to the first clinic visit), diagnosis, and service access. All of these stages are influenced by ecological factors including the individual patient/family, individual physician factors, factors reflecting the GP's community group practice (i.e., how the group has decided its members will approach cases of suspected ASD), and factors concerning the broader system of ASD care.

Conclusions: GPs practicing in small and medium-sized Ontario communities routinely diagnose ASD and see this as part of their scope of practice. Compared to their urban counterparts, they emphasized a stronger sense of responsibility to their colleagues and to their communities. Strategies aimed at increasing diagnostic capacity should target group practices, increase availability of ASD specific training programs, and improve efficiency of clinic visits through pre-clinic information gathering. Further research regarding accuracy of GP assessments as well as patient perspectives is required.

226 **130.226** Prevalence and Correlates of Employment and Postsecondary Education in Transition-Age Youth with Autism in Vocational Rehabilitation

J. Rast[1]*, A. Roux*[2]*, K. Anderson*[3] *and P. Shattuck*[1]*, (1)Drexel University A.J. Drexel Autism Institute, Philadelphia, PA, (2)A.J. Drexel Autism Institute, Drexel University, Philadelphia, PA, (3)Life Course Outcomes Research Program, Drexel University A.J. Drexel Autism Institute, Philadelphia, PA*

Background: Transition-age youth with autism (TAYA) experience poor postsecondary outcomes across a range of indicators related to employment and related services. Vocational Rehabilitation (VR) is a source of public assistance for youth who seek employment, and youth with autism are a growing segment of VR service users. Postsecondary education (PSE) facilitates skills building that can lead to employment and better wages. Recent federal legislation seeks to improve PSE opportunities and employment outcomes of youth with disabilities. We know little about how the employment and PSE outcomes of TAYA vary from those of other youth with disabilities who used VR services, or if the correlates of successful outcomes differ by group.

Objectives: We will describe the characteristics of TAYA who use VR services compared to transition-age youth (TAY) with other intellectual or developmental disabilities (IDD). We will analyze the correlates of employment and advancement of PSE after VR exit for TAYA in comparison toTAY with IDD.

Methods: This study used RSA-911 FFY 2015 data for TAYA (age 14-24). In comparison, we looked at TAY with intellectual disability, cerebral palsy, or traumatic brain injury, who did not have autism as a cause of their job impairment. The two outcomes of interest were exit from VR with employment and advancement of PSE. Previous studies have shown that VR outcomes vary by state for TAY with IDD. Therefore we considered state of service provision to accurately model the clustered nature of this data using generalized estimating equations (GEE) to estimate population average values of the correlates of the outcomes of interest.

Results: TAYA more often left VR with employment (59% of TAYA versus 51% of TAY with IDD) or advancement in PSE (13% versus 7.4%).

Overall, the correlates of exit from VR with employment were similar across groups: older age; having family or friends as the primary source of support; and receipt of most services were associated with increased odds of employment. Spending a higher than average number of days in VR services was associated with lower odds of employment.

The strongest correlate of advancement of PSE was receipt of PSE training services. Job readiness training and on-the-job supports were negatively associated with advancement of PSE in both groups, as was older age and public insurance. Having a “most significant disability” was associated with lower odds of advancement in PSE in TAYA, but not in TAY with IDD. Spending longer in VR services was positively associated with advancement of PSE.

Conclusions: While the main purpose of VR is to provide services and supports to achieve employment, support for advancement of PSE is a critical step on the pathway to employment. The correlates of successful employment differ from the correlates of advancement of PSE, indicating the importance of matching services to goals. Expectations for employment and educational advancement should be made clear in the Individualized Plan for Employment at the initiation of the VR process. Future study should examine state variation in receipt of PSE in relation to employment outcomes.

227 **130.227** Priorities for Treatment and Services Established By the Combating Autism Act: Costs and Outcomes

P. Doehring*, ASD Roadmap, Chadds Ford, PA*

Background: The 2006 Combating Autism Act or CAA is the most ambitious national research strategy focused on ASD to date. In response to growing concerns about the prevalence and impact of ASD, the InterAgency Autism Coordinating Committee or IACC was created via CAA to establish research priorities to allocate federal research funding. Between 2008 and 2013, IACC helped to direct more than $1 billion from the US National Institutes of Health or NIH alone. Researchers and advocates have begun to question IACC’s emphasis on basic health science relative to interventions, and the extent to which this emphasis has translated into improved outcomes for the population of people with ASD. To date, only a handful of independent researchers have sought to systematically reconsider IACC’s priorities and potential impact.

Objectives: To establish how much of the research (and resulting publications) funded by the NIH between 2008 and 2013 to address issues related to treatment or services for people with ASD resulted in testable interventions or services, especially those used in home- or community-based settings or targeting underserved populations.

Methods: Using the Autism Research Database, we assembled all NIH-funded research grants between 2008 and 2013 that addressed questions 4 (Treatments and Interventions) and 5 (Services). We have also begun to assemble all publications linked to these projects using existing federal databases supplemented by Pubmed/Psychinfo searches as needed. We have begun to conduct title, abstract, and full-text reviews as needed to identify the subset of these research projects and publications that either tested a specific and immediately applicable treatment, or that identified or sought to overcome specific barriers to treatment implementation (e.g., training, access to services, etc.). Within this subset, we are categorizing articles according to population, treatment focus, treatment setting, and treatment implementation.

Results: About 20% of the NIH’s ASD research funding between 2008 and 2013 was directed to Treatments or Services, significantly falling short of targeted funding allocations in many cases. Preliminary analyses reveal that less than two-thirds of these projects, and the publications which resulted, tested a specific treatment or considered specific barriers to implementation: other projects instead examined animal models or factors theoretically contributing to improved intervention or services. Many of the grants and publications that were focused on testable treatments were not home- or community-based, instead relying either on specialized settings, professionals, or levels of support. A small proportion of total research funding and publications addressing testable treatments or services focused on traditionally underserved populations. Very few grants and publications looked beyond specific treatments towards implementation barriers at the local, regional, or national level.

Conclusions: A small proportion of the research funded by the NIH between 2008 and 2013, and the publications which resulted, actually tested a specific treatment or service. The paucity of research on treatments that are community-based, or that address persistent barriers faced by underserved populations, limits the likely impact of the knowledge gained on the lives of people struggling with ASD right now. Implications for future research and policy are discussed.

228

130.228 Put It to the Test: Do Standardized Testing Practices Hurt Students with Autism?

M. Seidman[1]*, J. T. Russo*[1] *and D. S. Mandell*[2]*, (1)University of Pennsylvania, Philadelphia, PA, (2)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: The state of Pennsylvania mandates that all students between third and eighth grade, regardless of cognitive ability, take standardized achievement tests. These tests are administered in school during a 3-week period. State testing guidelines strongly encourage schools to assign teachers as proctors who are not the teachers of the students taking the test. As a result, autism support teachers often are asked to proctor the tests for classrooms that are not their own, effectively removing them from their autism support classrooms for most of several days or weeks in the spring. This practice disrupts the teachers' daily instructional routines and implementation of evidence based practices. With just a month and a half of school remaining when the standardized testing period ends, teachers may be less likely to resume routine EBP implementation. No research to date has investigated the effect that standardized test proctoring has on autism support teachers' use of EBPs and thus student cognitive and language ability.

Objectives: to estimate the impact of standardized testing practices on (1) autism support teachers' implementation of evidence based practices for children with autism and (2) student cognitive/language ability in a large school district in Pennsylvania.

Methods: The sample includes 69 kindergarten-through-second-grade autism support teachers and 143 students in a large school district in Pennsylvania; 19 teachers were pulled from their classrooms to proctor state exams. All teachers received coaching in five EBPs for children with autism: discrete trial training, pivotal response training, data collection, positive reinforcement, and visual schedules. Data on teachers' accuracy of EBP implementation was collected 3-4 times over a 7 month period through direct observation. Data on teachers' frequency of EBP implementation was collected 6-9 times over a 9 month period through teacher self-report. Students cognitive and language abilities were measured at baseline and exit using the DAS-II and the Bracken Basics Concepts Scale (Receptive and Expressive). A difference-in-differences design will be used to estimate the extent to which teachers' administration of the standardized testing to students with and without cognitive disabilities is associated with teachers' use of EBPs and their accuracy of EBP implementation for their students with autism. The effect of this disruption on student outcomes will be measured using linear regression with random effects for classroom.

Results: Data collection is complete and analyses are underway.

Conclusions: Over the last fifteen years, opponents of federal testing requirements have cited various harmful effects on public schools: teachers are forced to teach to the test, pressure on underperforming schools, teacher evaluations based on test results, pressure on school leaders and states to improve results, takes time away from teacher instruction. Results of this study will lead to a better understanding of the way in which school-wide standardized testing practices influence autism support teacher's use of evidence based practices. Findings indicating a decrease in teacher EBP use or poorer accuracy of EBP implementation would have significant policy implications on the practices associated with standardized testing administration.

229

130.229 Reducing Emergency Room Admissions for Individuals with ASD and Severe Behavior

M. D. Powers[1]*, M. J. Palmieri*[2] *and A. Laprime*[3]*, (1)The Center for Children with Special Needs, Glastonbury, CT, (2)Center for Children with Special Needs, Glastonbury, CT, (3)CCSN, Glastonbury, CT*

Background:

Individuals with Autism Spectrum Disorders are often remanded to the Emergency Departments (EDs) of local hospitals following episodes of severe aggression, self-injury, or property destruction. Unfortunately, community hospital EDs are often ill-equipped to stabilize these patients, resulting in excessive stays in the ED or premature release back to the home setting where repeat referrals to the ED are more likely. It is well-documented that children with ASD are 9 times as likely to visit the ED than children without ASD, that they are at greater risk for psychiatrist hospitalization than children with other disorders, and that aggressive and self-injurious behaviors combined with lack of appropriate community services increases the risk of hospitalization.

Objectives:

The BRISC project investigated the development and implementation of a subacute program providing a comprehensive and coordinated system of care, designed for children with ASD admitted to the ED. Key components included rapid deployment of functional analytic behavioral assessment and positive behavior supports for the child upon admission, discharge planning from the date of admission linking parents to effective community and educational resources, intensive parent training, and training parents to work with their child to generalize positive and adaptive replacement skills while maintaining the reduction of significant problem behavior upon returning home.

Methods:

Eight children (7M, 1F) and their families currently admitted to emergency departments at local hospitals for severe aggression, self-injury, or property destruction between the ages 5-13 years old with ASD participated in this program. Each had a history of high intensity and high frequency severe problem behavior, co-morbid psychiatric diagnosis or significant trauma history, repeated hospitalizations or emergency room visits, multiple school placements, complex family histories and different levels of community provider involvement. Comprehensive assessments were conducted to determine behavior function(s) and guide the development of function-based treatment plans. Treatment protocols emphasized acquisition of functional replacement skills, coping skills, and maintenance of zero or low rates of challenging behavior. Program staff, parents and community providers were trained on these plans to fidelity in the program, on home visits, and upon discharge.

Results: Compared to baseline assessments, results indicate a significant reduction in problem behavior in program and at home, high rates of acquisition of functional replacement skills, high rates of skill acquisition among staff and family caregivers upon discharge, and improvements on parent-reported quality of life and use of positive parenting strategies following discharge (see Table). Most importantly, of all children admitted to the program 2 experienced an ED re-admission within the 6 months after discharge but were quickly stabilized.

Conclusions: While hospitalization and ED visits are sometimes warranted, their overuse may also represent a failure to provide appropriate community-based care. As such, the need for intervention strategies that divert from ED and hospital admissions is evident. Results are discussed in terms of the importance of a coordinated system of care for these high-risk children, the importance of intensive and function-based assessment and treatment planning, and the critical impact of treatment fidelity in parent training.

230

130.230 School Psychologists' Confidence in Conducting ASD Assessments

L. J. Dilly[1,2] *and S. Richardson*[2,3]*, (1)Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA, (2)Emory University School of Medicine, Atlanta, GA, (3)Marcus Autism Center, Atlanta, GA*

Background: With Autism Spectrum Disorder (ASD) in the U.S. reaching prevalence rates of 1 in 68, and an average age of diagnosis well beyond the entry age for special needs preschool (CDC 2010), public schools are increasingly tasked with assessing these students (Christensen et al., 2016; Pettygrove et al., 2013). Furthering the demand on school psychologists, ASD identification rates vary across racial and ethnic groups, with average ages of diagnosis in the school age years in disadvantaged communities (Christensen et al., 2016; Daniels & Mandell, 2014). In addition, girls with ASD may be missed in assessment due to variations in their presentation (Dean et al., 2014; Dworzynski, Ronald, Bolton, & Happe, 2012).
Objectives: To examine school psychologists' confidence in assessing children with ASD. Specifically, school psychologists' confidence in assessing various childhood disabilities, including ASD, learning disabilities (LD), and emotional and behavioral disorders (EBD) was compared. Follow-up analyses evaluated confidence in ASD evaluations across gender and bilingual children.

Methods: A team of clinicians and researchers created a survey with Likert-scale (1-5) questions assessing ASD assessment procedures in the school setting. The survey was emailed to 557 valid email addresses. After two reminder emails, a total of 333 surveys were completed. The response rate was 59%. IDEA Section 618 data records indicate that in 2013 there were 720 school psychologists, indicating the respondents represent approximately 46% of school psychologists in state of Georgia.

Results: A repeated measures ANOVA indicated variations in school psychologists' confidence across ASD assessments (M=4.05; SD: .720), LD assessments (M=4.61; SD: .516), and EBD assessments (M=4.33; SD: .647) were significant (Greenhouse-Geisser correction F(1.748, 499) = 96.58; p<0.001). Effect sizes between ASD and LD assessment confidence were large (r = .617) and moderate for ASD as compared to EBD assessment confidence (r = .34). School psychologists were significantly less confident in assessing ASD than LD or EBD. Paired t-tests revealed significant differences in confidence assessing ASD in boys (M=4.07; SD=.693) versus girls (M=3.99; SD=.729) (t (286)= 4.23; p = 0.001; d= .112). School psychologists' confidence in assessing ASD overall (M = 4.05; SD = .72) versus assessing ASD in bilingual children (M= 2.54; SD=1.08) was also significantly different (t (286) = 24.16; p <0.001; *d* = 1.65).

Conclusions: While school psychologists are often called upon to conduct assessments of ASD in the schools, they are much less confident in assessing ASD versus learning disabilities and emotional/behavioral disorders. In particular, school psychologists are reticent about their ability to assess bilingual children for ASD. This likely contributes to the later age of diagnosis and lower prevalence rates of nonwhite, Hispanic children (Locke et al., 2017). School psychologists also indicated lower confidence assessing girls for ASD, although this effect size was relatively small. As research indicates that most school psychologists did not receive specific pre-service training in conducting ASD evaluations, the need for increased pre-service and continuing education for school psychologists is apparent (Aiello, Ruble, & Esler, 2017; Combes, Chang, Austin, & Hayes, 2016).

231

130.231 Stakeholder Validation of the Family Navigator Manual

B. Rappaport[1]*, T. Savion-Lemieux*[2]*, A. Yusuf*[3]*, R. Tesfaye*[1] *and M. Elsabbagh*[4]*, (1)Neuroscience, McGill University, Montreal, QC, Canada, (2)Research Institute-McGill University Health Centre, Montreal, QC, Canada, (3)Psychiatry, McGill University, Montreal, QC, Canada, (4)McGill University, Montreal, PQ, Canada*

Background: Parents of children with Autism Spectrum Disorder (ASD) experience significant barriers in the access and coordination of care. Families describe their experience with care systems as a "confusing maze", in contrast with local and international policies that clearly stipulate the importance of tailored, continuous, and coordinated services across the lifespan. The Family Navigator model (FN), which we developed, responds to these unmet needs by supporting caregiver empowerment and care continuity during different transition periods, beginning at the post-diagnostic period. Thus far, we have developed the FN based on best available evidence on: Navigation efficacy in other health conditions, research about the experience of families in routine services, and an in-depth review of care policy. Taken together, we have incorporated the evidence into a manual we developed to define the FN, including role and functions of the family navigator.
Objectives: The current qualitative study took a participatory approach engaging stakeholders (community professionals who are involved in care coordination or navigation) to validate the FN manual. Prior to beginning a randomized controlled trial of the FN, we sought to validate the model to ensure that the navigator's role and functions coincided with community stakeholders' views of navigation in autism care and services. Both community professionals who take on the role of a navigator, regardless of their professional title, and decision makers involved in navigation, were invited to participate in the stakeholder validation. We developed a workgroup activity where experienced facilitators guided small group discussions about active ingredients of navigation, following a series of pre-specified open-ended questions.

Methods: 49 individuals participated in the stakeholder validation. Included were different professionals, (e.g. social workers, clinicians, and educational consultants) with an average of 10 years of experience working with families with ASD, from a variety of sectors (i.e., health and social services, education, and community organizations). Fives groups of 8-10 participants answered and discussed open-ended questions posed by the facilitator. Group discussion were audio-recorded on iPads, and later transcribed by a research assistant. Using NViVo.10, and with a grounded theory approach, the data was coded into emerging themes related to active ingredients of navigation. After the initial coding of the transcripts, themes were extracted and grouped into broader categories.

Results: Overall, emerging themes from the stakeholder validation suggested that presently, within care services, the professionals responsible for coordination of care for families (i.e., navigation): acts as a go-to person; has an active partnership with the family; is knowledgeable about ASD and the pathways for accessing associated services; facilitates communications and information exchange across different services; and coaches families to be their "own navigator."

Conclusions: The themes derived from the stakeholder validation helped refine the role and functions of the Family Navigator within the FN manual. The next phase will consist of formally evaluating the FN model in a randomized control trial, while also continuing to engage stakeholders in order to ensure consideration of contextual aspects to implementation of the model within local care services and that knowledge generated leads to impact in the community.

232

130.232 State-Level Autism Policies and Their Impact on Families' Access to Early Intensive Behavioral Interventions

A. Chu[1]*, S. broder-Fingert*[2]*, K. Long*[3] *and E. Feinberg*[1]*, (1)Boston University School of Public Health, Boston, MA, (2)Pediatrics, Boston University,* *Boston, MA, (3)Boston University, Boston, MA*

Background: There is increasing evidence of the effectiveness of early intensive behavioral interventions (EIBI) to impact core autism symptoms. However, few young children have access to or engage in the recommended 20 hours of intervention. State-level policies affect access to EIBI by informing guidelines on who can provide an autism diagnosis, shaping workforce development policies for specialty service providers, and impacting insurance coverage and reimbursement for services. Yet, few studies have examined policy-responsive barriers to such services, instead focusing primarily on individual or systems-level barriers. Project EARLY is a multi-site comparative effectiveness trial of a strategy to improve early identification and linkage to services among ethnically diverse, low-income families of children at risk for autism. The trial takes place in Massachusetts, Connecticut, and Pennsylvania, and provides an opportunity to study state-specific policies and practices that may impact families' engagement with and access to EIBI.

Objectives: To identify the potential state-level policy levers that can address disparities in access to and engagement in EIBIs for children with autism.

Methods: We conducted semi-structured qualitative interviews with stakeholders in Massachusetts (n=8), Connecticut (n=1), and Pennsylvania (n=2), that included policy experts, service coordinators, and Part C Early Intervention directors. Interview questions were guided by the Consolidated Framework for Implementation Research (CFIR). Interviews were audio-recorded, transcribed, and double-coded. They were analyzed via thematic and content analyses and mapped on to CFIR domains. Data collection for Pennsylvania and Connecticut is ongoing. We project a total of 15 interviews at the end of this study. We will utilize triangulation and member-checking to assess new policy-levers identified in upcoming stakeholder interviews to assess their generalizability and applicability to different state policy environments.

Results: Preliminary results from Massachusetts stakeholder interviews identified several policy-sensitive barriers that low income, ethnically diverse families experiencing when accessing EIBIs: 1) a shortage of certified providers who can provide behavioral interventions; 2) delays in obtaining diagnostic assessments, a prerequisite to obtaining EIBI in Massachusetts; and 3) cultural and linguistic barriers among EIBI providers. Massachusetts stakeholders expressed interest in understanding state policies and regulations that a) support the provision of more integrated early childhood services – e.g. Pennsylvania, which integrates Part C and B services for children birth through age 5 and b) decrease barriers to diagnostic assessment - e.g. Connecticut, which offers diagnostic assessment through Part C programs. These findings map onto the CFIR domains of engaging, tension for change, and external policy and incentives.

Conclusions: Preliminary findings identified potential policy levers to address disparities in access to and engagement in EIBI. Findings from Massachusetts will inform areas of further exploration with Connecticut and Pennsylvania stakeholders regarding state policies regulating certification of providers, provision of diagnostic services, and workforce development. As demand and funding for EIBI expands, states are faced with the challenge of meeting the increased service needs. Using an implementation science framework – CFIR - as a scaffolding to understand the role of state-level policies to increase access and provision of EIBI will support dissemination of findings to state policy makers and advocates.

233 **130.233** Stick or Switch? Factors That Influence Educational Placement over Time for Children with Autism.

P. White[1], *S. Chandler*[1], *I. Yorke*[1], *V. Carter Leno*[1], *T. Charman*[2] *and E. Simonoff*[1], *(1)King's College London, Institute of Psychiatry, Psychology and Neuroscience, London, United Kingdom, (2)Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

Background:

A number of factors may influence education provision decisions for parents of children with autism, including advice from professionals, placement availability, primary school experience of inclusion and socio-economic status. The majority of studies exploring parental choice have taken a qualitative approach. Early child-, parent- and neighbourhood factors have not been systematically explored as predictors of educational support transition.

Objectives:

To use a longitudinal, community-based sample of children with autism, who were initially in mainstream primary schools, to investigate which factors predict later transition to specialist education, and investigate if later parent-rated school satisfaction significantly differs between the two groups (mainstream vs. specialist education).

Methods:

This observational study included 274 children with autism from two London boroughs, first seen at 4-9 years (Wave 1) and followed up 7 years later (age 11-15 years, Wave 2) when attending secondary school. Only children in mainstream school at Wave 1 were included in this analysis (n=157; 132 males, 25 females). Wave 1 measures included as predictors of secondary school placement were child IQ, child sex, parent-reported autism severity (Social Communication Questionnaire [SCQ]), parent and teacher-reported emotional/behavioural problems (Developmental Behaviour Checklist [DBC]), parental self-report of mental health (K10), parental education, ethnicity and neighbourhood deprivation. Secondary school placement was classified as mainstream (with/without support) or specialist provision. At Wave 2, parents completed the Engagement and Confidence Scale of the Wider Outcome Survey of Parents (WOSP-ECS; Humphrey et al., 2011). As IQ was an important predictor of placement, the association between each predictor variable and later school status was tested using logistic regression adjusted for IQ. Factors showing an association at p <0.1 were retained in the multivariate prediction model. The two parent-reported behaviour measures (SCQ and DBC) were highly correlated so an *a priori* decision was made to retain the parent-reported SCQ and the teacher-reported DBC in the fully adjusted model.

Results:

As expected, lower IQ predicted later school transition to a specialist setting. In addition, with IQ as a covariate, higher parent-reported SCQ, parent and teacher-reported DBC and white ethnicity also predicted specialist placement transition. However, only IQ remained significant in the full multivariate model, likely due in part to collinearity of the DBC and SCQ with IQ. Parents of children who had transferred to a specialist setting reported greater confidence with the school (WOSP-ECS M= 18.6, SD= 4.9) than those remaining in mainstream (WOSP-ECS M=16.4, SD= 5.3) (p=.02).

Conclusions:

In addition to IQ, results suggest that autism severity, emotional/behaviour problems and ethnicity may be important factors to consider regarding school placement for individuals with autism. These factors were fully significant in the simpler analyses and marginally significant in the multivariate analysis. In the current sample, it was difficult to disentangle ethnicity from locality and choice of education provision differences between the two boroughs. In the UK, there is still pressure for educational inclusion. The finding that parents of children who had transferred to specialist provision had more confidence in the school's ability to support their child should be communicated to education policy makers.

234 **130.234** Teacher Attitudes That Affect Implementation of Evidence-Based Practices in Self-Contained Autism Support Classrooms in Public Schools

J. Locke[1]*, M. Xie*[2]*, M. Seidman*[2]*, C. Spaulding*[2,3] *and D. S. Mandell*[4]*, (1)Speech & Hearing Sciences, University of Washington, Seattle, WA, (2)University of Pennsylvania, Philadelphia, PA, (3)Stony Brook University, Stony Brook, NY, (4)Center for Mental Health, University of Pennsylvania, Philadelphia, PA*

Background: The significant lifelong impairments associated with autism spectrum disorder (ASD), combined with the growing number of children diagnosed with ASD, have created urgency in improving school-based quality of care. Few empirically supported interventions have been effectively implemented in schools, the primary setting in which children with ASD receive services. EBPs for children with autism are intensive and require substantial training to achieve successful implementation. Several studies indicate that with training, teachers and classroom staff can implement autism EBPs; however, there are varying levels of EBP use and implementation fidelity, the degree to which an EBP is used as designed (Proctor et al., 2011; Suhrheinrich et al., 2013; Pellecchia et al., 2015; Mandell et al., 2013). Effective implementation ensures that EBPs go from being merely a good idea to actually being put into practice in organizations. A critical factor in effective implementation is the context in which implementation takes places. The field of implementation science has a variety of perspectives and advancements related to implementation, especially at the individual level, which have not been fully considered by autism researchers.

Objectives: The purpose of this study was to examine the individual factors associated with the implementation of EBPs (i.e., discrete trial training, pivotal response training, and visual schedules) for children with ASD in self-contained classrooms in public elementary schools.

Methods: Participants included 67 autism support teachers from 44 public elementary schools. Participants completed ratings of attitudes of EBPs using the Evidence-Based Practices Attitudes Scale, a 15-item psychometrically sound measure that assesses four general attitudes toward adoption of EBPs: appeal, requirements, openness, and divergence (Aarons, 2004). Teachers and classroom staff completed self-report ratings of the frequency with which they deliver each of the EBPs as a proxy for implementation fidelity (e.g. dose).

Results: We computed means and standard deviations to examine attitudes about EBPs and fidelity of each EBP. Despite the nested structure of the data (classrooms nested within schools), multilevel models (MLMs) were not conducted, as there was one teacher per self-contained classroom, which did not allow for clusters needed for MLMs. Instead, regression analyses were used. In the unadjusted models, separate linear regressions were used to test for associations between attitudes about EBPs and fidelity of each EBP. In separate adjusted models, we entered all variables of interest as independent variables with a bivariate association significant at p <.2 and fidelity of each EBP as the dependent variable. Attitudes about EBPs were significantly associated with teachers' use of discrete trial training (p=.01) and visual schedules (p=.04) but not pivotal response training.

Conclusions: The results of this study provide an in-depth understanding of individual-level factors that influence the implementation of EBPs for children with ASD in public schools. These data suggest that individual attitudes about EBPs may be important to consider when evaluating successful implementation of some autism EBPs in elementary schools. Positive attitudes about EBP use may lead to increased use when EBPs are highly structured (discrete trial training and visual schedules) as opposed to naturalistic (pivotal response training).

235 **130.235** Teleplay: A NOVEL Approach to Combat the EARLY Identification Disparity in a RURAL Community

A. B. Barber[1]*, L. G. Yerby*[2]*, J. Boothe*[3]*, D. Albertson*[4]*, C. J. Oslin*[5] *and B. Hargis*[1]*, (1)Communicative Disorders, University of Alabama, Tuscaloosa, AL, (2)Department of Community Medicine and Population Health, University of Alabama, Tuscaloosa, AL, (3)Family Medicine, University of Alabama, Tuscaloosa, AL, (4)Library and Information Studies, University at Buffalo, The State University of New York, Buffalo, NY, (5)University of Alabama, Tuscaloosa, AL*

Background:

Recent research suggests that Telehealth can be useful to accurately identify ASD (Reese et al., 2012; Smith et al., 2017), thereby demonstrating its potential for improving early identification in rural and underserved areas where accessibility to ASD diagnostic and intervention services are limited (Mandell et al., 2005, Stahmer, 2007). Although technology accessibility, limited insurance coverage, funding, and lack of in-person connections present barriers to Telehealth (Antezana et al., 2017, Machalicek et al., 2016), better utilization of technology for information sharing could provide physicians working in rural areas comparable access and online support to expedite the screening, intervention, and referral process.

Objectives:

To pilot Teleplay, an interactive Telehealth platform, in a rural physician's office in order to assess implementation feasibility, the impact on early ASD identification, and the impact on rural medical staff ASD knowledge relative to signs and management. The ultimate objective is to improve early identification in rural communities by integrating ASD specialists into the medical home via Teleplay and by increasing rural physicians' knowledge of ASD signs using their own patient's annotated video samples.

Methods:

Teleplay was developed with National Libraries of Medicine project development funds as an interactive tool to connect rural medical teams with university based ASD experts for communication about children who are at risk for ASD. Teleplay is implemented as follows. 1. When children fail the M-CHAT at 18- or 24-month well child visits, caregivers are invited to complete the Structured Play Assessment (SPA; Ungerer & Sigman, 1981) in the physician's office with their child; 2. The SPA is video recorded by a nurse and securely uploaded via Teleplay to a university-based ASD Clinic; 3. The ASD team observes the video, scores the CARS-2 (Schopler et al., 2010), which is embedded into the Teleplay interface, and time stamps and annotates red flags; 4. The ASD team then sends the annotated time clips with the overall description of any ASD symptoms, and general referral recommendations (i.e. early intervention, speech, full autism evaluation) back to the physician via Teleplay; and 5. The physician uses the videos to communicate feedback to caregivers. Using a logic model (Rubio et al., 2010), the feasibility of implementing Teleplay will be assessed. Finally, the physicians and staff will complete pre-and post ASD quizzes to assess the impact of Teleplay on knowledge of ASD symptoms and management.

Results:

The Teleplay pilot study is active and will conclude in early spring. ASD knowledge was assessed prior to Teleplay implementation. Physicians, residents, and nurses completed a 10-question quiz adapted from the CDC Autism Case Training for developmental-behavioral pediatrics and averaged 73.7% accuracy. The quiz will be re-administered post Teleplay implementation. According to initial assessment using the logic model, collecting and uploading the SPA, scoring and time stamping children's videos, and returning videos to physicians is feasible. Challenges and perceptions will also be assessed and discussed.

Conclusions:

Teleplay is a novel platform that offers a promising solution to the accessibility disparity experienced by children with ASD and their families living in underserved communities.

236

130.236 The Feasibility of an Adaptive Telehealth Program for Delivering Parent Mediated Intervention for Autism Spectrum Disorder

A. Wainer[1], *C. Leonczyk*[2] *and Z. Arnold*[1], *(1)Department of Psychiatry, Rush University Medical Center, Chicago, IL, (2)AARTS Center, Rush University Medical Center, Chicago, IL*

Background: There is strong empirical and theoretical support for parent involvement in interventions for autism spectrum disorder (ASD), with rapid growth in the development and evaluation of manualized parent-mediated early interventions (PMI). Despite purported benefits of PMI, such programs are highly under-utilized in community settings, due in large part to a lack of trained professionals, lengthy waitlists, child care, transportation, and reimbursement issues. These barriers compel examination of alternative service delivery methods, such as telehealth, to increase access to care.

Benefits of telehealth include greater provider and patient coverage and opportunities for standardized yet individualized learning. Indeed, telehealth is well-suited to deliver adaptive PMI (e.g., stepped-care models) as varying levels of intensity and support can be automatically provided as needed. Adaptive telehealth can deliver instruction to parents in a self-directed format or with the addition of remote "coaching." Thus, we have developed a telehealth program to provide PMI in a stepped-care format in an effort to increase dissemination and optimize delivery of early intervention for young children with ASD.

Objectives: We developed a stepped-care telehealth program, Me Too Online, to deliver PMI in an evidence-based imitation intervention called reciprocal imitation training (RIT). The goal of the current pilot randomized control trial (RCT) was to demonstrate feasibility of the stepped-care model, and evaluate the initial impact of the program on parent behavior and experiences, and child social communication.

Methods: This 15-week pilot RCT compared Me Too Online to a waitlist control in 20 young children with ASD and their parents (18 to 49 months). Families in Me Too Online used a self-directed website for five weeks and then responder status was evaluated based on parent fidelity and self-efficacy. Non-responding parents received remote coaching sessions over the next five weeks. Those in the control condition received usual care and were given the chance to participate in Me Too Online after 15 weeks. Parent report and standardized assessments were administered at baseline and at 15 weeks.

Results: Results of ANCOVA indicated children in Me Too Online demonstrated greater increases in parent report of social communication ($p<.05$, $d = 1.27$) on the Social Communication Checklist. Specifically, significant increases were observed in ratings of social engagement ($p< .05$, $d = 1.39$) and imitation ($p< .05$, $d = 1.49$). Results of ANCOVA also indicated significantly greater increases in parenting self-efficacy for Me Too Online relative to control ($p < .05$, Cohen's $d = 1.4$). Parents in Me Too Online showed improvements in fidelity concurrent with participation in the program; roughly seventy percent of parents required additional coaching after use of the website alone. Parents rated Me Too Online content and delivery method as highly acceptable, useful, and effective.

Conclusions: This study provides initial data supporting the feasibility and effectiveness of a stepped-care PMI telehealth program for young children with ASD. An important next step will be to evaluate the extent to which such a program can improve reach and reduce costs associated with early intervention for ASD on a larger scale.

237

130.237 The Impact of Online Computer Games on Mental Health of Children with Autism or Hearing Loss.

O. Alawajee[1], *J. Delafield-Butt*[2] *and C. Costa*[3], *(1)University of Strathclyde, Glasgow, United Kingdom of Great Britain and Northern Ireland, (2)Laboratory for Innovation in Autism, University of Strathclyde, Glasgow, United Kingdom, (3)University of Strathclyde, Glasgow, United Kingdom*

Background: Children with Autism Spectrum Disorder (ASD) or Deaf and Hard of Hearing (DHH) have relationship challenges and difficulties and/or mental health difficulties due to functional disturbance affecting social interaction, learning, and communication.

Objectives: This study examined the role of online computer games to facilitate learning relationships skills and to help improve mental health concerns of children with ASD and DHH. This study approached the role of these games as potential beneficial educational or psychological interventions that might improve social relations, social skills development, and mental health and well-being. Minecraft and its autism-specific modification, Autcraft, were chosen as the focus of this study due to their popularity, accessibility, and the co-operative, rather than competitive, gameplay characteristics.

Methods: This investigation recruited parents of children and children in the United Kingdom (UK) and the Kingdom of Saudi Arabia (KSA). It employed mixed methods data collection. It consisted of two parts: an exploratory questionnaire (n= 195) and a small selection of case studies (n=3), which consisted of post-surveys, observations, and interviews. Subjects for the questionnaire were parents of primary school children aged 8 and over from three groups: children with autism (n= 115), deaf and hard of hearing children (n=10), and children without a disability (n=41).

Results: Minecraft is a popular game among children with ASD and DHH conditions, especially in the UK sample. Positive associations were observed between children's Minecraft gameplay and the quality of those children's friendships and peer relationships, as well as home life skills. Adverse associations were observed between mental health difficulties and the ability to develop good relationships with others through Minecraft play.

Conclusions: Playful, creative interaction with others, such as peers, teachers and other experts is helpful in making learning socially meaningful. Minecraft appears helpful in giving players new freedoms to explore, to experiment, to fail or succeed, and to progress toward desired and self-created imaginative goals. Positive associations within the questionnaire data with Minecraft use suggest this sandbox, open world game might serve as an assistive or supportive tools that can facilitate social creativity and play to impact positively with psychological benefit. Concerns for possible adverse effects will be discussed, as well as current limits of research integrity. Altogether, these data suggest possible positive benefits for Minecraft gameplay for children with ASD and DHH that may be considered for incorporation into educational pedagogy or psychological support.

238 **130.238** The Impact of Participatory Design on the Wellbeing of Individuals with Autism

M. Magnee*, HAN University of Applied Sciences, Nijmegen, Netherlands*

Background: Participatory design (PD) methods have been used to facilitate individuals with autism contributing to the design of assistive technologies. Through appropriate structuring of the PD sessions, the likelihood of developing feasible and accessible technologies that are relevant to users' life worlds is increased. However, challenges remain regarding the integration of these design protocols in regular health care practice and regarding the value of PD in relation to how outcomes of projects are evaluated. Singular measuring instruments do not prove to be decisive, given the complex embedding of assistive technologies in the social life of its users and the multidimensional character of wellbeing.
Objectives: To provide an integral and multidimensional understanding of what constitutes a successful outcome of participatory designed assistive technologies, by means of an evaluation suite in which newly developed technologies are co-evaluated for and with individuals with autism and their caregivers.

Methods: Four separate assistive technologies were evaluated with a group (N=28) of young adult individuals with autism. These include: I) a mobile application called 'TasKing', that helps with fulfilling everyday chores, II) the M-Power tablet that helps people with face-to-face conversations, III) the OOC stress pillow that helps with stress relief by means of a tactile heartbeat inside the pillow, IV) the Tinybot, a robotized planning assistant. Drawing on concepts from the Capability Approach (Nussbaum, 2011; Sen, 1999), realistic evaluation (Pawson & Tilley, 1997) and Actor-Network Theory (Latour, 2005) we designed an evaluation suite consisting of a narrative interview, an actor-network map, quality of life questionnaires, practitioner log entries and user-experience/ usability checklists. These data were aggregated during several 'community of practice' meetings.

Results: Results will be presented from the evaluation of the four co-designed assistive technologies. The separate components of the evaluation suite provide us with a combined collection of subjective and objective effects on the wellbeing of the participants involved and the implications of participatory design processes on day-to-day care. Data from narrative interviews clarify subjective feelings of wellbeing, actor-network maps visualize the embedding of the technologies in the participants' life, quality of life questionnaires provide for quantitative data on quality of life domains (Schalock, 2000), practitioner log entries are deployed for mapping the actual use of the interventions following the CIMO-logic (Context, Intervention, generative Mechanism, Outcome), and usability checklists are used to gauge common usability aspects of the intervention.

Conclusions: This study will contribute to the understanding of what constitutes a successful outcome of participatory designed assistive technologies by emphasizing on the multidimensional aspect of human wellbeing as well as on the implementation of these design and evaluation protocols in everyday care.

239 **130.239** The Relationship between Socioeconomic Status and Use of Interventions in Families of Children with Autism Spectrum Disorder: Results from the ABC-CT Feasibility Study

A. Sridhar[1]*, S. Faja*[2]*, C. A. Nelson*[2]*, S. J. Webb*[3] *and J. McPartland*[4]*, (1)Michigan State University, East Lansing, MI, (2)Boston Children's Hospital, Boston, MA, (3)Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, (4)Child Study Center, Yale University School of Medicine, New Haven, CT*

Background: Prior research indicates significantly reduced utilization of autism-related services in families with lower socioeconomic status (SES). Specifically, research shows that families with lower SES receive fewer hours of autism-related services, and a smaller variety in the types of services they receive. The Autism Biomarkers Consortium for Clinical Trials (ABC-CT) is a multi-site project that aims to investigate biomarkers associated with autism spectrum disorder including their sensitivity to community-based intervention. It provides an opportunity to investigate the relations between SES, total hours of services received, and types of interventions used (evidence-based or complementary and alternative medicine), from data collected at five sites across the United States.
Objectives: To examine the relations between SES and total number of hours of interventions received and to examine patterns between SES and type of interventions received.

Methods: Twenty-five children with ASD and twenty-six typically developing children (M= 8.04 years old, SD= 2.2, range 4-11) participated in the feasibility phase of the ABC-CT project. Two participants did not provide complete data and were not included in analyses. Parents completed a series of questionnaires that included a demographics form and intervention and medication history. Demographics data collected included the participant's race, race of both biological parents, education level of both biological parents, and annual household income. In addition, parents completed an intervention and medication history log on the participant's use of medication (type of medicine and daily dose), the types of intervention received (e.g. speech and language therapy, equine therapy) and the total number of hours of intervention received in the previous six weeks.

Results: Poisson regressions examined the relations between socioeconomic status (measured by parental education level and household income), child age, and hours of intervention received (with significance < .05). Specifically, total hours of intervention received, total hours of evidence-based practices (EBPs) and total hours of complementary and alternative medicine (CAMs) were examined. Annual household income was significantly related to total number of hours of interventions received and total number of hours of CAM received. Maternal education level was significantly related to total hours of EBPs received, but unrelated to total hours of intervention received or total hours of CAM received. Paternal education level and participant's age were significantly related to total hours of interventions received, total hours of EBP received, and total hours of CAM received. Examination of SES by intervention type via Pearson's Chi-squared showed no differences related to SES level in the proportion of families who accessed EBPs, CAMs, or medication. Finally, no site-related differences were found for use of EBPs, CAMs, or medication.

Conclusions: These results indicate relations between parental education level, income, age, and total hours of intervention received by children with autism. Results indicate these effects were due to differences at higher levels of annual household income and parental education. Although these preliminary findings suggest relations between socioeconomic status and the amount of intervention received by children with autism across the U.S., in order to further explore these relations, they should be replicated in a larger sample.

240 **130.240** Theory of Planned Behavior Variables As Predictors of Community Providers' Intent to Implement a Parent-Mediated Intervention for Children with ASD.

D. Straiton *and B. R. Ingersoll, Psychology, Michigan State University, East Lansing, MI*

Background: Parent-mediated interventions are an effective method for improving outcomes for children with ASD (e.g. Ingersoll, Wainer, Berger, Pickard, & Bonter, 2016; Kasari, Gulsrud, Wong, Kwon, & Locke, 2010), yet they are underutilized in community settings where the majority of children receive their services (Lord et al., 2005; Stahmer & Aarons, 2009). The theory of planned behavior (TPB) posits that an individual's beliefs/attitudes, perceptions of norms, and perceived behavioral control predict their intent to perform a behavior (Ajzen, 1985). A strong research base has demonstrated that TPB is an effective model for understanding and changing health-related behaviors (e.g. Albarracin, Johnson, Fisbein, & Muellerleile, 2001; Godin & Kok, 1996) but TPB has thus far not been examined in reference to community providers' intentions to implement parent-mediated intervention for families of children with ASD.
Objectives: This study examined the extent to which TPB could predict community providers' intent to implement an evidence-based, parent-mediated social communication intervention for children with ASD.

Methods: Providers (n = 72) participated in a workshop for Project ImPACT and provided demographic variables (gender, age, racial/ethnic minority status, graduate degree, years of ASD experience, degree to which their caseload matched Project ImPACT's target population) as well as variables derived from TPB (attitudes towards parent-mediated interventions, agency norms regarding parent-mediated interventions, self-efficacy regarding parent coaching skills).

Results: Demographic variables associated with intent to use the intervention included the degree to which providers' caseloads matched Project ImPACT's targeted population and whether the provider had a graduate degree (r = .268, p =.031 and r = .360, p = .003, respectively). Providers' attitudes toward parent-mediated interventions and ratings of perceived behavioral control (i.e. perceived coaching skill level) were associated with intent to implement (r = .330, p = .004 and r = .247, p = .035, respectively), consistent with research on TPB regarding intentions to change health-related behaviors (Ajzen, 2007). Contrary to hypothesis, perceived agency norms were not associated with intentions, r = .002, p = .987. Multiple regression of demographic and TPB variables demonstrated that holding a graduate degree (β = .317, p = .006), having positive attitudes towards parent-mediated interventions (β = .251, p = .026), and having high ratings of self-efficacy regarding parent coaching skills (β = .242, p = .031) were each unique predictors of intention to implement Project ImPACT and together explained ~27% of variance.

Conclusions: Results demonstrate support for the application of TPB to providers' intentions to implement parent-mediated ASD interventions in community settings. TPB provides a theoretical foundation for understanding providers' intentions to implement parent-mediated interventions, which in turn can be used to develop intention interventions to increase implementation of these evidence-based practices. Future research will examine the efficacy of an intervention to influence providers' perceived behavioral control and attitudes towards parent-mediated intervention in an effort to increase provider implementation of parent-mediated interventions for families of traditionally underserved children with ASD served in community mental health settings.

241 **130.241** Using Technology to Support Early Identification of Autism Spectrum Disorder in Vietnam

H. Hoang*, H. S. Vu and G. Le, Center for Creative Initiatives in Health and Population, Hanoi, Viet Nam*

Background:
Early identification and intervention for children with Autism Spectrum Disorder (ASD) in low-middle income countries and in Vietnam in particularly is still a big challenge. Only some pediatric hospitals in big cities in Vietnam provide assessment and diagnosis services for children (VAN, 2012; Mang luoi tu ky Viet Nam, 2016). Young infants and children experience no routine health and development screening, and there is a lack of screening and other assessment tools translated into Vietnamese readily available for use (Ha et al., 2017; Cong et al., 2015). Meanwhile, information available on child development and ASD are not consistent or reliable, and can be confusing for parents leading to considerable misunderstandings and delayed reactions.

Telecommunication Vietnam has been rising rapidly and smartphone become very popular. The increasing use of technology provides the possibility of implementing screening for developmental delay and autism via online platforms. This paper presents our pilot project of developing a365.vn – a web-based platform to support early identification of ASD by both health professionals and parents/caregivers of young children.
Objectives:

- To describe the models and results from the online screening tools on A365 by two groups of users: healthcare professionals during regular child check-ups and parents/caregivers.
- To discuss the advantages and challenges for users, lessons learned and implications for applying technology to support autism screening and diagnosis.

Methods:
Quantitative data are collected from the back-end system, including registered users' demographics and behaviors and tests results, as well as from Google Analytics which provides further information about all visitors to the website. We also used qualitative data from group discussion and in-per-son and phone interviews with users.
Results:
As of June 2017, there were 5536 developmental and autism screening tests completed on the website by users from 59/63 provinces in Vietnam. Screening conducted by health professionals during health check-ups or at home by parents both have advantages and limitations. The

prevalence of children at-risk of developmental delay and autism identified by parents/caregivers was higher than by health professionals. This might imply that the majority of parent users of A365 already had some concerns about their child's development, and as a result become interested in using the tools provided by a365.vn. In contrast, integration of screening into regular health check-ups allows screening at wider scale. Our pilot project also shows that training in autism and using screening tools empowers and increases the health professionals' confidence level.

Conclusions: For both models, significant efforts for communications is required, both by traditional, mass media means such as posters, radios, etc,... to more technology-based, viral means such as social media and online forums. Collaboration with stakeholders, leaders and influencers at various levels, such as community leaders/authority, facebook influencers, etc. are also needed for the screening service to reach more parents. Last but not least, both models points to the need for follow-up services to confirm the diagnosis of at-risk children as well as further support for early intervention.

242 **130.242** Using the Dynamic Sustainability Framework to Adapt Family Navigation for Children with Autism Spectrum Disorder: Results from a Quasi-Experimental Trial

S. broder-Fingert[1]*, A. Chu*[2] *and E. Feinberg*[2]*, (1)Pediatrics, Boston University, Boston, MA, (2)Boston University School of Public Health, Boston, MA*

Background: Family Navigation (FN) is an evidence-based case management approach to helping families overcome systems and person-level barriers to care. Our previous pilot work in a population of low-income, minority children demonstrates the feasibility, acceptability, and suggests effectiveness of FN to enhance access to services for children with autism spectrum disorders (ASD).

Objectives: In the current study, we describe: 1) how we adapted FN to improve implementation; and 2) compare the implementation of this adapted version of FN to a previous trial of FN for children with ASD.

Methods: We used the Dynamic Sustainability Framework (DSF) and data from our previous pilot of FN to inform adaptations. First, we worked with an advisory group of clinicians and researchers to make specific adaptations – the goal of which was improved implementation. Then, we recruited 40 parents of children with positive ASD screens and randomly allocated them to receive an adapted form of FN or usual care. Using a quasi-experimental design, we compared implementation outcomes (utilization, feasibility, and acceptability) between the recruited population and a population of 40 parent-child dyads who participated in a previous pilot of a non-adapted version of FN. Finally, we measured the clinical outcome - time to diagnostic resolution - using survival analysis.

Results: Adaptations were made in all three domains of the DSF: Intervention (e.g. addition of motivational interviewing training), Practice Setting (e.g. change in recruitment location), and Ecological System (e.g. changes in appointment scheduling). Compared to the un-adapted version of FN, families referred to the study were more likely to have an initial visit with the FN (97.7% versus 81.4%, $p<0.001$), and had more interactions (phone, text, in-person) with their FN (mean of 7 interactions v. 22, $p<0.001$). Parents rated the relationship with their navigator (on the satisfaction with navigation questionnaire) similarly between groups (mean score 3.80 v. 3.82, $p=0.8$). For our clinical outcome, FN improved diagnostic resolution for children at risk of ASD at similar rates in the original and adapted FN model (95% versus 90%, $p=0.15$).

Conclusions: Using the DSF to adapt FN improved implementation without altering satisfaction with or effectiveness of the intervention. These data support an adaptive approach to future implementation of FN in new settings.

Oral Session -
Invited, Keynote Speakers, Awards
136 - Welcome Address & Sponsor Update
8:45 AM - 9:00 AM - Grote Zaal

8:45 Welcome Address & Sponsor Update.

Oral Session -
Invited, Keynote Speakers, Awards
137 - Keynote Address - Rosalind W. Picard, Sc.D, FIEEE
9:00 AM - 10:00 AM - Grote Zaal

Rosalind W. Picard is founder and director of the Affective Computing Research Group at the MIT Media Laboratory, faculty chair of MIT's Mind+Hand+Heart initiative, co-founder of Affectiva, providing emotion AI technology to help measure and communicate emotion, and co-founder and Chief Scientist of Empatica, improving lives with clinical-quality wearable sensors and analytics. Picard is the author of over two hundred and fifty peer-reviewed scientific articles. She is known internationally for authoring the book, Affective Computing, which is credited for launching the field by that name. She holds a Bachelors in Electrical Engineering from the Georgia Institute of Technology and Masters and Doctorate degrees in Electrical Engineering and Computer Science from MIT. Picard is an active inventor with over a dozen patents: her group's inventions have been twice named to "top ten" lists, including the New York Times Magazine's Best Ideas of 2006 for their Social Cue Reader used in autism, and 2011's Popular Science Top Ten Inventions for a Mirror that Monitors Vital Signs. Picard's lab at MIT creates new technologies to better understand, predict, and regulate emotion in service of better human health and well being.

9:00 How Emotion Technology Can Improve Science and the Future of Autism

R. W. Picard*, MIT, Cambridge, MA*

Computers, robots, and wearable technologies are gaining the ability to sense, recognize, and respond intelligently to human emotion. This talk will highlight several important findings made with these recent advances, including surprises about the "true smile of happiness," and how a wearable built to measure autonomic stress in autism led to unusual electrodermal signals on the wrist that reveal new insights into deep brain activity, with implications for anxiety, epilepsy, sleep-memory consolidation, mood disorders, pain measurement, and more. How might these technologies transform the way we do research in autism? How might we use these findings to enable more comfortable social-emotional communication and future improved health experiences for people on the spectrum?

Panel Session
Brain Function (fMRI, fcMRI, MRS, EEG, ERP, MEG)
138 - 'Sensory First' Approaches to Dissect Physiological Heterogeneity in ASD.
10:30 AM - 12:30 PM - Grote Zaal

Panel Chair: Hilgo Bruining, *Brain Centre Rudolf Magnus, Amsterdam, Netherlands*

Discussant: Patrick Bolton, *Department of Child & Adolescent Psychiatry, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom*

A prevailing theory is that imbalances of excitatory and inhibitory (E/I) signals in the brain underlie information processing defects in ASD. This theory relates to the observation that many individuals with autism experience seizures and display ongoing 'sharp spike' activity during wake stage and even more frequently in sleeps. E/I balance is regarded critical for the shaping of sensory processing networks during early postnatal stages as well as to maintain sensory functions through supporting roles such as network synchronization, noise filtering and sensory binding. Surprisingly, it has taken until the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) to formally acknowledge sensory difficulties as a core diagnostic feature of ASD and mechanistic understanding of sensory processing alterations in ASD is limited. In this panel, we present studies of two large ongoing sensory driven translational ASD research projects in the Netherlands, the Sensory Processing Program in Utrecht/Amsterdam and the BECAUSE project in Amsterdam. We will present novel neurophysiology approaches and techniques to elucidate associations between E/I balance and sensory processing components that may support rational treatment decisions in ASD with and without epilepsy comorbidity.

10:30 **138.001** Sensory-First Dissection of ASD with and without Epilepsy Using Combined Analysis of Auditory Event Related Potentials.

__C. Vlaskamp__[1], B. Oranje[1], D. M. van Andel[2], J. J. Sprengers[2], S. Durston[3] and H. Bruining[4], (1)Department of Psychiatry, Brain Center Rudolf Magnus, NICHE Lab, University Medical Center Utrecht, Utrecht, Netherlands, (2)Brain Center Rudolf Magnus, Department of Psychiatry, UMC Utrecht, Utrecht, Netherlands, (3)Department of Psychiatry, Brain Center Rudolf Magnus, University Medical Center Utrecht, Utrecht, Netherlands, (4)Brain Centre Rudolf Magnus, Amsterdam, Netherlands

Background:
Sensory processing is increasingly regarded as a critical cornerstone for understanding ASD. So far, mechanistic understanding of sensory processing alterations in ASD is limited. A leading theory is that these alterations are closely related to an imbalance of excitation and inhibition. This theory is supported by the frequent occurrence of seizures or epileptiform changes in patients with ASD. It is yet unknown how this comorbidity affects sensory processing and sensory behavioral reactivity. As part of the Sensory Processing Program in Utrecht, we tested how sensory processing of auditory stimuli might predict behavioral outcome in ASD with and without epilepsy comorbidity.

Objectives:
The objective of this study was to investigate the relationship between neurophysiological measures of sensory processing and sensory behavioral reactivity, such as irritability, and assess the influence of comorbid epilepsy.

Methods:
90 children with ASD (with and without comorbid epilepsy) and 30 typically developing (TD) children aged 7-12 were assessed with an extensive neurophysiological battery. Using EEG, measured mismatch negativity (MMN), an automatic orienting reflex occurring after deviation of stimuli in the environment without requiring conscious perception. On a more conscious level, we measured selective attention (SA) which demands the focus on stimuli while ignoring irrelevant information in the environment, captured in the P3b component. In addition, multiple behavioral parental questionnaires (ABC, SP-NL and SRS) were included in the analyses.

Results:
Children with ASD (with and without epilepsy) showed less selective attention, as indicated by lower P3b amplitude to attended auditory stimuli. Autonomous discrimination as measured with MMN was not significantly different between ASD and TD children on the ASD group level, but a discrepancy between ASD with and without epilepsy was found: children with ASD and comorbid epilepsy showed increased MMN compared to TD, whereas children with ASD without seizures showed decreased MMN. Furthermore, reduced selective attention was associated with increased irritability and sensory hyper-reactivity. Finally, concurrent problems in MMN and SA had additive effects on behavioral outcome as indicated by increased irritability.

Conclusions:
This sensory-first approach raises new possibilities for rational diagnostics and treatment on a neurophysiological basis. Results show that crucial sensory contrasts may be lost when ASD is analyzed without stratification. Epilepsy comorbidity has a profound impact on sensory processing as indicated by the MMN, suggesting the presence of opposing neural phenotypes within the autism spectrum. In addition, the integration of multiple sensory processing (ERP) components into the diagnostic equation might further disentangle the variability in clinical manifestations.

10:55 **138.002** EEG-Driven Stratification of Autism Spectrum Disorder with and without Epilepsy

__H. Bruining__[1], S. Simpraga[2], E. Juarez[2], J. J. Sprengers[3], S. S. Poil[2], H. Mansvelder[2] and K. Linkenkaer-Hansen[4], (1)Brain Centre Rudolf Magnus, Amsterdam, Netherlands, (2)CNCR, VU Medical Center, Amsterdam, Amsterdam, Netherlands, (3)Brain Center Rudolf Magnus, Department of Psychiatry, UMC Utrecht, Utrecht, Netherlands, (4)Department of Integrative Neurophysiology, CNCR, VU University Amsterdam, Amsterdam, Netherlands

Background:

Clinical heterogeneity makes understanding of autism spectrum disorder (ASD) challenging and complicates development of successful treatment. Neurophysiologically, excitatory-inhibitory (E/I) imbalance and disturbed neuronal oscillations have been proposed as central mechanisms behind ASD.

Objectives:

We aimed to use EEG biomarkers to assess neural disturbances and make ASD triage more precise than is currently feasible using current behavioral and sensory scales. We further investigated whether ASD children with (ASD-EPI) or without epilepsy (ASD) can be stratified using integrative indices derived from comprehensive EEG biomarker mapping and machine-learning.

Methods:

90 ASD and 30 typically developing (TD) children (age 7-12 years, IQ>70) were measured with 64- channel EEG in an eyes-closed resting-state condition. All EEG recordings were visually scored for (epileptiform) abnormalities. We quantified the EEG oscillations using spectral and temporal methods in the standard frequency bands and averaged values across channels within three large regions of interest. We also characterized long-range temporal correlations of ongoing oscillations as a proxy of E/I balance using detrended fluctuation analysis (DFA). Integration of biomarkers was done in the Neurophysiological Biomarker Toolbox (http://www.nbtwiki.net/), employing data-mining algorithms to combine information from multiple biomarkers into a single index.

Results:

We found a high number of EEG abnormalities within the ASD groups. ASD patients had high delta relative power and strong autocorrelations in widespread brain regions: both ASD and ASD-EPI subjects showed elevated long-range temporal correlations compared with TD, suggesting that the E/I balance is indeed disturbed in ASD (Poil et al., 2012). The machine-learning techniques resulted in integrated EEG-biomarker indices that discriminated the two ASD groups from TD with high accuracy, and predicted the EEG abnormality scores. The EEG index that optimally discriminated ASD and TD children showed high correlation with total IQ, Sensory Profile scores and Social Responsiveness Scale. The index discriminating ASD-EPI from ASD correlated highly with Autism Behaviour Checklist-Irritability subscale.

Conclusions:

Our findings suggest that these EEG markers can be used to stratify ASD patients, which might contribute to the development of a decision support system for diagnostic and prognostic use in the clinical assessment of children with various manifestations of ASD.

11:20 **138.003** Sensorimotor Gating Variability in ASD with and without Epilepsy Comorbidity May Indicate a Sensory Treatment Target.

J. J. Sprengers[1], *E. Juarez*[2], *D. M. van Andel*[1], *C. Vlaskamp*[3], *K. Linkenkaer-Hansen*[4], *H. Bruining*[5] *and B. Oranje*[3], *(1)Brain Center Rudolf Magnus, Department of Psychiatry, UMC Utrecht, Utrecht, Netherlands, (2)CNCR, VU Medical Center, Amsterdam, Amsterdam, Netherlands, (3)Department of Psychiatry, Brain Center Rudolf Magnus, NICHE Lab, University Medical Center Utrecht, Utrecht, Netherlands, (4)Department of Integrative Neurophysiology, CNCR, VU University Amsterdam, Amsterdam, Netherlands, (5)Brain Centre Rudolf Magnus, Amsterdam, Netherlands*

Background:

An increasing role for sensory dysfunctions is indicated in the pathogenesis of Autism Spectrum Disorder (ASD). The nature and severity of these dysfunctions in ASD may indicate specific subtypes and treatment targets. Event related potential (ERP) EEG paradigms in relation to clinical manifestations of ASD offer a framework to characterize and dissect sensory dysfunctions. Sensorimotor gating is an unconscious early sensory processing mechanism and found abnormal earlier in children with epilepsy. As proof of principle, we tested whether sensory gating deficits are influenced by focal EEG abnormalities and epilepsy comorbidities in ASD.

Objectives:

To test the association between sensorimotor gating abnormalities and epilepsy comorbidity in children with ASD.

Methods:

90 children aged 7-12 with an IQ above 70 and atypical sensory behavior (60 diagnosed with autism spectrum disorder (ASD), 30 diagnosed with epilepsy and ASD comorbidity) and 30 typically developing children aged were investigated. Sensory behavioral abnormalities (SP-NL, ABC-I, ADOS and SRS), quantitative and qualitative EEG parameters (p50, resting state and focal abnormality grading) were assessed. Comparative statistical analyses were used to test whether abnormal p50 suppression coincided with epilepsy diagnosis or focal abnormality grades and associated with different behavioural outcomes.

Results:

Sensory gating abnormalities were more frequent amongst children diagnosed with epilepsy and in children who showed focal EEG abnormalities. Presence of p50 abnormalities or epilepsy comorbidity seemed not to associated with autism severity or sensory abnormalities.

Conclusions:

Sensory gating abnormalities seem to be more frequent in ASD patients with epilepsy comorbidity. This association may elude to common mechanisms between ASD and epilepsy syndromes as has been hypothesized previously. Future studies may attempt to correct sensory gating deficits in ASD with antiepileptic treatment, especially when epielptiform abnormalities are noted in the EEG of children with ASD.

11:45 **138.004** The Because Project: Impaired Sensory Processing in ASD: From Clinical Profiles to Synaptic Mechanisms

M. Verhage, *CNCR, VU Medical Center, Amsterdam, Amsterdam, Netherlands*

Background:

The neurobiological mechanisms underlying ASD are still poorly understood. Recently, sensory sensitivities, such as extreme sensitivity to light, sound, or touch, were added to the ASD diagnostic criteria (DSM5) as negative and prevalent symptoms. A new network theory explains the sensory sensitivity problems in ASD by a disturbed excitation/inhibition (E/I) balance in synaptic networks in the brain.The current project aims to test this theory using behavioral, neuropsychological, neurophysiological and cellular analyses of sensory processing deficits in ASD.

Objectives:

In this presentation, I will highlight the progress of BECAUSE: From Behavior to Cell in AUtism SEnsory processing, a Dutch national project to test this theory using behavioral, neuropsychological, neurophysiological and synaptic analyses of sensory processing deficits in ASD.

Methods:

BECAUSE has exploited our Netherlands Autism Register to pre-select extreme cases of high and low sensory sensitivity among ASD participants (currently 683) and control subjects and examine the relationship between sensory sensitivity and other clinical characteristics and daily functioning skills. Eighty pre-selected participants have been assessing further, using customized sensory processing tasks and EEG, which we have previously optimized to analyze sensory sensitivity and E/I balance. We have previously optimied small, standardized neuronal networks in vitro, made of human neurons derived from induced pluripotent stem cells (iPSCs) and to record differences in synaptic and network properties. The sensory sensitivity and E/I balance tests is used to generate these standardized in vitro networks of the most extreme cases. Finally, it has been proposed that the (unknown) neurobiological mechanisms underlying sensory processing deficits are similar to those underlying higher order social function deficits (Baum et al., 2015). Therefore, we are testing whether the outcomes of our neuropsychological and neurophysiological tests are predictive for the reported higher order function deficits.

Results:

This presentation will be the first presentation of the BECAUSE screenings data. In addition, the completed pilot studies on EEG-analysis of excitation/inhibition balance and synapse physiology in patient-derived neurons will be discussed.

Conclusions:

BECAUSE brings together unique expertise to bridge across behavioral, neuropsychological, neurophysiological and cellular research domains of ASD, focusing on a symptom that is recently recognized as a central mechanism, also in relation to other indicators of ASD, but for which integrated studies across research domains are still lacking. Whereas higher order social functions are difficult to measure quantitatively, sensory processing can be easily quantified in a manner that is less biased for age, gender, or cultural background. BECAUSE is expected to lead to a more objective, unbiased and homogeneous ASD subtyping which is again expected to improve ASD diagnosis and facilitate cellular studies with neurons derived from ASD participants. Such iPSC-derived neuronal models, in contrast to current (monogenic) animal- or cell-models, present the full polygenic complexity of ASD. Together, BECAUSE provides a unique opportunity to bring together information from these different research domains, enhance our understanding of the complexity of ASD, and provide intervention targets to alleviate the burden of ASD.

Panel Session
Early Development (< 48 months)
139 - Brainview: Developing New Approaches to EARLY Detection of Autism Traits
10:30 AM - 12:30 PM - Willem Burger Zaal

Panel Chair: Grainne M. McAlonan, *Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom*

Discussant: Jan Buitelaar, *Radboud University Medical Center Nijmegen, Donders Institute for Brain, Cognition and Behaviour, Nijmegen, Netherlands*

Neurodevelopmental disorders such as autism spectrum disorders (ASD) likely arise well before a clinical diagnosis is made. Longitudinal studies in infants with and without familial risk for ASD provide the opportunity to identify biomarkers that predate later ASD symptoms. Here we report how Early Stage Researchers are collaborating to use novel multi-modal methods within such cohorts to reveal typical and atypical mechanisms of early development. The first presenter will start at birth, examining maturation of synchronous fMRI activity in the social brain network in neonates at-risk of ASD. In the second presentation, we look at responses to social stimuli in 8-month-old infants who later develop ASD and explain how this data can be used to predict later diagnostic outcome in classifier models. The third presenter will then report on the association between functional EEG connectivity in at-risk infants at 14-months and restricted and repetitive behaviours in ASD. Finally, the last talk will examine 2-4 year-old toddlers recently diagnosed with ASD and explore the association between autonomic arousal (heart rate and heart rate variability) and cognitive and social skills. Together, with the discussant, we will examine how these findings may have clinical meaning, both for early diagnosis and targeting novel treatments.

10:30 **139.001** Altered Maturation of Spontaneous Synchronous Neural Activity in the Social Brain of New-Born Infants with Risk Factors for ASD

J. Ciarrusta[1], *R. Dimitrova*[2], *J. Ó Muircheartaigh*[3], *D. Batalle*[1], *D. Edwards*[4], *E. Hughes*[2], *T. Arichi*[5], *D. G. Murphy*[6] *and G. M. McAlonan*[7], *(1)Department of Forensic and Neurodevelopmental Sciences, and the Sackler Institute for Translational Neurodevelopment, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (2)Centre for the Developing Brain, Division of Imaging Sciences and Biomedical Engineering, King's College London, London, United Kingdom, (3)Institute of Psychiatry, Psychology and Neurosciences, King's College London, London, United Kingdom, (4)Imaging Sciences & Biomedical Engineering, King's College London, London, United Kingdom, (5)Imaging Science & Biomedical Engineering, King's College London, London, United Kingdom, (6)Department of Forensic and Neurodevelopmental Sciences, Institute of Psychiatry, Psychology and Neuroscience, King's College London, London, United Kingdom, (7)Behavioural Genetics Clinic, Adult Autism Service, Behavioural and Developmental Psychiatry Clinical Academic Group, South London and Maudsley Foundation NHS Trust, London, United Kingdom*

Background:

Specific brain regions (such as the cingulate and fusiform gyri) play a key role in social cognitive processing. Although several studies have reported altered functional connectivity within these regions in individuals with ASD, it is unknown when such atypicalities emerge. Converging evidence from animal models of ASD indicates that genetic or environmental risk factors for ASD disrupt the maturation of ‘spontaneous synchronous’ brain activity in functional networks in early postnatal life. However, no-one has examined whether synchronous activity in social brain regions (e. g. fusiform gyrus and posterior cingulate) is altered in the first few weeks of life in human infants at-risk of ASD.

Objectives:
