evaluate patients after comprehensive treatment of epithelial ovarian cancer, and to provide evidence for subsequent clinical management. ***Materials and Methods:*** A total of eligible 83 patients with treated epithelial ovarian cancer were enrolled. Including 50 cases of ovarian cancer who underwent primary cytoreductive surgery plus 6 cycles of chemotherapy with complete clinical response of variable duration, and 50 ovarian patients received 3 cycles of chemotherapy preoperatively plus intermediate tumour cytoreduction plus 3 courses of postoperative chemotherapy with complete clinical remission periods of varying duration. All enrolled patients were performed CA125 test within two weeks before whole-body 18F-FDG PET/CT imaging, and whole-body tumour burden of recurrent or metastatic foci were calculated using multi-foci segmentation software. ***Results:*** Among 83 cases of treated epithelial ovarian cancers, 77 (92.8%)cases was positive and 6 cases was negative on PET imaging while tumor markers CA125 presented positive. Laboratory tumour markers CA125 were within normal range in 13(15.7%) patients, while they showed positive PET/CT imaging . There were 8 cases of clear cell carcinoma, among which 2 (25.0%) cases had elevated CA125 with positive PET/CT findings and 6 (75.0%) cases had CA125 in the normal range with 1 (16.7%) case of negative PET/CT image and 5 (83.3%) cases of positive PET/CT image.The diagnostic sensitivity of 18F-FDG PET/CT for recurrence or metastasis of treated ovarian cancer was 92.77% and the diagnostic sensitivity of CA125 for recurrence or metastasis of treated ovarian cancer was 83.13%. ***Conclusion:*** There was a strongly positive correlation between whole-body tumour burden and the tumour marker CA-125. The combination of CA125, which can predict the recurrence or metastasis of treated ovarian cancer, and PET/CT, which can locate the recurrence and metastasis of treated ovarian cancer and evaluate the tumour burden, could improve the diagnostic accuracy of the recurrence and metastasis of treated ovarian cancer and provide the guidance for the later clinical treatment.

Quantitative [18F]FDG PET metabolic parameters as prognostic indicators in pediatric Hodgkin lymphoma: a comprehensive analysis

M. Yadgarov, *M. Dunaykin, G. Shestopalov, C. Kailash, E. Kireeva, N. Myakova, Y. Likar;*
Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Pediatric Hodgkin lymphoma (HL) presents with high survival rates; however, there is an imperative need to minimize long-term treatment morbidities. This study assesses the prognostic significance of baseline and interim [18F]FDG PET parameters in pediatric HL for enhancing risk-adapted treatment strategies. ***Materials and Methods:*** This retrospective, single-center study encompassed pediatric HL patients diagnosed and treated according to EuroNet-PHL-C1 and DAL/GPOH-HD protocols. Eligibility criteria included patients under 18 with newly diagnosed HL, availability of baseline and interim PET/CT scans, and a minimum follow-up period of six months. Exclusion criteria were absence of baseline or interim PET/CT scans and incomplete data on treatment or clinical outcomes. [18F]FDG PET/CT imaging and analysis were standardized, with quantitative PET metrics evaluated by two nuclear medicine experts. We assessed SUVmax, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) at two segmentation thresholds (SUV 2.5 and 41% SUVmax). Cox regression analysis was utilized to evaluate survival outcomes. The primary endpoint was event-free survival (EFS). ***Results:*** The study included 115 pediatric HL patients, with a median follow-up of 35 months (16 cases [13.9%] of relapse or progression were noted). Event-free survival (3 years) was 86.3±3.3%. Elevated baseline and interim MTV and TLG values were significantly associated with poorer EFS (hazard ratios from 3.15 to 9.95) in univariate analysis. Interim SUVmax ≥2 was also associated with unfavorable outcomes (hazard ratio 15.11, p = 0.009). However, pre-therapy SUVmax was not significantly associated with EFS (p = 0.223). ***Conclusion:*** Baseline and interim [18F]FDG PET parameters are significant prognostic indicators for pediatric HL. Incorporating these quantitative measures can refine individualized treatment approaches, aiming to balance therapeutic efficacy against long-term health risks. Future research should focus on validating these parameters in larger, prospective studies to confirm their utility in clinical practice.

EP-0344

Deauville score and event-free survival in children with Hodgkin lymphoma

M. Yadgarov, *M. Dunaykin, G. Shestopalov, C. Kailash, E. Kireeva, N. Myakova, Y. Likar;*
Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Pediatric Hodgkin lymphoma (HL) is characterized by high survival rates. However, optimizing treatment to minimize long-term morbidities remains a challenge. The Deauville score (DS), derived from [18F]fluoro-2-deoxy-2-d-glucose positron emission tomography ([18F]FDG PET), is used for response assessment, but its prognostic value for event-free survival (EFS) in children with HL remains to be fully elucidated. ***Materials and Methods:*** This single-center, retrospective study examined pediatric HL patients treated between 2016 and 2023 according to EuroNet-PHL-C1 and DAL/GPOH-HD protocols. Patients underwent [18F]FDG PET/CT at diagnosis and after two chemotherapy cycles. The study aimed to evaluate the prognostic significance of the interim DS for EFS. Patients were categorized based on their DS, and analyses were performed using Cox regression models and receiver operating characteristic (ROC) analysis. ***Results:*** A total of 115 pediatric patients with HL were included, with a median follow-up of 35 months, during which 16 patients experienced relapse or progression (13.9%) and one patient died (0.9%). In the study, 19 patients (16.5%) were assigned a DS of 2, 66 patients (57.4%) a DS3, 23 patients (20.0%) a DS4, and 7 patients (6.1%) a DS5. The higher DS was found to be significantly associated with worse EFS (hazard ratio 2.63, 95% confidence interval 1.47-4.68, p = 0.001). Patients with scores of 4-5 showed a notably higher risk of relapse or progression compared to those with scores of 2-3 (hazard ratio 3.09, 95% confidence interval 1.16-8.22, p = 0.024). ***Conclusion:*** The Deauville score is a significant independent prognostic factor for EFS in children with HL. This finding supports the use of the Deauville score for risk stratification and guiding treatment decisions in pediatric HL. Implementing the Deauville score in clinical practice could

help identify patients at higher risk of adverse outcomes, thereby optimizing individualized treatment approaches. Further prospective studies are needed to validate these findings and refine treatment protocols accordingly.

EP-0345

Tumor Necrosis and Ascites on Baseline FDG PET/CT as Independent Prognostic Markers for Double-hit and Triple-hit Lymphoma: A Multi-center Retrospective Study of Rare Cases

C. Jiang;
Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: Double and triple hit lymphoma (DHL/THL) is a rare genetic subtype of diffuse large B-cell lymphomas (DLBCL) characterized by extremely aggressive behavior. This study aimed to assess the potential prognostic markers on baseline FDG PET/CT in DHL/THL patients. ***Materials and Methods:*** A total of 36 DHL/THL patients, with MYC and BCL2 and/or BCL6 rearrangements from 3 independent medical centers, were retrospectively studied. These patients all underwent baseline PET/CT scans between November 2012 and February 2023. Presence of tumor necrosis and ascites were visually assessed at PET and CT, as necrosisPET and ascitesCT, respectively. Survival analyses were performed using Cox regression and Kaplan-Meier methods. Progression-free survival (PFS) and overall survival (OS) were used as endpoints. Time-dependent receiver operator characteristics (ROC) curves were used to assess the predictive power of necrosisPET and ascitesCT. ***Results:*** Of the 36 patients, 14 experienced recurrences, and 12 died during the follow-up period. Multivariate analysis revealed that necrosisPET (HR=9.802, P=0.006; HR=6.723, P=0.026) and ascitesCT (HR=8.177, P=0.036; HR=8.027, P=0.045) were independently prognostic factors for PFS and OS. Time-dependent ROC analysis showed that necrosisPET and ascitesCT had good performance in predicting PFS (accuracy:0.671-0.758) and OS (accuracy:0.686-0.769) occurring within 1-4 years. The risk model, incorporating necrosisPET and ascitesCT, can effectively stratify patients for PFS ($\chi2$=11.804, P=0.003 and $\chi2$=15.754, P<0.001, respectively) and OS ($\chi2$=20.599, P<0.001 and $\chi2$=18.369, P<0.001, respectively) in subgroup analyses of patients treated with R-CHOP and intensive regimens, respectively. ***Conclusion:*** NecrosisPET and ascitesCT independently predict survival in DHL/THL patients and may improve risk stratification, potentially guiding personalized therapeutic strategies.

EP-0346

The effect of EARL-harmonization and scan time reduction on Deauville score in patients with lymphoma

D. Khodakova, *A. Khalimon, G. Khamadeeva, M. Khodzhibekova, S. Onishchenko, A. Leontyev;*
P. Hertsen Moscow Oncology Research Institute - branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Deauville score (DS) is a standard tool for treatment response assessment in patients with Hodgkin's lymphoma and aggressive non-Hodgkin's lymphomas. PET images assessment involves measuring the SUVmax (Maximum Standardized Uptake Value) in target lesions, the blood pool, and the liver. SUVmax is dependent on many biological and technical factors. The EARL program, developed by the EANM, aims to reduce SUV variability in multicenter studies. The aim of the study was to assess the impact of EARL-harmonization and scan time reduction on DS in patients with lymphoma. ***Materials and Methods:*** $^{[18F]}$FDG PET/CT scans were performed for 20 patients with lymphoma both before and during therapy, according to the EANM guideline, with list mode acquisition. Two EARL1 (3D OSEM #1 - 9i12s Gaussian filter 7mm , #2 - 4i12s Gaussian filter 6mm) and four EARL2 reconstructions (BSREM, upper β=160, lower - β=400; 3D OSEM+PSF #1 - 9i12s Gaussian filter 7mm, #2 - 4i12s Gaussian filter 6mm) with different frame durations (180s/bp, 150s/bp, 120s/bp, 90s/bp, 60s/bp) were analyzed. Segmentation of the mediastinal blood pool and liver was performed semi-automatically, lesion segmentation was performed manually. SUVmax (normalized by lean body mass) were obtained and DS were determined for all reconstruction modes. The percentage of DS discordance was calculated for clinical acquisition time scans (180 s/bp) as the reference, and for shorter acquisition time scans obtained through the list mode. Additionally, the coefficient of variation (CoV) of DS was analyzed for each reconstruction timeframe dataset. ***Results:*** All and clinically significant DS discordances were determined for the reference 180s/bp scans (EARL1 - 5% and 5%, EARL2 - 8,75% and 5%) and the shorter acquisition time scans: 150s/bp (EARL1 - 7,5% and 7,5%, EARL2 - 10% and 6,25%), 120s/bp (EARL1 - 17,5% and 12,5%, EARL2 - 10% and 10%), 90s/bp (EARL1 - 32,5% and 20%, EARL2 - 21,25% and 15%), 60s/bp (EARL1 - 32,5% and 20%, EARL2 - 25% and 20%). Additionally, EARL1 appeared to be more sensitive to scan time reduction in Deauville scoring, as evidenced by the minimal coefficient of variation (CoV) for EARL1 (3D OSEM #1 - 26.9%) compared to EARL2 (BSREM β=160 - 14.7%). ***Conclusion:*** DS changed even when using EARL-harmonized PET reconstructions with the standard clinical acquisition time (180s/bp) on the same PET/CT-system. Reduction of scan time led to increased variability in DS. It might distort the treatment response assessment by DS, especially in multicenter studies.

EP-0347

Baseline FDG-PET Derived Texture Feature Entropy May Serve as an Imaging Biomarker for Treatment Outcome in Hodgkin Lymphoma Patients

H. Wang[1], *H. Huang[2,3], Y. Fang[4], T. Hung[5], C. Lin[6,7];*
[1]Department of Nuclear Medicine, Chang Gung Memorial Hospital (Linkou Branch), Taoyuan, TAIWAN, [2]Institute of Medical Device and Imaging, College of Medicine, National Taiwan University, Taipei, TAIWAN, [3]Program for Precision Health and Intelligent Medicine, Graduate School of Advanced Technology, National Taiwan University, Taipei, TAIWAN, [4]Department of Radiology, University of Alabama at Birmingham, Birmingham, AL, UNITED STATES OF AMERICA, [5]Institute of Stem Cell and Translational Cancer Research, Chang Gung Memorial Hospital (Linkou Branch), Taoyuan, TAIWAN, [6]Chang Gung Memorial Hospital (Taoyuan Branch), Taoyuan, TAIWAN, [7]School of Chinese Medicine, Chang Gung University, Taoyuan, TAIWAN.

Aim/Introduction: Microscopically, Hodgkin lymphoma (HL) possesses a unique feature: tumor Reed-Sternberg cells comprise less than 1% of the total cell population, while the majority of cells actually belong to the bystander cells in the tumor microenvironment, as well as a high fibrosis component. On FDG-PET, HL lesions tend to demonstrate more heterogeneous uptake than other common lymphoma subtypes. In this retrospective study, our aim was to assess whether tumor heterogeneity, as assessed by baseline FDG-PET, can predict treatment outcome. ***Materials and Methods:*** Eighty-five newly-diagnosed HL patients with available pretreatment FDG-PET and at least 2 years of follow-up after completion of first-line therapy were included. For baseline tumor glycolysis characteristics, we analyzed maximum SUV (SUVmax) of the scan, SUVmax and the histogram-based

first-order entropy of the lesions at the biopsy region. Regions-of-interest were delineated slice-by-slice to encompass all lesions at the biopsy region, e.g., left neck. The low FDG uptake part was also included to ensure the evaluation of tumor heterogeneity. Among the 85 patients, 71 had an interim FDG-PET 2-4 months after initiation of chemotherapy, and a Deauville score of 4 or 5 was considered PET-positive. The performance of each parameter to predict unfavorable outcomes, i.e., refractory disease or relapse, was calculated using the receiver operating characteristic (ROC) curve. A P-value of less than 0.05 was considered statistically significant. ***Results:*** Out of the 85 patients, twenty-five (29%) experienced either a poor response to first-line therapy or disease relapse during the follow-up period. At diagnosis, the SUVmax of the PET scan measured 15.8 ± 5.3 (mean ± standard deviation, range 5.5-31.3). The SUVmax of all lesions at the biopsy region was measured at 13.9 ± 5.5 (range 2.6-30.0), with its corresponding 256-bit histogram-based first-order entropy calculated as 4.8 ± 0.3 (range 3.6-5.4). The areas under the ROC curve (AUC) to detect an unfavorable outcome were 0.420, 0.389, and 0.646, respectively, with the 256-bit entropy achieving the highest accuracy (optimal cutoff 4.9, P = 0.037). The prognostic value of a positive interim PET (n = 22) was confirmed in our subgroup of 71 patients (AUC = 0.789, P < 0.0001). ***Conclusion:*** Baseline tumor heterogeneity assessed by the histogram-based first-order entropy of FDG uptake may aid in identifying Hodgkin lymphoma patients with unfavorable outcomes. Our results, which focus on lesions at the biopsy region, offer the potential for correlation with the histological tumor microenvironment in future studies.

EP-0348

^{18}F-FDG Uptake Change in Liver, Mediastinal Blood Pool and Lymphoid Cell-rich Organs during PD-1 Immunotherapy in Lymphoma

L. Guo, *s. guohua;*
Department of Nuclear Medicine, West China Hospital of Sichuan University, Chengdu, CHINA.

Aim/Introduction: To evaluate metabolism change in reference organs (liver and mediastinum) and lymphoid cell-rich organs (spleen and bone marrow) during PD-1 immunotherapy in relapsed or refractory lymphoma patients. ***Materials and Methods:*** Sixty-six patients with baseline and serial monitoring FDG PET/CT scans were retrospectively enrolled. SUVmean and SUVmax of evaluated organs were obtained by two reviewers, and their association with tumor burden and clinical response were evaluated. Immune-related adverse events (IRAE) detected by FDG PET/CT were also recorded. ***Results:*** The SUV values of reference organs and lymphoid cell-rich organs did not change significantly during the immunotherapy process. The intersubject variability of these values ranged from 13.0% to 28.5%. Meanwhile, metabolism of reference organs was affected neither by the tumor burden nor clinical response. SUV change of lymphoid cell-rich organs was associated with clinical response to immunotherapy. Responders showed decreased metabolism while non-responders showed a reverse trend (spleen SUVmax: -0.30±0.47 vs. 0.18±0.39, p=0.001, spleen SUVmean: -0.24±0.39 vs. 0.14±0.31, p=0.001, bone marrow SUVmax: -0.14±0.37 vs. 0.07±0.46, p=0.042, respectively). The influence of IRAE on the SUV change in evaluated organs was not significant. ***Conclusion:*** During PD-1 immunotherapy, metabolism change of reference organs is influenced neither by tumor burden nor by clinical response while FDG uptake change of lymphoid cell-rich organs is significantly associated with clinical response. ***References:*** 1. EP-0349

Development of a Multivariable Scoring Model for Prognostic Prediction in Hodgkin Lymphoma Patients Undergoing Anti-PD-1 Therapy

Z. Wu, *X. Zhang, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Hodgkin lymphoma (HL) is characterized by Reed-Sternberg (RS) cells expressing programmed death-1 (PD-1) receptors, contributing to a favorable response to immunotherapy. However, traditional assessment methods like the Lugano standards are inadequate for evaluating immunotherapy in HL. LYRIC criteria, while comprehensive, are complex for physicians to apply in clinical practice, and the extended assessment periods are relatively time-consuming1. This study proposes a novel prognostic scoring model integrating 18F-FDG PET/CT parameters and clinical variables for HL patients undergoing immunotherapy. ***Materials and Methods:*** We reviewed 54 HL patients (age ≥ 18) undergoing anti-PD-1 immunotherapy and 18F-FDG PET/CT scans pre- and during treatment (after four cycles) from 2017 to 2023. Patients were categorized into monotherapy (anti-PD-1 only) and combination therapy (usually involving a combination of immunotherapy and other treatment regimes) groups, ensuring baseline comparability. Imaging parameters were analyzed alongside Deauville score (DS) and LYRIC criteria. LASSO regression and multivariable Cox models assessed the prognostic value of PET/CT parameters in progression-free survival (PFS). A nomogram was then constructed for prognosis prediction model. ***Results:*** Significant differences were found only in delay since diagnosis and previous treatments between monotherapy and combination therapy groups. We assumed the difference to be reasonable since patient in monotherapy group are primarily enrolled in novel anti-PD-1 agent clinical trials, which are considered a lower priority option in the treatment regime. LASSO and Cox models identified age > 55, baseline SULpeak > 9.43, and SUVmean percentage change from baseline > 0.11 as key prognostic factors. The 5-point scoring model, simplified from nomogram, outperformed LYRIC standards in PFS prediction (C-index 0.781 vs. 0.649, p = 0.002). ***Conclusion:*** We developed a multifaceted prognostic scoring system for HL patients undergoing immunotherapy, statistically surpassing prevailing LYRIC and Deauville standards. ***References:*** 1. Lee AJ, Kim KW, Cho YC, et al. Incidence of Immune-Mediated Pseudoprogression of Lymphoma Treated with Immune Checkpoint Inhibitors: Systematic Review and Meta-Analysis. EP-0350

The Role of F^{18} FDG PET/CT Metabolic Parameters in Predicting Bone Marrow Involvement in Lymphoma

B. Kocabeyoglu, *D. Demir, A. Akgun;*
Ege University, Izmir, TÜRKIYE.

Aim/Introduction: Detection of bone marrow involvement in lymphoma is important for accurate staging and patient management. Although bone marrow biopsy (BMB) remains the gold standard, visual assessment and standardized uptake value (SUV) obtained with F^{18} FDG PET/CT are frequently used for this purpose. In this study, we aimed to investigate the effectiveness of the semiquantitative metabolic parameters of F^{18} FDG PET/CT as predictors of bone marrow infiltration (BMI) in lymphoma. ***Materials and Methods:*** We retrospectively analyzed the clinical data of 79 patients diagnosed with lymphoma and underwent F^{18} FDG PET/CT imaging for staging in our clinic between 2015-2023 and had bone marrow biopsy before treatment. SUVmax values obtained from the area of highest uptake in bone/bone marrow, liver, lumbosacral vertebrae, and posterior iliac crest were recorded. Volumetric parameters such as metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were calculated for the average of 3 regions of interest drawn from lumbosacral vertebrae and posterior iliac crest. Pre-treatment hemoglobin (Hb) values were also noted. The cut-off value for the highest specificity and sensitivity to indicate bone marrow infiltration was determined according to the Youden index. ***Results:*** Twenty-five patients were diagnosed with Hodgkin lymphoma: 14 nodular sclerosis, 9 mixed cellularity and 2 nodular lymphocyte predominant subtypes. Fifty-four patients were diagnosed with Non-Hodgkin lymphoma: 12 marginal zone, 11 diffuse large B-cell, 8 follicular, 6 low-grade B-cell and others. BMB revealed infiltration in 49 patients. No statistically significant correlation was found between SUVmax measured in the areas of highest bone/bone marrow uptake or the ratio of this value to liver parenchymal SUVmax and the presence of BMI (p=0.31 and 0.80,respectively). However, there was a significant correlation between the presence of BMI and SUVmax measured from the posterior iliac crest (p=0.012), MTVaverage (p=0.002), MTVmax (p=0.010), TLGaverage(p=0.0049) and TLGmax(p=0.030). The highest sensitivity and specificity of the parameters for predicting BMI were as follows: MTVaverage: 69%, 76% (3.19 cm3), MTVmax: 74%,56% (3.60 cm3), TLGaverage: 89%, 53% (8.5 cm3), TLGmax: 91%, 46% (9.29 cm3). No significant relation or correlation was observed between SUVmax values measured from lumbosacral vertebrae or posterior iliac crest and pre-treatment Hb values. ***Conclusion:*** Although metabolic parameters have high sensitivity as a non-invasive method for predicting bone marrow infiltration, it was observed that their specificity is low. Semiquantitative metabolic parameters such as MTVaverage, MTVmax, TLGaverage, and TLGmax obtained with F^{18} FDG imaging may be helpful markers in predicting the presence of BMI.

EP-0351

Impact of metabolic tumor volume, total glycolysis and Deauville criteria in the assessment of treatment response in Hodgkin's lymphoma

M. Olarte, *J. Romero, A. Playas;*
National Autonomous University of Mexico (UNAM), Universidad Nacional Autonoma de Mexico, MEXICO.

Aim/Introduction: Hodgkin lymphoma (HL) is a hematological malignancy that, when properly diagnosed and treated, has a good prognosis. However, some patients do not respond and fail chemotherapy. HL is classified using the Ann Arbor scale (AA) and response to treatment with the Deauville criteria (DC), but this approach is insufficient to predict outcomes in some patients. Our objective was to evaluate the impact of tumor burden through PET parameters based on metabolic tumor volume (MTV), total lesion glycolysis (TLG), and Deauville criteria (DC) as predictors of response to treatment in Hodgkin lymphoma (HL). ***Materials and Methods:*** Patients with HL evaluated with initial and subsequent positron emission tomography/computed tomography (PET-CT) with ^{18}F-FDG were retrospectively included from November 2022 to April 2023. Information of clinical and tomographic markers was obtained. Percentages, median, interquartile range (IQR), Fisher exact, Mann-Whitney U with statistically significant p value <0.05 and relative risk (RR) with 95% confidence interval were calculated. ***Results:*** A total of 101 patients with HL were evaluated; 58 patients (53.4%) were men. The median age was 35 years (4-79 years). Higher MTV and TLG were significantly associated with unfavorable therapeutic response. Patients with favorable therapeutic response had initial median MTV of 24.68 mL, with IQR 54.55. Patiens with unfavorable therapeutic response had a median MTV of 38.86 mL, with IQR 168.36, p=0.03. In a subsequent study the median MTV was 5.67mL (IQR 30.42) and 41.04mL (IQR 191.64), p=0.002, respectively. Patients with favorable response, initial median TLG was 79.73 (IQR 215.59) and patiens with unfavorable response had a median TLG 113.97 (IQR 860.0), p=0.03). In the subsequent study, patints with favorable response TLG 16.49 (IQR 77.89) and with unfavorable response TLG 123.88 (IQR 634.38), p=0.002. For a favorable response, Deauville D2 had RR 2.97 (1.23-7.15), p=0.001. ***Conclusion:*** We conclude that MTV and TLG associated with Deauville criteria could be parameters to predict response to treatment in HL. Patients with low initial median MTV and TLG and low Deauville criteria will have a favorable therapeutic response. Higher MTV and TLG will be significantly associated with an unfavorable therapeutic response. ***References:*** Kanoun S, Rossi C, Berriolo RA. EP-0352

Impact of a Deep Progressive Reconstruction (DPR) Algorithm on Low-Dose or Fast-Scan PET Image Quality and Deauville Score in Patients with Lymphoma

W. Qiao[1], *T. Wang[1], H. Yi[2], Y. Lv[2], C. Xi[2], R. Wu[2], Y. Wang[2], Y. Xing[1], J. Zhao[1];*
[1]Department of Nuclear Medicine, Shanghai General Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, CHINA, [2]United Imaging Healthcare Group Co., Ltd, Shanghai, CHINA.

Aim/Introduction: A deep progressive learning method for PET image reconstruction named deep progressive learning reconstruction method (DPR) is developed and evaluated it with phantom and patient studies[1]. This has been shown in previous study that the DPR with one-third duration can maintain the image quality as OSEM with standard dose (3.7 MBq/kg)[2].As the clinical trials of the Deauville Score(DS) to the international guidelines were based on SUVmax measurements made with the use of the OSEM reconstruction algorithm, we found it necessary to explore the impact of DPR on DS of lymphoma patients from two aspects of low dose and fast scan respectively,

in order to explore the impact of DPR on image quality and DS. ***Materials and Methods:*** A total of 77 lymphoma patients underwent [18F]FDG PET imaging for during or post-treatment follow-up were prospectively enrolled. Fourty-four patients were injected with 1/3 standard dose (1.23 MBq/kg) and scanned for 6 minute per bed and were reconstructed: ordered-subsets expectation maximization (OSEM) with 6 minute per bed (OSEM_6min_1/3), OSEM with 2 minute per bed (OSEM_2min_1/3), and DPR with 2 minute per bed (DPR_2min_1/3). Thirty-three patients were scanned according to the standard protocol (standard dose group) (3.7 MBq/kg) and were reconstructed: OSEM with 2 minute per bed (OSEM_2min_full), OSEM with 40 second per bed (OSEM_40s_full), and DPR with 40 second per bed (DPR_40s_full). Additionally, a 5-point Likert scale measurement analysis was performed and DS for lymphoma were determined in different groups. ***Results:*** No significant difference was found between the OSEM_6min_1/3 and DPR_2min_1/3 groups in terms of liver SUVmax, mediastinal blood pool (MBPS) SUVmax, and Likert scale. In all 44 cases, the DS results were concordant (100%). Similarly, there was no significant difference between the OSEM_2min_full and DPR_40s_full groups regarding Liver SUVmax, MBPS SUVmax, and Likert scale. In all 33 cases, the DS results were concordant (100%). ***Conclusion:*** DPR reconstruction demonstrated feasibility in reducing PET injection dose or scanning time, while ensuring the preservation of image quality and DS for during or post-treatment follow-up patients with lymphoma. ***References:*** [1] Lv Y, Xi C. EP-0353

Improving lymphoma diagnosis, treatment and follow-up with F^{18} FDG PET-CT imaging: Contribution of Artificial Intelligence and Radiomics Analysis.

S. Hasanabadi[2], *S. Aghamiri[3,4], A. Abin[5], H. Arabi[6], H. Zaidi[6], M. Nejabat[1];*
[1]Radiology & Nuklearmedizin, Wien, AUSTRIA, [2]Radiology & Nuklearmedizin, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]medical radaiation engineering, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Medical Radiation Engineering, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Computer Science and Engineering, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Nuclear Medicine and Molecular Imaging, Geneva, SWITZERLAND.

Aim/Introduction: Lymphoma,a wide spectrum of immune system malignancies, presents significant complexities in its early detection, management, and prognosis assessment since it can mimic post-infectious/inflammatory diseases. Although molecular imaging modalities, such as positron emission tomography/computed tomography (PET/CT), specifically 18F-FDG PET/CT, hold significant importance in the diagnosis of lymphoma, prognostication, and assessment of treatment response, they still face significant challenges. Recently Artificial Intelligence (AI) used for detecting subtle features that may not be easily discerned by visual assessment. Radiomics and AI capabilities seem to be promiosing. This review aims to provide a perspective on the current literature regarding the application of AI and radiomics applied/extracted on/from 18F-FDG PET/CT in the management of lymphoma patients. ***Materials and Methods:*** We undertook a comprehensive exploration of the PubMed database using a set of search phrases and keywords. These search terms included: 'lymphoma', 'artificial intelligence', machine learning', 'radiomics', 'deep learning', and 'radiogenomics'. Our search covered from the year 2000 to October 1st, 2023. We used the Boolean operators 'AND' and 'OR' to combine the main terms and keywords, refining the search results.Publications with a wide range of diseases, conference papers, literature reviews, and articles in non-English languages were excluded using specific criteria to narrow down our study selection. ***Results:*** 155 articles were selected. After applying the specified inclusion/exclusion criteria, a total of 78 articles that were considered relevant. Up to 95% of the research were retrospective.The predominant approach in lymphoma research was using radiomics or a combination of radiomics with AI for disease progression and outcome prediction.Radiomics and AI are used in diagnosis , risk assesment , possibility of Bone Marrow infiltration and differentiation of different lymphoma subtypes as well as outcome prediction. ***Conclusion:*** AI holds great promise in enhancing the quality of 18F-FDG PET imaging, particularly in cases where structural imaging is unavailable. Nevertheless there are still several formidable hurdles that must be overcome to practically implement AI-based physician assistant tools in clinical settings. One of the key challenges is the availability of large and diverse datasets. Efforts should be made to collect and curate datasets that encompass a wide range of patient demographics, disease stages, and image variations. Additionally, validation through multi-center studies is crucial. In light of the growing integration of AI and radiomics, it is rational to posit that the outcomes of these research endeavors will make substantial contributions to the enhancement of patient management in the foreseeable future.

EP-0354

Harmonisation of conventional and advanced methods of image reconstruction and analysis in the FDG-PET assessment of therapy response in lymphoma

A. Harman[1], *M. Yakubu[1], J. Dunn[1], G. Krokos[1], A. Pettitt[2,3], A. Davies[4], G. Collins[5], V. Warbey[1], M. Subesinghe[1], P. Marsden[1], S. Barrington[1];*
[1]King's College London & Guy's and St Thomas' PET Centre, Division of Biomedical Engineering and Imaging Sciences, King's College London, London, UNITED KINGDOM, [2]Department of Molecular and Clinical Cancer Medicine, University of Liverpool, Liverpool, UNITED KINGDOM, [3]The Clatterbridge Cancer Centre NHS Foundation Trust, Liverpool, UNITED KINGDOM, [4]Southampton NCRI/Cancer Research United Kingdom Experimental Cancer Medicines Centre, University of Southampton, Southampton, UNITED KINGDOM, [5]Oxford Cancer and Haematology Centre, Churchill Hospital, Oxford, UNITED KINGDOM.

Aim/Introduction: In lymphoma, modern technology including advanced reconstructions give more 'positive' FDG-PET reads than established technology using the 5-point Deauville score (DS) for response and creates challenges for PET harmonisation. Alternatives to commonly used maximum standardised uptake value (SUVmax) measurements e.g. peak and mean SUV are being explored to improve harmonisation. Our aims were to: a) quantify the change in DS and tumour-to-liver ratio (TLR) moving from conventional iterative to advanced reconstructions and using alternative SUV measurements, and b) evaluate the relationship between standard and alternative methods across lymphoma subtypes. ***Materials and Methods:*** PET-CT scans were assessed from 3 clinical trials, with subtypes Hodgkin/HL, diffuse large B-cell/DLBCL and follicular/FL lymphomas. DS and TLR were determined, for the hottest residual lymphoma lesion,

in two ways for each scan, 'TLR1' - EARL1-compliant iterative reconstruction; SUVmax for lesion, liver and mediastinal blood pool (MBP), 'TLR2' - EARL2-compliant point spread function modelled reconstruction; SUVpeak for lesion and SUVmean for liver and MBP. TLR was categorised as ≤1, >1 to <2, ≥2 to <3, 3+ where a change of category reclassifies patient response. The relationship between TLR1 and TLR2 was evaluated using scans from 2 of the trials with the equation describing the relationship applied to measurements from the third trial to assess change in DS and TLR categorisation, with the process repeated three times. ***Results:*** 289 scans were included from 3 trials involving HL (n=45), DLBCL (n=114), and FL lymphoma patients (n=130). Moving from TLR1 to TLR2, 33% of patients changed DS and 30% changed TLR category, 20% from 'responders' (TLR≤1) to 'non-responders' (TLR>1). The relationship between TLR1 and TLR2 was linear with slopes of 1.42, 1.49, and 1.39 and intercepts of -0.09, -0.16, and -0.08 for the 3 evaluations, respectively. There was a near perfect correlation with R2 = 0.985, 0.985 and 0.9855 for the 3 comparisons. When TLR1 measurements were scaled using the equation describing the relationship between TLR1 and TLR2, they agreed very closely with the actual TLR2 measurements; in 93% of cases the TLR varied by ≤0.5 and in 89% HL, 93% DLBCL and 95% FL patients the TLR category was unchanged. ***Conclusion:*** Careful evaluation is required before adopting new methods for response assessment in lymphoma. Evidence-based criteria using the DS and TLR from large clinical trials using EARL1 technology remain valid with new EARL2 compliant technology by application of a simple scaling factor across lymphoma subtypes.

EP-0355

AI-based Automated Segmentation Algorithm Enables Total Metabolic Tumor Volume Estimation in Non-Hodgkin Lymphoma

E. Romano Gargarella[1], *F. Vocaturo[1], F. D'Alo[2], E. Alma[2], E. Maiolo[2], S. Hohaus[3], A. Giordano[1], L. Leccisotti[1];*
[1]Section of Nuclear Medicine, Department of Diagnostic Imaging and Radiation Oncology, Università Cattolica del Sacro Cuore, Roma, ITALY, [2]Unit of Hematology, Department of Diagnostic Imaging and Radiation Oncology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, ITALY, [3]Section of Hematology, Department of Diagnostic Imaging and Radiation Oncology, Università Cattolica del Sacro Cuore, Roma, ITALY.

Aim/Introduction: The current lymphoma staging system might be improved by including Total Metabolic Tumor Volume (TMTV), but its clinical implementation is still challenging. This study aims to assess the ability of an AI-based automated segmentation algorithm to identify regions from which TMTV could be automatically calculated and to evaluate the ability of the resulting TMTVs in predicting patient outcome in NHL. ***Materials and Methods:*** This is a single-center retrospective study including newly diagnosed NHL patients who underwent FDG PET/CT using an EARL accredited digital scanner from March 2020 to January 2024. TMTVs were calculated using an AI-based automated segmentation algorithm (Siemens Healthineers; PERCIST-recommended liver-based threshold for lesion identification with 41%SUVmax and 4.0SUVmax thresholds for lesion segmentation). Two independent observers rated the success or failure of the tool to classify FDG-avid lesions and delineate visible tumor, adding new regions or removing erroneous regions such as sites of FDG excretion and physiologic uptake (sFEPU). Scans requiring no interaction or less than 2 editing steps were rated as a success while scans that missed more than 50% of the visible tumor or required more than 2 editing steps were rated as failure. Time to results calculated from lesion identification to TMTV computation was also noted. ROC curve analysis was used to investigate the discrimination performance of both SUV4.0 and SUV41% TMTVs for prediction of PFS and OS. ***Results:*** Seventy-four patients were finally assessed (43% males, median age 65 years; 55% DLBCL, 20% PMBL, 25% others). Interobserver agreement was 95% for SUV4.0 and 90% for SUV41%, respectively. Median time to results was 41sec and 69sec with SUV4.0 and SUV41% respectively (p=0.12). TMTVs were greater using SUV4.0 than SUV41% (p=0.016). A high correlation (r=0.93) was observed between TMTVs derived from the 2 thresholds. SUV4.0 performed better than SUV41% method with higher success and lower failure rates (34% vs 24% and 66% vs 76%, respectively). The most common reason for failure in SUV41% was the inclusion of sFEPU in 31 (55%) pts, while for SUV4.0 was the missing of lesions in 26 (53%) pts. High SUV4.0 and SUV41% TMTVs (>618 and >198 cm3 respectively) were associated with a worse PFS (p<0.002); high SUV4.0 and SUV41% TMTVs (>388 and >248 cm3 respectively) were also associated with a worse OS (p<0.01). ***Conclusion:*** AI-based automated segmentation algorithms may considerably simplify TMTV estimation, reduce observer variability, and facilitate the use of TMTV as a predictive factor in NHL.

EP-0356

Dmax or SDmax may help for prognostic stratification in DLBCL with interim PET Deauville Standard 3

X. Chen, *X. Sun, Y. Zhang, R. An, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medica College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: iPET DS 3 patients are classified as complete metabolic response (CMR) in the guidelines, despite still having lesions with higher than background uptake. The prognostic assessment's value and significance remain controversial. This study aims to investigate the utility of ^{18}F-FDG PET imaging in risk stratification of DLBCL iPET DS 3 patients, with the goal of informing clinical treatment decisions. ***Materials and Methods:*** A retrospective analysis was conducted on patients who were diagnosed with DLBCL and underwent PET examination from January 2017 to December 2020. A total of 28 iPET DS 3 patients were included. The included clinical indicators: age, gender, Ann-Arbor stage, number of extranodal involvement, ECOG score, LDH, Hans classification, CD5, Bcl-2, C-Myc, and double expression. The included baseline PET metabolic indicators: metabolic tumor volume (MTV) and total lesion glycolysis (TLG) measured by threshold 41% SUVmax and 4. The included baseline tumor spread parameters: Dmax (the farthest distance between centroid of two lesions) and body surface area standardized Dmax (SDmax). The included iPET metabolic indicators: DS score, ΔSUVmax% and lesion-to-liver SUVmax ratio(LLR). The follow-up method used case collection and telephone follow-up, with a median follow-up time of 54 months. ***Results:*** In this study, 28 patients with DLBCL iPET DS 3 were analyzed, comprising 14 males and 14 females, with a median age of 46 years (range 19-74 years). The 3-year PFS and OS rates were 67.8% and 85.7% respectively, while the 5-year rates were 64.3% and 82.1% respectively. Univariate regression analysis identified MTV measured by threshold 4(P=0.047), Dmax(P=0.0048), and SDmax(P=0.0048) as risk factors for PFS in DLBCL iPET DS 3 patients. Furthermore, multivariate regression analysis indicated that Dmax or SDmax independently impacted PFS in these patients(P=0.02). ROC analysis showed that both SDmax(AUC:3-year-PFS 0.760 P=0.024; 3-year-OS 0.927 P=0.007) and Dmax (AUC:3-year-PFS 0.789 P=0.012; 3-year-OS 0.927

P=0.018)could predict PFS and OS in patients with DLBCL iPET DS 3, while IPI (AUC:3-year-PFS 0.678 P=0.104; 3-year-OS 0.869 P=0.018)had limited predictive value in PFS. ***Conclusion:*** In DLBCL iPET DS 3 patients, both Dmax and SDmax before treat are identified as independent risk factors. This implies that including SDmax and Dmax in clinical practice could provide added value in risk assessment and clinical decision-making for these patients. However, further validation of these findings is necessary in multiple centers and with larger sample sizes.

EP-0357

Prognostic value of pre-treatment ^{18}F-FDG PET/CT in non-Hodgkin's lymphoma patients receiving chimeric antigen receptor T-cell therapy

S. Mirshahvalad[1], *A. Kohan[1], R. Kulanthaivelu[1], C. Chen[2], D. Hodgson[2], R. Kridel[2], S. Bhella[2], U. Metser[1], P. Veit-Haibach[1];*
[1]University Medical Imaging Toronto, Toronto Joint Department Medical Imaging, University Health Network, Sinai Health System, Women's College Hospital, University of Toronto, Toronto, ON, Canada, Toronto, ON, CANADA, [2]Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada, Toronto, ON, CANADA.

Aim/Introduction: To evaluate the prognostic value of pre-treatment 18F-FDG-PET/CT in non-Hodgkin's lymphoma (NHL) patients undergoing chimeric antigen receptor T-cell (CAR-T). ***Materials and Methods:*** In this IRB-approved retrospective study, we reviewed patients treated with CAR-T between 2018 and 2023. The inclusion criteria were NHL patients with 18F-FDG-PET/CT prior to CAR-T infusion. Overall, 129 patients fulfilled the inclusion criteria. All had histopathology-proven diffuse large B-cell lymphoma and were diagnosed with relapsed/refractory disease. 18F-FDG-PET/CT was conducted based on the standardized protocol (EARL-compliant). Two expert physicians in consensus interpreted scans. Cases with Deauville scores IV/V were considered to have a significant disease burden. SUVs (max/mean/peak), whole-body metabolic tumour volume (MTV; 41%threshold) and whole-body total lesion glycolysis (TLG) were calculated. Additionally, the furthest distance between tumoral lesions throughout the body (Dmax) and their maximum distance from the spleen (spleen Dmax) were calculated. Progression-free survival (PFS) was defined as the time from CAR-T infusion until relapse, progression, death, or the last follow-up date. Overall survival (OS) was defined as the time from CAR-T infusion until patient death or the last follow-up date. Among 18F-FDG-PET/CT-derived variables with high collinearity (three main groups: "SUVs", "MTV/TLG", and "Distances"), we selected parameters with the highest prognostication (stepwise selection). The statistical significance level was set at a two-sided p-value <0.05. ***Results:*** Overall, 129 patients (mean age of 59y) with pre-CAR-T 18F-FDG-PET/CT (median interval of 12 days) were studied. Among them, 117/129 (91%) were positive for an 18F-FDG-avid significant residual disease. The median PFS and OS were 181 and 277 days after CAR-T, respectively. Notably, 35/117 (30%) deaths were documented during follow-up, with a median of 173 days. Among the baseline parameters, serum lactate dehydrogenase (LDH) level, SUVmax, SUVmean, SUVpeak, SUVmax-to-Liver background, SUVmean-to-Liver background MTV, TLG, Dmax and spleen Dmax were significant predictors of PFS (p-values<0.05). In a multivariate assessment, LDH (hazard ratio [HR]=1.69; 95%CI:1.00-2.85) and TLG (HR=4.55; 95%CI:1.06-19.61) retained their significance. Considering OS, the significant baseline parameters (p-values<0.05) were LDH, SUVmax-to-Liver background, MTV, TLG, Dmax and spleen Dmax. The only variable which retained its significance in the multivariate analysis was standardized Dmax (HR=3.28; 95%CI:1.16-9.34). ***Conclusion:*** Baseline 18F-FDG-PET/CT can provide valuable prognostic information in patients receiving CAR-T therapy. In particular, it may help clinical decision-making management by identifying patients with poor survival. The amount of whole-body glycolysis shown by 18F-FDG-PET/CT, as well as the extent of the disease on the scan, are of significant value in terms of survival prognostication.

EP-0358

Can we obtain prognostic information from healthy organ volume and uptake in baseline ^{18}F-FDG PET/CT imaging in Diffuse large B-cell lymphoma?

N. Gerards[1], *G. J. C. Zwezerijnen[1], S. E. Wiegers[1], A. L. Bes[1], P. J. Lugtenburg[2], J. M. Zijlstra[1], R. Boellaard[1];*
[1]Amsterdam UMC, Amsterdam, NETHERLANDS, [2]Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: 18F-FDG PET/CT tumor uptake measures provide prognostic information in diffuse large B-cell lymphoma (DLBCL) patients. However, most studies so far focused on assessing tumor uptake and metabolic tumor volume only. Our objective is to explore if volume and 18F-FDG uptake of healthy organs contain added prognostic value. ***Materials and Methods:*** In this study, 264 newly diagnosed DLBCL patients from the HOVON 84 trial were included. Progression-free survival was assessed two years after starting treatment and dichotomized as either progression or no progression. Automatic segmentation of the anatomical structures was performed on the low-dose CT images using TotalSegmentator (1), followed by manual adjustments if needed. Tumor lesions were outlined using a semi-automated segmentation method (standardized uptake value ≥ 4) and subtracted from the organ segmentations. Volume, mean standardized uptake value (SUVmean), and total lesion glycolysis (TLG) were determined for the spleen, liver, kidneys, lungs, and brain and group differences between patients with and without progression were calculated. As half-body PET-scans were available, only the SUVmean was determined for fat, bone, and skeletal muscle and compared between groups. ***Results:*** Patients with progression (n = 45) showed significantly lower SUVmean and TLG values in the brain, and a lower SUVmean in skeletal muscle. However, the within-group variability hampered the discriminatory power between the two groups. No statistically significant differences of volume, SUVmean, and TLG were observed in any other investigated organ. Moderate negative correlations were found between the SUVmean of the liver and brain (r = -0.43, r = -0.50) and TLG of the tumor. We calculated an organ-to-blood ratio to adjust for 18F-FDG supply by dividing the SUVmean of the anatomical structures by the SUVmean of the metabolic blood pool. After this correction, patients with progression showed a significantly higher ratio in the spleen and fat tissue. ***Conclusion:*** Although there are group differences in 18F-FDG uptake in healthy organs between DLBCL patients with and without progression, the within-group variabilities are presumably too large to contribute to identifying patients at risk for progression. ***References:*** 1. Wasserthal et. al. DOI: https://doi.org/10.1148/ryai.230024.

EP-0359

Inter-observer agreement in the measurements of sarcopenia-related parameters (skeletal muscle and adiopse tissue area) with low-dose attenuation correction CT of ^{18}F-FDG PET/CT in elderly hodgkin lymphoma

D. Albano[1], *S. Vio[2], F. Bergesio[3], S. Chauvie[3], A. Versari[4], V. Tarantino[5], C. Villano[6], V. R. Zilioli[7], A. Tucci[8], A. Arcari[9], F. Elisei[10], L. Guerra[11];*
[1]University of Brescia and Spedali Civili of Brescia, Brescia, ITALY, [2]Padova University Hospital, Padova, ITALY, [3]Medical Physics Division, Santa Croce e Carle Hospital, Cuneo, ITALY, [4]Nuclear Medicine Unit, Azienda Unità Sanitaria Locale IRCCS, Reggio Emilia, ITALY, [5]Division of Hematology, Azienda Ospedaliera Ospedali Riuniti Villa Sofia-Cervello, Palermo, ITALY, [6]Department of Nuclear Medicine and Radiometabolic Therapy, "Spirito Santo" Hospital, Pescara, ITALY, [7]Division of Hematology, ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY, [8]ASST Spedali Civili of Brescia, Brescia, ITALY, [9]Hematology and Bone Marrow Transplant Unit, Guglielmo da Saliceto Hospital, Piacenza, ITALY, [10]Department of Nuclear Medicine, Fondazione IRCCS San Gerardo dei Tintori University of Milano Bicocca, Monza, ITALY, [11]Department of Nuclear Medicine, Fondazione IRCCS San Gerardo dei Tintori University of Milano Bicocca, Monza, ITALY.

Aim/Introduction: Sarcopenia is defined as the loss of the skeletal muscle mass and function and it is mainly a phenomenon age-related. Currently, high dose computed tomography (CT) seems to be the most accurate, diffuse and reproducible tool to assess sarcopenia. The fluorine-18-fludeoxyglucose positron emission tomography/CT (^{18}F-FDG-PET/CT) scan includes a low-dose CT whose aim is the attenuation correction and the anatomical localization of radiotracer uptake. Preliminary evidence underline a potential usefulness of CT part of PET/CT to estimate sarcopenia-parameters. Our study aims to investigate the inter-observer agreement in the measurements of the skeletal muscle and adipose tissue area in elderly Hodgkin Lymphoma (HL) by low-dose CT of PET/CT. ***Materials and Methods:*** This is a prospective observational multicentric study enrolled into the Fondazione Italiana Linfomi (FIL). We recruited 69 patients with a confirmed histological diagnosis of HL and aged ≥65 at the time of diagnosis. Two readers (a radiologist and a nuclear medicine physician) measured skeletal muscle and adipose area using the software Coreslicer. An axial section at third lumbar vertebra was used to measure the skeletal muscle area (SMA) considering psoas, paraspinal, abdominal transverse rectum, internal and external obliques and visceral, subcutaneous and intramuscular adipose tissue (VAT, SAT, IMAT). CT HU thresholds were -29 to 150 for SMA, -190 to -30 for SAT and IMAT, and -50 to -150 for VAT. The intraclass correlation coefficient(ICC) and Bland-Altman plot were applied for the calculation of interobserver agreement. ***Results:*** For SMA, only in 3 (2%) scans the difference in the measurements between the two readers was higher than 10% (a value considered arbitrary as significant); for SAT in 5 (3%) scans and for VAT in 10 (6%) scans. For IMAT the difference was higher than 10% in most studies (n=74, 54%). Inter-observer agreement was very good for SMA (ICC=0.98), SAT (ICC=0.98) and VAT (ICC=0.95), while moderate for IMAT (ICC=0.68). Applying Bland-Altman analysis, the mean difference between the two readers was low, with 0.2% for SMA (limits of agreement -27.5 to 27.9), 1.4% for SAT (limits of agreement -16.6 to 16.7), 0% for VAT (limits of agreement -44.4 to 47.2), and 2.1% for IMAT (limits of agreement -5.2 to 9.3). ***Conclusion:*** CT of PET/CT is a safe, accurate and precise method for the measurements of skeletal muscle area, visceral and subcutaneous adipose tissue. Inter-observer agreement for the measurement of sarcopenia parameters assessed on low-dose CT of PET/CT was very good, except for IMAT.

Gemelli IRCCS, Rome, ITALY, [4]Medipass S.p.a. Integrative Service PET/CT - Radiofarmacy TracerGLab, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY, [5]Nuclear Medicine Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS; Section of Nuclear Medicine, Department of Diagnostic Imaging, Oncological Radiotherapy and Haematology, Università Cattolica del Sacro Cuore, Rome, ITALY, [6]Department of Diagnostic Imaging, Oncological Radiotherapy and Haematology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY, [7]Nuclear Medicine Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY.

Aim/Introduction: Patients with low tumour burden follicular lymphoma (FL) are managed with a watchful waiting (WW), starting chemotherapy after the onset of symptoms. Clinical prognostic models used at staging, including the follicular lymphoma international prognostic index (FLIPI), only poorly identify patients at elevated risk of progression. 18F-FDG PET/CT in FL is recommended for staging, particularly to determine disease extension and metabolic burden. This study investigated whether radiomic features extracted from baseline PET/CT could improve the prediction of starting treatment in FL patients on WW. ***Materials and Methods:*** Thirty-eight patients on initial WW (grade 1-3a), with a baseline PET/CT and a follow-up ≥24 months, were retrospectively included at Fondazione Policlinico A. Gemelli IRCCS of Rome from 2010 to 2019. Metabolic tumour burden was obtained using an automatic whole-body segmentation (LesionID, MIM-Software Inc.). Time to treatment (TTT) was calculated from the date of diagnosis until the date of starting the systemic therapy. Eighty-one morphological and first-level intensity radiomic features were extracted from the metabolic tumour burden, the lesion having the highest SUVmax and a reference region-of-interest (ROI) placed in the healthy liver. A linear regression (LR) model and an SVM classification model were constructed to assess the feasibility of using PET-derived radiomic features to predict TTT. We implemented four different models increasing the number of predictors from one to four for each model. A leave-one-out cross-validation approach was used to assess the model performance on an independent dataset. ***Results:*** For LR models, we found a root-mean-squared-error (RMSE) of 29.7, 28.4, 26.0, 25.3 and a R2 of 0.01, 0.09, 0.02, 0.28, computed over the test set, respectively using incrementally from one to four features. Accordingly, the best model was the last, using the following features: liver ROI minimum SUV value, suv-max ROI morphological asphericity, overall homogeneity in the tumour burden, elongation after principal component analysis of the suv-max ROI. For SVM models, an accuracy of 0.79, 0.76, 0.68, 0.63 and an AUC of 0.86, 0.81, 0.80, 0.75 were found incrementing the features from one to four. Thus, the best performing model used one feature, such as the overall centre of mass shift within the lesions. ***Conclusion:*** Some radiomic features obtained from baseline PET/CT could predict TTT of FL patients on WW. It is mandatory to explore the biologic mechanism underlying radiomic features in a larger and prospective assessment to

validate their integration with FLIPI and other clinical parameters. (Ricerca Finalizzata GR-2019-12370372)A.

EP-0361

White blood cell counts as a predictive marker to determine the pretest staging on ^{18}F-FDG PET/CT in Hodgkin's lymphoma patients.

B. Nayak, *S. Sagar, S. Kanankulam Velliangiri, D. Khan, A. Gawande, S. Sharma, L. Goriparti, A. Tilak, J. Krishna P, M. Tripathi, R. Kumar, C. Bal, K. Jain, R. Wakankar; ALL INDIA INSTITUTE OF MEDICAL SCIENCES, New Delhi, INDIA.*

Aim/Introduction: ^{18}F-FDG PET/CT scan is used to stage Hodgkin's lymphoma with Ann Arbor stage 1 & 2 classified as low risk and stage 3 & 4 as high risk based on the prognosis. In this study we aimed to assess the predictive value of the WBC (White blood cell) counts to stage low and high risk Hodgkin's lymphoma. ***Materials and Methods:*** We conducted a retrospective study in a tertiary care centre of India, during the period of November 2023 to April 2024. 76 biopsy proven Hodgkin's lymphoma patients were included with baseline (pre-treatment) ^{18}F-FDG PET/CT data , out of which complete clinical data of 33 patients were not available. After staging the included patients, based on the ^{18}F-FDG PET/CT, the WBC counts of these patients were classified into two groups. Group 1 consists of WBC counts of the low risk lymphoma patients and group 2 consists of WBC counts of the high risk lymphoma patients. Statistical analysis was done using IBM-SPSS software version 26. ***Results:*** In this study, we included a total of 43 patients (14 low risk, 29 high risk), in which 11 (8 male, 3 female) were pediatrics (<18 years) patients with a mean age of 9.45 ± 4.63 years while 32 (22 male, 10 female) were adults (>18 years) patients with a mean age of 37.75 ± 13.7 years. The mean WBC count of group 1 and group 2 was (8.43 ± 2.8 x 109/L) & (11.43 ± 5.07 x 109/L). Unpaired T test was applied to look for significance of WBC counts between the two groups, which depicted significant (p=0.043) difference in the WBC counts of low risk and high risk Hodgkin's lymphoma patients staged by ^{18}F-FDG PET/CT. ***Conclusion:*** The WBC counts were significantly different between low risk and high risk groups of lymphoma patients, concluding that WBC counts can be used as a parameter to predict the pretest ^{18}F-FDG PET/CT staging of Hodgkin's lymphoma patients. However, Larger sample size studies are warranted to validate this study and pin point the cut-off level of WBC counts.

EP-0362

Prognostic value of massiveness parameters measured on baseline FDG PET in advanced-stage Hodgkin lymphoma

S. Draye-Carbonnier[1], *S. Mihailescu[1], P. Pinochet[1], E. Texte[2], A. Stamatoullas-Bastard[1], P. Vera[1], S. Becker[1], P. Decazes[1]; [1]Henri Becquerel Centre, Rouen, FRANCE, [2]Centre d'Explorations Isotopiques, Rennes, FRANCE.*

Aim/Introduction: The prognostic value of radiomic quantitative features measured on pre-treatment 18F-FDG PET/CT was investigated in patients with advanced-stage Hodgkin lymphoma (HL). ***Materials and Methods:*** We conducted a retrospective study of 176 HL patients diagnosed between 2006-2017. A dozen of PET/CT-derived features were extracted via Oncometer3D from baseline 18F-FDG PET/CT images. The receiver operating characteristic (ROC) curves, Kaplan-Meier method and Cox analyses were used to assess the prognostic factors for Overall Survival (OS) and Progression-Free Survival (PFS) censored at 5 years. ***Results:*** Four different clusters were identified among the twelve PET parameters analyzed: activity, tumor burden, fragmentation-massiveness and dispersion. On ROC analyses, medEDGE, the median edge distance had the highest AUC for OS (0.72) and PFS (0.6). Patients with high baseline medEdgeD had a significantly worse PFS (HR=1.02; p=0.04) and OS (HR=1.03; p=0.003) in both Kaplan-Meier and Cox univariate analyses. Furthermore, medEdgeD remained statistically significant in a multivariate analysis including various TEP and clinical parameters used in daily routine. In addition, in sub-group analyses, we highlighted the significantly worst prognosis for patients with bulky disease, treated with ABVD and with high baseline medEdgeD value. ***Conclusion:*** PET parameters describing massiveness appeared to be significantly correlated with prognosis in HL patients for OS and PFS, notably the medEdgeD. ***References:*** Draye-Carbonnier S, Camus V, Becker S, et al. Prognostic value of the combination of volume, massiveness and fragmentation parameters measured on baseline FDG pet in high-burden follicular lymphoma. Sci Rep. 2024;14:8033.

Can metabolic parameters of ^{18}F FDG PET predict cell of origin classification of Diffuse Large B-cell lymphoma (DLBCL) ?

S. Choudhury, *V. Rangarajan, A. Agrawal, S. Ghosh, N. Purandare, S. Shah, A. Puranik, J. Sastri Goda; Tata Memorial Hospital, Mumbai, INDIA.*

Aim/Introduction: Depending on the cell of origin DLBCL can be broadly classified into two groups, Germinal center B -Cell like subtype (GCB) and nonGCB group or Activated B-cell (ABC) subtype. Non-GCB DLBCL is known to be associated with unfavorable prognosis (1). ^{18}F FDG PET is the investigation of choice for staging DLBCL. However, correlation between the COO classification and PET derived SUV parameters have rarely been investigated. In this study, we aim to see if there is any correlation between SUVmax and COO subtypes of DLBCL. ***Materials and Methods:*** This retrospective observational analysis includes 70 patients who have undergone pretreatment ^{18}F FDG PET/CT during the period of 2017-2021 and have complete histopathology report(HPR) available. The scans of the patient were reviewed by an experienced Nuclear Medicine Physician, who was blinded to the HPR data. The hottest lesion in each scan was selected and SUVmax was evaluated. Hans algorithm based on expression of three markers, CD10, BCL6 and MUM1 was used to differentiate between GCB and non-GCB DLBCL. Mann-Whitney U Test was used to assess the mean SUVmax between GCB and nonGCB DLBCL. ROC analysis and Youden Index was used to find a SUVmax cut off. Chi square test was used to further validate the cut off. ***Results:*** Of the 70 patients 18 were stage I, 19 stage II, 20 stage III, 13 stage IV. Patients were classified into GCB and non GCB subtypes equally, 35 each. The median SUVmax between the GCB and non GCB subtypes were 23.7 (range 5.48-50.45) and 29.1 (range 7.25-64.81) respectively. The mean SUVmax between the GCB and non GCB subtypes were 29.54 and 41.46(p value=0.014; r=0.3, moderate effect size). Using ROC analysis a SUVmax cutoff of 20 was found (sensitivity=83%, specificity 43%, AUC=0.670, p value=0.014). 73% of the cases with SUVmax <20 were correctly identified as GCB subtype and 60% of the cases with SUVmax > 20 were correctly identified as non GCB subtype (p value 0.019). ***Conclusion:*** SUVmax in GCB subtype of DLBCL was found to be significantly higher than that of nonGCB type DLBCL, however, the effect size was moderate. ***References:***

EP-0364

The Role of Quantitative PET parameters in the identification of non-responsive patients withrelapsed/refractory large B-cell Lymphoma treated with chimeric antigen receptor T-cell therapy

R. Ussia[1], *A. Farolfi[2], B. Casadei[3], A. Paccagnella[1], C. Malizia[2], L. Argnani[1], P. Zinzani[1], S. Fanti[1];*
[1]Department of Medical and Surgical sciences (DIMEC), University of Bologna, Bologna, ITALY, [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna: Nuclear Medicine, Bologna, ITALY, [3]IRCCS Azienda Ospedaliero-Universitaria di Bologna: Istituto di Ematologia "Seràgnoli", Bologna, ITALY.

Aim/Introduction: CAR T-cell therapy has shown remarkably efficacy in treating relapsed/refractory large B-cell lymphomas (LBCLs). However, response to therapy varies among patients with approximately half of them progressing or relapsing within one year after treatment. F^{18} fluorodeoxyglucose positron emission tomography/computed tomography (PET/CT) is commonly used to assess treatment response, typically using Deauville score (DS), a visual scale. ***Materials and Methods:*** We investigated whether PET semiquantitative parameters (SUVmax, total lesion glycolysis [TLG], and metabolic tumor volume [MTV]) measured before CAR T-cell infusion (PET0) and one month after (PET1) could better identify non-responder patients. MTV, TLG, SUVMax, DS and variations of these parameters between the two scans were calculated and associated with the durationof response (DoR), overall survival and progression free survival. ***Results:*** We prospectively enrolled 61 consecutive patients with a diagnosis of LBCL treated at our institution. The median follow-up was 18 months (30% women, median age 59 years with 75.4% who received a bridging therapy to CAR T). Median PET0 parameters were 125 ml for MTV, 728.8 g for TLG and 17.6 for SUVmax, respectively, whereas at PET1 were 1.9 ml, 5.0 g, and 4.4, respectively. Twenty-eight (45.0%) patients died during follow-up with an overall survival of 51.6% at 3.5 years. Patients with SUVMaxPET0 >14.75, TLGPET0 > 571.768 g, PET1MTV > 60.8 ml, TLGPET1 > 97.0 g and DS PET1 ≥4 had a statistically significant increased risk of death (all $p < 0.05$). Patients with MTVPET0 > 109.9 ml, SUVMaxPET0 > 11.8, TLGPET0 > 571 g, MTV PET1 > 48.3 ml, TLG PET1 >v204 g and PET1 DS ≥4 had a statistically significant increased risk of disease progression (all $p < 0.05$). Patients with MTVPET0 > 225.7 ml and TLGPET0 > 728.8 g, were associated with a statistically significant reduced DoR. Also, MTVPET1 was associated with longer DoR. ***Conclusion:*** PET semiquantitative parameters measured both before and one month after CAR T-cell infusion demonstrate significant correlation with overall survival, progression free survival and DoR. These findings suggest that PET-based metrics should be considered for early treatment decisions in LBCL patients. overall survival, progression free survival and DoR.

EP-0365

Assessment of bone marrow involvement in patients with follicular lymphoma: Correlation between ^{18}F-FDG PET/CT and bone marrow biopsy

R. M. Angulo Amorese[1], *J. Rodríguez Gómez[1], F. Pena Pardo[1], E. Noriega-Álvarez[2], M. Sicilia Pozo[1], J. Gatón Ramírez[1], C. Lucas Lucas[1], F. López-Bermejo García[1], M. Contreras Ameduri[1], G. Molina Mendoza[1], M. Carrero Lérida[1], A. Padilla Bermejo[1], M. Talavera Rubio[1], V. Poblete García[1];*
[1]Nuclear Medicine Department, University General Hospital of Ciudad Real, Ciudad Real, SPAIN, [2]Nuclear Medicine Department, University Hospital of Guadalajara, Guadalajara, SPAIN.

Aim/Introduction: To analyse the correlation between the results of bone marrow (BM) biopsy and the findings of the 18F-FDG PET/CT in the assessment of BM involvement (BMI), as well as its diagnostic accuracy. ***Materials and Methods:*** Retrospective analysis of 105 consecutive patients with follicular lymphoma (FL) undergoing 18F-FDG-PET/CT staging scan between January/2017 and November/2020, and BM biopsy. Eight patients were excluded due to inconclusive results or absence of biopsy. Hypermetabolic foci higher than the hepatic pool with/without CT lesions and/or diffuse hypermetabolism in the BM greater than the hepatic pool (having ruled out other causes such as moderate/severe anaemia or active infectious process) were considered as suspicious of BMI in 18F-FDG-PET/CT. Statistical analysis was performed calculating kappa index, and sensitivity (S), specificity (E), positive predictive value (PPV), negative predictive value (NPV) and diagnostic accuracy (Ac) were calculated. ***Results:*** Ninety-seven patients (47 women), with a mean age of 59.6 years (13-86), were finally included. Forty-one BM biopsies were reported as positive and 56 as negative, whereas only 25 18F-FDG-PET/CT scans were considered having BMI (versus 42 negative). Statistical metrics were as follows: Kappa index of 0.362, statistically significant ($p<0.001$); S= 61%, E= 75%, PPV= 64.1%, NPV= 72.4%, and Ac= 69.1%. ***Conclusion:*** 18F-FDG-PET/CT showed a weak concordance with BM biopsy and only a moderate diagnostic Ac for BMI assessment in FL. Therefore, given the prognostic importance of a correct initial staging in patients with FL, the BM biopsy cannot be avoided based on a negative 18F-FDG-PET/CT scan.

EP-0366

Measuring maximum tumour dissemination (Dmax) in diffuse large B cell and follicular lymphoma in ^{18}F-FDG PET/CT. Which method is preferable in clinical practice?

F. López-Bermejo García[1], *J. Rodríguez Gómez[1], M. Contreras Ameduri[1], R. Angulo Amorese[1], E. Noriega Álvarez[1], F. Pena Pardo[1], M. Sicilia Pozo[1], J. Gatón Ramírez[1], M. Amo Salas[2], S. Pozuelo Campos[2], A. Padilla Bermejo[1], M. Talavera Rubio[1], V. Poblete García[1];*
[1]Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN, [2]Universidad de Castilla la Mancha, Ciudad Real, SPAIN.

Aim/Introduction: To evaluate the differences between measuring maximum tumour dissemination (Dmax) from centre to centre (Dmax1) or from top to bottom margins (Dmax2) of the lesions in patients with diffuse large B cell and follicular lymphomas (DLBCL and FL) in staging PET-CT scans. And to analyse the role of normalizations for body surface area (BSA) and height in calculatingDmax. ***Materials and Methods:*** A retrospective observational study including consecutive patients diagnosed with DLBCL or FL between January/2016-May/2019 was conducted. The distance (in millimetres) between the two most distant lesions was measured from centre to centre (Dmax1) and from top margin to bottom margin (Dmax2) These distances were additionally normalized by height (HDmax) and BSA (SDmax), obtaining 6 different measurements in both DLBCL and FL: Dmax1, Dmax2,HDmax1, HDmax2, SDmax1 and SDmax2.The differences between Dmax1/2, HDmax1/2, and SDmax1/2 were assessed using paired sample analysis and their Hazard Ratio (HR) for disease free survival (DFS) was compared with a Cox regression

analysis. ***Results:*** One hundred and forty-three DLBCL patients with a mean age of 64.6 years were evaluated, obtaining the following mean distances: Dmax1 355.8, Dmax2 382.9, SDmax1 195.8, SDmax2 210.4, HDmax1 217.6, and HDmax2 234.1 mm. One hundred and seven FL patients were also studied, obtaining: Dmax1 480.2, Dmax2 496.7, SDmax1 263.1, SDmax2 272.0, HDmax1 290.9, and HDmax2 300.9 mm.The paired sample analysis showed statistically significant differences between Dmax1 and Dmax2, HDmax1 and HDmax2, SDmax1 and SDmax1 in both subgroups (DLBCL and FL) with a p-value <0.001, as expected. Nevertheless, Cox regression analysis for DFS showed very similar HR for all of them in both subgroups:- DLBCL: HR 1.002 in both Dmax1 and Dmax2, CI 95% [1.001-1.003]; HR 1.003 in the rest of distances (HDmax1 and HDmax2, SDmax1 and SDmax2), CI 95% [1.001-1.005].- FL: HR 1.001 in both Dmax1 and Dmax2 CI, 95% [0.999-1.003]; HR 1.002 inHDmax1 and HDmax2, SDmax1 and SDmax2, CI 95% [0.999-1.005].Although HR values obtained in FL subgroup were not statistically significant, a resembling trend was found in both subgroups. Furthermore, note that these values are HR per unit (millimetre). ***Conclusion:*** Despite the fact that significant differences were found between the differentmethods of measuring the Dmax (and their normalizations), the values of HR obtained are similar in DLBCL and FL allowing any of the 6 measurements to be used interchangeably in clinical practice.

EP-0367

Whole Body PET Parameters Predicting Progression after CAR-T Cell Therapy in Relapsed/Refractory Aggressive B-cell Lymphoma

A. Guarneri[1], *E. Galli[2], F. Sorà[3], E. Alma[2], E. Maiolo[2], S. Hohaus[3], S. Sica[3], A. Giordano[4], L. Leccisotti[4];*
[1]Unit of Nuclear Medicine, Department of Diagnostic Imaging and Radiation Oncology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY, [2]Unit of Hematology, Department of Diagnostic Imaging and Radiation Oncology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY, [3]Section of Hematology, Department of Diagnostic Imaging and Radiation Oncology, Università Cattolica del Sacro Cuore, Rome, ITALY, [4]Section of Nuclear Medicine, Department of Diagnostic Imaging and Radiation Oncology, Università Cattolica del Sacro Cuore, Rome, ITALY.

Aim/Introduction: Among patients with relapsed/refractory aggressive B-cell lymphoma treated with chimeric antigen receptor (CAR)-T cell therapy, only around 40% have long-term benefit. This study aims to identify prognostic biomarkers in patients treated with CAR-T cell for aggressive B-cell lymphomas. ***Materials and Methods:*** Consecutive pts treated with CAR-T cell infusion for aggressive B- cell lymphoma were retrospectively enrolled in this single centre study. All pts underwent FDG PET/CT before CAR-T, and at 1 (PET-1) and 3 months after cell infusion. Whole body PET metrics (TMTV and WB-TLG) were extracted using an AI-based automated segmentation algorithm (Lesion Scout with Auto ID, Siemens Healthineers; PERCIST- recommended liver-based threshold for lesion identification with 4.0 SUVmax threshold for lesion segmentation). Response to treatment was assessed using both clinical and imaging criteria every 3 months after CAR-T or anytime in case of clinical progression. ***Results:*** Forty pts were enrolled (median age 55 yrs, range 28-75), 50% were males. The stage was advanced (III-IV) in 26 (65%) pts. Parameters as IPI, LDH levels or extranodal sites were also analysed. Median baseline TMTV and WB-TLG were 28.34 cm3 (0-1306) and 222.36 (0-12318), respectively. Median PFS was 12 months, with an overall PFS of 48% at 2 yrs. Baseline TMTV and WB-TLG were predictive of PFS (p<0.001) with high baseline TMTV (≥48) and WB-TLG (≥407) being associated with a lower PFS (median PFS, 1.4 months vs. not reached and 2.5 months vs. not reached; p<0.001, respectively). On multivariate analysis baseline TMTV (cut-off 48.4) and LDH above upper normal limit were independent prognostic factors for PFS (p<0.001 and p = 0.003 respectively). We therefore assigned 1 point each for TMTV ≥48 and LDH above normal, discriminating 3 groups with 0 (15 pts), 1 (14 pts) or 2 (11 pts) points each. Pts with 0, 1 or 2 points had increasingly worse response to CAR-T cell therapy (median PFS not reached vs 12 months vs 1.5 months, p<0.001). In addition, TMTV and WB-TLG of PET-1 were predictors of PFS (p<0.001). On multivariate analysis PET-1 TMTV (cut-off 1.99) was an independent prognostic factor for PFS (p=0.008). ***Conclusion:*** Baseline PET metrics may allow for identification of patients who will benefit most from CAR-T cell infusion. The combination of clinical variables with baseline and PET-1 metrics could lead to a better patient selection and early adaptation of clinical management.

EP-0368

Exploring the Clinical Implications of LAFOV Digital PET Scanners: Does contrast enhanced CT affect quantification of FDG uptake?

A. Weissensee[1], *H. Sari[2], S. Acikgoez[3], C. Mingels[1,3,4], J. Ferdinandus[5,6], T. Pyka[1], K. Shi[1], A. Rominger[1], R. Seifert[1];*
[1]Department of Nuclear Medicine, Inselspital, University Hospital Bern, University of Bern, Bern, SWITZERLAND, [2]Advanced Clinical Imaging Technology, Siemens Healthcare AG, Lausanne, SWITZERLAND, [3]University of Bern, Bern, SWITZERLAND, [4]Department of Radiology, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [5]Department I of Internal Medicine, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, University of Cologne, Medical Faculty and University Hospital Cologne, Cologne, GERMANY, [6]German Hodgkin Study Group (GHSG), Cologne, GERMANY.

Aim/Introduction: The introduction of long axial field-of-view (LAFOV) digital PET scanners has significantly influenced clinical management by offering the potential to increase signal collection efficiency, improve spatial resolution and reduce the dosage of injected tracers. However, the heightened sensitivity of these PET systems—up to 20 times greater than traditional models—could lead to the identification of clinically irrelevant findings and deviations in tracer uptake quantification. While some scanners enable the use of contrast-enhanced CT for PET attenuation correction, its impact on FDG uptake quantification and the necessity of an additional low-dose CT for accurate assessment remain uncertain. In this work, we aim to measure the degree of deviation between LAFOV PET images reconstructed with contrast-enhanced CT and non-enhanced low-dose CT. ***Materials and Methods:*** Patients were scanned on a digital LAFOV PET/CT with a 106 cm axial field-of-view. Data from 8 tumor lesions from 3 patients were used. All patients received a diagnostic full-dose CT with administration of contrast agent and an additional low-dose CT for attenuation correction. PET images were reconstructed using the contrast-enhanced CT (cePET) and the low-dose PET (non-cePET) for attenuation correction with PSF-TOF and full acceptance angle. Tumor and liver uptake were quantified by using a 40% iso-contour volume-of-interest. Wilcoxon signed rank exact test was used for statistical analysis. Further analysis of additional 30 patients with verified lymphoma will be performed. ***Results:*** On a per patient basis, the maximum liver uptake (median kBq/ml + IQR) was significantly higher in cePET compared to non-cePET reconstructions (+7.8 %; 11.082 [3.517]

vs. 10.274 [3.591], p = 0.014). On a per lesion level, the maximum tumor uptake was significantly higher in cePET compared to non-cePET (+3.8 %; 18.470 [11.011] vs. 17.792 [10.935]; p = 0.008) and the ratio of maximum tumor uptake to liver was lower in cePET (-4.1 %; 1.538 [0.757] vs. 1.604 [0.811], p = 0.039). ***Conclusion:*** Preliminary findings indicate a significant impact of utilizing contrast-enhanced CT for attenuation correction in LAFOV PET/CT reconstruction. These results might have significant implications for response assessment frameworks such as the qPET (Deauville) criteria, which depend on comparing lesional uptake to liver uptake. Given these results, corroboration and assessment of clinical implications are warranted.

EP-0369

Role of [18F] FDG-PET/CT and assessment of basal metabolic parameters in mantle cell lymphoma

J. Diaz-Moreno[1], *M. Cortés-Romera[1], S. Verdesoto-Cozzarelli[2], R. Martín-Vaello[3], B. Hervás-Sanz[1], C. Martínez-Ramos[1], M. Pudis[1], G. Reynes-Llompart[3], E. González-Barca[2], S. Bondía-Bescos[1], A. Bagán-Trejo[1], M. Zamorano-Rivas[1], L. Rodríguez-Bel[1];*
[1]Nuclear Medicine-PET (IDI) Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [2]Hematology Department. Hospital Duran i Reynals-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [3]Radiophysics Department. Hospital Duran i Reynals-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN.

Aim/Introduction: Mantle cell lymphoma (MCL) is a rare B-cell lymphoma subtype comprising 3-10% of non-Hodgkin's lymphoma, with aggressive behavior, poor prognosis and avidity to [18F]FDG on PET/CT. Several studies have demonstrated a predictive value of baseline [18F]FDG-PET/CT metabolic parameters in some lymphoma subtypes. In MCL there are few studies on the role and assessment of metabolic parameters. The aim of this study is to assess the prognostic value of baseline [18F]FDG-PET/CT metabolic parameters in MCL. ***Materials and Methods:*** Patients diagnosed as MCL were referred for [18F]FDG-PET/CT at initial staging. Pretreatment metabolic parameters SUVmax, SUVmean, metabolic tumor volume (MTV) and total tumor glycolysis (TLG) of PET/CT were measured, retrospectively, using MIM software. It was compared two segmentation methods (PERCIST and SUVmax2.5) with T-student analysis. The metabolic parameters MTV and TLG estimated by PERCIST and SUVmax2.5 methods were correlated with PFS and OS. Survival curves were determined with the Kaplan-Meier method. ***Results:*** Twenty-seven patients(p) were studied (24 men), mean age was 64 years (42-75), 22/27p had advanced disease (stage III/IV). Mean follow-up was 79 months (m), with a maximum of 160m. The histological subtype identified was: 10p pleomorphic (37%), 5p blastic (18.5%), 4p classic (14.8%), 1p small-cell (3.7%) and 7p unclassified (26%). The average SUVmax was 7.61 (1.66-17.4). Three patients were excluded due to the low uptake and the VOI were not identified. The MTV and TLG cut-offs that allowed significant differences, for PERCIST method: 265 and 1005. And for the SUVmax2.5 method: 568 and 2162, respectively. Patients with high MTV and TLG by both methods had worse prognosis than those with low MTV and TLG (PFS 42.2m vs 76.4m for SUVmax 2.5 and 44.1 vs 77.6 m for PERCIST, respectively), p<0.05. Fifteen patients had relapsed/progressed (R/P) disease, with a mean PFS 41m and mean OS of 77m. Nine of 27p died (6p related to lymphoma) with mean PFS of 20m (11d-61m). Relapsed patients had higher MTV for both methods than non-relapsed patients (443/711 vs 59/149: PERCIST/SUVmax 2.5). SUVmax and SUVmean were not related to outcome survival. ***Conclusion:*** Baseline [18F] FDG-PET/CT metabolic parameters MTV and TLG in MCL by different segmentation methods (PERCIST and SUVmax 2.5) were correlated with PFS. Patients with high MTV and TLG had significantly worse prognosis than those with low MTV and TLG. No relationship was observed between SUVmax and SUVmean with PFS. More studies are needed due to our limited number of patients.

EP-0370

Combined Application of Laboratory Prognostic Index and Baseline PET-Based Metrics in Diffuse Large B-Cell Lymphoma: Does It Have Any Impact On The Early Detection Of 'Non-Responders'?

L. García Belaústegui[1], *S. Browne Arthur[1], A. Martínez Lorca[2], M. Romera Caballo[1], F. Martín Moro[2], M. Garcia-Velloso[1], C. Grande[1];*
[1]Clinica Universidad de Navarra, Madrid, SPAIN, [2]Hospital Ramón y Cajal, Madrid, SPAIN.

Aim/Introduction: Diffuse Large B-cell Lymphoma (DLBCL) is a heterogeneous disease with a 40% of patients resulting in progression to R-CHOP-like regimens. In this regard, it is essential to identify 'non-responders' so that an alternative treatment strategy can be considered. The revised International Prognostic Index (R-IPI) is used in daily practice, but does not optimally detect patients with a high probability of poor long-term outcomes. The recently validated Laboratory Prognostic Index (LABPI) has instead shown potential predictability in DLBCL. This study aimed to test a predictive model in DLBCL combining LABPI and baseline-PET features that allows better risk stratification and early detection of 'non responders'. ***Materials and Methods:*** DLBCL patients treated with R-CHOP-like regimens who had undergone a baseline 18F-FDG PET/CT were retrospectively reviewed. LABPI score was calculated in relation to three pretreatment laboratory parameters: beta-2-microglobulin, lactate dehydrogenase and hemoglobin. PET-based features were obtained from baseline images: Metabolic Tumor Volume (MTV) and Disease dissemination (Dmax). SUV4-Method was applied for automated segmentation of MTV using the Syngo. via software. Dmax was measured as the distance between the two farthest hypermetabolic lesions. PFS rate was calculated using the Kaplan-Meier method followed by log-rank tests and analyzed with multivariate Cox and logistic regressions. ***Results:*** A cohort of 154 patients (88 men) was selected, with a median age of 67 years (range:26-90) and PFS follow-up of 39 months (IQR:5-152). Patients were divided into three risk groups based on LABPI [0 (Low); 1-2 (Intermediate); 3-4 (High)]. Dichotomization was applied to MTV and Dmax (thresholds: 106.54 cm3 and 7.9 cm). Univariate Cox regression analysis for Dmax showed a HR of 7.3 (95% CI: 1.4 to 38.3; p=0.003). A multivariate regression was performed for LABPI and MTV, with HR resulting in 4.7 (95% CI: 1.2 to 18.7; p=0.026) and 2.8 (95% CI: 1.0 to 7.8; p=0.054). Statistical difference in MTV between two groups with Intermediate LABPI was considered for reclassification, demonstrating a PFS of 92% and 66% in 36 months. A 38% of the cohort was reclassified as good prognosis, which is higher than what R-IPI classifies as good (8%) (p<0.001). Multivariate logistic regression analysis showed considerable statistical predictiveness, with OR of 4.4 for LABPI and 4.0 for MTV, and an area under the curve of 0.73 (p<0.001). ***Conclusion:*** Our preliminary results suggest that combination of LABPI and baseline-PET features shows potential predictiveness in DLBCL. Further validation with larger series is requested.

EP-0371

[18F]FDG PET/CT biomarkers in patients with Relapsed/Refractory Diffuse Large B-cell Lymphoma treated with Loncastuximab tesirine

***R. Zanca*[1,2],** *C. M. Improta*[1,3], *M. Magagnoli*[3], *R. Mazza*[3], *M. Rodari*[2], *C. Carlo-Stella*[1,3];
[1]*Department of Biomedical Sciences, Humanitas University, Milan, ITALY,* [2]*Nuclear Medicine, IRCCS Humanitas Research Hospital, Milan, ITALY,* [3]*Department of Oncology and Hematology, Humanitas Cancer Center, IRCCS Humanitas Research Hospital, Milan, ITALY.*

Aim/Introduction: Loncastuximab Tesirine is a CD-19-directed antibody-drug conjugate approved by the FDA as a single-agent treatment for relapsed/refractory diffuse large B-cell Lymphoma. The association between PET/CT biomarkers and treatment response is increasingly studied, particularly for total metabolic tumor volume (TMTV). This work aimed to assess the predictive potential of TMTV for treatment response in r/r aggressive large B-cell Lymphoma (r/r LBCL) treated with Loncastuximab Tesirine. ***Materials and Methods:*** We retrospectively evaluated a series of 69 r/r LBCL (M:F = 44:25; median age 62 yrs, range 23-87). From March 2017 to June 2021, patients were treated at Humanitas Research Hospital with Loncastuximab Tesirine single agent (ADCT-402-101 and ADCT-402-202 trials) or in combination with Ibrutinib (ADCT-402-103 trial). TMTV was obtained by automatic method (Syngovia, Siemens) using the SUV 40% threshold and SUV ≥4.0 threshold, also used for the evaluation of the International Metabolic Prognostic Index (IMPI). Cox proportional hazards regression analysis and Kaplan-Meier curves were used to correlate PET/TC biomarkers and progression-free survival (PFS). An unpaired t-test was conducted using the Fisher method to compare the best response groups. Statistical analysis was performed using R software and GraphPad Prism software. ***Results:*** The median baseline TMTV value (90 mL) was used to separate the high vs low MTV cohorts (34 and 35 patients, respectively). Response rates according to high vs. low TMTV were 12% vs. 31% for complete response, 29% vs. 37% for partial response, 21% vs. 12% for stable disease, and 38% vs. 20% for progressive disease, respectively. PFS by median TMTV at baseline was 4.8 months for low TMTV (<90 ml) and 2.6 months for high TMTV (>90 ml) (HR: 2.7, P= .0003). Patients achieving a complete response as the best response exhibited a significantly greater reduction in TMTV at the first disease assessment, with a mean log10 fold-change of -1.709. In our series, IMPI demonstrated no significant correlation with PFS. ***Conclusion:*** Our results demonstrated TMTV's predictive potential for complete response and PFS in patients with aggressive large B-cell Lymphoma treated with Loncastuximab Tesirine.

EP-0372

Relationship between Metabolic Activity of Bone Lesions Assessed by SUVmax Detected by [18F]FDG PET/CT and Clinical Parameters in Newly Diagnosed Multiple Myeloma Patients

T. Stoeva, *M. Dyankova, Z. Dancheva, T. Yordanova, S. Chausheva, B. Chaushev, A. Klisarova;*
UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.

Aim/Introduction: Accurate staging is pivotal for prognosis and treatment planning in newly diagnosed multiple myeloma (MM) patients. While the International Staging System (ISS) categorizes MM based on β2-microglobulin and albumin values, the variable survival in MM challenges the adequacy of current staging practices. This study aims to explore the correlation between [18F] FDG PET/CT findings and clinical parameters in newly diagnosed MM patients. ***Materials and Methods:*** Thirty-seven patients with histologically confirmed newly diagnosed MM were enrolled. All patients underwent [18F]FDG PET/CT before treatment initiation. Statistical analysis, including chi-square tests and Student's T-tests, aimed to uncover relationships between staging laboratory values and SUVmax. ***Results:*** Results revealed 13.2% with diffuse bone-marrow involvement and metabolically active osteolytic lesions in 86.8% of patients. Among these, 21.1% presented with up to 5 bone lesions, while 63.2% had more than 5 lesions. The average SUVmax was 4.29 (range 2.10-13.2). Laboratory findings included: anemia (64.9%), elevated serum creatinine (29.7%), elevated alkaline phosphatase (16.2%), elevated lactate dehydrogenase (70.3%), β2-microglobulin above 3.5 mcg/mL (43.2%), and elevated albumin (29.7%). No statistically significant relationships were found: paraprotein (p=0.632), albumin (p=0.654), β2-microglobulin (p=0.479), lactate dehydrogenase (p=0.904), alkaline phosphatase (p=0.705), hemoglobin (p=0.832), and creatinine (p=0.636). Additionally, one-way analysis of variance (ANOVA) did not yield statistically significant results. ***Conclusion:*** This study underscores the complexity of multiple myeloma staging, as conventional laboratory parameters did not correlate with SUVmax from [18F]FDG PET/CT. The absence of significant associations suggests that metabolic activity assessed by SUVmax may provide unique insights beyond traditional staging methods. Future studies with larger cohorts are warranted to validate these findings and explore the potential of SUVmax as a prognostic indicator in MM.

EP-0373

Correlation of Metabolic Activity in Bone Lesions by 5-Point Scale on [18F]FDG PET/CT with Clinical Parameters in Newly Diagnosed Multiple Myeloma Patients

T. Stoeva, *Z. Dancheva, M. Dyankova, T. Yordanova, S. Chausheva, B. Chaushev, A. Klisarova;*
UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.

Aim/Introduction: Accurate staging is paramount in multiple myeloma (MM) to guide treatment decisions and predict patient outcomes. Despite the International Staging System's (ISS) use of β2-microglobulin and albumin, the heterogeneous nature of MM survival prompts a reevaluation of current staging methods. This study investigates the potential correlation between metabolic activity in bone lesions, assessed by 5-Point Scale (5-PS) on [18F]FDG PET/CT, and clinical parameters in newly diagnosed MM patients. ***Materials and Methods:*** Thirty-seven newly diagnosed MM patients were enrolled for [18F]FDG PET/CT examination prior to treatment initiation. Statistical analysis, including chi-square tests

and Student's T-tests, aimed to discover relationships between staging laboratory values and 5-PS. ***Results:*** Results revealed 13.2% with diffuse bone-marrow involvement and 86.8% with metabolically active osteolytic lesions. Notably, 21.1% had up to 5 bone lesions, while 63.2% had more than 5 lesions. Among the patients, 73% were categorized with 5-PS scores of 3 and 4, with the remaining 27% scored as 5. Laboratory findings included: anemia (64.9%), elevated serum creatinine (29.7%), elevated alkaline phosphatase (16.2%), elevated lactate dehydrogenase (70.3%), β2-microglobulin above 3.5 mcg/mL (43.2%), and elevated albumin (29.7%). Statistical analyses, comprising Student's T-tests and ANOVA, did not yield statistically significant relationships between 5-PS-assessed bone lesion metabolic activity and conventional laboratory values: paraprotein (p=0.185), albumin (p=0.116), lactate dehydrogenase (p=0.169), alkaline phosphatase (p=0.519), hemoglobin (p=0.336), and creatinine (p=0.446). However, a chi-square analysis revealed a significant association between β2-microglobulin levels below 3.5 mg/L and 5-PS scores of 3 and 4 (p=0.046). This finding underscores the link between increased metabolic activity in lesions, as indicated by 5-PS, and lower β2-microglobulin levels, suggesting lower disease activity. Conversely, patients with higher metabolic activity, based on 5-PS, tended to exhibit higher β2-microglobulin levels. ***Conclusion:*** This study elucidates the intricate interplay between metabolic activity in bone lesions, assessed by 5-PS on [18F]FDG PET/CT, and clinical parameters in newly diagnosed MM patients. While no direct correlations were observed between 5-PS-assessed metabolic activity and traditional laboratory values, the significant relationship with β2-microglobulin levels highlights the potential utility of 5-PS in gauging disease activity. These findings underscore the need for further research with larger cohorts to validate the role of 5-PS as a prognostic indicator in newly diagnosed MM.

EP-0374

Comparison study between ^{18}F-FDG PET/CT metabolic activity assessed by SUVmax and 5-Point Scale (5-PS) value as prognostic factors for overall survival (OS) and progression-free survival (PFS) in patients with multiple myeloma after chemotherapy

T. Stoeva, *Z. Dancheva, M. Dyankova, T. Yordanova, S. Chausheva, B. Chaushev, A. Klisarova;*
UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.

Aim/Introduction: [18F]FDG PET/CT is a useful imaging technique for evaluating treatment response in multiple myeloma (MM). It can detect changes in glucose metabolism in the bone marrow, extramedullary disease and other tissues affected by the disease, can identify residual disease after treatment and detect relapse. These capabilities of [18F]FDG PET/CT are related to the prediction of overall survival. In addition to evaluating treatment response, [18F]FDG PET/CT can also be used to guide treatment decisions. ***Materials and Methods:*** A total of 31 patients with proven multiple myeloma and post-treatment [18F]FDG PET/CT were included in the present study. We used Kaplan-Meier survival analysis and the Log Rank test to compare the two groups of patients. We used Student's T-test to determine whether there was a statistically significant difference in the mean OS and PFS values of the individual groups. ***Results:*** .The majority (93.55%) of the patients had osteolytic lesions. The average SUVmax was 4.28, ranging from 1.3 to 12.4. Patients were categorized based on SUVmax values (cut-off of 3.13) and 5-PS visual assessment into negative (score 2 and 3) and positive (score 4 and 5) groups.Results indicated that patients with SUVmax less than 3.13 had a significantly longer median OS (26.8 months) compared to those with SUVmax equal to or greater than 3.13 (20.37 months), with a p-value of 0.039. For PFS, patients with SUVmax less than 3.13 also had a longer median PFS (25.6 months) compared to those with SUVmax equal to or greater than 3.13 (16.2 months), with a p-value of 0.011. Patients evaluated with a 5-PS score of 2 and 3 had a longer median PFS (25.67 months) compared to those with a score of 4 and 5 (16.2 months), with a p-value of 0.009. There were no statistically significant relationship was found between 5- PS and the overall survival. ***Conclusion:*** These findings suggest that SUVmax measured by ^{18}F-FDG PET/CT may serve as a prognostic factor for both OS and PFS in MM patients, with lower SUVmax values correlating with longer survival times and longer periods without disease progression. The 5-PS visual assessment also showed significance in predicting PFS. Incorporating ^{18}F-FDG PET/CT, particularly SUVmax, into clinical practice could improve risk stratification and treatment planning for MM. Further research with larger cohorts is needed to confirm these results and optimize the use of these parameters in MM management.

EP-0375

Role of ^{18}F-FDG PET/CT in Hemangiopericytoma

L. Goriparti[1], *D. Khan[1], S. K V[1], S. Sagar[1], A. Gawande[1], B. Nayak[1], R. Kumar[1], C. Bal[1], A. Dhiman[1], S. sharma[1], J. Krishna P.[1], R. Wakankar[2], C. Ganapathy[1];*
[1]All INDIA INSTITUE OF MEDICAL SCIENCES, NEW DELHI, INDIA,
[2]All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Hemangiopericytomas (HPC) are rare tumor (0.060 per 100,000 individuals) that originate from pericytes and can anywhere in the body along the blood capillaries, the most common locations reported are lower extremities, retroperitoneum, pelvis, brain, lungs, and pleura .This entity can either be benign or malignant, with the latter showing metastases primarily to the lungs and bones. They also have high incidence of local recurrence and distant metastases. Currently ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) imaging is the standard of care for staging and restaging for various malignancies but there is very little information about its application in HPC. ***Materials and Methods:*** We retrospectively evaluated clinical and imaging data of 10 HPC patients who underwent ^{18}F-FDG PET/CT for staging, restaging and surveillance, during the period from January 2017 to March 2024. All the 10 PETCT scans were analyzed for primary tumor site and response assesment . The maximum standardized uptake value (SUV max) of the primary lesion and background was calculated. ***Results:*** Total 10 patients (8 males and 2 female and, M:F=4:1) with median age of 28.5 years (range- 6 to 47 years) were included in the study. The primary sites of involvement were brain (7/10), pelvis (1/10) and tibia (2/10) in these patients with metastasis noted to liver (2 patients) ,axial(3 patients) and appendicular(2 patients) skeleton,lung(1patient),cutaneous nodules(1 patient) and abdominal (drop metastasis through CP shunt) with lymph nodes (1patient). The mean SUV-max of the primary tumors was 6.25±4.08 and the background was 1.79 ±0.92. Two patients underwent scan for baseline staging, 7 for restaging and 1 for surveillance purpose. There was a significant difference detected between the mean SUV max of primary lesions and the background with a p value of 0.013(<0.05, paired student T test). ***Conclusion:*** ^{18}F-FDG PET/CT can be used for staging and re staging purpose in HPCs thus helping in the management of the disease. Additionally, parameters like SUV-max assessed on ^{18}F-FDG PET/CT can give semiquantitative assessment of the lesions.

EP-0376

Prognostic value of SIOPEN and Curie scores of 123I-MIBG scintigraphy in neuroblastoma

A. Talin, *F. Dondi, D. Albano, P. Furtuna, F. Bertagna; Università degli Studi di Brescia, Brescia, ITALY.*

Aim/Introduction: The aim of the study was to verify the prognostic value of the Curie and International Society of Pediatric Oncology Europe Neuroblastoma (SIOPEN) scoring systems in paediatric patients with neuroblastoma undergoing staging 123I-meta-iodobenzylguanidine (MIBG) scans. ***Materials and Methods:*** Patients with a diagnosis of neuroblastoma and without prior therapies were retrospectively enrolled. All 123I-MIBG staging scintigraphies and SPECT/CT were evaluated according to SIOPEN and Curie semiquantitative scores. Patients' clinical histories were collected by examining oncology visits and diagnostic tests performed to obtain data on relapse, progression and death events. Event-free survival (EFS) and overall survival (OS) were calculated in months from the date of the staging scintigraphy to the date of the first event of progression or relapse for EFS and to the date of death or the last follow-up for OS, respectively. Curie and SIOPEN scores at diagnosis were correlated with EFS and OS by dichotomizing them on the basis of their median value. Kaplan-Meier analysis was used to draw survival curves and log-rank test applied to compare these curves, considering a p value <0.05 as statistically significant. ***Results:*** A total of 32 patients were included: 19 male and 13 female. Age range went from newborn to 12 years with a median of 2,5. After the staging scan the whole patients were treated with chemotherapy and/or surgery. SIOPEN staging scores went from 0/72 to 59/72 and their median value was 1/72. Curie staging scores went from 1/30 to 24/30 and their median value was 2,5/30. There were 12 patients who had progression or relapse events and 8 of them died. Calculated EFS went from a minimum of 1 month to a maximum of 323 months (26,9 years) and its median value was 60. Calculated OS went from a minimum of 1 month to a maximum of 323 months and its median value was 77,5. Based on Kamplan-Meier analysis, Curie staging score was a significant predictor for EFS (p<=0,001) and OS (p<=0,003). Similarly, SIOPEN staging score was a significant predictor for EFS (p<=0,001) and OS (p<=0,003). ***Conclusion:*** According to these results, higher scores of Curie and SIOPEN on 123I-MIBG staging scintigraphy are correlated with low EFS and OS, thus they could predict unfavourable prognosis. This study demonstrates the presence of significant negative correlations between both scoring systems and the two calculated survival parameters (EFS and OS), confirming the high prognostic value of these scores. ***References:*** doi: 10.4274/mirt.52533. doi: 10.4149/neo_2015_053. doi: 10.1007/s00259-017-3660-1.

EP-0377

Comparison of FDG PET/MRI and Whole Body Diffusion Weighted Imaging in Multiple Myeloma

Y. Unluer Ates, *E. Erbil Capci, U. Aydos, L. Atay; Gazi University Mecine Faculty, Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: The aim of this study was to evaluate the diagnostic performances of whole-body FDG PET/MRI and whole-body diffusion weighted imaging (DWI) in primary staging of multiple myeloma (MM) patients, to investigate their impact on disease stage and to compare their contribution to survival prediction. ***Materials and Methods:*** The data of 106 MM patients who underwent FDG PET/MRI and whole-body DWI in the same session for primary staging were evaluated retrospectively. Visual assessment included detecting FDG (+) and DWI (+) focal lesions (FL) throughout the entire body and in spesific regions (skull, vertebrae and other skeletal areas) by using FDG PET, T1 and T2-w images, DWI and ADC maps. Additionally, DWI and PET images were used to evaluate diffuse bone marrow (BM) involvement and extramedullary lesions (EMD). The diagnostic performances of the two modalities were evaluated by using McNemar, chi-square and Wilcoxon signed-rank tests. Durie-Salmon (D-S) stages of the patients were recorded. D-S plus stages were also identified using PET/MR and DWI data. The prognostic values of clinical parameters, D-S and D-S plus stages for overall survival (OS) were evaluated by using Cox proportional hazard regression models. Statistical analyses were performed on SPSS version 23.0. ***Results:*** DWI detected significantly higher numbers of FLs in the whole body, calvarium and vertebrae compared to FDG PET/MRI (mean: 31.5 vs 24.7, p=0.01; 2.5 vs 2.2, p=0.027; 16.4 vs 11.3, p=0.003, respectively). The number of EMD lesions was significantly higher in FDG PET/MRI (mean: 4.8 vs 2.8, p=0.027). There was no significant difference between the two modalities in terms of the presence of FL or EMD on patient based analysis. A higher proportion of patients showed positive DWI findings for diffuse BM involvement compared to FDG PET/MR (55.7% vs 39.6%, p<0.001). While D-S plus_DWI stages changed in 43 patients (40.6%; 32 upstaged, 11 downstaged), D-S plus_FDG PET/MRI stages changed in 44 patients (41.5%; 24 upstaged, 20 downstaged) compared to standard D-S staging. The discordance between D-S plus DWI and FDG PET/MR was observed in 28 patients (p=0.011). Patient age and D-S plus FDG PET/MR stages emerged as independent prognostic factors (p=0.032, p=0.011, respectively). ***Conclusion:*** WB-DWI detected more FLs, while FDG PET/MR detected more EMD lesions. However, no significant difference in FL detection per patient was observed. Although, DWI was observed to increase the stage in more patients compared to FDG PET/MR, staging with FDG PET/MR provided better prognostic risk stratification.

EP-0378

Combined Use of [18F]FDG PET/CT and Whole-Body Diffusion Weighted Magnetic Resonance in the Assessment of Multiple Myeloma: a Prospective Study

M. Di Franco[1], *D. Bezzi[2], M. Talarico[3], E. Zamagni[3], A. Cattabriga[4], F. Galuppi[4], S. Brocchi[4], C. Mosconi[4,5], S. Fanti[1,6], C. Nanni[6]; [1]Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine Unit, AUSL Romagna, Forlì, ITALY, [3]Seràgnoli Institute of Hematology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Department of Radiology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [5]DIMEC, Alma Mater Studiorum, University of Bologna, Bologna, ITALY, [6]Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: This is a non pharmacological, interventional, monocentric prospective study to compare the diagnostic performance of [18F]FDG PET/CT (FDG-PET/CT) and Whole-body Diffusion Weighted Magnetic Resonance (WB-MRI) in patients (pts) with smoldering multiple myeloma (SMM) or newly diagnosed multiple myeloma (NDMM) at staging and pre-maintenance. The aims are to compare the two modalities' positivity rates and to correlate baseline and post-treatment FDG-PET/CT and WB-MRI findings with prognostic markers and outcomes. ***Materials and Methods:*** FDG-PET/CT and WB-MRI were performed at baseline in pts with SMM or NDMM and repeated in the NDMM subgroup after ASCT or 1 year of treatment. IMPeTuS criteria and MY-RADS criteria were used for image interpretation and

reporting. ***Results:*** Up to Feb 2024, we enrolled 79 patients (n=25 SMM; n=54 NDMM). After the staging imaging, pts were excluded from further evaluations for early progression (n=4), death (n=1) and loss at follow up (n=1). In NDMM, baseline FDG-PET/CT and WB-MRI were concordant in 44/54 pts (82%): 35/54 (65%) were both positive and 9/54 were both negative (17%) (moderate agreement with k=0,53). In the remaining 10 pts the two imaging procedures were discordant (p<0.01): 1/10 was WB-MRI- and FDG-PET/CT+ for DS4 bone marrow (BM) diffuse uptake. In the other 9/10 pts with WB-MR+/PET-, WB-MR detected up to 3 bone focal lesions (FL) in 7/9 pts, more than 10 FL in 1/9 and BM involvement alone in 1/9. It is notable however that 7/9 pts had DS3 BM diffuse uptake at the FDG-PET/CT (borderline positivity). Overall, FL were detected more frequently by WB-MRI than by FDG-PET/CT (p<0.05), while significant BM involvement (DS4) was seen more frequently at FDG-PET/CT than WB-MRI (58/79 vs 21/79; p<0,01; K=0,35). Diffuse disease at baseline PET/CT and WB-MR correlated with R-ISS III (p=0,04 and p=0,048 respectively). 11/54 pts were also evaluated before maintenance (ongoing phase of the study). FDG-PET/CT and WB-MRI were concordant in 7/11 cases, discordant in 1/11 (non-responding at FDG PET/CT, RAC1 at WB-MRI, clinical PR), and not compared in 3/11 (2 FDG-PET/CT not performed due to negativity at baseline and 1 WB-MRI not performed due to recent positioning of internal metallic fixators). In the SMM subgroup, baseline positivity rates of WB-MRI and FDG PET/CT were comparable (k=0,13; p=0,5). ***Conclusion:*** Preliminary data support a combined use of FDG-PET/CT and WB-MRI imaging at staging in patients with NDMM. Data on response assessment and prognostic roles of the two modalities compared are awaited.

EP-0379

Usefulness of ^{18}F-FDG-PET/CT in the multidisciplinary management of muscle-invasive urothelial bladder carcinoma with inconclusive nodal involvement in CT scan

O. Ajuria Illarramendi[1], *P. Gajate Borau[1], T. Navarro Martinez[1], P. Azpeitia hernandez[1], A. Martinez Lorca[1], L. Flynt[2], J. Brasero Burgos[1], E. Corral de la fuente[1], I. Hernandez Perez[1], U. Vera Schmulling[1], M. Gutierrez Guerrero[1], E. perez de los rios[1], M. Ottino Lombardi[1], p. Paredes rodriguez[1], d. tamayo carabaño[1], M. Orduña diez[1];*
[1]Hospital universitario ramon y cajal, Madrid, SPAIN,
[2]The University of Texas at MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: The standard treatment for non-metastatic muscle-invasive urothelial bladder carcinoma (MIUC) consists of radical cystectomy and bilateral pelvic lymphadenectomy with neoadjuvant chemotherapy in patients eligible for cisplatin-based chemotherapy. At least 20-40% of patients will have lymph node involvement at diagnosis, despite having a negative staging study with conventional techniques (contrast enhanced Computed Tomography (ceCT)), which is a poor prognostic factor.The aim of this study is to demonstrate the value of 18F-FDG(fluorine-18 fluorodeoxyglucose)-PET/CT in the staging of MUIC and its consequent implications for clinical management. ***Materials and Methods:*** Retrospective review of patients with muscle-invasive urothelial carcinoma (MUIC) staged pT2 with inconclusive lymph nodes on ceCT who underwent staging with 18F-FDG-PET/CT scan between 2022-2024. Patients with evidence of MUIC with locoregional nodal disease were administered neoadjuvant chemotherapy and underwent follow-up 18F-FDG-PET/CT scan. The gold standard for determining response was histopathological examination in patients who underwent surgery (absence of disease on initial ^{18}F-FDG-PET/CT or complete nodal response on follow-up 18F-FDG-PET/CT), or based on clinical and radiological features in patients who did not undergo surgery. ***Results:*** ^{18} patients (4 women;14 men; mean age 74) were included. Initial 18F-FDG-PET/CT showed: 3/18 cN0M0, 1/18cN1M0, 3/18cN2M0, 1/18cN3M0, 8/18cM1a and 2/18 cM1b. 4/18 patients (3 cN2M0; 1 cN3M0) received neoadjuvant chemotherapy and a 18F-FDG-PET/CT follow-up was acquired: 3/4 achieved complete nodal response (post-chemotherapy-cN0M0) and 1/4 showed partial nodal response (post-chemotheraphy-cN2M0). 2/3 of cN0M0 and 3/3 post-chemotherapy-cN0M0 had surgery which confirmed pN0M0. 1/3 cN0M0 was not eligible for surgery due to comorbidities and received chemotherapy and remains disease-free at follow-up. cN1M0 was surgically treated and did not demonstrate lymph node involvement (pN0). Post-chemotheraphy-cN2M0 kept on with chemotheraphy. The presence of cM1 in 10/18 ruled out surgery and were given chemotherapy. 18F-FDG-PET/CT showed a sensitivity of 100%, specificity of 66.7%, PPV of 93.8%, and NPV of 100%, which resulted in a change in clinical management in 10/18 cases (55,5%). ***Conclusion:*** The implementation of 18F-FDG-PET/CT in the staging of MUIC provides greater precision in the diagnosis of lymph nodes and leads to a change in clinical management in a high percentage of patients. ***References:*** Einerhand SMH, Zuur LG, Wondergem MJ et al. The Implementation of FDG PET/CT for Staging Bladder Cancer: Changes in the Detection and Characteristics of Occult Nodal Metastases at Upfront Radical Cystectomy? J. Clin. Med. 2023, 12, 3367.

EP-0380

Correlation between bone involvement measurements calculated with ^{18}F-FDG and ^{68}Ga-PSMA in multiple myeloma patients

M. Seren Takahashi, *S. P. M. Souza, F. C. Frasson, G. B. Oliveira, V. P. Castro, F. V. Pericole, L. A. Velloso, C. A. Souza, I. Lorand-Metze, A. O. Santos, C. Ramos;*
University of Campinas, Campinas/SP, BRAZIL.

Aim/Introduction: 18F-FDG-PET/CT plays a significant role in the context of multiple myeloma (MM), being well established as an important tool for clinical management of these patients. However, due to the nonspecificity of FDG and the genetic heterogeneity of the lesions, other radiotracers have been proposed. Among them, PSMA has emerged as another important marker for MM[1]. Methods for quantifying bone involvement in MM patients have also been proposed, such as Percentage of Bone Involvement (PBI) and Intensity of Bone Involvement (IBI)[2]. Here, we aim to determine whether there is a correlation between PBI and IBI calculated in PET/CT with 18F-FDG and 68Ga-PSMA. ***Materials and Methods:*** In this study, 15 patients with MM were included, consisting of 8 men, with an average age of 66.7±10.7 years. All patients underwent PET/CT scans with 18F-FDG and 68Ga-PSMA on different days, with a maximum interval of 8 days between the scans. PBI was calculated as the percentage of bone tissue considered metabolically active. For 68Ga-PSMA and 18F-FDG, PBI was determined by a fixed threshold, with the mean SUV of the left atrium used for the former and the mean SUV of the liver used for the latter. Bone tissue volume was calculated using CT-based segmentation. IBI was calculated as PBI multiplied by the mean SUV of the metabolically active volume. The Spearman correlation, with a p-value<0.05, was used to assess the correlation between PBI and IBI in both imaging modalities.

Results: No significant correlations were found between the values calculated for 18F-FDG and 68Ga-PSMA for both PBI and IBI. For PBI, the Spearman correlation coefficient was 0.39 with a p-value=0.16. For IBI, the Spearman correlation coefficient was 0.41 with a p-value=0.13. The highest PBI and IBI values were found in different patients for both radiotracers. ***Conclusion:*** There was no correlation between bone involvement measurements calculated from 18F-FDG and 68Ga-PSMA PET/CT images, reinforcing the idea that the radiotracers are complementary in the context of MM. It is believed that the heterogeneous genetic profile of the disease leads to different uptake patterns for the two radiotracers. ***References:*** [1] Souza, Stephan PM, et al. "Head-to-head comparison of [68Ga] Ga-PSMA-11 and [18F] FDG PET/CT in multiple myeloma." European journal of nuclear medicine and molecular imaging 50.8 (2023): 2432-2440. EP-0381

Exploring the relationship between PET-CT ^{18}F-FDG parameters and cytogenetic features at multiple myeloma diagnosis

M. Sanchez Torrente, *S. Martin Aguilar, P. Guardia Jimena, L. Mena Bares, M. Ureña Lara;*
Hospital Universitario de Jaen, Jaen, SPAIN.

Aim/Introduction: Multiple myeloma (MM) is a common hematologic cancer, requiring ≥10% clonal bone marrow plasma cells or biopsy-proven plasmacytoma, with myeloma-defining events like hypercalcemia and anemia. Certain cytogenetic mutations at diagnosis have independent prognostic value. Treatment involves multi-drug regimens and, in eligible cases, autologous stem cell transplantation.Non-invasive risk stratification methods could optimize MM management. F^{18} fluorodeoxyglucose positron emission tomography/computed tomography (F^{18} FDG PET/CT) detects medullary and extramedullary disease, recommended for initial diagnostic workup and follow-up. Beyond diagnosis, FDG PET/CT findings predict prognosis. Extramedullary disease and high standardized uptake value (SUV) indicate poor progression-free survival. Volumetric parameters like metabolic tumor volume (MTV) and total lesion glycolysis (TLG) offer additional prognostic information. ***Materials and Methods:*** The study retrospectively analyzed 41 MM patients who underwent PET imaging and Certain cytogenetic analysis at diagnosis. PET parameters SUVmax, MTV, and TLG, were quantified, correlating cytogenetic mutations (Del1p/Amp1q, Del17p, t(4;14), t(11;14), t(14;16), Del13q) and bone marrow plasma cell percentage (PCP) with PET findings (pearson correlation-ANOVA). Additionally, a descriptive analysis was conducted to provide further insights into the study cohort. ***Results:*** Preliminary results didn't find correlation between the parameters studied, (P>0,05), probably due to a small sample size. Nonetheless, further patient enrollment is underway to elucidate PET parameters' relationship with cytogenetic features in MM diagnosis.The descriptive analysis showed: mean age=65; gender distribution=60%women-39%men; SUVmax mean= 4,6; SUVmax median=4,01; MTV mean=87,8; MTV median=6,4; TLG mean=318,8; TLG median=65; PCP mean=28%; PCP median=22%; Del1p/Amp1q+=7, Del17p+=1, Trasl 4-14+=0, Trasl11-14+=2, Trasl14-16+=0, Del13q+=3. ***Conclusion:*** While current findings lack certainty, ongoing research is crucial. Expanding sample sizes and refining methodologies promise more robust insights into PET parameters' association with MM cytogenetic features. The descriptive analysis shows normal parameters for the population studied, according to what has been published so far. Ultimately, this research aims to enhance MM understanding and clinical outcomes.

EP-0382

$^{[18F]}$Fluciclovine Compared to $^{[18F]}$FDG for Multiple Myeloma Imaging

M. Revheim[1,2], *J. Blakkisrud[3], J. Nørgaard[2,4], J. Connelly[3], A. Sherwani[3], F. Schjesvold[4,5], C. Stokke[3,6];*
[1]The Intervention Centre, Oslo University Hospital, Oslo, NORWAY, [2]Institute of Clinical Medicine, University of Oslo, Oslo, NORWAY, [3]Division for Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, [4]Oslo Myeloma Center, Department of Hematology, Oslo University Hospital, Oslo, NORWAY, [5]KG Jebsen Center for B Cell Malignancies, University of Oslo, Oslo, NORWAY, [6]Department of Physics, University of Oslo, Oslo, NORWAY.

Aim/Introduction: Multiple myeloma (MM) presents challenges in accurate imaging due to its multifocal nature and the need of early detection of minimal residual disease (MRD). Anti-1-amino-3-$^{[18F]}$-fluorocyclobutane-1-carboxylic acid (Fluciclovine), an analogue of leucine, offers an alternative to the commonly used 2-Deoxy-2-$^{[18F]}$F-fluoroglucose (FDG) PET. In this prospective pilot study, we performed a head-to-head investigation of Fluciclovine PET and FDG PET imaging in MM patients undergoing autologous stem cell transplantation (ASCT). ***Materials and Methods:*** Thirteen patients were included (NCT03966443). PET/CT imaging was conducted at baseline and three months after ASCT. Fluciclovine PET was performed using 4 MBq/kg, with image acquisition mainly at 15 minutes post-injection. For the FDG examinations, 3 MBq/kg was injected and acquisitions performed 60 minutes p.i. Visual assessments were performed by two nuclear medicine physicians, who categorized patients as positive or negative for each tracer. Additionally, a quantitative analysis was conducted for six patients. The bone marrow was segmented using a deep learning CT segmentation method. Volumes with high uptake were defined using thresholds based on the mean standardized uptake value (SUV) measured in liver plus two standard deviations (SDs) for FDG, and the mean SUV in aorta plus five SDs for Fluciclovine. SUVmax, and SUVmean multiplied by the volume above threshold (TLGeq) were extracted. Progression-free survival (PFS) data were recorded for all except one patient. ***Results:*** At baseline, 12/13 patients were positive for Fluciclovine and 10/13 for FDG. Three months after ASCT 1/12 patients were positive for Fluciclovine and 2/10 for FDG. Mean (SD) high uptake volume SUVmax for Fluciclovine was 9.8 (4) and 5.6 (0.9) for baseline and three months, respectively Mean FDG-SUVmax were 7.0 (3.0) and 5.0 (2.5) for baseline and three months, respectively. For Fluciclovine, mean TLGeq was 3175 (3060) ml for baseline and 202 (176) ml for three months. Mean FDG-TLGeq was 804 (1146) ml at baseline and 34 (72) at three months. No statistically significant difference in PFS was found between positive/negative-stratified patient groups, except at baseline for Fluciclovine (log rank $p < 0.001$). However, only one patient was Fluciclovine-negative. ***Conclusion:*** Fluciclovine demonstrates promise as an alternative to FDG-imaging in patients with MM. While no clear differences in PFS were observed using visual assessment of positive/negative status, this population was limited. Future work will investigate Fluciclovine in a larger cohort, and also explore quantitative parameters further.

Prognostic impact of [18F]FDG PET metabolic parameters in adult and pediatric soft-tissue sarcoma: a systematic review and meta-analysis

M. Yadgarov[1,2], *L. Berikashvili[2], E. Rakova[3], D. Kachanov[1], Y. Likar[1];*
[1]Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, RUSSIAN FEDERATION, [2]Federal Research and Clinical Center of Intensive Care Medicine and Rehabilitology, Moscow, RUSSIAN FEDERATION, [3]K+31 City Hospital, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Soft-tissue sarcomas (STS) are rare and heterogeneous malignancies with varied outcomes, highlighting the need for reliable prognostic indicators. This meta-analysis aims to evaluate the prognostic significance of [18F]FDG PET parameters in patients with, differentiating between adult and pediatric populations. ***Materials and Methods:*** We conducted a systematic review and meta-analysis following PRISMA guidelines, searching multiple databases (Medline, PubMed, Google Scholar, and the Cochrane Library) without language restrictions. Studies assessing the prognostic value of pre- and post-treatment [18F] FDG PET parameters (SUVmax, metabolic tumor volume [MTV], total lesion glycolysis [TLG]) in relation to event-free survival (EFS) and overall survival (OS) in patients with STS were included. Data extraction and risk of bias assessment were independently performed by two researchers. We used STATA 17 (StataCorp LLC, Texas, US) and Cochrane tool Review Manager (RevMan version 5.3) to perform meta-analysis. ***Results:*** Thirty-one studies involving 1,932 patients (adult and pediatric) were included. In adults, high pre-treatment SUVmax, MTV, and TLG and post-treatment SUVmax were significantly associated with worse EFS and OS (HR ranges for SUVmax: 1.68-3.13; MTV: 2.29-3.05; TLG: 2.85-3.23, all p-values < 0.05). However, in pediatric patients, these associations were not statistically significant. The prognostic impact of [18F]FDG PET parameters in pediatric STS remains unclear due to limited studies and non-significant findings. ***Conclusion:*** In accordance with the best available evidence to date, [18F]FDG PET metabolic parameters serve as significant prognostic markers in adults with STS but not in pediatric patients. Disparities between adult and pediatric STS highlight the necessity for age-specific research and prognostic tools. Future prospective, multicenter studies with standardized methodologies are essential to validate these findings and explore the clinical utility of [18F]FDG PET in STS treatment strategies.

EP-0384

Incidence of exclusive extrapelvic skeletal metastasis in prostate carcinoma on bone SPECT-CT scintigraphy

K. Agrawal[1], *P. Singh[1], T. Singhal[1], G. K. Parida[1], P. S. Patro[1], G. Gnanasegaran[2], A. Rahman[1];*
[1]AIIMS, Bhubaneswar, INDIA, [2]Royal Free Hospital, London, UNITED KINGDOM.

Aim/Introduction: Bone is one of the common sites of metastasis from prostate carcinoma. Bone scintigraphy is one of the most sensitive imaging modalities currently used for bone metastatic work-up. Skeletal metastasis in prostate carcinoma commonly involves pelvic bones. We retrospectively analyzed the bone scintigraphy data to determine the pattern of skeletal metastases in the prostate carcinoma. ***Materials and Methods:*** This retrospective observational study involves patients with biopsy-proven prostate carcinoma referred for bone scintigraphy for staging assessment. Patients with abnormal bone scintigraphy (BS) were evaluated for the pattern of skeletal involvement and data was presented in descriptive format in the form of percentages. ***Results:*** A total of 150 patients with biopsy proven prostate cancer who were referred for staging were included in the study. 13 of 150 patients (8.67%) had no abnormal uptake on planar images ruling out metastatic disease. 24 patients (16%) had heterogenous uptake in spine with distribution characteristic of degenerative disease and no scan pattern of metastatic disease. 30 patients (20%) had multifocal uptake involving both pelvic and extrapelvic bones on planar images typical for skeletal metastasis and were considered metastatic. 83 out of 150 patients (55.3%) had increased tracer uptake which were indeterminate, thus, SPECT-CT was acquired which showed 51 metastatic disease, 31 benign lesions and 1 indeterminate finding. 7 of 150 patients had exclusive pelvic bone uptake which was found to be metastatic in 4/7 patients in SPECT-CT. 56 out of 150 patients showed exclusive extrapelvic tracer uptake of which only 3 patients had vertebral metastatic disease. None of the patients with increased uptake exclusively in the extrapelvic-extraspinal location was metastatic. ***Conclusion:*** Incidence of exclusive extrapelvic skeletal metastatic disease in prostate carcinoma is 2% (excluding one patient with indeterminate finding). Further, none of the patients in the current study had exclusive extrapelvic-extraspinal metastasis. Thus, exclusive extrapelvic- extraspinal focal abnormality on planar BS, carries a very low probability of metastatic disease and hence, further imaging or SPECT/CT can be safely avoided in such cases. ***References:*** 1. EP-0385

Uterine sarcomas: our experience with PET-CT as an EURACAN reference center.

P. Nespral, *G. Cuesta Domingo, P. Daudén Oñate, P. Bascuñana Almarcha, A. Berardinelli Issea, M. Vaillant López, C. Rodríguez Rey, A. Ortega Candil, M. Cabrera-Martín;*
Department of Nuclear Medicine, Instituto de Investigación Sanitaria San Carlos (IdISSC). Hospital Clínico San Carlos, Universidad Complutense., Madrid, SPAIN.

Aim/Introduction: Uterine sarcomas are a rare entity, being characterized by a more aggressive behavior than the rest of uterine tumors. They are classified into several histological subtypes: carcinosarcomas, leiomyosarcomas, endometrial stromal sarcomas and adenosarcomas. PET-CT can be used both to assess distant involvement and to detect recurrence. Since we are a EURACAN reference center for these tumors, we intend to describe our experience. ***Materials and Methods:*** We retrospectively reviewed PET-CT studies with ^{18}F-FDG between 2014-2024, obtaining a total of 17 patients. The studies were analyzed by an expert nuclear physician and a radiologist. ***Results:*** The age range was 41-88 years. The most frequent

histological type was leiomyosarcoma in 12 patients (70%); in 3 high grade endometrial stromal sarcoma (18%), 1 carcinosarcoma (6%) and 1 undifferentiated sarcoma (6%). The indication was: 9 staging (52%) and 8 suspected recurrence (48%). Of the 17 patients, 5 had positive regional lymph nodes on PET (29%), with pelvic lymph node involvement being more frequent in staging (4 patients: 44%) than in recurrence (1 patient: 12.5%). The mean SUVmax of these nodes was 19.3 (31.2-11.3). 12 patients (70%) had metastases at diagnosis: 6 (66%) of the staging and 6 (75%) of the recurrences. The most frequent site of metastasis was the lung (9 patients: 53%), with mean SUVmax 5.05 (18.5-1.6). Six (35%) presented peritoneal carcinomatosis, with mean SUVmax 19.4 (39-20.1). The third most frequent were bone metastases (3, 17%) with mean SUVmax of 8.9. Only one patient had liver disease. ***Conclusion:*** Uterine sarcomas are a very rare group of neoplasms, generally associated with poor prognosis, so early diagnosis is essential. PET-CT with ^{18}F-FDG is a promising tool and appears to be useful both for initial staging and for recurrence.

EP-0386

Relationship between SUVmax and overall survival rate at FDG-PET scans in patients with leiomyosarcomas: a retrospective multicenter analysis

B. Ronchi, *G. Peña;*
FUESMEN, Mendoza, ARGENTINA.

Aim/Introduction: Our retrospective study aimed to assess the potential benefit of SUVmax in FDG-PET/CT and FDG-PET/MR scans for the characterization of leiomyosarcomas and its impact on overall survival. Researchers looked at FDG-PET/CT and FDG-PET/MR scans from 12 patients. They found that patients with an SUVmax value in the primary lesion under 11, were correlated with a 5-year overall survival and did not have metastatic disease at the moment of the diagnosis. These findings suggest that SUVmax values could be a clinically significant dependent prognostic marker for progression-free survival. The study highlights the importance of pre-surgery PET scans as a prognostic factor. ***Materials and Methods:*** Twelve patients with leiomyosarcoma tumors were included, from 2018 to 2023 at FUESMEN and COIR. We utilized a PET/TC GE-STE-16 and a 3.0T PET/MRI SIGNA GE with 3D TOF, which differ due to their disponibility and the medical request from the oncologist. Univariate analysis with Fisher analysis was performed between SUVmax values and the presence of metastasis at the first visit, tumor greatest dimension, and mainly with a 5-year overall survival. ***Results:*** After anatomopathological confirmation, we included 4 men (33%) and 8 women (66%). The primary localization of the leiomyosarcoma differed: 4 raised from the inferior vena cava (33.3%), 4 from the uterus (33.3%), 2 originated from muscle (16.6%), 1 from the scrotum (8.3%) and the last one from the retroperitoneal as unknown origin. The median SUVmax of the primary tumor lesion was 13.09 (range, 5-17.4). Distant metastasis was observed in 58.3% of the total. We noticed that the patients with an SUVmax value in the primary tumor equally or higher than 11 had distant metastasis at the moment of the diagnosis and particularly, they died in less than 5 years. This association was seen independently of the location of the primary lesion, age, gender, or tumor's greatest dimension. Thus, an SUVmax value higher than 11 could be related to a 5-year OS rate in leiomyosarcomas malignancies ($p < 0.01$). We also compared in a per-patient analysis, the characteristics of the SUVmax about the different locations of the LMS. We did not find a statistical association between the diverse origins, SUVmax 11 taken as objective, disease relapse nor a medium of tumor greatest dimension. ***Conclusion:*** The study highlights the importance of pre-surgery PET scans as a prognostic factor. SUVmax values could be a clinically significant dependent prognostic marker for progression-free survival.

EP-0387

Navigating metastatic Dermatofibrosarcoma protuberans: Harnessing ^{18}F-FDG PET/CT for prognostic insight

Y. Khandelwal, *S. A. Shamim, B. Jain, N. Kumar, S. Rastogi;*
AIIMS, New Delhi, INDIA.

Aim/Introduction: Dermatofibrosarcoma protuberans (DFSP) is an uncommon cutaneous soft tissue sarcoma characterized by locally aggressive growth and tendency for local recurrence. Metastatic DFSP presents significant challenges in management and prognosis. Imaging modalities such as computed tomography (CT) have traditionally been employed for assessing metastatic spread. However, role of FDG PET/CT in prognosis remains underexplored. ***Materials and Methods:*** We conducted a retrospective study involving 25 patients diagnosed with metastatic DFSP after local recurrence assessing utility of 18F-FDG PET/CT in prognostic evaluation. Patients underwent FDG PET/CT for restaging and subsequently for response assessment. Imaging findings were analyzed by experienced nuclear medicine physicians blinded to clinical outcomes. Prognostic parameters including metabolic activity, and presence of distant metastases were evaluated and correlated with clinical outcomes. ***Results:*** Total of 25 patients (M:F;15:10) with mean age of 41.9 years (18-76 years) were included undergoing treatment in tertiary care hospital in India. 10 patients had trunk as primary site, 8 patients had extremities and 7 patients had primary in head and neck region. All patients had local recurrence after surgery of primary site with 11 patients showing fibrosarcomatous variant of DFSP at histopathology after WLE of local recurrence site. On restaging FDG PET/CT, 72% had metabolically active lesion in post-operative bed indicating local recurrence with 88% patients having lung, 60% with lymph node s, 36% showing skeletal and marrow , 16% showing liver and 24% showing other rare sites of metastases with more than one site of metastases in few patients. Among quantitative parameters SUVmax was significantly higher ($p<0.001$) for patients with fibrosarcomatous transformation which are more aggressive than non-fibrosarcomatous variant. FDG PET/CT demonstrated superior sensitivity in detecting distant metastases (92% vs. 70% for CT) and provided additional metabolic information crucial for prognostication. SUVmax of metastatic lesions on FDG PET/CT correlated strongly with poorer overall survival ($p<0.008$). Furthermore, FDG PET/CT facilitated early detection of progressive disease in response evaluation and enabling timely therapeutic interventions. ***Conclusion:*** Metabolic information provided by FDG PET/CT, particularly SUV max of metastatic lesions, serves as valuable predictor of overall survival. Early detection of distant metastases and response evaluation with FDG PET/CT may guide treatment decisions and improve patient outcomes. Integration of FDG PET/CT into routine management of metastatic DFSP holds promise for enhancing prognostic accuracy and optimizing therapeutic strategies. To our knowledge, this is largest series of patients showing role of FDG PET/CT in this uncommon entity (DFSP).

EP-0388

Dynamic carbon-11-labeled methionine positron-emission tomography with texture analysis for the differential diagnosis between benign and malignant musculoskeletal lesions

T. Shinya, *T. Matsushita, Y. Otomi, M. Kubo, S. Takao, T. Nishisho, K. Sairyo, M. Harada;*
Tokushima University Hospital, Tokushima-city, JAPAN.

Aim/Introduction: This retrospective study assessed the diagnostic capacity of dynamic carbon-11 methionine (C-11 MET) positron-emission tomography (PET)/computed tomography for the diagnosis of pathologies in patients with primary unknown musculoskeletal lesions (MSLs) and explore the diagnostic performance of the texture analysis (TA) in differentiation between benign MSLs (BMSLs) and malignant MSLs (MMSLs). ***Materials and Methods:*** In total, 14 patients with 17 MSLs underwent dynamic scans (5-15 [phase 1], 15-25 [phase 2], and 25-35 [phase 3] min post-injection of C-11 MET). Volume of interest (VOI) was created for the entire musculoskeletal lesions and TA was performed using LIFEx software. We statistically compared the maximum standardised uptake values (SUVmax) for seven BMSLs, six primary malignant musculoskeletal tumours (PMMSTs), and four metastatic musculoskeletal tumours (MMSTs) cases and explored their diagnostic capacities using receiver operating characteristic (ROC) curve analyses. In addition, we statistically analyze the results of TA in BMSLs and MMSLs. ***Results:*** SUVmax gradually decreased or remained similar with minimal fluctuations in all BMSL cases and four of six PMMST cases. In contrast, SUVmax had been increasing tendency over time in two cases of PMMST and in all cases of MMST. Significant differences were observed in SUVmax for all time phases between BMSLs and MMSLs, in SUVmax for all time phases between BMSLs and PMMSTs, in SUVmax for all time phases between BMSLs and MMSTs, and in SUVmax for all time phases between PMMSTs and MMSTs. In ROC analyses, the areas under the curve (AUC) are higher than 0.917 in all analyses and AUC yielded the highest values at 1.00 for differentiating most intergroup comparisons. ***Conclusion:*** Dynamic C-11 MET PET scans and TA for C-11 MET PET have the potential to be good predictors of discriminating MSLs in patients with primary unknown MSLs in clinical practice.

EP-0389

Comparison of bone metastasis detection between bone scintigraphy recorded with a single fast whole-body 3D recording from a high-sensitivity 360° CZT camera and a conventional protocol combining whole-body planar with several SPECT acquisitions on an Anger camera

M. Perrin[1], *S. Ouguirti[1], A. Verger[1,2,3], P. Marie[1,2,3], A. Bahloul[1,3], L. Imbert[1,2,3];*
[1]CHRU de Nancy, Vandoeuvre-lès-Nancy, FRANCE,
[2]Nancyclotep, Vandoeuvre-lès-Nancy, FRANCE, [3]IADI INSERM U1254, Vandoeuvre-lès-Nancy, FRANCE.

Aim/Introduction: The OSS single-center non-inferiority trial aimed to determine whether a single high-speed whole-body CZT-SPECT recording of almost 18 min (CZT) provides equivalent results to a conventional longer duration recording protocol (40 to 60 min) combining whole-body planar with several SPECT acquisitions on an Anger hybrid system (ANG), in a total population of 146 cancer patients who were referred to bone scintigraphy for the detection or survey of bone metastasis. ***Materials and Methods:*** Patients were randomly assigned to ANG followed by CZT SPECT/CT recordings or the opposite, 3 to 4 hours after injection of 571 ± 42 MBq [99mTc]Tc-HDP. The SPECT/CT images were first analyzed independently, and then consensually by three experienced blinded observers, with bone metastasis results classified into three categories known to be associated with different therapeutic options: none, oligometastatic (< 5), or polymetastatic (≥ 5). ***Results:*** From the first 52 patients included in the OSS trial were analyzed and can thus be reported here. There were 17 men and 35 women, with mean age 66 ± 11 years, and mean body mass index of 28 ± 6 kg.m-2. All patients had a history of cancer (breast: 30, prostate: 17, others: 5), and 16 had a previous history of bone metastasis. The rates of total agreement between the three observers in the 3-group classification were high and were equivalent for ANG (89%) and CZT (87%) recordings. In total 8 (15%) and 10 (19%) patients were consensually considered to have, respectively, oligometastatic and polymetastatic metastasis on ANG images, and the corresponding rates were very close on CZT images, 9 (17%) and 10 (19%). The concordance rates between classifications consensually extracted from ANG and CZT images were 92% (48/52, kappa score: 0.89 ± 0.06), with only three discordant patients. These three patients were all considered to have single metastases, but only on ANG images in one case and CZT images in two cases. ***Conclusion:*** In cancer patients referred to bone scintigraphy for the detection or survey of bone metastasis, results extracted from a single fast (18 min) whole-body 3D bone scintigraphy recording provided by a high-sensitivity 360° CZT camera seem at least equivalent to those provided by a conventional and much longer (40 to 60 min) recording protocol combining whole-body planar and several additional SPECT recordings.

EP-0390

The usefulness of ^{18}F-FDG PET/CT imaging in theassessment of primary osseous and soft tissue sarcomas

F. Chaltout, *M. Somai, A. Mazhoud, o. ben hmida, i. yeddes, i. slim, i. meddeb, a. mhiri;*
Salah Azaiez institute, tunis, TUNISIA.

Aim/Introduction: Sarcomas are a heterogeneous group of aggressive connective tissue malignancies arising insoft tissues and bone.The aim of this retrospective study was to analyze the diagnostic accuracy of ^{18}F-FDG PET/CT in staging and detecting recurrence, in comparison with conventional imaging (CI) studies. ***Materials and Methods:*** We retrospectively evaluated 50 patients with histologically proven soft tissue or osseous sarcoma who had undergone a FDG PET/CT in our department from January 2020 until December 2023. We reviewed the pathology reports of these patients: epidemiological features, histological type of sarcoma, morphologic data, the maximum standardized uptake value (SUVmax) of each primary and/or most intense metastatic lesion, and the results of CI studies compared to ^{18}F-FDG PET/CT. ***Results:*** A total of 50 patients (31 women and 19 men) were referred for initial staging (10%), assessment of recurrence (68%), or evaluation of treatment response (22%). The mean age of these patients was 28 ± 19 years. Thirty-two percent were under the age of 16. Among those patients, 27 cases were soft tissue sarcomas and 23 were osseous sarcomas. The 27 cases of soft tissue sarcomas include 11 rhabdomyosarcomas, 5 leiomyosarcomas, 5 synovialosarcomas, 4 liposarcomas, 1 epitheloid sarcoma, and 2 unknown types. The 23 cases of osseous sarcomas include 12 ewing sarcomas (52%) and 11 osteosarcomas (48%).The mean SUVmax of the positive lesions for the cases of soft tissue and osseous sarcomas were respectively 11,6 and 12.Among those 50 cases, 35 patients (70%) have undergone CT and/or MRI before

referring to our department. PET/CT results, compared with conventional imaging, were concordant in 20 patients (57%) and discordant in 15 patients (43%). PET/CT shows false negative results in 6 patients due to lung micronodules (2). Moreover, 4 liver metastases were not detected by PET/CT. However, PET/CT detected more lesions in 9 cases (peritoneal carcinomatosis, muscular metastasis, bone polymetastasis···). PET/CT was effective in clarifying uncertain findings from CT and/or MRI in 10 cases. Therefore, PET/CT led to a change in the stage of the disease in almost half of patients. ***Conclusion:*** Overall, this study showed that PET/CT can be an important contributor towards sarcoma initial staging, detection recurrent disease, and evaluation of treatment response due to the combined metabolic and morphological information provided by this imaging. Nevertheless, larger studies will be helpful to further establish the clinical value of PET/CT in sarcomas.

EP-0391

Hybrid Imaging-Driven Adjuvant Treatment for Early Stage Malignant Melanoma (ESMM)

L. Chavdarova[1], *V. Georgiev[2], I. Gavrilova[3], E. Piperkova[4];*
[1]Clinic Of Nuclear Medicine, University Specialized Hospital for Active Treatment in Oncology, Sofia, BULGARIA, [2]Clinic Of Surgery, University Specialized Hospital for Active Treatment in Oncology, Sofia, BULGARIA, [3]Clinic Of Oncodermatology, University Specialized Hospital for Active Treatment in Oncology, Sofia, BULGARIA, [4]Clinic Of Nuclear Medicine, University Specialized Hospital for Active Treatment in Oncology, Sofia, UNITED KINGDOM.

Aim/Introduction: Adjuvant immune-(ImT) and target-therapies (TT) for stage IIB/C/III melanoma show big promise for improving outcome. High-risk ESMM patients, including SPECT/CT-detected-sentinel lymph node (SLN)-micrometastatic disease, require accurate ^{18}F-FDG-PET/CT staging for treatment tailoring. While in advanced MM PET/CT is established via elaborated criteria, its role in earlier stages-adjuvant setting is not that well acknowledged. The aim of our study was to assess the input of hybrid imaging in clinical algorithm, with special regard to ImT/TT-monitoring and SLN-status. ***Materials and Methods:*** This prospective study included 98 ESMM patients (50 female, 48 male, 28-83y; T-stage IA-IIC, cN0cM0), diagnosed 11.2019-11.2023. SPECT/CT-sentinel lymphoscintigraphy (SLSc) was performed in all pts, gamma-probe-guided biopsy (SLNB) followed. Micrometastasis-positive (+)SLN pts were tailored to adjuvant treatment (AT: ICIs or BRAF/MEK-inhibitors). Post-SLNB full-digital-PET/CT was indicated in all SLN(+)-cases or in high-risk SLN(-), with follow-up 3-6 months-scans to discriminate no evidence of disease (NED), progressive (PD), stable disease (SD), partial (PR), or complete metabolic response (CMR). Time-to-PD (TTP-first diagnose to PET-PD) and overall survival (OS-first diagnose to last PET) were estimated. ***Results:*** SPECT/CT found 11,3% more SLN than planar imaging, more than one route of lymphatic drainage in 28,6% of pts, in-transit SLN of 3-4mm in 4 pts - one with solitary in-transit-SLN. 18,4% of pts had (+)SLN, including 2(+) in-transits. Higher MM T-stage showed 2,4-fold higher chance for (+)SLN. One post-SLNB-PET/CT was performed in 59 pts (PET1 60%), 11 (18,6%) (+) SLN. Thirty pts had a second scan (PET2), 18 pts PET3, 7pts PET4, 5pts PET5, 1 pt - PET6-7. PET1 showed PD in 8pts (13%), 4 of them with (+)SLN, progression sites - metastatic LNs (6pts), in-transit (1), bone (1), breast lesion (1). TTP ranged 9-19 months (mo) for SLN(-), 2-14 mo for SLN(+). ImT was started in 5pts, TT in 2, radiotherapy in 2, 1 watch-and-wait approach. In 16pts PET1 found inconclusive findings to be observed (TBO), 37 pts - NED. Follow-up PET/CTs reported overall 3 CMR-, 9 PR-, 2 SD-, 1 sarcoid-like TT-reaction, 9 NED-, 9 PD, with consequent AT-adjustment. OS ranged 29-45 mo for SLN(-) and 12-30 mo for SLN(+) pts. ***Conclusion:*** Hybrid imaging in ESMM plays an essential role for individualized treatment. SLSc-SPECT/CT is needed for correct staging, in-transit SLN-detection and prognosis-critical early start of AT. Post-SLNB-PET/CT should be implemented in SLN(+)-cases, patient/lesion associated risk factors and therapy response assessment. Our ongoing study shows longer TTP and OS for SLN(-)-PD-pts undergoing AT, further analysis follows.

EP-0392

Comprehensive and longitudinal PET features of all metastatic lesions improves progression-free survival (PFS) prediction in metastatic melanoma (MM) patients receiving immune checkpoint inhibitors (ICIs)

V. Santoro-Fernandes[1], *K. Strašek[2], B. Schott[1], A. Deatsch[1], K. Škalič[3], A. Doma[3,4], M. Reberšek[5,4], N. Hribernik[5,4], V. T. Ma[6,7,8], R. Jeraj[1,7,2];*
[1]Department of Medical Physics, School of Medicine and Public Health, University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA, [2]Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, SLOVENIA, [3]Department of Nuclear Medicine, Institute of Oncology Ljubljana, Ljubljana, SLOVENIA, [4]Faculty of Medicine, University of Ljubljana, Ljubljana, SLOVENIA, [5]Department of Medical Oncology, Institute of Oncology Ljubljana, Ljubljana, SLOVENIA, [6]Department of Medicine, Division of Hematology, Medical Oncology, and Palliative Care, School of Medicine and Public Health, University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA, [7]Carbone Cancer Center, University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA, [8]Department of Dermatology, School of Medicine and Public Health, University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Predicting clinical outcomes of ICI-treated MM patients is an unmet need. Relatively low performance is achieved using traditional approaches (EORTC, PERCIST), which analyze a limited number of lesions on one time-point, overlooking complex spatial response patterns. In this study, we explored the added value of comprehensive (all lesions) assessment and longitudinal treatment response features in predicting clinical outcome of ICI-treated MM patients. ***Materials and Methods:*** We retrospectively assessed $^{[18F]}$FDG PET/CT scans acquired at baseline and after anti-PD-1 based ICIs (post-treatment). PFS was determined from ICI start to clinical progression and used to stratify favorable (PFS>11.5 months) from unfavorable responders. All lesions were contoured, and quantitative features extracted. Lesions were matched between time-points and feature variation was calculated. The lesion-level features were aggregated into patient-level features. Using five-fold cross validation, optimal features were selected for maximum relevance and minimum redundancy and a multivariate linear regression (MLR) model was fitted for PFS regression., which was used for patient stratification. The all-lesions results were compared to five-lesions (PERCIST) and one-lesion (most conspicuous). The longitudinal results were compared to baseline-only and post-treatment-only. The

regression was evaluated using RSME and stratification using AUROC, Kaplan-Meier, and Proportional-Hazards analyses. ***Results:*** Images from 53 patients were identified (post-treatment median=3 months, min=1.6, max=4.2). Patients received ipilimumab+nivolumab (n=11), nivolumab (n=6), or pembrolizumab (n=36). Median follow-up and PFS were 42 and 9 months. Twenty-three patients responded favorably. Altogether, 632 lesions were identified (patient median=5, min=1, max=77]). Patient stratification and HRs were significant using features from one-lesion, five lesions, baseline-only, and post-treatment-only. However, longitudinal features from all-lesions yielded the most significant stratification (p=5×10-7, log rank) and HR=0.002 (95% C.I. [0.0002, 0.038]; p=1.6×10-5). MLR using features from all-lesions (RMSE=21 months) was superior to five lesions (RMSE=23), and one lesion (RMSE=28). The AUROC using all-lesions was 0.84, significantly higher than five lesions (AUROC=0.76, p=.001), and one lesion (AUROC=0.72, p=<.001). MLR using longitudinal features (RMSE=21) was superior to baseline-only (RMSE=23), and post-treatment-only (RMSE=22). The AUROC using longitudinal features was 0.84, significantly higher than baseline-only (AUROC=0.79, p=.04) and post-treatment-only (AUROC=0.76, p<.001). ***Conclusion:*** We are the first to investigate the utility of longitudinal features from all lesions for outcome prediction in ICI-treated MM patients. Our work suggests that an MLR framework combining multiple imaging features yields PFS prediction that leads to significant binary patient stratification. The PFS prediction and patient stratification are improved using longitudinal features from all lesions.

EP-0393

^{18}F-FDG PET/CT imaging predictions of immunotherapy-related adverse effects - single Center experience

S. Rogan[1], *A. Tabain[1], I. Radumilo Klarić[1], J. Maric Brozic[2];*
[1]Departament of Radiology and Nuclear Medicine, PET/CT Centre Polyclinic Medikol, Zagreb, CROATIA,
[2]Departament of Oncology and Nuclear Medicine, U.H.C. Sestre milosrdnice, Zagreb, CROATIA.

Aim/Introduction: Immunotherapies represent a major advance in melanoma therapy and various types of immunotherapy (IT) have been established in recent years as a standard of care in melanoma patients resulting survival benefit. However, a wide range of immune related adverse events (irAEs) have been reported, some of which can be apparent on PET/CT imaging. ***Materials and Methods:*** This is a retrospective study of the patients (pts) diagnosed with metastatic melanoma who were subjected to immunomodulating therapy during up to 2 years period with nivolumab and pembrolisumab. F^{18} FDG PET-CT findings from single PET/CT Centre were reviewed, and the patients with immune-mediated side effects were selected for further analysis, in conjunction with review of clinical progress notes, the results of laboratory tests, and findings of other imaging tests to confirm side effects of IT found on PET/CT imaging. ***Results:*** During 12 months period ^{18}F-PET/CT were performed 904 times in 669 patients with melanoma in our Centre. Among them 196 pts have metastatic melanoma and they have two, three or even four times repeated PET/CT to monitor treatment response (evaluation with PET/CT is done in a three months period). Out of 196 pts, 29 of them were on immunotherapy alone (12 pts receive nivolumab and 17 pembrolizumab), while others received specific therapy and were not included in these study. PET/CT were identified six patients with immune-mediated side effects among the 29 patients being treated with IT. These immune mediated side effects include new findings of abnormal increased FDG uptake associated with immune-mediated thyroiditis (2 pts), pneumonitis (3 pts), duodenitis (1 pt), colitis (3 pts) and athritis (3 pts) but some of patient show more than one site of increased FDG uptake related to irAEs . Patient with duodenitis was admitted twice to endoscopic procedure and biopsy to confirmed inflammation and rolled out new site of metastases. ***Conclusion:*** FDG PET-CT was highly predictive of treatment outcome in a retrospective evaluation of 196 patients who had unresectable metastatic melanoma and receive specific or IT. FDG PET-CT was also highly predictive of irAEs among 29 pts received IT alone and accurately identified pts who has severe irAEs and need to change therapy management. So, we concluded that early detection of irAEs is essential to aid management of patients and to reduce associated morbidity. It is also important not to mistake treatment related effects of IT for disease.

End of planar bone scintigraphy: increased diagnostic performance of SPECT only scans in breast and prostate cancer

J. Hammes, *V. Bohuslavizki, W. U. Kampen;*
Radiologische Allianz, Hamburg, GERMANY.

Aim/Introduction: Bone scintigraphy is an essential tool in assessing osseous metastatic burden in the workup of oncological conditions, especially in breast and prostate cancer, due to its sensitivity to osteoblastic activity. This study investigates the potential for SPECT-only and SPECT/CT-only imaging protocols or surpass the diagnostic accuracy of conventional imaging protocols in bone scintigraphy. ***Materials and Methods:*** This retrospective analysis involved 74 breast cancer and prostate cancer patient datasets from routine diagnostic bone scintigraphy. Patients underwent planar whole body imaging as well 4-bed SPECT scans (head to mid of thighs) with reduced acquisition duration and auxiliary CT scans of thorax and abdomen. Imaging was performed on a hybrid 2-detector SPECT/CT scanner. Metastases, degenerative and unclear lesions were counted by two independent experienced readers. The study compared sensitivity and specificity in metastasis detection of a conventional imaging protocol (planar scans together with 1-bed position SPECT) with SPECT/CT only-protocols of various axial field of view lengths. Deviations from the conventional imaging protocol were assessed using T-tests and ANOVA. ***Results:*** 4-bed position SPECT-only and SPEC/CT protocols demonstrated a significant reduction in the number of unclear lesions, indicating improved diagnostic specificity (p-value: 0.0022). A notable difference was also observed in the detection rate of metastases with the SPECT-only protocols showing an advantage over the conventional protocols (p-value: 0.0011), particularly in prostate cancer patients. Missed metastases in lower body parts not comprised in the the SPECT-only protocols were negligible and did not affect the total clinical assessments. ***Conclusion:*** SPECT-

only and SPECT/CT-only imaging protocols show a potential for enhanced diagnostic sensitivity and specificity as compared to conventional imaging protocols. With reduced SPECT acquisition durations, the total scan time of 40 minutes does not exceed typical conventional scan times by a lot. Reduced SPECT imaging statistics are compensated by additional information from the auxiliary CT. When combined with diagnostic CT imaging in a one-stop-shop examination, patient comfort could be increased further by eliminating the need for an additional CT-only scan in the workup of breast and prostate cancer patients.

EP-0395

Preliminary comparison of 68Ga-FAPI-46 against ^{18}F-FDG, 68Ga-DOTATATE and 68Ga-Pentixafor PET/CT/MR imaging in the assessment of various cancer types

***H. Dadgar*[1],** *A. Al-Ibraheem[2], M. Haidar[3], A. A Esmail[4], B. Al-balooshi[5], F. Marafi[6], H. Al-Alawi[7];*
[1]Nuclear Medicine and Molecular imaging research center, RAZAVI Hospital, Mashad, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Nuclear Medicine, King Hussein Cancer Center, Amman, Jordan, Jordan, JORDAN, [3]Diagnostic Clinical Radiology Department, American University of Beirut, Lebanon, Beirut, LEBANON, [4]8Nuclear Medicine department, Kuwait Cancer Control Center, Kuwait, Kuwait, KUWAIT, [5]Dubai Nuclear medicine & Molecular imaging Center- Dubai Academic Health corporation- DAHC, UAE, Dubai, UNITED ARAB EMIRATES, [6]Jaber Alahmad Center of Nuclear Medicine and Molecular imaging, Kuwait, Kuwait, KUWAIT, [7]Nuclear Medicine department, Amir Al-momineen Specialty Hospital, Al-Najaf Governorate, Iraq, Najaf, IRAQ.

Aim/Introduction: 68Ga-FAPI PET/CT imaging allows for effective lesion detectability in cancer microenvironment owing to the relatively high intra-tumoral uptake and low background. This work reports on preliminary comparison between 68Ga-Pentixafor and 68Ga-FAPI-46 PET radiotracers against commonly used ^{18}F-FDG and 68Ga-DOTATATE PET radiotracers in the assessment of various cancer types. ***Materials and Methods:*** Eleven patients with histopathologically confirmed breast cancer, gastric, cervical, glioblastoma multiform (GBM), well-differentiated adenocarcinoma, papillary thyroid carcinoma (PTC), Ewing's sarcoma, colon, and medullar thyroid cancer (MTC) were retrospectively studied. Nine patients were scanned with ^{18}F-FDG, eleven patients with 68Ga-FAPI, three patients with 68Ga-DOTATATE, and one patient with 68Ga-Pentixafor on a Siemens Biograph 6 PET/CT scanner. PET/CT images were evaluated by two nuclear medicine physicians to identify malignant lesions and perform semi-quantitative analysis to calculate maximum standardized uptake value (SUVmax) and target-to-background ratio (TBR). ***Results:*** The evaluation of the eleven subjects demonstrated the effectiveness of 68Ga-FAPI-46 compared to ^{18}F-FDG for the detection of metastasis in the lymph nodes (55 vs. 49), liver (4 vs. 3), and bone (4 vs. 3). 68Ga-Pentixafor and 68Ga-DOTATATE PET/CT scans exhibited no significant differences with both being inferior to 68Ga-FAPI-46 PET radiotracer in terms of metastasis detection. Semi-quantitative analysis showed that the TBR and SUVmax were significantly higher in 68Ga-FAPI-46 PET than ^{18}F-FDG PET for bone metastases and lymph nodes. ^{18}F-FDG and 68Ga-FAPI-46 images exhibited similar SUVmax in liver metastases. However, the TBRs in 68Ga-FAPI-46 images were significantly higher than those in ^{18}F-FDG images. ***Conclusion:*** Improved malignancy detection rates for metastases in the liver, lymph nodes, and bone were observed for 68Ga-FAPI-46 PET compared to 68Ga-DOTATATE, ^{18}F-FDG, and 68Ga-Pentixafor PET.

EP-0396

Using ^{18}F-FDG PET/MR as an initial staging procedure for pediatric malignant tumors

Y. Xu; *Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.*

Aim/Introduction: The purpose of this study was to determine the clinical value and cost-effectiveness of PET/MR as an initial staging procedure for pediatric malignant tumors compared with the PET/CT and conventional work-up (CWU). ***Materials and Methods:*** From August 2017 to October 2022, 1359 pediatric malignant tumor patients(Including 296 neuroblastoma, 126 nephroblastoma, 240 hepatoblastoma, 108 rhabdomyosarcoma, 244 lymphoma, 142 malignant germ cell tumors, 203 non-habdomyosarcoma soft tissue sarcoma)confirmed by pathology in our center were included in this study. Among them, 318 patients underwent PET/MR before treatment,440 underwent PET/CT and the remaining 601 only underwent CWU. Charges were used as issued in 2021 by the Medical Insurance Administration Bureau of Zhejiang, China. Each patient should be followed up for at least 1 year, with the final clinical staging as the gold standard. Incremental costeffectiveness ratio (ICER) measured cost of using PET/MR per percent of patients who avoid missed or misdiagnosis. ***Results:*** The percentages of missed or misdiagnosed cases in PET/MR, PET/CT, and CWU were 4.7%, 9.1%, and 20.8%, respectively($p<0.001$). The mean interval from pathological diagnosis to initiation of treatment was 4.2 days in the PET/MR group, 8.1 days in the PET/CT group and 13.8 days in the CWU group ($p< 0.001$). Mean cost per patient was \$1381 for PET/MR,\$739 for PET/CT and \$446 for CWU. Compared to CUW, the ICER for patients using PET/MR and PET/CT to avoid missed or misdiagnosis is \$58 and \$25 per percentage, respectively.The ICER between PET/MR and PET/CT is \$145. ***Conclusion:*** Compared with CWU and PET/CT, PET/MR reduced missed or misdiagnosed cases risk and decreased workup of incidental findings, allowing for earlier treatment start. Meanwhile, PET/MR can significantly reduce radiation exposure in pediatric patients during examination. It may be cost-effective in initial staging procedure for pediatric malignant tumor patients.

EP-0397

Clinical-radiomics nomogram based on [18F]FDG PET/CT for differentiation of lymphoma and cancer of unknown primary

M. Xu, *W. Chen, B. Gu, S. Song;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: To develop and validate a [18F] fluorodeoxyglucose ([18F]FDG) PET/CT-based nomogram combined with clinical and radiomic signatures to distinguish lymphoma and cancer of unknown primary. ***Materials and Methods:*** The retrospective study was conducted from January 1, 2010, to July 31, 2022 at Fudan University Shanghai Cancer Center (FUSCC). All patients underwent [18F]FDG PET/CT to simultaneously obtain metabolic and structural images. Patients with cervical poorly differentiated cancer and were clinically and pathologically diagnosed with lymphoma and cancer of unknown primary (CUP) were randomly divided into training group (n = 134) and test group (n = 58) with a ratio of 7:3. Radiomic signatures (n = 1967) were extracted from the volume of interest on PET/CT images. The least absolute shrinkage and selection operator (LASSO) algorithm and multivariable logistic regression analysis were used to screen for radiomics signatures and clinical features and construct clinical-radiomics model. ***Results:*** This study comprised 151 CUP patients (female: 23/151, 15.2%) and 41

lymphoma patients (female: 22/41, 53.7%). The area under curves (AUCs) for the PET/CT radiomics signatures selected from the nodule area with highest SUVmax were 0.851 and 0.736 in the training and test group. The integrated clinical-radiomics model, incorporating radiomics signatures, gender and heterogeneity index, demonstrated benign diagnostic efficacy with the AUCs of 0.929 and 0.837 in the training and test group, respectively. The nomogram showed satisfactory calibration and clinical benefit in distinguishing CUP and lymphoma patients. ***Conclusion:*** The study developed a nomogram combining clinical and radiomics signatures and validated the potential to predict the pathological type of patients with cervical poorly differentiated cancer.

EP-0398

Exploring the role of ^{18}F-FDG PET/CT in functioning and non-functioning adrenocortical carcinomas

***C. Ganapathy*[1],** *N. Damle*[1], *M. Tripathi*[1], *C. Bal*[1], *S. Sagar*[1], *L. Goriparti*[1], *N. Tandon*[2], *Y. Gupta*[2], *S. Chumber*[3], *P. Ranjan*[3], *K. Kataria*[3], *S. Agarwal*[4], *G. Puri*[3];
[1]Department of Nuclear Medicine, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA, [2]Department of Endocrinology, Metabolism and Diabetes, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA, [3]Department of Surgical Disciplines, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA, [4]Department of Pathology, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA.

Aim/Introduction: Adrenocortical carcinoma (ACC), a rare malignant adrenal cortex neoplasm, carries poor prognosis due to its aggressive nature, rapid progression and high recurrence rate. It can be functioning (secreting hormones) or non-functioning. This study aims to assess the role of 18F-FDG PET/CT in patients with adrenocortical carcinoma and compare findings between those with functioning and non-functioning tumors. ***Materials and Methods:*** Data from consecutive patients with histopathologically proven ACC, who underwent 18F-FDG PET/CT between January 2017 and April 2024 in our department were retrospectively analyzed and correlated with hormone profile. Follow-up scans categorized responses as progressive disease, stable disease, partial response or complete response according to PERCIST 1.0 criteria. Quantitative variables were assessed for normality using the Shapiro-Wilk test, presented as mean (SD) and compared using the T-test. ***Results:*** Fifty-nine patients (27-men, 32-women) with adrenocortical carcinoma underwent 102 18F-FDG PET/CT scans: 54.2% (32/59) for baseline evaluation and 45.8% (27/59) for re-staging/response assessment/surveillance only. Among those undergoing baseline evaluation, 40.6% (13/32) had functioning tumors (median age 27.9 years) and 59.4% (19/32) had non-functioning tumors (median age 50 years). Resectable disease was noted in 61% (8/13) with functioning tumors and in 36.8% (7/19) with non-functioning tumors, while the remainder had unresectable/distant metastatic disease. Adrenal to blood-pool SUVmax ratio was significantly higher in non-functioning tumor group [9.39 (3.79) vs 5.84 (2.51), p=0.022]. Common distant metastatic sites were lungs (11/16) and liver (7/16). Among those undergoing post-treatment follow-up scans, 37% (10/27) had functioning tumors and 63% (17/27) had non-functioning tumors. In the functioning tumor group, 60% had localised disease, with 33% (2/6) developing recurrence post-surgery, while in the non-functioning tumor group, 57.4% (4/7) developed local/metastatic disease recurrence post-surgery and overall the common site being post-surgical bed. Disease progression on systemic therapy was comparable between groups: 61% (8/13) in non-functioning and 66% (4/6) in functioning groups. ***Conclusion:*** In adrenocortical carcinoma patients, 18F-FDG PET/CT showed differential uptake in functioning and non-functioning tumors. Non-functioning tumors often present with higher adrenal to blood-pool SUVmax ratios and have higher rates of recurrence.

EP-0399

Detection Efficiency of ^{18}FDG PET/CT for Detecting Primary Tumor in Carcinoma of Unknown Primary (CUP): Single Center Cross Sectional Study over 2017-2023 (Extension Study)

N. Fatima, *M. u. Zaman;
Aga Khan University, Karachi, PAKISTAN.*

Aim/Introduction: This is an extension of an already published parent study by same group in 2020 by Fatima et al1 over smaller cohort, to further validate the published facts of detection efficiency of 18Fflourodeoxyglucose positron emission tomography/computed tomography (18FDG PET/CT) in patients with CUP over larger sample from 2017-2023. ***Materials and Methods:*** This single center cross sectional study was conducted at PET/CT Section of Aga Khan University Hospital Karachi, Pakistan (ERC:2024-9755-28071). Patients with CUP and had baseline 18FDG PET/CT for identification of hypermetabolic primary site were retrospectively recruited from 2017-2023 (included 47 patients of parent study1). 18FDG PET/CT scan was acquired using standardized protocol, and patients with suggested hypermetabolic primary sites underwent biopsies. Scan findings and biopsy results were analyzed to find the detection rate, sensitivity, area under curve (AUC), and positive predictive value (PPV). As no biopsy was performed in unidentified primary site, all those cases were considered false negative. ***Results:*** During study, 230 consecutive patients with CUP were included. Similar trend was observed in patients' demographics in mean age (58 ± 14 years), body mass index (26.82 ± 5.43) and male predominance (63%). 18FDG PET/CT based suggested hypermetabolic primary site was identified in 60% (138/230) patients (74% parent study2) and 92% (127/138) true positive (TP) and remaining 08% (11/138) were false positive respectively on performed biopsy (76% TP and 24% FP in parent study1). Detection rate, sensitivity and PPV of 18FDG PET/CT for CUP were 55%, 58%, and 92%, respectively (57%, 68% and 76% respectively in parent study1). The remaining 40% (92/230) patients with unidentified primary site on 18FDG PET/CT did not have justification of biopsy. No statistically significant difference was found in patients and tumor' demographics in true positive and false negative cases. Receiver operating characteristic curve revealed statistically significant diagnostic strength of 18FDG PET/CT for detecting unknown primary with AUC 0.710; P <0.0001; standard error = 0.017; confidence interval: 0.647-0.768 (AUC 0.667; p=0.054 non-significant in parent study1). ***Conclusion:*** We support our previous published findings that detection efficiency of18FDG PET/CT for identifying primary tumor in CUP is 55% with enhanced PPV, reduced FP and overall, statistically significant better diagnostic accuracy in current study over larger sample size. We strengthen our previous conclusion that 18FDG PET/CT is an effective tool for detecting primary tumor in patients with CUP and its upfront use could preclude the use of many futile diagnostic procedures. ***References:*** World J Nucl Med 2020;19:47-51.

EP-0400

What can serum vascular endothelial growth factor do for ^{68}Ga-PSMA image for patients with clear cell renal cell carcinoma?

M. Zhang; *Xijing Hospital, the Fourth Military Medical University, Xi'an, CHINA.*

Aim/Introduction: To investigate the value of serum VEGF in selection of patients with ccRCC suitable for 68Ga-PSMA-11 PET and its use in patient prognosis prediction. ***Materials and Methods:*** This was a retrospective study of ccRCC patients who underwent 68Ga-PSMA-11 between January 2021 and October 2023. Analysis was based on radiological parameters and angiogenesis indicators, including visual score of PSMA, SUVmax, volume rate (VR) of SUV≥50%SUVmax, and serum VEGF. Evaluated the correlation of serum VEGF and PSMA, the efficacy of serum VEGF in selecting high PSMA uptake ccRCC and the role of PSMA in predicting patient risk. ***Results:*** Totally of 44 ccRCC patients evaluated serum VEGF before PSMA scan and operation were included in this study. Serum VEGF was 86.7±34.4 pg/mL, average SUVmax was 15.3±8.97, VR was 0.32±0.28, the median of PSMA IHC stain was 2 and visual score was 2. Serum VEGF showed no correlation with PSMA IHC stain (r=-0.054, P=0.816) and VR (r=0.065, P=0.748), moderate correlation with SUVmax (r=0.338, P=0.025) and visual score (r=0.405, P=0.008). Based on the visual score of PSMA image, low group (0-1) and high group (2-3), serum VEGF was significant different in two groups (P=0.029). Serum VEGF was a good predictor of PSMA PET visual score with an AUC value of 0.707 (P=0.043), with cut-off value 67.71 pg/mL, the sensitivity 85% and specificity 78% for PSMA visual scores. Patients had high pre-operation serum VEGF might show high PSMA uptake. 19 patients measured serum VEGF post-operation and the median of follow-up was 81 days (IQR: 36-181 days). All patients imaging examination and clinical signs were normal during follow-up time, while serum VEGF of 9 patients increased during the follow-up time. Compared the pre-operative PSMA uptake characteristics between groups, SUVmax was no statistically difference (P=0.464), VR showed significantly difference (P=0.049), patients with increased VEGF had lower VR. ROC curve analysis found that using VR to predict postoperative VEGF changes, with an AUC value of 0.750 (P=0.143), sensitivity 50% and specificity 100%. Patients with preoperative VR≤0.42 were more likely to have increased VEGF post-operative. Serum VEGF was associated with patient prognosis, and results suggested that patients with low VR (high intratumoral heterogeneity) may have poor prognosis. ***Conclusion:*** Our study showed that pre-operative serum VEGF levels can provide assistance in screening patients suitable for PSMA imaging. Base on the change of serum VEGF, the Intra-tumoral heterogeneity index VR had potential value in predict of tumor prognosis risk.

EP-0401

Prognostic Role of FDG PET/CT Findings in Oligometastatic Bladder Cancer

S. Demir, *E. Tuncay Ibis, U. Aydos, E. Balcı, L. Atay; Gazi University, Faculty of medicine, Ankara, TÜRKIYE.*

Aim/Introduction: A recently published consensus report for the definition of oligometastatic disease in bladder cancer (OMBC) made some recommendations regarding the definiton of oligometastatic disease and total number of metastatic lesions (≤ 3 lesions) in muscle-invasive bladder cancers [1]. In this study, it was aimed to investigate the relationship between FDG PET/CT findings and patient prognosis in OMBC. ***Materials and Methods:*** The data of 40 patients diagnosed with muscle-invasive bladder cancer, who underwent PET/CT for primary staging or restaging and had oligometastatic disease were evaluated retrospectively. The number of distant metastatic lesions and metastatic organs, distant metastatic sites and the presence of pelvic lymph node (LN) metastasis were examined. The highest SUVmax, total MTV and total TLG values of the lesions were determined. Progression-free survival (PFS) and overall survival (OS) times of the patients were calculated from the date of PET/CT imaging. Cox proportional hazards regression models were used to identify predictors for PFS and OS. Statistical analyses were performed on SPSS 23.0. Additionally, nomograms were created to determine the probability of 1-year-progression and 2-year-mortality by using the lrm() and nom() functions in the R software rms package. ***Results:*** Synchronous disease was present in 19 and metachronous disease was present in 21 patients. 19, 10 and 11 patients had 1, 2 and 3 distant metastatic lesions, respectively. 33, 6 and 1 patients had distant metastasis in 1, 2 and 3 organs, respectively. Pelvic LN metastasis, distant LN metastasis, lung metastasis, bone metastasis and extrapulmonary soft tissue metastasis were observed in 6, 13, 13, 11 and 11 patients, respectively. There were 24 patients who received local treatment to metastatic lesion in addition to systemic treatment. While there were 15 patients with progression within the first year, there were 19 patients with mortality within the two years. In multivariate Cox regression analysis with backward stepwise selection, the number of distant metastasic lesions, SUVmax and soft tissue metastasis were found as independent predictors for PFS (p=0.004, p=0.007, p=0.009, respectively). The number of involved organs, SUVmax and the presence of local treatment were also found as independent predictors for OS (p=0.001, p=0.034, p=0.048, respectively). ***Conclusion:*** In our study, the number of metastatic lesions and involved organs, the presence of soft tissue metastasis, SUVmax level and treatment modality were found as prognostic factors in OMBC. ***References:*** [1] Labaki C, et al: Oligometastatic Bladder Cancer: Defining a Novel Entity. Eur Urol 2023;84(4):390-392.

Novel and Precise Volumetric Tools for Assessing the Activity of Brown Adipose Tissue and Uncovering the Mysteries Underlying its Function

W. Jalloul[1,2,3], *M. Moscalu[1], M. Gutu[4], M. Gutu[4], D. Jalloul[1], I. Grierosu[1,2], V. Ghizdovat[1,2], C. Stolniceanu[1,2], C. Stefanescu[1,2]; [1]University of Medicine and Pharmacy U.M.F „Grigore T. Popa", Iasi, ROMANIA, [2]County Emergency Hospital „Sf. Spiridon", Iasi, ROMANIA, [3]Oncology and Radiotherapy Centre "Elytis Hope" Hospital, Iasi, ROMANIA, [4]County Hospital of Emergency "Saint John the New", Suceava, ROMANIA.*

Aim/Introduction: Due to its standardisation and ease of measurement, SUVmax remains the primary method for evaluating 18F-FDG uptake in oncology and brown adipose tissue (BAT). Furthermore, metabolic tumour volume (MTV) and total lesion glycolysis (TLG) have demonstrated their utility in quantifying the volume of the 18F-FDG uptake. Considering SUVmax's limitations and the benefits of MTV and TLG, we investigated the reliability of these two PET volumetric tools in measuring BAT activity. ***Materials and Methods:*** After retrospectively analysing 1377 18F-FDG PET/CT scans conducted in 648 cancer patients over three years, we chose post-therapy images that showed high 18F-FDG uptake in brown fat. Based on the normal distribution of BAT SUVmax and the mean value of 2.07±0.95 (median = 1.95), we categorised the BAT+ patients into two groups: BAT-moderate activation (BAT-MA) with SUVmax between 1-2, and BAT-high

activation (BAT-HA) with SUVmax > 2. Moreover, we calculated the sum of all MTV (TotMTV) and TLG (TotTLG) values measured in all the VOIs drawn from all BAT locations in every BAT+ scan. Finally, we conducted statistical analysis to determine the accuracy of these two parameters in demonstrating the degree of BAT activity. ***Results:*** Out of the included 92 BAT+ individuals, 48 had BAT-MA, whereas the remaining 44 had BAT-HA. The AUC for TotMTV was 0.69 (CI = 0.55-0.84, p = 0.009), while for TotTLG, it represented 0.72 (CI = 0.67-0.80, p = 0.015). Thus, the ROC curves showed that these PET instruments could significantly predict BAT function. Additionally, the precision-recall curves confirmed the effectiveness of both tools in categorising BAT activation intensity with high precision and recall. Furthermore, the findings indicate that TotMTV and TotTLG demonstrated high sensitivity levels of 80% and 88%, respectively. Likewise, both instruments showed an increased degree of specificity, with values of 77% and 78%, respectively. According to the generated paired histogram, along with the resulting sensitivities and specificities, BAT-HA was significantly correlated to TotMTV and TotTLG values above the established cutoffs of 56,1 and 78,4, respectively. Moreover, the resulting correlation showed that TotMTV (p = 0.0045) and TotTLG (p = 0.0003) increased significantly with the elevation of "the gold standard tool" for assessing BAT, SUVmax. ***Conclusion:*** MTV and TLG can classify brown fat activity levels and provide additional information about total BAT volume, overcoming SUVmax's limitations. Introducing these tools in the study of brown fat can help develop BAT-based therapies against obesity, diabetes, and other metabolic pathologies.

EP-0403

Role of F18-FDG PET/CT in the management of angiosarcoma.

R. Kumar[1], *S. Sagar[2], D. Khan[2], N. Kundu[2], S. K V[2]; [1]AIIMS, New Delhi, INDIA, [2]All India Institute of Medical Sciences, New Delhi, INDIA.*

Aim/Introduction: Angiosarcoma, an infrequent malignancy, is defined by multiplying anaplastic cells originating from blood vessels, populating irregular blood-filled spaces. Its proclivity for recurrence and metastasis underscores the importance of accurate diagnosis for timely intervention. Employing 18F-FDG PET/CT enables comprehensive assessment of primary lesions and metastatic dissemination in affected individuals. ***Materials and Methods:*** At our institute, we gathered clinicopathological and PET/CT imaging data from 21 patients diagnosed with angiosarcoma. Utilizing dedicated PET/CT scanners (Biograph mCT, Siemens Inc and Discovery PET/CT, GE), we conducted 18F-FDG PET/CT scans 45-60 minutes following the intravenous administration of 8-10mCi of radiotracer. These scans were meticulously interpreted by two seasoned Nuclear Medicine Physicians to evaluate the localization of primary lesions and the presence of metastatic spread. ***Results:*** Among the 21 patients, there were 11 males and 10 females. Their mean age was 34.6 ± 14.3 years, ranging from 20 to 72 years. Thirteen patients underwent ^{18}F-FDG PET/CT as part of baseline evaluation, while the remaining 8 underwent it for response evaluation. Among the latter group, three patients exhibited progressive disease on follow-up ^{18}F-FDG PET/CT scans. The remaining patients showed varied responses: partial response in 2, stable disease in 2, and complete metabolic response in 1. The most common areas of metastatic foci detected on ^{18}F-FDG PET/CT were lymph nodes in 6 patients, bone in 3 patients, and adrenals in 2 patients, with less common involvement observed in the liver, lungs, and spleen. ***Conclusion:*** F^{18}-FDG PET/CT played a crucial role in both the initial assessment and treatment response evaluation of rare malignancies like angiosarcoma, providing comprehensive metastatic workup during baseline evaluation and aiding in therapy response monitoring.

EP-0404

^{18}f fdg pet/ct dynamic / blood flow imaging in urinary bladder cancer: nuclear medicine's answer to the oncologists' question of muscle invasion

R. Elumalai, *K. KORAMADAI KARUPPASAMY; Kovai Medical Center and Hospital, Coimbatore, INDIA.*

Aim/Introduction: Muscle invasion in urothelial carcinomas is a treatment defining parameter. Magnetic resonance imaging (MRI) is the gold standard modality to know about muscle invasion. Positron emission tomography imaging with ^{18}Fluorine-fluorodeoxyglucose (FDG PETCT) has demonstrated utility in metastasis evaluation of carcinoma urinary bladder, but its utility in tumour (T) staging is limited owing to high urinary FDG concentration. The aim of this study was to identify muscle invasion in bladder cancer with early dynamic /blood flow imaging using the logic of angiogenesis observed in malignancies. ***Materials and Methods:*** Early dynamic ^{18}F-FDG PET/CT scan imaging the blood flow to the lesion were performed on 68 patients with pathology confirmed bladder cancer. A series of 5 consecutive frames of 2 minutes each, starting at injection time, were obtained on each patient's urinary bladder. SUV max was calculated for each frame as (SUVmax1, SUV max2, SUV max3, SUV max4, SUV max5). The tracer uptake in initial frames is matched with pathology reports of the corresponding patients to look for relationship between muscle invasion and increase in blood flow in initial images. ***Results:*** Patients were grouped into two broad categories based on muscle invasion status. Patients with muscle invasion demonstrated increased tracer uptake in the first two frames. Patients without muscle invasion did not demonstrate significant tracer uptake in initial two frames. The tracer uptake was quantitatively marked using SUV max. Patients with muscle invasion also showed consistent increase in the SUV max over the next consecutive frames. Patients without muscle invasion demonstrated no significant increase in SUV max over the next consecutive frames. The average maximum standard uptake values (SUVmax +/- SD), at 2 to 4 minutes postinjection, of bladder wall areas in muscle invasion positive and muscle invasion negative patients were 8.5 and 1.8 respectively ***Conclusion:*** Out of 28 patients who showed muscle invasion in pathology, 23 patients demonstrated increased SUV max in the initial two frames and increased SUV max in successive frames. 5 patients demonstrated no uptake due to various reasons. So, Our study findings of early dynamic / blood flow ^{18}F FDG PET CT imaging can help as an adjunct to find muscle invasion status in carcinoma bladder patients. Hence ^{18}f fdg pet/ct can be tried as a one stop imaging solution in staging of carcinoma urinary bladder in patients, where mri cannot be used due to varying reasons.

EP-0405

^{18}F-FDG PET/CT: atool for diagnosing and prognosticating sarcomatoid differentiation in renal cell carcinoma

L. Kang, *R. Na, Z. Chen, Y. Liu, Q. Chen, Y. Qiu, W. Huang; Peking University First Hospital, Beijing, CHINA.*

Aim/Introduction: Sarcomatoid differentiation renal cell carcinoma (SDRCC) is a specific type of renal cell carcinoma, which

is often aggressive and more likely to present as locally advanced or metastatic lesions than non-sarcomatoid differentiation renal cell carcinoma (non-SDRCC). 18F-FDG PET/CT can be used to evaluate tumor characteristics and metastatic status of RCC and predict its prognosis by measuring metabolic parameters such as SUVmax. Therefore, the aim of this study was to evaluate the diagnostic and prognostic performance of 18F-FDG PET/CT for SDRCC. ***Materials and Methods:*** This retrospective study assessed newly diagnosed SDRCC patients staged with 18F-FDG-PET/CT, categorizing sarcomatoid differentiation into high-grade (HG-SDRCC) and low-grade (LG-SDRCC) based on a > 50% threshold, and compared their characteristics with a G3/G4 non-SDRCC control group. SUVmax, SUVmean, metabolic tumor volume (MTV) and the total lesion glycolysis (TLG) were compared among HG-SDRCC, LG-SDRCC and non-SDRCC groups, and receiver operating characteristic (ROC) curves were analyzed for the optimal cutoff value and area under the curve (AUC). Patients with SDRCC were retrospectively followed up to analyze their overall survival (OS) and progression-free survival (PFS), and Kaplan-Meier curves, the log-rank test and the multivariate Cox proportional hazards analyses was performed to compare the survival rates and identify the prognostic factors. ***Results:*** The SUVmax (P = 0.0027), MTV (P = 0.0299) and TLG (P = 0.0109) was significantly higher in SDRCC than in non-SDRCC. And ROC shows AUC of SUVmax (AUC = 0.6561), MTV (AUC = 0.6137) and TLG (AUC = 0.6330) for SDRCC and non-SDRCC. Meanwhile, the SUVmax (P = 0.0004), MTV (P = 0.0414) and TLG (P = 0.0126) was significantly higher in HG-SDRCC than in non-SDRCC, while the SUVmax, MTV and TLG was not significantly different between LG-SDRCC and non-SDRCC. ROC shows AUC of SUVmax (AUC = 0.7364), MTV (AUC = 0.6388) and TLG (AUC = 0.6689) for HG-SDRCC and non-SDRCC. The log-rank test shows SUVmax > 11 (PFS: HR = 2.554, P = 0.0404; OS: HR = 3.542, P = 0.0093). Multivariate Cox proportional hazards analyses show SUVmax > 11 (PFS: HR = 2.196, P = 0.053; OS: HR = 3.445, P = 0.022) and TLG > 500 (PFS: HR = 2.281, P = 0.049) were still risk factors under the mixing of age and gender. ***Conclusion:*** The metabolic parameters of 18F-FDG PET/CT including SUVmax, MTV and TLG could be effectively utilized for the diagnosis and prognosis of SDRCC.

EP-0406

The Place of [18F]FDG PET/BT imaging in bladder cancer patients

E. Inal, *D. Denizmen, M. Kiran, D. Has Simsek, A. Tantekin, E. Isik, S. Erdem, O. Sanli, Y. Sanli;*
istanbul faculty of medicine, Istanbul, TÜRKIYE.

Aim/Introduction: It is essential to know lymph node involvement in patients with muscle-invasive bladder cancer (MIBC) scheduled for neoadjuvant chemotherapy. The aim of this study was to compare lymph node involvement detected by F^{18} fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) imaging with pathological findings after surgical resection in patients with MIBC. ***Materials and Methods:*** We retrospectively reviewed 34 patients with locally/locally advanced bladder cancer who underwent surgery at our institution and underwent simultaneous preoperative F^{18} FDG PET/CT scan. Patients with distant metastases detected on PET/CT, patients who did not undergo surgery, and patients who received nonsurgical treatment for malignancy were excluded from the study. Clinical outcomes, FDG-PET/CT findings, and postoperative pathology results were reviewed. Primary tumor localization, primary tumor SUV max values, lymph node localization, number, and SUV max values on FDG PET/CT scan were documented. Overall survival of the patients was determined by the Kaplan-Meier test, and the association between lymph node positivity and survival was investigated by log-rank analysis. ***Results:*** The mean age of the 34 patients (88% [n=30] men, 12% [n=4] women) included in the study was 68 years (53-85). F^{18} FDG PET/CT showed no metastases outside the primary tumor in 20 patients, while metastases in the pelvic lymph nodes were detected in 14 patients. The mean number of metastatic lymph nodes was 1.2 (0-7). The mean SUVmax of the metastatic lymph nodes was 5.1 (15.1-1.2), while the mean SUVmax of the primary bladder tumor was 14.63 (6.2-36). According to pathology results, 31 patients had at least one pathological lymph node. The sensitivity and specificity of PET/CT for detecting lymph node metastasis were 61.36% (45.5%-75.64%) and 95.82% (93.09%-97.70%), respectively. The overall survival of patients with positive lymph nodes was 29 months (95% CI: 21.8-36.2), the overall survival of patients with negative lymph nodes was 33 months (95% CI: 13.8-52.1), and the overall survival of the entire cohort was 33 months (95% CI: 17.2-48.7). Log-rank analysis showed no statistically significant difference in survival between patients with positive and negative lymph nodes (p: 0.871). ***Conclusion:*** The low sensitivity of F^{18} FDG PET/CT in bladder cancer imaging limits the role of F^{18} FDG PET/CT in the assessment of lymph node status in MIBC and, thus, in clinical decision-making.

EP-0407

Diagnostic Utility of ^{18}F-FDG PET-CT in the detection of underlying malignancy in Paraneoplastic Syndrome.

J. Krishna P., *D. Khan, S. Sagar, S. Kanankulam Velliangiri, L. Goriparti, S. Sharma, B. Nayak, A. Gawande, A. Jaiswal, C. Patel, R. Kumar, M. Tripathi, N. Damle, C. Bal;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Diagnostic Utility of 18FDG PET-CT in the detection of underlying malignancy in Paraneoplastic Syndrome. Introduction: Paraneoplastic syndromes are a spectrum of rare systemic complications of malignancy that arise from tumour secretion of peptides or immune cross-reactivity between malignant and normal tissues. It can affect many organ systems most notably neurological, dermatologic and rheumatologic systems. It is estimated to affect upto 8% of patients with cancer (1). However, they also represent conditions that occur outside of a cancer association and there are few prospective clinical trials to guide management. 18FDG PET-CT has emerged as a practical imaging modality in localizing metabolically active tumours along with infective and inflammatory conditions. Hence, timely recognition of these symptoms and detecting the underlying etiology can play a critical role in management and improving patient's survival. ***Materials and Methods:*** We retrospectively analysed imaging data of 1320 patients clinically suspected to have paraneoplastic syndrome who underwent 18FDG PET-CT to assess the underlying etiology during the period of July 2018 to April 2024. Histopathological correlation was considered the reference standard. All the PET-CT scans were analysed by nuclear medicine physicians. ***Results:*** Out of 1320 patients, a total of 143 paraneoplastic syndrome patients with positive findings on ^{18}F-FDG PET-CT were included for the study purpose. The mean age of the study group was 50+15.7 years with a total of 75 male and 68 female patients. All underwent histopathological and cytological examinations. Out of which, 52 had no records available and 54 had nonspecific findings. In the remaining 37, we observed malignancies in 19 patients namely, thyroid

- 4, breast - 3, DLBCL - 2, ovary - 3, duodenum - 2, lung, colon, plasmacytoma, GIST and prostate - one each. Furthermore, 9 cases of inflammatory conditions were noted with the most common pathology being Dermatomyositis (5/9). Infective conditions were observed in 6 patients with the most common being tuberculosis. We also noted benign conditions in breast and thyroid in 3 patients. ***Conclusion:*** The study describes the diagnostic utility of ^{18}FDG PET-CT in paraneoplastic syndrome revealing diverse underlying pathologies including malignancies, inflammatory and infective etiologies. However, a larger cohort study is warranted to substantiate the role of 18FDG PET-CT in ascertaining the underlying etiology of paraneoplastic syndromes. ***References:*** 1. Pelosof LC, Gerber DE. Paraneoplastic syndromes: an approach to diagnosis and treatment. Mayo Clin Proc. 2010 Sep;85(9):838-54. doi: 10.4065/mcp.2010.0099. Erratum in: Mayo Clin Proc. 2011 Apr;86(4):364. PMID: 20810794; PMCID: PMC2931619.

EP-0408

Role of ^{18}F-FDG PET/CT in response assessment to imatinib in Dermatofibrosacroma protuberans

S. Shamim, *Y. Khadelwal, N. Kumar, S. Yadav, S. Rastogi; AIIMS New Delhi, Delhi, INDIA.*

Aim/Introduction: Dermatofibrosarcoma protuberans (DFSP) is a rare soft tissue sarcoma characterized by slow growth and high rates of local recurrence. Accurate assessment of treatment response is crucial for guiding clinical management and optimizing patient outcomes. Fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) has emerged as a valuable tool for evaluating treatment response in various cancers, but its utility in DFSP remains understudied. ***Materials and Methods:*** We conducted a retrospective study to investigate the efficacy of 18F-FDG PET/CT in assessing treatment response in DFSP. Twenty-one patients with histologically confirmed DFSP with local recurrence and metastases who underwent FDG PET/CT for response assessment following imatinib were included. FDG PET/CT images were analyzed for maximum standardized uptake value (SUVmax) and compared with clinical and radiological data to determine response to therapy. ***Results:*** A total of 39 patients were analysed undergoing treatment in the sarcoma clinic in the Department of Medical Oncology, AIIMS. Out of 39 only 22 patients were followed with PET/CT for response assessment and included in the study. Seven patients (31.8%) showed a response to therapy including a complete metabolic response (CMR) and partial metabolic response (PMR), while six patients (27.2%) showed stable disease. The remaining patient (40.9%) showed an increase in SUVmax, suggestive of disease progression or resistance to therapy. Baseline SUVmax of the hottest lesion was compared among patients with response to therapy (CMR and PMR) with the patient group who had progressive disease. Baseline SUVmax was higher among progressive disease group with mean SUVmax of 15.8 and SUVmax of 8.6 in patients showing response to therapy. ***Conclusion:*** FDG PET/CT represents a promising imaging modality for response assessment in DFSP, offering valuable prognostic information and guiding therapeutic decision-making in DFSP.

EP-0409

FGF23 - Related Hypophosphatemia in a TIO patient diagnosed by SSTR-based functional imaging

C. Stolniceanu[1,2], *C. Ungureanu[1,2], D. Rotariu[3,4], O. Olariu[2], O. Roata[2], I. Grierosu[1,2], W. Jalloul[1,2], T. Ionescu[1], C. Stefanescu[1,2]; [1]University of Medicine and Pharmacy "Grigore T Popa" Iasi, Iasi, ROMANIA, [2]"Sf. Spiridon" Emergency Clinical County Hospital, Iasi, ROMANIA, [3]University of Medicine and Pharmacy "Grigore T Popa" Iasi, iasi, ROMANIA, [4]"N. Oblu" Clinical Emergency Hospital, Iasi, ROMANIA.*

Aim/Introduction: Tumour-induced osteomalacia (TIO) is a rare condition due to overproduction of fibroblast growth factor 23 (FGF23), with profound impact on patient quality of life. TIO finding could be a major diagnostic challenge due to the occurrence anywhere in the body, with similar prevalence in soft tissue and bone. TIO variably express somatostatin receptors (SSTR), allowing SSTR-based functional imaging by somatostatin receptor scintigraphy (SRS). ***Materials and Methods:*** We present a female patient with a 5-year-long history of an important chronic osteoarticular pathology (generalized osteomalacia, multiple bone fractures), which severely limited her daily activities. In 2021, she was admitted to the Neurology, where, based mainly on the laboratory results (high serum levels of FGF23 - 371 RU/mL, NR 44-140 RU/mL), the hypothesis of a possible secreting FGF23 mesenchymal tumor was issued. The patient underwent a comprehensive imaging examination (^{18}F-FDG PET/CT, thoracic-abdominal-pelvic CT / IRM, skull and appendicular skeleton X-ray), but without any suggestive TIO findings. To assess the possible SSTR TIO overexpression, in 2023 the patient underwent SRS. The whole body and SPECT images were acquired at 2, 4 and 24 hours after administration of 702,80 MBq 99mTc-EDDA/HYNIC-Tyr3-Octreotide. ***Results:*** SRS revealed a very intensive radiotracer uptake in the right lacrimal bone projection area, being suggestive for an expressing SSTR tumor. For further tumor localization, a cranio-cerebral MRI was performed which identified the tumor at the left ethmoidal level, with invasion of the left nasal fossa. The patient was referred to Neurosurgery where the surgical treatment was performed. The pathological exam confirmed the ki67- 1% secreting FGF23 TIO. Three months after surgery, all symptoms previously reported retreated and laboratory results revealed the normalization of the serum level of FGF23 = 109.3 RU/mL.Discussion In our case, the single mesenchymal tumor secreting FGF23 in the ethmoidal bone was responsible for osteomalacia and her pain over 2 years. FGF23 producing TIO are usually very small, with wide variety of its localization, their identification being difficult. Due to variety of FGF-producing TIO localizations, structural imaging should be preceded by functional imaging. ***Conclusion:*** SSTR-based functional imaging by SRS is a useful way to precise localize TIO, with the advantage of multiple acquisition images, without an increased radiation exposure. This investigation could represent a precious personalized tool for multidisciplinary management of the TIO.

EP-0410

Prognostic value of intra-tumoral metabolic heterogeneity on baseline ^{18}F-FDG PET/CT in patients with thymic epithelial tumors

F. Chao, *X. Han; Department of Nuclear Medicine,the First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.*

Aim/Introduction: The prognostic value of heterogeneity indices in thymic epithelial tumors (TETs) remains explored. This study aimed to evaluate the impact of intra-tumoral metabolic heterogeneity and quantitative 18F-FDG PET/CT imaging parameters on the prognosis of patients with TETs. ***Materials and Methods:*** This retrospective analysis involved 96 patients diagnosed with thymic epithelial tumors (TETs) who received pre-treatment ^{18}F-FDG PET/CT scans. We measured the highest

and average standardized uptake values (SUVmax and SUVmean), along with total lesion glycolysis (TLG) and metabolic tumor volume (MTV) from the PET/CT scans. We also assessed two heterogeneity indices: HI-1 (SUVmean divided by the standard deviation) and HI-2 (linear regression slopes of MTV based on different SUV thresholds). Associations between these parameters and patient survival outcomes were analyzed. ***Results:*** Among the 96 patients we studied, 47 experienced disease progression and 19 passed away during the observation period. In our analysis, we found certain factors to be significant indicators of progression-free survival (PFS), such as Masaoka stage, TNM stage, WHO classification, SUVmax, SUVmean, TLG, and HI-1, while others like MTV, HI-2, age, gender, presence of myasthenia gravis, and maximum tumor diameter didn't show significance. Further investigation through multivariate analyses revealed that HI-1 (P=0.001, HR: 54.564; 95% CI: 5.285-563.371) and TNM stage (P=0.002, HR: 10.415; 95% CI: 2.448-44.318) were identified as independent prognostic factors for PFS. Similarly, when we looked at overall survival (OS), factors like TNM stage, WHO classification, SUVmax, and HI-1 emerged as significant in the univariate analysis. However, Masaoka stage, SUVmean, MTV, TLG, HI-2, age, gender, presence of myasthenia gravis, and maximum tumor diameter didn't show significance. Multivariate analyses underscored TNM stage as an independent prognostic factor for OS (P=0.027, HR: 9.682; 95% CI:1.288-72.802). ***Conclusion:*** The findings suggest that HI-1, derived from initial 18F-FDG PET/CT scans, alongside TNM stage, independently predict progression-free survival in TETs. HI-1, which reflects intra-tumoral metabolic heterogeneity, might be promising to identify patients with poor prognosis.

EP-0411

Experience with Ga68-FAPI PET-CT Imaging in a Variety of Cancers

K. Luthra, *A. Mohite, S. Doppalapudi;*
Sir HN Reliance Foundation Hospital and Research Centre, Mumbai, INDIA.

Aim/Introduction: Ga68 FAPI (Fibroblast Activation Protein Inhibitor) is a new PET radiopharmaceutical, targeting Fibroblast Activation Protein (FAP). We aimed to evaluate FAP expression, imaging features, diagnostic performance in a variety of malignancies. ***Materials and Methods:*** Patients included a)Primary tumors with low glucose metabolism and not optimally imaged by FDG PET b) Head-Neck (HN) cancers where interpretation difficulties arise due to physiological activity in FDG PET c) Solid cancers otherwise well imaged by FDG, to assess their FAP expression. Ga68-FAPI(04) at dose of 0.1 mCi/kg body weight was administered intravenously. Whole Body PET-CT scans were acquired after 1hour. Diagnostic Contrast CT and in abdominal cases Triphasic contrast CT was done as part of the PET-CT. Standardized Uptake Values were calculated. Uptake was also qualitatively assessed as mild, moderate, intense. Findings were classified as Definitive for Diagnosis, Indeterminate, False Negative (FN), False Positive (FP). ***Results:*** Total 107 FAPI PET-CT were performed for 75 patients between April'2023 to March'2024. Cancers included HN carcinoma, hepatobiliary tumors, signet cell adenocarcinoma stomach (SCCS), few cases of lung, breast, colon, poorly differentiated prostate and Neuroendocrine tumors. FDG PET-CT correlation was additionally available in 31/107 scans. 15/15 HN cancers demonstrated intense FAP expression, with Definitive diagnosis. Was useful for follow up evaluation. No FP activity seen. For HCC, 10/15 at primary diagnosis showed intense, 4 showed moderate activity. 7/15 showed high background activity in cirrhotic liver -Definitive diagnosis was still possible in 6/7 due to higher than background activity, and enhancement patterns of simultaneous multiphasic CT. In 1/7 scan was Indeterminate. In 3/4 HCC post TACE/ RFA false positive uptake in involved segment caused Indeterminate results. 7/7 SCCS showed moderate to high FAP activity with Definitive Results in initial staging, compared to FDG PET. In response evaluation scans, FAP expression was variable and correlation with CT component was necessary. 6/6 cholangiocarcinoma, 11/11 Breast, colon and Lung cancers showed intense activity. False negatives included 2/2 endometrial adenocarcinoma, 1 dedifferentiated prostate, 1/1 RCC, 1/3 pancreatic adenocarcinoma, 2/3 NET. FP uptake seen in fractures, scar, lung infection, granulomatous nodes. ***Conclusion:*** FAPI PET-CT performed well for Definitive interpretations in good variety of tumors and could be performed in lieu of FDG in HN, Lung, Breast, SCCS without any loss of diagnostic information. For HCC it was superior to FDG PET, however some difficulties encountered in staging and Post intervention setting, where optimal use of multiphasic CT was essential for characterization.

EP-0412

Comparison of PET/CT Imaging with $^{[18F]}$PSMA-1007 and $^{[18F]}$FDG in Muscle-Invasive Bladder Urothelial Carcinoma

C. Ramos, *R. Tineo, N. Avilez, J. Rodrigues, H. Saito, F. Leal, B. Amorim, J. Carvalheira, L. Reis;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: Muscle-invasive bladder cancer (MIBC) poses challenges in monitoring due to its high rates of metastasis and recurrence. PET/CT with $^{[18F]}$FDG can be used for MIBC evaluation, but the tracer urinary excretion can hinder analysis in some cases, even with diuretic use. Prostate-specific membrane antigen (PSMA) expression in neoangiogenesis of MIBC makes it a potential disease marker. Notably, the radiotracer $^{[18F]}$PSMA-1007, primarily excreted through the biliary tract, facilitates urinary tract evaluation. This study aimed to compare PET/CT with $^{[18F]}$FDG and $^{[18F]}$PSMA-1007 in evaluating MIBC. ***Materials and Methods:*** Four male patients (ages 57-73 years) underwent prospective PET/CT studies. $^{[18F]}$FDG PET/CT was performed 60 minutes after tracer injection, while $^{[18F]}$PSMA-1007 PET/CT was conducted 5 and 90 minutes post tracer administration. Additional late (2h) pelvic images were obtained with both tracers after intravenous furosemide injection. Experienced nuclear physicians and a radiologist analyzed the images. Maximum standardized uptake value (SUVmax) of each lesion was measured for both radiotracers. ***Results:*** $^{[18F]}$PSMA-1007 uptake in bladder lesions and regional lymph nodes increased progressively between 5, 90 minutes, and 2 hours. Eleven lesions were identified in the 4 patients with $^{[18F]}$PSMA-1007, compared to 9 with $^{[18F]}$FDG. Two patients who had undergone transurethral resection showed no active macroscopic lesions in the bladder. $^{[18F]}$PSMA-1007 detected bladder lesions in the other 2 patients (SUVmax= 9.8 and 23.4), while FDG detected only 1 (SUVmax= 30.0), with the other lesion obscured by radioactive urine, despite diuretic administration. Both tracers detected lymph node metastases in 3 patients (SUVmax= 4.1 to 15.8, and 9.5 to 18.3, respectively, for $^{[18F]}$PSMA-1007 and $^{[18F]}$FDG), and bone metastasis in 1 patient (SUVmax= 11.1 and 10.1 for $^{[18F]}$PSMA-1007 and $^{[18F]}$FDG, respectively). Two patients had FDG-avid pulmonary inflammatory/infectious processes which were not $^{[18F]}$PSMA-1007-avid. ***Conclusion:*** PET/CT with $^{[18F]}$FDG and $^{[18F]}$PSMA-1007 demonstrates similar sensitivities for MIBC lesions. With lower uptake in inflammatory processes, $^{[18F]}$PSMA-1007 appears to exhibit higher specificity and, due to significantly lower urinary excretion than $^{[18F]}$FDG, may be more advantageous for evaluating

primary bladder lesions. The substantial uptake of [18F]PSMA-1007 in some MIBC lesions suggests a potential theranostic approach in select patients.

EP-0413

Role of ^{18}F-FDG PET-CT in the Evaluation of Hemangioendothelioma (HE)

S. Shamim, *Y. Dharmashaktu, R. Wakankar, N. Kumar, S. Rastogi;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: Hemangioendothelioma (HE) is a rare vascular neoplasm characterized of epithelioid or histiocytoid cells, typically detected between the ages of 20-60 years. The clinical manifestations vary from mild illness to severe illness with poorer prognosis in patients having metastatic disease. Imaging is important in HE to determine lesion resectability, stage, assess response to therapy, and evaluate for local recurrence following primary treatment. To date, most imaging studies have focused on the CT and MRI appearances of HE. In comparison, there is relatively limited data regarding the role of 18F-FDG PET/CT in evaluation of HE. Therefore, the present study is aimed to evaluate the imaging features of pathologically proven HE on staging FDG PET/CT. ***Materials and Methods:*** Eight (08) patients with HE were retrospectively evaluated and descriptive statistics related to patient demographic and clinical details were generated. All patients underwent 18F-FDG PET-CT for staging, treatment planning and follow up. ***Results:*** There were 8 patients (6 males, 2 females) with mean age of 44.3 ±14.1 years. The primary site for involvement was cardiac (1/8), left femur (1/8), liver (4/8), right elbow (1/8) & right thigh (1/8). Four (4) of 8 patients underwent surgical excision, 2/8 patients received chemotherapy, 1 patient underwent trans-arterial chemoembolization (TACE), 1 patient received radiotherapy (mean absorbed dose was 4.5 Gy), 5/8 patients received immunotherapy. Seven (7) patients presented with metastases at the time of initial diagnosis on 18F-FDG PET/CT and the ECOG PS was 1 in 7/8 & 4 in 1/8 patients. Total 9 sites of metastases were identified; lungs (7/9), lymph nodes (1/9) & bone (1/9) on 18F-FDG PET/CT. Baseline and follow up PET/CT was done for 7/8 patients. Mean longest axis dimension (LAD) on CT was 3.6 (±4) cm and mean SUV max for the primary site was 5.9 (±4.4). Follow up of 7/8 patients revealed progression of disease in 2 of the patients with a mean progression free survival (PFS) of 8.9 (±9) months. ***Conclusion:*** 18F-FDG PET-CT is a useful tool in staging, restaging and treatment planning in HE patients.

EP-0414

Is a tandem FAPI and FDG PET study effective in predicting the etiology of peritoneal disease

V. Malasani[1], *C. Soham[2], S. Dash[1], A. Raj[1], V. Hari[1], D. Parwan[1], N. Singhal[1], S. Chaudhuri[3], D. Pendharkar[1];*
[1]Sarvodaya hospitals, Faridabad, INDIA, [2]SRM institute of science and technology, Chennai, INDIA, [3]Pushpanjali cancer care institute, Agra, INDIA.

Aim/Introduction: In India, peritoneal tuberculosis is a common presentation. However histopathology is not always feasible and treating it as infective might harm patients with early-stage metastatic peritoneal disease. Aim - To investigate the effectiveness of using sequential dual tracer PET scans with FAPI and FDG in distinguishing malignant from benign peritoneal disease. ***Materials and Methods:*** This is a single-institutional interventional study. The study included patients over 18 years of age who had ascites and, or peritoneal disease and faced a diagnostic challenge of determining whether they had an infection or malignancy based on their 18F FDG PETCT scan. The patients underwent a 68Ga FAPI-46 PETCT scan on a different day, not later than 5 days Analysis - All the images were analyzed by two experienced nuclear medicine physicians. Any well-defined focus of increased tracer uptake greater than the background activity in the expected anatomical region was considered positive Combined data - Results were grouped into categories based on quantification marker SUV Max Category I - Very likely benign -> FDG positive & FAPI negative or both negative Category II- Likely benign -> both positive with FAPI SUV≤50% FDG SUV Category III - Indeterminate -> both positive with FAPI SUV-50-70% of SUV of FDG Category IV- Likely malignant -> both positive with FAPI SUV≥70% of FDG SUV or only FAPI positive Histopathology and, or follow-up imaging are considered the gold standard for diagnosing medical conditions. ***Results:*** We included a total of 50 patients of them 25 had malignant peritoneal disease. The true positive, false-positive, true- negative & false-negative values of FAPI and FDG were 25, 9, 16 & 0, and 14,16, 9 & 11 respectively. The sensitivity, specificity, accuracy, positive predictive, and negative predictive values of FDG vs FAPI were 56% vs100%, 36% vs 64%, 46% vs 82%, 46.67% vs 73.53%, and 45% vs 100% respectively. Hence when compared FAPI- 46 PET CT scan had better diagnostic accuracy and also helped in detecting the primary site in 7 patients. ***Conclusion:*** This method reduced false positives by differentiating benign from malignant peritoneal disease. We attempted to introduce a triage system for patient biopsy selection criteria by preventing immediate biopsy in the 'Very likely benign' and 'Likely benign' categories.

The Relationship Between Biometric Data And Lymphoscintigraphic Findings In Patients With Lower Extremity Lymphedema

G. Mutevelizade, *G. Aymandir, R. Kilic, N. Aydin, B. Bozdemir, Y. Parlak, F. Gumuser, E. Sayit Bilgin;*
Manisa Celal Bayar University Hospital Department of Nuclear Medicine, Manisa, TÜRKIYE.

Aim/Introduction: Lymphedema is a chronic disease caused by functional insufficiency of the lymphatic system. Lymphoscintigraphy is an essential tool in the diagnosis and staging of lymphedema. Obesity has pressure on the lymphatic system and this pressure has effects on the development or aggravation of lymphedema. This study was aimed to evaluate the relationship between lymphoscintigrapic and biometric data [height, body weight and body mass index (BMI)] of the patients. ***Materials and Methods:*** The study included 115 patients who underwent lymphoscintigraphy ,with a diagnosis of lymphedema, in our clinic between January 2020 and February 2024. 95 patients who underwent lower extremity lymphoscintigraphy were included in the study. Lymphoscintigraphies were evaluated normal and between Grade 1-4. Biometric data, stemmer sign and medical history that may cause secondary lymphedema were obtained and BMI classifications were made according to the

World Health Organisation (1). Patients with a BMI value of 30 and above were considered obese. Statistical analyses were performed using IBM SPSS version 29.0. ***Results:*** In this study, 13 (13.7%) of the patients were male and 82 (86.3%) were female. Medical history that may cause secondary lymphedema was found in 17 (17.9%) of the patients and 38 (40%) of them had a positive stemmer sign. Mean age was 54.1±12.8 years, mean body weight was 89.2±18.3 kg, and mean BMI was 33.9±7.2 kg/m2. According to Chi-Square analysis, a significant relationship was found between lymphoscintigrapic grade with the positivity of stemmer sign and BMI ($p<0.001$). There was a significant correlation between lymphoscintigraphic grade with body weight and BMI ($p=0.014$, $p=0.031$ respectively) by Spearman analysis. BMI mean values of the patients with and without lymphedema were compared by Mann-Whitney U analysis, a statistically significant difference was found between the BMI mean values of the two groups ($p<0.05$). According to Kruskal-Wallis analysis the relationship between BMI mean values and the grade of primary lymphedema was statistically significant ($p<0.05$). ***Conclusion:*** Obesity may lead to a decreased lymphatic flow and increased risk of lymphedema. Obesity-related chronic inflammation may increase the severity of lymphedema by affecting the function of lymphatic vessels. We conclude that, there is a relationship between BMI and severity of lymphedema and this relationship is important for holistic and multidisciplinary management of these two conditions. ***References:*** Weir CB, Jan A. BMI Classification Percentile And Cut Off Points. [Updated 2023 Jun 26]. In: StatPearls [Internet]. Treasure Island (FL): StatPearls Publishing; 2024 Jan.

EP-0416

The impact of glucose intake on screening FDG-PET/CT image before FDG infusion for hypoglycemia with diabetes mellitus examinees

T. Nobashi[1], *R. Nakamoto[1], R. Sakamoto[1], M. Yakami[1], A. Nakakura[2], H. Isoda[1], Y. Nakamoto[1];*
[1]Kyoto University Hospital, Kyoto city, JAPAN,
[2]Kyushu University Hospital, Kyoto city, JAPAN.

Aim/Introduction: FDG-PET studies strictly require at least 4 hours of fasting before FDG infusion to avoid study failures due to diffuse distribution to muscles. However, there is no consensus or rationale whether glucose intake before FDG infusion for hypoglycemia affects the image quality. In screening PET facilities, examinees with diabetes mellitus sometimes experience iatrogenic hypoglycemia during the screening course, but the standard policy for such examinees has not been determined, i.e., cancellation and re-scheduling of PET study. The study purpose is to investigate if the glucose intake prior to FDG influences the assessment of image evaluation. ***Materials and Methods:*** Subjects who received glucose due to hypoglycemia before FDG administration were explored from 2016 to 2021 in our membership health screening institute. The FDG PET images were evaluated from multiple perspectives; 1) reviewing PET reports retrospectively, 2) visual analysis of a randomized FDG PET dataset including normal scans of examinees without diabetes by two independent blinded readers, and 3) semiquantitative analysis on muscles, comparing with corresponding PET images from different years without hypoglycemia, and normal scans without diabetes. ***Results:*** A total of 17 studies of 14 patients (age, 61.5 ± 10) were identified as receivers of glucose before FDG administration due to hypoglycemia. The average blood sugar level was 70.2 ± 9 mg/dL when noticed as hypoglycemia. Symptoms were recorded in 4 subjects. The taken glucose dose was 10g in 13 studies, 5g in one, one candy in two, and twice of 10g in one study. The interval between glucose intake and FDG administration was 36 ± 44 minutes. None of the FDG PET reports mentioned elevated muscular uptake. There was no statistical difference of image evaluation between scans with glucose intake and normal scans by either reader. No statistical difference was observed in muscles among glucose intake group and other groups without glucose intake. ***Conclusion:*** Glucose intake before FDG venous infusion due to hypoglycemia in diabetes mellitus did not affect the quality of FDG-PET/CT scans. Clinical staff may be advised to instruct examinees to take glucose without hesitation at the noticed timing of hypoglycemia for examinees safety and encourage the examinees to undergo FDG PET as scheduled.

EP-0417

Effects of Bisphenol A and Bisphenol S Exposure on the metabolic parameters on FDG PET/CT image

L. Xiao, *L. Li;*
West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: Bisphenol A (BPA) and its analogues have been proved to be harmful to human health. This study aimed to assess the impact of Bisphenol A (BPA) and its major analogue, Bisphenol-S (BPS), on metabolic parameters within normal main organs using 18F-fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT) imaging. ***Materials and Methods:*** A retrospective analysis was conducted on patients who had undergone FDG PET/CT imaging and were also examined for BPA and BPS levels. Urine samples were collected for detection of BPA and BPS. Standardized uptake values (SUVmax and SUVmean) of normal main tissues including liver, blood, spleen, muscle, thyroid, and cerebral cortex were quantified. Statistical analysis was performed using Spearman's rank correlation. ***Results:*** Forty patients (20 female, 20 male; mean age: 56.1±15.4 years) were included. Mean urine BPA and BPS concentrations were 2.1±1.2 ng/mL and 1±0.6 ng/mL, respectively. Urine BPA exhibited a moderate positive correlation with liver SUVmax ($r=0.351$, $P=0.026$) and SUVmean ($r=0.361$, $P=0.022$). No significant correlations were found between BPA and blood, muscle, spleen, thyroid, and cerebral cortex ($P > 0.05$). Conversely, urine BPS demonstrated a negative correlation with thyroid SUVmax ($r=-0.43$, $P=0.012$) and SUVmean ($r=-0.432$, $P=0.012$), while a positive correlation was observed between BPS and cerebral cortex SUVmax ($r=0.366$, $P=0.033$). ***Conclusion:*** Urinary levels of BPA and BPS exerted distinct influences on tissue metabolic parameters observed via FDG PET/CT imaging, particularly affecting the liver, thyroid, and cerebral cortex. This finding suggests that SUV derived from FDG uptake by these organs on 18F-FDG PET/CT imaging may reflect the extent of BPA and BPS exposure in the body. However, further prospective studies are needed to validate these findings.

EP-0418

A new methodological approach to lower limbs lymphoscintigraphy

G. Grassetto[1], *A. Osele[1], L. Turk[1], P. Zucchetta[1], P. Turco[1], A. Poretto[2], L. Bonaldo[3], S. Fontana[4], G. Rossitto[5], D. Cecchin[6];*
[1]Nuclear Medicine, Azienda Ospedale Universita' di Padova, Padova, ITALY, [2]Angiology Dimed, Universita' di Padova, Padova, ITALY, [3]Orthopedic Rehabilitation, Azienda Ospedale Universita' di Padova, Padova, ITALY, [4]Lymphoedema HUB Center, ULSS 7 Santorso Asiago, Vicenza, ITALY, [5]Emergency

Medicine and Hyertension, Dimed, Azienda Ospedale Universita' di Padova, Padova, ITALY, [6]Nuclear Medicine, Dimed, Azienda Ospedale Universita' di Padova, Padova, ITALY.

Aim/Introduction: Lymphoscintigraphy is the gold standard procedure to diagnose lymphoedema. To date several methods have been proposed mainly based on static planar acquisitions and cut-offs derived from mixed protocols and gamma-cameras. The purpose of our study is to find and test, in a single tertiary clinical center, an easy and accurate protocol to semi-quantify limb lymphatic drainage reliably in daily clinical practice. ***Materials and Methods:*** From 2024 we replaced the lymphoscintigraphic semi-quantitative protocol developed by Brauer et al in 2002, with 3 simple WB scans respectively acquired soon after radiopharmaceutical administration (37 MBq of 99mTc-Nanocolloid in each side), 1 hour post-injection (after 45 consecutive minutes of walking-stress) and 2 hours after injection. Two-days lymphoscintigraphy study to evaluate separately. Superficial lymphatic system and deep lymphatic system have been studied separately in two distinct days. As injection sites we used intradermal injection for superficial lymphatic system and subfascial injection for the deep one. All the scans were performed on a gamma-camera, from feet to chin, with a fixed acquisition speed of 15cm/min. In case of doubtful findings, a SPECT/CT acquisition was acquired. After decay correction we estimated percentage wash-out from injection site, percentage accumulation in popliteal, crural-inguinal, iliac lymph nodes (both right and left) and liver uptake at 60 and 120 minutes. We compared this new approach to a validated method. ***Results:*** Until now we studied 10 consecutive patients referred for suspected lymphoedema of the lower limbs. All patients were acquired separately for superficial and deep lymphatic system. The proposed method is about 20% quicker as compared to the validated method and easier to be performed. Furthermore, the method provides 18 semi-quantitative separated metrics instead of the two usually adopted. There is a significant correlation between the new method and the validated one. ***Conclusion:*** Although cases are still limited and the proposed method needs more validation, it seems easy, quick and clinically useful. ***References:*** Brauer W and Weissleder H. Methods and results of lymphoscintigraphic function tests: Experience in 924 lymphedema patients; 2002/12/01, Phlebologie, Stuttgart.

EP-0419

The impact of preliminary patient hydration on urinary bladder uptake in cases of routinely high renal excretion of [18F]PSMA-1007 on PET/CT

T. Antonevskaya[1], *A. Khalimon[1], O. Mukhortova[2], M. Khodzhibekova[1], A. Nikiforuk[1], D. Zubkov[2], A. Leontyev[1], I. Aslanidi[2];*
[1]Moscow Research Oncology Institute named after P.A. Hertzen - branch of "National Medical Research C, Moscow, RUSSIAN FEDERATION, [2]A.N. Bakulev National Medical Research Center for Cardiovascular Surgery of the Russian Ministry of Health, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: [18F]PSMA-1007 has minimal renal excretion in comparison to 68Ga-labeled PSMA-ligands. It allows a better assessment of the pelvic area in patients with prostate cancer (PCa). Nevertheless, in our clinical practice, we routinely observed a notably high [18F]PSMA-1007 uptake in the urinary bladder. The underlying reasons for this phenomenon remain inadequately explored. The aim of this study was to assess the impact of preliminary hydration of patients on [18F]PSMA-1007 uptake in the urinary bladder. ***Materials and Methods:*** Prospective, multicenter, randomized controlled study included 180 patients with PCa who underwent [18F]PSMA-1007 PET/CT. Scans were performed 90 minutes after intravenous administration of [18F] PSMA-1007 using three different PET/CT-systems and according to the current EANM/SNMMI guideline v2.0. All patients were divided into two groups: the group with hydration (n=95, 53%), which included the subgroups of patients with oral (n=76, 80%) and parenteral (n=19, 20%) routes of hydration, and the control group with no hydration (n=85, 47%). The hydration procedure was carried out using 1000 ml of liquid after [18F]PSMA-1007 administration with no bladder voiding all uptake time. [18F] PSMA-1007 uptake in the urinary bladder was quantified using SUVmean (Mean Standardized Uptake value), measured within a spherical VOI with a fixed volume of 2.5cm3 delineating the bladder boundaries. Additionally, the TBRmean (Mean Target-to-Background Ratio), reflecting the ratio between bladder and right gluteal muscles SUVmean, was calculated to reduce the influence of inter-scanner SUV variability. Intergroup differences were assessed for statistical significance using the nonparametric Mann-Whitney U test. ***Results:*** SUVmean and TBRmean were significantly lower (p<0,001) in the group with hydration compared to the control group, regardless of PET/CT-system, with the following values: 1.3 [0.8; 2.0] versus 4.5 [2.7; 8.5] for SUVmean and 4.0 [2.3; 6.3] versus 13.0 [7.7; 24.0] for TBRmean. There was no significant differences in SUVmean and TBRmean between the subgroups with oral and parenteral routes of hydration (p=0.95 for SUVmean, p=0.49 for TBRmean). Additionally, comparatively lower interquartile range (IQR) values for both SUVmean and TBRmean in the group with hydration were noted, regardless of PET/CT-system (1.2 versus 5.8 for SUVmean, 4.0 versus 16.3 for TBRmean). ***Conclusion:*** Preliminary hydration of patients significantly reduces both the level and variability of [18F]PSMA-1007 uptake in the urinary bladder. This approach may be beneficial in cases of routinely increased renal excretion of [18F]PSMA-1007. The route of hydration did not affect [18F]PSMA-1007 uptake in the urinary bladder.

EP-0420

Clinical utility of 99mTc-MDP in detection and site localization of suspected protein losing enteropathy patients.

A. Gawande, *D. Khan, S. Sagar, Y. Manikya, B. Nayak, H. Khairwa, V. Goenka, M. Umar, J. Krishna P., L. Goriparti, A. Tilak, S. Sharma, N. Damle, R. Kumar, C. Bal;*
ALL INDIA INSTITUTE OF MEDICAL SCIENCES New Delhi, New Delhi, INDIA.

Aim/Introduction: Protein-losing enteropathy (PLE) is an unusual cause of hypoproteinemia, characterized by the loss of protein from the gastrointestinal mucosa. This condition arises due to various etiologies that lead to injury or breakdown of the gastrointestinal epithelium, leading to varying clinical manifestations.The primary diagnostic test for PLE typically involves a 24-hour stool collection to test for the presence of alpha-1 antitrypsin. Additionally, a nuclear medicine technique utilizing 99mTc-labeled Methylene diphosphonate (MDP) has been found to be useful in detecting and localizing the site of the protein leak in PLE. ***Materials and Methods:*** We conducted a retrospective study to detect and localize protein leakage sites in suspected pediatric and adult PLE patients at our Department of Nuclear Medicine, AIIMS New Delhi. We administered 740 MBq (20mCi) of 99mTc-MDP intravenously to all the suspected adult PLE patients. However, in pediatric patients, we administered a dose adjusted based on age (using Webster's rule). After the intravenous injection of the

radiotracer, serial planar images were acquired from 15 minutes until 24 hours post-administration. Scan considered as positive, if visible tracer uptake was observed in the gut and it moved distally from the site of localization in subsequent planar static images. Additionally, SPECT/CT was acquired to confirm the positive findings on planar imaging. ***Results:*** In a study of 41 suspected pediatric and adult PLE patients, we observed 23 male and 18 female patients. The mean age of all patients were 37.6 ± 16.3. At an average time point of 180 minutes, we detected and localized the site of the protein leak in these patients. Out of the total 41 patients, 7 (17%) showed positive uptake on the scan, of which 6 were adults and 1 was a pediatric patient. The most common site was the cecum (3/7), followed by the ascending colon (2/7), small bowel (1/7), and transverse colon (1/7). The diagnostic yield of 99mTc-MDP was 33.3% (1/3) in pediatric PLE patients, while in adult PLE patients, it was 15.8% (6/38). These patients were managed conservatively based on protein diet and specific etiology-based treatment. On follow-up, we observed clinical improvement in the majority (5/7) of the positive cases. ***Conclusion:*** Our study highlights the significance of the 99mTc-MDP scan as a crucial alternative modality for the detection and localization of protein leakage sites in both pediatric and adult patients with PLE, thereby improving clinical outcomes.

EP-0421

Lymphoscintigraphic results in patients with lipedema. Preliminary data.

D. Donner[1,2], *M. Povolato[3], A. Macciò[4], A. Onorato[5];*
[1]OU Nuclear Medicine– Azienda Provinciale per i Servizi Sanitari, Trento - Italy, TRENTO, ITALY, [2]DIMEC, Bologna University, ITALY, [3]Istituto di Medicina Nucleare, Azienda Ospedaliera-Universitaria, Udine, ITALY, [4]Lymphological Reference Centre Humanitas, Bergamo, ITALY, [5]Linfamed Srl, Udine, ITALY.

Aim/Introduction: Lymphoscintigraphy (LS) is the gold standard for diagnosing lymphedema.In our experience, it is required for prognostic evaluation in established clinical diagnoses, differential diagnosis in edema of uncertain origin, and early detection of lymphatic disorder in lipedema.A complete lymphoscintigraphic study includes the investigation of both the superficial and the deep circulation.The alterations can affect both network's drainage simultaneously or even just one. All combinations of superficial and/or deep, uni-or bilateral damage were found.The object of our study was identifying LS patterns in patients with lipedema at 2nd and 3rd stages, or lipohypertrophy. ***Materials and Methods:*** A retrospective study was performed on LSes performed from 2013 to 2021.The exams were performed in a 1st session to visualize the superficial system and in a 2nd session, after 2-4 days, to study the deep circulation.After acquiring static images, performed immediately after the radionuclide injection, continuous segmental motor activity was performed for 45'; whole body images were acquired 1h and 2h after radiopharmaceutical administration. ***Results:*** 247 LSes of the lower limbs were performed.The exams were pooled, on the clinical data, into the following groups: lipedema at the 2nd stage (19 cases), lipedema at the 3rd stage (5), lipohypetrophy (4), suspected or established lymphedema (213), and other (6).In the case of lipedema at 2nd stage, we found no damage in 3 cases (3/19); impairment regarded only the superficial circulation in 2 cases (2/19), and both superficial and deep networks (in various combinations) in 8 patients (8/19); a mechanical insufficiency of deep circulation alone was found in 5 cases (bilateral in 4). In patients with lipedema at the 3rd stage, we found impairment of superficial and deep circulation in 3 cases, while in 2 patients, only the deep network was damaged bilaterally.In the case of lipohypertrophy, we found superficial damage together with deep circulation in 2 cases, while in 4 patients, the impairment regarded deep circulation (bilaterally in 2). ***Conclusion:*** Through LS, damage to lymphatic circulation has already been demonstrated in cases of lipedema. This condition is thought to happen in very evolved cases. Our data suggested that a lymphatic mechanical insufficiency can develop earlier, with different damage patterns. In many cases, the impairment concerns only the deep circulation. These results could motivate a broader but more subtle clinical picture and justify closer monitoring and treatment of lipedema. ***References:*** Reich-Schupke S, et al. S1 guidelines: Lipedema. J Dtsch Dermatol Ges. 2017 Jul;15(7):758-767. doi: 10.1111/ddg.13036. PMID: 28677175.

EP-0422

Exploring the Uptake of [18F]FDG by the Gallbladder in PET Studies: Impact of Biological, Pathological, and Procedural Factors

A. Rebelo, *P. Soeiro, J. Pires;*
Unidade Local de Saúde de São João, EPE, Porto, PORTUGAL.

Aim/Introduction: [18F]Fluorodeoxyglucose(FDG)-PETiscommonly used in cancer and inflammatory studies. The biodistribution of FDG varies and can be affected by intrinsic or iatrogenic factors. Identifying these factors is crucial for accurately interpreting FDG-PET results. While the gallbladder (GB) typically shows low FDG uptake in routine PET/CT, newer scans reveal increased GB activity unrelated to inflammation or neoplasia. Understanding these factors is essential for interpreting FDG-PET comprehensively. This study aimed to assess the impact of biological, pathological, and procedural factors on FDG uptake by the gallbladder. ***Materials and Methods:*** A unicentric prospective study was conducted in February 2024. Participants aged over 18 years undergoing FDG-PET were enrolled, excluding those with prior gastric/biliary reconstruction or gastroenteropancreatic endoscopic procedures. Biological factors (age, gender, BMI, blood glucose levels), pathological factors (tumor burden including SUVpeak, SUVmax, SUVmed, TLG, MTV, and differentiation between neoplastic and inflammatory/infectious lesions), and procedural factors (temperature, administered activity dose, and acquisition time) were evaluated for their impact on FDG uptake by the gallbladder. ***Results:*** A cohort of 107 patients participated, with 61.7% being males and a mean age of 62 years. Predominantly, solid tumors (64.5%) were examined, followed by hematologic tumors (19.6%) and investigations for infectious/inflammatory foci (15.9%). Mean blood glucose level was 110.2 mg/dL, with an average BMI of 1.76. Patients received an average FDG activity of 205.17 MBq, and imaging occurred approximately 62.3 minutes post-radiopharmaceutical administration. The room temperature remained stable at 22.3°C, contrasting with the external temperature of 13.4°C. Additionally, 14% of patients underwent delayed image acquisition. Statistically significant correlations were found between FDG uptake in the gallbladder, TLG, and biodistribution time, with no significant associations observed with other variables. ***Conclusion:*** Physiological FDG uptake in the gallbladder observed in modern imaging equipment is a norm rather than an anomaly. This uptake can be predicted based on biodistribution time and tumor burden. It is crucial to differentiate this physiological uptake from inflammation to avoid misdiagnosis and unnecessary examinations ***References:*** doi:10.1186/s12880-022-00957-5. doi:10.1097/RLU.0000000000002769.

EP-0423

Evaluation of the Contribution of Prone Positioning in Lung Perfusion SPECT/CT Imaging

O. Sahin, *K. Sahin, S. Asa, L. Uslu, K. Saglam, K. Sonmezoglu, H. B. Sayman;*
Department of Nuclear Medicine, Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: Lung perfusion scintigraphy is a widely used imaging technique for evaluating pulmonary arterial blood flow and diagnosing pulmonary embolism (PE). False positive defects can occur due to the continuous movement of the lungs and diaphragm. Additionally, imaging performed in the supine position may result in less distribution of activity in the anterior parts of the lungs, creating difficulties in evaluating these areas. Our study aims to evaluate the contribution of lung perfusion imaging obtained in the prone position to reporting. ***Materials and Methods:*** We included 131 patients who underwent perfusion SPECT/CT imaging in both supine and prone positions between 2020 and 2024 to investigate pulmonary embolism (PE). Lung parenchyma was evaluated with the CT component of SPECT/CT, and mismatch defects involving at least 2 subsegments or 1 segment were considered positive. Perfusion defects showing filling in either supine or prone imaging were considered false positives. Three different nuclear medicine physicians with varying levels of experience (2, 10, and 14 years) individually evaluated supine (S) and prone (P) SPECT/CT images, as well as combined (S+P) images. The contribution of prone images to reporting was investigated. Additionally, interobserver agreement between two experienced nuclear medicine physicians was evaluated using Cohen's kappa analysis. ***Results:*** In the evaluation of S, the positive reporting rates of the three readers were 53%, 31%, and 24%, respectively. These rates partially decreased in the evaluation of P images (33%, 21%, 20%, respectively), and significantly decreased in the S+P (28%, 17%, 13%, respectively). There was also a significant decrease in the total defect counts for each reader in the evaluation of S+P compared to S (350/208; 236/139; 209/130, respectively). The distribution of defects is given in Table 1, with the most significant changes observed in the anterior regions of the lungs, specifically the right lung medial lobe and the left lung lingular lobe. In the assessment of consistency between the two experienced nuclear medicine physicians, higher agreement was found in the evaluation of S+P and P compared to the evaluation of S (kappa values S: 0.62; P: 0.72; S+P: 0.73, respectively). ***Conclusion:*** In lung perfusion SPECT/CT imaging, obtaining additional images in the prone position reduces false positive results, particularly in the anterior regions, thereby enhancing reporting accuracy. ***References:*** 1.Suzuki, H et al. Prone positioning improves distribution of pulmonary perfusion: noninvasive magnetic resonance imaging study in healthy humans. Eur Radiol 18, 522-528 (2008).

EP-0424

Total-Body Dynamic PET/CT Imaging Reveals Kinetic Distribution of [^{13}N]NH_3 in Normal Organs

G. Liu, *T. Gu, H. Shi;*
Department of Nuclear Medicine, Zhongshan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: To systematically investigate kinetic metrics and metabolic trapping of [13N]NH3 in normal organs, which remains unclear. ***Materials and Methods:*** Eleven participants performed total-body [13N]NH3 dynamic positron emission tomography (PET). Regions of interest were drawn in organs to obtained time-to-activity curves (TACs), which were fitted with an irreversible two-tissue compartment model (2TC) to investigate constant rates K1, k2 and k3. Additionally, one-tissue compartment model using all of the data (1TCfull) and using the first four minutes of data (1TC4min) were fitted to TAC data. Comparison of K1 and k2 were compared among different models to assess potential kinetic trapping of [13N]NH3 in organs. ***Results:*** Kinetic rates of [13N]NH3 varied significantly among organs. The mean K1 ranged from 0.049 mL/cm3/min in the muscle to 2.936 mL/cm3/min in the kidney. The k2 and k3 were lowest in the liver (0.001 min−1) and in the pituitary (0.009 min−1), while highest in the lung (0.502 min−1) and in the liver (0.800 min−1), respectively. Three groups of organs with similar kinetic characteristics were revealed: (1) the thyroid, the lung, the spleen, the pancreas, and the kidney; (2) the liver and the muscle; and (3) the cortex, the white matter, the cerebellum, the pituitary, the parotid, the submandibular gland, the myocardium, the bone, and the bone marrow. Obvious k3 was identified in multiple organs, and significant changes of K1 in multiple organs and k2 in most of the organs were found between 2TC and 1TCfull, but both K1 and k2 were comparable between 2TC and 1TC4min. ***Conclusion:*** The kinetic rates of [13N]NH3 differed among organs with some have obvious 13N-anmmonia trapping. The normal distribution of kinetic metrics of 13N-anmmonia in organs can serve as a reference for its future potential use in tumor imaging.

EP-0425

Intraobserver concordance analysis of a quantification method of pulmonary reperfusion after pulmonary thromboembolism using lung perfusion SPECT/CT

N. Alvarez Mena*, A. Hurtado Romero, F. Sebastian Palacid, R. Zambrano Infantino, S. Pena Vaquero, R. Ruano Perez;*
Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: Our aim is to analyse intraobserver concordance by applying a method in development for the quantification of pulmonary reperfusion after pulmonary thromboembolism (PTE) using lung perfusion SPECT/CT. ***Materials and Methods:*** We conducted a prospective study of 45 patients in follow-up for PTE who underwent a lung perfusion SPECT/CT at diagnosis and at 6 months post-PTE.For assessment of the degree of pulmonary reperfusion, 3D quantification was performed by manual SPECT/CT segmentation (Q.Volumetrix software, GE). The relative evolution (%) of the perfusion defect (differences in volume and mean counts) at baseline and at scintigraphic control was calculated.Patients were classified into 4 groups according to the degree of reperfusion: complete reperfusion (>80%), major partial reperfusion (>50-80%), minor partial reperfusion (>15-50%) or no reperfusion (≤ 15%).To assess the degree of intraobserver consistency of the method a repeated measurement was made by the same observer.Intraobserver concordance was calculated using the kappa index (κ). According to the clinical impact on the therapeutic decision, 3 variables were considered for analysis (1: no reperfusion; 2: minor partial reperfusion; 3: major partial reperfusion/complete reperfusion). ***Results:*** Of the 45 patients analysed, up to 76% (34/45) showed concordance between the two measurements. Statistical analysis showed substantial-moderate agreement with a kappa value of 0.6.Furthermore, of the 11 patients with non-concordant results between the two measurements, it should be noted that only 4 had strong variability in their interpretation (in one measurement they were considered to be in complete or major partial reperfusion and in the other one in no reperfusion). ***Conclusion:***

This proposed method to assess the degree of pulmonary reperfusion in the context of pulmonary thromboembolism presents an adequate intraobserver concordance. Therefore, it suggests to be a diagnostic support tool, which may have a clinical impact on the therapeutic decision.Since the population studied is limited, the application of this method in a larger number of patients is necessary in order to reach more robust conclusions for a real application in clinical practice.

EP-0426

Potential Impact of Bile Acid Scintigraphy in the Cost and Time Saving of the Diagnostic Process of Chronic Diarrhoea

M. Sicilia Pozo, *M. Talavera Rubio, A. Padilla Bermejo, R. Angulo Amorese, J. Gatón Ramírez, N. Disotuar Ruiz, C. Ortiz Muñoz, B. González García, C. Lucas Lucas, M. Carrero Lérida, F. Pena Pardo, J. Rodríguez Gómez, V. Poblete García;*
Nuclear Medicine Department, University General Hospital of Ciudad Real, Ciudad Real, SPAIN.

Aim/Introduction: To evaluate the potential impact of the scintigraphic study with 75Se-taurocholic acid (SeHCAT scan) on the management of patients with chronic diarrhoea. ***Materials and Methods:*** Retrospective study including consecutive patients undergoing a SeHCAT scan from 21/06/21 to 22/12/22. The retention index (RI) was obtained, determining patients with a negative result (RI>15%) or with mild (10-15%), moderate (5-10%) or severe (<5%) bile acid malabsorption (BAM). For patients with moderate-severe BAM, the following exclusion criteria were applied: insufficient follow-up and complicated concomitant pathology. The diagnostic time delay until the SeHCAT scan was calculated, as well as the total cost of the diagnostic tests performed from the first gastroenterology appointment.The association between the different variables with respect to diagnostic delay and economic cost was analysed using Student's t-test. ***Results:*** One hundred and eighty-four patients were included (70.1% women), with a mean age of 51.97 years (16-87), 59.78% of them presenting a positive SeHCAT scan result for BAM. After applying exclusion criteria, we obtained a sample of 57 patients (23/57 cholecystectomized) with SeHCAT scan results compatible with moderate (43.86%) or severe (56.14%) BAM. During the diagnostic process, the following tests were performed: basic blood test (in 93% of the patients), determination of anti-transglutaminase IgA antibodies (73.7%), stool for microbiology culture (56.1%), faecal occult blood test (54.4%), determination of faecal calprotectin (49.1%), colonoscopy (43.9%) and other studies in a lower percentage. The mean diagnostic time was 59 weeks (1-326) and the mean cost of the diagnostic process prior to SeHCAT scan was €964.71 (325.91-3181.61). Performing the SeHCAT scan after the first gastroenterology appointment was statistically associated with a lower total cost (t=7.272, p<0.001) and a shorter diagnosis time (t=4.299, p<0.001), getting an average saving of €856.2/patient and an average reduction in diagnostic time of 81 weeks. Colonoscopy was the most determining test in the increasing of cost (t=8.202, p<0.001) and diagnostic time (t=3.659, p=0.001). Moreover, 100% of patients presented at least partial clinical improvement after starting medical treatment. ***Conclusion:*** Performing a SeHCAT scan in the early evaluation of patients with chronic diarrhoea could potentially reduce the delay and the cost of the diagnostic process.

EP-0427

Standardization of a hypoallergenic meal for gastric emptying scintigraphy. "One diet to empty almost everyone".

P. Zaragoza Ballester[1], *M. I. González Martín[1], M. I. Cabanillas Pérez[1], C. Martín-Arriscado Arroba[1,2], D. Vega Pérez[1], Á. Galiana Morón[1], S. Ruiz Solís[1], X. Guarnizo Poma[1], S. Angiolillo Grau[1], M. Avilés Jurado[1], M. Tabuenca Mateo[1], P. Sarandeses Fernández[1];*
[1]Hospital Universitario 12 De Octubre, Madrid, SPAIN,
[2]Unidad de Soporte Científico i+12, Madrid, SPAIN.

Aim/Introduction: Several test meals have been proposed for gastric emptying scintigraphy, but any of them consider intolerances or allergens. The aim of the present study is to establish normal values for gastric emptying of a hypoallergenic meal which can be used in all patients. ***Materials and Methods:*** We present a prospective and observational study in volunteers (good health without gastrointestinal diseases and non-previous intra-abdominal surgery except for appendectomy) from 1 centre. Gastric emptying of a novel hypoallergenic meal was assessed by scintigraphy at 0, 30, 60, 110, 120, 130, 180, 230, 240 and 250 minutes after its ingestion. Diet composition: 100g of pasteurized egg labelled with 2 mCi of 99mTc-DTPA, 100g baked potato, 50g white rice, 16mL of olive oil and 120 mL of water. Caloric content of 495 Kcal with nutritional composition of 60% carbohydrate, 21% fat, 17% protein and 2% fiber. We collect clinical and demographic dates (age, gender, body mass index (BMI), menstrual state, menstrual cycle, smoking habit, alcohol consumption). Statistical analysis was based on demographics dates description and covariance analysis between variables. ***Results:*** We included 50 healthy volunteers (median aged 41.46±13.56 years (range 26-69), 29 women and 21 men). Median and standard deviation (5-95th percentiles) at 60, 120, 180 and 240 minutes were 52±9.36 (36.55-70.00%), 22.42±10.47 (6.55-45.00%), 7.92±6.15 (1.55-21.90%), 3.04±2.23 (1.00-9.00%), respectively. Gastric emptying was faster in men than in women at 60 minutes (48.57±10.51 versus 54.48±7.68, p-value=0.026) and at 120 minutes (18.10±11.64 versus 25.55±8.49, p-value=0.011). 5-95th percentiles at 60 and 120 minutes in men were 34.30-76.40% and 4.20-46.80%, respectively, and in women 39.00-70.00% and 13.00-43.00%, respectively. Age was positively correlated with slower gastric emptying at 240 minutes (r=0.344, p-value=0.014). We observed a significant positive correlation between BMI and gastric emptying at 240 minutes (r=0.302, p-value=0.033) and negative correlation in alcohol consumption (r=-0.291, p-value=0.04). Smoking habit, menstrual state and menstrual cycle did not affect gastric emptying values. ***Conclusion:*** This study provides gastric emptying values in healthy subjects using a hypoallergenic meal, alternative to the previous meals described and applicable to other departments. ***References:*** 1. Analysis of the measurement of the retention index 75SeHCAT with collimated gamma camera by different mathematical methods

J. Diaz-Moreno[1], *P. Notta-González[1], G. Reynes-Llompart[2], M. Crespí-Busquets[3], B. Hervás-Sanz[1], M. Zamorano-Rivas[1], A. Bagán-Trejo[1], D. Rodríguez-Puig[3], A. Rodríguez-Gasén[1], J. Guardiola-Capón[4], M. Cortés-Romera[1];*
[1]Nuclear Medicine-PET (IDI) Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [2]Radiophysics Department. Hospital Duran i Reynals-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [3]Radiopharmacy Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [4]Gastroenterology Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN.

Aim/Introduction: Diarrhea resulting from bile acid malabsorption (BAM) is a prevalent yet often overlooked cause. The assessment of [75Se]tauroselcholic acid retention (75SeHCAT) is the gold standard diagnostic method. With over 20 years of experience conducting this test at our center, recent published studies indicate variances in the retention index (RI) with and without the use of the collimator. The aim of this study is show that employing the collimator during the acquisition process does not introduce uncertainties on the final diagnosis. ***Materials and Methods:*** Prospective study involving 103 patients (p) with suspected bile acid malabsorption (BAM), the RI of 75SeHCAT was evaluated. All patients underwent RI measurements following a minimum 4-hour fast and were administered a capsule containing 0.37 MBq of 75SeHCAT. Measurements were conducted in anterior and posterior projections with patients positioned supine and centered on abdominal region, using a large field of view (LFOV) gamma camera equipped with two low energy, high resolution, high sensitivity (LEHRS) dual-peak collimators at 136-264 KeV. Images were captured at 3 hours and 7 days, with acquisition times of 5 minutes each, and a fixed distance of 15 cm. A normal RI was defined as greater than 10%. Patients were categorized based on their weight, using body mass index (BMI), and RI results were compared between the geometric means of patient/background activity on days 0 and 7, in comparison to the equation recommended by Gregory James et al. ***Results:*** Out of the 103 patients (p) assessed, 70.8% (73 female), with ages from 21 to 79 years. The average BMI was 27.6 (14.9 to 48.8), and 59% of patients were classified as overweight or obese, having a BMI>24.9. The average retention rate was 13.9% (0-80.5%). The mean absolute error of the retention rate was 0.13% (maximum error 0.88%). Among all evaluated patients, there were no statistically significant differences detected in the utilization of collimator gamma cameras and retention index estimation methods that could impact the final diagnosis, irrespective of BMI. ***Conclusion:*** The RI of 75SeHCAT using collimated gamma cameras, as per our protocol, demonstrates no significant difference when compared to the equation endorsed by Gregory James et al., and no patient had change in diagnosis. Furthermore, the utilization of collimated gamma cameras offers advantages over non-collimated imaging, as it is easily integrated into routine clinical workflows and mitigates the risk of detector damage due to enhanced protection.

EP-0429

Exploring the use of a mobile high resolution PET/CT-camera for imaging surgical specimens in (para)thyroid surgery

B. Lambert, *C. Gabriel, M. Rottiers, M. Coppens, C. Van Haverbeke, T. Van Oostveldt, D. Berwouts, J. Mertens, B. Van Den Bossche, F. Ameye, H. Vanoverschelde, V. Vergucht;*
Maria Middelares hospital, Gent, BELGIUM.

Aim/Introduction: We evaluated a compact mobile PET/CT camera designed to capture submillimeter resolution images of surgical specimens. Initial clinical trials indicate its positive impact on breast and prostate cancer surgeries, primarily through precise assessment of surgical margins. We investigated its potential application in thyroid cancer and parathyroid adenoma surgeries. ***Materials and Methods:*** This investigator-initiated study assessed a mobile PET/CT device's performance in a general hospital with a significant caseload of thyroid and parathyroid surgeries. We explored various clinical scenarios to gauge the peroperative PET/CT's utility in managing thyroid cancer and hyperparathyroidism. In thyroid carcinoma cases, 4 MBq/kg FDG was intravenously injected 1h before tumor or lymph node removal, while for parathyroidectomy, 2-4 MBq/kg F18-Choline was administered. The device captured images of the surgical specimen within 10minutes, allowing immediate review of PET and CT images by the surgeon in the operating room. Specimen PET/CT images were compared with pathology findings. ***Results:*** We tested the mobile PET/CT in 4 procedures involving thyroid carcinomas: 1 total thyroidectomy with lymphadenectomy and 3 interventions for lymph node recurrence, with/without local thyroid recurrence. The technique facilitated margin assessment for recurrent thyroid carcinoma, particularly in delicate areas. Assessment of lymphadenectomy specimens, when compared with pre-operative FDG PET/CT images, aided in confirming complete lymph node removal. One thyroid cancer patient exhibited small FDG avid lymph node recurrences in both sides of the neck on pre-operative FDG PET/CT. However, precise delineation of the lesions was hindered by significant physiological brown fat uptake. Administration of propranolol on the day of surgery effectively suppressed the brown fat uptake, enabling clearer identification of the lesions when the surgical specimen was scanned. Peroperative PET/CT findings aligned with pathologists' conclusions in all but one node. The mobile PET/CT was also evaluated in 3 hyperparathyroidism patients undergoing parathyroidectomy. Within 10minutes post-resection, the device assessed F18-Choline avidity of the suspected parathyroid adenoma. High SUVmax values correctly predicted adenoma removal, allowing surgeons to review images before frozen section results, thus shortening intervention times. Further analysis indicated that reducing administered activities by a factor of 2-4 still resulted in satisfactory image quality. ***Conclusion:*** This study marks the initial exploration of peroperative use of a mobile high-resolution PET/CT camera for imaging surgical specimens of thyroid carcinoma and parathyroid adenoma in the operating room. The device demonstrated significant utility in

thyroid carcinoma (using FDG) and parathyroid adenoma (using F18-Choline) surgeries, showcasing promising applications for future clinical practice.

EP-0430

Use of 125I Seeds in Breast Tumor and Axillary Labeling Prior to Conservative Surgery in Patients with Response to Neoadjuvant Chemotherapy (NAC)

M. García Aragón, *B. Jaramillo López, R. Zambrano Infantino, F. Sebastián Palacid, N. Álvarez Mena, J. Gómez Hidalgo, B. Pérez López, M. Moral Cano, R. Ruano Pérez;*
Hospital Universitario Clínico Valladolid, Valladolid, SPAIN.

Aim/Introduction: Assessment of labeling with 125I seeds in residual tumor and positive axilla in breast cancer patients who have received NAC and are candidates for conservative surgery. ***Materials and Methods:*** Prospective study of 38 patients diagnosed with breast cancer (average age 57.2 ± 11.6 years) who, after NAC, are candidates for conservative surgery and staging via sentinel lymph node biopsy. Labeling with 125I seeds was performed in the residual tumor and, in cases with pre-NAC metastatic axilla, in the previously biopsied lymph node (marked with a coil). Post-NAC radiological response was assessed with mammography, ultrasound, and MRI, classified as complete response, major partial response, minor partial response, and no response. Concordance between the sentinel lymph node and labeling with 125I seeds was evaluated. ***Results:*** 52.63% (20/38) had a complete radiological response, 39.47% (15/38) had a major partial response, and 7.89% (3/38) had a minor partial response. 39.47% (15/38) also had axillary labeling due to pre-NAC positive lymph nodes. 10.52% (4/38) required rescue surgery in a second time due to insufficient margins: in 3 cases, mastectomy was performed, and in 1 case, margin enlargement was performed. 38.23% (17/38) had no residual tumor (all with complete response). The size of the residual tumor in partial response cases was 17.53 ± 10.65 mm. In the 15 cases with pre-NAC positive axilla, at least 3 lymph nodes were obtained in all of them: in 7 cases (46.66%), it coincided with the isotopic sentinel lymph node. In 8/15 (53.33%), lymphadenectomy was completed due to metastasis. ***Conclusion:*** Labeling with 125I seeds in breast cancer after NAC is a technique that facilitates complete tumor resection in the context of breast-conserving surgery. Similarly, labeling of axillary lymph nodes with imaging response to NAC ensures detection and accurate staging with sentinel lymph node biopsy in this patient group.

EP-0431

Usefulness of roll technique in injuries/adenopathies in the cervical region. Our experience

L. Giraldo, *C. Escabias del Pozo, P. P. Portilla, J. Otero-Gonzalez, S. Rizkallal, D. Monachello-Araujo, Y. Abadi, M. Coronado Poggio, J. Cordero-Garcia, L. Dominguez-Gadea;*
Hospital Universitario La Paz, MADRID, SPAIN.

Aim/Introduction: Radioguided localization of occult lesions (ROLL) in oncological surgery consists of the direct administration of a radiopharmaceutical to a target lesion. In recent years this technique has spread, allowing lesions and/or metastases of different tumor strains to be located.Assess the usefulness of the ROLL technique in radiologically suspicious lesions/adenopathy and/or with histological confirmation of malignancy in the cervical region. ***Materials and Methods:*** Retrospective study of 7 patients (p), referred to our service from February 2020 to June 2023, to perform the ROLL technique for lesions/adenopathy in the cervical region, after evaluation by the multidisciplinary committee. Together with the radiology service and using ultrasound guidance, we marked radiologically suspicious lesions/adenopathy (2 PET-Dopa and 4 PET-^{18}F-FDG, finding 14 pathological lesions) and/or histologically confirmed by FNA.1 mci of MAA-99mTC was administered to each of the lesions, subsequently, 60 minutes later, lymphoscintigraphy with planar images and SPECT-CT of the neck was obtained. With the help of a gamma detector probe, surgical excision was performed the day after marking. Demographic data, histology of the primary tumor, number of marked lesions, location of the lesions, correlation between marked lesions and histopathological findings and clinical follow-up were collected, mean follow-up: 26 months (M) (9-50 M). ***Results:*** Mean age 50 years old, 57% women and 43% men, 6p with a history of thyroid CA: 3p medullary CA and 3p with papillary CA; 1p with a history of difuse large B cell lymphoma (DLBCL). 18 lesions/adenopathy were marked, of which 72% (13) were positive for malignancy, 28% (5) were negative. All lesions/adenopathy were located and removed during surgery.In all patients with thyroid CA, laterocervical dissection was performed, finding 7 lesions/adenopathy positive for malignancy that were not previously marked.In the patient with DLBCL, only the marked lymphadenopathy was resected, which was suggestive of Castleman Disease.Of the patients with thyroid CA, 6p have stable disease and 1p with medullary thyroid CA with distant progression (mediastinum and hepatic). ***Conclusion:*** The ROLL technique is a useful technique in localizing previously marked lesions/adenopathy in this group of patients, ensuring their histopathological correlation.In patients with thyroid cancer, the ROLL technique added to the laterocervical dissection procedure has allowed the surgical removal of metastases, obtaining adequate locoregional control of the disease.

EP-0432

Radioguided surgery with [^{125}I] seeds for localization of non-palpable malignant breast lesions. Experience in our center and analysis of the learning curve

L. M. Ramos, *M. Rosado Hidalgo, J. F. Vela León, S. Romero Acevedo, M. F. Lara Martínez, F. Medina Romero, M. A. González Díaz, M. Á. Gómez Rodríguez-Bethencourt;*
Complejo Hospitalario Universitario de Canarias, San Cristóbal de La Laguna, SPAIN.

Aim/Introduction: Since 2005, our center has been performing selective sentinel lymph node biopsy and radioguided localization of occult lesions (ROLL). In 2021, radioactive seed localization (RSL) with [125I] was implemented and to date we have performed more than 400 procedures with this technique. Our objective is to verify an improvement in the results of surgery with [125I] RSL over time in our center. ***Materials and Methods:*** Descriptive study of 2 sample groups (mean age: 57 and 60 years respectively) corresponding to the first 30 and last 30 patients (first and last group) undergoing [125I] RSL of non-palpable malignant breast lesions. The following variables were analyzed: affected quadrant, histological type, closest margin to tumor, surgical piece volume, tumor volume, healthy tissue volume (surgical - tumor volume), ideal volume (adding 1 cm of margin to the tumor radius). surgical/ideal volume ratio, number of intraoperative margin widenings and number of reinterventions. ***Results:*** In both groups, the most frequent tumor location was the upper outer quadrant (58.3%), the histological type was infiltrating ductal carcinoma (80%), and the closest margin to tumor was the posterior margin (55%). The mean tumor volume of the first and last group was 1.5 and 1.3

cm3 respectively. A total of 15 intraoperative margin widenings were performed, 10 (66%) in the first group and 5 (33%) in the last one, finding presence of tumor cells in 6 of them: 5 (83%) in the first group and 1 (17%) in the last one. Likewise, 8 surgical reinterventions were performed, 5 (63%) in the first group and 3 (37%) in the last one, finding tumor cells in 4 of them: 3 (75%) in the first group and 1 (25%) in the last one. Considering patients with free margins, there were no significant differences between the first and last group when comparing healthy volume resected (33 vs 32.6 cm3 respectively) nor the surgical/ideal volume ratio (2.4 vs 2.2). Given that, between the first and last group, the number of margin widenings and reinterventions decreased by 50% and 40%, these results show an improvement in the localization of lesions while respecting the surgical margins. ***Conclusion:*** [125I] RSL is a useful and effective technique for localizing occult breast lesions and requires a learning curve to improve its surgical performance.

EP-0433

Quantitative analysis of 99mtc-sestamibi parathyroid scintigraphy: An accessible tool in single parathyroid adenoma localization prior to minimally invasive radioguided surgery

R. Zambrano Infantino, *J. Piñerúa-Gonsálvez, M. García-Aragón, N. Álvarez-Mena, M. Alonso-Rodríguez, R. Ruano-Pérez;*
Hospital Clínico Universitario de Valladolid, VALLADOLID, SPAIN.

Aim/Introduction: To evaluate the accuracy of quantitative analysis of early-phase in parathyroid scintigraphy with 99mTc-sestamibi for the localization of single parathyroid adenomas before minimally invasive radioguided surgery. ***Materials and Methods:*** A retrospective study was conducted, including 49 patients who underwent minimally invasive radioguided surgery based on clinical diagnosis and scintigraphic localization of single parathyroid adenoma. Quantitative analysis of early-phase in parathyroid scintigraphy was performed by using workstation (Xeleris, GE Healthcare). Initially, the activity of the parathyroids in both thyroid lobes was compared in early image. Subsequently, symmetrical regions of interest (ROIs) containing the same number of pixels were placed over the activity in both thyroid lobes in the early image. A ROI ratio was calculated by dividing the number of counts (Kc) from the side with higher activity by the number of Kc from the contralateral side. The ROI ratios were used to assess the accuracy of quantitative analysis using ROC analysis. The optimal cutoff point for localizing a single parathyroid adenoma was identified using the Youden index. ***Results:*** The studied cohort had a mean age of 66.6 ± 11,7 years with 67.3% being female. In 79,6% of cases, histopathological analysis confirmed the presence of a parathyroid adenoma. Quantitative evaluation showed an area under the curve of 0.64 (95% CI 0.46-0.82 Regarding adenoma localization, an optimal cutoff point of 1.13 was identified, with a sensitivity of 58.9%, specificity of 70.0%, positive predictive value of 88.4%, and negative predictive value of 30.4%. ***Conclusion:*** Quantitative image analysis of the early-phase technetium-99m sestamibi scintigraphy is a useful method for identifying single parathyroid adenomas, because of its high positive predictive value. This aspect is particularly beneficial in uncertain situations where conventional visual analysis is limited. Therefore, its use may reduce the need for resorting to more expensive diagnostic methods for localization of the adenoma responsible for hyperparathyroidism.

EP-0434

Development and Implementation of a Standardized Protocol for I-125 Seed Localization Technique (ROLL) across Diverse Pathologies: Initial Experience

C. Castillo Arias, *N. A. Colombo Vina, L. Blanco Verdejo, L. Asensio Valero, J. Orozco Cortes, H. Rodriguez Parra, J. Sabater, D. Soriano Mena, M. Flores Fuentes, P. Lombao Gracia, R. Díaz Espósito;*
Hospital Clínico Universitario de Valencia, Valencia, SPAIN.

Aim/Introduction: The primary aim of this study is to assess the efficacy of the standardized protocol developed at our institution for I-125 seed implantation, facilitating accurate localization of occult lesions. Secondary objectives encompass evaluating the safety profile of the implantation procedure, encompassing the incidence of intra- and postoperative complications. Additionally, we aim to analyze seed retention at the implantation site to ensure precise localization during subsequent surgical interventions. Clinical outcomes will be described, and the success rate of the technique will be determined. ***Materials and Methods:*** Cases necessitating radio-guided occult lesion localization (ROLL) between April 2023 and March 2024 were included in the study. A systematic workflow was established, comprising seed implantation, radiological confirmation of intralesional localization, surgical extraction, and radiological assessment of the specimen. Nuclear medicine specialists provided assistance in histopathological processing and seed retrieval. ***Results:*** A total of 103 seeds were successfully implanted in 72 patients, with 96 guided by ultrasound and 7 by CT scan. Breast pathology constituted the majority, with 87 cases (84,4%), while the remaining cases consisted of 2 melanomas (1.9%), 7 lung carcinomas (6.7%), and 7 axillary lymphadenopathies(6.7%). In all instances, seeds were accurately localized within the lesions, with complete lesion retrieval achieved in 86% of cases without margin involvement. In seven cases, portable gamma cameras facilitated real-time intraoperative assessment, with three incidents (4.1%) observed during seed extraction. ***Conclusion:*** The adoption of a standardized protocol for the ROLL technique using I-125 seeds has yielded a 100% success rate in lesion localization, with a minimal incidence of complications, thus underscoring its safety and reproducibility across diverse clinical scenarios. This approach demonstrates its utility as a reliable adjunct in clinical practice, regardless of surgical complexity, thereby enhancing precision and patient outcomes.

EP-0435

Molecular surgery in breast cancer: our first experience.

L. Blanco Verdejo[1], *J. Sabater Sancho[1], J. Orozco Cortés[1], E. Buch Vila[2], E. Muñoz Sornosa[2], L. Terrádez Mas[3], H. Rodríguez Parra[1], M. Adrianzen Vargas[2], N. Colombo Vina[1], V. López Flor[2], C. Castillo Arias[1], L. Asensio Valero[1], A. Palazón Palazón[4], C. Quilis Sebastiá[5], R. Díaz Expósito[1];*
[1]Servicio de Medicina Nuclear, Hospital Clínico Universitario de Valencia, Valencia, SPAIN, [2]Servicio de Cirugía General, Hospital Clínico Universitario de Valencia, Valencia, SPAIN, [3]Servicio de Anatomía Patológica, Hospital Clínico Universitario de Valencia, Valencia, SPAIN, [4]Servicio de Radiofarmacia, Hospital Clínico Universitario de Valencia, Valencia, SPAIN, [5]Servicio de Radiofísica y Protección Radiológica, Hospital Clínico Universitario de Valencia, Valencia, SPAIN.

Aim/Introduction: The aim of this paper was to analyse the usefulness of molecular imaging in the localization and assessment of affected edges in breast cancer. Additionally, the effectiveness and safety of the standardised work protocol (SWP) developed in

our centre were evaluated. ***Materials and Methods:*** Descriptive and prospective study. Patients diagnosed with breast cancer who had surgical indication and hypermetabolic lesions in preoperative positron emission tomography (PET) and computed tomography (CT) were included from November 2023 to March 2024. A SWP for radioguided surgery was elaborated. The procedure consisted in a preoperative intravenous injection of 18F-FDG, followed by surgical intervention assisted by a nuclear medicine physician who localised the lesion with a gamma probe. Afterwards, the surgical specimen and its edges were assessed in a 5-minute PET-CT image and subsequent histopathological analysis (HA). A dosimetric study with radiological protection physicist was performed in the first two surgical procedures. ***Results:*** Seven radioguided surgeries (4 lumpectomies, 2 mastectomies and a systemic ROLL of an axillary adenopathy) were performed. The surgical specimens corresponded to 6 breast lesions (luminal A infiltrating carcinoma, luminal B with neoadjuvant treatment, luminal A infiltrating lobular carcinoma, 2 triple negative with neoadjuvant treatment and a local relapse due to spindle cell sarcoma) and a triple negative axillary lymphadenopathy. 100% of the lesions were located, 6 pieces and 36 surgical edges were analysed. There was a correlation between PET-CT imaging results and HA in 30 edges (24 negative and 6 positive, 83% agreement). However, discordances were found in 6 of the analysed edges. No complications occurred during the nuclear medicine procedure or the surgical intervention. ***Conclusion:*** Hybrid molecular imaging techniques following our SWP have shown to be helpful in lesion's localization and the assessment of surgical edges without increasing surgical timing or an additional dosimetric risk. Despite our reduced sample, this technique could be used in the future as an intraoperative tool, reducing the need for other surgical interventions, but further investigation is needed.

EP-0436

Offline PET Proton Therapy Verification Protocol: A Fast Transport Trial Using Total-body PET/CT

Y. Wu[1], *S. Wang[2], H. Tang[1], S. Song[1], Z. Chen[1], Y. Wang[3], Y. Dong[3], X. Zhu[1];*
[1]Department of Nuclear Medicine, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]Central Research Institute, United Imaging Healthcare Group Co., Ltd, Shanghai, CHINA, [3]United Imaging Healthcare, Shanghai, CHINA.

Aim/Introduction: Verification of proton therapy is difficult as proton beams cannot penetrate human body to provide tomographic information for imaging. While, high energy proton beam generates isotopes that decay by positron emission. Positron annihilation produces 511 keV photons and a PET scanner can receive signals indicating the annihilation location. The proton range is concordant with the generated isotope location. Now PET is the only method amenable to noninvasively finishing proton therapy verification. Due to the extremely short halflife of proton-produced isotopes, the time interval between proton therapy and PET scan is vital for the PET verification process. In this research, we proposed a clinical trial using total-body PET/CT to verify proton therapy within an extreme short time. ***Materials and Methods:*** Tongji Hospital, Wuhan, China has a proton therapy gantry on the first floor and a total-body PET/CT on the second floor. The close layout of the two devices makes it proper to run offline PET verification protocol of proton therapy. The protocol is designed to finish PET scan as fast as possible after patient receives proton therapy. One mobile stretcher was used to transport patients between two devices. Overhead lasers were applied to locate and place patient on PET coach quickly. A total-body PET scan was then performed for at least 30 minutes to obtain enough counts for PET image reconstruction due to proton-excited radionuclides' low activity and short halflife. After PET scan, attenuation correction CT is performed to provide attenuation and anatomical information. PET images are reconstructed using a long decay constant (2.6 years) to unify different halflife of mixed isotopes. Dynamic total-body PET images are generated to track the metabolism of radionuclides or the so-called "washout effect". ***Results:*** We used a polymethyl methacrylate (PMMA) phantom to verify the protocol's time consumption and image quality. The protocol ran smoothly at Tongji Hospital, with only 70 seconds of transport time. A Monte-Carlo simulation of phantom PET image showed good cooperation with proton therapy range. Following study will focus on head & neck tumor patient verification before clinical application. The estimated time for patient transport time is 90 seconds. ***Conclusion:*** We proposed a fast transport proton therapy offline PET verification protocol and did phantom verification. This protocol can run fluently and show offline PET an efficient and precise way for proton therapy PET verification.

EP-0437

Clinical utility of PET/CT-guided metabolic biopsies in diagnosing metastatic or doubtful lesions

S. Shamim, *N. Kumar, S. Yadav, G. Arora, Y. Khadelwal, B. Jain; AIIMS New Delhi, Delhi, INDIA.*

Aim/Introduction: PET imaging offers metabolic information complementing CT scans, potentially aiding in the localization and characterization of lesions with increased metabolic activity. The integration of PET/CT-guided metabolic biopsies offers a promising approach to resolve diagnostic uncertainties and improve patient outcomes. The present study is aimed to investigate the utility of PET/CT-guided biopsy in diagnosing metastatic or doubtful lesions with a focus on improving diagnostic precision and guiding optimal clinical management strategies. ***Materials and Methods:*** A total of 18 patients (13 male; 8 female) with mean age 50.44±13.16 years initially underwent 18F-FDG PET/CT imaging for lesion characterization and identification. Biopsy was performed either on the same day that the whole-body PET/CT examination was performed or on another day (injection of lower activity of 18F-FDG, 110-185 MBq), after discussion with the referring physician, with use of the same PET/CT scanner used for the whole-body examination. We used a PET/CT-guided robotic positioning system (Maxio v2, Perfint Healthcare) that assists in fast and submillimeter and subdegree accuracy in targeting lesions accurate tumor targeting and tool placement for interventions, including biopsy. The pathologic diagnoses from PET-guided biopsies were compared with the final diagnosis based on findings from pathologic, clinical, and radiologic follow-up examinations. ***Results:*** Of the 18 patients assessed, 16 were oncology patients with suspected metastasis or residual disease. The pathologic diagnosis was not known for remaining 2 patients with clinically suspected benign (n = 1) or malignant (n = 1) disease. Fifteen (12) soft tissue lesions (including muscles, intercostal spaces, liver and lung nodules), 3 lymph nodes and 3 bony lesions were targeted. All procedures were technically successful and safe, and no major complication was observed. Pathologic diagnosis was confirmed for 16 patients, for a diagnostic yield of 89%. For 2 patient for whom repeat biopsy was advised due to presence of scanty fibro-collagenous tissue with focal foreign body giant cells. Biopsy results revealed 8 true-positive findings, 7 true-negative findings, zero false-positive findings, and 3 false-negative finding. The sensitivity, specificity,

positive predictive value, negative predictive value and accuracy for the detection of malignancy were 72.7%, 100%, 100%, 70%, and 83.33%, respectively. The procedure was helpful in determining the treatment plan for 91.7% of patients. ***Conclusion:*** The integration of PET/CT-guided metabolic biopsies into clinical practice has the potential to optimize patient management strategies and facilitate timely initiation of appropriate treatments.

EP-0438

Utility of Radioactive Iodine125 seed as preoperative method for localization of cervical thyroid cancer recurrence.

J. Velez Medina[1], *T. Cambil Molina[1], M. Camacho Falcon[1], T. Martin Hernandez[2], P. De la Riva Perez[1], M. Calvo Moron[1]; [1]Hospital Virgen Macarena. Servicio Andaluz de Salud, Sevilla, SPAIN, [2]Servicio Endocrinología. Hospital Virgen Macarena. Servicio Andaluz de Salud, Sevilla, SPAIN.*

Aim/Introduction: The use of radioactive seeds (RSL) has been documented for lesions localization in patients with recurrence or persistence of thyroid cancer. Our group wanted to evaluate its usefulness to improve the surgical result in patients re-operated of cervical metastasis of thyroid cancer. ***Materials and Methods:*** Prospective study with twenty three patients (19/4 F/M) with a mean age of 48.6 years (21-71) with differentiated thyroid carcinoma with cervical lymphatic involvement due to recurrence/persistence evidenced by ultrasound and confirmed by cytology and/or Tg-FNAB, submitted to new surgical intervention with curative purpose. Prior to surgery, an I-125 seed was placed, under aseptic conditions and under local anesthesia, in the target lymph node using an 18G needle guided by ultrasound performed by an endocrinologist with experience in the follow-up of thyroid cancer. Its correct position was verified by a radiation detector and ultrasound image. In the operating room, we used a gamma probe (Navigator GPS®) and a portable gamma camera (Oncovision Sentinella 102®) were utilizes to identify the maximum activity point (125-I seed) in order to locate the suspicious lymph node. We locate this point within the surgical field, removing the target tissue and verifying that the seed was included in the excised tissue. Analysis of seed placement time, surgical procedure duration and difficulty, lesion size and localization, surgeon advantages, average nodal index and pre and post surgery TG levels. ***Results:*** All marked lymph nodes were positive in histology (33 metastatic nodes). The mean duration of the sonographic insertion was 14±3.99 minutes. Days from placement prior to surgery was 3,2 days (1-7) and average surgical duration was 40 min (12-120). The average nodal index of 0,77. The average maximum diameter of excised lypnh nodes was 11,05±5.53 mm. Presurgery levels Tg levels were 6,4±3.17 ng/dl significantly decreased after surgery 0,97±0,0.46ng/dl ($p < 0.05$) with positive antithyroglobulin antibodies were three. There was not major complications. In three cases, seed migrated near the lesion but only in two cases seeds were not helpful. Surgery team evaluation average was excellent (2,6/3) considering radioguided surgery was faster and safe in node location. ***Conclusion:*** The implementation of the RSL has shown benefits for the patients and for surgery team, as a safe and uncomplicated procedure, reducing surgical time and improving the programming of the operating room activity.

EP-0439

PET integration in re-irradiation treatment planning for recurrent high-grade gliomas: impact on patient outcomes.

A. Chaban[1], *K. Sun[1], W. Weber[1], C. Diehl[2], I. Yakushev[1]; [1]Klinik und Poliklinik für Nuklearmedizin, Klinikum rechts der Isar, Technische Universität München, München, GERMANY, [2]Klinik und Poliklinik für Radioonkologie und Strahlentherapie, Klinikum rechts der Isar, Technische Universität München, München, GERMANY.*

Aim/Introduction: Conventional radiation therapy planning of recurrent high grade gliomas (rHGG) is based on magnetic resonance imaging (MRI). Because positron emission photography with amino acid tracers (AA-PET) is known to delineate HGG more accurately than MRI, PET has been integrated into re-irradiation treatment planning of rHGG by some academic and non-academic centers. Yet, impact of PET-guided re-irradiation treatment on patient outcomes is still unknown. Thus, the aim of this study was to evaluate the impact of AA-PET-guided re-irradiation treatment planning on progression-free survival (PFS) and overall survival (OS) of patients with rHGG. ***Materials and Methods:*** Our institutional database was searched for patients with the first recurrence of a HGG, who had been treated with radio(chemo)therapy alone, i.e., without re-resection, and for whom data on PFS, OS, and quality of life (QoL) were available. Out of 80 identified patients, 28 and 52 were treated based on MRI alone and MRI plus AA-PET, respectively. The Kaplan-Meier analysis was performed to evaluate the impact of AA-PET integration on the primary (PFS and OS) and secondary (QoL) endpoints. ***Results:*** The MRI alone group showed a significantly shorter PFS compared to MRI plus PET group (mean 3.6 vs. 8.1 months, $p=0.005$). No significant difference was found for OS (mean 16.1 vs 16.9 months, n.s.). Age significantly impacted PFS, while WHO grade, Karnofsky performance scale and time to recurrence significantly impacted OS. No significant impact of tumor to background ratio was found. The total dose delivered to patients showed a significant impact on QoL in the acute phase. The difference in planning target volume between two groups was not significant. ***Conclusion:*** Integration of PET into re-irradiation treatment planning of patients with rHGG significantly improved PFS. However, there was no significant impact on OS. These results are no unexpected, because in a longer term other factors such as variability in patient general condition, tumor biology, and treatment may overweight the initial benefit of a more efficient AA-PET-guided rHGG re-irradiation. These results play an important role in understanding of rHGG and might impact patient management.

EP-0440

Radio-guided surgery for non-palpable lesions in different clinical scenarios

A. Barrera, *A. Alomar Casanovas, J. Cruz Vasquez, C. Villaprado Meza, I. Blanco Saiz, F. Lozada Delgado, E. Goñi Girones; Hospital Universitario de Navarra, Pamplona, SPAIN.*

Aim/Introduction: Thanks to advances in imaging techniques, it is possible to detect non-palpable lesions that can be located and biopsied through radio-guided surgery. The objective of this study was to analyse our experience in radio-guided surgery for non-palpable lesions (ROLL) in different pathologies. ***Materials and Methods:*** Retrospective study that includes all consecutive patients referred for marking non-palpable lesions to the Nuclear Medicine Service from December 2017 to March 2024. Data

collected was based on: the service of origin, initial imaging technique, location and size, technique used for marking, success rate of marking and excision and pathological data. The labelling techniques used were the ultrasound-guided injection of 99mTc-albumin macroaggregates with 18.5MBq or 37MBq in a volume of 0.1 ml of physiological saline, depending on whether the excision was performed on the same day of inoculation or the following day, and the eco-guided seed arrangement 125-I.The labelling success rate was verified by reviewing planar scintigraphic ± SPECT/CT acquisitions. Surgical removal of the lesion was assisted by a gamma probe and in some cases a portable gamma camera. ***Results:*** A total of 64 lesions were marked in 62 patients, 39 (62.9%) were women, with a mean age of 56±13.9 years. Of the total, 51 came from plastic surgery, 10 from breast surgery and 1 from endocrine surgery. Most lesions were initially located by CT (46.8%) followed by PET/CT (30.6%), ultrasound (21.0%) and mammography (1.6%). A total of 48 (75.0%) lesions were marked with 99mTc-macroaggregates and 16 (25.0%) with 125-I seed. The location of the lesions was 37 (57.8%) axillary region, 13 (20.3%) inguinal, 6 (9.4%) cervical and 8 (12.5%) in other locations (dorsal, sartorius, pectoral). The median size was 20.5 mm (IQ: 18.0-26.0). The marking and excision technique was successful in all lesions. Oncological anatomopathological findings were positive in 7/13 patients with melanoma, 19/25 lymphoproliferative syndromes, 5/8 breast neoplasms and in 5/16 patients with other pathologies (fever of unknown origin, dermatofibroma protuberans and recurrence of thyroid cancer). ***Conclusion:*** Our experience in the ROLL technique has proven to be simple, safe and effective in detecting and biopsying non-palpable lesions, allowing pathological study of suspicious lesions. A technique requires multidisciplinary work between radiology, nuclear medicine and surgery.

EP-0441

Analysis of response and survival following treatment by hepatic radioembolization for unconventional indications

A. Gjukaj[1], *E. Woff[2], M. Vouche[3], P. Flamen[2], H. Levillain[2], B. Vanderlinden[2];*
[1]ULB, Brussels, BELGIUM, [2]HUB, Brussels, BELGIUM, [3]CHU Saint-Pierre, Brussels, BELGIUM.

Aim/Introduction: Based on a multidisciplinary selection, some patients with dominant hepatic metastatic disease of hypervascular nature might benefit from treatment by radioembolization (SIRT). However, the literature on SIRT for indications not listed in international guidelines and referred to as unconventional (NC) is limited. The objective of this study is to evaluate survival (in comparison to our SIRT cohort for colorectal cancer (CRC)) and response after SIRT treatment for NC indications. ***Materials and Methods:*** In this single-center retrospective study, overall survival (OS) and progression-free survival (PFS) data were collected for 37 patients with NC indications and for 65 patients with CRC treated in our institution. On the other hand, the response to treatment was analyzed for each patient and for each lesion according to RECIST and PERCIST criteria. Kaplan-Meier survival curves were used to compare OS and PFS between NC and CRC. The Mann-Whitney test was used to compare the absorbed dose between responder and non-responder patients/lesions respectively for RECIST and PERCIST criteria. ***Results:*** The median OS for NC was 501 days and the median PFS was 58 days. The median OS for CRC was 408 days and the median PFS was 57 days. There was no difference in OS (adjusted HR: 0.90; 95% CI: [0.59-1.38]; p=0.64) or in PFS (adjusted HR: 0.84; 95% CI: [0.55-1.28]; p=0.40) between NC and CRC. In the patient-based analysis, the minimum absorbed dose was similar between patients categorized as responders compared to non-responders according to RECIST and PERCIST criteria (p=0.43 and p= 0.62 respectively). In the lesion-based analysis, the absorbed dose was similar between lesions categorized as responders vs. non-responders according to RECIST and PERCIST criteria (p= 0.77 and p= 0.61 respectively). ***Conclusion:*** Our study did not show a difference in OS and PFS between NC indications and our SIRT cohort for CRC. We did not demonstrate a relationship between absorbed dose and response according to RECIST/PERCIST criteria in analysis by patient or by lesion.

EP-0442

Performance of DROP-IN beta probe for 68Ga-PSMA-11 in high-risk prostate cancer patients eligible for robotic-assisted radical prostatectomy.

F. Mattana[1], *F. Collamati[2], S. Luzzago[3], F. A. Mistretta[3], G. Renne[4], R. Mirabelli[2], S. Morganti[2], O. De Cobelli[3], N. Fusco[4], G. Musi[3], F. Ceci[1];*
[1]IEO European Institute of Oncology IRCCS, Nuclear Medicine, Milan, ITALY, [2]INFN National Institute of Nuclear Physics, Nuclear Physics, Rome, ITALY, [3]IEO European Institute of Oncology IRCCS, Division of Urology, Milan, ITALY, [4]IEO European Institute of Oncology IRCCS, Pathology, Milan, ITALY.

Aim/Introduction: The primary aim of this analysis was to evaluate the diagnostic accuracy of the combined approach with a DROP-IN positron detector (β-Probe) and 68Ga-PSMA-11 PET/CT (PSMA-PET) in the correct identification of lymphnode metastases, in high-risk prostate cancer (PCa) patients undergoing robotic radical prostatectomy (RARP) and extended pelvic lymph-node dissection (ePLND). The standard of reference was the histopathological analysis. ***Materials and Methods:*** This is a prospective, single-arm, single-center, non-interventional, phase II trial (NCT05596851), aimed at enrolling fifteen (n=15) PCa patients. We present an interim analysis in the first eight consecutive (n=8) patients enrolled. Inclusion criteria were: a) biopsy proven, high-risk PCa; b) patients candidate to RARP + ePLND as primary therapy; c) PSMA-PET performed within 6 weeks prior to surgery; d) PSMA-positive nodes in PSMA-PET; e) age>18. The surgery procedure started with the intravenous injection of 1.1 MBq/Kg of 68Ga-PSMA-11 directly in the surgery theatre. After the injection the surgery procedure proceeded first with ePLND followed by RP. The in-vivo measurements of the surgery templates with β-Probe were performed with a DROP-IN system, inserting the probe into a trocar. All removed nodes were also measured ex-vivo. The tumor-to-background-ratio (TBR). was evaluated graphically in a display showing real-time counts per time. Furthermore, a dedicated, operator-independent, algorithm to reliably identify pathologic vs. non-pathologic nodes was developed. PSMA-staining was performed in all specimens. Data derived by the PSMA-PET, β-Probe and histopathological analysis were compared in a per-region analysis. ***Results:*** The live β-Probe-guided ePLND was a feasible procedure, without significant changes in the surgery practice. No side effects have been observed during ePLND. In total, 64 specimens were removed and analyzed. Pathology results were used to validate in vivo and ex-vivo β-Probe counts interpreted according to the operator-indipendent algorithm. Four (n=4) false positive and seven (n=7) false negative findings were detected. The intra-operative β-Probe sensitivity to detect PCa nodal metastasis was 76.7%, while specificity was 88.2%. ***Conclusion:*** These are the first ever published data derived from a live surgery experience using a β-Probe to identify PSMA-positive lymph nodes. This new approach proved to be feasible and safe. Visual TBR interpretation (operator-dependent) revealed to be

more challenging than expected. After the implementation of a dedicated, operator-independent, algorithm for the identification of a cut-off in TBR analysis, the diagnostic accuracy improved. The completion of this phase II trial will provide more data about the efficacy of this new generation image-guided approach.

EP-0443

Pulmonary radioguided occult lesion localization (ROLL) by electromagnetic navigator-guided bronchoscopy (ENGB) in a single surgical time.

***M. Zapardiel*[1],** *M. Vaillant[1], L. León[1], E. Fernández[2], C. Fraile[2], A. Berardinelli[1], P. Dauden[1], G. Cuesta[1], P. Nespral[1], M. Cabrera[1];*
[1]Department of Nuclear Medicine. Hospital Clínico San Carlos. Instituto de Investigación Sanitaria San Carlos (IdISSC). Madrid, Spain., Madrid, SPAIN, [2]Department of Thoracic Surgery. Hospital Clínico San Carlos. Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, SPAIN.

Aim/Introduction: Our aim was to evaluate the success rate of ROLL technique with 99mTC-MAA using electromagnetic navigator-guided bronchoscopy (ENGB) in the intraoperative localization of small lung nodules and resection with video-assisted thoracoscopy (VATS) in a single surgical time. ***Materials and Methods:*** EBGN was performed under general anesthesia by a thoracic surgeon.The target lesion was localized using a therapeutic bronchoscope and a working set consisting of an extensible channel (2.7 mm diameter x 1070 mm long) and a localization guide with an electrode at the tip to navigate the electromagnetic field. ROLL is performed intralesionally or as close as possible with a range of 2 cm using a 21G needle 137 cm long with a 2 mm working channel. Radiotracer 99mTc-MAA (37-185 MBq) was administered in a volume of 0.6 ml under simultaneous visual control with a portable gamma camera. Subsequently, lung resection was performed using a video-assisted approach (VATS) or thoracotomy. Intraoperatively, the radiolabeled area was located with a laparoscopic gamma probe and surgical resection was performed with endograpators. The radioactivity in the specimen and its location were confirmed ex-vivo using a gammaprobe and a portable gammacamera. ***Results:*** A total of 19 lung ROLL techniques were performed between 2022 and 2024. The majority of patients (75%) were male, with an age range of 21 to 86 years. The last imaging technique performed prior to surgery was a chest CT in 62.5% of cases and PET-CT in 37.5%. The dimensions of the lung lesions ranged between 5-21 mm (mean 10.9 mm). They were located in left upper lobe (47%), left lower lobe (26%), right lower lobe (15.8%) and right upper lobe (10.5%). By diagnostic imaging techniques, 62.5% of the marked lesions were solid, 25% subsolid nodules/nodular opacities and 12.5% cystic lesions. Among 19 ROLL procedures, only three resulted unsuccessfully, two of them due to an incorrect localization of the navigator and the other one because of technical difficulties. A total of 84% of pulmonary lesions were successfully detected. ***Conclusion:*** Pulmonary ROLL using electromagnetic navigator is a simple, reliable and reproducible technique. It facilitates intraoperative localization in the same surgical act. The concurrent monitoring of the radiotracer administration with a portable gamma camera could potentially enhance the success rate.

Impact of neoadjuvant chemotherapy on sentinel lymph node performance and recurrence-free survival in breast cancer patients

A. GARCIA RUIZ*, I. Martínez-Rodríegez, A. Sánchez-Salmón, J. Jiménez-Binilla, F. Gomez-de-la-Fuente, N.Martínez-Amador, B. Lucas-Velázquez, V. Mendi-Barcina, M. De Arcocha-Torres, M. Pombo-López, Pez, A. Bota-Bota, N. Carvalcho-Duarte, F. Rodrígez-Izquierdo, L. Cabrera-Portillo, M. Botanch-Domingo, R. Quirce;*
Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, SANTANDER, SPAIN.

Aim/Introduction: To assess the impact of neoadjuvant chemotherapy (NAC) on sentinel lymph node (SLN) biopsy performance and recurrence-free survival (RFS) in patients with breast cancer (BC). ***Materials and Methods:*** Retrospective study including 107 women (mean age: 51.7±11.6, 28-80 years) with BC treated with NAC who underwent SLN biopsy between 2018 and 2023. Histological type was invasive ductal carcinoma (IDC) in 73 patients (2 bilateral), invasive lobular carcinoma in 12, and other types in 22. Seventy-one patients had complete response to NAC, 35 partial response and 1 no response. Lymphoscintigraphy was complemented with SPECT/CT in 17 patients. Parameters evaluated: SLN detection by lymphoscintigraphy, lymphographic drainage patterns, surgical detection, histological status of the excised nodes, distant recurrence disease and survival (follow-up interval: 1-5 years). ***Results:*** Lymphoscintigraphy detected lymphatic drainage in all the patients included. In total, 153 axillary SLNs were identified: 63 patients showed drainage to 1 SLN, 42 patients to 2 SLNs, and 2 patients to 3 (one of them having bilateral BC with 1 SLN detected in the right axilla and 2 in the left axilla). Drainage to the internal thoracic chain was detected in 9/107 patients. During surgery, 150/153 axillary SLNs were removed, 10 of them (corresponding to 8 patients, 7.4%) were metastatic (8 macrometastasis/2 micrometastasis). The subsequent lymphadenectomy showed other metastatic nodes in 3/8 patients. The other 140 excised SLNs were negative (corresponding to 97 patients, 90.6%). Three SLNs (2 patients, 1.9%) were not localized during surgery, performing axillary sampling instead that revealed no metastasis. None of the 8 patients with metastatic SLNs showed recurrence during follow-up. Five of the 97 patients (5.2%) with non-metastatic SLNs experienced recurrence (1 patient in the contralateral breast, and 4 patients at distant sites, including extra-axillary lymph nodes in 2). Of the 2 patients who underwent axillary sampling, one had triple-negative IDC unresponsive to NAC and later developed local recurrence (bilateral breasts and right axillary nodes) and distant metastasis. In summary, 6/107 patients (5.6%) showed recurrence. No mortality was documented in any of the patients during the follow-up. ***Conclusion:*** In our experience, lymphoscintigraphy is a reliable technique for the identification of the SLN in patients with BC after NAC with good results and low percentage of lymph nodes recurrence (in the present study only in extra-axillary territory), and distant metastasis. Our results reinforce

the indispensable role of SLN biopsy in this clinical scenario in a context of personalized patient management.

EP-0445

Accuracy of sentinel lymph node detection with indocyanine green compared to technetium 99m in early-stage vulvar cancer.

L. Travaini, *E. Preti, L. Gilardi, P. Rocca, M. Ferrari, S. Fracassi, F. Mattana, G. Buonsanti, G. Aletti, M. Colandrea, A. Maggioni, B. Parducci, M. Cuomo, D. Radice, F. Ceci;*
European Institute of Oncology, Milano, ITALY.

Aim/Introduction: Lymph node pathologic status is the most important prognostic factor in vulvar cancer. Lymphoscintigraphy (LY) with gamma-probe guided surgery is nowadays the most cost-effective approach than lymphadenectomy in early-stage vulvar cancer. Next to the LY there is an increasing interest for others approach, like indocyanine green (ICG). This study evaluates the accuracy of sentinel lymph node (SLN) detection using ICG compared to the gold standard of LY with technetium 99m (99mTc)-nanocolloid in women affected by early-stage vulvar cancer in high-level experienced oncological setting. ***Materials and Methods:*** Thirty-seven patients with vulvar squamous carcinoma stage IB were enrolled in a prospective observational study from December 2014 to April 2023. Patients underwent standard LY using 99mTc-nanocolloid, the day before surgery. In addition, a total dose of 2 ml ICG solution (1.25 mg/ml) was intradermally administered before surgery at the same sites of the 99mTc injections. All SNLs were identified and sent to histological examination. ***Results:*** Eighteen patients had a midline tumor and nineteen a unilateral tumor (12 left and 9 right), therefore 57 groins were investigated. Mean body mass index (BMI) was 24.9, mean age was 65.4 years. Overall, SLN detection rate (DR) was 94.6% and 89.2% by ICG and LY, respectively. Considering laterality and for patients, ICG showed a SLN DR of 94.4%, 100% and 85.7% for midline, left and right tumors. LY demonstrated a lower DR for midline tumors (83.3%) but not statistically impactful. For groins, ICG and LY had an overall DR of 94% and 92%, divided in 94% vs 100% in midline, 100% vs 83 in left and 86% vs 86 in right. BMI was significantly associated with SLN detection discordance between ICG and LY (p= 0.03) as well as surgical diagnostic excision (p= 0.04). ***Conclusion:*** Our data show that ICG tracer is feasible and safe. It has a high accuracy to identify SLN, better or at least comparable to LY detection rate. Moreover, a combined technique (ICG + 99mTc) could be suggested in patients with midline tumors and high body mass index.

EP-0446

Breast Cancer in Women Over 70 Years Old - Incidence of Positive Cases After Sentinel Node Biopsy

N. Vasconcelos, *H. Duarte, L. Violante, I. Próspero, D. Barbosa, D. Silva, I. Lucena Sampaio;*
Instituto Português de Oncologia do Porto, Porto, PORTUGAL.

Aim/Introduction: In recent years there has been a growing concern to avoid overtreatment of breast cancer in older women. In 2016, the North American Society for Surgical Oncology recommended against routine sentinel node biopsy (SNB) in women aged ≥70 years, diagnosed with early-stage invasive breast cancer (cT1), node-negative (N0), hormone receptor-positive (HR+) (oestrogen and/or progesterone) and human epidermal growth factor receptor 2-negative (HER2-), based on studies that demonstrated that the omission of SNB does not seem to have a significant impact in patient's survival, given that there is good control of the disease with adjuvant hormone therapy. They note however, that axillary staging may be considered individually if its results have an impact on the therapeutic decision. Our objective was to evaluate the incidence of positive SNB in women aged ≥70 years, with invasive breast carcinoma, cT1N0/RH+/HER2-, in a treatment centre for oncology. ***Materials and Methods:*** Retrospective analysis of patients with early-stage breast carcinoma aged ≥70 years, referred for lymphoscintigraphy for SNB, over a 5-year period (01/01/2019 and 12/31/2023). ***Results:*** Of 621 patients aged ≥70 years referred for lymphoscintigraphy, 187 met the inclusion criteria (cT1N0/RH+/HER-), median age 76 years (range 70-93). Of these 187 patients, there was no migration of 99mTc-Nanocolloids in 6 (3.2%). 167 (89.3%) patients underwent lumpectomy and 20 (10.7%) total mastectomy. Medium tumour size on histology was 1.6 cm (range 0.6-4.8 cm). Most tumours were ductal (133/187, 71.1%) with low/intermediate grade (135/187,72.2%). All patients were offered hormone therapy, except for one patient (without clinical conditions). Of the total of 187 patients, 26 (13.9%) had nodal metastases: 1 (3.8%) - isolated tumour cells [pN(i+)]; 8 (30.8%) - micrometastases [pN(mi)]; 15 (57.7%) - metastases in 1-3 axillary nodes [pN1] and 2 (7.7%) - metastases in 4-9 axillary nodes [pN2]. ***Conclusion:*** We conclude that in our centre, there is a low incidence of patients with positive SNB in women ≥70 years old, with invasive breast carcinoma (cN0T1, HR+/HER2-). Furthermore, several clinical trials have shown a lack of survival benefit for axillary dissection (ALND) versus no ALND in both node-positive and node-negative breast cancer. These data are in favour of a more restricted selection of patients aged ≥70 years (cT1N0, HR+/HER2-) for SNB since this procedure is associated with some long-term morbidity. It will also be important to carry out a future analysis of overall survival in this group of patients.

EP-0447

Into the Lymph Nodeverse: The Role of Sentinel Lymph Node Biopsy in Managing Oral Squamous Cell Carcinomas. Our experience

M. R. Marusso Fizzani, *M. de Bonilla-Candau, A. Palomar-Muñoz, M. Sáez-Barba, O. Hernández Cristancho, N. Calviño, J. Echeverri Díaz, S. Asadurova, F. M. Velazquez, C. Gámez-Cenzano;*
Hospital Universitario Vall d'Hebron, Barcelona, SPAIN.

Aim/Introduction: While surgical treatment of primary tumours in early stages oral cavity squamous cell carcinoma (OCSCC) is well established, controversy remains regarding clinically node-negative (N0) neck management. The selective sentinel lymph node biopsy (SLNB) emerges as the sole technique capable of guiding towards potentially affected nodes, given that micro metastases are undetectable in pre-surgical tests. Considering lymph nodes metastasis represent the primary prognostic factor, this study aims to describe the SLNB as a treatment modality and as a mapping technique for a subsequent neck dissection (ND) in handling clinically N0 early OCSCC. Additionally, to assess the treatment's impact on disease-free survival (DFS) time conducting a pilot survival analysis, facilitating thereby the groundwork for broader longitudinal studies. ***Materials and Methods:*** Thirty-six patients diagnosed with clinically N0-OCSCC between February 2022 and April 2024 were selected and categorized into three groups based on the surgical interventions received: SLNB alone, SLNB with ND or ND alone. The number and pathological state of sentinel lymph nodes (SLN) removed were analysed. Additional patient data such as smoking habit, tumour differentiation grade, immunohistochemical markers, and adjuvant treatment were also collected. A DFS analysis

was conducted for SLNB and SLNB+ND groups on R Commander Software, with Kaplan-Meier curves generated from the data. ***Results:*** The primary tumour was predominantly located at the tongue (61.11%), with only one lesion being central. A slightly higher incidence was observed in males (52.77%). Ipsilateral level II drainage was the most frequent (81.81%). Pathological SLNs were found in 21.21% of patients (7/33). Subsequent ND was performed in 16 patients (44.44%), although 9 of them had a previous negative SLNB, due to intraoperative assessment. Pathological lymph nodes were identified in 12.5% of patients who underwent consecutive ND (2 out of 16). Regarding recurrences, six-month DFS in SLNB and SLNB+ND groups was 33.33% and 30%, respectively (p=0.81). ***Conclusion:*** SLNB proves to be a valuable technique for mapping the lymphatic drainage, with ipsilateral level II being the most frequently involved. We observed ND was performed in several patients, considering this could potentially increase morbidity; we propose further comprehensive investigation into this approach. Although there is no statistical significance, similar survival rates were observed between groups (SLNB vs SLNB+ND). Acknowledging that our study's main limitation is constrained follow-up time, ongoing future studies will allow a log-rank analysis comparing treatments and advancing towards a more effective management of these patients.

EP-0448

Intra-operative lymphatic mapping and sentinel node biopsy in laryngeal carcinoma using radiotracer injection

P. Sahafi, *A. Saber Tanha, M. Daghighi, E. Khadivi, K. Khazaeni, V. Dabbagh Kakhki, R. Sadeghi;*
Ghaem Hospital, Mashhad university of medical science, mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The purpose of this study was to determine the value of sentinel lymph node biopsy in the laryngeal SCC, using intra-operative peri-tumoral injection of Tc-99m-phytate. ***Materials and Methods:*** Patients with biopsy-proven squamous cell carcinoma of the larynx were included. On the day of surgery, after anesthesia induction, suspension laryngoscopy was performed to inject 74MBq/0.4 ml Tc-99m-phytate in four aliquots into the sub-mucosal peri-tumoral location. After 10-minute wait, portable gamma probe was used to locate sentinel nodes. Subsequently, all patients underwent laryngectomy and neck dissection. Both sentinel nodes and non-sentinel nodes were examined using hematoxylin and eosin (H&E) staining. ***Results:*** Twenty-six patients with diagnosis of laryngeal carcinoma were included in the study. The sentinel lymph node (SLN) detection rate was 65.4%, with 100% detection rate in the supraglottic region and 52.6% detection rate for glottis/transglottic patients. Permanent pathology results showed lymph node involvement in four patients, but only one patient had negative result in the sentinel lymph node biopsy (SLNB), resulting in an overall false negative rate of 25%. The sensitivity of the SLN technique was 75% overall, 100% in the supraglottic region, and 67% in the glottis/transglottic region. ***Conclusion:*** Accuracy and feasibility of sentinel lymph node biopsy may be related to the location of the tumors in the larynx. For supraglottic tumors, the technique seems to be feasible with low false negative rate. For glottis/transglottic tumors both detection rate and false negative rate seem to be suboptimal. Further studies are needed to validate our results.

EP-0449

Lymphatic drainage rate in breast cancer recurrence and its relationship with surgical and medical management in the first breast tumor

X. Guarnizo Poma, *P. Zaragoza-Ballester, S. Angiolillo Grau, M. Avilés Jurado, A. Galiana Morón, P. Sarandeses Fernandez, P. Arias Gallego, S. Aragón Sánchez, D. Vega Perez, M. Tabuenca Mateo; Hospital Universitario 12 de Octubre, Madrid, SPAIN.*

Aim/Introduction: The aim of this study is to analyze the relationship between lymphatic drainage of sentinel node selective biopsy (SLNB) in breast cancer recurrence, considering the surgical approach and adjuvant treatment administered in the first breast tumor. ***Materials and Methods:*** Descriptive and retrospective study of 1266 patients undergoing SLNB between the years 2020-2023. Of these, 39 patients were diagnosed with breast cancer recurrence. Patients with local recurrence or with a second ipsilateral primary breast tumor were included. The results of axillary lymphoscintigraphy of the second breast tumor were evaluated, analyzing the relationship between the type of lymphatic drainage (ipsilateral, aberrant and exclusive aberrant) and previous axillary surgical management, as well as adjuvant medical treatment administered during the first breast tumor.The data obtained were analyzed using mean and standard deviation for quantitative variables, and frequency and percentage for categorical variables. The comparative analysis was performed using the ANOVA test for quantitative variables and Fisher's test for qualitative variables, with values of $p<0.05$ being considered significant. ***Results:*** All patients were female with mean age 57.5 years. Lymphatic drainage was evident in 82% (n=32), of these, 81.25% (n=26) had ipsilateral axillary drainage, 31.25% (n=10) had aberrant migration, and exclusive aberrant drainage in 18.75% (n=6).A higher drainage rate was observed on lymphoscintigraphy in patients without axillary lymphadenectomy (90.3% vs. 50%) ($p<0.022$), with majority migration to the ipsilateral axilla (80.6%) ($p<0.001$). A significant relationship was identified between chemotherapy administration and the incidence of axillary lymphatic drainage, showing a lower drainage rate in patients treated with chemotherapy ($p<0.020$). No significant differences were observed between chemotherapy and the incidence of aberrant drainage. On the other hand, the rate of aberrant lymphatic drainage is significantly higher in patients who received radiotherapy in their first breast tumor ($p<0.014$), and a significant decrease ($p<0.004$) of ipsilateral lymphatic drainage was observed in patients who received in association radiotherapy and chemotherapy as adjuvant treatments. ***Conclusion:*** There is a high rate of axillary lymphatic drainage in breast cancer recurrence, even in patients who have previously undergone axillary lymph node resection. The rate and type of axillary lymphatic drainage in breast cancer recurrence are influenced by the surgical and medical management of the initial breast tumor. Chemotherapy was associated with a lower incidence of lymphatic drainage, whereas radiotherapy was associated with a higher incidence of aberrant drainage. And the combination of radiotherapy and chemotherapy showed a significant reduction in ipsilateral lymphatic drainage.

EP-0450

Drainage Patterns in Breast Cancer Assessed by SPECT/CT Sentinel Lymph Node Mapping: Our Experience

C. Ferreira, *E. Silvera, G. Dos Santos, J. Hermida, O. Alonso; Hospital de Clínicas, Montevideo, URUGUAY.*

Aim/Introduction: The sentinel lymph node (SLN) technique

using planar imaging has high accuracy in axillary staging of clinically localized breast tumors.The incorporation of the hybrid SPECT/CT technique has enabled better staging by allowing precise determination of the number/location of SLNs. ***Materials and Methods:*** Patients between January 2016 and May 2023 were included. All underwent routine SLN procedure by periareolar subdermal administration of 37-148 MBq 99mTc-nanocolloid and subsequent acquisition of planar images and SPECT/CT on a 16-slice scanner. In a subgroup of patients, an intra-individual comparison of planar vs SPECT/CT results was performed using the Lin concordance correlation coefficient (ρc) with its respective 95% confidence interval (CI 95%). Suggestions for interpreting the Lin concordance correlation coefficient are as follows: almost perfect agreement (>0.99); substantial concordance (>0.95-0.99); moderate agreement (0.90-0.95); and poor concordance (<0.90). Concordance was also evaluated using 95% concordance limits, and the range within which 95% of the differences in the number of nodes between planar and SPECT/CT were estimated. ***Results:*** A total of 782 breast cancer patients were included, 778 female and 4 male. A single injection was performed in 708 patients (90%), while two or three injections were performed in the rest (n=63; 8% and n=11; 1%; respectively). Breast cancer was right-sided (n=350; 45%), left-sided (n=407; 52%), or bilateral (n=15; 3%), with 1 node identified (n=342; 44%), 2 nodes (n=290; 37%), 3 nodes (n=101; 13%), 4 nodes (n=30; 3%), or "5 or more nodes" (n=6; <0.1%). Axillary drainage was identified in 758/782 patients (97%): Level I (n=748), Level II (n=205), Level III (n=48). Single (n=530; 70%) or multiple (n=228; 30%) axillary drainage: two levels (n=205; 27%) or three levels (n=23; 3%). Extra-axillary drainage (27/782 patients; 3%) was intramammary (n=11; 40%), supraclavicular (n=6; 22%), and internal mammary chain (n=10; 37%).The estimated Lin concordance correlation coefficient (CCC) was 0.9243 (95% CI: 0.8779-0.9535), classifying it as moderately accurate, although according to the interval, it could range from poor to substantial.The average difference was 0.13 (95% CI -0.84-1.1), which was not significant. ***Conclusion:*** Accurate axillary staging and identification of drainage patterns influence surgical management and allow for minimal morbidity compared to axillary clearance.SPECT/CT has higher accuracy in SLN localization than planar imaging. ***References:*** McBride, 2005, 2007Bland and Altman, 1986, 1999.

EP-0451

Selective Sentinel Lymph Node Biopsy in Cervical Cancer: 99m-Tc-Nanocolloids versus Indocyanine Green and Their Combined Benefit

M. Avilés Jurado, *E. Martínez Albero, P. Zaragoza-Ballester, S. Angiolillo Grau, X. Guarnizo Poma, P. Sarandeses Fernández, D. Vega Pérez, A. Galiana Moron, A. Tejerizo García, R. Oliver Pérez, M. Tabuenca Mateo;*
Hospital Universitario 12 de Octubre, Madrid, SPAIN.

Aim/Introduction: To compare the efficacy of selective sentinel lymph node biopsy (SLNB) technique using two tracers: 99mTechnetium nanocolloid and Indocyanine Green in patients with cervical cancer in stages IA1-IIB. ***Materials and Methods:*** Retrospective descriptive study including all patients (p) between 2017-2024 diagnosed with cervical cancer in stage IA1-IIB without nodal or distant metastasis, who underwent SLNB with dual tracer. The radiopharmaceutical was injected the day before surgery, and static images and SPECT/CT were acquired to locate its drainage. In the operating room, the dye injection was performed using the same injection technique. Sentinel lymph nodes were biopsied with the assistance of a gamma probe and polarized light. Pelvic lymphadenectomy was performed in patients with stages ≥ IB or with aggressive features. Subsequently, patient follow-up was conducted in consultation. Statistical analysis was performed using SPSSv23 for both qualitative and quantitative variables. ***Results:*** Thirty-seven patients (100% female) with a mean age of 47.35 years (range 28-69) were included. Tumor staging: IA1 8.1%, IA2 24.3%, IB1 51.4%, IB2 10.8%, and IIB 5.4%. The radiopharmaceutical had a higher overall drainage rate than the dye (94.6 vs 89.2%), although it showed a higher unilateral drainage rate (35.1% vs 18.9%). In 50% of cases without dye drainage (n=2/4), the radiopharmaceutical drained bilaterally. The intraoperative detection rate of sentinel lymph nodes using the radiopharmaceutical was similar to the imaging localization rate. The combined use of both tracers showed significantly higher overall drainage rates than the isolated use of dye (94.6 vs 89.2%) and similar to those of the radiopharmaceutical, although it improved the bilateral drainage rate of the latter (83.8% vs 59.5%). Only one sentinel lymph node tested positive for malignancy. Eighteen standard lymphadenectomies were performed with negative results for malignancy. Median follow-up was 4 years (range 0-6). Of the 33 patients (89.2%) with a minimum follow-up of 3 years, only 1 (4.2%) had lymph node recurrence. ***Conclusion:*** SLNB with dual tracer in cervical cancer improves overall drainage rates and increases the likelihood of bilateral drainage. Likewise, it allows for accurate lymph node staging, as it presented only one case of lymph node recurrence after a minimum three-year follow-up.

EP-0452

Limited Generalizability and Potential Bias in a Deep Learning Model for Predicting Obstructive Coronary Artery Disease from Myocardial Perfusion SPECT Imaging: Insights from Cross-Institutional Evaluation

Y. Shih[1], *C. Ko[2,3,4], S. Wang[1,5], C. Chen[4], Y. Wu[1,2,6];*
[1]Department of Nuclear Medicine, Far Eastern Memorial Hospital, New Taipei City, TAIWAN, [2]Department of Nuclear Medicine, National Taiwan University Hospital, Taipei, TAIWAN, [3]College of Medicine, National Taiwan University, Taipei, TAIWAN, [4]Department of Biomedical Engineering, National Taiwan University, Taipei, TAIWAN, [5]Electrical and Communication Engineering College, Yuan Ze University, Taoyuan, TAIWAN, [6]School of Medicine, National Yang Ming Chiao Tung University, Taipei, TAIWAN.

Aim/Introduction: Deep learning (DL) models for predicting obstructive coronary artery disease (CAD) with stress myocardial perfusion imaging (MPI) have shown promising potential to improve diagnostic accuracy compared to visual interpretation and current quantitative methods. However, the consistency of DL model performance across healthcare institutions or different populations remains an important area of investigation. This study aimed to evaluate the generalizability and potential bias of our in-house MPI DL model between two hospital-based cohorts stratified by demographic factors and comorbidities. ***Materials and Methods:*** We included subjects who underwent stress and

redistribution thallium-201 (201Tl) MPI SPECT using a cadmium-zinc-telluride camera followed by coronary angiography within 90 days as the reference standard, from two tertiary medical centers, National Taiwan University Hospital (NTUH) and Far Eastern Memorial Hospital (FEMH), in Northern Taiwan. A polar map-free 3D DL model was trained on 928 MPI images from NTUH to predict obstructive CAD and subsequently tested on an internal cohort (933 tests from NTUH) and an external cohort (3315 tests from FEMH). Diagnostic performance, assessed by area under the receiver operating characteristic curves (AUCs), was compared using DeLong's test between the internal and external cohorts to evaluate generalizability, and to detect potential confounding factors across patient groups. Additionally, diagnostic performance was compared between datasets propensity-matched for key demographic factors and comorbidities. ***Results:*** The external cohort had significantly lower prevalence of obstructive CAD (46% vs. 58%, $p < 0.001$), higher body mass index, and higher proportions of women, smokers, and patients with diabetes and dyslipidemia compared to the internal cohort (all $p < 0.05$). The DL model exhibited lower diagnostic performance in the external cohort than in the internal cohort, both in patient-based (AUC = 0.709 vs 0.813) and vessel-based (AUC = 0.730 vs 0.782, both $p < 0.001$) analyses. After propensity matching for key clinical parameters except sex, the DL model still exhibited lower diagnostic performance in the external cohort compared to the internal cohort, in both patient-based (AUC = 0.711 vs 0.844, $p = 0.014$) and vessel-based (AUC = 0.740 vs. 0.810, $p = 0.049$) analyses. ***Conclusion:*** The current study demonstrated limitations in the generalizability of this DL-based model across institutions. Alongside demographic characteristics and comorbidities, factors such as sex or disease probability may affect the DL model's diagnostic accuracy. Therefore, including low-risk patients in the training dataset and validating the DL model across diverse populations are crucial.

EP-0453

Adenosine-induced Splenic Switch-off Evaluation in ^{99m}Tc Tetrofosmin Myocardial Perfusion Studies as Marker of Stress Adequacy by Semiquantitative Analysis of Acquired SPECT/CT Images

I. Loutfi, *N. Alkandery, D. Aldhafiri, F. Alshammari, M. Bouzabar, H. Humoud;*
College of Medicine-Kuwait University, Kuwait, KUWAIT.

Aim/Introduction: Adenosine IV infusion is commonly used as pharmacological stress method in myocardial perfusion imaging (MPI) using radiotracers to induce vasodilation of the coronary arteries thus enabling detection of critical coronary artery stenosis. Usually, MPI studies are done in 2 parts: stress and rest with imaging of the heart using gated SPECT/CT. Recently, a phenomenon known as splenic switch off (SSO) has been observed in which reduced perfusion to the spleen occurs after adenosine infusion and its presence suggests adequate effect of adenosine stress on the heart. The aim of the study is to evaluate the SSO effect in adenosine stress 99mTc tetrofosmin MPI studies using semiquantitative analysis of the acquired SPECT/CT data. ***Materials and Methods:*** 17 MPI studies with adenosine stress were selected successively from the PACS system. Each study had a stress and a rest part processed using software for cardiac reconstruction involving slice reorientation in the heart's short, horizontal and vertical long axis. In addition, the data were reconstructed in the body transaxial, coronal and sagittal planes using SPECT/CT software. In the resulting images, the spleen was identified on the CT component and regions of interest (ROIs) were drawn on spleen, adjacent thoracic vertebra and myocardium. The average count per pixel was recorded for each ROI and the ratios Spleen/Vertebra (S/V Ad, S/V Rst) and Myocardium/Vertebra (M/V Ad, M/V Rst) were calculated. Statistical analysis of the imaging data was done using paired t-test and descriptive statistics for non-imaging data. ***Results:*** Mean patient age was 60.35±12.97 yr. There were 9 males (53%). Clinically, 11 (65%) had ischemia, 1 scar (6%) and 5 (29%) were normal. The mean count-for spleen adenosine (S Ad) was 308±136, spleen rest (S Rst) 144±77 ($t=4.64$, $p<0.001$). For the heart, M Ad 793±282, M Rst 263±149 ($t=7.612$, $p<0.001$). Vertebra (background) V Ad 349±170, V Rst 80±26 ($t=6.888$, $p<0.001$). Mean S/V Ad was 0.98±0.38 and S/V Rst 1.87±0.87 ($t=-3.707$ $p<0.01$). The mean M/V Ad was 2.86±1.65 and M/V Rst 3.75±2.41 ($t=-1.323$, $p=0.204$). ***Conclusion:*** Using the semiquantitative method outlined especially the S/V ratio, evaluation of the SSO can be achieved from the acquired data. Comparison of the results with other stress modalities such as exercise would establish its value as a marker for adequate effectiveness of adenosine stress in doubtful cases. ***References:*** Manistry C et al. Splenic Switch-off: A Tool to Assess Stress Adequacy in Adenosine Perfusion Cardiac MR Imaging. Radiology 276, 2015 https://doi.org/10.1148/radiol.2015142059.

EP-0454

Assessment of gated-SPECT disturbance to determine ejection fraction in patients with left bundle branch block

F. González Hernández, *C. Carballo Menayo, V. Molina Pérez, R. González Couto, S. Cifuentes Díaz, J. Miranda Ramos, J. Herrera Henríquez, M. Isla Gallego;*
Hospital Universitario Insular Materno-Infantil, Las Palmas de Gran Canaria, SPAIN.

Aim/Introduction: To analyze the diagnostic accuracy of the ejection fraction (EF) of the gated-SPECT study in patients with Left Bundle Branch Block (LBBB) contrasting results given by echocardiography. ***Materials and Methods:*** We performed a retrospective study of patients with LBBB who had undergone cardiac perfusion SPECT-CT with Tc99m-tetrofosmin performed between January/2021 and December/2023 and who also had a recent echocardiography. The exclusion criteria were the presence of atrial fibrillation (AF) and previous coronary bypass. A total of 50 patients were studied, 35 men and 15 women. They were compared with a group of 50 other patients without LBBB who met the same inclusion criteria (19 men and 31 women). A statistical analysis was performed to calculate the intraclass correlation between Gated-SPECT EF and echocardiography with a 90% confidence interval using the two-factor mixed-effects model. Likewise, a subgroup analysis was performed studying those patients with ≥3 segments with low uptake artifact secondary to LBBB (with 24 patients) and those with <3 affected segments (with 26 patients). ***Results:*** In the group of patients without LBBB, an intraclass correlation coefficient of 0.85 (90% CI: 0.7-0.9) was obtained. In the group of patients with LBBB, a coefficient of 0.71 was obtained (90% CI: 0.5-0.8).In the subgroup analysis, patients with ≥3 more affected segments had a coefficient of 0.58 (90% CI: 0.1-0.7) and those with <3 segments had a coefficient of 0.77 (90% CI: 0.4-0.9). ***Conclusion:*** In patients without LBBB, the concordance between EF and echocardiography is adequate. In patients with LBBB, concordance decreases, with Gated-SPECT presenting an underestimation of EF. The extent of the low uptake artifact observed in SPECT has a straight association with the underestimation of EF. ***References:*** Myocardial Perfusion SPECT in Right Bundle Branch Block and Left Anterior Hemiblock. EP-0455

Role of coronary artery calcium score in the detection of silent myocardial ischemia in diabetic patients with high cardiovascular risk.

***A. Bouzidi*[1],** *R. Belakroum[1], T. Zehnati[2], R. Merghit[1];*
[1]University Hospital, Constantine, ALGERIA,
[2]University Hospital, Oran, ALGERIA.

Aim/Introduction: According to various studies, no contribution from systematic screening for silent myocardial ischemia (SMI) in diabetics was found. The selection of patients for screening must not only be based on the assessment of cardiovascular (CV) risk but also on the use of non-invasive "risk-modifying" tests such as the Coronary Artery Calcium (CAC) score. Our study aimed to evaluate the CAC score for diagnosing SMI in diabetics with high CV risk. ***Materials and Methods:*** From April 2022 to September 2023, 105 diabetic patients were recruited for this prospective study. All of them were asymptomatic, had a normal ECG, and were classified as high CV risk with a SCORE 2-Diabetes between 10 and 20% over 10 years. These patients benefited from a quantification of the CAC score by CT scan and then searching for SMI by Sestamibi-99mTechnetium myocardial perfusion scintigraphy (MPS) after physical stress or under dipyridamole. ***Results:*** Our sample had an average age of 58+/-7 years and was made of 39% men. The mean SCORE 2-Diabetes was 17+/-2% over 10 years. SMI was diagnosed with MPS in 9 patients (8,6%). The average CAC score was 82+/-224 Agatston units (AU) minimum 0AU and maximum 1431AU. A CAC score <10UA was found in 59% of patients, a CAC score between 10 and 100UA was found in 26,7% of patients, a CAC score between 100 and 400AU was found in 7,6% of patients and a CAC score>400AU was found in 6,7% of patients. The CAC score was associated with ischemic status: in patients without SMI, the average CAC score was 62+/-183AU; in patients with SMI, the average CAC score was 298+/-446AU (p=0,002). Using the CAC score with a threshold value of 10AU we have found for the diagnosis of SMI: Sensitivity (Se) 77%, Specificity (Sp) 62%, positive predictive value (PPV) 16%, and negative predictive value (NPV) 96%. For a threshold value of 100AU, we have found: Se 44%, Sp 88%, PPV 26%, and NPV 94%. For a threshold value of 400AU, we have found: Se 22%, Sp 94%, PPV 28%, and NPV 92%. ***Conclusion:*** Searching for SMI in diabetic patients with high CV risk using the CAC score presents an insufficient sensitivity but a satisfactory negative predictive value, useful in screening situations. ***References:*** 1- Marx N et al. 2023 ESC Guidelines for the management of cardiovascular disease in patients with diabetes. Eur Heart J. 2023; 44(39): 4043-140.

EP-0456

Deep learning quantitative angiography (DL-QCA) versus total perfusion deficit (TPD): Quantitative analysis of myocardial perfusion studies (MPI)

***M. Ochoa Figueroa*[1],** *J. Dahl[1], A. Davidsson[1], A. Heyden[2], K. Åström[2], N. Overgaard[2], C. Pagonis[1], E. Good[1], I. Arvidsson[2];*
[1]Universitetssjukhuset i Linköping, Linköping, SWEDEN, [2]Centre for Mathematical Sciences, Lund University, Lund, SWEDEN.

Aim/Introduction: Evaluate the severity of ischemia using MPI and comparing DL-QCA with TPD, using invasive coronary angiography (ICA) as gold standard. ***Materials and Methods:*** Retrospective study of 82 patients (65 males, mean age 70 years) from December 2015 to March 2017 undergoing MPI, followed by ICA within six months after the MPI. The MPI was performed in a dedicated CZT cardio camera with a two-day protocol, according to current EANM guidelines. DL-QCA was evaluated using a novel software, the severity of ischemia was expressed in % and divided in different thresholds ≤50%, 50-70%, ≥70%. TPD was evaluated using stablished values in routine clinical praxis to determine the degree of isquemia; below 5%=normal, 5-10%= slight abnormality, 11-14% moderate abnormality, and ≥15% significant abnormality, a value of ≥11% was regarded as a positive test. All ICA studies were examinated visually and with a quantitative angiography software, any stenosis ≥50% was considered significant and regarded as a positive test. ***Results:*** The overall diagnostic accuracy of DL-QCA to identify patients with significant obstruction at MPI was 62%, sensitivity 67%, specificity 100%. For TPD ranging from 10-14% was sensitivity 46%, specificity 100%, accuracy 49%. For TPD ranging from ≥15% was sensitivity 35%, specificity 100%, accuracy 38%. For the visual analysis was sensitivity 81%, specificity 100%, accuracy 82%. ***Conclusion:*** The novel DL-QCA software outperforms TPD in the quantification of significant obstruction in MPI, providing additional information on the degree of artery stenosis, something which if further developed, could possibly avoid unnecessary ICA interventions. Further studies are necessary to confirm our results. ***References:*** Arvidsson I, Davidsson A, Overgaard NC, Pagonis C, Åström K, Good E, Frias-Rose J, Heyden A, Ochoa-Figueroa M. Deep learning prediction of quantitative coronary angiography values using myocardial perfusion images with a CZT camera. J Nucl Cardiol. 2023;30(1):116-26.

EP-0457

Effect of myocardial flow reserve measured by cadmium zinc telluride cameras on the diagnosis of coronary artery disease

T. Niimi, *K. Hirayama;*
Japanese Red Cross Aichi Medical Center Nagoya Daini Hospital, Nagoya, JAPAN.

Aim/Introduction: A cadmium-zinc-tellurium (CZT) camera can simultaneously evaluate myocardial flow reserve (MFR) and myocardial perfusion imaging (MPI) without positron emission tomography scans. Adding MFR to MPI for coronary artery disease (CAD) screening may help identify high-risk patients and improve diagnostic performance. This technological innovation has renewed interest in single-photon emission computed tomography (SPECT) MFR assessment in patients with CAD. We quantitatively measured the contribution of MFR to improving the diagnostic performance of CAD by adding MFR to the increase rate (IR) in myocardial radionuclide uptake during stress and transient ischaemic dilatation (TID), which have traditionally been used as indicators to assess CAD severity in MPI. ***Materials and Methods:*** We retrospectively analysed the clinical images of 60 patients who underwent dynamic CZT SPECT to evaluate suspected CAD (40 men and 20 women; mean age: 65.9 ± 10.1) after injection of 99mTc-sestamibi for rest and stress imaging. The additional effects of MFR on the IR and TID indices were examined to assess the severity of CAD. Receiver operating characteristic (ROC) and multivariate ROC analyses were used to quantify the ROC curve (area under the curve (AUC)), how CAD diagnostic performance improved when IR, TID, and MFR were used alone, when IR and TID were combined, and when IR, TID, and MFR were combined. ***Results:*** The AUC for the IR, TID, and MFR alone were 0.57, 0.62,

and 0.80, respectively. The diagnostic performance improved the AUC to 0.63 when IR and TID were combined and to 0.87 when IR, TID, and MFR were combined. Adding MFR to the conventional combination of IR and TID significantly improved CAD diagnostic performance by 24% (p=0.002). Furthermore, combining MFR with IR and TID improved detection by 7% compared to MFR alone, but the difference was insignificant (p=0.086). ***Conclusion:*** The effect of MFR on improving the diagnostic performance of CAD relative to the combination of IR and TID, a measure of ischaemia calculated using MPI, was 24%. Adding MFR to MPI for CAD screening is thought to significantly contribute to high-risk patient identification and enhance diagnostic performance.

Transient ischemic dilatation with adenosine ^{99m}Tcsestamibi stress: prognostic significance in diabetic patients with normal myocardial perfusion SPECT/CT scans

M. Juweid[1,2], *N. Kasasbeh[3], R. Hammoudeh[4], B. Alsyouf[3], M. Aloqaily[5], M. Alqudah[1], H. Makhamreh[1,2], K. Ajlouni[6];*
[1]University of Jordan, Amman, JORDAN, [2]The National Center for Diabetes Endocrinology and Genetics, Amman, JORDAN, [3]Jordan University Hospital, Amman, JORDAN, [4]Jordanian Ministry of Health, Amman, JORDAN, [5]Hamad Medical Corportation, Doha, QATAR, [6]The National Center for Diabetes, Endocrinology and Genetics, University of Jordan, Amman, JORDAN.

Aim/Introduction: Previous studies have shown that transient ischemic dilatation (TID) does not predict adverse prognosis in patients with otherwise normal perfusion. However, data in diabetic patients is limited. The objective of this study is to investigate the prognostic significance of non-attenuation corrected (NAC) and attenuation corrected (AC) TID in diabetic patients with normal perfusion on adenosine stress/rest 99mTc-sestamibi imaging. ***Materials and Methods:*** We analyzed 274 patients with normal perfusion on 2-day adenosine stress/rest 99mTc-sestamibi SPECT/CT. A group of patients with Framingham 10-year coronary heart disease risk < 10% was used to derive abnormal AC and NAC TID thresholds (derivation group). The significance of TID at these thresholds was validated in the remaining patients (validation group) followed for cardiac events for 43.6 ± 9.5 (mean ± SD) months. ***Results:*** NAC TID in the derivation group was 1.14 ± 0.15 while AC TID was 1.14 ± 0.19. Three definitions of an abnormal TID were used: > mean + 2SD (NAC TID ≥ 1.43, AC TID ≥ 1.52), > mean + 1SD (NAC TID ≥ 1.28, AC TID ≥ 1.33) and a TID in the derivation group's highest quartile (NAC TID ≥ 1.25, AC TID ≥ 1.26). Of the validation group patients, 8 (3.1%), 29 (11.3%) and 39 (15.2%) had NAC TID ≥ 1.43, 1.28 and 1.25, respectively, while 5 (1.9%), 13 (5.1%) and 23 (8.9%) had AC TID ≥ 1.52, 1.33 and 1.26, respectively. Gender, family history of coronary artery disease (CAD), known CAD, smoking, hypertension, dyslipidemia, post-stress LVEF, ΔLVEF, ≥ 5% or 10% decrease in LVEF did not predict abnormal AC or NAC TID at the thresholds mentioned above. However, NAC TID ≥ 1.25 and 1.28 were predicted by rest LVEF (p = 0.001 and 0.009, respectively). Cardiac event-free survivals were similar in patients with NAC TID ≥ and < 1.43 (p = 0.49), ≥ and < 1.28 (p = 0.78) and ≥ and < 1.25 (p = 0.90). Similarly, cardiac event-free survivals were similar in patients with AC TID ≥ and < 1.52 (p = 0.58), ≥ and < 1.33 (p = 0.37) and ≥ and < 1.26 (p = 0.53). ***Conclusion:*** TID, whether based on attenuation or non-attenuation corrected scans, does not confer adverse prognosis in diabetic patients with normal perfusion on adenosine stress/rest 99mTc-sestamibi SPECT/CT irrespective of the threshold used for its definition.

EP-0459

Evaluation of Critical Stenosis Involving The Inferior Wall of the Left Ventricle Using Czt Camera and 4DM Software

A. Ozturk[1], *R. Sahin[1], M. C. Baloglu[1], Z. Tosunoglu[1], Ö. F. Şahin[1], E. Beyhan[1], Ö. Erol Fenercioglu[2], G. Alcin[1], N. Ergül[1], T. F. Çermik[1], E. Arslan[1];*
[1]Istanbul Training and Research Hospital, Istanbul, TÜRKIYE, [2]Tekirdağ Dr. İsmail Fethi Cumalıoğlu City Hospital, Tekirdağ, TÜRKIYE.

Aim/Introduction: CZT cameras have significant advancements in MPS imaging. The aim of this study is to compare visual scoring with the quantitative scoring provided by 4DM software in examining inferior wall perfusion using CZT camera and to investigate the importance of providing ischemia percentage in detecting critical stenosis by comparing with coronary angiography (CAG) findings. ***Materials and Methods:*** Data of 890 patients suspected myocardial ischemia underwent imaging with CZT-SPECT camera system (GE NM-530c). 207 cases who underwent CAG within 30 days after MPS and whose data were available were included in the study. Perfusion defects in seven segments involving inferior, inferoseptal, and inferolateral walls according to the left ventricular 17-segment model were visually scored and scored using 4DM software. Summed stress-rest difference score (SDS) and ischemia percentage were calculated using both visual and 4DM software. Patients were grouped into ischemia rates of <%10 and > %10 in the inferior wall according to both scoring systems. The presence of >70% stenosis in Cx or RCA on CAG results was considered as a confirmation criterion, and scoring groups were statistically compared. ***Results:*** Of the 207 cases included in the study, 56 were male (mean±SD: 61.65±10.32 years) and 151 were female (mean SD: 61.85±10.44 years). Significant stenosis was detected in 65 patients (31%) on CAG. In 19 patients where ischemia was detected visually, no ischemia was detected to any degree according to 4DM software, confirming the CAG results. The positive predictive value (PPV) of visual scoring in detecting critical stenosis was 51%, with a negative predictive value (NPV) of 71% (p: 0.014), while the PPV of 4DM software was 56%, with an NPV of 73% (p: 0.001). (Table1-2). ***Conclusion:*** In our study aimed at investigating the contribution of quantitative software programs in overcoming difficulties in evaluating inferior wall perfusion, most patients with critical stenosis in coronary vessels supplying the inferior wall (Cx, RCA) constituted those with ischemia percentage below 10% according to both visual and quantitative scoring. This suggests that even low-level ischemia detected in the inferior wall may be clinically significant. Our study also found that 4DM software was statistically superior to visual assessment in detecting the presence of critical ischemia in the inferior wall. Considering all the data together, we believe that the contribution of quantitative software programs to MPS reporting should not be overlooked.

EP-0460

Evaluation of Myocardial Perfusion and Its Heterogeneity in HIV-Infected Patients Using Myocardial SPECT Imaging

D. Mosin[1], *I. Znamenskiy[1], N. Khabarov[2];*
[1]Petrovsky National Research Centre of Surgery, Moscow, RUSSIAN FEDERATION, [2]Pirogov Russian National Research Medical University, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Cardiovascular disease remains a leading cause of morbidity and mortality worldwide, and its intersection with chronic infectious conditions like HIV has become a crucial

area of medical research. Despite significant advancements in the treatment and management of HIV, including the widespread adoption of antiretroviral therapy (ART), HIV-infected individuals continue to face an elevated risk of cardiovascular complications. This increased risk is partly attributed to the chronic inflammation and immune system alterations associated with HIV, as well as potential side effects from ART. This study aims to utilize myocardial perfusion SPECT imaging to quantitatively evaluate myocardial perfusion abnormalities in patients with HIV compared to a non-HIV-infected control group. ***Materials and Methods:*** Thirty-eight HIV-positive patients and twenty five control subjects were assessed using myocardial perfusion SPECT with technetium-99m methoxyisobutylisonitrile (99mTc-MIBI). Traditional scores—summed stress score (SSS), summed rest score (SRS), and summed difference score (SDS)—along with novel quantitative indices such as severity sigma and heterogeneity sigma, were analyzed. The novel indices were calculated as mean-square deviations of relative perfusion values (in %) in each of 17 standard segments in reference to maximum of 100% and to arithmetical mean of those values accordingly [1]. ***Results:*** HIV patients demonstrated significantly elevated myocardial perfusion heterogeneity compared with the control group, with mean values of 10.1 and 6.0, respectively (p=0.02). Traditional scores, however, have shown no statistically significant difference between the groups. This finding might suggest highly irregular myocardial blood flow distribution without critical perfusion decline. This can be fully or partially explained by multiple smaller-grade stenoses. It was previously shown that the virus itself or viral proteins can trigger the release of inflammatory mediators that cause endothelial dysfunction, which in turn could lead to stenotic changes and thrombosis [2]. ***Conclusion:*** The use of novel quantitative indices alongside traditional perfusion scores in SPECT imaging enhances the characterization of myocardial perfusion abnormalities in HIV-infected patients. These results substantiate the significant impact of HIV on myocardial health and underscore the need for further research. ***References:*** 1. Ansheles, A. A. et al. (2015). EP-0461

The utility of quantitative parameters of dynamic myocardial perfusion imaging performed by cardiac dedicated CZT gamma camera

C. Civan[1], *D. Has Simsek[1], D. Arslan[1], D. Denizmen[1], S. Emet[2], E. Isik[1], Z. Ozkan[1], Y. Sanli[1], S. Kuyumcu[1];*
[1]Istanbul University, Istanbul Faculty of Medicine, Nuclear Medicine Department, Istanbul, TÜRKIYE,
[2]Istanbul University, Istanbul Faculty of Medicine, Cardiology Department, Istanbul, TÜRKIYE.

Aim/Introduction: We aimed to evaluate the utility of dynamic myocardial perfusion imaging with cardiac-zinc-telluride detectors (MPI-CZT) and the impact of quantitative parameters on the diagnosis of coronary artery disease (CAD). ***Materials and Methods:*** We enrolled patients who underwent two day dynamic MPI (GE NM-530C) due to suspected CAD and subsequently underwent coronary angiography within 30 days. Dynamic stress images were acquired after iv injection of 140 mcg/kg/min adenosine, and SPECT images obtained after 45-60 minutes. GE Health Care-4 DM Reserve Software Program has been used to calculate myocardial blood flow reserve (MFR). Findings were noted on both patient-based and coronary region-based. Ischemia was defined as stenosis of >%70 on coronary angiography. The cutoff values of MFR were measured using ROC analysis. ***Results:*** In our study, we enrolled 61 patients (32 female, 52% and 29 male, 48%). 18 patients (29%) had clinically significant stenosis. The cutoff values of MFR were 1.95, 1.9. and 1.95 for LAD,RCA, CX, respectively. The sensitivity and specifity of MPI were 100% and 46% on patient based analysis, while they were 94% and 70% for MFR. Region based analyses of MPI showed that sensitivity and specifity were 100% and 84% for LAD; 90% and 80% for RCA and 100% and 72% for CX; while region based analyses of MFR showed that sensitivity and specifity were 67% and 71% for LAD; 90% and 80% for RCA and 87% and 79% for CX. All patients with normal MPI (n=20) had no significant stenosis. Of 41 patients who had abnormal MPI results, 23 patients (56%) had no significant stenosis. 6 out of 23 patients had also abnormal MFR values and one patient from those had coronary artery ectasia. The sensitivity and specifity to define ischemia with using MFR values for patients with only abnormal MPI results were 94% and 74% respectively. ***Conclusion:*** MFR values measured by performing dynamic MPI-CZT might improve the diagnostic capability of MPI with reducing false positivity of MPI.

EP-0462

Prognostic Value of Chemotherapy-induced Myocardial Injury before Hematopoietic Stem Cell Transplantation Based on Myocardial Perfusion Imaging in Patients With Hematologic Malignancies

K. Li, *J. Wang, Y. Lin, Y. Wang;*
The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: Chemotherapy-induced myocardial injury was assessed by myocardial perfusion imaging (MPI) in patients with hematologic malignancies before hematopoietic stem cell transplantation (HSCT), the purpose of this study was to explore the long-term prognostic value of chemotherapy-induced myocardial injury before HSCT in patients with hematologic malignancies. ***Materials and Methods:*** This retrospective study included patients who underwent MPI from March 2016 to August 2022 and subsequently underwent HSCT. MPI abnormalities were assessed visually by two experienced physicians, and a summed rest score (SRS) ≥ 4 defined myocardial injury. Patients were divided into myocardial injury and non-myocardial injury groups. Long-term adverse outcomes (>100 days post-transplant), including post-transplant mortality and overall survival (OS), were followed up for all patients. Kaplan-Meier analysis and Cox regression analysis were used to identify independent risk factors affecting OS. ***Results:*** A total of 139 patients with hematologic malignancies were included, with a mean age of (45.7 ± 13.0) years, including 80 males. The median follow-up was 41.6 (3.4~95.1) months, with 40 deaths recorded. Among the 139 patients, 44 had myocardial injury. Pre-transplant eukocyte levels were slightly lower in the myocardial injury group [3.50 (2.74-5.23) vs. 4.11 (3.16-5.89), P = 0.044]. There were no statistically significant differences in cardiac enzymes or electrocardiographic results between the two groups, but the left ventricular ejection fraction (LVEF) was lower in the myocardial injury group compared to the non-myocardial injury group [(60.0 ± 4.6) % vs. (63.2 ± 4.0) %, P < 0.001]. Post-transplant mortality was significantly higher in the myocardial injury group to

the non-myocardial injury group [22/44 (50%) vs. 18/95 (18.9%), $\chi 2 = 14.148$, $P < 0.001$], with significantly shorter OS time [26.17 (17.89-50.69) months vs. 48.73 (24.98-69.50) months, $Z = -2.706$, $P = 0.004$] in the myocardial injury group. Kaplan-Meier analysis revealed significant differences in OS time ($P < 0.001$). Cox regression analysis indicated that myocardial injury on pre-transplant MPI was an independent risk factor affecting OS after HSCT in hematologic malignancies (HR = 2.70, 95% CI: 1.33~5.46, P = 0.0057). ***Conclusion:*** Patients with abnormal MPI before HSCT for hematologic malignancies have a poorer prognosis, with higher post-transplant mortality rates and shorter OS. Using MPI to assess myocardial injury before HSCT in hematologic malignancies helps predict adverse long-term prognosis after transplantation.

EP-0463

The relationships between myocardial blood flow by dynamic SPECT CZT with clinical and laboratory profile in patients with non-obstructive coronary artery disease

K. Zavadovsky, *A. Maltseva, K. Kopeva, A. Mochula, E. Kravchenko, E. Grakova;*
Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Patients with non-obstructive coronary artery disease (NOCAD) have a high frequency of cardiovascular risk factors, which may cause the development of microvascular dysfunction. Currently, there are a limited number of studies on the noninvasive assessment of microvascular dysfunction in the NOCAD population. The aim of the study is to evaluate the relationships between dynamic SPECT CZT derived myocardial blood flow and clinical and laboratory profile in patients with NOCAD. ***Materials and Methods:*** Based on coronary computed tomography angiography results, patients with NOCAD (stenosis <50%) were included in the study. All patients underwent dynamic SPECT on cardiac hybrid system (CT-NM) with Cadmium-Zinc-Telluride (CZT) with the assessment of stress and rest myocardial blood flow (MBF), myocardial flow reserve (MFR), flow difference (FD) [1,2]. The Net Retention with attenuation correction flow model was used for quantitative analysis. Additionally, the blood lipid levels: total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), non-high-density lipoprotein cholesterol (non-HDL-C); and coagulation testing (activated partial thromboplastin time (APTT)) were also assessed. Based on MFR results, all patients were divided into two groups: 1. with reduced MFR <2.0 (n=32), 2. with a normal value of MFR ≥2.0 (n=51). ***Results:*** The study included 83 patients (53 men, age 58.2±9.5 years) with stable angina pectoris and/or dyspnea. Patients with reduced MFR had statistically significant ($p<0.05$) higher blood lipid levels: TC 5.34(4.3;6.29) vs 4.6(3.8;5.34) mmol/l, LDL-C 2.95(2.35;3.56) vs 2.11(1.84;3.17) mmol/l, non-HDL-C 4.1(3.15;4.6) vs 3.39(2.24;4.1) mmol/l; and lower APTT level 26.5(25.5;28.2) vs 28.55(26.75;33.6), respectively. The Spearman correlation showed that scintigraphic parameters had negative relationships with lipid profile: stress MBF and TC ($\rho=-0.24$,$p=0.03$), MFR and TC ($\rho=-0.22$,$p=0.045$) and LDL-C ($\rho=-0.22$,$p=0.049$), FD and TC ($\rho=-0.24$,$p=0.03$). According to a stepwise multivariate logistic regression analysis, non-HDL-C (OR 2.64; 95%CI 1.21-5.76; p=0.01) and APTT (OR 0.69; 95%CI 0.49-0.96; p=0.03) were independent predictors of reduced MFR ≤2.0. ***Conclusion:*** Non-HDL-C and APTT levels are independent predictors of reduced MFR ≤2.0 in NOCAD patients. Prospects for further research include the use of dynamic SPECT-CT for the identification of high-risk groups based on MFR analysis and the assessment of prognosis and response to pharmacological therapy. ***References:*** 1. EP-0464

The evaluation of myocardial blood flow and reserve by dynamic SPECT CZT in patients with non-obstructive coronary artery disease: comparison with semiquantitative MPI data

K. Zavadovsky, *A. Maltseva, K. Kopeva, A. Mochula, E. Grakova;*
Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Currently, myocardial perfusion imaging (MPI) is a well-established method for identification of myocardial ischemia. However, the data regarding the possibility of dynamic SPECT CZT for identification of coronary microvascular dysfunction in patients with non-obstructive coronary artery disease (NOCAD) is lacking. The aim of the study is to compare the results of standard perfusion MPI and quantitative parameters of myocardial blood flow and reserve by dynamic SPECT CZT in patients with non-obstructive coronary artery disease. ***Materials and Methods:*** Based on coronary computed tomography angiography results, patients with NOCAD (stenosis <50%) were included in the study. All patients underwent dynamic SPECT on cardiac hybrid system (CT-NM) with Cadmium-Zinc-Telluride (CZT), including MPI. Standard indexes of myocardial perfusion imaging (SSS, SRS, SDS) and quantitative global parameters (stress and rest myocardial blood flow (MBF), myocardial flow reserve (MFR), flow difference (FD)) were assessed [1,2]. The NetRetention model with attenuation correction was used for quantitative analysis. ***Results:*** The study included 58 patients (37 men, age 55.9±9.9 years) with stable angina pectoris and/or dyspnea. According to MPI, 15 (26%) patients had abnormal myocardial perfusion (SSS and SDS ≥2.0 or in two segments with SSS and SDS ≥1.0). Standard indexes of myocardial perfusion imaging were the following: SSS 0.0 (0.0;2.0), SRS 0.0 (0.0;0.0), SDS 0.0 (0.0;2.0). According to dynamic SPECT, 22 (38%) patients had reduced MFR <2.0. Quantitative global parameters were characterized greater variability compared to MPI: stress MBF 1.34 (1.03;1.64) ml/min/g, rest MBF 0.58 (0.42;0.73) ml/min/g, MFR 2.42 (1.48;2.85), FD 0.68 (0.36;1.09). A total of 7 (12%) patients showed matched results MPI and dynamic SPECT: SSS ≥2.0 and MFR <2.0; in 28 (48%) the results were opposite - SSS <2.0 and MFR ≥2.0. However, 15 (26%) patients had normal myocardial perfusion and reduced MFR <2.0, which may indicate the initial stages of the development of microvascular dysfunction before myocardial ischemia. ***Conclusion:*** Dynamic SPECT CZT allows identifying impairment of MFR in NOCAD patients with normal results of MPI in a quarter of cases. ***References:*** 1. Mochula A, et al. The Influence of Kinetic Models and Attenuation Correction on Cadmium-Zinc-Telluride Single-Photon Emission Computed Tomography (CZT SPECT)-Derived Myocardial Blood Flow and Reserve: Correlation with Invasive Angiography Data. EP-0465

Identification of lower limb diabetic vasculopathy: a novel indication of 99mTc-MIBI perfusion imaging

T. Singhal, *P. Singh, G. K. Parida, P. S. Patro, K. Agrawal;*
AIIMS Bhubaneswar, BHUBNESHWAR, INDIA.

Aim/Introduction: Diabetes constitute one of the largest global health emergencies of the current century. Diabetic complications in lower extremities are a major cause of morbidity and mortality impacting heavily upon the public-health system. Diabetic vasculopathy is one of the prime drivers of lower-limb (LL) complications of diabetes. Early and accurate recognition of these abnormalities is crucial, enabling early initiation of treatment and thus avoiding or minimizing deformity, dysfunction, and amputation. Current practice relies mainly on clinical findings and conventional imaging. Unfortunately, these are highly subjective and can detect vasculopathy-related consequences that appear late in the pathogenesis, rather than actual disease processes. LL perfusion imaging performed with 99mTc-MIBI offers accurate functional assessment of LL perfusion. Thus, LL perfusion at maximal stress and perfusion reserve(PR) assessment can efficiently overcome this lacunae. It has the potential to identify the patients at risk of future LL vasculopathy at very stages of disease process where institution of lifestyle modification and other preventive measures can prove to be gamechanger. This study evaluated the utility of lower extremity 99mTc-MIBI imaging as a non-invasive imaging to assses the vasculopathy in diabetics compared to non-diabetic controls. ***Materials and Methods:*** The current study included a total of 40 patients including 20 patients with long-standing diabetes(>3years) and 20 controls matched for sex, age and BMI. 99mTc-MIBI perfusion scintigraphy was performed for calf muscles at stress and rest. PR for bilateral calves was calculated as: (average stress counts-average rest counts)/ average rest counts x 100. The mean-difference between diabetics and non-diabetics was evaluated and significance of difference of means was assessed using unpaired t-test. The p-value <0.05 were considered significant. ***Results:*** Forty patients(15 males and 5 females in each subgroup) with median age 55.5(range 33-69) years were included in the study. Mean PR for left and right calf muscles in diabetic group was 57.9%±40.8% and 59.4%±41.2% respectively while that for control group was 88.5%±33.4% and 89.7%±38.4% respectively. There was significant difference between PR of the two groups. Also, mean exercise time and METS achieved were similar in both groups (Table 1). ***Conclusion:*** Radionuclide imaging with 99m-Tc MIBI allows non-invasive assessment of changes in both macrovascular and microvascular perfusion under dynamic exercise and thus, can efficiently identify the diabetes related vasculaopathy early in the course of disease. This can aid in early institution of lifestyle modifications and preventive stratigies, thus, slowing down if not preventing diabetic vasculopathy complications.

EP-0466

Influence of attenuation correction on regional perfusion during low dose cardiac spect on a digital SPECT/CT

P. De Bondt[1], *V. Nuttens[1], D. Ooms[1], S. Vermeulen[1], O. De Winter[1], N. Dorny[2];*
[1]OLV Ziekenhuis Aalst Asse Ninove, Aalst, BELGIUM, [2]ASZ, Aalst, BELGIUM.

Aim/Introduction: The benefit of attenuation correction (AC) in cardiac single photon emission computed tomography (SPECT) is well established and thoroughly described. It was nevertheless underused but since the availability of digital spect/ct cameras, the use of AC in clinical routine has augmented profoundly, and we wanted to examine the regional differences of perfusion in AC and non AC corrected cardiac perfusion images, since AC corrected and camera based normal databases are not yet available to calculate perfusion defects. ***Materials and Methods:*** We analysed 59 consecutives cardiac SPECT examinations from a 1-day low dose scan protocol, acquired on a digital SPECT/CT camera (Véritón, Spectrum Dynamics). Stress examinations were executed after a bolus of 5 ml Regadeson during clinical supervison with blood pressure and ECG monitoring. Stress acquisition was performed first with 2.5 MBq/kg, followed by rest acquisition with 7 MBq/kg. All scans were acquired 30-45 min after injection of Tc-Sestamibi. The reconstructed short axis slices were imported into the 4DM software version 2018, Invia, Ann Arbor, USA. ***Results:*** Perfusion of the left ventricle was segmented into the 17 segment model (American Heart Association) and into the vascular territory model (left anterior descendens LAD, left circumflex LCX and right corronary artery RCA). Perfusion was normalised to 100% within its segment. Perfusion was in every of the 17 segments of the left ventricle significantly higher in the AC corrected image compared to the non AC corrected ones, except segments 12 (mid anterolateral), 16 (apical lateral) and 17 (apex). When the heart was segmented into vascular territories, all three coronary teritories (LAD, LCX and RCA) showed significant higher perfusion in AC corrected compared to non AC corrected ones. There was a significant higher increase in inferoseptal regions (regions 3 and 9 with resp 16,2% and 10,5%) compared to inferolateral ones (regions 5 and 11 with resp. 10,9% and 7,3%). The highest increase in perfusion was seen in segment 4 (20,2%), basal inferior, what is in concordance with findings in literature. There were no significant differences found between man and women, and between low or high body mass index, but this could be due to the relatively small amount of scans included. ***Conclusion:*** On a digital SPECT/CT camera, regional perfusion differs substantially after AC correction, compared tot non AC corrected images, especially in the inferior wall and software packages should take these differences into account to create normal databases.

EP-0467

Sex-specific prognostic value of LVEF derived by SPECT MPI in patients with diagnosed or suspected ischemic heart disease

Y. Hu, *S. Li;*
Department of Nuclear Medicine, First Hospital of Shanxi Medical University, Taiyuan, CHINA.

Aim/Introduction: Ischemic heart disease (IHD) is the leading cause of death worldwide. LVEF is one of the commonly used prognostic indicators for IHD. Recent studies have found that supra-normal LVEF (snLVEF) is associated with poor prognosis in women, but some studies showed snLVEF was a protective factor in female patients. SPECT myocardial perfusion imaging (MPI) plays an important role in the diagnosis and treatment of IHD. However, the classification of LVEF mainly refers to the cutoff value of ultrasound, and there is no data on the sex-specific cutoff value of LVEF derived by SPECT MPI (hereafter referred to as LVEF). Therefore, the purpose of this study was to find sex-specific cutoff values for LVEF and investigate its prognostic value in patients of different genders. ***Materials and Methods:*** This study included patients who received SPECT MPI due to symptoms or signs of IHD from 2016 to 2021. Patients were followed up with MACE as the endpoint. The relationship between LVEF and MACE in patients

of different genders was analyzed. According to literature reports, 40% and 45% are the cutoff values for reduced LVEF in male and female patients, respectively. The optimal cut-off value of increased LVEF was obtained based on the receiver operation characteristics (ROC) curve. Then, patients of different genders were divided into the low, normal and high LVEF groups. The prognosis of the three groups was compared by Kaplan Meier (KM) survival analysis, and the prognostic factors of the patients with different genders were obtained by univariate and multivariate Cox regression analysis. ***Results:*** A total of 1292 patients (487 females) were enrolled. After a follow-up of 3.2 (1.7-5.0) years, 496 patients developed MACE. The optimal cutoff for increased LVEF was 52% for men and 72% for women. KM analysis showed the prognosis of male patients with low LVEF was the worst. The female patients with high LVEF had the worst prognosis. For men, univariate analysis showed low and high LVEF were predictors. High LVEF was still an independent protective factor after multivariate analysis. In women, age, diabetes, hypertension, and low and high LVEF were predictors. However, multivariate analysis showed only age and hypertension were independent predictors. ***Conclusion:*** This study preliminarily explored sex-specific SPECT LVEF cutoff values for patients with diagnosed or suspected IHD and showed men with reduced LVEF had a poor prognosis, while women with reduced or increased LVEF both had a poor prognosis.

EP-0468

Large-scale comprehensive analysis of factors affecting the coherence between results reported from low-dose stress myocardial perfusion imaging and coronary angiography

P. Marie[1], *M. Perrin[1], M. Claudin[1], K. Djaballah[1], C. Boursier[1], A. Verger[1], L. Imbert[1], V. Roch[1], M. Doyen[2], G. Karcher[1], B. Popovic[1], E. Camenzind[1];*
[1]CHRU Nancy, Vandoeuvre, FRANCE, [2]Université de Lorraine, Vandoeuvre, FRANCE.

Aim/Introduction: The reliability of cardiac stress imaging techniques is frequently perceived through the coherence of routinely reported results with those from coronary angiography, and factors affecting this coherence are not well known. This study aimed to analyze on a large scale (i) the coherence between results reported from coronary angiography and low-dose myocardial perfusion SPECT-imaging (MPI) and (ii) interacting factors, in a comprehensive way. ***Materials and Methods:*** Data extracted from reports of stress-MPI obtained with a high-sensitivity CZT-camera and low-dose Sestamibi protocol (4.5±2.1 mSv), involving no attenuation correction and favoring exercise (75%) rather than pharmacological stress, were compared with the coronary angiography data routinely reported for the same patients. ***Results:*** We considered 1070 pairs of coronary angiography and stress-MPI reported by 11 different physicians. The extent of MPI-ischemia was predictive of angiographic findings of (i) significant CAD, when defined by > 70% stenosis and excluding the 50-70% stenoses, and (ii) a severe CAD category encompassing multivessel and proximal left anterior descending > 70% stenoses ($p < 0.001$ vs. less severe > 70% significant CAD). Main independent stress-MPI predictors of such significant and severe CAD were moderate-to-severe MPI-ischemia (≥ 3 segments, $p<0.001$), low-to-mild MPI-ischemia (< 3 segments, $p<0.001$), and ST-segment depression ($p<0.001$), with MPI-infarction being only predictive for significant CAD detection ($p<0.001$). However, independently of stress-MPI results, the rates of significant and/or severe CAD were (i) increased in patients with previous CAD history and in male, elderly, and diabetic patients, and (ii) decreased in patients with left bundle branch block or pacemaker (LBB/PM) and in the obese. In the absence of any previous CAD history, the respective rates of significant and severe CAD were 27.9% (67/240) and 9.2% (22/240) for patients having neither ischemia nor infarction, and 76.2% (61/80) and 48.8% (39/80) for patients with MPI-ischemia of moderate-to-severe extent or associated to ST-segment depression. ***Conclusion:*** Reports from low-dose stress-MPI, preferentially scheduled with exercise stress and uncorrected for attenuation, are globally coherent with the coronary angiography data reported in the multi-observer, high-throughput conditions of current medical practices. However, this coherence may be affected by the definitions for classification of significant and severe coronary lesions, and environmental factors (LBB/PM, CAD history, age, gender, obesity, and diabetes). ***References:*** Perrin M, et al. Stress-first protocol for myocardial perfusion SPECT imaging with semiconductor cameras: high diagnostic performances with significant reduction in patient radiation doses. EP-0469

Left Ventricular Dyssynchrony in Patients with Viable and Non-Viable Myocardium: Insights from Global and Territorial Assessments

G. Mani, *F. Ben Amar, W. El Ajmi, A. Sellem, H. Hammami;*
Military Hospital of Tunis, Tunis, TUNISIA.

Aim/Introduction: Phase analysis in gated Myocardial Perfusion Single-photon emission tomography (gMPS) has been used to non-invasively evaluate mechanical dyssynchrony in patients with Coronary Artery Disease (CAD). Our study aimed to evaluate left ventricular (LV) dyssynchrony parameters in patients with viable and non-viable myocardium using gMPS techniques, examining both global and territorial phases analyses. ***Materials and Methods:*** We retrospectively studied examinations evaluating myocardial viability during the period: January 2023-March 2024. When segmental loss of radiotracer's activity was ≥ 50% was associated to akinesia, we considered it as non-viable. The Phase standard distribution (PSD), phase histogram bandwidth (PHB), and entropy were computed from gMPS scans for LV dyssynchrony assessment. The range of normal values in QGS software were based on the database of the Japanese Society of Nuclear Medicine: PHB: 5 to 39°, PSD: 0 to 11° and the valid entropy range is 7-41%. ***Results:*** Examinations of 31 patients were included (26 men, 83.8%). Differences were observed between viable (n=14) and non-viable (n=17) groups in both global and territorial analyses. Non-viable myocardium exhibited higher mean PHB values both globally (85.4 ± 44.6) and per territory (75.7 ± 48.1) compared to viable myocardium (Global: 36.4 ± 16.9; Territory: 33 ± 21.5) with a statistically significant difference (p=0). Similarly, PSD values were higher in non-viable myocardium both globally (22.7 ± 11.9) and per territory (21.2 ± 15.9) compared to viable myocardium (Global: 9.6 ± 4.8 p=0.03; Territory: 8.9 ± 6.4; p=0). Entropy values also varied significantly between non-viable (Global: 56.2 ± 11.4; Territory: 51.3 ± 15.9) and viable territories (Global: 37.2 ± 9.2; Territory: 33.4 ± 12.4); p=0 for both. ***Conclusion:*** This study provides comprehensive insights into LV dyssynchrony patterns associated with myocardial viability status, highlighting significant differences in PHB, PSD, and entropy parameters both globally and per territory. These findings underscore the potential clinical utility of combining global and territorial analyses in more precise assessment of myocardial viability.

EP-0470

Myocardial Scintigraphy For Emergency Care In Patients Presenting With Acute Chest Pain And Negative High-Sensitivity Troponin

F. Lattuada[1], *I. Gotuzzo[2], P. Ferro[2], R. Boni[2], P. Vai[2], R. H. J. A. Slart[3], P. Erba[1];*
[1]Department of Medicine and Surgery, University of Milano-Bicocca and Nuclear Medicine Department, ASST Ospedale Papa Giovanni XXIII, Bergamo, ITALY, [2]Nuclear Medicine Department, ASST Ospedale Papa Giovanni XXIII, Bergamo, ITALY, [3]Medical Imaging Center, University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Acute chest pain (ACP) constitutes a significant portion of emergency department (ED) admissions worldwide, requiring thorough evaluations to assess and manage potential acute coronary syndrome (ACS) cases effectively. Patient history, physical examination, electrocardiogram (ECG), echocardiography, and serial high-sensitive troponin (hsTn) aid in ruling out ACS. However, further diagnostic testing may be necessary to guide patient management and potential hospitalization, especially for low to intermediate-risk patients. Myocardial perfusion scan (MPI) is a well known valuable tool in this scenario, offering a strong negative predictive value for identifying coronary artery disease (CAD). Our study aims to assess the utility of MPI in clinical decision making for ED patients with ACP, facilitating safe discharge for those at low to intermediate ACS risk. ***Materials and Methods:*** Between July 2017 and January 2024, we enrolled 77 patients presenting to the ED with ACP and suspected ACS who at the end of the standard work-out presented negative hsTn. We collected clinical data, risk factors, ECG, echocardiography results, troponin levels, and any prior cardiac events. Patients underwent stress and rest MPI using 99mTc-tetrofosmin/99mTc-sestamibi on a CZT tomograph. The study analyzed MPI results, ED physicians' decisions, and follow-up data. ***Results:*** Initial assessments revealed 36,36% of patients with echocardiographic abnormalities (hypo or akinesia), 1,3% with STEMI-indicative ECG findings, and 18,18% with moderate elevated hsTn levels. MPI was negative in 66,2% of cases, 15,6 % of scans showed ischemia, and 7,8% showed signs of both ischemia and necrosis. Accordingly, patients with MPI positive for ischemia were hospitalized. Coronary angiography was performed, showing discordance with MPI in only 4 cases. 86,3 % of patients with negative MPI were discharged. Follow up demonstrated that nearly all (92.6%) remained event-free. After discharge, the remaining 7,4% of patients required further evaluation, such as elective coronary angiography, revealing either microvascular disease or multivessel pathology. Notably, only 3,9% of MPI results were inconclusive. ***Conclusion:*** The study confirms the utility of MPI in the clinical acute setting for patients with negative hsTn at the standard work-out, revealing ischemia in approximately 15% of patients. Alignment between positive MPI findings and coronary angiography was very high, accurately identifying CAD-affected myocardial territories. Negative MPI results allowed ED clinicians to safely discharge patients as shown by long term follow-up data demonstrating no subsequent cardiac events. Larger-scale studies could better elucidate the clinical impact of MPI in the emergency setting and its cost-effective benefits, favoring early discharge over hospitalization.

EP-0471

Feasibility and first experience of cardiac flow calculation on a digital SPECT/CT with attenuation correction

P. De Bondt[1], *V. Nuttens[1], S. Wouters[1], D. Ooms[1], O. De Winter[1], S. Vermeulen[1], A. Manrique[2];*
[1]OLV Ziekenhuis Aalst Asse Ninove, Aalst, BELGIUM, [2]Médecine Nucléaire, CHU de Caen, Caen, FRANCE.

Aim/Introduction: The ability to acquire cardiac flow from SPECT data is possible with the digital SPECT/CT camera. The validation of these data is lacking, so we acquired cardiac SPECT in dynamic and gated SPECT mode, and compared perfusion with flow data. ***Materials and Methods:*** We analysed 51 consecutives dynamic cardiac SPECT examinations on a digital SPECT/CT camera (Véritón, Spectrum Dynamics). The scan protocol was: scout low dose CT scan, injection of bolus of 200 MBq Tc-Sestamibi immediately followed by a dynamic scan for 6 min, static gated SPECT/CT of 8 min. After 15 minutes, 5 ml Regadenoson and a bolus of 700 MBq Tc-Sestamibi was injected, followed by dynamic scan for 6 min and a static gated SPECT/CT of 4 min. All scans were reconstructed with 2 iterations and 16 subsets and attenuation correction and imported into 4DM software v2018, Invia, Ann Arbor, USA. Perfusion was visually analysed with the 5-point scale. The stress flow and flow reserve data were recorded in ml/min/g in polar maps and in vascular territories. ***Results:*** We had no impression of bad or low quality input curves. Three of the scans were not imported correctly into 4DM due to too high pixel values. Three other patients had to be corrected for Rate Pressure Product, when the latter was above the upper limit of 12000. All stress scans were subtracted for the counts in the previous rest study, this functionality is foreseen within 4DM. In 11 patients, data from perfusion agreed with flow measurements, including 8 patients with normal perfusion and normal flow, 2 patients with moderate and 1 with significant perfusion and flow abnormalities. In 13 patients, data from flow was in disagreement or of added value, compared to the perfusion data. Most of the flow evaluation resulted in a mix of different segments and walls going from mild and moderate reduced, to ischemia, steal and scar. Since flow is a representative of tracer activity going from one to another physiological compartment and perfusion is a reflection of tracer deposition in a perfused myocyte, resulting in different results is logical. ***Conclusion:*** On a digital SPECT/CT camera, flow measurement of perfusion with Tc-sestamibi is possible in a low dose and less than 1 hour imaging protocol. During processing, different factors seem to influence the flow substantially. Further validation of this technique is mandatory and will be helpful to introduce this technique into clinical practice.

EP-0472

The prognostic value of coronary flow reserve by CZT stress myocardial perfusion and PET/CT imaging in selected patients without history of CAD: a systematic review and meta-analysis

T. Mannarino, *V. Cantoni, R. Green, A. D'Antonio, R. Assante, E. Zampella, P. Buongiorno, A. Cuocolo, W. Acampa;*
Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY.

Aim/Introduction: We performed a systematic review and meta-analysis of published studies evaluating the prognostic value of myocardial flow reserve (MFR) assessed by cadmium-zinc-telluride (CZT)-SPECT systems and cardiac positron emission tomography (PET) imaging in predicting adverse cardiovascular events in

patients with suspected coronary artery disease (CAD). ***Materials and Methods:*** Studies published until March 2024 were identified by database search. We included studies evaluating MFR by CZT-SPECT systems or PET providing data on adjusted hazard ratio (HR) for the occurrence of adverse cardiovascular events. Annualized event rates were calculated and the incidence rate ratios with 95% confidence interval (CI) were estimated to compare patients with impaired and preserved MFR. Summary risk estimates for impaired MFR by CZT-SPECT and PET imaging were derived in random effect regression analysis and causes of heterogeneity were determined in meta-regression analysis. ***Results:*** We identified 13 eligible articles (3 CZT-SPECT and 10 PET studies) including 12,766 patients with a mean follow-up of 2.6±0.48 years. The pooled HR for the occurrence of adverse cardiovascular events was 2.48 (95% CI 2.06-2.99) and no heterogeneity was found. Among the included publications, three studies reported the HR for the occurrence of adverse cardiovascular events evaluated by CZT camera. The pooled HR was 5.05 (CI 95% 2.63-9.69) and no heterogeneity was found, while seven studies reported the HR for the occurrence of adverse cardiovascular events evaluated by PET imaging with a pooled HR of 2.30 (CI 95% 1.92-2.76) and no heterogeneity. A total of 7 studies reported data calculating separately the incidence rate of adverse cardiovascular events in patients with impaired versus preserved MFR. The pooled IRR was 3.98 (CI 95% 2.92-5.41) and the heterogeneity was 34.42%. Among studies evaluated MFR by CZT camera, the pooled IRR was 5.87 (CI 95% 3.15-10.94) and no heterogeneity was found, while among studies evaluated MFR by PET imaging, the pooled IRR was 3.62 (CI 95% 2.53-5.16), and the heterogeneity was 47.2%. At meta-regression analysis no significant association was found between the hazard ratio for adverse cardiovascular events and demographic and clinical variables considered. ***Conclusion:*** The evaluation of MFR by both CZT-SPECT and PET showed a significant prognostic power in the evaluation of patients with suspected CAD, with a higher value for MFR by CZT-SPECT. This result suggests that the use of the CZT systems in clinical routine practice in this cohort of patients, also considering the improvements in acquisition time and radiation exposure reduction.

EP-0473

Comparing AI based attenuation correction (AC) in myocardial perfusion imaging (MPI) with a dedicated CZT SPECT system to the gold standard of CT based AC

D. Heute, *J. Heute;*
PKA for Nuclear Medicine Telfs, Telfs, AUSTRIA.

Aim/Introduction: Attenuation correction by CT is the gold standard in myocardial SPECT. Most dedicated cardiac SPECT cameras do not include a CT for attenuation correction (AC). Therefore an AI based software tool (TruCorr) has been introduced in MPI. The aim of this study is to test the quality of a new AI based AC tool in comparison to the standard of CT based AC. ***Materials and Methods:*** Using a cardiac phantom (Antropomorphic Torso PhantomTM) we made comparative images on a whole ring general purpose SPECT/CT (VeritonCT) and a dedicated cardiac SPECT (D-SPECT cardio). Both systems are equipped with CZT detectors. The images of the phantom were taken with and without a 90° insert mimicking a defect of tracer uptake in the posterior wall. ***Results:*** All of the SPECT images without AC showed a typical attenuation in the posterior wall being more dominant in the D-SPECT images than in those of on the whole ring system. Using CT for AC of the SPECT/CT images one can see a homogenous image of the phantom and a clear distinction of the posterior insert representing 2 % of the volume of the LV. Applying the CT data to the D-SPECT images significantly reduced the attenuation in the posterior wall and an even better reduction can be obtained using the AI based software. On one hand AI based AC improves of image quality in the posterior wall, on the other hand it reduces the homogeneity in the apex. The AI based AC seems to get closer to the gold standard of the general purpose SPECT/CT than the CT based AC of the D-SPECT images. ***Conclusion:*** AI based software seems to improve the diagnostic performance of MPI detecting attenuation artefacts in the posterior wall. ***References:*** Ochoa-Figueroa M., Valera-Soria C., Pagonis C., Ressner M., Norberg P., Sanchez-Rodriguez V., Frias-Rose J., Good E., Davidsson A.: Diagnostic performance of a novel deep learning attenuation correction software for MPI using a cardio dedicated CZT camera. Feasibility of shortening scan time on ^{18}F-FDG myocardial metabolism imaging using a total-body PET/CT scanner

L. Jiang;
Guangdong Provincial People's Hospital, Guangzhou, CHINA.

Aim/Introduction: To evaluate 18F-FDG myocardial metabolism imaging (MMI) using a total-body PET/CT scanner and explore the feasible scan time to guide the clinical practice. ***Materials and Methods:*** A retrospective analysis was conducted on 41 patients who performed myocardial perfusion-metabolism imaging to assess myocardial viability. The patients underwent 18F-FDG MMI with a total-body PET/CT scanner using a list-mode for 600 s. PET data were reconstructed and split to simulate images of 600-s, 300-s, 120-s, 60-s, and 30-s acquisition time (G600-G30). Images among different groups were subjectively evaluated using a 5-point Likert scale. Semi-quantitative evaluation was performed using standardized uptake value (SUV), myocardial to background activity ratio (M/B), signal to noise ratio (SNR), contrast to noise ratio (CNR), contrast ratio (CR), and coefficient of variation (CV). Myocardial viability analysis included indexes of Mismatch and Scar. G600 served as the reference. ***Results:*** Subjective visual evaluation indicated a decline in the scores of image quality with shortening scan times. All the G600, G300, and G120 images were clinically acceptable (score≥3), and their image quality scores were 4.9±0.3, 4.8±0.4, and 4.5±0.8, respectively (P>0.05). Moreover, the semi-quantitative parameters of SUV, M/B, SNR, CNR, CR, and CV decreased with reduced scan time, and significant difference was observed in G300-G30 groups when comparing to G600 group (P<0.05). For myocardial viability analysis of left ventricular and coronary segments, the Mismatch and Scar values of G300-G30 groups were almost identical to G600 group (ICC: 0.974-1.0, P<0.001). ***Conclusion:*** Sufficient image quality could be achieved at G120 for MMI using a total-body PET/CT scanner, while the image quality of G30 was acceptable for myocardial viability analysis.

EP-0475

The Effect of Non-Cardiotoxic Chemotherapy on Myocardial ^{18}F-FDG Metabolism in Patient with Non-Small Cell Lung Cancer

E. Kaya[1], *A. Büyükçelik[2], E. Seyfeli[3], E. Vardareli[4];*
[1]Acibadem Univesity, Medical Faculty, Istanbul, TÜRKIYE, [2]Acıbadem Kayseri Hospital, Department of Medical Oncology, Kayseri, TÜRKIYE, [3]Acıbadem Kayseri Hospital Department of Cardiology, Kayseri, TÜRKIYE, [4]Acibadem Univesity Medical Faculty, Istanbul, TÜRKIYE.

Aim/Introduction: Cardiotoxicity occurs during therapy with several cytotoxic drugs in Non-small cell lung cancer (NSCLC). However, it is stated in different studies that non-cardiotoxic chemotherapeutics do not have a direct cardiotoxic effect. The aim of the study is to evaluate effect of non-cardiotoxic chemotherapy (paclitaxel, carboplatin, gemcitabine, cisplatine, pemetrexed, docetaxel) on myocardial ^{18}F-FDG metabolism in patient with NSCLC. ***Materials and Methods:*** A total of 29 patients (19 men, 10 women) were included in the study (mean age: 69.4±11.0 years). The patients did not have any chronic disease, coronary heart disease, risk factors for coronary disease (diabetes, smoking, etc.) and a history of continuous drug use. Patients with liver metastases were excluded from the study. The ^{18}F-FDG PET/CT study was performed before and after chemotherapy treatment. After 12 hours of fasting, ^{18}F-FDG was administered intravenously at a rate of 0.14 mCi/kg, and a whole body PET/CT study was performed approximately 60 minutes later. Images were evaluated by two nuclear medicine specialists. Semiquantitative SUVmax values were obtained from the anterior, septal, lateral and inferior walls of the heart by creating ROI on transaxial sections. To normalize myocardial ^{18}F-FDG uptake with liver (heart/liver ratio) ROI was generated in each ^{18}F-FDG PET/CT study to obtain SUVmax value from liver. Findings from the cardiac examination and ^{18}F-FDG PET/CT study were compared with findings before and after chemotherapy treatment. ***Results:*** During the time period of the studies, no cardiac complaints/symptoms occurred in the patients. No significant difference was observed in cardiac examinations (ECHO, EKG) before and after chemotherapy. Normalized myocardial uptake (heart/liver ratio) was higher in anterior, septal, lateral, and inferior cardiac walls after chemotherapy treatment ($P < 0.001$). ***Conclusion:*** The ^{18}F-FDG PET/CT study showed that non-cardiotoxic chemotherapeutic agents (paclitaxel, carboplatin, gemcitabine, cisplatine, pemetrexed, docetaxel) significantly increased myocardial ^{18}F-FDG metabolism in anterior, septal, lateral and inferior cardiac walls in non-small cell lung cancers.

EP-0476

Association between the Quantity of Hibernating Myocardium and Coronary Collateral Circulation in Patients with Chronic Total Occlusion

X. Shao, *Y. Wang, F. Zhang;*
the Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: To explore the association between the quantity of hibernating myocardium (HM) and the grading of collateral circulation in patients with chronic total occlusion (CTO) of the coronary arteries. ***Materials and Methods:*** We conducted a retrospective analysis on 88 CTO patients who underwent evaluation for HM using 99mTc-MIBI SPECT myocardial perfusion imaging in conjunction with 18F-FDG PET myocardial metabolic imaging, as they considered coronary revascularization. During coronary angiography, based on the Rentrop grading, we categorized coronary collateral circulation into two groups: the poorly-developed collateral circulation group (PD group, Rentrop 0-1) and the well-developed collateral circulation group (WD group, Rentrop 2-3). After adjusting for the potential confounding factors and conducting a stratified analysis, we explored the correlation between the HM index in the CTO region and the grading of collateral circulation. ***Results:*** In the WD group, the HM index of the CTO region was notably higher than in the PD group (46.2±15.7% vs. 20.9±16.7%, $P<0.001$). When dividing the HM index of the CTO region into tertiles, the proportion of patients with well-developed collateral circulation was 17.4%, 63.3%, and 88.6% in Tertile 1, Tertile 2, and Tertile 3, respectively. After adjusting for potential confounders, we observed that the proportion of patients with well-developed collateral circulation rose in tandem with an increase in the HM index of the CTO region (OR: 1.099, 95% CI: 1.043-1.158, $P<0.001$). This increasing trend was statistically significant (OR: 1.088, 95% CI: 1.036-1.144, $P<0.001$), most notably between Tertile 3 versus Tertile 1 (OR: 3.724, 95% CI: 1.148-12.072, $P=0.028$). Curve fitting indicated that the HM index in the CTO region was linearly and positively correlated with the proportion of patients with well-developed collateral circulation. Importantly, this correlation was consistent across different left ventricular ejection fraction (LVEF) groups, with no significant interaction observed (P for interaction = 0.330). ***Conclusion:*** In CTO patients evaluating revascularization options, the HM index in the CTO region is an independent correlation factor for the grading of collateral circulation. A greater HM index in the CTO region corresponded to an increased likelihood of well-developed collateral circulation, displaying an almost linear positive correlation between the two.

EP-0477

Usefulness of visual classification for cardiac pathophysiology using count-washout rate polarmap in iodine-123-β-methyl-p-iodophenyl-pentadecanoic acid scintigraphy

R. Ono[1], *H. Miyauchi[1], K. Hoshi[2], Y. Kobayashi[1];*
[1]Chiba University Graduate School of Medicine, Chiba, JAPAN, [2]The University of Tokyo Hospital, Tokyo, JAPAN.

Aim/Introduction: Myocardial washout rate (WR) is utilized in nuclear cardiology to evaluate the clinical pathophysiology of the heart. WR is defined as the ratio of the difference between the count in the early image and the time-decay-corrected delayed image divided by the former. WR of iodine-123-β-methyl-p-iodophenyl-pentadecanoic acid (BMIPP) is an indicator of myocardial lipolysis, and a decreased WR (<10%) of BMIPP is one of the diagnostic criteria for triglyceride deposit cardiomyovasculopathy (TGCV), a rare cardiovascular disorder characterized by the accumulation of triglycerides in the myocardium [1, 2]. However, decreased BMIPP uptake in early images, such as old myocardial infarction (OMI), also causes markedly decreased WR. To address this, we developed a novel technique called the count-washout rate polar map (CWRM), a graphical representation of the count and WR values in a polar coordinate system. This map provides a comprehensive view of the myocardial distribution of counts and WR, allowing for more accurate and intuitive interpretation of the data. ***Materials and Methods:*** To differentiate between TGCV and non-TGCV with OMI, both of which show decreased BMIPP WR, we visually evaluated CWRM consisting of two axes: count in the early image and WR. The count window was set to the maximum of the mean plus two standard deviations and a minimum of 50 counts, and the WR window was set to a maximum of 30% and a minimum of -20%. The color scale used

was as follows: high count and high WR represents light blue, low count and high WR represents blue, high count and low WR represents orange, and low count and low WR represents black. ***Results:*** In normal cases, sufficient counts were observed in the early images, and the WR did not decrease; CWRM showed light blue. In TGCV, sufficient counts were observed in the early image, but the WR markedly decreased; CWRM showed orange evenly. In non-TGCV with OMI, the regions with decreased and preserved counts coexisted; CWRM showed light blue in the normal region and black in the OMI region. In TGCV with OMI, CWRM showed orange in the TGCV myocardium and black in the OMI region. ***Conclusion:*** CWRM is useful for visually differentiating TGCV from non-TGCV with OMI. CWRM can be applied to other cardiovascular diseases with count and WR variations for visual classification. ***References:*** [1] Li M, et al. Orphanet J Rare Dis. 2019;14:134. [2] Kobayashi et al. Ann of Nucl Cardiol. 2020;6:99-104.

EP-0478

The use of [18F] FDG PET/CT in the diagnosis and management of patients with sarcoidosis and suspected cardiac involvement.

M. Kalnina[1], *D. Reitere[2], I. Priedite[1];*
[1]ARS Nuclear Medicine Clinic, Riga, LATVIA, [2]Riga East Clinical University Hospital, Riga, LATVIA.

Aim/Introduction: While [18F]FDG PET/CT is not typically part of the usual evaluation for sarcoidosis, there is increasing evidence that it is valuable in determining the level of inflammation. Sometimes the initial, and occasionally the only, sign of sarcoidosis is cardiac involvement. Cardiac sarcoidosis is more common than expected and is linked to increased morbidity and mortality. The aim of this study was to evaluate the role of [18F] FDG PET/CT in the diagnosis and management of cardiac sarcoidosis in a single center receiving all sarcoidosis patients from the country. ***Materials and Methods:*** We retrospectively describe the clinical profile, age, sex, stage of the disease, and previously received treatment and indications used in real life for [18F] FDG PET/CT. Our center has a strict recommendation to have a low-carbohydrate and high-fat diet with prolonged fasting and mostly we achieve physiologic myocardial metabolism suppression. We compare clinical, imaging, and Scadding classifications before PET and analyze the additional diagnostic value of PET. We describe further management decisions after PET/CT and propose its role in the diagnostic pathway. ***Results:*** Our data indicates that the 49 patients referred to PET/CT in 2022 and 2023 are predominantly relatively young individuals, aged between 22 and 57, who have more or less active sarcoidosis. After clinical evaluation and conventional imaging results, patients have an unclear metabolic volume of the disease and an uncertain management plan, so they are referred to PET. In several patients (35%), PET/CT provided additional information on disease involvement in other lymph node groups, the liver, bone marrow, and a few cases of positive cardiac sarcoidosis. Most of the patients had a clinical indication to assess cardiac involvement in PET, and nearly all of them (95%) had active cardiac sarcoidosis ruled out. These patients were not referred to an additional MRI or SPECT/CT for further care due to the absence of any practical justification. ***Conclusion:*** In our clinical practice, [18F]FDG PET/CT has shown to be a useful imaging method for ruling out active cardiac sarcoidosis and figuring out how widespread and active the disease is throughout the body. The use of PET helps to minimize unneeded further imaging, particularly those that involve ionizing radiation, which is important for relatively young patients. We suggest utilizing [18F]FDG PET/CT as the initial imaging modality to assess disease metabolic volume and to rule out active cardiac sarcoidosis provided that the individual adheres to stringent dietary guidelines.

Diagnostic utility of 99mTc-pyrophosphate (99mTc-PYP) scintigraphy in cardiac amyloidosis: a retrospective study

S. Stanzel, *M. Ashjaei, T. Nazerani-Zemann, R. M. Aigner;*
Medical University of Graz, Department of Radiology, Division of Nuclear Medicine, Graz, AUSTRIA.

Aim/Introduction: Cardiac amyloidosis (CA) poses a significant diagnostic challenge, necessitating noninvasive imaging modalities. 99mTc-pyrophosphate (99mTc-PYP) is a useful radiotracer that can specifically identify ATTR-CA. This study aims to assess the diagnostic efficacy of amyloid scintigraphy utilizing 99mTc-PYP in suspected CA patients. ***Materials and Methods:*** We retrospectively analyzed 150 patients with suspected CA who underwent 99mTc-PYP amyloid scintigraphy with static imaging of the thorax 60 min post-injection. Additionally, whole-body scintigraphy was performed 3-4 hours post-injection in 134 patients, with 41 patients undergoing SPECT/CT and two undergoing SPECT alone. Cardiac retention was evaluated using semi-quantitative (Perugini score 0-3) and quantitative (heart-to-contralateral lung ratio, H/CL ratio) methods, compared against myocardial biopsy and cardiac MRI results. ***Results:*** Myocardial biopsies (n=16) confirmed CA in 13 patients, with 7 of those diagnosed with ATTR-CA. Cardiac MRI (n=77) diagnosed CA in 44 patients. 99mTc-PYP scintigraphy demonstrated a sensitivity of 92.3% (Perugini score) and 53.8% (H/CL ratio), with a specificity of 33.3% and 66.7%, respectively, using myocardial biopsy as the gold standard. Compared to cardiac MRI, sensitivity was 90.9% (Perugini score) and 63.6% (H/CL ratio), with a specificity of 15.2% and 63.6%, respectively. Additional SPECT/CT or SPECT improved specificity to 85.7% when using cardiac MRI as the reference standard. Notably, a Perugini score of 3 and 2 exhibited 100% sensitivity in diagnosing ATTR-CA, while a H/CL ratio > 1.5 showed 85.7% sensitivity. ***Conclusion:*** 99mTc-PYP scintigraphy presents high sensitivity in diagnosing CA and excellent sensitivity in detecting ATTR-CA, offering a noninvasive diagnostic alternative in evaluating suspected CA cases. The application of SPECT/CT and SPECT enhances specificity, facilitating differentiation of blood pool and myocardial uptake. ***References:*** 1. Castano A, et al. Diagnostic accuracy of Tc-99m pyrophosphate scintigraphy in cardiac amyloidosis

X. Zhang, *Q. Zhang;*
Sichuan University West China Hospital, Chengdu,Sichuan, CHINA.

Aim/Introduction: This study aims to evaluate the accuracy of Tc-99m pyrophosphate (PYP) in diagnosing cardiac amyloidosis (CA) and examining the clinical and imaging features of amyloid transthyretin (ATTR) patients with positive results on Tc-99m PYP scintigraphy. ***Materials and Methods:*** In this retrospective study, 247 patients underwent Tc-99m PYP scintigraphy at West China Hospital, Sichuan University between January 2018 and December 2022, with the Perugini visual score1 utilized for interpretation. Patient demographics, clinical manifestations, myocardial biopsy, Tc-99m PYP scan results, and laboratory findings, including immunoglobulin light chain analysis, were meticulously recorded and analyzed. Only 75 patients had a final diagnosis of CA. The study further evaluated the sensitivity, specificity, accuracy, and positive predictive value of Tc-99m PYP scintigraphy for detecting CA-ATTR and the negative predictive value for cardiac amyloid light chain (CA-AL). ***Results:*** Tc-99m PYP scan had a sensitivity of 80%, specificity of 60%, accuracy of 67%, and positive predictive value of 50% in identifying CA-ATTR. The negative predictive value of the Tc-99m PYP scan for CA-AL was 86%. Peripheral neuropathy was observed in 10 out of 25 CA-ATTR patients and 7 out of 50 CA-AL patients. Autonomic neuropathy was observed in 13 out of 25 CA-ATTR patients and 9 out of 50 CA-AL patients. Only 1 of the 20 CA-ATTR patients with positive Tc-99m PYP scan results had low QRS voltage, while all 5 CA-ATTR patients with negative Tc-99m PYP scan results had low QRS voltage. In CA patients, an increased likelihood of CA-ATTR was associated with follows: troponin T levels ≤ 57.15 ng/L (sensitivity 82%, specificity 76%), NT-proBNP levels ≤ 2548 ng/L (sensitivity 73%, specificity 76%), and LVEF ≥ 55% (sensitivity 79%, specificity 58%). ***Conclusion:*** Tc-99m PYP scan is a reliable method for distinguishing CA-ATTR from CA-AL. Since CA-AL patients may exhibit positive Tc-99m PYP scan results, it is advisable for suspected CA-AL patients to undergo Tc-99m PYP scintigraphy2. For phenotype, CA-ATTR patients presented a more common autonomic neuropathy and peripheral neuropathy. Moreover, CA-ATTR patients with positive Tc-99m PYP scan results tend to have a lower prevalence of low QRS voltage than those with negative scan results. ***References:*** 1.Perugini E, Guidalotti PL, Salvi F, et al. Noninvasive etiologic diagnosis of cardiac amyloidosis using 99mTc-3,3-diphosphono-1,2-propanodicarboxylic acid scintigraphy. EP-0481

Bone Scintigraphy Coupled To Heart Function Evaluation By First Pass Radionuclide Angiography

H. Ramdane[1], *B. Mourad[2], Z. Toufik[2];*
[1]University Military Hospital, Tamanrasset, ALGERIA,
[2]University Military Hospital, Oran, ALGERIA.

Aim/Introduction: Chemotherapeutic drugs, particularly Anthracycline and its derivatives, are known to adversely affect heart function. This toxicity, which is dose-dependent, initially impacts diastolic function before progressing to affect systolic function. Given this risk, assessing left ventricular function becomes imperative by anatomical and/or isotopic imaging techniques. Equilibrium radionuclide angiography stands out as the gold standard among various isotopic imaging methods and is frequently used in our department. Recognizing that cancer patients often undergo bone scans for staging or follow-up, we propose a novel approach to enhance patient care. Our aim is to integrate the evaluation of cardiac function with routine bone scanning protocols. This involves modifying the bone scan injection protocol by administering the radiotracer bolus under the gamma-camera detector, allowing us to record its first pass through the heart and great vessels. ***Materials and Methods:*** Six cancer patients were referred to our department for bone scintigraphy for staging purposes. Given our dual objective of detecting bone metastases and evaluating heart function, these patients underwent radiopharmaceutical injection under the gamma camera detector, and we recorded the first pass of the radionuclide (Diphosphonate bone scanning agents) bolus through the heart and great vessels by synchronizing the data acquisition with the cardiac cycle. Three hours post-injection, we completed the protocol acquisition with whole-body bone scanning. ***Results:*** In addition to the conventionally acquired whole-body bone scans, we have obtained, for each patient, the time/activity curve, the left ventricular ejection fraction, the diastolic filling parameters, and the parametric images. These data inform us about the diastolic and systolic states of the left ventricle, similar to conventional first-pass radionuclide angiography with blood tracers. ***Conclusion:*** Bone scintigraphy combined with heart function evaluation can serve as a new follow-up protocol for patients undergoing cardiotoxic chemotherapy. It allows for the completion of two essential exams in cancer patients on the same day with a single radioactive product injection. Furthermore, it can enhance the existing arsenal of cardiac function follow-up and may present an alternative to currently available procedures.

EP-0482

Gender-dependent myocardial distribution patterns of ^{99m}Tc-DPD in patients with transthyretin amyloidosis (TTR-CA): Demonstration by SPECT-CT

F. Sebastián Palacid[1], *N. Álvarez Mena[1], M. García Aragón[1], R. C. Zambrano Infantino[1], B. M. Jaramillo López[1], B. Pérez López[2], R. Ruano Pérez[1];*
[1]Hospital Clínico Universitario Valladolid, Valladolid, SPAIN,
[2]Hospital Clinico Universitario Valladolid, Valladolid, SPAIN.

Aim/Introduction: To demonstrate whether the gender of patients with cardiac TTR amyloidosis influences the distribution of the radiopharmaceutical in the myocardium and whether SPECT-CT is able to detect it. ***Materials and Methods:*** SPECT-CT chest was performed on a sample of 65 patients with TTR-CA confirmed by 99mTc-DPD scintigraphy, immediately after the scan. CT and SPECT images were processed together using the Emory Cardiac Toolbox software (GE Healtcare®), which merged both studies, subjecting them to attenuation and motion correction and iterative reconstruction. Finally, polar maps were obtained for each patient, obtaining a score for each of the 17 myocardial segments based on 99mTc-DPD uptake. The score was divided into 5 levels (0=very high uptake, up to 4=very low/no uptake). Mean scores were obtained according to the sex of the patients and we sought statistically significant differences in the distribution pattern of the radiopharmaceutical. ***Results:*** 51 males (78.5%) and 14 females (21.5%) were assessed. Based on the Perugini visual uptake scale, 54 (83.1%) were classified as grade 3 and 11 (16.9%) as grade 2. The sum of the scores obtained on each polar map gave a result of 277 points in the female group

and 876 points in the male group. In detail, females showed lower 99mTc-DPD accumulation in the mid anterior (p=0.035) and basal anterior (p=0.001) segments, while males showed higher scores in the basal anteroseptal (p=0.009) and basal inferoseptal (p=0.009) segments, and lower scores in the lateroapical segment (p=0.039). ***Conclusion:*** Gender of patients with TTR cardiac amyloidosis is a variable that influences the distribution of the radiopharmaceutical in the myocardium. SPECT-CT is a useful and reliable tool in the evaluation of this characteristic, as well as in transforming it into a quantitative value.

EP-0483

Correlation between 123I-metaiodobenzylguanidine liver washout rate and plasma brain natriuretic peptide concentrations in the fontan patients

M. Ota[1], *T. Yamamoto[1], S. Kasama[2], M. Matsuo[3];*
[1]Gifu prefectural general medical center, Gifu, JAPAN, [2]Shiga University of Medical Science, Otsu, JAPAN, [3]Gifu University, Gifu, JAPAN.

Aim/Introduction: In planar 123-I metaiodobenzylguanidine (123I-MIBG) myocardial imaging of Fontan patients, the timing of liver accumulation varies from patient to patient. The aim of this study is to investigated on the relationship between the liver washout rate (LWR) of 123I-MIBG and plasma brain natriuretic peptide (BNP) concentrations in the Fontan patients. ***Materials and Methods:*** The consecutive 30 Fontan or Fontan candidate patients (including 18 patiens of Glenn : mean age, 2.1±0.82 years, and 12 patients of Total cavopulmonary connection(TCPC) mean age, 14.0±8.7 years) were entered in this study. We examined 123I-MIBG scintigrams for Fontan patients of suspect heart failure. 123I-MIBG planar images from an anterior view were obtained 20 minute and 3hour after an intravenous injection of 123I-MIBG . The injection activity in pediatric nuclear medicine were decided by "Japanese consensus guidelines for pediatric nuclear medicine". Cardiac sympathetic activity was assessed by 123I-MIBG planar images as the Washout Rate of heart (HWR).HWR and LWR was assessed by MIBG planar images (early and delayed). The washout rate of heart (HWR) and LWR were calculated using the following formula:{([H or L]-[M])× early-([H or L]-[M])× delayed} ÷ ([H or L]- [M])× early× 100 (%) :where [H] equals the mean count per pixel in the left ventricle, [L] equals the mean count per pixel in the liver and [M] equals the mean count per pixel in the upper mediastinum. In this study, time decay was not corrected for the calculation of WR. The relationships between BNP concentrations and HWR, or LWR were examined. ***Results:*** HWR was significantly positively correlated with logBNP in Glenn patients(r=0.580 p<0.01). In TCPC patients, HWR was not correlated with logBNP (r=0.430 p=0.163). LWR was significantly negatively correlated with logBNP in Glenn patients(r=0.465 p<0.05). In TCPC patients, LWR was not correlated with logBNP (r=0.253 p=0.428). ***Conclusion:*** There were significant correlations between the parameters of HWR and BNP concentrations. Moreover, there were significant negatively correlations between the parameters of LWR and BNP concentrations in Glenn patients.This finding indicated that liver accumulation timing of 123I-MIBG image is meaned of congestive circulation in the patients of Glenn.

EP-0484

Clinical and Scintigraphic Characteristics in Patients with Cardiac Amyloidosis

T. Palalija, *B. Gužič Salobir, M. Štalc, A. Cuderman, J. Jamšek, D. Šfiligoj Planjšek;*
University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: The two main forms of cardiac amyloidosis are light chain amyloidosis (AL) and transthyretin amyloidosis (ATTR). Different tracers make it possible to image cardiac amyloidosis, the most extensively studied being 99mTc-labeled bone-seeking tracers. The intensity of uptake in the heart is described with the Perugini score, which has four grades (0-3). In patients with specific clinical signs, changes on echocardiography or magnet resonance imaging and an uptake of grade 2 or 3, we can diagnose ATTR without biopsy, if AL was excluded. ***Materials and Methods:*** We included consecutive adult patients who underwent scintigraphy, due to suspicion of cardiac ATTR amyloidosis, between July 2023 and March 2024. Three hours after intravenous application of 500 MBq 99mTc-labeled 3,3-diphosphono-1,2-propanodicarboxylic acid ([99mTc]Tc-DPD) we obtained planar whole body images and single photon emission tomography with computed tomography (SPECT/CT) images of the chest. Uptake on planar images was scored visually while uptake on SPECT/CT images was scored in a semiquantitative manner measuring standardized uptake value (SUV). SUV of the whole heart, the anterior, lateral and inferior left ventricular wall, the apex, interventricular septum and the right ventricle wall was measured. The uptake pattern and the region with the highest SUV on SPECT/CT was noted. In the report we defined the intensity of tracer accumulation on a scale from 0 - 3 and described the presence of extracardiac amyloidosis. Clinical and scintigraphic data were collected prospectively. ***Results:*** 72 patients were included in the study. Among them, 36 were female (50%), with a mean age of 71.6 (± 13.9) years. Grade 2/3 uptake was observed in 18 patients (25%), with diffuse uptake in 11 (61.1%), focal in 4 (22.2%), and focal on diffuse in 3 (16.7%). Older age (79.7 ± 6.3 vs 69.0 ± 14.7) and male sex (66.7%) were more common in patients with grade 2/3 uptake. The heart regions with the highest uptake were the interventricular septum in 12 patients (66.6%) and the inferior and lateral wall with 3 patients each (16.7% each). Mean SUVs were 9.7 for the interventricular septum, 8.3 for the inferior wall, and 7.2 for the lateral wall. Extracardiac amyloidosis was detected in 10 patients (13.9% overall, 55.6% in patients with grade 2/3 myocardial uptake). ***Conclusion:*** In patients suspected of cardiac ATTR 25% showed signs of amyloidosis, with a higher prevalence in males and older individuals. Diffuse uptake was most common, with the interventricular septum exhibiting the highest uptake.

EP-0485

[99mTc]Tc-PYROPHOSPHATE (PYP) SCINTIGRAPHY FINDINGS OF CARDIAC AMYLOIDOSIS: IS IT A PREDICTOR FOR SURVIVAL?

E. Akgun[1], *U. Aksu[1], A. Guler[2], G. Babur Guler[2], B. Esen Akkas[1];*
[1]University of Health Science Turkey, Basaksehir Cam and Sakura City Hospital, Istanbul, TÜRKIYE, [2]University of Health Sciences Turkey, Mehmet Akif Ersoy Thoracic and Cardiovascular Surgery Training and Research Hospital, Istanbul, Türkiye., Istanbul, TÜRKIYE.

Aim/Introduction: Association [99mTc]Tc-pyrophosphate (PYP) uptake with survival of cardiac amyloidosis (CA) is still unkown. This study aimed to describe the scintigraphic findings of CA suspected cases and determine the prognostic value of scintigraphy. ***Materials and Methods:*** Between September 2020-December 2023, all [99mTc]Tc-PYP scintigraphy images of CA suspected cases were evaluated retrospectively. The scintigraphy images were obtained 1h and 3h after intravenous injection of 740 MBq [99mTc]Tc-PYP. The quantitative and semiquantitative results of scintigraphy were analyzed, and their correlation with clinical outcomes was explored. ***Results:*** Among the 268 cases

(147 female, 121 male; median age:65), 12 (4.5%) were diagnosed with ATTR CA, 19 (7.1%) with AL CA. The median follow-up time was 386 days. ATTR CA cases exhibited significantly higher [99mTc]Tc-PYP uptake than AL CA and non-CA cases. The 1h and 3h heart-to-contralateral lung ratios were positively high degree correlated each other and SPECT/CT imaging reduced equivocal results from 82% to 37%. Eight of 19 patients with AL CA, one of 12 with ATTR CA, and 15 of non-CA cases died on follow-up. Median survival was 22 days in ATTR CA, 201 days in AL CA, and 105 days in non-CA ex cases. Survival analysis indicated significantly lower survival in non-CA cases compared to ATTR CA and AL CA. ***Conclusion:*** [99mTc]Tc-PYP scintigraphy demonstrated varying uptake patterns in different CA forms. The study emphasizes the importance of combining scintigraphic findings with laboratory tests for accurate CA diagnosis and highlights the poor survival of individuals investigated for CA, even if the diagnosis is not confirmed.

EP-0486

Ventricular function assessment with gated-SPECT/CT using [^{99m}Tc]Tc-HDP in TTR Amyloidosis

J. Carvalho, *J. Duarte, A. Marques, F. Abreu, S. Pintão;*
Unidade Local de Saúde de Lisboa Ocidental, E.P.E., Carnaxide, PORTUGAL.

Aim/Introduction: Cardiac transthyretin amyloidosis (ATTR) is a disease characterized by abnormal deposition of altered transthyretin fibrils in the myocardium. Technetium-99m-labelled diphosphonates have been used for the non-invasive diagnosis of ATTR, obviating the need for invasive procedures such as cardiac biopsy in many patients. The aim of this study was to evaluate the usefulness of ventricular function assessment by gated-SPECT/CT with these tracers. ***Materials and Methods:*** This study included 29 patients with a non-invasive diagnosis of TTR amyloidosis. All patients underwent a thoracic gated-SPECT/CT study 3 hours after injection of technetium-99m hydroxydiphosphonate ([99mTc]Tc-HDP). We compared the obtained ventricular function parameters with those obtained by morphological studies (echocardiography and magnetic resonance). ***Results:*** A total of 29 patients with Perugini grade ≥2 were included in this study (22 males; mean age 82.48±7.04 years; 51.72% with Perugini grade 3). Mean left ventricular ejection fraction (EF) obtained by gated-SPECT/CT was 39.79±13.51%, mean end-systolic volume (ESV) was 57.72±35.39 mL and mean end-diastolic volume (EDV) was 89.79±38.33 mL. A moderately strong positive correlation was found between EF values obtained by gated-SPECT/CT and morphological studies (r=0.60; p=0.01), although gammagraphic results tended to underestimate the EF (mean difference -6.79±12.00%). A strong positive correlation between both methods was found for ESV and EDV (r= 0.81 and r=0.81, respectively; p<0.01). When taking into account only those patients with Perugini grade 3, a stronger positive correlation was found regarding EF values (r=0.82; p<0.01), ESV (r=0.90; p<0.01) and EDV (r=0.87; p<0.01). In these patients, mean difference between EF obtained by gated-SPECT/CT and by morphological studies was -6.73±2.06%. ***Conclusion:*** SPECT/CT is an essential technique in the diagnosis of TTR amyloidosis, being able to identify the presence of diphosphonate uptake in the myocardium and its distribution. Additionally, it may also have a role in ventricular function assessment, being able to simultaneously identify patients with impaired EF and abnormal ventricular volumes, thus providing prognostic value that may influence patient's management. This may obviate the need for further morphological procedures and may be of particular importance in cases where echocardiography or magnetic resonance aren't feasible options.

EP-0487

SPECT/CT Scintigraphy in the Diagnosis of ATTR Cardiac Amyloidosis - The Ultimate Noninvasive Tool

C. Fragkaki, *S. Maragkoudakis, A. T. Archontaki;*
Chania General Hospital "St. George", Chania, GREECE.

Aim/Introduction: Amyloidosis is a systemic disease with poor prognosis when there is heart involvement. The most common inherited amyloidosis, is caused by a mutation in the transthyretin (TTR) gene that produces abnormal transthyretin protein fibril deposition in the heart. The aim of our study was to compare the use of SPECT and SPECT/CT scintigraphy, in the diagnosis of TTR-cardiac amyloidosis (Attr-CM) in patients with heart failure and preserved ejection fraction (HFpEF). ***Materials and Methods:*** A total of 91 patients with HFpEF, LVEF>50%, elevated proBNP levels, low ECG dynamics and an ultrasound image showing reduction in the longitudinal strain of the basal wall segments with normal strain levels in the apical segments (apical-sparing), were examined. Up to September 2023, imaging was performed with a dual headed SPECT γ-camera, but thereupon a SPECT/CT dual-headed γ-camera was used. Planar & SPECT and Planar & SPECT/CT imaging was performed in 53 and 38 patients, respectively. The protocol used in all patients was imaging with either 99mTc-PYP or 99mTc-DPD, at one hour and at three hours post radiopharmaceutical administration. All acquired images were visually assessed by two Nuclear Medicine physicians and myocardial uptake was also evaluated with the Perugini Grading Scale. ***Results:*** Nine (9) patients were positive for Attr-CM and 56 patients were negative. With SPECT/CT scintigraphy, there were no equivocal results. The 35 negative results from this group showed clearly no uptake to the heart muscle. Blood pool was easily distinguished from any heart uptake in the SPECT/CT fused images and the three hours delayed imaging helped to clear images even more. From the SPECT only group, 26 had an equivocal result and were categorized as Grade 1 or 2. A total of 17 patients with Grades 3 and 2 started therapy. ***Conclusion:*** Scintigraphic imaging of the heart is already an established tool in the differential diagnosis of Attr-CM from other causes of cardiomyopathy. Nowadays, planar imaging alone is considered to be inadequate and SPECT imaging should always be performed. When SPECT/CT is available the images obtained have better quality, correspond more accurately to visual assessment than SPECT only imaging and reduce false positive results which, in our opinion, makes SPECT/CT the ultimate noninvasive tool in the diagnosis of Attr-CM.

EP-0488

Quantification parameters in 99mTc-DPD-SPECT/CT imaging, in patients with suspected cardiac Amyloidosis by transthyretin, our experience.

F. Caltagirone Gutierrez, *J. C. Cañadas, J. A. Badell, P. Garcia-Talavera, E. Campaña, S. Rama, A. C. Peñaherrera, J. G. Villanueva, L. G. Diaz, F. Gomez, E. Casillas, C. Montes, M. E. Eiros, M. P. Tamayo;*
Hospital Universitario de Salamanca, Salamanca, SPAIN.

Aim/Introduction: To establish the usefulness of quantification parameters in hybrid SPECT/CT images and their correlation with analytical and ultrasound values in patients with suspected cardiac amyloidosis due to transthyretin (AcTTR). ***Materials and Methods:*** We retrospectively reviewed 243 scintigraphy scans

(153-men/90-women; mean age: 83 years) from January, 2022 to January, 2023, in patients with clinical suspicion of AcTTR. Planar images were obtained in anterior and posterior projections, after administration of 700-740 MBq of 99mTc-DPD and those who were positive according to Perugini visual scale, underwent SPECT/TCxQUANT, obtaining measures of cardiac quantification (SUV max, peak, mean) and adjacent areas (blood pool, sternum, vertebrae, ribs). Biochemical (troponins, probnp, total proteins and albumin), electrocardiographic and echographic (LVEF, E/E', TAPSE, GLS) findings were collected. Subsequently, the data were analyzed by Pearson correlation between SUV values, biochemical and echographic parameters, using SPSS v25 software. ***Results:*** Of the total number of patients, 76 presented positive scintigraphy. Of these, 45 were studied with ultrasound to confirm/rule out ventricular dysfunction (GLS). In these patients, correlation analysis was performed between these parameters of scintigraphic, biochemical and ultrasound quantification, with no statistically significant results (p>0.05). The percentage of cardiovascular processes present in the sample are also detailed: congestive heart failure (51%), HT (76%), dyslipidemia (67%) and diabetes (27%). Likewise, 64% had altered troponins and 89% had altered proBNP. 29% had AVB, 51% AF and 27% low voltage. ***Conclusion:*** These results show that, at this point, gammagraphic parameters cannot adequately stratify patients with AcTTR, probably because of the sample size. However, it is likely that, after further studies and enlargement of the sample, they could be predictors of disease associated with other parameters such as ultrasound and biochemical parameters.

EP-0489

Cardiac amyloidosis: comparison between visual analysis and quantification of uptake in cardiac scintigraphy with 99mTc-diphosphonates

J. Diaz-Moreno[1], *L. Gràcia-Sánchez[1], P. Notta-González[1], I. Sánchez-Rodríguez[1], B. Hervás-Sanz[1], M. Zamorano-Rivas[1], M. Pudis[1], A. Rodríguez-Gasén[1], J. Martín-Marcuartu[1], J. Robles-Barba[1], A. Bagán-Trejo[1], A. Fritsch-Medina[1], M. Perlaza-Jiménez[1], C. Díez-López[2], J. González-Costello[2], E. Claver-Garrido[2], S. Yun-Viladomat[3], D. Plaza-González[4], M. Cortés-Romera[1];*
[1]Nuclear Medicine-PET (IDI) Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [2]Cardiology Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [3]Internal Medicine Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN, [4]Quality Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, Barcelona, SPAIN.

Aim/Introduction: Cardiac amyloidosis (CA) is an infiltrative disease due to protein deposition, which can cause restrictive cardiomyopathy. Cardiac scintigraphy (CS) with 99mTc-diphosphonates has diagnostic value by visual analysis. The aim of this study is compare patients with clinical suspicion of CA with the Perugini Score of CS, cardiac quantification by ratios and correlate these results with Cardiac Magnetic Resonance (CMR) variables. ***Materials and Methods:*** Retrospective study of 37 patients (p) with suspected CA (22 men), mean age 74 years (46-86), in whom CS and CMR were performed. Total body scintigraphy was performed in anterior and posterior projections at 3 hours of 99mTc-diphosphonates administration. Maximal cardiac uptake (CMC), maximal cardiac uptake/contralateral thoracic activity (CMC/HCL) and CMC/HCL indexes with background activity subtraction (CMC/HCL-Bkg) were calculated. Cardiac quantification results were correlated with Perugini Score. Interventricular septal thickness (IVS), ventricular ejection fraction (LVEF) of CMR variables were analyzed and correlated with the Perugini Score of the CS. ***Results:*** Of the 37p assessed, 21p were diagnosed with CA. 13p were diagnosed with ATTR (7p with Score 3, 1p with Score 2, 3p with Score 1 and 2p with Score 0), 5p had light chain amyloidosis (AL) (4p with Score 0 and 1p with Score 1) and 3p with other types of systemic amyloidosis (2p with Score 1 and 1p with Score 0). - Median CMC: 73 (36-1927). Score 0 with CMC: 66.8 (36-123). Score 1 with CMC: 279 (69-960). Score 2-3 with CMC: 699 (149-1927); p<0.01. - Mean CMC/HCL ratio: 1.22 (0.68-3.76). Score 0 the CMC/HCL ratio: 0.97 (0.68-1.13). Score 1 the CMC/HCL ratio: 1.13 (0.97-1.22). Score 2 and 3 the CMC/HCL ratio: 2.1 (1.20-3.76); p<0.01.- The average CMC/HCL-Bkg ratio: 3.27 (0.07-34.9). Score 0 the CMC/HCL-Bkg ratio: 1.26 (0.68-2.4). Score 1 CMC/HCL-Bkg ratio: 1.33 (0.26-2.1). Score 2 and 3 the ratio CMC/HCL-Bkg: 10.53 (1.26-34.4); p<0.01. - The mean IVS was 15.6mm (12-25) and LVEF was 55.1% (26-87%); without finding significant correlations with the Perugini Score. - A positive correlation (0.96) was identified between the cardiac uptake indexes and the Perugini Score. ***Conclusion:*** CS with 99mTc-diphosphonates is a useful method in the noninvasive assessment and classification of patients with CA. Quantitative methods based on CMC indexes, CMC/HCL and CMC/HCL-Bkg, are simple procedures and help in the classification of patients with Perugini Score. The IVS and LVEF obtained in MRI do not present statistically significant correlation with Perugini scores or CMC/HCL indexes.

EP-0490

Potential prognostic value of quantified right ventricle involvement in Cardiac Transthyretin Amyloidosis. A preliminary, single center case-control study.

M. Zapardiel[1], *M. Vaillant[1], C. Wakfie[1], F. Ferrando-Castagnetto[2], S. Murguía[2], K. Bayardo[2], P. Nespral[1], A. Berardinelli[1], P. Dauden[1], G. Cuesta[1], M. Cabrera[1];*
[1]Department of Nuclear Medicine. Hospital Clínico San Carlos. Instituto de Investigación Sanitaria San Carlos (IdISSC). Madrid, Spain., Madrid, SPAIN, [2]Department of Cardiology. Hospital de clínicas Dr. Manuel Quintela., Montevideo, URUGUAY.

Aim/Introduction: To quantify right ventricle (RV) amyloid deposits in ATTR-CA patients referred to 99mTc-DPD scintigraphy and to estimate its potential prognostic value. Myocardial uptake of phosphate bone-seeking radiotracer 99mTc-DPD is remarkably sensitive for detecting transthyretin cardiac amyloidosis (ATTR-CA). However, the prognostic value of quantifying RV cardiac amyloid deposit is still unknown. ***Materials and Methods:*** Scintigraphic images were acquired in a sample of consecutive patients with ATTR-CA through a dual head hybrid SPECT/CT camera. Perugini score were obtained in each case. Cardiac SPECT/CT images were processed to quantify RV involvement applying a dedicated processing protocol. Through 12-16 pixels ROIs we calculated the ratio between maximal counts in RV and maximal counts in LV septum. RV/LVseptx100 ratio (%) was defined to estimate RV amyloid burden, both in attenuation corrected (iterative reconstruction: IRAC and filtered back projection: FBP) and non-corrected (NC) images. We compared RV/LVsept between dead patients ("cases") and alive ("controls"). ***Results:*** We included 22 patients with diagnosed ATTR-CA based on expert consensus criteria (Perugini score of 2 or 3); 77% males, mean age of 84 years. All patients presented 99mTc-DPD uptake in RV. A total of 14 patients died during follow-up (mortality: 64%). RV/LVsept activity ratio did not differed between NC and AC images. NC LVsept activity was 22.9 ± 4.4 % in cases vs. 20.0 ± 2.9 % in controls (p = 0.109). NC RV/LVsept was 41,4% ± 15.5 % in cases and 52.9 ± 13.6 % in controls (p = 0.098). A RV/LVsept ratio of at least 50% presented

an OR of 0.16 (95% CI: 0.0065 - 1.114) for the development of death during follow-up (p = 0.0815). ***Conclusion:*** RV involvement is a rule in patients with ATTR-CA. A more pronounced amyloid deposit in septal LV vs. RV supports the hypothesis of a greater prognostic value of quantified deposits in septum than in RV, with RV uptake as a later phenomenon with less influence in prognosis. The real prognostic value of different patterns of biventricular amyeloid deposit deserves further evaluation through larger, multicentric experiences.

Relationship of HF severity with mitochondrial dysfunction assessed by PBMC respiratory function and ^{99m}Tc-MIBI washout imaging in patients with CRT indications

T. Atabekov, *V. Korepanov, A. Mishkina, S. Krivolapov, M. Khlynin, S. Sazonova, T. Rebrova, E. Muslimova, S. Afanasiev, R. Batalov, S. Popov;*
Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: The mitochondrial dysfunction (MD) is important mechanisms affecting the heart failure (HF) pathogenesis. The 99mTc-methoxy-isobutyl-isonitrile (99mTc-MIBI) scintigraphy has been reported to be a functional imaging tool for in vivo detection of MD in myocardium. According to studies is possible to evaluate the respiration activity of cardiomyocyte mitochondria by the respiration of mitochondria from peripheral blood mononuclear cells (PBMC). We aimed to evaluate the relationship of HF severity with MD assessed by PBMC respiratory function and 99mTc-MIBI washout imaging in patients with cardiac resynchronization therapy (CRT) indications. ***Materials and Methods:*** In this single-center study patients with HF of New York Heart Association (NYHA) II and III functional class (FC) and CRT indications underwent transthoracic echocardiography (TTE) and MD assessment using laboratory (respiratory function of PBMC mitochondria) and radionuclide (myocardial perfusion scintigraphy with 99mTc-MIBI) approach. Mitochondrial respiration rate (MRR) (pyruvate + malate + adenosine diphosphate; succinate + adenosine diphosphate; pyruvate + malate - adenosine diphosphate [V4.1]; succinate - adenosine diphosphate) and washout rate (WR) indicators were calculated. Correlations between HF NYHA FC, TTE, MRR and WR indicators were evaluated. Based on our data, we developed a risk model regarding HF severity. ***Results:*** In overall 26 (100.0%) HF patients, 11 (42.3%) had mild HF defined as NYHA FC II (1st group) and 15 (57.7%) had moderate-to-severe HF defined as NYHA FC III (2nd group). Patients with moderate-to-severe HF were likelier to have a lower V4.1 (p<0.001) values. This indicator was independently associated with moderate-to-severe HF in univariate and multivariate logistic regression (odds ratio 0.87; 95% confidence interval 0.77-0.98; p<0.001). The developed HF severity risk model allowed us to correctly predict the moderate-to-severe HF in our study cohort with an accuracy of 84.62%. The sensitivity of the model was 80.00%, while the specificity was 100.00%. ***Conclusion:*** The severity of HF is associated with PBMC mitochondrial respiratory dysfunction, but not correlated with WR assessed by 99mTc-MIBI scintigraphy in patients with CRT indications. Our HF severity risk model including V4.1 parameters is able to distinguish mild and moderate-to-severe HF patients. Further investigations of their predictive significance are warranted.

EP-0492

Evaluation of Clinical Feasibility of Preoperative Perfusion Scintigraphy in Patients with Peripheral Artery Disease

B. Choi, *J. Lee, K. Park;*
Daegu Catholic University School of Medicine, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: The purpose of this study is to investigate clinical feasibility of preoperative perfusion scintigraphy (PerS) in patients with peripheral artery disease (PAD) of lower extremity (LE). ***Materials and Methods:*** We enrolled a consecutive series of 49 patients (43 men, 6 women, 70.8±9.6 years, range 37-89) with PAD who underwent primary endovascular treatment of LE arteries and had preoperative PerS and ankle-brachial index (ABI). In PerS, we obtained the ratio of the LE blood pool to whole body bool pool (LE/WBratio). Blood flow to time (BF/T) ratios were also obtained by quantifying blood flow at 30, 60, 120, 180, and 300 seconds in each LE. We prospectively enrolled 28 normal subjects (5 men, 23 women, 43.0±10.2 years, range 25-58) with PerS as a control group. Thirty-eight patients have unilateral lesions, and 11 patients have lesions in both LE. Statistical analysis was performed on a total of 60 LE of patients and compared with 56 LE of normal subjects. Non-parametric test was used for statistical analysis. ***Results:*** When comparing patients and normal subjects, LE/WBratio was significantly lower in patients than that of normal subjects (3.7±0.7 vs. 4.3±0.6, p <0.001). In BF/T analysis, the ratios of 60-to-180 (0.178±0.054 vs. 0.194±0.040), 60-to-300 (0.086±0.029 vs. 0.100±0.024), 120-to-180 (0.553±0.107 vs. 0.575±0.049), 120-to-300 (0.264±0.045 vs. 0.296±0.028), and 180-to-300 (0.481±0.055 vs. 0.514±0.032) were significantly different between patients and normal subjects (p = 0.015, 0.002, <0.001, <0.001, and <0.001, respectively). The relationship between ABI and parameters of PerS was investigated, and there were significant mild to moderate correlations between ABI and LE/WBratio, BF/T of 30-to-120, 30-to-180, 30-to-300, 60-to-120, 60-to-180, 60-to-300, 120-to-180, 120-to-300, and 180-to-300 (p = <0.001, 0.035, 0.031, 0.004, 0.003, 0.001, <0.001, <0.001, <0.001, and <0.001, respectively). ***Conclusion:*** In this study, we demonstrated the clinical feasibility of preoperative PerS in patients with PAD of the LE. This quantitative method is objective and reproducible and could be a new complementary and diagnostic tool for patient management.

EP-0493

Coronary Sodium Fluoride PET Detects High-risk Plaque Correlating with Intravascular Ultrasound in Patients with Suspected Coronary Stenosis

J. Huang[1], *C. Huang[1], Y. Wu[2], K. Chien[1];*
[1]National Taiwan University Hospital, Taipei, TAIWAN, [2]Far Eastern Memorial Hospital, New Taipei City, TAIWAN.

Aim/Introduction: 18F-Sodium Fluoride (NaF) positron emission tomography (PET) non-invasively detects micro-calcification, while 18F-fluorodeoxyglucose (FDG) PET detects active

inflammation, both are promising approaches for assessing vascular plaques. This study aimed to evaluate the value of NaF and FDG PET in evaluation of coronary atherosclerotic plaques, including detection and characterization of plaques by correlating with invasive coronary angiography (CAG) and intravascular ultrasound (IVUS). ***Materials and Methods:*** Patients with suspected coronary artery disease (CAD) who were scheduled for elective CAG were prospectively enrolled. All patients underwent dual cardiac and respiratory-gated NaF and FDG PET/computed tomography (CT) before CAG. IVUS were performed in all three coronary arteries. The maximum tissue to background ratios (standardized uptake value (SUV) max/SUVblood pool) were measured in each coronary segment according to the American Heart Association classification. Correlations between NaF positive, FDG positive lesions and CAG with IVUS were analyzed. The performance was compared using receiver operating characteristic (ROC) curves analysis. ***Results:*** A total of 33 patients (88% men, mean age: 65.7±10.3 years) were included. 24 patients were diagnosed CAD (3 left main, 11 left anterior descending,13 left circumflex and 15 right coronary artery stenoses). In patient-based analysis, NaF PET demonstrated a sensitivity and specificity of 1.000 (95% CI 0.631, 1.000) and 0.600 (0.147, 0.947), while FDG PET showed a sensitivity and specificity of 0.625 (0.245, 0.915) and 0.800 (0.284, 0.995), respectively. In vessel-based analysis, NaF PET yielded a sensitivity and specificity of 0.714 (0.719, 0.916) and 0.790 (0.627, 0.905), whereas FDG PET exhibited a sensitivity and specificity of 0.286 (0.084, 0.581) and 0.947 (0.822, 0.994), respectively, with significant differences (p=0.03 for sensitivity and specificity). The areas under ROC curves (AUCs) for NaF and FDG PET correlated with CAG with IVUS on a vessel basis were 0.752 (0.613, 0.861) and 0.617 (0.471, 0.748), respectively. In this pilot study with a small sample size, there was a trend of better diagnostic value of NaF PET (p=0.07) comparing between two AUCs. Additionally, combining FDG PET may enhance the specificity of detecting plaques. ***Conclusion:*** In the current study, we have demonstrated that dual-tracers, dual-gated PET with NaF and FDG are clinically feasible to non-invasively detect coronary plaques within the heterogeneous lesions. NaF shows advantages comparing FDG with better lesion-to-background ratio regarding cardiac region, and combination of NaF and FDG PET might enhance the ability to distinguish vulnerable plaques especially in intermediate coronary stenoses; which should be further validated in the future.

EP-0494

^{18}F-NaF PET/CT guides complete revascularization of multi-vessel coronary artery disease and the prognostic value study

X. Yu, *L. Li, Y. Hong, J. Song, B. Wang;*
First Hospital of Shanxi Medical University, Taiyuan, CHINA.

Aim/Introduction: coronary atherosclerotic plaque progression, rupture, and erosion are important causes of poor prognosis in patients with coronary artery disease (CAD) . In acute coronary syndrome (ACS), about 40%-65% of ST-elevation myocardial infarction patients show coronary multi-vessel disease, and the mortality and morbidity are higher in patients with multi-vessel coronary disease.However, CR based mainly on coronary angiography (CAG) and clinical guidance still fails to obtain the best prognosis, possibly because CAG examination based on anatomical perspective cannot eally identify the histological features of vulnerable coronary plaques . 18F-NaF PET/CT coronary imaging can identify and quantify plaque vulnerability by targeting microcalcification .Therefore, this study aims to explore the clinical value of 18F-NaF PET/CT guiding revascularization therapy for multi-vessel coronary artery disease and its evaluation of long-term prognosis. ***Materials and Methods:*** In this study, patients with clinically confirmed CAD were selected from multiple centers. The enrolled patients underwent 18F-NaF PET/CT and CAG examination within one week. The 18F-NaF PET/CT coronary plaque quantitative analysis used SUVmax and TBRmax to determine the degree of lumen stenosis at the site of coronary lesions according to CAG. The clinical cardiovascular MDT team selected treatment strategies according to the guidelines and followed up major adverse cardiovascular adverse events (MACE). ROC curve was established to obtain the optimal threshold of SUVmax and its cumulative value (S-SUVmax) for predicting MACE. Cox proportional hazard regression model and Kaplan-Meier method were used to analyze the predictive value of PET parameters to MACE. ***Results:*** 54 CAD patients (37 males and 17 females) completed the clinical study with a median follow-up of 6 years, of whom 13 (24.1%) developed MACE, including 7 deaths, 5 myocardial infarction and 1 readmission due to severe arrhythmia. The cumulative value of coronary lesions SUVmax (S-SUVmax) in MACE patients was significantly higher than that in the non-MACE group, and S-SUVmax (cut-off=2.05, AUC=0.690, P=0.041) was a strong predictor of MACE (HR=1.856, 95%CI: 1.323 ~ 2.604, P<0.001); Among the 25 patients further screened, the incidence of MACE was significantly higher in those with positive 18F-NaF uptake (SUVmax≥0.55) than in those with negative 18F-NaF uptake (35.71% vs. 0, $\chi 2$=6.07, P=0.014). ***Conclusion:*** 18F-NaF PET/CT can be used as an independent predictor of MACE in CAD patients. In the future, complete revascularization based on 18F-NaF PET/CT guidance may improve the long-term prognosis of patients with multi-vessel coronary artery disease to some extent.

EP-0495

First in Southeast Asia (Singapore) clinical study utilizing an automated synthesis of [^{11}C] Martinostat on Tracerlab FX MeI & FX M in compliance with PIC/S GMP

X. Wee;
Clinical Imaging Research Centre, National University of Singapore, SINGAPORE.

Aim/Introduction: [^{11}C]Martinostat ([^{11}C]MSTAT) potential as a radiotracer for epigenetic imaging has been reported by Martinos Centre1. It is able to exhibit the expression and activity of histone deacetylase (HDACs). In collaboration with Cardiovascular Research Institute (CVRI)1, patients will undergo HDAC inhibitor therapies and evaluate with [^{11}C]MSTAT as a HDAC inhibitor biomarker by imaging using PET/MR and/or PET/CT. Herein is the report of the fully automated synthesis of [^{11}C]MSTAT with compliance to PIC/S GMP at CIRC in Singapore to support the first clinical study in Southeast Asia. ***Materials and Methods:*** [^{11}C]CO2 obtained via the 14N(p,a)11C reaction (GE PETtrace 860 cyclotron) were delivered to GE TRACERlab FX-MeI unit, where the catalytic reduction of [^{11}C]CO2 to [^{11}C]CH4, and radical reaction of [^{11}C]CH4 with I2 occurred, producing [^{11}C]CH3I. [^{11}C]CH3I was bubbled through a solution of desmethyl precursor (2.0 mg) in DMSO-d6 (300 mL) and allowed to react for 5 minutes at 120°C. The crude mixture was then diluted with 0.8mL mobile phase (70% 0.01M HCl / 30% EtOH) and purified using a reverse phase semi-preparative HPLC (Gemini 5mm NX-C18, 110A, 10x250 mm2) at 2 mL/min. The radioactive fraction was collected and diluted with saline (0.9%, 8.6 mL), 0.01M HCl (1.0 mL) and EtOH (0.7 mL). The resulting formulation solution was filtered through a 0.2mm sterile filter and dispensed using Eckert & Ziegler ModularPharm

dispensing system into 4 separate vials; patient, sterility, QC, and retention. ***Results:*** Process validation of [^{11}C]MSTAT was carried out on three consecutive batches in accordance with PIC/S GMP. Average synthesis time was 35 minutes, with patient vial activity of 283.0 ± 92.4 MBq (n=3) at the time of injection (TOI). Good radiochemical of >90% was observed on analytical HPLC, with specific activity of 32-2677 GBq/mmol at the TOI. The formulated product met ICH requirements notably for residual solvents and sterility. The QC analysis of [^{11}C]MSTAT can be completed within 20 minutes. Product can be released within three half-life for [^{11}C]-radioisotope. The validation demonstrated the prospect of using [^{11}C]MSTAT for human trials. ***Conclusion:*** A fully automated radio-synthesis of [^{11}C]MSTAT has been successfully validated in compliance with PIC/S GMP. Human PET imaging of this radiopharmaceutical are in plan to commence at CIRC. The findings will be pivotal to evaluate the efficacy of HDAC imaging. ***References:*** This work has been funded by Cardiovascular Research Institute (CVRI) of Yong Loo Lin School of Medicine.[1] Wang et al., J. Med. Chem. 2014, 57, 7999 - 8009.

Computer aided diagnosis of Alzheimer's Disease from brain perfusion scans using interpretable AI

S. Michopoulou[1], *A. M. J. Prosser[2], J. C. Dickson[3], M. J. Guy[1], N. S. O'Brien[1], J. L. Teeling[2], C. M. Kipps[1];*
[1]University Hospital Southampton NHS Foundation Trust, Southampton, UNITED KINGDOM, [2]University of Southampton, Southampton, UNITED KINGDOM, [3]University College London Hospitals NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: Perfusion SPECT is used to detect subtle changes in regional brain perfusion which can help identify neurodegeneration. In this study, we used interpretable AI to develop a computer aided diagnosis system for Alzheimer's Disease from brain perfusion scans. ***Materials and Methods:*** 420 participants' brain perfusion SPECT scans from a heterogenous clinical cohort were used to train two interpretable artificial intelligence models. The models were subsequently prospectively validated on a clinical cohort of 444 scans separate to the training set. To extract input features for training the models, the scans were registered to the Montreal Neurological Institute template and counts were normalised to the cerebellar maximum. The input features represent regional brain perfusion, for regions of interest defined by the Automated Anatomical Labelling Atlas, averaged over the left and right hemisphere. Feature selection was performed using a Minimum Redundancy Maximum Relevance (MRMR) algorithm. Two regularised logistic regression models were trained to identify: 1. Abnormal scans, 2. Alzheimer's Disease. The clinical report served as ground truth. ***Results:*** The training set of 420 scans included 318 (76%) abnormal scans and 210 (50%) scans from participants with Alzheimer's Disease. The prospective validation dataset of 444 scans included 321 (72%) abnormal scans and 183 (41%) scans from participants with Alzheimer's Disease. The MRMR algorithm selected the following regions of interest (ROIs) for Model 1: supramarginal gyrus, medial temporal gyrus, lingual gyrus, supplementary motor area, caudate and for Model 2: precuneus. Model 1 identified abnormal scans with an Area Under the Receiver Operator Characteristic curve (AUROC) of 0.89, a sensitivity of 76% and a specificity of 87%. Model 2 identified Alzheimer's Disease with an AUROC of 0.86, a sensitivity of 87% and a specificity of 72%. ***Conclusion:*** The MRMR algorithm selected clinically relevant ROIs for the two models. These ROIs were subsequently represented as z-scores further supporting interpretability of the computer aided diagnosis models, alongside the prediction probability and odds ratio for each model. The proposed models demonstrated good overall performance in identifying abnormal brain perfusion scans and detecting Alzheimer's disease in prospective validation on a heterogenous clinical cohort.

EP-0497

Ultra-fast Amyloid PET Scan with uMI Panorama PET/CT Scanner

M. Wu[1], *X. Yang[1], M. Liang[1], B. Li[1], H. Zhang[1], Y. Wang[1], H. Xing[1], C. Ren[1], Z. Huang[1], C. Mao[1], L. Dong[1], Q. Ge[2], Z. Yu[2], F. Feng[1], J. Gao[1], L. Huo[1];*
[1]Peking Union Medical College Hospital, Beijing, CHINA, [2]Central Research Institute, United Imaging Healthcare, Shanghai, CHINA.

Aim/Introduction: [^{18F}]Florbetapir positron emission tomography (AV45 PET) is commonly utilized to detect cerebral amyloid-β (Aβ) deposition, with a 10-minute static scan recommended for clinical settings. There is a need for faster amyloid PET scans to reduce patients' discomfort, minimize movement artifacts, and increase throughput. The recently introduced uMI Panorama PET/CT (United Imaging Healthcare) featuring enhanced spatial resolution and sub-200ps TOF offers the potential for shorter scan duration without sacrificing image quality or efficacy to detect Aβ. This study aims to determine the minimal scan duration necessary to maintain Aβ detectability and improve scanning efficiency with uMI Panorama PET/CT. ***Materials and Methods:*** In this cross-sectional study, 38 participants (29 Aβ positive and 9 Aβ negative) from an ongoing prospective dementia cohort at Peking Union Medical University Hospital were enrolled. Each participant underwent a 10-minute AV45 PET scan with the uMI Panorama PET/CT scanner and a 3D T1-weighted brain MRI scan within three days. The list-mode PET data were reconstructed into varying durations: 10 minutes, 2 minutes, 1 minute, 45 seconds, and 30 seconds (G10min, G2min, G1min, G45s, G30s). Two trained nuclear physicians independently evaluated the randomized PET images using a 5-point scale (uninterpretable to excellent: 1-5) and provided a binary diagnosis. Standardized uptake value ratios (SUVr) of the composite cortex (frontal, lateral parietal, lateral temporal, and cingulate cortices) with the whole cerebellum as a reference were calculated to objectively discriminate Aβ status. The coefficient of variation (CoV) of the composite cortex was assessed for objective image quality. Statistical comparisons of image quality and Aβ detectability between the various fast scan groups and the G10min group were conducted. ***Results:*** There was a high level of agreement on subjective scores between the two physicians (Kappa = 0.851, P<0.001). The subjective and objective image qualities of the G2min scans were comparable to G10min scans, whereas the shorter duration scans displayed declines in image quality. Nevertheless, acceptable image quality (≥3 points)was achieved with G1min and G45s scans. The objective detection of Aβ status by cortex SUVr across all scan durations maintained consistent discriminatory efficacy (AUC = 1.00, Sensitivity = 100%, Specificity = 100%). Subjective visual

diagnosis yielded consistent accuracy for G10min, G2min, and G1min, while lower specificity was observed with G45s and G30s scans. ***Conclusion:*** A 1-min AV45 PET scan on the uMI Panorama PET/CT scanner yields adequate image quality and Aβ diagnostic efficacy for clinical use.

EP-0498

Simulation of Different Progression Stages of Alzheimer's Disease in Amyloid PET: First Study Using an Anatomical Brain Phantom

E. Di Giorgio[1], *M. A. Pirozzi[2], D. Ciotola[1], S. Imbimbo[1], G. Pecchia[1], L. Mansi[3], A. Bruno[4], M. Quarantelli[5], A. Restaino[1], M. Spadafora[1];*
[1]Nuclear Medicine Unit, Ospedale del Mare, Naples, ITALY, [2]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, ITALY, [3]CIRPS, Interuniversity Research Center for Sustainability, Rome, Italy - Medicina Futura, Acerra, Naples, ITALY, [4]Human Shape Technologies S.r.l., Naples, ITALY, [5]Institute of Biostructures and Bioimaging, National Research Council, Naples, ITALY.

Aim/Introduction: Research using human imaging to find markers of neurodegenerative diseases is a major global health challenge. In diagnostic imaging, anatomical phantoms play a crucial role in equipment characterization, including the standardization of PET scanners for multicenter studies, when quantitative images simulating different tracer concentration gradients can be generated.This study aims to evaluate the efficacy of the innovative anatomical brain phantom, StepBrain (SB) (Human Shape Technologies S.r.l., Naples, Italy), in accurately representing different stages of Alzheimer's disease (AD) as in real patients studied with an amyloid tracer. ***Materials and Methods:*** SB, a 3D-printed brain phantom replicated the anatomy of three compartments, allow simulation of the in-vivo activity distribution of gray matter (GM), white matter (WM), and dorsal striatum (DS). Two PET/CTs of the phantom were acquired using ^{18}F-FDG on the Siemens Biograph mCT scanner, in list mode, to be able to reconstruct the images with different counting statistics. In the first scan, 18F-FDG was introduced into the WM while in the second into the GM and DS, with appropriate doses to obtain concentrations equal to 120% of WM.The CT volume of the first scan was co-registered with the CT volume of the second scan using Statistical Parametric Mapping software (SPM12) to provide the second PET volume in the same space as the first one. Afterward, weighted sums of the two PET volumes were carried out to simulate twelve different phantom PET volumes with GM/WM concentration ratios from 0 to 120%, finally compared with amyloid PET of AD patients with increasing progression stages. PET images of phantom and AD patients were evaluated by three experienced independent observers. ***Results:*** Qualitatively, the phantom PET images were unanimously evaluated to be extremely realistic when compared to AD patients' images. Real patients negative for AD were well represented by the phantom with a GM/WM concentration up to 30%. Real patients with advanced AD were well represented by the phantom with GM/WM concentration from 90% to 120% ***Conclusion:*** The SB phantom can simulate both the physiological distribution of the tracer and various pathological distributions, providing simulated PET images very similar to real patients, as well as useful reference images for various AD progression degrees, even for multicenter studies. Furthermore, it could allow hypothesizing the in-vivo quantitative relationships between the amyloid accumulations of the GM and the non-specific ones of the WM, the discriminability thresholds on real images, also in the perspective of semi-quantitative analyses.

EP-0499

Differential diagnosis of occipital hypometabolism with ^{18}F-FDG PET-CT: dementia with Lewy bodies or posterior cortical atrophy?

P. Daudén Oñate[1], *P. Bascuñana[1], G. Cuesta Domingo[1], P. Nespral Torres[1], A. Berardinelli Isea[1], M. Vaillant Lopez[1], M. Zapardiel Martínez-Falero[1], J. Matias-Guiu Antem[2], M. Cabrera Martin[1];*
[1]Nuclear Medicine Department, Hospital Clinico San Carlos, Madrid, SPAIN, [2]Neurology Department, Hospital Clinico San Carlos, Madrid, SPAIN.

Aim/Introduction: Posterior cortical atrophy (PCA) and Dementia with Lewy bodies (DLB) are neurodegenerative entities both associated with occipital metabolism on ^{18}F-FDG PET-CT studies. Relative sparing of posterior cingulate has been described as a differentiating feature of Lewy body Dementia, but although some additional areas have been described (ej. frontal in DLB), the literature is sparse and series are small (Whitwell JL et al. JNM, 2017). We aimed to identify differential regional patterns of 18F-FDG PET-CT hypometabolism that allow differential diagnosis of PCA and DLB. ***Materials and Methods:*** 22 patients with a diagnosis of PCA and 61 with disgnosis of DLB, who underwent 18F-FDG PET-CT scans between may-2012 and november-2024 were included. The pattern of involvement of both entities was analyzed based on voxels with SPM12, T test for two independent samples ($p<0.001$). Regional hypometabolism was assessed compared with a control cohort (n= 62). The covariates were sex and age. ***Results:*** The mean age of patients with PCA was 61.55 years (sd 6,617); 77.3% women, DLB mean age of 74.93 (sd 7,127); 45.9% women. Compared to healthy controls, a lower bilateral temporo-parieto-occipital metabolism was observed in both groups. The DLB group showed lower metabolism compared to the PCA in the frontal lobe (bilateral superior frontal gyrus, superior, medial and orbital frontal lobe, and right anterior cingulate). Regarding DLB, PCA showed lower metabolism in the right occipital, temporal, cuneus/precuneus, superior parietal, and right fusiform and angular gyri. ***Conclusion:*** DLB and PCA show an important overlap in the pattern of hypometabolism that makes differential diagnosis difficult based solely on visual assessment, but the extent of hypometabolism at the frontal lobe or the greater right involvement suggests the diagnosis of DLB or ACP respectively.

EP-0500

Whitematter impairment distinctly associated with cerebral metabolism in Parkinson's disease

M. Wang[1], *W. Han[1], L. Lin[1], Y. Jiao[1], Y. Hu[2], Y. Yang[3], P. Fu[1], C. Zhao[1];*
[1]The First Affiliated Hospital of Harbin Medical, Harbin, CHINA, [2]Central Research Institute, United Imaging Healthcare Group, Shanghai, CHINA, [3]Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA.

Aim/Introduction: Patients of Parkinson's disease (PD) may suffer with heterogeneous white matter integrity damage and metabolic disruption. The purpose of this study was to investigate white matter microstructure injury and its relationship with cerebral metabolism in Parkinson's disease. ***Materials and Methods:*** A total of 37 subjects were included in this study, including 25 patients with PD and 12 age- and sex-matched healthy individuals. Basic clinical information and clinical cognitive scale assessments were collected, including the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA). All subjects underwent an integrated ^{18}F-fluorodeoxyglucose

(18F-FDG) PET/MR scan, acquiring high-resolution T1-weighted structural images, diffusion-tensor images and 18F-FDG images. Normalized PET standardized uptake value ratio (SUVR) images were obtained using the FSL. Brain region without significant SUVr difference between PD and HC subjects was set to be reference region. Anatomical Automatic Labeling (AAL) atlas was utilized in ROI-wise analysis to evaluate abnormalities in brain metabolism. Auto Fiber Quantification (AFQ) was utilized to calculate tract-wise diffusion properties of 20 major white matter tracts and further divide each fiber into 100 nodes. ***Results:*** PD patients showed reduced mean MMSE and MoCA scores compared to HC subjects ($P < 0.05$). PD patients showed higher mean diffusivity (MD) and axial diffusivity (AD) along right corticospinal tract (CST) compared to HC. The microstructural change of CST was mainly located in parietal part (node 67-100). Hypermetabolism was found in right paracentral lobule, which connects with the parietal part of right CST, and positively correlated with MD and AD. ***Conclusion:*** We observed microstructural change and hypermetabolism in PD patients. Change of white matter microstructure in CST, which was related to the control of random muscle movement, was significantly correlated with cerebral metabolism. We further found that there was structural connection between region with metabolic disruption and white matter injury. These results may provide imaging evidence for investigating the pathology of PD.

EP-0501

The association of sleep spindles and Alzheimer's disease pathology

A. Buchal[1], *D. Temizyürek[1], E. Doering[1], J. Wahlen[1], V. Dzialas[1], K. Giehl[1], H. Theis[1], E. Jäger[1], A. Bauer[2], T. Kroll[2], A. Matusch[2], P. Krapf[2], B. Neumaier[2], C. Lerche[2], L. Tellmann[2], S. Frensch[2], P. Zeyen[1], F. Sand[1], N. Richter[1], F. Jessen[1], Ö. Onur[1], A. Ramirez[1], G. Bischof[1], T. van Eimeren[1], D. Elmenhorst[2], A. Drzezga[1], M. Hönig[1];*
[1]University Hospital Cologne, Cologne, GERMANY,
[2]Forschungszentrum Jülich, Jülich, GERMANY.

Aim/Introduction: Accumulating evidence suggests that Alzheimer's disease (AD) is associated with decreased deep sleep (N3) and lower sleep spindle expression, which may be due to a bi-directional relationship between disturbed sleep and the accumulation of AD pathology. In this study, we investigated the regional link between AD pathology and changes in sleep spindle characteristics using PET imaging and a portable sleep-monitoring device. ***Materials and Methods:*** 14 healthy controls (HC; M(Age) = 63.57 (7.23), Sex (M/F) =4/10) and 14 patients with MCI/early AD (M(Age) = 64.79 (7.42), Sex (M/F) =7/7) were included from the "Tau Propagation Over Time" (T-POT) study. For all participants, [^{11}C]-PIB (amyloid) and [^{18F}]-AV1451 (tau) PET scans were available, which were normalized and intensity standardized to the whole cerebellum. Sleep monitoring was performed at home of the participants using the portable EEG-headbands by Beacon Biosignal, which is a reliable alternative to the gold-standard polysomnography (PSG). Sleep recordings were performed within six months of the PET acquisition and for three consecutive nights. For the current analysis, only recordings of sufficient quality (> 80%) were included. Sleep spindle characteristics were defined based on the raw EEG data using a self-implemented python script based on the 'spindle detect' algorithm of the Yasa toolbox. Spindle parameters including number, duration, amplitude and frequency were extracted and averaged across the recordings with sufficient quality and across the five EEG channels. First, respective spindle characteristics were compared between the groups using non-parametric tests. Next, whole-brain voxel-wise analyses were conducted in SPM12 to assess the association between spindle parameters and regional tau and amyloid burden (pFWE < .005). All analyses were corrected for age and N3 duration (given the dependence of spindle occurrence during N3 phase). ***Results:*** MCI/AD patients showed significantly higher amplitudes than HC ($p = .033$), but no differences in terms of spindle number, frequency or duration. The whole-brain voxel-based analysis yielded that spindle amplitude was linked to greater tau burden in the left hippocampus. Interestingly, no significant association was observed in terms of amyloid burden. ***Conclusion:*** The current findings provide evidence for changes in sleep spindle characteristics being linked to hippocampal tau pathology. This may be due to the initial location of tau aggregation in AD (i.e., entorhinal cortex/hippocampus). It remains unknown whether this observation represents a causal or consequential relationship.

EP-0502

Assessing the Predictive Capability of FDG-PET in Primary Progressive Aphasia

G. Cuesta Domingo[1], *P. Nespral[1], P. Dauden[2], P. Bascuñana[1], M. Vaillant[1], A. Berardinelli[1], J. Matias-Guiu[3], M. Cabrera Martín[1];*
[1]Department of Nuclear Medicine, Hospital Clínico San Carlos, Madrid, SPAIN, [2]Hospital Clínico San Carlos, Madrid, SPAIN, [3]Department of Neurology, Hospital Clínico San Carlos, Madrid, SPAIN.

Aim/Introduction: Primary progressive non-fluent primary aphasia (PPNFA) may be the onset of several neurodegenerative diseases. These symptoms may progress to syndromes such as frontotemporal dementia (FTD), corticobasal degeneration (CBD) or progressive supranuclear palsy (PSP). The aim of this study was to assess whether variations in brain metabolism observed on initial PET/CT-^{18}F-FDG can predict progression to the different clinical syndromes. ***Materials and Methods:*** We performed a retrospective study including 67 patients diagnosed with PPNFA between 2011-2022, who had undergone PET/TC-^{18}F-FDG after first symptoms manifestation. Images were spatially normalized to a brain template and corrected to whole brain uptake using PMOD software. Subsequently, images from patients in different progression groups were compared with a group of healthy controls using Statistical parametric mapping (SPM), corrected for multiple comparisons. ***Results:*** Of the 67 patients (56% women; mean age: 72 years), 17 developed PSP, 7 CBD, 13 FTD and 3 ALS (the latter not included in the analysis). When analyzing the images in SPM, we observed that patients in all groups showed hypometabolism affecting to different degrees the frontal lobe, temporal lobe and insula compared to the control group. However, patients who developed CBD showed a right prevalence and involvement of the caudate and putamen, while patients with PSP did not present this laterality but showed hypometabolism in the thalamus and central sulcus. Patients who progressed to FTD showed the characteristic pattern of this syndrome with left laterality and preservation of the basal ganglia. ***Conclusion:*** In summary, brain PET/CT-^{18}F-FDG might contribute to predict which syndrome patients diagnosed with PPNFA will develop, by showing specific patterns of metabolic alteration months before they progress.

EP-0503

^{89}Zr-DFO-AP-101 PET/CT first in human imaging for amyotrophic lateral sclerosis

E. Croteau[1,2,3], *S. Tremblay[1], A. Tétu[1,2], E. Espinosa[1,2,3], É. Lavallée[1,2,3], S. Côté-Bigras[1,2], S. Ait-Mohand[1], M. Houde[1,2], E. E. Rousseau[1], M. Maier[4], M. salzmann[4], E. Lareau-Trudel[1,5], S. Gosselin[1,5], E. Turcotte[1,2,3], B. Guérin[1,2,3];*
[1]Sherbrooke University, Sherbrooke, QC, CANADA, [2]Centre de Recherche du Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, CANADA, [3]Centre d'imagerie moléculaire de Sherbrooke, Sherbrooke, QC, CANADA, [4]Neurimmune AG, Schlieren, SWITZERLAND, [5]Neurology department, CIUSSS de l'Estrie-CHUS, Sherbrooke, QC, CANADA.

Aim/Introduction: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease resulting from the loss of motor neurons. Mutations in superoxide dismutase-1 enzyme (SOD1) are the second most common genetic cause of ALS and misfolded SOD1 (mSOD1) is also increased in sporadic forms of ALS.1 Currently, there is no approved diagnostic tool for ALS. We previously reported, in a transgenic mouse model, that 89Zr-DFO-AP-101 could detect mSOD1 involved in apoptosis and ALS.2 The aim of this study is to evaluate 89Zr-DFO-AP-101 biodistribution and dosimetry in humans by PET imaging. ***Materials and Methods:*** This ongoing study follows patients with ALS and healthy participants for 10 days after 89Zr-DFO-AP-101 injection. Whole-body PET/CT are performed at 120 minutes, 1, 3, 7 and 10 days on a Siemens Biograph Vision 600, along with clinical biochemistry and vital signs measurements. Biodistribution and dosimetry are performed from regions of interest to obtain organ time-integrated activity. We assess both the kinetic of 89Zr -DFO-AP-101 in the different organs, and the absorbed and effective doses. So far, five healthy participants have been recruited and imaged. Two ALS patients have been recruited and will be imaged in the upcoming weeks. The study should be completed by the fall of 2024. ***Results:*** Five healthy volunteers (2 males, 3 females) aged 63±8 years with a BMI of 27±5 kg/m2 were imaged. They received 41±4 MBq of 89Zr -DFO-AP-101 by intravenous injection without any serious adverse or clinical effect. Total urinary excretion was 4%, and hepatobiliary excretion was 2%. At 2h post-injection, 44±5% of the radiotracer remained in the blood pool, with an effective half-life of ± 53 h. According to sex-specific dosimetry, the liver is the dose-limiting organ with 2.24 mSv/MBq (male) and 2.65 mSv/MBq (female). The effective dose was 0.48 mSv/MBq (male) and 0.54 mSv/MBq (female). ***Conclusion:*** The PET 89Zr-DFO-AP-101 tracer is safe, its clearance is predominantly physical, with an early urinary excretion. Therefore, this tracer can be safely used in patients. Upcoming data in ALS patients will validate its capacity to measure mSOD1 levels in vivo for diagnosis and treatment monitoring. ***References:*** 1. Maier M, et al. Sci Transl Med. 2018;10(470). 2. PET-amyloid in newly diagnosed multiple sclerosis: biomarker of white matter damage and disease activity

A. Piñeiro[1], *J. Barrios López[2,3], M. Pérez García[4], F. Segovia Román[5], E. Triviño Ibáñez[1,6];*
[1]Nuclear Medicine Department, Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [2]Neurology Department, Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [3]Doctoral student of the PhD program in "Medicina clínica y salud pública" at the University of Granada from 2022, Granada, SPAIN, [4]Radiology Department, Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [5]Departamento de Teoría de la Señal, Telemática y Comunicaciones. Universidad de Granada, Granada, SPAIN, [6]Instituto de Investigación Biosanitaria ibs.GRANADA, Granada, España., Granada, SPAIN.

Aim/Introduction: To evaluate amyloid uptake in damaged white matter (DWM) and normal-appearing WM (NAWM) in patients with newly diagnosed multiple sclerosis (MS) and the relation to clinical status. ***Materials and Methods:*** This observational and prospective study enrolled patients with recent MS onset between March to May 2023. Participants underwent a neurological examination, disability (EDSS), neuropsychological (SDMT) and quality of life (EQ-5D) assessment, brain MRI and $^{[18F]}$-florbetaben PET in early (0-10') and late phase (90') post-i.v. Patients were classified as having highly active MS if they had ≥2 relapses (with/without sequelae) and increasing lesional burden, or a relapse with severe sequelae (EDSS score≥ 2). MRI and PET images were co-registered, and results are presented as standardized uptake values (SUV), using cerebellum (SUVRc) and NAWM (SUVRwm) as the reference region. ***Results:*** ten patients were included (35.10±11.32 years; 70% women). We found, both in early- and late-phase, a lower mean SUVR in DWM compared to NAWM ($p<0.01$) in all patients. SUVRwm correlated with EQ-5D index ($r:0.652$, $p=0.041$). A trend toward lower SUVRwm was observed in the highly active onset group compared to the non-highly active group (0.62±0.43 vs. 3.62±3.20, $p>0.05$). Considering only highly active onset patients, SUVRwm correlated with EDSS score (rho = -0.896, $p=0.0031$). The lesions analysis showed a negative correlation between SUVmean in DWM with EDSS and SDMT scores (rho: -0.534, $p=0.004$ and rho: -0.670, $p=0.006$, respectively); and SUVRc with SDMT (rho: -0.585, $p=0.022$). ***Conclusion:*** Preliminary results of this work in progress suggest that amyloid PET could be a promising tool to monitor myelin changes in patients with MS and may have a predictive role in disease activity and quality of life.

EP-0505

Utilizing Amyloid PET SUVr's as features in an RF classifier to aid in the prognosis of Alzheimer's Disease

H. Morgan, *J. Thorpe, E. Twyeffort, S. Michopoulou;*
University of Southampton, Southampton, UNITED KINGDOM.

Aim/Introduction: Early diagnosis of Alzheimer's Disease (AD) is a key step in the development of appropriate treatment for this disease. Current diagnoses and prognoses clinicians make are aided by standard cognitive tests that assess a patient's function. Amyloid PET is a sensitive but not specific early marker of AD. In this paper, we build a Machine Learning (ML) model to improve the current prognosis method and identify potential markers that indicate a patient's future decline from Mild Cognitive Impairment to Alzheimer's Disease. We hypothesise that patients can be differentiated to a higher accuracy through a model that combines amyloid Positron Emission Tomography (PET) Standard Uptake Value ratios (SUVr) with current cognitive test scores than by a cognitive test score model alone. ***Materials and Methods:*** We process and analyse 462 PET images taken from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database and extract from them the amyloid burden of that patient in the form of an SUVr. We build an ML model trained on a combination of patient information (age, sex and education), baseline cognitive test scores and these amyloid PET SUVr to classify patients on whether they will progress from MCI to AD within 24 months. We are interested in potential information within the 166 clinical regions of the brain in terms of determining the future cognitive state of a patient. We use a feature selection algorithm in the

form of a Maximum Relevance, Minimum Redundancy (mRMR) to determine the most relevant brain regions to the task. This is backed up by an Explainable Artificial Intelligence (XAI) model in the form of a Local Interpretable Model-Agnostic Explanations (LIME) plot that determines regions important to individual patient classifications. ***Results:*** The Area under the Receiver Operating Characteristic (auROC) for cognitive tests alone is 0.78, for amyloid PET alone it is 0.83. When we combine cognitive tests and amyloid PET the auROC is 0.91. LIME suggests that the Precuneus left, Anterior cingulate cortex pregenual left, middle temple left, superior frontal gyrus (medial orbital) left and inferior temporal gyrus left are all important regions in the differentiation of patients along the Alzheimers timeline. ***Conclusion:*** The results suggest that our model improves on the current methods for prediction of progression to AD with increased accuracy and higher auROC score for the combination model. We found several regions appear to be indicators of cognitive function and decline of patients.

Amyloid PET: Discrepancies between Visual and Quantitative Analysis in a Cognitively Normal Elderly Population.

D. Rivas-Navas[1], *P. Solis-Urra[2], J. Villa-Palacios[1], I. Esteban-Cornejo[2,3,4], M. Gomez-Río[1,4];*
[1]Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [2]Department of Physical Education and Sports, Faculty of Sport Sciences, Sport and Health University Research Institute (iMUDS), University of Granada., Granada, SPAIN, [3]Centro de Investigación Biomédica en Red Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Instituto de Salud Carlos III., Madrid, SPAIN, [4]Ibs. GRANADA Bio Sanitary Research Institute, Granada, SPAIN.

Aim/Introduction: Quantitative analysis of amyloid PET is gaining ground in clinical practice. However, contrasting visual analysis with quantitative methods is necessary to establish the clinical value of such quantification. The aim of this study is to compare visual assessment and two quantitative analysis methods in a population of cognitively normal older adults. ***Materials and Methods:*** This cross-sectional study included 90 participants from the AGUEDA trial (Code: NCT05186090). Amyloid PET scans ([18F]-florbetaben) were evaluated visually (by two expert readers masked to any type of information) and quantitatively using centiloid methodology (positive >12 centiloids) and standardized uptake value ratio (SUVR) estimation in consensus target regions (VOIs) extracted from the syngo.via platform. ***Results:*** The mean age of participants was 71.75 ± 3.96 years, 57.8% female, and a mean education level of 11.54 ± 4.90 years. Of the total studies, 66 (73.3%) were considered negative and 8 (8.9%) positive both visually and quantitatively. Six (6.7%) cases were visually considered 'indeterminate': quantitatively, 5 were negative and 1 positive. In the remaining 10 (11.1%) studies, there were discrepancies between visual assessment (considered negative) and centiloid scale. In this subgroup of discrepant cases, centiloid value showed a strongly positive correlation with SUVR in parietal (r=0.893; p<0.001) and temporal (r=0.864; p<0.001) VOIs and a moderate correlation with frontal VOI (r=0.831; p=0.003). Additionally, mean SUVR values in all locations were significantly higher compared to the SUVR of scans considered negative visually and quantitatively (p<0.017). ***Conclusion:*** Preliminary results of this study show discrepancies between visual and quantitative assessment of amyloid PET in 1 out of 10 cognitively normal older adults, with greater magnitude in parietal and temporal regions.

Nucleare Azienda sanitaria universitaria Giuliano Isontina (ASU GI), Trieste, ITALY, [6]Medicina Nucleare - Azienda Ospedaliera Perugia, Perugia, ITALY, [7]Medicina Nucleare - Azienda Ospedaliero-Universitaria di Parma, Parma, ITALY, [8]Medicina Nucleare - Fondazione Salvatore Maugeri di Pavia, Pavia, ITALY, [9]Nuclear Medicine Unit, Bolzano, Bolzano, ITALY, [10]Istituto Nazionale di Fisica Nucleare - INFN, Genova, Genova, ITALY.

Aim/Introduction: [18F]Amyloid PET is routinely used to ascertain if the patient is in the Alzheimer continuum filling the "A" portion of the ATN classification. In this context MR or [18F]FDG PET or early frames of [18F]amyloid PET (FBB - perfusion-like information) could be used to fill the "N" portion of the classification. In patients with a clinical suspicion of an atypical form of Alzheimer's disease, the presence or absence of Amyloid plaques and the pattern of neurodegeneration are crucial for a definite diagnosis. We aimed at investigating whether the early frames of the FBB are comparable to the FDG PET images in atypical forms of AD and to assess the optimized protocol to be used. ***Materials and Methods:*** Recruitment of the AMY-ITA multicenter study (conducted in 8 Italian centers) has been closed. 107 patients have been scanned, and data from brain magnetic resonance imaging (T1 3D 1mm isotropic acquired less than 3 months from PET scans), FBB (early frames acquired from 0 to 15 min and reconstructed at 0-5, 0-10 and 0-15 min/frame and late frames acquired from 90 to 110 and reconstructed at 90-100 and 90-110 min/frame) and FDG PET scan were collected. Clinical data including initial clinical suspect and final clinical diagnosis at follow up (1 year later) were collected. FDG and FBB were visually and semi-quantitatively compared after segmenting MR and PET using Freesurfer. ***Results:*** Spearman test of visual scores (between early-frame FBB PET and FDG PET) showed statistically significant correlations (p< 0.0001)Although semi-quantitatively some areas (for example cerebellum and pons) showed (expected) significant differences between FDG and FBB, on a whole, cortical similarity was very high. When comparing 0-5, 0-10 and 0-15 minutes acquisitions with FDG, the 0-5 minute frame showed the highest pearson correlation (>96). Semi-quantification using know methods (SUVr, ELBA and TDR) showed however no statistical differences between 0-5, 0-10 and 0-15 frames. ***Conclusion:*** Early-phase FBB PET acquisitions, in atypical AD forms, correlated qualitatively and semi-quantitative well with FDG PET demonstrating its possible use as a surrogate marker. The 0-5 minutes of FBB correlated better than 0-10 and 0-15 minutes with FDG. ***References:*** Eur J Nucl Med Mol Imaging 2022 Oct;49(12):4097-4108. doi: 10.1007/s00259-022-05846-1. Epub 2022 Jun 2. A comparison of advanced semi-quantitative amyloid PET analysis methods

Aim/Introduction: High-dose intravenous steroid treatment (HDIST) represents the first choice of treatment for multiple sclerosis (MS) relapses. Chronic oral glucocorticoid (GC) administration correlates with bone loss whereas data regarding HDIST in MS are still conflicting. The aim of this study was to evaluate Bone Mineral Density (BMD) values in newly diagnosed MS patients before HDIST and during a 12-month follow-up in correlation with bone turnover markers (BTMs) and a direct comparison with healthy control subjects. ***Materials and Methods:*** 25 newly diagnosed MS patients (12-women) and 13 age-matched (9-women) healthy controls were prospectively enrolled meeting the following eligibility criteria: age 18-45yrs, fully ambulatory, women with normal menstruation. Exclusion criteria: history of any chronic disease, previous GC-treatment in any dosage regimen. Patients received 1000mg Methylprednisolone intravenously daily for 5 consecutive days. 3/25pts were excluded due to mobility impairment, 4/25 were lost to follow-up. In the remaining 18pts (9-women) as well as in the healthy controls serum levels of:Calcium, Phosphorus, Albumin, Magnesium, Creatinine, 25-OH-D, Parathyroid Hormone, Thyroid Hormones, Bone-fraction Alkaline-Phosphatase (BALP), N-terminal propeptide procollagen type-1 (P1NP), C-terminal peptide type of collagen (CTx), Receptor-Activator of Nuclear Factor Kappa-β-Ligand (RANK-L), Osteoprotegerin, Sclerostin, Dickkopf-1 (DKK-1), Periostin, Interleukins (IL)-1β,6,17 were determined prior to GC-administration and consecutively the days:2-4-6-90 and months:6-12. BMD of both hips and lumbar spine as well as whole-body measurement of adipose/lean tissue were assessed with Dual-X-ray-Absorptiometry-(DXA)-scan, prior to GC-administration and consecutively every six months. ***Results:*** In the patient group a significant decrease in total left hip BMD was observed between baseline and month 12 (mean difference:0,0113±0,0045g/cm2,p=0.022). No significant differences between patients and healthy controls were observed at baseline while at 12-month f-up left femoral neck BMD was marginally higher in the healthy controls group (mean difference:0,098±0,047g/cm2,p=0.053). Bone formation markers, P1NP and BALP, showed an initial non-significant fall (P1NP day 6:-0.414±0.128ng/mL, BALP day 4:-0.864±0.334μg/L) followed by a significant increase in day 90 (P1NP:+0.567±0.13ng/mL,BALP:+1.838±0.464μg/L,p<0.05). ***Conclusion:*** Despite the small sample size we aimed to elucidate the impact of HDIST on BMD and simultaneously on biochemical parameters of bone metabolism in newly diagnosed MS patients; HDIST seems to have a long term negative effect on BMD in this group of patients. The observed transient increase in bone formation markers -90 days after GC administration- probably indicates a high bone turnover phase as a "response" to the adverse effects of GC on bone-metabolism. More prospective studies with larger sample size on similarly selected patients should be performed.

EP-0509

Combining [18F]PI-2620 tau PET binding characteristics to quantitative susceptibility mapping in progressive supranuclear palsy

M. Xin[1], *P. Yuan[1], G. Huang[1], J. Hao[2], C. Zhang[1], G. Huang[3];*
[1]Renji hospital, School of medicine, Shanghai Jiao Tong university, Shanghai, CHINA, [2]Central Research Institute, UIH Group, Shanghai, China, Shanghai, CHINA, [3]Shanghai Key Laboratory of Molecular Imaging, Shanghai University of Medicine and Health Sciences, Shanghai, CHINA.

Aim/Introduction: Progressive supranuclear palsy (PSP) is a neurodegenerative disease and one of the common causes in atypical Parkinsonism. Hidden onset, rapid progression, difficulty in direct diagnosis together with poor prognosis, all bring obstacles to the proper diagnosis and differentiation of PSP in clinical practice. Based on the four-repeat (4R) tauopathy in PSP, it is beneficial for second-generation tau PET tracers in visualizing its pathophysiological features, thus shedding light on the early and precise diagnosis of the disease. In this study, we aimed to investigate the performance of [18F]PI-2620 tau PET uptake characteristics combined with quantitative susceptibility mapping (QSM) in patients of PSP. ***Materials and Methods:*** Seventeen participants (nine patients diagnosed with PSP and eight age-matched healthy controls) were retrospectively enrolled for this study. All participants underwent [18F]PI-2620 PET imaging together with 3.0 T brain multimodal MRI scans. SUVR of tau uptakes in brain regions including bilateral pallida, midbrain and pons were analyzed, with inferior cerebellum cortex as the reference region. For QSM data, regions of interest were manually drawn within bilateral caudates, pallida, subthalamic nuclei (STN), substantia nigra and red nuclei, to generate mean magnetic susceptibility (MS) values. Unpaired t tests were used to compare the differences of SUVR and MS values in each brain region between the two groups. ***Results:*** Quantitative findings on [18F]PI-2620 PET images determined that patients with PSP had definitely higher tau uptakes in the left pallidum ($p<0.01$), right pallidum ($p<0.001$), and mean value of bilateral pallida ($p<0.001$), when compared to the healthy controls. The MS values of right caudate ($p<0.05$), left pallidum ($p<0.01$), mean value of bilateral pallida ($p<0.05$), left STN ($p<0.001$), right STN ($p<0.001$), and mean value of bilateral STN ($p<0.001$) were significantly higher in PSP than the healthy participants. ***Conclusion:*** A combined use of second-generation [18F]PI-2620 tau PET imaging and QSM modalities preliminarily revealed the unique tau deposition and iron quantification in the diagnosis of PSP, rendering a promising basis for further study of the radiological-pathological mechanism of pallido-nigro-luysian axis.

[2]Nuclear Medicine Department, University of Leipzig Medical Center, Leipzig, GERMANY.

Aim/Introduction: PET image analyses can be biased by mass dose effects, where cold tracer binds to an excessive proportion of the target molecules. If target density is low, as for example for tau pathology in progressive supranuclear palsy (PSP), the mass dose could have an impact on tracer binding. This study aimed to estimate the effect of tracer mass doses on ^{18}F-PI-2620 scans from Alzheimer's disease (AD) and PSP patients. ***Materials and Methods:*** Five AD and five PSP patients underwent two dynamic ^{18}F-PI-2620 PET scans. Every patient received a low tracer mass injection (0.31 ± 12 µg PI-2620) at the first PET visit, and a high mass dose (44.56 ± 2.82 µg PI-2620) at the second PET visit. Activity values (180 ± 11 MBq 18F-PI-2620) were kept similar for both injections. Three blinded readers evaluated the scans independently. MRTM2 was used to estimate DVRs, using a relevant set of ROIs [1]. A model of target occupancy as a function of mass dose was fitted to the data [2]. The possible bias in DVR values was assessed using a real-world range of mass doses. ***Results:*** Visual assessment (positive/negative) was not impacted by high mass dose administration in any region. The real-world mass doses for ^{18}F-PI-2620 were <1 µg/mL for 98% of the batches, as determined from the global tracer productions during the last years. This implies that the maximum injected mass dose would be <10 µg, when using the maximum allowed volume (10 mL). Under these conditions, the averaged results of the occupancy model for AD patients show that the bias in DVR values would be <2%. This degree of bias is below the test-retest variability measured for ^{18}F-PI-2620 [1]. As DVR values for both scans were very similar for PSP patients, no relevant effect of mass dose could be measured, even at the highest mass dose used. ***Conclusion:*** The effect of ^{18}F-PI-2620 high mass doses on visual and quantitative PET readouts is negligible for both AD and PSP in real-world conditions, allowing tracer Usage several half-lives after the end-of-synthesis (e.g. after longer dose transportation). This provides compelling support for the use of ^{18}F-PI-2620 to detect AD and PSP tau over a broad range of mass doses in future studies and clinical evaluations. ***References:*** [1] Bullich et al., JNM, 2020;61(6):920-927; [2] Madsen et al., Nuc Med Biol, 2011; 38(8):1085-1091.

EP-0511

Interobserver agreement in the visual analysis of brain PET/CT studies with Tau tracer [18F]PI-2620 in patients with Down syndrome.

P. Stefaneli Mormandi[1], *P. Zaragoza Ballester[2], M. Calls[1], S. Ramírez Aguirre[3], A. Fernandez Leon[1], G. Guzman[1], C. Soldevila Lozano[1], S. Castejon[1], M. Velasco Nuño[1], J. Duch[1], J. Fortea[1], V. Camacho[1], A. Flotats Giralt[1];*

[2]Hospital Universitario 12 de Octubre, Madrid, SPAIN,
[3]Fundación Universitaria Sanitas, Bogotá, COLOMBIA.

Aim/Introduction: Down syndrome (DS) is considered a genetic form of Alzheimer's disease (AD) and a unique model for the study of its pathophysiology. The [18F]PI-2620 PET tracer reflects the neurofibrillary deposition of the Tau protein.The aim of the study was to assess interobserver agreement in the visual analysis of brain PET studies with [18F]PI-2620 in patients with DS. ***Materials and Methods:*** 80 brain PET/CT studies (20 healthy controls and 60 subjects with DS) performed 45 minutes after e.v. administration of 5 mCi of [18F]PI-2620 were analyzed. The images were visually evaluated by six independent nuclear medicine physicians with different levels of experience according to the presence/absence of tracer deposits in the mesial temporal (MT), fusiform gyrus (FG), lateral anterior temporal (LAT), lateral posterior temporal (LPT), occipital, posterior cingulate/precuneus (PC), parietal, frontal, dentate nucleus (ND) and striatum. We considered a positive study for AD if detected deposits in LAT, occipital, PC, parietal and frontal. Interobserver agreement (Fleiss Kappa coefficient) was assessed in the analysis of the described regions and in the final PET/CT categorization for the diagnosis of AD. ***Results:*** The interobserver agreement for the diagnosis of AD was very high (Kappa 0.9; p <0.001). A high agreement was also observed in the assessment of the LPT, PC, frontal and parietal regions (Kappa>0.9; p<0.001). The agreement for the diagnosis of AD was equal between expert and non-expert observers (Kappa 0.9; p< 0.001). In the assessment of areas not relevant to AD, the agreement was greater between experts (MT region: Kappa 0.7 vs 0.2; p< 0.001 and FG: Kappa 0.6 vs 0.2; p< 0.001). ***Conclusion:*** PET/CT with [18F]PI-2620 is a highly reproducible technique with high interobserver agreement in the diagnosis of AD in patients with DS, mainly in the evaluation of the areas relevant to its diagnosis.

Predicting antiepileptic drug response through the coupling of glucose metabolism and cerebral blood flow in temporal lobe epilepsy patients

S. Jia, *K. Guo, Z. Quan, X. Meng, G. Li, M. Wang, T. Han, J. Wang, J. Wang, F. Kang;*
Xijing Hospital, Xi'an, Shaanxi, CHINA.

Aim/Introduction: Anti-epileptic drugs (AEDs) therapy is the first line treatment scheme for temporal lobe epilepsy (TLE). However, even with the use of a combination therapy of multiple appropriate AEDs at a reasonable dosage and sufficient duration, approximately 30%-40% of patients still are still unable to control seizures. The development of resistance to AEDs is related to multiple factors, but the impact of these factors on newly diagnosed epilepsy patients who have not taken AEDs is still unclear, and there is a lack of feasible methods for early prediction of AEDs response in clinical practice. ***Materials and Methods:*** 32 newly diagnosed TLE patients were prospectively enrolled, and 23 healthy volunteers matched in age and gender were also included. ^{18}F-FDG positron emission tomography (PET) and arterial spin labeling (ASL) magnetic resonance imaging (MRI) were obtained from a simultaneous PET/MRI scanner, and CBF was calculated based on ASL. The changes in seizure frequency of TLE patients after 2 years of appropriate AEDs treatment were compared with the situation during PET/MRI scans. Patients were divided into drug response group (seizure frequency reduction ≥ 50%) and drug resistance group (seizure frequency reduction<50%). By spatial standardization and data normalization, the CBF, SUV to SUV/CBF ratio within the gray matter mask of all subjects were obtained, and further normalized to Z score for comparison between different subjects. ***Results:*** Compared with healthy controls, patients with TLE showed a decrease in CBF-SUV coupling and a significant difference in SUV/CBF ratio within the gray matter mask. In patients with TLE, the decrease in SUV/CBF ratio mainly occurs in the thalamus, insula, hippocampus, and superior temporal gyrus, while the increase in SUV/CBF ratio

mainly occurs in the middle frontal gyrus, posterior central gyrus, cerebellum, and occipital lobe (P<0.05, FDR corrected). Compared with the drug response group, there was a significant difference in SUV/CBF ratio among patients in the drug resistance group. In the drug resistance group, the increase in SUV/CBF ratio mainly occurred in the frontal and occipital lobes (P<0.05, FDR corrected). ***Conclusion:*** There are differences in glucose metabolism and CBF coupling among TLE patients with different AEDs response. Based on the coupling of glucose metabolism and CBF, it is helpful to predict AEDs response in TLE patients.

Understanding the Interplay Between Cerebral Glucose Metabolism and Functional Connectivity in the Healthy State and Alzheimer's Disease

S. Xie[1], *I. Yakushev[2,1];*
[1]Graduate School of Systemic Neurosciences, Munich, GERMANY, [2]Department of Nuclear Medicine, School of Medicine, Klinikum Rechts der Isar, Technical University of Munich, Munich, GERMANY.

Aim/Introduction: Regional glucose hypometabolism and disrupted functional connectivity (FC) at rest have been proposed as biomarkers of Alzheimer's disease (AD). However, there are ongoing debates about the nature of disrupted FC in AD: if it is an independent process or an epiphenomenon of regional neurodegeneration. In the latter case, one would expect a stronger association of regional glucose hypometabolism and FC in AD than in the healthy state. To address this question, our study summarized evidence on associations between regional glucose metabolism and FC in the healthy state and AD. ***Materials and Methods:*** We conducted a comprehensive literature search on Google Scholar and PubMed using various combinations of keywords " PET," "fMRI," "functional connectivity," "healthy," and "Alzheimer's disease". It resulted in 10 studies in healthy subjects and 8 studies in patients with AD (in comparison with healthy control individuals). ***Results:*** Overall, the results were consistent across the studies. In the healthy state, FC and glucose metabolism were associated positively (Table 1). In AD, the strength of the (positive) association was consistently weaker than in control subjects, the association was not significant or negative (Table 2). No study reported a stronger positive association in AD than in control subjects. Both in the healthy state and AD the above associations were evident at the regional and global (whole brain) level. ***Conclusion:*** Our study provides unequivocal evidence for a positive association between glucose metabolism and FC in the healthy state. Furthermore, this coupling is consistently disrupted in AD, where weaker positive associations, not significant or even negative associations between glucose metabolism and FC have been reported. Thus, functional disconnectivity in AD is not an epiphenomenon of regional degeneration. In fact, studying patterns of decoupling between glucose metabolism and FC might provide valuable insights into the mechanisms of neurodegenerative disorders, beyond AD.

EP-0514

Skull glucose uptake as a novel biomarker for Parkinson's disease

W. Lu, *J. Lu;*
Xuanwu Hospital Capital Medical University, Beijing, CHINA.

Aim/Introduction: Parkinson's disease (PD) is often accompanied with osteoporosis. Additionally, the impairment of motion and coordination abilities in PD can further impact bone health. A growing number of studies have demonstrated that the skeleton is an endocrine organ that is involved in glucose metabolism and plays a significant role in glucose homeostasis. However, it remains unclear whether metabolic changes occur in the bones of PD patients. The aim of this study was to investigate whether glucose uptake alterations occur in the skulls of patients with PD using the integrated positron emission tomography/magnetic resonance (PET/MR) scanner. ***Materials and Methods:*** 18F-fluorodeoxyglucose (18F-FDG) PET and T1-weighted structural MR data from PD patients (n = 34) and healthy controls (HC) (n = 25) were acquired by an integrated PET/MR scanner. Standardized uptake value ratio (SUVr) maps were calculated from 18F-FDG PET images by dividing voxel-wise SUV maps by the mean global SUV value. Skulls were automatically delineated from T1-weighted structural MR data using a recently-proposed approach [1], and were further separated into 8 regions of interest (ROIs), including the bilateral frontal, temporal, parietal and occipital bones. T1-weighted MR data were co-registered to the SUVr maps, and the transformation matrix was applied to the skull ROIs. Then, mean SUVr values of the skull ROIs were extracted, and were compared between PD and HC groups via the independent t-test. In addition, correlation analysis was performed between the mean SUVr values of the 8 skull ROIs and clinical ratings including Hoehn and Yahr stage (HY stage), Unified Parkinson's Disease Rating Scale-part III (UPDRS-III) and disease durations. ***Results:*** The two groups were well-matched for age and sex, as shown in Table 1. In terms of SUVr comparisons, PD patients demonstrated increased glucose uptake in the right frontal bones (PD SUVr: 0.0959 ± 0.0404, HC SUVr: 0.0721 ± 0.0487, T = 2.0526, p = 0.0487). Furthermore, although not statistically significant, PD patients exhibited slight increases in SUVr values in other bone ROIs. No significant associations were observed between mean SUVr values of the skull ROIs and clinical ratings. ***Conclusion:*** Compared to HC, patients with PD exhibited significant changes in the skull glucose uptake, which has the potential to serve as a novel biomarker for PD and warrants further investigation. ***References:*** [1] Zhang J, Treyer V, Sun J, et al. Automatic analysis of skull thickness, scalp-to-cortex distance and association with age and sex in cognitively normal elderly. Brain Stimul. 2023;16:653-656.

EP-0515

A Comparative Study of Tau Deposition and Glucose Metabolism in Anti-IgLON5 Disease Versus Progressive Supranuclear Palsy

C. Jia, *M. Liang, R. Cui;*
Department of Nuclear Medicine, Peking Union Medical College Hospital Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.

Aim/Introduction: The anti-IgLON5 disease is a rare neurological disorder characterized by the combination of autoimmunity and neurodegeneration, with prominent tau protein deposits primarily observed in the brainstem and hypothalamus. Its clinical manifestation similarity to other neurodegenerative diseases, such as progressive supranuclear palsy (PSP).^{18}F-Florzolotau is a second tau PET tracer characterized by high binding affinity for 3- and 4-repeat tau protein deposits that has not yet been applied in anti-IgLON5 disease.The aim of this study was to distinguish anti-IgLON5 disease from PSP by analysis of tau deposition and metabolic activity in vivo using ^{18}F-Florzolotau and ^{18}F-FDG PET. ***Materials and Methods:*** We enrolled three groups: patients with anti-IgLON5 disease (n=10), patients diagnosed with PSP (n=20), and healthy controls (n=40). The ^{18}F-Florzolotau and ^{18}F-FDG PET

imaging was analyzed by visual and semi-quantitative analysis. ***Results:*** Patients with anti-IgLON5 disease identified a significant uptake of ^{18}F-Florzolotau in the midbrain, pons, cerebellum, caudate, putamen, thalamus and parietal lobe. Similarly, in patients with PSP, significant tau deposition was observed in the midbrain, pons caudate, putamen, thalamus, and frontal lobe. The ^{18}F-FDG PET images of patients with anti-IgLON5 disease demonstrate diffuse metabolic reduction in the cerebral cortex. However, PSP patients exhibit reduced metabolic activity in the frontal lobe, caudate, putamen, midbrain and pons. ***Conclusion:*** This study revealed distinct tau protein deposition patterns and FDG metabolic alterations between anti-IgLON5 disease and PSP. The combination of ^{18}F-FDG and ^{18}F-Florzolotau PET further improves diagnostic confidence.

Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, SPAIN, [2]Department of Computer Architecture and Automation, Universidad Complutense, Madrid, SPAIN, [3]Department of Computer Architecture and Communications, Centro Universitario de Mérida, Universidad de Extremadura, Madrid, SPAIN, [4]Neurofunctionality and Language Group, Neurosciences Programm, Hospital del Mar Medical Research Institute (IMIM), Barcelona, SPAIN.

Aim/Introduction: We aimed to evaluate the capacity of neuropsychological assessment to predict the regional brain metabolism in patients with amnestic Alzheimer's disease (AD) and behavioral variant frontotemporal dementia (bvFTD) using Machine Learning algorithms. ***Materials and Methods:*** We included 360 participants, including 186 patients with AD, 87 with bvFTD and 87 cognitively healthy controls. This included a cohort of training and an independent cohort of validation. We trained several Machine Learning algorithms, including artificial neural networks (ANN) and traditional Machine Learning models that incorporate genetic algorithms (GAs), to predict the presence of regional hypometabolism in FDG-PET imaging based on cognitive testing results. ***Results:*** The models were able to predict the presence of regional hypometabolism with adequate accuracy, especially in the temporal lobe, followed by parital, and some regions of frontal and occipital lobe. Some areas (e.g. ventromedial prefrontal cortex) were not adequately predicted. Diagnosis played a significant role in the estimation of hypometabolism, and several neuropsychological tests were identified as the most important predictors for different brain regions. In our experiments, classical ML models, such as support vector machines enhanced by a preliminary feature selection step using Gas outperformed ANNs. ***Conclusion:*** A successful prediction of regional brain metabolism of patients with AD and bvFTD was achieved based on the results of comprehensive neuropsychological examination and Machine Learning algorithms, although some areas remain unpredicted. These findings support the neurobiological validity of neuropsychological examination and the feasibility of a topographical diagnosis in patients with neurodegenerative disorders, and the complementary value between cognitive testing and FDG-PET imaging for the diagnosis.

Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [7]PET Unit, Department of Nuclear Medicine. Hospital Universitari de Bellvitge-IDIBELL, L'Hosptalet de Llobregat, SPAIN, [8]Neurology Department. Hospital Universitari de Bellvitge-IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: Niemann-Pick disease Type C (NPC) is a rare, genetic, and progressive neurological disorder. NPC is caused in most cases (95%) by mutations in NPC1 protein, resulting in an intralysossomal cholesterol storage that causes neuronal dysfunction. [18F] FDG PET/CT (FDG-PET) is a well-established tool for imaging neurodegenerative diseases and prior studies have demonstrated its usefulness in NPC disease. The study aimed to assess the pattern of hypometabolism detected on FDG-PET of NPC patients and to evaluate the relationship between the location of hypometabolism and neurological symptomatology. ***Materials and Methods:*** Sixteen patients (11 males; mean age: 38 years ±11,9) with genetically confirmed NPC (adult-onset form) were included. The average symptom onset was 19yrs (±11,5) and the average time between the clinical onset and the study was 18,5yrs (±10,1). All patients underwent an exhaustive neurological and neuropsychological assessment (MMSE and the disability, dysphagia, and ataxia scales). FDG-PET was performed the same week as the clinical assessment. The evaluation of the FDG-PET images was visual (from two experienced nuclear medicine physicians) and semiquantitative (SMQ), using Cortex ID. Linear regression analysis was performed comparing the Z-scores with the average symptom's onset time and aforementioned scales ***Results:*** Both visual and SMQ assessments of the images showed a pattern of hypometabolism in the cerebellum, the prefrontal cortex, and the cingulate gyrus ($p<0,05$). The thalamus and brainstem showed hypometabolism in most patients based on visual assessment, areas where the software does not conduct SMQ analysis. Cerebellar involvement was observed in most patients (75%; 12/16p). In addition to cerebellar involvement, thalamic, cingulate gyrus, and prefrontal cortex involvement were also identified in 56% (9 out of 16 patients). The mean values of the MMSE and disability, dysphagia, and ataxia scales were 22,2 [16-29], 9,2 [2-14], 2,06 [0-15], and 10,97 [1-21,5], respectively. Linear regression analysis showed a moderate relationship between pons region ($R2adj=0,55$; $p<0,001$), cerebellar Z-scores values and ataxia ($R2adj=0,38$; $p=0,004$), and medial prefrontal cortex ($R2adj=0,19$; $p=0,036$) and posterior cingulate Z-scores ($R2adj=0,34$; $p=0,005$) with MMSE values. No significant relationship was found between

the Z-scores of the different brain regions and the dysphagia and disability scales nor with the average symptom's onset time. ***Conclusion:*** Our findings contribute to the growing body of evidence supporting the integration of FDG-PET as a valuable tool for assessing neurodegeneration in NPC. This enables the identification of hypometabolic patterns and their correlation with neurological symptoms, thereby enhancing our understanding of the disease progression.

EP-0518

APOE4 Association with Amyloid and Tau Positron Emission Tomography and Cognitive Decline

D. Peretti[1], *C. Boccalini[1], F. Ribaldi[1], J. Blouin[2], C. Wyss-Dominguez[2], M. Abramowicz[2], V. Treyer[3], A. F. Gietl[3], C. Hock[3], G. B. Frisoni[2], V. Garibotto[2];*
[1]University of Geneva, Geneva, SWITZERLAND, [2]Geneva University Hospitals, Geneva, SWITZERLAND, [3]University Hospital of Zurich, Zurich, SWITZERLAND.

Aim/Introduction: The apolipoprotein E4 (APOE4) is the strongest genetic risk factor for Alzheimer's disease. Presence of at least one APOE4 allele has been related to earlier and faster deposition of amyloid plaques in the brain, and faster cognitive decline. However, further studies disentangling genotype influence on amyloid and tau deposition in memory clinic populations are still necessary. The aim of this study was to evaluate the association between amyloid and tau pathology and cognitive decline with APOE4 carriership. ***Materials and Methods:*** A cohort of 237 individuals from two memory clinics underwent amyloid- and tau-PET, APOE genotyping, and neuropsychological assessment was selected. Amyloid uptake was converted into centiloid values, and tau was quantified as SUVR in a global and medial, lateral and superior temporal (MTL, LTL, and STG) regions, normalised to cerebellar crus. Subjects were classified as APOE carriers if they had at least one E4 allele, or non-carriers. Positivity for amyloid deposition was based on a centiloid threshold of 19. A Wilcoxon test was used to assess differences between carriers and non-carriers for amyloid and tau SUVR. A mediation analysis was performed to assess the mediation effects of centiloid in the association between global tau and APOE4 carriership in the whole sample and by amyloid status, corrected for age, sex, and cognitive stage. A subsample of 95 individuals underwent follow-up MMSE examination at least 1 year after baseline. A linear mixed model was used to assess the predictive value of APOE4 carriership for cognitive decline, corrected by age, sex, global tau, and centiloid. ***Results:*** Mean (SD) age of participants was 71.8 (7.9) years, 57% were men, 32% were APOE4 carriers, 38% were amyloid-positive (A+), and 47% were cognitively unimpaired. Carriers, compared to non-carriers, showed significantly higher centiloid and tau SUVR values in all regions ($p<0.01$). In A- individuals, the association between APOE4 carriership and global tau was not mediated by centiloid, but there was a significant direct association between tau and APOE4 ($p<0.01$). No mediation by centiloid or direct effects between tau and APOE4 were found in the A+ group. The linear mixed effect model showed that APOE4 carriers showed a faster cognitive decline compared to non-carriers ($B=-0.82, p<0.01$). ***Conclusion:*** APOE4 carriers present a significant increase of both tau and amyloid load with respect to non-carriers, and declined significantly faster than non-carriers. Importantly, carriership was a predictor of cognitive decline regardless of amyloid and tau deposition.

EP-0519

Early-phase [18F]Flortaucipir tau-PET as a measure of neurodegeneration in Alzheimer's disease: a comparison with [18F]FDG-PET and early-phase amyloid-PET

C. Boccalini[1], ***G. Mathoux[2],*** *D. E. Peretti[1], F. Ribaldi[1], D. Perani[3], G. B. Frisoni[2], V. Garibotto[2];*
[1]University of Geneva, Geneva, SWITZERLAND,
[2]Geneva University Hospitals, Geneva, SWITZERLAND,
[3]San Raffaele Hospital, Milan, ITALY.

Aim/Introduction: Alzheimer's disease (AD) is characterized by several neuropathologic changes, including β-amyloid (A) deposition, pathologic tau (T), and neurodegeneration (N). While [18F]FDG PET is widely used for investigating N by detecting changes in cerebral glucose metabolism, dual-phase amyloid-PET offers the possibility to assess both A and N with a single tracer injection. Moreover, through regional analysis, distinct patterns of brain metabolism and perfusion that indicate neurodegeneration can be identified throughout the spectrum of AD, frontotemporal, and Lewy body dementias. Dual-phase tau-PET could also offer insights into both T and N. Our study aims to evaluate the association of tau-PET early frames with [18F]FDG PET and amyloid PET early frames, and determine their comparability in discriminating AD patients and in their ability to discern different neurodegenerative patterns. ***Materials and Methods:*** We included 58 subjects, spanning from no cognitive impairment (n=10) to mild cognitive impairment (n=34) and dementia (n=14), from the Geneva Memory Center. Within a year, they underwent dual-phase [18F]Flortaucipir-PET (eTAU) and [18F]FDG-PET. Additionally, a subsample of 36 participants underwent dual-phase amyloid-PET using either [18F]Florbetapir (eFBP) (n=21) or [18F]Flutemetamol (eFMM) (n=15). Uptake distribution images were visually inspected by a nuclear medicine expert blinded to clinical diagnoses and classified into hypometabolism and hypoperfusion patterns suggestive or not of neurodegenerative diseases. Standardized uptake value ratios (SUVR) were extracted from key regions sensitive to AD (metaROI) to evaluate the correlation of eTAU with their respective [18F]FDG-PET and eFBP/eFMM scans. Receiver operating characteristic analyses were performed to compare the discriminative power of eTAU, FDG and eFBP/ eFMM SUVR between A-/T- and A+/T+ participants. ***Results:*** Strong positive correlations were found between eTAU and FDG SUVR ($r=0.711$, $p<0.001$) and eTAU and eFBP/eFMM SUVR ($r>0.713$, $p<0.001$), independently of T status. Visual classification of eTAU uptake distribution revealed clusters of significant hypoperfusion with good correspondence to hypometabolism topography and eFBP/eFMM hyperfusion patterns ($k>0.57$), independently of the underlying neurodegenerative pattern. Both eTAU and FDG SUVR significantly distinguished A+/T+ patients from A-/T- (AUCeTAU=0.604, AUCFDG=0.748) with FDG performing better than eTAU ($p=0.04$). eFMM/eFBP and eTAU SUVR showed a comparable discriminative power (AUC>0.587). ***Conclusion:*** Our findings suggest that eTAU offers perfusion information closely linked to regional brain glucose metabolism and perfusion measured by early amyloid-PET phases, supporting their utility as a surrogate biomarker for neurodegeneration in clinical settings.

EP-0520

Characterizing sporadic early-onset Alzheimer's disease using dual-probe PET/CT and fluid (CSF and plasma) AD core biomarkers.

Z. Zhu[1,2], *X. Lv[3,2], J. Peng[3,2], M. Ni[1], Q. Xie[1], S. Wang[1], Y. Shen[3,2,4], J. Shi[3,2], China Aging and Neurodegenerative Initiative (CANDI) Consortium;*

[1]Department of Nuclear Medicine, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, CHINA, [2]Neurodegenerative Disorder Research Center, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, CHINA, [3]Department of Neurology, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, CHINA, [4]Anhui Province Key Laboratory of Biomedical Aging Research, University of Science and Technology of China, Hefei, CHINA.

Aim/Introduction: Early-onset Alzheimer's disease occurs before 65 years old and accounts for about 10% of all AD cases. Previous studies mainly focused on familial forms of EOAD, while sporadic EOAD have been under-studied.PET/CT can be used not only to improve sEOAD diagnostic acumen but also enhance our understanding of fundamental pathobiological changes before the onset of symptoms. We endeavor to integrated dual-probes PET/CT and fluid biomarkers, with the goal of showing how the described approaches can be used to improve our understanding of diagnostic acumen for sEOAD and its heterogeneous clinical presentations. ***Materials and Methods:*** Patients were recruited between 2019 and 2023 from the CANDI study, a prospective cohort study on AD. It included 76 patients with sEOAD, 51 with late-onset AD, 21 young controls, and 11 older controls. All AD patients met the ATN diagnostic criteria. Patients with familial EOAD or non-AD dementia were excluded.Single molecule array technology was used to measure fluid biomarkers,cerebral glucose metabolism and β-Amyloid burden were further assessed by using dual-probes PET/CT(18F-FDG-PET and 18F-AV45-PET) for sEOAD biological definition. PET imaging data were analyzed by SPM12 software implanted in MATLAB 2020b. ***Results:*** The cerebral hypometabolism pattern of sEOAD was limited to bilateral precuneus and the cerebral hypermetabolism pattern was observed in medial supra- frontal gyrus [$p < 0.05$, family-wise error (FWE) corrected with cluster size (KE) above 20 contiguous voxels]. The same hypermetabolism pattern was detected in comparisons between young healthy controls and older healthy controls. It was also showed that sEOAD acounts for lower Aβ. burden in the bilateral precuneus, anterior cingulate gyrus, posterior cingulate gyrus, and medial superior frontal gyrus ($p < 0.05$, FWE corrected, KE>20). However, there was no significant Aβ deposition observed in the same cortical areas in healthy controls group. CSF P-tau181 levels (t=3.696, p=0.0003)was elevated in patients with sEOAD, while other AD core biomarkers (plasma P-tau181, plasma T-tau, Aβ42,Aβ40, Aβ42/Aβ40,etc.) accounts for no statistically significant differences. SUVR values calculated from the precuneus ROI region based on FDG imaging showed the most significant differences (t=3.783, p =0.0002) and showed the best efficacy for diagnosing sEOAD from sLOAD (AUC=0.768, p <0.0001). ***Conclusion:*** As a result of these preliminary findings, we can conclude that the spatial metabolic profile and Aβ heterogeneity discriminated sEOAD from sLOAD .The bilateral precuneus hypometabolic and lower Aβ deposition pattern may integrated as one potential neuroimaging biomarker for characterizing sporadic early-onset Alzheimer's disease.

EP-0521

Metabolic Disparities Between Patients with Suspected non-Alzheimer's Pathophysiology Exhibiting AD Clinical Features and AD-like Hypometabolism, and Patients Diagnosed with AD.

R. Ferrando[1,2], *A. Damian[1,2], G. Falasco[2], L. Urrutia[2], P. Duarte[2], O. Alonso[1,2];*

[1]Nuclear Medicine and Molecular Imaging Centre, Clinics Hospital, University of the Republic, Montevideo, URUGUAY, [2]Uruguayan Centre for Molecular Imaging (CUDIM), Montevideo, URUGUAY.

Aim/Introduction: Patients with suspected non-Alzheimer's pathophysiology (SNAP) with clinical signs resembling Alzheimer's disease (AD) and an AD-like metabolic pattern (AD-like SNAP) represent a distinct subgroup posing diagnostic challenges, sparking debate over their characterization. While some may suffer from dementia of non-AD origin (e.g., Lewy body disease), others may fall within the spectrum of AD-related processes, yet lack sufficient amyloid deposits detectable by amyloid PET imaging. This study aims to assess the metabolic alterations in these patients and compare them with those observed in AD. ***Materials and Methods:*** This retrospective study examined 12 patients with AD-like SNAP (10 male, age 67.8 ± 7.6 years, MMSE 25.8 ± 2, symptom duration 2.0 ± 2 years, mean ± SD) and 19 patients with AD (12 women, 65.5 ± 9.1 years, MMSE 24.3 ± 3.9, symptom duration 3.0 ± 2.4 years) who underwent 18F-FDG and 11C-PIB PET/CT scans. While all patients exhibited an hypometabolic pattern consistent with AD, all SNAP patients were PIB-negative, and all AD patients were PIB-positive. Groups were compared to each other and to age- and gender-matched normal controls using ANCOVA in SPM8 ($p<0.001$ non corrected). ***Results:*** As expected, patients with AD displayed hypometabolism in bilateral posterior parietal and temporal cortex, precuneus, posterior cingulate and frontal cortex compared to normal controls. AD-like SNAP patients exhibited decreased metabolism in these same regions. Direct comparison between AD-like SNAP and AD revealed lower metabolism in the inferior and anterior frontal and right anterior cingulate cortex, and higher lateral temporal metabolism in the former group. ***Conclusion:*** These findings suggest metabolic differences between AD-like SNAP and AD, particularly in frontal and temporal cortex, aiding in the characterization of these contentious subtype of patients. Further characterization using tau PET is warranted, although other abnormal proteins such as alfa-synuclein and TDP-43 may also contribute to their pathophysiology.

Increased blood-brain barrier permeability and cognitive impairment in patients with chronic kidney disease

M. Bobot[1,2], *E. Guedj[1,2], N. Resseguier[1,2], J. Faraut[1], P. Garrigue[1,2], V. Nail[1,2], G. Hache[1,2], S. Gonzalez[1], N. McKay[2], R. Vial[1], D. Bouchouareb[1], G. Lano[1], N. Jourde-Chiche[1,2], A. Duval-Sabatier[1], F. Guillaume[2], B. Guillet[1,2], S. Burtey[1,2];*

[1]Assistance Publique Hôpitaux de Marseille, Marseille, FRANCE, [2]Aix-Marseille Université, Marseille, FRANCE.

Aim/Introduction: Chronic kidney disease (CKD) is associated with an increased risk of cognitive impairment. We previously demonstrated that this cognitive impairment is associated with an increased permeability of blood-brain barrier (BBB) in rodents

with CKD, linked to activation of aryl hydrocarbon receptor (AhR) by indoxyl sulphate (IS)(1). The objective of BREIN study is to confirm the increased BBB permeability in humans with CKD. ***Materials and Methods:*** The BREIN comparative study (NCT04328415) prospectively included patients with end-stage kidney disease (ESKD), and healthy volunteers (Ctrl) matched in age, gender, and educational level to a patient. In all participants, BBB permeability was quantified by brain 99mTc-DTPA SPECT/CT as percentage of injected activity (%IA). A battery of neurocognitive tests was performed, serum uremic toxins accumulation and AhR activation were assessed. ***Results:*** Fifteen ESKD patients and 14 healthy volunteers were analysed. ESKD patients had higher BBB permeability compared to controls: 0.29±0.07 vs. 0.14±0.06 %IA, p=0.002. ESKD patients displayed lower MoCA score: 22.0±5.0 vs. 27.3 ± 2.8, p=0.008, impaired short-term memory (doors test): 12.5±3.4 vs. 16.5±3.4, p=0.005, higher Beck depression score 8.1±9.1 vs. 2.7±3.4, p=0.046, and slightly more daily cognitive complaints: 42.5±29.3 vs. 29.8±14.0 p=0.060. ESKD patients displayed higher IS levels (86.1±48.4 vs. 3.2±1.7 µmol/L, p=0.001) and AhR activating potential (37.7±17.8% vs. 24.7±10.4%, p=0.027). BBB permeability was inversely correlated with MoCA score (r=-0.60, 95%CI [-0.772; -0.339], p=0.001) in the overall population. ***Conclusion:*** ESKD patients display an increased BBB permeability compared to matched healthy volunteers. Association with uremic toxins and cognitive impairment needs to be assessed in larger cohorts of patients. ***References:*** (1) Bobot M, Thomas L, Moyon A, Fernandez S, McKay N, Balasse L, et al. Uremic Toxic Blood-Brain Barrier Disruption Mediated by AhR Activation Leads to Cognitive Impairment during Experimental Renal Dysfunction. J Am Soc Nephrol JASN. 2020 Jun 11.

EP-0523

Combined Brain Perfusion SPECT with Cognitive Stress using LASSI-L for Prediction of Brain Amyloid Status

S. Tepmongkol, *C. Tunvirachaisakul, A. W. Saraya, T. Sathaporn, N. Channarong, S. Tangwongchai;*
Chulalongkorn University, Bangkok, THAILAND.

Aim/Introduction: This study was aimed to use cognitive stress (Loewenstein-Acevedo Scale for Semantic Interference and Learning, LASSI-L) combined with brain perfusion SPECT for the detection of brain amyloid positivity which reflects Alzheimer's pathology. ***Materials and Methods:*** Brain SPECT using Tc-99m ECD were performed at baseline and during cognitive stress test (LASSI-L) in amyloid positive (AP) and amyloid negative (AN) subjects. F^{18} florbetaben amyloid PET scan was used as a gold standard to determine Alzheimer's pathology. Brain SPECT perfusion changes in both groups during cognitive stress compared to baseline were assessed by paired t-test on statistical parametric mapping. Positive and negative perfusion in each group were defined with statistically significant of p<0.05 at cluster level. ***Results:*** We analyzed 72 subjects (25 AP with age 71.16±8.54 years, 47 AN with age 69.19±5.80 years). There was no significant perfusion change in the AP group for both the positive contrast (Cognitive Stress-Baseline) or negative contrast (Baseline-Cognitive Stress). In the AN group, there were significant positive perfusion changes after cognitive stress at bilateral anterior prefrontal cortices (BA10), left visual association cortex (BA19), right secondary visual cortex (BA18), left premotor & supplementary motor area (BA6). There was significant negative perfusion change at right dorsal posterior cingulate cortex (BA31). ***Conclusion:*** Brains with amyloid deposition have blunt brain perfusion response to cognitive stress using LASSI-L, while amyloid negative brains are able to respond. Combining brain perfusion SPECT with LASSI-L can be used for segregation of brains with amyloid positive and negative with potential application for early detection of Alzheimer's disease in those with mild cognitive impairment. ***References:*** 1. EP-0524

Validation of a Brain Dedicated PET Scanner for Amyloid Imaging

P. Nespral, *G. Cuesta Domingo, P. Daudén Oñate, B. García Raldúa, M. Zapardiel Martínez-Falero, M. Vaillant López, A. Berardinelli Issea, J. Matías-Guiu, P. Bascuñana Almarcha, M. Cabrera Martín;*
Department of Nuclear Medicine, Instituto de Investigación Sanitaria San Carlos (IdISSC). Hospital Clínico San Carlos, Universidad Complutense., Madrid, SPAIN.

Aim/Introduction: With the advent of new anti-amyloid therapies, a considerable increase in brain PET studies is expected. Amyloid tracers make it possible to select candidates for therapy and evaluate their efficacy. Moreover, quantitative analysis of these images can improve diagnostic reliability and is indispensable for response assessment. The aim of this work is to compare the image quality and resolution of Siemens Biograph mCT (wbPET) vs PET dedicated to CareMiBrain (CMB) brain. ***Materials and Methods:*** Ten amyloid-PETs were included in this study, of which 7 were healthy controls without known neurological pathology and 3 patients with a definitive diagnosis of neurodegenerative disorder. An 18F-Florbetaben PET-CT was first performed on the Siemens wbPET machine 90 minutes after injection and consecutively after signing the informed consent on the dedicated CMB machine. PET images were normalized to ^{18}F-florbetapir template and SUV-corrected in Pmod 4.1. Subsequently, image contrast was quantified using the centiloid cortex ROI and an ROI in the white matter. In addition, centiloid was calculated for each image. The results were compared using the Student's t-test. ***Results:*** The white matter-to-cortex ratio shows a similar contrast between both systems [PB1] (1.53 vs. 1.53, p = 0.94). However, centiloid calculation shows expected values in Siemens images (controls: [-27, -1]; patient: 93[PB2]), whereas a higher variability is observed in CMB images with values not corresponding to the centiloid scale (controls: [-12, 35]; patient: 523). ***Conclusion:*** Image quality on dedicated PET is sufficient for clinical diagnosis with contrast similar to our reference equipment (Siemens). However, the centiloid calculated with CMB images is overestimated, probably due to underestimation of the reference region because of its proximity to the field-of-view limits.

EP-0525

Characterization of glymphatic system and early-phase amyloid metabolism in Alzheimer's disease: a simultaneous PET/MR study

Y. Jiao[1], *W. Han[1], L. Zhang[1], M. Wang[1], Z. Lv[1], Y. Su[1], Y. Hu[2], Y. Yang[3], P. Fu[1];*
[1]Department of Nuclear Medicine, 1st Hospital of Harbin Medical University, Harbin, CHINA, [2]Central Research Institute, United Imaging Healthcare, Shanghai, CHINA, [3]Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA.

Aim/Introduction: The damage to the glymphatic system, pathological amyloid (Aβ) deposition, and cognitive impairment are closely related in patients with Alzheimer's disease (AD). Early-phase Aβ imaging reflects cerebral perfusion and its relationship with the glymphatic system damage in the progression of AD is not well understood. The purpose of this study, which utilized the simultaneous PET/MRI, was to assess the glymphatic system and early-phase Aβ imaging in relation to cognitive impairment among patients with healthy control (HC), prodromal Alzheimer's disease (pAD), and AD. ***Materials and Methods:*** A total of 33 subjects were included in this study, including 11 patients with AD, 11 patients with pAD, and 11 age- and sex-matched healthy individuals. Cognitive assessments, including the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA), were collected along with clinical information. Every enrolled subject underwent an integrated 18F-Florbetapir (18F-AV45) PET/MR scan. High-resolution T1-weighted structural images, diffusion-tensor images and early-phase 18F-AV45 images were acquired for all subjects. Normalized PET standardized uptake value ratio (SUVR) images, with whole cerebellum as the reference region, and an index for diffusivity along the perivascular space (ALPS-index) were obtained using the FSL. Anatomical Automatic Labeling (AAL) atlas was utilized in ROI-wise analysis to evaluate abnormalities in brain metabolism. ***Results:*** AD patients showed reduced mean MMSE and MoCA scores compared to HC and PAD subjects (both $P < 0.01$). Compared to HC, lower mean ALPS-index was found in AD patients ($P < 0.01$). AD patients showed hypometabolism of early-phase Aβ in bilateral hippocampus, parahippocampal gyrus and caudate (all $P < 0.001$). Mean ALPS-index was correlated with early-phase Aβ metabolism in bilateral hippocampus, caudate, amygdala, left cingulate gyrus and right pallidum (all $P < 0.001$) ***Conclusion:*** We observed lower mean ALPS-index and cerebral perfusion level of early-phase Aβ imaging and higher cognitive impairment in the patients of AD as compared with participants of HC or pAD group. The glymphatic system damage is positively correlated with early-phase Aβ imaging. These results may provide imaging evidence for the early diagnosis and personalized management of AD.

EP-0526

Y. Chang[1], *R. Wang;*
[1]Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: To investigate the impact of the correlation between plasma glial fibrillary acidic protein (GFAP) levels and subcortical Tau-PET uptake on cognitive function in patients with Alzheimer's disease (AD). ***Materials and Methods:*** This cross-sectional study recruited 47 cognitive impaired patients (22 AD, 25 MCI)and 17 control subjects. Plasma based biomarkers, including amyloid-β 42 (Aβ42), Aβ40, phosphorylated-tau (p-tau181, p-tau217, p-tau231), neurofilament light (NfL) and GFAP of all participants were measured. Participants underwent amyloid-β (11C-PIB) and tau (^{18}F-MK6240) PET as well as cognitive testing. SUVR maps of Aβ and Tau-PET were obtained using cerebellum gray matter as reference region. SUVR of subcortical regions were extracted to perform ROI- and voxel-wise comparison between groups. Correlation between plasma biomarkers and cognitive performance were calculated using multiple regression, with controlling effect of age and sex. Correlation between image measurement and cognitive performance were studied as well. Mediation analysis was performed to investigate the role of plasma GFAP played in relationship of Tau pathology and cognitive decline. ***Results:*** Results showed that plasma GFAP, NfL, Aβ42/40 ratio, p-tau 217 and p-tau 181 of AD group and MCI group were higher than NC group. Aβ-PET load at amygdala, accumbens, caudate, putamen, pallidum, PHG, thalamus and olfactory of AD and MCI group were higher than NC group ($p<0.05$). Tau-PET load at amygdala, putamen, hippocampus and PHG of AD and MCI group were higher than NC group ($p<0.05$). In CI group, higher Tau-PET load at amygdala (β=-0.389, p=0.029), accumbens (β=-0.396, p=0.025), hippocampus (β=-0.376, p=0.035), PHG (β=-0.408, p=0.021), and olfactory (β=-0.423, p=0.015) was associated with lower global cognitive scores. Mean subcortical Tau-PET load was negatively correlated with global cognitive scores (β= -0.389, p=0.029), in CI group. Higher plasma GFAP (β=-0.579, p=0.001), NfL (β=-0.46, p=0.013), p-tau 217 (β=-0.352, p=0.055) and p-tau 181 (β=-0.473, p=0.008) was associated with lower global cognitive scores in CI group. Higher mean subcortical Tau-PET load was associated with higher plasma GFAP (β=0.313, p=0.068), NfL (β=0.476, p=0.003), p-tau 217 (β=0.485, p= 0.004) and p-tau 181 (β=0.382, p=0.026) in CI group. Results of mediation analysis showed that about 36.7% of relationship between mean subcortical Tau-PET load and cognitive impairment could be explained by increase of plasma GFAP, in CI group. ***Conclusion:*** This study shows that plasma GFAP is an early marker associated with subcortical Tau pathology, contributing to cognitive impairment in AD. This study also highlights the importance of quantifying subcortical regional Tau retention values in these individuals.

EP-0527

Gray-White Matter Contrast of ^{11}C-PIB uptake in a cognitively unimpaired population: relationship to Aβ1-42/Aβ1-40 ratio of amyloid peptides in the cerebral spinal fluid

J. Jiménez-Bonilla[1], *M. De Arcocha-Torres[1], S. López-García[2], F. Gómez-De la Fuente[1], N. Martínez-Amador[1], C. Lage[2], I. Martínez-Rodriguez[1], V. Mendi-Barcina[1], A. Sánchez-Salmón[1], B. Lucas-Velazquez[1], M. Pombo-López[1], A. Bota-Bota[1], A. García-Ruiz[1], F. Rodríguez-Izquierdo[1], N. Carvalho[1], P. Botanch[1], L. Cabrera-Portillo[1], E. Rodríguez-Rodríguez[2], R. Quirce[1];*
[1]Nuclear Medicine Service. Marqués de Valdecilla University Hospital. Molecular Imaging Group (IDIVAL). University of Cantabria, Santander, SPAIN, [2]Neurology Service. Marqués de Valdecilla University Hospital., Santander, SPAIN.

Aim/Introduction: In the normal brain, amyloid tracer uptake occurs in white matter (WM) but not cortical gray matter (GM), creating a clear GM-WM contrast (G-WC). We investigated changes in global and regional 11C-PIB G-WC in cognitively unimpaired subjects, correlating with Aβ1-42/Aβ1-40 ratio in cerebrospinal fluid. ***Materials and Methods:*** We selected 13 healthy subjects (mean age: 64.2 years) from a cohort of cognitively unimpaired volunteers with normal MRI and CSF amyloid values obtained within the past year. Subjects underwent dynamic PET/CT imaging for 45 minutes starting 40 minutes post-administration of 11C-PIB. Volumes of interest (VOIs) were delineated in cerebellar, frontal, temporal, occipital, and parietal regions of both hemispheres.

SUVmean values in GM and WM were measured at sequential time points. Aβ1-42/Aβ1-40 ratio was considered normal > 0.07. Regional G-WC was calculated as SUVmean in GM/SUVmean in WM for each region, and global G-WC was the average of all cortical regional G-WC values in each subject. ***Results:*** In the total group (n=13) the better G-WC was obtained in latest phases and correlated with Aβ1-42/Aβ1-40 ratio values (r= -0,736). In 7/13 subjects Aβ1-42/Aβ1-40 ratio was normal showing global G-WC of 0,729 ± 0,093 and in 6/13 it was pathologic showing global G-WC of 0,908 ± 0,152 (p< 0,05) at 85 minutes. Regional differences were observed between subgroups: right frontal (0.722 ± 0.150 vs. 0.888 ± 0.119) (p< 0.05); left frontal (0.660 ± 0.158 vs. 0.934 ± 0.246) (p<0.001); right parietal (0.669 ± 0.170 vs. 0.898 ± 0.150)(p<0.05); left parietal (0.719 ± 0.149 vs. 0.805 ± 0.200) (p=ns); right temporal (0.673 ± 0.112 vs. 0.908 ± 0.304) (p=ns); left temporal (0.680 ± 0.126 vs. 0.829 ± 0.250) (p=ns); right occipital (0.821 ± 0.217 vs. 1.014 ± 0.150) (p<0.1) and left occipital (0.888 ± 0.204 vs. 1.057 ± 0.233) (p=ns).PIB retention assessed as SUVmean in GM increased in the pathological subgroup (0,69 ± 0,148 vs 0,395 ± 0,065; p< 0,001) and in WM globally (0,708 + 0,062 vs 0,565 ± 0,143) (p< 0.1), with high correlation between regional G-WC and Aβ1-42/Aβ1-40 ratio in frontal and parietal areas (r= 0,931 and 0,908 respectively). ***Conclusion:*** In cognitively unimpaired subjects with abnormal Aβ1-42/Aβ1-40 ratio in CSF, the G-WC in 11C-PIB tracer decreased significantly showing a characteristic topographic pattern. This alteration, affecting gray and white matter, differs from others known conditions, making it a potentially valuable early parameter in preclinical cognitive neurodegenerative disease evaluation.

EP-0528

Visual Assessment and Semi-Quantitative Parameters of ^{18}F-FDG in the Clinical Diagnosis of Alzheimer's Disease among Patients with Memory Impairment: A Comprehensive Study

C. Zhang, *Y. Zhang, G. Huang, M. Xin, J. Liu;*
Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: The objective of this study was to assess the diagnostic performance of ^{18}F-FDG PET visual assessment and semi-quantitative parameters in Alzheimer's disease (AD) among patients with memory impairment. ***Materials and Methods:*** A retrospective analysis was conducted on 96 initially diagnosed memory impairment patients. The ATN criteria, based on ^{18}F-AV-45+^{18}F-PI-2620 PET/CT+MRI imaging results, were employed as the diagnostic standard for AD patients. A visual analysis of the temporoparietal and posterior cingulate cortex (PCC) hypometabolism and semi-quantitative analysis methods, including PET-SCORE scoring and NeuroQ software analysis, were employed to assess the diagnostic performance of ^{18}F-FDG PET/CT imaging in AD patients. A Chi-square test was employed to assess the accuracy, sensitivity, and specificity of visual assessment and semi-quantitative parameters. Pearson correlation analysis was conducted to determine the relationship between PET-SCORE and the cognitive scale. ***Results:*** Of the 96 patients initially diagnosed with memory impairment, 61 were clinically diagnosed with Alzheimer's disease (AD), while 35 patients were excluded from the AD diagnosis (18 for vascular dementia, 14 for frontotemporal dementia and 3 for dementia with Lewy bodies). There were statistically significant differences in the sensitivity and specificity of visual assessment and semi-quantitative analysis of ^{18}F-FDG PET/CT imaging for diagnosing AD (χ2=5.8229.03, P<0.05). The visual assessment of temporoparietal hypometabolism demonstrated the highest sensitivity (91.80%), while the semi-quantitative assessment using PET-SCORE exhibited the highest specificity (100.00%). A ROC curve (AUC=0.69) was constructed for the diagnosis of AD according to PET-SCORE. The optimal threshold was determined to be 3.20, with a sensitivity of 40.98%, a specificity of 100%, and an accuracy of 62.5%. PET-SCORE exhibited statistically significant correlations with patient cognitive scale scores, including MMSE, MoCA, and ADL (R = -0.380.31, P < 0.01). ***Conclusion:*** Among patients initially diagnosed with memory impairment, visual assessment in ^{18}F-FDG PET/CT imaging analysis demonstrated higher sensitivity, while semi-quantitative analysis using PET-SCORE exhibited higher specificity. PET-SCORE scoring demonstrated a statistically significant correlation with the severity of cognitive decline in AD patients.

EP-0529

The significance of SUVR in ^{18}F-PI-2620 PET imaging for the diagnosis of different cognitive disorders, alongside cognitive correlation analysis

C. Zhang, *G. Huang, M. Xin, Y. Zhang, J. Liu;*
Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: The objective of this study was to evaluate the values of ^{18}F-PI-2620 PET/CT brain imaging with SUV ratio (SUVR) in the assessment of tau protein deposition in the brain of patients with different cognitive disorders and to determine its correlation with cognition. ***Materials and Methods:*** A total of 67 subjects were enrolled in the study, which included 54 patients with Alzheimer's disease (AD; 21 males, 33 females, age (68.6±7.8) years), 7 patients with mild cognitive impairment (MCI; 1 male, 6 females, age (63.1±11.2) years) and 6 healthy controls (HC; 4 males, 2 females, age (69.0±5.8) years). All participants underwent examination by ^{18}F-PI-2620 PET/CT. SUVR of brain regions were analysed with inferior cerebellum cortex serving as the reference region. All participants were evaluated using cognitive scales, including the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA). One-way analysis of variance and t-test were employed to compare the differences in SUVR in each brain region between the HC, MCI and AD groups. ROC curve analysis was used to determine the optimal cutoff value for differential diagnosis of SUVR. Pearson correlation analysis was employed to examine the correlations of SUVR with cognitive scale scores. ***Results:*** The SUVR of the whole brain was 1.40±0.31 in the AD group, 1.08±0.19 in the MCI group, and 1.01±0.12 in the HC group. SUVR analysis of the whole brain and each brain region was able to distinguish AD from HC (F values: 1.76-10.09, t values: 2.98-7.47, all P<0.05), but not HC from MCI (t values: 0.17-1.53, all P>0.05). ROC curve analysis revealed that the optimal cutoff value of SUVR for differential diagnosis of AD-HC group was 1.18 for the whole brain (AUC=0.89), 1.13 for the amygdala (AUC=0.94) and 1.26 for the parahippocampal gyrus (AUC=0.94). The ROC curve analysis revealed that the optimal cutoff value for differential diagnosis of AD and MCI was 1.06 for the whole brain (AUC=0.82), 1.18 for the amygdala (AUC=0.88) and 1.28 for the infratemporal gyrus (AUC=0.88). The SUVR of the whole brain, frontal, occipital, parietal, temporal and insula were found to be significantly negatively correlated with MMSE and MoCA cognitive scale scores (r values: from -0.64 to -0.40, all P<0.01). ***Conclusion:*** SUVR quantitative analysis in ^{18}F-PI-2620 PET imaging could assist the differential diagnosis of AD and HC, AD and MCI. The SUVR of the whole brain and five lobes demonstrated a negative correlation with MMSE and MoCA scores.

EP-0530

Tracking changes in cerebral activity in patients with lymphoma receiving chemotherapy using sequential [18F]FDG PET/CT

J. O, *S. Kwon, I. Chung, W. Ryoo, J. Min, S. Ha;*
The Catholic University of Korea, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Patients commonly describe having troubles with thinking after chemotherapy, but the mechanism of "chemo brain" is not fully understood. [18F]FDG PET/CT can serve as a proxy for neural activity of the brain. This study aimed to assess changes in cerebral activity with chemotherapy using [18F]FDG PET/CT of lymphoma patients. ***Materials and Methods:*** [18F]FDG PET/CT of 93 consecutive newly diagnosed lymphoma patients were assessed. All had three sets of [18F]FDG PET/CT: at BASELINE, after 3 cycles (INTERIM) of standard R-CHOP regimen, and after 6 cycles (END-of-TX). The PET slices of the brain were separated, spatially normalized using the PET template, smoothened, and gray matter-extracted using SPM12 of MATLAB. Intensity normalization of each voxel was performed by calculating the standardized uptake value ratio (SUVR) with whole brain the reference region. Clusters were identified according to AAL3 using the REX toolbox, the mean SUVR computed for each cluster, and the values from three time points were compared by paired T-test. P-value < 0.01 after Bonferroni correction was considered significant. ***Results:*** [BASELINE to INTERIM] Activity significantly decreased in multiple clusters - bilaterally in inferior frontal pars orbitalis, gyrus rectus, lateral/posterior-orbital, middle temporal, and anterior cingulate. Unilateral decrease was noted in areas of the thalamus, middle cingulate, and parahippocampal gyrus, all in right side. Increased activity was observed bilaterally in postcentral, superior/middle/inferior-occipital and lingual gyruses, and unilaterally in left supramarginal gyrus. [BASELINE to END-of-TX] All of the clusters that showed decrease at INTERIM showed significant decrease at END-of-TX. All clusters showing unilateral decrease at INTERIM showed decrease in the contralateral cluster as well at END-of-TX. New clusters in the olfactory cortex, medial/anterior-orbital, superior frontal gyruses, and areas of the thalamus and basal ganglia showed decreased activity at END-of-TX. The clusters with increased activity at INTERIM showed increased activity at END-of-TX, in all but the lingual gyruses. The inferior parietal gyrus and cuneus, all in left side, were new clusters with increased activity at END-of-TX. [INTERIM to END-of-TX] Activity decreased from INTERIM to END-of-TX in the posterior-orbital gyruses and anterior cingulate. ***Conclusion:*** Chemotherapy was associated with decreased [18F]FDG activity in clusters in the frontal and temporal lobes (especially the orbital gyruses), thalamus and limbic system, with more clusters showing diminished activity at END-of-TX. Several clusters in the parietal and occipital lobes showed increased activity, possibly as compensation. These changes in neural activity may be depictions of the chemo brain in lymphoma patients.

EP-0531

Potential Utility of Amyloid and Metabolic PET Imaging in Differentiating Cerebral Amyloid Angiopathy from Alzheimer's Disease

M. Liang[1], *C. Jia[1], Y. Sha[2], J. Ni[2], R. Cui[1];*
[1]Department of Nuclear Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, Beijing, China, CHINA,
[2]Department of Neurology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China, Beijing, China, CHINA.

Aim/Introduction: Amyloidogenic proteins can undergo conformational changes, resulting in the formation of insoluble amyloid fibrils, which are implicated in several central nervous system disorders, such as Alzheimer's disease (AD) and cerebral amyloid angiopathy (CAA). In both conditions, amyloid β (Aβ) is the primary amyloidogenic protein. This retrospective study aimed to investigate whether the complementary information provided by ^{18}F-florbetapir PET, which detects Aβ deposition, and ^{18}F-FDG PET, which measures glucose metabolism, can enhance the differential diagnosis between CAA and AD. ***Materials and Methods:*** Patients with CAA (n = 37), AD (n = 30), and cognitively healthy controls (HCs, n=14) underwent ^{18}F-florbetapir and ^{18}F-FDG PET imaging within a one-month period. Region of interest and voxel-wise analyses were performed to compare Aβ deposition and glucose metabolism patterns among the three groups. Standardized uptake value ratios were calculated using white matter and brainstem as reference regions for ^{18}F-florbetapir and ^{18}F-FDG PET, respectively. ***Results:*** Patients with CAA exhibited significantly higher ^{18}F-florbetapir uptake in the cerebellum, global cerebral cortex, and various cortical regions compared to both patients with AD and HCs. Voxel-wise analysis revealed that patients with CAA had greater ^{18}F-florbetapir uptake predominantly in the cerebellum and occipital cortex compared to those with AD. The patterns of glucose hypometabolism in CAA did not differ significantly from those observed in AD. ***Conclusion:*** The distinct patterns of Aβ deposition, particularly the increased amyloid burden in the cerebellum and occipital cortex, could serve as a valuable biomarker for differentiating CAA from AD. However, the absence of significant differences in glucose metabolism patterns between CAA and AD limits the clinical utility of ^{18}F-FDG PET imaging for distinguishing between the two disorders. Further investigation in larger, well-characterized cohorts of patients with various CAA subtypes is warranted.

PET-CT with ^{18}F-FDG: a tool for ruling out neurodegenerative causes in assessing unclear cognitive decline

B. Pérez López[1], *J. Gómez Hidalgo[1], F. Sebastián Palacid[1], N. Álvarez Mena[1], M. D. Pérez López[2], M. García Aragón[1], R. C. Zambrano Infantino[1], B. M. Jaramillo López[1], M. J. González Soto[1], C. Gamazo Laherrán[1], M. Alonso Rodríguez[1], R. Ruano Pérez[1];*
[1]Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN,
[2]Hospital Universitario Ramón y Cajal, Madrid, SPAIN.

Aim/Introduction: This study aimed to assess the effectiveness of PET-CT with ^{18}F-FDG in examining patients presenting with cognitive symptoms but lacking a definitive diagnosis. By focusing on cases with uncertain clinical manifestations, this research aimed to highlight the significance of normal PET-CT findings in guiding diagnostic and therapeutic approaches. ***Materials and Methods:*** A retrospective analysis was conducted on a cohort of patients presenting with cognitive symptoms without a clear etiology, all referred from neurology to our nuclear medicine department. Patients were referred for PET-CT studies with ^{18}F-FDG between January and April 2024. PET-CT studies were performed using a digital PET-CT scanner, and images were acquired 30 minutes after radiopharmaceutical administration. Analysis was exclusively performed on those patients whose studies showed normal findings on PET-CT, and their demographic characteristics, clinical presentation, and neuropsychiatric comorbidities were described. ***Results:*** Among 189 brain studies conducted from January to April 2024 for cognitive decline, 42 (22%) revealed

normal PET-CT findings. All of them showed ambiguous cognitive symptoms, with mild cognitive complaints, such as forgetfulness and attention difficulties. Patients exhibited normal metabolic activity, suggesting non-neurological origins for their cognitive complaints. These patients tended to be younger, with a mean age of 70.6 years, and predominantly female (69%). The mean Mini-Mental State Examination (MMSE) score was 25/30, with no significant differences between genders. A majority (54.76%) of patients had a history of psychiatric pathology, with anxious-depressive syndrome being the most common. Additionally, 28.57% of patients had an associated neurological disorder, such as trigeminal neuralgia, headache, or recovered stroke. Radiological studies (CT/MRI) were age-appropriately normal in 92.85% of patients. Interestingly, 52.38% of patients lived alone. These findings underscore the complexity of cases of cognitive decline with uncertain clinical presentations. Despite the absence of abnormal findings on PET-CT, a significant proportion of patients had a history of psychiatric pathology and associations with other neurological diseases. The prevalence of living alone in this group suggests possible social and support implications that may influence the management and prognosis of these patients. ***Conclusion:*** The findings underscore the significance of normal PET-CT results in the evaluation of patients with unclear clinical presentation of cognitive decline, particularly in the context of comorbid anxious-depressive syndrome. By excluding neurodegenerative etiologies clinicians can provide targeted management strategies and enhancing patient care. This highlights the importance of comprehensive imaging assessments in guiding clinical decision-making and optimizing patient care.

Enhancing Lewy-body disease diagnosis using probability assessment: The SMILe index for 123I-mIBG imaging

K. Nakajima, *T. Matsumura, J. Komatsu, H. Wakabayashi, K. Ono, S. Kinuya;*
Kanazawa University, Kanazawa, JAPAN.

Aim/Introduction: Sympathetic 123I-metaiodobenzylguanidine (mIBG) imaging, typically analyzed via the heart-to-mediastinum ratio (H/M), has been extensively employed in diagnosing Lewy-body diseases (LBD), such as Parkinson's disease and dementia with Lewy bodies. However, variable threshold values for the H/M ratio have limited its practical utility. Our study aims to develop a more pragmatic diagnostic tool, the SMILe index (Sympathetic mIBG Index for LBD), which quantifies the likelihood of LBD directly through a standardized, outpatient-friendly H/M-based model. This index also aims to establish criteria that could exempt patients from undergoing late imaging. ***Materials and Methods:*** We collected early and late mIBG images from 92 consecutive patients suspected of LBD, excluding those with young-onset Parkinson's disease (age < 50 years) and genetic transthyretin-type amyloidosis. The initial step involved standardizing the H/M ratio for collimator differences using a phantom-based cross-calibration method prevalent in Japanese and partly European clinical settings. Logistic models were then developed to incorporate H/M ratios with or without additional variables like age or washout rate, leading to the creation of the SMILe index for LBD. This index categorizes LBD likelihood on a scale from 0 (lowest) to 1 (highest). Its diagnostic accuracy was evaluated using the area under the receiver operating characteristic (ROC) curve (AUC), and its performance was compared with traditional H/M ratios. The necessity for late imaging was also assessed with the early SMILe index. ***Results:*** The SMILe index, using just the H/M ratio, effectively differentiated between LBD and non-LBD cases. Additional variables such as age or washout rate did not enhance the diagnostic value. The AUC values for the early and late SMILe indexes were 0.88 and 0.89, respectively, both statistically significant ($p<0.0001$). Patients with/without LBD showed proportional errors between early and late H/M ratios, while Bland-Altman plots confirmed the absence of fixed and proportional errors between early and late SMILe indexes. Furthermore, sensitivity and specificity for both early and late indexes at a 0.5 threshold were 90% and 73%, and 87% and 76%, respectively. Notably, only 16% of patients with an early SMILe index between 0.3 and 0.7 required late imaging for the correct mIBG diagnosis. ***Conclusion:*** The 123I-mIBG-derived SMILe index demonstrates excellent diagnostic accuracy for LBD at a 50% threshold. It successfully identifies patients who do not require late imaging, with thresholds of < 0.3 or > 0.7, thus enhancing patient comfort and streamlining the clinical process in mIBG imaging for LBD.

EP-0534

Optimization of acquisition time for [^{123}I]-FP-CIT SPECT examination

T. Noponen[1], *L. Kääriä[1], T. Kangasmaa[2], R. Siekkinen[1], V. Kaasinen[3], M. Seppänen[4];*
[1]Department of Clinical Physiology, Nuclear Medicine, Turku PET Centre and Medical Physics, Turku University Hospital and Wellbeing Services County of Southwest Finland and University of Turku, Turku, FINLAND, [2]Department of Clinical Physiology and Nuclear Medicine, Vaasa Central Hospital, Wellbeing Services County of Ostrobothnia, Vaasa, FINLAND, [3]Clinical Neurosciences and Neurocenter, University of Turku, Turku University Hospital and Wellbeing Services County of Southwest Finland, Turku, FINLAND, [4]Department of Clinical Physiology, Nuclear Medicine and Turku PET Centre, Turku University Hospital and Wellbeing Services County of Southwest Finland and University of Turku, Turku, Finland, Turku, FINLAND.

Aim/Introduction: Dopamine transporter (DAT) imaging using [123I]-FP-CIT SPECT is a pivotal examination in assessing patients with Parkinson's disease (PD). Motor and non-motor related challenges such as tremor, rigidity and cognitive disorders often limit patients from remaining still during imaging. These issues necessitate an optimal acquisition time to minimize motion artifacts and enhance patient comfort while maintaining diagnostic accuracy. ***Materials and Methods:*** Ninety-two patients with clinically uncertain parkinsonian syndrome underwent DAT SPECT imaging. Patients were administered with 185 MBq of [123I]-FP-CIT and imaged 3-hours post-injection using a digital dual-head SPECT/CT system capable of list-mode acquisition. The acquisition protocol, adhering to EANM recommendations, included 120 projections with an original frame-time of 35 s, a zoom of 1.28, and a matrix size of 128x128

resulting in a total imaging time of approximately 38 min. Data were reframed using a commercial listering software to create three additional sinograms per acquisition with frame times of 21, 15 and 10 s. All 368 sinograms were similarly reconstructed using 3D OSEM-based iterative-algorithm including Chang's attenuation, collimator and Monte-Carlo-based scatter correction and Gaussian post-filtering.Regional specific-binding ratios (rSBRs) were defined using a commercial semi-automatic software. Four striatal volume-of-interests (VOIs) (the right (RP) and left putamen (LP) and the right (RCN) and left caudate nucleus (LCN)) and a reference occipital VOI were delineated in the reference image and transferred into a registered patient image to derive the rSBR values. Mean and standard deviation (SD) of rSBRs were calculated. Statistical normality assumptions were confirmed and a mixed model was used to evaluate differences between rSBRs using four different frame times. ***Results:*** The mean (SD) rSBRRCNs for frame times of 10-35 s ranged between 2.035 - 2.079 (0.481 - 0.539) and the mean (SD) rSBRLCNs between 2.043 - 2.068 (0.488 - 0.515). The corresponding rSBRRP values ranged between 1.717 - 1.740 (0.592 - 0.621) and the rSBRLP values between 1.576 - 1.604 (0.510 - 0.577). No statistically significant differences were observed in rSBRs between difference frame times (pRCN = 0.11, pLCN = 0.53, pRP = 0.67 and pLP = 0.58). ***Conclusion:*** Semi-quantitative DAT imaging results remain stable despite reducing frame time from 35 to 10 s in SPECT examination. This reduction in frame time promises significant enhancement in DAT imaging practices. Further validation through visual analysis is warranted in future studies.

EP-0535

Correlation between I-123 mIBG myocardial uptake and dopamine-related clinical symptoms in Parkinson's disease patients

Y. Lee, *S. Na;*
Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: The prevalence of Parkinson's disease (PD) increases as the senior population grows. I-123 mIBG cardiac scintigraphy has a clinical role in the early detection of autonomic failure in PD patients. However, it is not well elucidated whether there exists a correlation between myocardial mIBG uptake and dopamine-related clinical symptoms. Therefore, the aim of this study is to evaluate the correlation between myocardial uptake in mIBG scintigraphy and clinical symptoms related to dopaminergic degeneration. ***Materials and Methods:*** In this retrospective study, one hundred-four consecutive PD patients, from March of 2018 and March of 2024, were enrolled in this cohort. All included subjects underwent F-18 FP-CIT PET/CT and showed diminished dopamin transporter (DAT) activity in at least one of the striatum. The intensity of I-123 mIBG myocardial uptake was calulated with heart-to-mediastinal ratio (H/M ratio) at 30 and 120 minutes, respectively. Clinical data including age, sex, education years, tremor/rigidity severity scores from Unified Parkinson's Disease Rating Scale (UPDRS), Clinical Dementia Rating (CDR), Korean Mini-Mental State Examination (K-MMSE) were acquired and compared with H/M ratio. After dichomotizing the subjects at the cutoff value of 1.8 for the H/M ratio, clinical data were compared between the high mIBG uptake group and the low mIBG uptake group. Pearson correation test and student T-test was performed. ***Results:*** The H/M ratio of each 30-minute (r=-0.259, p=0.008) and 120-minute (r=-0.227, p=0.021) images showed weak negative correlation with age. No significant correlation was observed between H/M ratio and other clinical data including rigidity (r=0.070, p=0.479) and tremor severity scores (r=-0.142, p=0.149). In the dichotomized group analysis, there were no significant differences between the high mIBG uptake group (n=34) and the low mIBG uptake group (n=70). ***Conclusion:*** Our results, using mIBG myocardial scintigraphy, indicate that autonomic degeneration slowly occurs with age, rather than severity of dopamine-related clinical symptoms in PD patients.

EP-0536

The role of 123I-MIBG cardiac scintigraphy in the patients with movement disorders (MD).

A. Marongiu[1], *S. Nuvoli[1], A. Mura[1], P. Solla[2], A. Spanu[1], G. Madeddu[1];*
[1]Unit of Nuclear Medicine, University of Sassari, viale S. Pietro 8 - 07100 Sassari, Italy, Sassari, ITALY, [2]Unit of Neurology, University of Sassari, viale S. Pietro 8 - 07100 Sassari, Italy, Sassari, ITALY.

Aim/Introduction: The differential diagnosis between Parkinson's disease (PD) and atypical parkinsonism disorders (APD) is often difficult with undeniable prognostic and treatment repercussions. 123I-Ioflupane SPECT is usually employed to distinguish degenerative parkinsonism from essential (ET) and vascular (VT) tremors, but in the last years 123I-MIBG scintigraphy, which evaluates cardiac sympathetic denervation, proved good performance in discriminating PD from APD (PSP, MSA and CBD), improving Ioflupane imaging accuracy. ***Materials and Methods:*** Among a large series of over 300 MD patients submitted to 123I-MIBG cardiac scintigraphy, in the present study, we retrospectively enrolled 135 consecutive patients who had vascular damage in basal ganglia at MRI and pathologic but inconclusive 123I-Iofluopane SPECT for definitive differential MD diagnosis. After 111 MBq of 123I MIBG i.v. injection, cardiac scintigraphy was performed (anteroposterior and anterior-left oblique planar views) after 15 min (early-E) and 240 min (delayed-D). The images were analyzed by qualitative and quantitative methods, the latter with heart/mediastinum (H/M) ratio calculation in interest regions with 1.55 cut-off value. ***Results:*** At qualitative evaluation, MIBG uptake was slight to severe reduced in 77/135 patients (Group 1), while preserved uptake was observed in 58/135 cases (Group 2). The quantitative method showed H/M ratio <1.55 in 75/77 Group 1 patients, in both E (1.32±0.16) and D (1.27±0.18) phases, not statistically significant (p=0.074). These patients were classified as PD. The remaining two Group 1 patients had borderline H/M ratio in both E and D phases and APD was diagnosed. In Group 2 patients, H/M ratio was >1.55 in all 58 cases, mean values being 1.71±0.16 (E) and 1.75±0.22 (D), not statistically significant (p=0.25). APD was diagnosed in 47 Group 2 patients and VT in 11 cases. Comparing H/M ratio of Group 1 with Group 2 patients in both phases, the difference was statistically significant (p<0.0001). H/M comparison between all 49 APD and 75 PD patients, in both phases, showed a significant (p<0.0001) difference as well as between PD and VT. Patient diagnosis was confirmed with careful clinical long-term follow up during specific treatments. ***Conclusion:*** In the present study, 123I-MIBG cardiac scintigraphy proved a valuable tool for discriminating PD from APD and VT. In particular, H/M ratio showed better performance than qualitative diagnostic method. No statistical difference was found comparing E and D phases, thus suggesting that E evaluation alone can be sufficient for disease diagnosis. A larger cardiac 123I-MIBG scintigraphy use is suggested in the diagnostic MD strategy.

Digital SPECT with123 I-Ioflupane and analog image-based normality databases - The Semi-QuantifiQuestion

***M. Monteiro*[1],** *J. Silva*[1], *L. Lemos*[1], *P. Gil*[1], *A. Moreira*[1,2], *R. Silva*[1,2], *M. Cunha*[1], *G. Costa*[1,3];
[1]*CHUC, Coimbra, PORTUGAL,* [2]*ICNAS, Coimbra, PORTUGAL,* [3]*FMUC, Coimbra, PORTUGAL.*

Aim/Introduction: Despite the typically straightforward nature of cerebral the [123I]I-FP-CIT(123I-ioflupane) brain SPECT images' visual interpretation, semi-quantitative parameters such as the striatal binding ratio (SBR) enhance diagnostic certainty, particularly in borderline cases. Given their improved spatial resolution, sensitivity, signal-to-noise ratio, and the utilization of new reconstruction algorithms, the introduction of digital gamma-cameras in clinical practice allows for increasingly accurate and reproducible SBR calculation. However, their comparison with normality values obtained from the analog gamma-camera data provided by most commercial softwares is questionable. In this study we aimed to compare SBR values from healthy control analog gamma-camera images with those calculated from normal case clinical images acquired on a CZT 3D-ring detector gamma-camera. ***Materials and Methods:*** Bilateral SBR values for the striatum, caudate, whole putamen, anterior putamen, and posterior putamen were analyzed. SBR values from healthy controls were obtained from non-attenuation corrected ordered subset expectation maximization (OSEM) reconstructions available on the PPMI (Parkinson Progression Markers Initiative) database. Normal case images were reconstructed without attenuation correction using OSEM (same parameters as the healthy controls' images) and block sequential regularized expectation maximization (BSREM) algorithms, with SBRs calculated using a dedicated software. ***Results:*** Thirty-five normal cases (mean age 69±10 [47-86] years) and 70 healthy controls (mean age 66±9 [44-84] years) with a statistically similar age distribution between groups (p>0.05) were processed. No statistically significant difference was found between the mean SBR OSEM values of the normal cases and the controls for any of the analyzed regions (p>0.05). However, BSREM images showed statistically higher SBR values in all regions when compared to the same cases' OSEM reconstructions (p<0.05; 2-10% increase). ***Conclusion:*** Our results indicate that, using the same reconstruction algorithm, it could be acceptable to use analog gamma-camera normality databases to aid in the visual analysis of state-of-the-art CZT gamma-camera images. However, new reconstruction algorithms may require dedicated databases.

Striatal Dopamine Transporter Binding in Individuals With 22q11.2 Copy Number Variants: An [^{123}I]FP-CIT SPECT Study

***R. Schalbroeck*[1,2],** *C. F. M. van Hooijdonk*[2], *C. Vingerhoets*[2], *T. van Amelsvoort*[2], *J. Booij*[1];
[1]*Amsterdam UMC, Amsterdam, NETHERLANDS,* [2]*Maastricht University, Maastricht, NETHERLANDS.*

Aim/Introduction: 22q11.2 deletion syndrome (22q11Del) is a relatively common genetic disorder associated with an increased risk of developing early-onset Parkinson's disease (PD). It is unknown whether individuals with 22q11.2 duplication syndrome (22q11Dup) have an altered risk of PD. As PD is characterized by loss of striatal dopamine transporter (DAT) binding, we explored the striatal DAT availability in non-psychotic individuals with 22q11Del, 22q11Dup and healthy controls (HC). We hypothesized that striatal DAT binding ratios would be highest in 22q11Del and lowest in 22q11Dup, since studies suggest higher striatal DAT expression in subjects at risk to develop PD. ***Materials and Methods:*** Six individuals with 22q11Del (age 36.5 years, 4F/2M), four individuals with 22q11Dup (age 37.3 years, 2F/2M), and eight HC (age 39.1 years, 4F/4M) not taking any psychopharmacological medication were included. [123I]FP-CIT single photon emission computed tomography was administered for determination of DAT binding ratios. ***Results:*** After correction for age and sex, we found statistically significant overall group differences in left and right putamen (p=0.025 and p=0.014 respectively), and left and right caudate (p=0.014 and p=0.010 respectively). Post hoc analyses revealed significantly increased DAT binding ratios in 22qDel versus 22q11Dup in all four subregions (left putamen p=0.02, right putamen p=0.012, left caudate p=0.026, right caudate p=0.005). Effect sizes were large (ηp2≥0.577) in all regions. ***Conclusion:*** Our preliminary results are in line with a previously reported hyperdopaminergic state in 22q11Del. This hyperdopaminergic state, which may be partially driven by COMT haploinsufficiency in 22q11Del, might eventually cause auto-neurotoxicity and subsequent death of dopaminergic neurons, which could explain the increased occurrence of PD in individuals with 22q11Del. Future larger studies are necessary to replicate our findings and investigate whether DAT imaging could be used as a predictor of progression to PD in individuals with 22q11Del.

EP-0539

Synthesis and evaluation of ^{11}C-phenethylamine analogues as PET tracers for the imaging of 5-HT$_{2A}$ receptors

***M. Zabrocki*[1],** *C. Madsen*[2], *U. M. Battisti*[1], *G. M. Knudsen*[2], *M. M. Herth*[1];
[1]*University of Copenhagen, Copenhagen, DENMARK,* [2]*Copenhagen University Hospitals, Copenhagen, DENMARK.*

Aim/Introduction: In recent years, a renewed interest in psychedelics for treatment of disorders such as depression or anxiety has emerged.[1] Classical psychedelics stimulate the brain's G protein-coupled receptor (GPCR) serotonin 2A receptor (5-HT2AR). However, animal studies have indicated that not all 5-HT2AR agonists have psychedelic effects. These differences in pharmacological profiles might originate from a favored modulation of either the β-arrestin2 signaling pathway or the GPCR-pathway via biased signaling.[2] The development of new positron emission tomography (PET) tracers that are biased towards specific 5-HT2AR signaling pathways is crucial to elucidate mechanisms of such drugs and offer insight on their therapeutic benefits. ***Materials and Methods:*** Four PET tracers based on structures of phenethylamines previously found to be biased towards the β-arrestin2 signaling pathway were synthesized along with their corresponding reference compounds. 11C-labelings of precursors were performed using [^{11}C]methyl triflate following the radiolabeling protocol of [1^{11}C]CIMBI-36. Briefly, [^{11}C] methyl triflate was formed from [^{11}C]methane and trapped

in a reaction vessel containing the precursor dissolved in a solution of acetone and sodium hydroxide. The reaction time was one minute and deprotection was carried out by adding a 1:1 solution of acetone and trifluoracetic acid (TFA), followed by heating at 80 °C for 10 minutes. After neutralization, the products were purified via preparative HPLC using 25% EtOH in milliQ water and 0.1% of phosphoric acid on an Onyx Monolithic semi-PREP C18 HPLC column (100 × 10 mm, Phenomenex). ***Results:*** The four PET tracers were obtained with activities ranging from 0.5 to 2.0 GBq, with RCY over 30% and with molar activities ranging from 115 to 800 GBq/µmol. A radiochemical purity above 98% was detected for all compounds. ***Conclusion:*** Four new PET tracers biased towards the β-arrestin2 signaling pathway were successfully synthesized. The ligand-receptor interactions will be assessed to determine the in vitro affinity to the target, association and dissociation constant, as well as the half-life of residence time. Their pharmacokinetics and selectivity for 5-HT2AR will be determined in pigs via pre-dosing studies with volinanserin, a 5-HT2AR antagonist, and compared to each other and 11C-CIMBI-36. These tracers might be useful tools in uncovering mechanisms underlying therapeutic benefits of psychedelics for disorders such as depression or anxiety. ***References:*** [1]Goodwin, G. M. et al. EP-0540

Mapping multimodal connectomes to neurocognition and neurological diseases across shared modular architecture

L. Xiao, *Y. Tang, L. Feng, S. Hu;*
Xiangya Hospital Central South University, Changsha, CHINA.

Aim/Introduction: The brain is characterized by heterogeneous patterns of connectivity, abstracting away biological and pathological hallmarks of the neural population. Yet the shared organization underlying unimodal brain networks, and the mapping principle between network architecture, flexible neurocognition, and progressive neurological disorders remain unclear. ***Materials and Methods:*** Here we integrate multiscopic measures ranging from transcription to metabolism, identifying the shared anatomic structure and anterior-posterior/midline hierarchy across connectomes. ***Results:*** We find unimodal and cross-modal gradients separate cognitive processes alongside the putative perceptual/motor-affective axis, bridging connectomes to the metadata of neurocognition. Finally, we determine the dominance of networks to the typical progressive neurological diseases, temporal lobe epilepsy (TLE), and amyotrophic lateral sclerosis (ALS). We find the opposite distribution pattern of metabolic abnormality in TLE and ALS, and the unique or shared contributions. ***Conclusion:*** Collectively, our work bridges heterogeneous connectomes to cognitive functions and neurological diseases, laying the foundation for the next-generation cross-modal studies.

Brain Incidentalomas in PET CT: a Meta-Analytic Literature Review

F. Chehade[1], *Z. Salman[2], J. Hadchiti[3], L. Abouabbas[2], S. Hajeer[2], A. Mohanna[4];*
[1]Nuclear Medicine Gustave Roussy, 94805 Villejuif, FRANCE, [2]Neuroimaging, Medical Sciences, Lebanese University, Hadath, LEBANON, [3]Radiology Gustave Roussy, 94805 Villejuif, FRANCE, [4]Radiology, Lebanese University, Hadath, LEBANON.

Aim/Introduction: Various structural and functional imaging modalities have been largely helpful in the discovery of incidentalomas. The identification of incidentalomas in the brain, a critical organ, and their management, make it possible to apply appropriate therapeutic means early, thus improving the prognosis of patients, particularly when they are malignant. Positron emission tomography (PET) has seen considerable innovation in recent decades in the diagnosis of cancer and systemic diseases, increasing among others, the rates of cerebral incidentalomas. This fact urges to investigate their etiologies and prevalence in order to improve their recognition by nuclear medicine physicians, depending on the radiotracers used. It therefore becomes important to establish a global synthesis of the data available in the literature regarding cerebral incidentalomas observed in PET. ***Materials and Methods:*** Following the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) checklist guidelines, a systematic review and a meta-analysis were undertaken. Literature was searched through several main engines including PubMed, CORE, and Web of Science. Our reviewers navigated the literature and extracted the adequate information. Data synthesis consisted of qualitative and quantitative analyses. Quality of bias was assessed using the Newcastle-Ottawa Scale for observational studies, and Joanna Briggs Institute Critical Appraisal Checklist For Case Reports. ***Results:*** A total of 1218 studies were singled out; however, only 33 articles meet the inclusion criteria, of which 10 articles are retrospective cohorts and 23 are case reports. Descriptive and qualitative analyzes have revealed that the most common brain incidentalomas are metastatic tumors (24%), meningiomas (21.9%) and pituitary adenomas (10,7%) for observational studies, which were mostly detected with F18-FDG and Ga68-DOTA-peptides. The metastatic incidentalomas are predominantly related to cancers of lung (53.7%) and breast (11.9%). As for the cohort of 23 case reports, 6 cases were diagnosed with meningiomas. Meta-analysis has reported a pooled prevalence rate of 2.4% among the cohorts, with a heterogeneity I^2 index of 96.6% indicating a major variability within selected studies. ***Conclusion:*** This review is the first to have gathered and summarized findings available in the literature on the identification of brain incidentalomas using PET. It certainly has fulfilled its main objective by presenting the compiled findings derived from the literature and deducing a pooled prevalence rate along with a description of their etiologies, while highlighting investigative radiopharmaceuticals. Results undeniably solicit more research and studies for a better management of these entities whose etiologies are quite diverse.

EP-0542

Temporal CBF changes in patients with moyamoya disease and non-moyamoya steno-occlusive disease on a day after bypass surgery evaluated by ^{99}mTc-ECD SPECT

K. Kaneko, *K. Yamaguchi, K. Chiba, Y. Maekawa, A. Yamamoto, M. Nagao, T. Kawamata, S. Sakai;*
Tokyo Women's Medical University Hospital, Shinjuku-ku, Tokyo, JAPAN.

Aim/Introduction: To investigate temporal cerebral blood flow (CBF) changes in the moyamoya disease (MMD) and non-moyamoya steno-occlusive disease (NMSOD) patients on a day after bypass surgery. ***Materials and Methods:*** Patlak plot 99mTc-ECD SPECT studies were performed on 68 hemispheres in 51 MMD/ NMSOD patients (range 6-74 years) who underwent superficial temporal artery-middle cerebral artery double anastomosis on a postoperative day (POD) 1. We investigated pre to post-operative focal CBF (qualitative CBF ratio) changes using three-dimensional stereotaxic ROI template. We evaluated the incidences, degrees, patterns, and major complications of hyper perfusion (HP) and compared the differences among the 44 hemispheres in adult MMD (≧20 years), 13 in young MMD (< 20 years), and 11 in NMSOD patients. When HP was suspected, a subsequent SPECT study was performed on a next day to assess CBF changes. ***Results:*** In total, mild (≧30 to < 50% increase than pre-operative CBF), moderate (≧50 to < 100%) , and severe (100%≧) HP were observed in 7.4% (5/68), 14.7% (10/68) and 2.9% (2/68) of the patients, respectively. Most of HP occurred with frontal lobe dominant (70.6%, 12/17), and the incidence (17.6%, 12/68) of frontal lobe dominant HP was significantly higher than those of temporal (2.9%, 2/68) or parietal lobe (4.4%, 3/68) dominant HP ($p < 0.01$ for both). In 17 hemispheres with HP, focal CBF increase (%) were higher in frontal lobe (58.7±50.1%, mean±SD) than those of temporal (27.4±26.1%) and parietal lobes (28.8±26.1%) ($p = 0.01$ for parietal lobe). The 9 subsequent brain SPECT studies on a POD 2, eight hemispheres showed CBF reduction, while one hemisphere developed to a moderate HP. A cerebral hemorrhage and an infarction occurred in 2 hemisphere of the adult MMD patients with moderate to severe HP, but no none in the mild HP, NMSOD and young MMD patients. The incidence of moderate to severe HP was significantly higher in hemispheres of the adult MMD patients than those of the non-adult MMD patients (22.7% vs. 4.2%, $p < 0.05$). ***Conclusion:*** HP could sometimes occur mainly in frontal lobe in adult MMD patients on POD 1, while rarely occur in young MMD and NMSOD patients, and most of them could improve on a next day. Increased focal CBF≧50% than pre-operative condition could be a risk of major complication in adult MMD patients.

EP-0543

Cerebral Hypometabolism in Left-Ventricular Assist Device (LVAD) Recipients: Evaluation of a Most Suitable Intensity Normalization Method

M. S. Jungclaus[1], *F. Wilke*[2], *C. P. Czerner*[2], *T. Derlin*[2], *R. A. Werner*[3], *J. S. Hanke*[4], *J. D. Schmitto*[4], *F. M. Bengel*[2], *H. Worthmann*[1], *M. M. Gabriel*[1], *G. Berding*[2], *D. Weiberg*[2];
[1]*Department of Neurology, Hannover Medical School, Hannover, GERMANY,* [2]*Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY,* [3]*Department of Nuclear Medicine, Goethe University Frankfurt, Frankfurt am Main, GERMANY,* [4]*Department of Cardiac, Thoracic, Transplantation and Vascular Surgery, Hannover Medical School, Hannover, GERMANY.*

Aim/Introduction: Left ventricular assist devices (LVAD) have gained importance in the therapy of severe heart failure. Stroke is a common post-implantation complication of LVAD patients. However, apart from stroke-related consequences the effect of LVAD therapy on neurocognitive function remains ambiguous.18F-FDG-PET/CT is a widely used non-invasive imaging method that enables the investigation of various neurocognitive disorders of the brain. Using state-of-the-art parametric imaging 18F-FDG-PET/CT as gold standard, we aimed to clarify changes in absolute brain metabolism, as well as validate a simple intensity normalization method for regional metabolic alterations in larger cohorts of LVAD patients. ***Materials and Methods:*** We evaluated the results of whole body dynamic 18F-FDG-PET/CT images of 9 LVAD patients with and without a history of stroke (meanage=52years, range 30-74y). Single-subject statistical parametric mapping (SPM) against a control group consisting of 16 subjects (meanage=58,7y, range 36-77y) without conditions influencing the cerebral metabolism was performed after intensity normalization based on proportional scaling (PS) and the pons as reference region (Pons). The parametric images of the cerebral metabolic rate of 18F-FDG (MRFDG) calculated using the Patlak-plot method was determined as gold standard (Patlak) for comparison. ***Results:*** SPMs two-sample t test ($p<0.001$) of the Patlak images between the LVAD patients and the control group revealed a widespread hypometabolism (106235 suprathreshold voxel (sVx)) and no hypermetabolism (0sVx) in the LVAD-group. PS could not reproduce the widespread hypometabolism (165sVx), contrary to the Pons method (55367sVx), but found hypermetabolic clusters (PS: 2565sVx, Pons: 323sVx). In single subject analyses PS showed considerably more hypermetabolic clusters than Pons, reflected by deviant sensitivity (PS: 70%; Pons: 100%). The hypermetabolic clusters were presumably artefacts as they were not prevalent in the Patlak results. Comparing the three methods revealed significant differences in both hypo- ($p=0.027$) and hypermetabolism ($p=0.001$). In the Dunn-Bonferroni post-hoc-test PS and Pons did not show significant differences with Patlak for total hypometabolic volume (pPS=0.075, ppons=0.055; effect size rPS=0.352, rpons=0.37). Contrary to Pons (ppons=0.102, rpons=0.333), PS showed significant difference with Patlak for total hypermetabolic volume (pPS=0.001, rPS=0.556). ***Conclusion:*** The absolute measurement of the MRFDG reveals a widespread cerebral hypometabolism in LVAD patients. The PS method is not applicable for LVAD patients, as it fails to reproduce the widespread hypometabolism and additionally creates hypermetabolic artefacts. As groundwork for our subsequent neurocognitive studies, we will propose the Pons as reference region, as it most adequately reproduces the widespread hypometabolism as well as the regional MRFDG results.

EP-0544

Neuronal mechanisms underlying cochlear implant performance in single-sided deafness: a [^{15}O]water PET study

I. Speck[1], *G. Blazhenets*[1], *S. Arndt*[2], *J. Thurow*[1], *L. Frings*[1], *T. Wesarg*[2], *A. Aschendorff*[2], *P. T. Meyer*[1];
[1]*Department of Nuclear Medicine, Freiburg, GERMANY,* [2]*Department of Otorhinolaryngology - Head and Neck Surgery, Freiburg, GERMANY.*

Aim/Introduction: We examined regional cerebral blood flow (CBF) changes as a marker of neuronal activity in single-sided deaf (SSD) cochlea implant (CI) recipients and normal-hearing (NH) controls to unravel neuronal mechanisms underlying CI performance. ***Materials and Methods:*** Twenty right-handed SSD-CI subjects (CI left) and 10 right-handed NH

controls underwent [15O]water PET (12 scans each). For auditory stimulation we used sentences of the Oldenburg Sentence Test played forward or backward (semantic and non-semantic condition, respectively), either presented unilaterally to the right (i.e., NH ear in all subjects) or bilaterally. Voxel-wise comparison between stimuli in all subjects were performed to identify regions with significant activation caused by 'Listening' (bilateral vs. unilateral) and 'Processing' (semantic vs. non-semantic). Relative CBF in these regions was then compared between groups of SSD-CI subjects with high and low CI benefit (CI benefit: bilateral speech recognition in PET minus unilateral speech recognition in PET) and NH controls. ***Results:*** Voxel-wise analyses across all subjects yielded strong activations of the right primary auditory cortex (PAC) for 'Listening' and of the left superior temporal gyrus (STG) for the 'Processing'. The activation of the right PAC (pooled semantic and non-semantic conditions) was comparable and significant in all groups (all $p \leq 0.001$). In contrast, a highly significant activation of the left STG was only observed in SSD-CI subjects with high CI benefit ($p < 0.001$ for both, uni- and bilateral stimulations) and NH controls ($p = 0.001$ and $p = 0.006$, respectively), while a significant activation of the left STG was not observed in SSD-CI subjects with low CI benefit, neither for unilateral (NH ear) nor bilateral stimulation. ***Conclusion:*** The comparable activation of the PAC across groups suggests that the CI provides quantitatively comparable auditory input in SSD-CI subjects. In contrast, SSD-CI subjects with low CI benefit lack activation of the left STG, not only with bilateral but also unilateral stimulation (i.e., NH ear only). Future studies need to clarify if this abnormal recruitment of the left STG is a result of CI treatment or exists already before CI treatment, thus being a possible predictor of CI performance.

EP-0545

How is the rs6971 polymorphism accounted for in clinical studies using second-generation PET radiopharmaceuticals targeting TSPO?

***Y. Girard*[1],** *A. Callaud*[2], *A. Dupont*[3,1], *V. Hardillier*[1], *G. Simon*[1], *H. Boutin*[3], *N. Arlicot*[3,1,4];
[1]*CHRU de Tours, Unité de Radiopharmacie, Tours, FRANCE,* [2]*CHRU de Tours, Service de Médecine Nucléaire, Tours, FRANCE,* [3]*Imaging Brain and Neuropsychiatry iBraiN U1253, INSERM, Université de Tours, Tours, FRANCE,* [4]*INSERM CIC 1415, Université de Tours, Tours, FRANCE.*

Aim/Introduction: The 18kDa translocator protein (TSPO) is the most used biomarker of microglial activation and has contributed to the understanding of the role of neuroinflammation in numerous pathologies. However, the clinical use of second-generation TSPO radiopharmaceuticals has been impacted by their sensitivity to the TSPO rs6971 polymorphism in human discovered in 2012[1] and resulting in three affinity profiles: high-affinity binders (HABs), mixed-affinity binders (MABs) and low-affinity binders (LABs) which affect tracer uptake and PET quantification. Patient genotyping is therefore necessary in clinical trials using these radiopharmaceuticals. This work aimed to review how this polymorphism has impacted the use of the second-generation TSPO radiopharmaceuticals1C-PBR28, 11C-DAA1106, 11C-DPA713, 18F-DPA714, 18F-PBR111, 18F-FEPPA and 18F-PBR06 in clinical studies. ***Materials and Methods:*** 200 clinical articles using these radiopharmaceuticals, published between 2012 and 2022, and representing 5929 subjects, were extracted from PubMed. Demographic data, pathology studied, radiopharmaceuticals, PET analysis and rs6971 polymorphism analysis were collected and analyzed. ***Results:*** The frequency of genotyping initially increased since 2012, before stabilizing for several years at around 90% of the studies. In the Caucasian population, the distribution of genotype profiles was consistent with what had been reported[2]: ~65% HABs, ~35% MABs and ~5% LABs. In order to pool HABs and MABs subgroups, several studies proposed a correction factor of the volume of distribution (VT) of MABs subjects, fairly consistent between 1.4 and 1.8 depending on the tracer, whatever the pathology studied and the radiopharmaceutical used. ***Conclusion:*** This analysis confirmed that the rs6971 polymorphism is a limiting factor in the analysis of PET images because it imposes a genotyping to identify LABs, MABs and HABs subjects to perform in each study. Moreover, there is always a hypothetical bias introduced in excluding MABs and LABs from the cohort, although overall no findings obtained with rs6971-insensitive tracer [11C]PK11195 has been contradicted when the same pathology was investigated with one of those 2nd generation tracer. No consensus exists to date to account for the effect of polymorphism on the PET signal, we therefore propose guidelines considering characteristics of the research protocol (kinetics of microglial activation in the pathology studied, need for therapeutic intervention, etc.), and regarding timing of genotyping relative to inclusion and PET, and LABs exclusion. The clinical impact of third-generation TSPO radiopharmaceuticals, insensitive to the polymorphism, should also be considered. ***References:*** [1]Owen DR, et al. J Cereb Blood Flow Metab. 2012 Jan;32(1):1-5.[2]Mizrahi R, et al. J Cereb Blood Flow Metab. 2012 Jun; 32(6):968-72.

EP-0546

^{18}F-FDG-PET/CT in the diagnosis of autoimmune limbic encephalitis: a case series

S. Georga, *D. Katsampoukas, V. Mpalaris, A. Georgiou, E. Moralidis, G. Arsos;*
3rd Dept. of Nuclear Medicine, Aristotle University Medical School, Papageorgiou General Hospital, Thessaloniki, GREECE.

Aim/Introduction: Autoimmune limbic encephalitis (ALE) is a rare condition characterized by autoimmune inflammatory lesions of the medial temporal lobe (MTL) associated with circulating antibodies against surface or intracellular neuronal antigens. Whole-body 18F-FDG-PET/CT is commonly performed to detect/exclude paraneoplastic origin of ALE, but current consensus criteria propose brain 18F-FDG-PET/CT as an alternative to MRI for the establishment of definite diagnosis of ALE [1]. We present a small series of ALE cases in which 18F-FDG-PET/CT, performed for investigating potentially paraneoplastic ALE, detected brain metabolic changes compatible with ALE. ***Materials and Methods:*** We retrospectively reviewed 18F-FDG-PET/CT scans performed in patients suspect of ALE between 8/2016 and 12/2023. We found 11 scans performed in 7 patients with definite diagnosis of ALE according to current consensus criteria. All had short-term memory deficits, behavioural disorders, slow-wave temporal EEG activity and no imaging evidence of malignancy. Serum and CSF antineuronal antibodies were detected in 5/7 patients (anti-LGI1, anti-LGI1/anti-CASPR2, anti-Hu/anti-CV2, anti-CV2, anti-GABABR), while 2/7 patients were seronegative. Baseline brain MRI showed bilateral (in 3) or unilateral (in 4) hyperintensity of the MTL on T2-weighted and FLAIR images. All patients underwent dedicated brain and whole-body 18F-FDG-PET/CT scans, repeated in 3 post-treatment. 18F-FDG temporal cortex uptake was visually and semi-quantitatively assessed. ***Results:*** Brain PET revealed altered 18F-FDG medial temporal lobe metabolism in all patients. Unilateral hypermetabolism in MTL was present in 5/7 patients (SUVmax 8.7-16.9), while unilateral

hypometabolism in MTL was detected in 2 patients. Of notice,18F-FDG-PET/CT showed an additional hypermetabolic (SUVmax 15.8) focus in the right parietal lobe, without MRI abnormality, in an anti-LGI1/anti-CASPR2-positive patient. Whole-body 18F-FDG-PET/CT ruled out underlying malignancy in 5/7 patients. In an anti-Hu/anti-CV2-positive patient, 18F-FDG-PET/CT revealed a hypermetabolic (SUVmax 12.0) lesion in the left pulmonary portal, histopathologically confirmed as primary SCLC. In an anti-GABABR-positive patient, 18F-FDG-PET/CT revealed hypermetabolic mediastinal lymphadenopathy (SUVmax 10.5) strongly suspected as metastatic disease. FDG temporal abnormalities returned to normal on all 4 follow-up PET scans performed in 3 patients post treatment. ***Conclusion:*** Our study suggests that 18F-FDG-PET/CT may be a valuable tool in the diagnostic work-up of ALE. Beyond detecting previously unrecognized malignancies underlying paraneoplastic ALE, it also, by detecting brain metabolic changes (commonly medial temporal 18F-FDG hypermetabolism), may substantiate the diagnosis of ALE even in the absence of MRI or biomarkers abnormalities, and further, assess ALE response to treatment. ***References:*** [1] Graus F, Titulaer MJ, Balu R, et al. Clinical approach to diagnosis of autoimmune encephalitis. Lancet Neurol. 2016; 15: 391-404.

EP-0547

Using Synthetic MRI for Improved Stroke Lesion Characterization and Metabolism Prediction By Hybrid PET/MR

B. Cui[1], *J. Lu[1], Y. Zhang[2];*
[1]Department of Radiology and Nuclear Medicine, Xuanwu Hospital Capital Medical University, Beijing, CHINA, [2]GE Healthcare, MR Research China, Beijing, China, Beijing, CHINA.

Aim/Introduction: Stroke is a common disease, with one in four people affected over their lifetime, and is the first leading cause of death in adults worldwide. Positron Emission Tomography (PET)/Magnetic Resonance Imaging (MRI) is a vital tool for assessing stroke and can provide more valuable information. Synthetic MRI (syMRI) is a rapid quantitative MRI technique which enables the simultaneous acquisition of relaxometry measures using multi-echo and multi-delay acquisition method. It allows for not only tailored contrast optimization to enhance stroke lesion delineation, but also provides quantitative data potentially predictive of PET value, which reflect metabolic activity in tissues. This study aims to explore the feasibility of applying synthetic MRI technology to improve stroke lesion characterization and to predict regional metabolic activity of the lesion area. ***Materials and Methods:*** Twenty stroke patients underwent T2-FLAIR, syMRI and PET scanning with a 3.0 T scanner (SIGNA PET/MR, GE Healthcare). We derived T1 values of lesions and surrounding tissues from syMRI scans. Two synthesized inversion recovery images, aimed at suppressing the lesion (TI=800ms) and surrounding tissue (TI=500ms), were merged to create a composite image that maintained anatomical clarity while enhancing lesion contrast. We compared these images with traditional T2-FLAIR for tissue contrast. We also used quantitative relaxation values to construct a predictive model for PET SUV, indicating metabolic activity within lesions. ***Results:*** Logistic regression analysis demonstrated a correlation between the synthesized images and PET image in stroke lesion (R2=0.729, p<0.01). This improved visualization aids more accurate clinical and research assessments. The predictive model based on T1, T2, and PD relaxation values reliably estimated regional metabolic activities, highlighting syMRI's potential in metabolic assessment of stroke lesions. ***Conclusion:*** This study demonstrates syMRI's enhanced imaging capabilities in stroke diagnosis through better lesion visualization and metabolic activity prediction. These advancements could improve diagnostic accuracy and treatment strategies, offering significant benefits in stroke management.

EP-0548

^{18}F FDG PET/CT, the game changer in management of seronegative autoimmune encephalitis patients: an experience from a tertiary care centre

R. Elumalai, *K. Koramadai Karuppasamy;*
Kovai Medical Center and Hospital, Coimbatore, INDIA.

Aim/Introduction: Diagnostic criteria for diagnosis of auto immune encephalitis emphasised more on antibody testing, MRI and EEG changes. Ab testing is not accessible in many institutions and time consuming. Absence of Abs also does not rule out the diagnosis because of the entity called Seronegative Autoimmune encephalitis. MRI and EEG changes were also less specific , non-contributory in many cases. Many case series have highlighted the importance of ^{18}F FDG PET CT for early diagnosis of antibody positive auto immune encephalitis. But no specific study is available regarding the imaging spectrum of seronegative auto immune encephalitis. Hence we decided to retrospectively analyse the ^{18}F FDG PET CT imaging findings of patients with seronegative AE. ***Materials and Methods:*** We retrospectively reviewed 88 (24 females and 64 males, age range 13- 80 years) patients who underwent FDG PET/CT with clinical suspicion for AE and given report as probable AE based on PET/CT . All 88 patients tested negative for autoimmune encephalitis panel of antibodies. Each FDG-PET/CT study was evaluated in consensus by two nuclear medicine physicians with a mean experience of 5.5 years. The brain FDG-PET/CT images were spatial and intensity normalized, and a semi quantitative analysis comparing each patient's image to a database of normals was performed using syngovia software (Siemens, Germany). CSF pleocytosis and MRI were compared with ^{18}F FDG PETCT results. The data was analysed using appropriate statistical methods. ***Results:*** 88 patients underwent FDG-PET/CT imaging at median 7 weeks of symptoms (earliest being 2.5 weeks , late being 12 weeks). Most(55/88, 62%) patients demonstrated bilateral medial temporal lobes, basal ganglia hypermetabolism on PET/CT. Hypo metabolism in frontal and temporal cortices were observed in (27/88, 31%) patients on PET/CT. patients with hyper metabolism and who had an earlier scan responded well to the treatment. patients, who had a scan after 4 weeks of symptoms and with hypo metabolism responded poorly to the treatment. FDGPET/CT diagnosed more cases of auto immune encephalitis than MRI and CSF studies. ***Conclusion:*** Out of 88 patients, PET/CT and MRI concordance was found in only 42 patients. Hence FDG PET/CT was more useful than MRI and CSF studies in diagnosing sero negative auto-immune encepahlitis. Our study also suggests the imaging predictive markers for treatment response. In acute clinical setting, abnormal FDG PET CT being more common than MRI, may serve as an early imaging biomarker of seronegative Autoimmune encephalitis, thus helping in early treatment.

EP-0549

Association Of Ipsilateral Thalamic Hypometabolism On FDG PET-CT With Clinico-Electro-Radiological Features In Patients With Mesial Temporal Lobe Epilepsy.

S. Taywade, *A. Mandal, S. Panda, S. Tiwari, D. Datta, R. Kumar;*
All India Institute of Medical Sciences Jodhpur, Jodhpur, INDIA.

Aim/Introduction: Mesial temporal lobe epilepsy(MTLE) is one of the most common types of drug refractory focal epilepsy. The cortico-subcortical circuit of epilepsy is well known. Thalamic involvement has been emphasized because of its diffuse reciprocal interconnection with cortex physiologically. Recently, there has been special interest to address the relationship between thalamus and focal seizures. In this study, we investigated the association of ipsilateral thalamic hypometabolism on PET-CT with clinical(epilepsy duration & semiology), EEG and radiological(MRI) features in patients with MTLE. ***Materials and Methods:*** We retrospectively reviewed FDG PET-CT brain images of 61-patients who were diagnosed as mesial temporal lobe sclerosis(MTLS) on MRI. Out of 61-patients, 6-patients who had ipsilateral thalamic hypometabolism were included in this study. Both qualitative and semiquantitative analysis was done for PET-CT images. ROI was drawn over each thalamic region on coronal section of fused PET-CT images and SUVmax for the ipsilateral and contralateral side to the disease involvement was calculated. Ipsilateral to contralateral thalamic SUVmax ratio(I/C-ratio) was analyzed. SUVmax values in bilateral thalami were compared using the independent sample t-test. Correlation between I/C ratio with epilepsy duration(years from onset) was determined by means of spearman correlation coefficient. The association between EEG patterns, seizure semiology & MRI findings were also studied. ***Results:*** Demographic details of patients were as follows:3-females, 3-males; median age-20.5years(range 15-50). MRI revealed right MTLS in 4/6patients and left MTLS in 2/6 patients. 3/6 patients had secondary MTLS(2-right sided and 1-left sided). For all patients, SUVmax in the thalamus ipsilateral to the MTS(7.83±2.99) was significantly lower than the contralateral side(10.49±1.97)(p=0.049). There was a significant(p=0.049) strong, negative(rs=-0.81) correlation between I/C-ratio and duration of seizure. Impaired awareness and generalized tonic-clonic movements of all 4-limbs were observed in 4/6-patients(66.6%). Whereas, generalized tonic movements and tonic posturing of left upper limb was observed in one-patient each. EEG was not available for 2/6-patients. 3-patients had alpha range background(1-generalised;2-posterior dominant) and 1-patient showed delta & theta activity on EEG. EEG changes were concordant with PET-CT findings in 4-patients. MRI revealed ipsilateral thalamic atrophy in only 1/6 patients. ***Conclusion:*** The ipsilateral thalamic involvement is uncommon and eminent in patients with longstanding MTLE.Thalamic abnormality on FDG PET-CT precedes structural abnormality on MRI and correlates well with seizure duration & semiology. Semiquatitative analysis on FDG PET-CT is reliable and useful tool in assessment of metabolic alterations in thalamus. However, prospective study with large sample size is warranted to establish these facts precisely.

EP-0550

The role of F^{18}-fluro-ethyl-tyrosine PET/CT for detecting corticotropinomas in Cushing's disease

A. Golubic, *D. Huic;*
University Hospital Centre Zagreb, Department of Nuclear Medicine and Radiation Protection, Zagreb, CROATIA.

Aim/Introduction: Cushing's disease is an endocrine disorder caused by adrenocorticotropic hormone (ACTH)-secreting pituitary adenomas. Magnetic resonance imaging is the current standard imaging method for diagnosing and localizing corticotropinomas, with a failure to detect adenomas in up to 40% of cases. Different molecular imaging methods are being studied for their complementary value. The aim of this study was to observe the value of F^{18}-FET PET/CT in Cushing's disease. ***Materials and Methods:*** Seven patients (five women) were referred from the endocrinology clinic with Cushing's disease for further imaging and possible localization of microadenomas. Their age ranged from 24 to 78 years (mean 50 years). Two patients had prior transsphenoidal surgery. Brain MRI was negative for pituitary macroadenomas in all patients. Standard protocol F^{18}-fluoro-ethyl-tyrosine brain PET/CT was performed 20 minutes after intravenous injection of 200 MBq of F^{18}-FET. ***Results:*** No focal pathological uptake of F^{18}-FET was found in the pituitary in this patient group. Diffuse low-intensity uptake of F^{18}-FET was found in the pituitary in four patients, within normal biodistribution of F^{18}-FET and with a pituitary-to-brain ratio SUVmax < 1,5. ***Conclusion:*** No focal amino acid metabolism pathology was found in the pituitary indicative of corticotropinomas in our small patient group. Variable cell biology of the pituitary warrants further research in different molecular pathways and the potential use of alternative radiopharmaceuticals for the detection of microadenomas in Cushing's disease. ***References:*** Bauman MMJ, Graves JP, Harrison DJ, Hassett LC, Bancos I, Johnson DR, et al. The utility of PET for detecting corticotropinomas in Cushing disease: a scoping review. Neurosurg Rev. 2023;46:160.

Investigation of vermal [18F]PI-2620 signal and its sex-related differences in dynamic tau-PET imaging

A. Kling[1], *J. Kusche-Palenga[1], M. Zaganjori[1], M. Groß[1], J. Levin[2,3,4], G. Bischof[5], T. van Eimeren[5], A. Drzezga[5], O. Sabri[6], M. Rullmann[6], H. Barthel[6], J. Herms[2,4,7], G. Höglinger[2,3,4], N. Franzmeier[4,8], S. Roeber[7], M. Brendel[1,2,4], J. Gnörich[1];*
[1]Department of Nuclear Medicine, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [2]German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, GERMANY, [3]Department of Neurology, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [4]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY, [5]Department of Nuclear Medicine, University Hospital Cologne, Cologne, GERMANY, [6]Department of Nuclear Medicine, University Hospital Leipzig, Leipzig, GERMANY, [7]Center of Neuropathology and Prion Research, University of Munich, Munich, GERMANY, [8]Institute for Stroke and Dementia Research, LMU University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: The evaluation of tau PET imaging data can be affected by off-target binding. First-generation tau PET tracers exhibit off-target binding to MAO-B, neuromelanin and blood products. Second-generation tracers, including [18F] PI-2620, demonstrate more specific binding properties due to their low binding activity for monoamine oxidases. However, the recurring tracer signal in the cerebellar vermis and paravermal region in [18F]PI-2620 scans and its association with tau burden has not yet been investigated. ***Materials and Methods:*** We included dynamic [18F]PI-2620 PET scans from 329 cases with clinically diagnosed Alzheimer's disease (n=119), progressive supranuclear palsy (n=115), corticobasal syndrome (n=46), frontotemporal dementia (n=41), and controls (n=18) in our study. Standardized uptake values (SUV) of the vermis and paravermal region were calculated using the inferior cerebellum as reference region (SUVRVER/CBL) and compared among cohorts. Correlation analyses were conducted between vermis signal and age, gender as well as p-Tau levels in cerebrospinal fluid (CSF). For histopathological evaluation, we performed combined autoradiography and immunohistochemistry experiments of post-mortem brain tissue of deceased patients

(n=9) with different neurodegenerative diseases. ***Results:*** Correlation analysis revealed a significant association between vermal tracer uptake and sex. The mean SUVRVER/CBL in male patients (1.33±0.37, n=176) is elevated compared to female patients (1.14±0.25, n=153), p < 0.0001. Thus, male patients exhibit a higher and more frequent vermal [18F]PI-2620 uptake. Accordingly, there is a significant correlation between SUVRVER/CBL and haemoglobin value in blood sampling (n=80, p=0.01). In histopathological experiments, vermal white matter containing high tau burden in immunohistochemistry evinced elevated [18F] PI-2620 signal in autoradiography. Interestingly, leptomeningeal pigmented cells were colocalized with strong signal spots in autoradiography. No significant association was found between vermal [18F]PI-2620 uptake and age or p-Tau levels in CSF. ***Conclusion:*** Our results suggest that vermal tau accumulation and leptomeningeal pigmented cells contribute to vermal [18F]PI-2620 uptake. Further investigation will include sex-specific signal sources as well as kinetic parameters and microautoradiography to decipher the signal origin at cellular level.

EP-0552

Transcriptional Signatures of Cerebellar Astrocytes Underpin the Aberrant Metabolism in Focal to Bilateral tonic-clonic Seizures

B. Chen, *L. Xiao, Y. Tang, S. Hu;*
Department of Nuclear Medicine, Xiangya Hospital Central South University, Changsha, CHINA.

Aim/Introduction: Focal to bilateral tonic-clonic seizures (FBTCS) is one of the severest forms of epilepsy that is associated with a higher risk of epilepsy-related injury, sudden unexpected death in epilepsy, and unfavorable prognosis after epilepsy surgery. This study aims to establish a link between metabolic phenotypes and transcriptional signatures in patients with temporal lobe epilepsy (TLE), aiming to enhance our comprehension of the mechanisms underlying potential epileptic discharge propagation and biological changes in TLE-FBTCS. ***Materials and Methods:*** The study included three cohorts. The 2-[18F]-fluoro-2-deoxy-D-glucose ([18F]FDG) positron emission tomography (PET) cohort comprised 128 TLE patients treated at Xiangya Hospital, followed for at least one year after surgery. The transcriptome dataset consisted of hippocampal dentate gyrus tissue samples from six TLE patients who underwent standard anterior temporal lobectomy at the Department of Neurosurgery in Xiangya Hospital and a publically available transcriptomic dataset. Metabolic factors and corresponding loading coefficients for each participant were evaluated using non-negative matrix factorization applied to [18F]FDG PET images. The association between metabolic factors and TLE-related gene expression was modeled using partial least squares regression (PLS), and cell-type enrichment of PLS-derived genes was performed using Cell-type Specific Expression Analysis. ***Results:*** This study included 85 TLE-FBTCS patients, 43 TLE patients with focal seizures (FS), and 80 healthy controls. TLE-FBTCS patients showed overloading of metabolic factors characterized by hypometabolism in the ipsilateral hippocampus and temporal lobe, and hypermetabolism in the bilateral cerebellum and thalamus. Metabolic factors were significantly correlated with the linear combination of TLE-related gene expression (R272=0.559, Ppermutation<0.0001; R272=0.883, Ppermutation<0.0001), and cerebellum weighted most in the PLS component. PLS-derived genes were significantly enriched in cerebellar astrocytes (PFDR<0.01). ***Conclusion:*** These findings suggest that cerebellar astrocytes underpin the metabolic disruptions in FBTCS, shedding new light on the cellular mechanism of seizure generalization, and potential target of therapeutic strategies for patients with TLE.

EP-0553

Distinct Neuroimaging Patterns of Autoimmune Encephalitis Revealed by Combined FDG and TSPO PET/MR Imaging

Y. Wang[1], *H. Shao[1], Y. Zhang[1], G. Huang[1], S. Bai[2], Y. Hao[2], J. Liu[1];*
[1]Department of Nuclear medicine; Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA, [2]Department of Neurology; Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: To explore the neuroimaging characteristics of autoimmune encephalitis (AE) based on 18F-fludeoxyglucose (FDG) and 18F-PBR06 (the translocator protein 18 kDa translocator protein [TSPO] radioligand) positron emission tomography/magnetic resonance (PET/MR). ***Materials and Methods:*** The study was approved by the Ethics Committee of our institute (KY2021-152-B). Forty AE patients (48.48±18.50y), 11 FDG healthy controls (53.91±4.25y) and 9 TSPO healthy controls (42.44±21.48y) were included in the study. All subjects in AE group underwent brain 18F-FDG and 18F-PBR06 PET/MR scan, separately. Using MATLAB and SPM12 software, the mean standardized uptake value ratio (SUVR) of FDG and PBR06 between AE patients and healthy control groups was compared to explore abnormal uptake brain regions. Specifically, cut-offs values were set at ±2 standard deviations (SD) for FDG and +2 SD for PBR06. To mitigate the potential interference of skull uptake in voxel-based analysis, the skull was removed from 18F-PBR06 PET images based on T1-weighted images. Two-sample t-tests were used, statistical significance was determined at P<0.001 with an additional cluster-level family-wise error (FWE) correction set at P<0.05. ***Results:*** Among the AE patients, 38 exhibited both increased and decreased FDG uptake in distinct brain regions, while the remaining two displayed either solely increased or decreased uptake. Notably, 82.5% (33/40) of AE patients exhibited increased FDG uptake in the lenticular nucleus, while 55% (22/40) exhibited decreased FDG uptake in the right angular. Using ^{18}F-PBR06 PET, 75% (30/40) of patients was detected in AE, with the left superior temporal gyrus showing the highest positive rate (37.5%, 15/40). Statistical analysis highlighted an increase in FDG uptake in the cerebellum, hippocampus, and parahippocampus, accompanied by a decrease in uptake in the parietal and occipital lobes. While no significant increase in TSPO uptake was observed, decreased uptake was evident in the right posterior central gyrus, superior marginal gyrus, and middle cingulate gyrus. ***Conclusion:*** Our findings indicate that abnormal FDG and TSPO uptake in distinct brain regions is a characteristic neuroimaging feature of AE. The findings provide valuable insights into the underlying neuropathological processes of AE and may aid in the diagnosis and management of this complex neurological disorder.

EP-0554

[18F]FDG-PET IN REFRACTORY EPILEPSY: EPILEPTIC FOCI LOCALIZATION AND COMPARISON WITH MAGNETIC RESONANCE IMAGING.

A. Castillo Simón, *D. Lisei Coscia, M. Nevares Herrero, C. Salvat Dávila, J. Gómez Hidalgo, I. Lanchas Alfonso, M. Miguel Martinez, J. Duque Gallo;*
Hospital Universitario de Burgos, Burgos, SPAIN.

Aim/Introduction: Epilepsy is a chronic multifactorial disease characterized by epileptic seizures and is one of the most

disabling neurological disorders. It can affect all age groups and etiologies are multiple. Standard complementary studies are: electroencephalography (EEG) and magnetic resonance imaging (MRI). However, in patients with refractory epilepsy, 2-[18F] fluoro-2-deoxy-D-glucose positron emission tomography ([18F] FDG-PET) has become a well stablished component of the non-invasive lesion localization (1,2). In this study, we evaluate the [18F] FDG-PET metabolic findings in patients with refractory epilepsy and compare its usefulness with MRI. ***Materials and Methods:*** Unicentric cross-sectional study, which includes 16 patients with epilepsy between June 2021 and December 2023. Every patient underwent a [18F]FDG-PET using a digital PET/CT and a 3T MRI. Visual and semiquantitative PET imaging evaluation was performed. [18F]FDG-PET and MRI results were compared according to the epileptic foci localization. ***Results:*** Among the 16 patients, 9 were female, with an age average of 33 years old (9-58). [18F]FDG-PET was pathologic in 10/16 of the patients (62.5%); MRI in 4/16 (25%). [18F]FDG-PET showed hypometabolic foci in: temporal lobe (5), insular lobe (4), hippocampus (3) and frontal lobe (3). ***Conclusion:*** [18F]FDG-PET showed a greater detection of hypometabolic foci compared to the morphologic lesions described by the MRI. The most frequent epileptic foci localization by [18F]FDG-PET was the temporal lobe. ***References:*** 1. Traub-Weidinger, T., Arbizu, J., Barthel, H. et al. EP-0555

The utility of FDG-PET/CT in meeting Graus criteria for limbic encephalitis

A. Monaci, *S. Cornacchini, V. Damato, E. Rosati, F. Montanini, L. Massacesi, V. Berti;*
University of Florence, Firenze, ITALY.

Aim/Introduction: The diagnosis of autoimmune encephalitis (AE) requires the use of paraclinical exams, and among these, magnetic resonance imaging (MRI) is the primary neuroimaging tool according to the 2016 criteria proposed by Graus et al.However, a considerable number of AE cases lack MRI abnormalities. In such instances, ^{18}F-fluorodeoxyglucose positron emission tomography (FDG-PET/CT) can provide valuable assistance. Indeed, previous reports showed that brain FDG-PET/CT can reveal metabolic abnormalities even when the results of all other ancillary tests (MRI, cerebrospinal fluid (CSF), or electroencephalogram) are normal. This study explores the diagnostic efficacy of brain FDG-PET/CT in AE patients and its correlation with clinical improvement. ***Materials and Methods:*** This retrospective, observational study conducted at a single center included all patients meeting the Graus criteria for definite limbic encephalitis who underwent brain FDG-PET. Clinical and paraclinical data were collected from medical records. ***Results:*** Out of 39 patients suspected of autoimmune or paraneoplastic encephalitis (2012-2022), 12 with definite limbic encephalitis were included. MRI criteria for AE were not met in 6/12 patients (50%), In these patients the fulfilment of the Graus criteria relied on the presence of neural antibodies (n=3/6) and/or brain FDG-PET/CT abnormalities (n=6/6). Notably, FDG-PET/CT was abnormal in all but one patient, who underwent FDG-PET/CT post-immunotherapy. FDG-PET detected abnormalities in 7 patients without CSF pleocytosis and all seronegative cases (n=8/12). During the acute phase, FDG-PET/CT revealed bilateral (n=4/12) or unilateral (n=3/12) mesial temporal lobes (MTL) hypermetabolism, whereas in the chronic phase, bilateral (n=6/12) or unilateral (n=1/12) mesial temporal lobes hypometabolism was found. Follow-up FDG-PET/CT in 4 patients showed an evolution from hypermetabolism to normal or reduced metabolism in the same regions, correlating with clinical improvement. ***Conclusion:*** Brain FDG-PET/CT proved more sensitive than MRI for confirming limbic AE diagnosis, especially in seronegative patients. Furthermore, a longitudinal correlation between regression of FDG-PET/CT hypermetabolism and clinical improvement was observed in individual patients. These findings suggest that FDG-PET/CT is a valuable tool for diagnosing and managing autoimmune encephalitis and should be included in the main diagnostic criteria for limbic AE patients.

EP-0556

CANVAS syndrome is associated with cerebellar hypometabolism in ^{18}F-FDG PET imaging.

M. Zapardiel[1], *J. Matías-Guiu[2], V. Gajate[2], A. Delgado[2], A. Horga[2], M. Cabrera[1];*
[1]Department of Nuclear Medicine. Hospital Clínico San Carlos. Instituto de Investigación Sanitaria San Carlos (IdISSC). Madrid, Spain., Madrid, SPAIN, [2]Department of Neurology. Hospital Clínico San Carlos. Instituto de Investigación Sanitaria San Carlos (IdISSC), Madrid, SPAIN.

Aim/Introduction: CANVAS caused by RFC1 biallelic expansions is a recently described entity, in which diagnosis is usually challenging. The main clinical characteristics include cerebellar ataxia, neuropathy, vestibular impairment, sensory impairment, areflexia, autonomic dysfunction, and cough. However, other different phenotypes have been described, including motor neuron disorders, hyperkinetic movement disorders, sleep disorders, or cranial neuropathies. Some studies have reported cerebellar and basal ganglia atrophy in structural MRI, but to our knowledge, there are not studies investigating the pattern of brain metabolism. ***Materials and Methods:*** Cross-sectional study including 11 patients with a genetically confirmed diagnosis of RFC1-related disorder. Patients underwent comprehensive clinical examination and ^{18}F-FDG PET-CT imaging. Voxel-based brain mapping analysis was conducted with SPM12. Patients were compared with a healthy control group of 40 subjects. ***Results:*** The mean age was 68.55±9.55, 4 (36.4%) were women. All patients have clinical symptoms at the moment of assessment. A lower metabolism in the bilateral cerebellum was observed in patients with RFC1-related disorder compared with healthy controls. No regions of higher metabolism were detected. ***Conclusion:*** Our study found a pattern of bilateral cerebellar hypometabolism in patients with RFC1 biallelic expansion. This suggests that ^{18}F-FDG PET could be a novel biomarker for this disorder. Future studies should compare the usefulness of ^{18}F-FDG PET imaging in the differential diagnosis with other disorders.

Quantitative single-photon emission computed tomography for dose calculation of radioiodine therapy in hyperthyroidism

***J. Rijntjes*[1]**, *L. Deden*[1], *W. Wormgoor*[1], *L. de Geus-Oei*[2], *F. Intema*[1];
[1]*Rijnstate Hospital, Arnhem, NETHERLANDS,*
[2]*University of Twente, Enschede, NETHERLANDS.*

Aim/Introduction: Treatment of hyperthyroidism with radioiodine (131I) therapy in Graves' disease (GD) and toxic multinodular goiter (TMNG) preferably avoids early hypothyroidism and still effectively cures hyperthyroidism. Currently, patient-specific 131I dose is calculated based on iodine uptake (123I or 131I) and thyroid volume measured in planar scintigraphy (PS). However, especially planar volume measurements lack accuracy and have large inter and intra observer variation. 131I dose calculation using quantitative SPECT/CT may be more accurate and potentially improve clinical outcome. This study aims to determine accuracy of quantitative SPECT/CT for volume and uptake measurements and compares 131I dose for radioiodine therapy as calculated based on PS and quantitative SPECT/CT. Furthermore, the administered 131I dose concentration is correlated to clinical outcome. ***Materials and Methods:*** Quantitative SPECT/CT was validated in a phantom study. For patients with GD or TMNG, planar 123I uptake and volume measurements were retrospectively compared to 123I quantitative SPECT/CT. Furthermore, the administered 131I dose concentration (MBq/ml) was determined using quantitative SPECT/CT and was correlated to thyroid function one year after therapy. ***Results:*** In patients with GD (n=31), the uptake in quantitative SPECT/CT was 65% (IQR 53-78) vs. 52% (IQR 44-60) in PS ($p<0.001$). The thyroid volume was 22 mL (IQR 17-31) vs. 26 mL (IQR 21-42), respectively ($p<0.001$). Subsequently, when quantitative SPECT/CT was used to calculated the required 131I dose, this would have reduced the dose by 38% ($p<0.001$). One year after therapy, 29% of patients developed euthyroidism, 29% had persistent hyperthyroidism and 42% developed hypothyroidism. Corresponding dose concentrations were 5.6 MBq/mL (IQR 4.4-8.2), 6.1 MBq/mL (IQR 4.4-8.1) and 7.8 MBq/mL (IQR 6.1-9.1) (nonsignificant (ns.)). In patients with TMNG (n=34), the uptake in quantitative SPECT/CT was 37% (IQR 31-48) vs. 26% (IQR 20-37) in PS ($p<0.001$). The thyroid volume was 38 mL (IQR 26-74) vs. 42 mL (IQR 26-79), respectively (ns.). Subsequently, when quantitative SPECT/CT was used to calculated the required 131I dose, this would have reduced the dose by 23% (ns.). One year after therapy, 59% of patients developed euthyroidism, 12% had persistent hyperthyroidism and 29% developed hypothyroidism. Corresponding dose concentrations were 8.3 MBq/mL (IQR 5.6-9.8), 6.7 MBq/mL (IQR 4.0-9.3), and 10.4 MBq/mL (IQR 10.2-11.7) ($p<0.05$). ***Conclusion:*** Quantitative SPECT/CT allows for more accurate 131I dose calculations based on both more accurate thyroid volume and 123I uptake measurements, compared to PS. Quantitative SPECT/CT might improve clinical outcome after radioiodine therapy in patients with GD or TMNG.

EP-0558

Diagnostic value of 68Ga-Pentixafor PET/MR in Functional nodules of Primary Aldosteronism

X. Meng, *F. Kang, J. Wang;*
Xijing Hospital of Airforce Military Medical University, Xi'an, CHINA.

Aim/Introduction: To investigate the clinical value of 68Ga-Pentixafor PET/MR in the diagnosis of primary aldosteronism (PA) of functional adrenal nodules, especially those with diameter < 10mm, and compare it with the single PET model. ***Materials and Methods:*** We prospectively assessed 39 patients diagnosed with PA and 13 patients with non-functional adrenal adenoma (NFA). All patients underwent 68Ga-pentixafor PET/MR before adrenalectomy. Receiver-operating characteristic (ROC) curves were constructed to determine the threshold of semi-quantitative parameters and the diagnostic accuracy of 68Ga-pentixafor PET/MR for the diagnosis of functional nodules. ***Results:*** The subtypes of 39 PA patients included 30 aldosterone-producing nodules, 5 cases of suspected unilateral adrenal hyperplasia, and 4 cases of idiopathic aldosterone hyperplasia. The cut-off value for diagnosing functional nodules by ROC curve was SUVmax >7.87. In further subgroup analysis, the cut-off value of nodules less than 10mm in diameter was less than the total (SUVmax>6.49), while the cut-off value of nodules greater than 10mm was the same as the total. Compared with a single PET model, the sensitivity of PET/MR increased from 72.7% to 90.5%, and the area under the ROC curve increased from 0.865 to 0.937. In subgroups, PET/MR mainly improved the sensitivity of PET with a diameter less than 10mm, from 68.8% to 87.5%, and the area under the ROC curve increased from 0.760 to 0.854. ***Conclusion:*** 68Ga-pentixafor PET/MR demonstrated promising diagnostic accuracy in functional nodules of PA patients, especially improved the sensitivity of PET for adrenal nodules with diameters less than 10mm.

EP-0559

Evaluating 68Ga-DOTANOC PET/CT for TIO Culprit Lesion Detection and Comparing with CT

D. Khan, *S. Sagar, S. K V, N. Damle, S. A. Shamim, M. Tripathi, B. Chandra, R. Kumar, C. Bal;*
AIIMS Delhi, Delhi, INDIA.

Aim/Introduction: Assessing the Clinical Efficacy of 68Ga-DOTANOC PET/CT in Identifying the Underlying Culprit Lesion in Tumor-Induced Osteomalacia (TIO) and Contrasting its Performance Against Computed Tomography. ***Materials and Methods:*** Fifty-eight patients suspected of TIO underwent 68Ga-DOTANOC PET/CT scans, with their clinical data documented. Experienced nuclear medicine physicians interpreted the PET/CT images. The detection rates of lesions using 68Ga-DOTANOC PET/CT and CT were compared, and the correlation between SUVmax and TLG values with lesion size on CT was assessed. ***Results:*** The study comprised 58 patients, with 48 males and 10 females. Their mean age was 36.86 ± 13.19 years, spanning from 14 to 68 years old. Among the 58 patients enrolled in the study, culprit lesions were identified in 36 patients, yielding a lesion detection rate of 62% (36/58). Among those with detected lesions, four patients underwent follow-up scans to monitor the progression or treatment response of their TIO. CT scans were individually examined for all patients, revealing a lesion detection rate of 32.7% (19/58). In the 17 cases where CT did not identify a culprit lesion, 68Ga-DOTANOC PET/CT provided an additional diagnostic benefit of 47.2% (17/36) over CT in detecting these lesions. The average size of the identified culprit lesions on CT was 1.5 ± 0.1 cm, ranging from 0.5 to 4.4 cm. ***Conclusion:*** 68Ga-DOTANOC PET/CT exhibited heightened sensitivity in identifying culorit lesion in TIO compared to CT. This advanced imaging technique offered valuable insights into lesion detection and associated metabolic activity, facilitating treatment planning and ongoing monitoring of the condition.

EP-0560

Effects of Mirabegron and Quinolone on the Activation of Brown Adipose Tissue Identified by [18F]FDG-PET/CT in Humans (MIRAQL-BAT STUDY)

C. Ramos, *M. Lima, B. Geloneze, M. Mori;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: Brown adipose tissue (BAT) has regulatory functions on energy (thermogenesis), glucose and lipid homeostasis. BAT activation can be detected by [18F] fluorodeoxyglucose positron emission tomography/computed tomography ([18F]FDG-PET/CT). Drugs such as β3-adrenergic agonists and quinolones are candidates for activating BAT for therapeutic purposes. We aimed to evaluate the effects of mirabegron (β3-adrenergic agonist), ciprofloxacin (quinolonone), or the combination of both, on the activation of BAT, glucose and lipid homeostasis. We present here the preliminary results of this ongoing study. ***Materials and Methods:*** Prospective, double-blind, randomized, crossover study. Twenty participants [18-40 year-old women, BMI 27-35 kg/m2, insulin resistance (HOMA-IR >2,7)]. Two random-order interventions: mirabregron 100 mg/day plus placebo (4 weeks) (M intervention); mirabregron 200 mg/day plus placebo (2 weeks), followed by mirabregron 200 mg/day plus ciprofloxacin 1000 mg/day (2 weeks) (MQ intervention). Ten of the participants were also randomized to a third intervention: placebo (2 weeks), followed by ciprofloxacin 1000 mg/day plus placebo (2 weeks). Washout period between interventions: 4 weeks. Outcomes: BAT activation after each intervention [visually identifiable in [18F]FDG-PET/CT (room temperature: 25 oC) compared to background activity; BAT SUVmax]; changes in weight, circumferences of waist, hip, neck; changes in glucose, insulin, hemoglobina A1c, total cholesterol and fractions and triglycerides. ***Results:*** Thirteen participants were included so far (median age 31 years, range 19-38 years; median BMI 32.9 kg/m2, range 29.3-35.0 kg/m2). Circumferences (cm) of neck, waist and hip were [median (range)] 36.0 (33.5-42.0), 95.0 (87.0-102.0) and 120.0 (109-126), respectively. Fasting glucose (mg/dl), insulin (uUI/ml) and HOMA-IR were [median (range)] 94.0 (83-106), 24.5 (16.7-36.9) and 6.4 (3.7-8.6), respectively. Anthropometric and metabolic parameters did not change significantly after interventions. BAT was not activated by ciprofoxacin alone (n=10). Ten participants completed both M and MQ. BAT SUVmax ranged from 4.78 to 23.5 (median 12.1) across interventions. BAT activation was observed after neither of the interventions in four participants, only after MQ in one, only after M in two, and after both M and MQ in three. Compared to M, one participant had higher SUVmax after MQ (22.7 vs 12.1) and two had lower SUVmax after MQ (15.1 vs 23.5; 4.78 vs 6.7). ***Conclusion:*** Mirabegron-stimulated BAT activation at room temperature is viable in a tropical country. BAT is not activated by ciprofloxacin alone, but may be activated by mirabegron, either alone or in combination with ciprofloxacin. However, mirabregron effect lacks consistency across interventions and the effect of drug combination is not clear yet.

EP-0561

Contribution of ^{18}F-Fluorocholine PET/MRI in the post-operative follow-up of pituitary adenomas: head-to-head comparison with ^{11}C-Methionine.

C. Mathey[1,2], *J. Spitaels[1], N. Trotta[1], F. Devuyst[1], G. Omatuku Wetshosele[1], C. Mabiglia[1], S. Goldman[1], O. Dewitte[1], G. Leurquin-Sterk[1];*
[1]Université libre de Bruxelles (ULB), Hôpital Universitaire de Bruxelles (HUB), CUB Hôpital Erasme, Anderlecht, BELGIUM, [2]UMC Saint Pierre, Bruxelles, BELGIUM.

Aim/Introduction: The detection of residual or recurrent pituitary adenoma (RPA) by MRI is hindered by the tissue remodelling that follows surgery or radiotherapy. 11C-Methionine (MET) PET has shown high diagnostic accuracy and sensitivity in detecting RPA, but its use remains restricted to centers with an onsite cyclotron. This study assessed the clinical usefulness of ^{18}F-Fluorocholine (FCH) PET/MRI compared to MET PET/MRI for accurate localization of RPA and its differentiation from the pituitary gland remnant (PGR) after trans-sphenoidal adenomectomy. ***Materials and Methods:*** This is a prospective study on 24 patients addressed for post-surgical evaluation of pituitary adenoma. The patients underwent a standard MET PET/MRI acquisition and subsequently a 20 min dynamic FCH PET/MRI acquisition followed by an additional FCH PET/CT acquisition performed at 40-55min post-FCH injection. For MET and FCH, the uptake of the RPA and PGR were compared visually and quantitatively by means of maximum standardized uptake value (SUVmax). Moreover, the FCH time activity curves for both the RPA and PGR were analyzed. ***Results:*** 13 of the 24 patients included had a non-functional adenoma. For the RPA, the FCH uptake was similar to the MET uptake, with a mean SUVmax of 6.15 for early static (3-20 min PI) FCH images and 5.12 for late static FCH images compared to 5.45 for MET (p=NS). Visually, all RPA were detected on FCH images. Contrary to RPA, PGR showed a decreasing kinetic of FCH uptake over time with a mean SUVmax of 5.73 for early FCH and 3.73 for late FCH (p<0.0001). ***Conclusion:*** FCH PET/MRI localized residual and recurrent pituitary adenoma similarly to MET PET/MRI. Moreover, a dual-phase FCH PET acquisition allows for better discrimination of the PRG from RPA.

68Ga-DOTANOC PET/CT in patients with Tumour Induced Osteomalacia - A retrospective single center experience.

N. Damle[1], *A. Vishnu[1], G. Priyanka[1], C. Ganapathy[1], K. Chandekar[1], K. Mathiazhagan[1], C. Bal[1], P. Namjoshi[2], S. Das[2], N. Tandon[2], Y. Gupta[2], A. Goyal[2], S. Chumber[3], G. Puri[3];*
[1]Department of Nuclear Medicine, All India Institute of Medical Sciences, New Delhi, INDIA, [2]Department of Endocrinology, Metabolism and Diabetes, All India Institute of Medical Sciences, New Delhi, INDIA, [3]Department of Surgical Disciplines, All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Tumor-induced osteomalacia (TIO), is a paraneoplastic syndrome caused by small mesenchymal tumors. Detecting these occult mesenchymal tumors is of utmost importance, as they are completely curable after resection. This occult source can be imaged with SSTR positron-emission tomography-computed tomography (PET/CT). We aimed to study the role of 68Ga-DOTANOC PET/CT in the localization of culprit lesion. ***Materials and Methods:*** Records of consecutive patients with clinically and biochemically suspected TIO syndrome who underwent 68Ga-DOTANOC PET/CT at our tertiary care institution, between January 2019 and Febrauary 2024 were retrospectively reviewed. All patients were injected 3-4mCi 68Ga DOTANOC intravenously and underwent whole-body PET/CT 30-40 minutes post-injection. Scanned images were interpreted by two nuclear physicians independently. 68Ga DOTANOC PET/CT findings were corroborated with clinical details. Histopathology details were reviewed for the patients who underwent surgery. Findings of biochemical and conventional imaging were also utilized for correlation. ***Results:*** 47 patients with biochemically proven hypophosphatemia and elevated Fibroblast growth factor-23 (FGF-23) were included in the final analysis. 68Ga-DOTANOC

PET/CT was positive for a lesion in 29/47 patients (61.7%). 68Ga DOTANOC identified the primary lesion in 11/29 patients (37.9 %) in facial bones, 8/ 29 (27.5%) were localized to the upper and lower extremities, 8/29 (27.5 %) to the spine and pelvis, and 2/29 (6.8 %) to the soft tissue. Clinical and biochemical follow-up of the operated patients showed post-operative normalization of phosphate and FGF 23 levels. ***Conclusion:*** 68Ga-DOTANOC PET/CT proved to be a valuable modality in the workup of patients with suspected TIO by revealing the primary tumor in almost 60% of the patients with TIO.

Is Tc99m-leukocytes a sufficient modality for detection of osteomyelitis in Charcot Neuroarthropathy?

S. Episkopopoulou, *A. Velidaki, I. Sevaslidou, T. Kostou, A. Kolindou;*
Nuclear Medicine Department Gha Laiko, Athens, GREECE.

Aim/Introduction: We describe the contribution of bone marrow scan (BMS) in the investigation and diagnosis of osteomyelitis in Charcot Neuroarthropathy (CN). CN is a rare condition, but a really destructive disease of the ankle joint. Many diabetic patients suffer from foot disorders such us ulcers, neuroarthropathy, and osteomyelitis. X-Rays fail to show bone inflammation unless there is at least 30-50% destruction of the corresponding bone. MRI has difficulties in differential diagnosis osteomyelitis from CN. 3 Phase Bone Scan is positive in most of these situations, especially in bone inflammation, fracture and neuroarthropathy. Leukocytes do accumulate in rapidly evolving Charcot (aseptic inflammation, fracture, bone reconstruction processes) even in absence of infection (septic osteomyelitis). In such case, the combination of bone scan and Tc99m-Leukocytes is not enough. In presence of haematopoietically active bone marrow, the specificity of labeled leukocytes decreases. For the confirmation of septic osteomyelitis in CN, bone marrow scan (BMS) is the cornerstone modality, when in doubt. ***Materials and Methods:*** Four patients with radiographically confirmed CN and positive findings in hindfoot in both bone scan and Tc99m-leukocytes, underwent bone marrow scan. A leukocytes/ BMS concordant distribution ruled out osteomyelitis and indicated an active bone marrow due to rapidly evolving Charcot. A positive labeled leukocyte scan without corresponding findings in BMS (unconcordant pattern) indicated septic osteomyelitis. ***Results:*** A leukocyte/ BMS concordant pattern was present in one of four patients. If we had stopped after the bone scan/ leukocyte combined study, we would have concluded to a wrong diagnosis. In this situation bone marrow scan helped us to exclude osteomyelitis and the patient avoided to take unnecessary antibiotics. ***Conclusion:*** We conclude that a bone marrow scan is a very useful study to exclude septic osteomyelitis, in rapidly evolving Charcot neuropathy where 3 Phase Bone Scan and Tc-99m-leukocytes are both positive. We have to keep it in mind when we evaluate diabetic feet.

Various sites and patterns of granulomatosis with polyangiitis involvement detected by the versatile imaging tool F^{18} FDG PET/CT

S. Ananth Kumar, *R. Kumar, B. R. Mittal;*
Postgraduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: Granulomatosis with polyangiitis, previously known as Wegener's granulomatosis, is a rare multi-system autoimmune disorder of unknown etiology and form of vasculitis affecting a host of different organs in the body. Literature review suggests F^{18} FDG PET/CT can help in assessing the disease burden, finding out the various sites of involvement by the disease, identifying appropriate sites for targeted biopsy and monitoring the response to systemic therapy. This study aimed to identify the various patterns of disease involvement that can be detected using F^{18} FDG PET/CT. ***Materials and Methods:*** This retrospective observational study included all patients presenting with histopathologically diagnosed or clinically and biochemically suspected granulomatosis with polyangiitis who underwent a whole-body F^{18} FDG PET/CT between January 2015 and April 2024 at a tertiary care centre. The clinical and imaging findings were analyzed to identify the various patterns of disease involvement. ***Results:*** Thirty-five patients (20 females and 15 males) were included in this study, with a mean age of 47.7 years (SD ±16.7). The most common presenting symptoms were nasal stuffiness with epistaxis and fever, both seen in 8/35 patients (22.8% each), closely followed by shortness of breath which was seen in 7/35 patients (20%). One patient presented with a clinical history of recurrent cerebrovascular accident, who, on evaluation, was found to have granulomatosis with polyangiitis. In the F^{18} FDG PET/CT, single-organ involvement was seen in 9/35 patients (25.7%),with lungs (6/9 patients) being the commonest site, followed by paranasal sinuses (3/9 patients). Two or more organs were involved in the rest of the study population. Overall, lung involvement was the most common finding seen in 28 patients (80%), followed by paranasal sinus involvement in 16 patients (45.7%), lymph nodal involvement in 9 patients (25.7%),with renal lesions in 4 participants (11.4%). Patterned FDG uptake in the dilated blood vessels was present in 14.3% of the study population. Classical presentation with involvement of the paranasal sinuses and pulmonary and renal lesions were present in only 2 participants. Involvement of any one or two of the above findings coupled with FDG uptake in the nasal septum, blood vessels, locoregional lymphadenopathy and laryngeal cartilages should alert the physician towards the diagnosis of granulomatosis with polyangiitis. ***Conclusion:*** F^{18}- FDG-PET/CT helps to detect the various organ systems involved by granulomatosis with polyangiitis with different patterns of involvement, thereby estimating the true disease burden by identifying multiple occult sites of disease involvement.

EP-0566

Infective Endocarditis Associated with a Percutaneous Mitral Valve Repair

I. Sánchez Rodríguez[1], *V. Carrero-Vasquez[1], M. Pudis[1], F. Escrihuela-Vidal[2], G. Cuervo-Requena[1], A. Ruiz-Majoral[3], L. Gracia-Sánchez[1];*

[1]Nuclear Medicine Department. Bellvitge University Hospital, Barcelona, SPAIN, [2]Infectious Diseases Department. Bellvitge University Hospital, Barcelona, SPAIN, [3]Cardiology Department. Bellvitge University Hospital, Barcelona, SPAIN.

Aim/Introduction: The incidence of infective endocarditis (IE) associated with prosthetic valves ranges from 1 to 6%, and for bioprosthetic aortic valve transcatheter implantation (TAVI), it ranges from 0.5-3.1%. This study aims to review and analyze all published cases of IE associated with an edge-to-edge mitral repair (MitraClip). ***Materials and Methods:*** We conducted a comprehensive literature search on MEDLINE and Google Scholar. The search keywords employed were "MitraClip" and "Endocarditis." Additionally, a manual search of reference lists was performed. ***Results:*** We identified a total of 20 cases (13 males) of endocarditis associated with the MitraClip procedure. The mean age was 72 years (range 51-88), and patients tended to have multiple complex medical comorbidities. The average time from implantation to IE diagnosis was 10 months (range 24 hours to 4 years). In all cases, transthoracic or transesophageal echocardiography confirmed IE. The most frequently isolated pathogens were Staphylococcus aureus (10 cases, including 4 methicillin-resistant) and Enterococcus faecalis (3 cases). ***Conclusion:*** The use of the MitraClip device is on the rise for managing severe mitral regurgitation in patients with high surgical risk. Although the incidence of IE associated with MitraClip is relatively low compared to other valve procedures, given the clinical profile of these patients, it represents a potentially life-threatening complication requiring complex and multidisciplinary management.

"SPECIFIC" Trial of ^{68}Ga-triacetylfusarinine C (TAFC) Siderophore PET/CT for Detection of Invasive Aspergillus Infection: First-In-Human Imaging Result

S. Levy[1,2,3], *B. Z. Sim[4,2], M. Haskali[1,2], C. Decristoforo[5], H. Haas[6], B. Emmerson[1], U. Kamil[1], M. Slavin[4,2], M. Hofman[1,2], A. Douglas[4,2];*
[1]Molecular Imaging and Therapeutic Nuclear Medicine, Cancer Imaging, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [2]Sir Peter MacCallum Department of Oncology, The University of Melbourne, Melbourne, AUSTRALIA, [3]Department of Nuclear Medicine, The Royal Melbourne Hospital, Melbourne, AUSTRALIA, [4]Department of Infectious Diseases, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [5]Department of Nuclear Medicine, Medical University of Innsbruck, Innsbruck, AUSTRIA, [6]Institute of Molecular Biology, Biocenter, Medical University of Innsbruck, Innsbruck, AUSTRIA.

Aim/Introduction: Invasive Aspergillus infection (IAI) is a common infection in immunocompromised patients. Prompt diagnosis is paramount given high morbidity and mortality. Whilst 18F-fluorodeoxyglucose (FDG) PET/CT is useful in diagnosis, it remains non-specific and invasive procedures such as bronchoalveolar lavage are generally required to confirm the diagnosis. Siderophore-radiolabelled PET/CT may facilitate rapid and non-invasive diagnosis of IAI. Siderophores are natural scavengers of iron produced by pathogens, and specific for certain pathogens. Aspergillus fumigatus secretes two siderophores, fusarinine C and TAFC, which are not taken up by human cellular systems. TAFC is an attractive candidate for labelling due to its short half life and rapid renal clearance. Preclinical studies have demonstrated the diagnostic potential of 68Ga-TAFC PET/CT with specific visualisation of Aspergillus fumigatus infection in mouse models[1]. This study aims to evaluate whether these preclinical findings can be confirmed in humans with proven or probable IAI. ***Materials and Methods:*** We report results of the first patient enrolled in a 10 patient pilot imaging study of patients with probable or proven IAI. Patients satisfying inclusion and exclusion criteria are recruited to undergo 68Ga-TAFC-PET/CT within two weeks of IAI diagnosis. Whole body PET/CT was performed at 15, 62 and 209 minutes following intravenous injection of 139 MBq 68Ga-TAFC. 68Ga labelling was optimised to yield 68Ga-TAFC quantitatively at 50 C (pH 4.0) in 7 minutes. Findings pertinent to IAI and physiologic uptake were qualitatively and quantitatively analysed. ***Results:*** The first patient had probable invasive pulmonary aspergillosis in the setting of new diagnosis of leukemia, with positive galactomannan antigen and Aspergillus fumigatus PCR on bronchoalveolar lavage fluid. 68Ga-TAFC-PET/CT was performed 10 days after empiric antifungal treatment and 4 days after microbiological confirmation of invasive infection, which was clinically effective with resolution of fevers by 72 hrs. PET/CT demonstrated blood pool activity (SUVmax 15/60/209 mins: 4.1/2.7/1.9) with minimal liver, spleen and gastrointestinal tract uptake (SUVmax 2.7), early renal excretion, and no marrow or other organ uptake. Low grade focal uptake was visualised in multiple pulmonary lesions, similar to blood pool activity, with synchronous washout over time. No adverse effects were encountered. ***Conclusion:*** Very low background physiologic biodistribution was seen in the first participant in this first-in-human study. Focal low grade pulmonary uptake was visualised, presumably representing specific activity, and likely attenuated reflecting successful response to antifungal treatment. Trial recruitment continues. ***References:*** [1] Journal of Fungi 2021; doi: 10.3390/jof7070558.

EP-0568

Increased gastrointestinal FAPI uptake in systemic sclerosis patients with gastrointestinal symptoms

E. Lim, *S. B. Tai, G. S. K. Ooi, W. W. C. Lam, M. Noviani, A. H. L. Low, W. Xie;*
Singapore General Hospital, Singapore, SINGAPORE.

Aim/Introduction: Systemic sclerosis is a complex disease process with multisystem involvement, with the gastrointestinal (GI) tract involved in up to 90% of patients. Gallium-68 labeled fibroblast activation protein inhibitor (FAPI) is an emerging imaging biomarker of fibroblast activation, which is implicated in the pathogenesis of systemic sclerosis. We report the detection of FAPI uptake in the GI tract of systemic sclerosis patients with GI symptoms. ***Materials and Methods:*** We retrospectively analyzed FAPI PET/CT imaging performed for patients with confirmed diagnosis of systemic sclerosis. GI symptoms were scored according to the UCLA GIT 2.0 questionnaire. Bowel segmentation was performed using MIM 6.9.9 software. The SUVmax and SUVmean of the affected segments were analyzed. ***Results:*** Preliminary results showed that 50% (3/6) of patients with GI symptoms demonstrated increased FAPI bowel uptake. ***Conclusion:*** To our knowledge, this is the first study describing FAPI bowel uptake in systemic sclerosis patients, with associated

GI symptoms. Our findings suggest that FAPI PET/CT imaging may have potential as a non-invasive tool in detection and monitoring of GI disease activity in systemic sclerosis patients. ***References:*** Shreiner AB, Murray C, Denton C, Khanna D. ^{18}F-FDG PET/CT in Pyrexia of unknown origin: Guiding the differentials and site of biopsy.

A. Phulia[1], *D. Khan[2], S. Sagar[2], R. Wakankar[2];*
[1]Maulana Azad Medical College, New Delhi, INDIA, [2]All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: This study aims to assess the significance of F^{18}-FDG PET/CT in directing clinicians towards the site of biopsy and to evaluate the agreement between our preliminary differential diagnosis and the final histopathological findings. ***Materials and Methods:*** We retrospectively assessed 207 patients of pyrexia of unknown origin (PUO) referred to our centre for F^{18}-FDG PET/CT. Evaluation was based on our imaging reports and final biopsy results. Imaging findings were categorised into first, second and third differentials, with consensus reached by two experienced nuclear physicians with 5-20 years of experience. ***Results:*** Out of 207 patients, site of biopsy was advised for 104 patients to guide clinicians to establish a quick diagnosis. From those 104 patients, 36 patients had a conclusive diagnosis after biopsy results. As per our first differential diagnosis 5 out of 8 patients, 9 out of 14 patients, 2 out of 5 patients and 4 out of 9 patients came out to be tuberculosis, lymphoma, malignancy and other infections respectively, in accordance with the biopsy report. The other 103 patients had already underwent biopsy, according to the first differential given on PET/CT, 9/22(40.9%), 18/30(60%), 10/28(35.7%), 8/18(44.4%) and 5/5(100%) patients came out to be tuberculosis, lymphoma, other infections, malignancies and vasculitis, respectively and had concordance with the histopathological examination. ***Conclusion:*** Early utilisation of F^{18}-FDG PET/CT in the diagnostic process significantly enhances the management of pyrexia of unknown origin (PUO) patients. By offering initial diagnosis and directing clinicians to the most feasible biopsy site, it facilitates expedited and improved patient care.

EP-0570

Positron Emission Tomography/Computer Tomography in the Diagnosis of Inflammation of Unknown Origin: A Systematic Review and Meta-Analysis

K. Easton, *G. Hallam, Y. Lee, S. Saluja, T. Erfani;*
University of Newcastle, Newcastle, AUSTRALIA.

Aim/Introduction: Inflammation of unknown origin (IUO) is persistent or recurrent inflammation with no identifiable cause despite extensive examination and investigation (1). Positron Emission Tomography (PET)/Computer Tomography (CT) has gained recent attention in its potential to differentiate the underlying diseases of IUO. Our aim was to conduct the first systematic review to assess the diagnostic accuracy of PET/CT in IUO specifically. ***Materials and Methods:*** A systematic review was conducted via comprehensive search of electronic databases (Cochrane, Embase, MEDLINE and PubMed) from the earliest data available to January 2024 following the Cochrane Handbook for Systematic Reviews of Diagnostic Test Accuracy and the Preferred Reporting Items for Systematic Reviews and Meta-Analyses of Diagnostic Test Accuracy Studies (PRISMA-DTA). Studies were screened following the defined inclusion criteria and data was extracted by two pairs of independent reviewers. A meta-analysis was performed using the Review Manager 5.4.1 (RevMan) and STATA 18 using the random effect bivariate model. Studies were also assessed qualitatively for the outcomes not included in the meta-analysis. ***Results:*** 16 studies were included in the systematic review meeting the eligibility criteria. 6 of these reported the required diagnostic outcomes for IUO specifically and were included in the meta-analysis with a total patient sample size of 789. The sensitivity and specificity of PET/CT in diagnosing IUO was 88% (95% CI = 74-95%) and 80% (95% CI = 50-94%), respectively. The resulting diagnostic odds ratio was 28.51 (95% CI = 8.79-92.46). The positive likelihood ratio and negative likelihood ratio was 4.37 (95% CI = 1.55 - 12.35) and 0.15 (95% CI = 0.02 - 0.29. An exploratory subgroup analysis suggested that PET/CT sensitivity and specificity improved when C-reactive protein (CRP) levels were above 53 mg/L. Non-infectious inflammatory diseases were the most frequent cause of IUO, with vasculitis and polymyalgia rheumatica the most frequently diagnosed diseases across the included studies. ***Conclusion:*** Our study showed that PET/CT has good diagnostic performance in the diagnosis of IUO. This review could aid in establishing evidence based IUO diagnostic pathways and guiding indications for PET/CT scans. Consideration of undertaking a PET/CT scan earlier in the diagnostic pathway of patients with IUO could result in better patient care and outcomes. ***References:*** 1) Boulu X, et al. value of positron Emission tomography coupled with computed Tomography for the diagnosis of inflammatory syndrome of unknown origin in an internal medicine department. EP-0571

Unexpected non-neoplastic focal high-uptake in liver on [^{68}Ga]Ga-DOTA-FAPI-04 PET

Y. Song, *C. Qin, Y. Lv, Y. Gai, W. Ruan, X. Zhang, M. Li, F. Liu, R. An, Y. Zhang, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medica College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: [68Ga]Ga-DOTA-FAPI-04 positron emission tomography (PET) is an emerging imaging modality in oncological imaging. This study aims to investigate the occurrence of unexpected high uptake in non-neoplastic liver lesions during the detection of malignant neoplastic lesions using [68Ga]Ga-DOTA-FAPI-04 PET. ***Materials and Methods:*** We retrospectively reviewed [68Ga]Ga-DOTA-FAPI-04 PET/magnetic resonance imaging (MRI) or PET/computed tomography (CT) scans from 1,000 patients conducted at our PET center between January 2021 and January 2024. Foci of elevated [68Ga]Ga-DOTA-FAPI-04 uptake in the liver were identified and further evaluated using CT, MRI, and biochemical analysis to determine their nature. We recorded and analyzed the locations, shapes, maximum standard uptake values (SUVmax), liver-to-muscle uptake ratios (LMR), and liver-to-background blood uptake ratios (LBR) of the benign lesions. ***Results:*** Among 1,000 patients, 41 demonstrated unexpected focal high uptake of [68Ga]Ga-DOTA-FAPI-04 in the liver, diagnosed as focal liver fibrosis due to regional cholestasis

(11/41, 26.8%), treatment-related changes (17/41, 41.5%), and underlying chronic liver disease (13/41, 31.7%). The uptake linked to cholestasis generally appeared in a wedge-shaped pattern accompanied by bile duct dilation, with SUVmax of 6.67 ± 2.63, LMR of 3.71 ± 2.54, and LBR of 3.89 ± 1.92. Treatment-related uptake often occurred adjacent to tumors, manifesting in striated or patchy patterns, and presented an SUVmax of 6.14 ± 4.76, LMR of 2.54 ± 2.16, and LBR of 3.27 ± 2.20. Uptake from underlying liver disease, predominantly diffuse, showed an SUVmax of 6.79 ± 3.74, LMR of 3.15 ± 1.77, and LBR of 3.39 ± 1.92. No statistically significant differences were observed in SUVmax, LMR, and LBR across the different causes of uptake (all P > 0.05). Imaging typically indicated normal density on computed tomography, mild hyperintensity on T1-weighted and diffusion-weighted imaging, with areas showing contrast enhancement. ***Conclusion:*** Unexpected non-neoplastic high uptake of [68Ga]Ga-DOTA-FAPI-04 in the liver can indicate focal liver fibrosis with various etiologies, requiring differentiation from tumors and other benign conditions. [68Ga]Ga-DOTA-FAPI-04 PET imaging effectively assesses the functional and pathological status of the liver, aiding in the development of personalized treatment plans for patients with malignant tumors.

EP-0572

The role of [18]F-FDG PET/CT in patients with Nocardiosis

***C. Sandoval Moreno*[1]**, *M. Azorin Belda*[1], *M. Torres Tarraga*[1], *G. Figueroa Ardila*[1], *E. Marques Aparicio*[1], *M. Tagliatori Nogueira*[2], *M. de la Rubia Marcos*[1], *P. García Alonso*[2], *P. Gonzalez Cabezas*[1];
[1]*Hospital Universitario del Vinalopó, Elche, SPAIN,*
[2]*Hospital Universitario de Getafe, Getafe, SPAIN.*

Aim/Introduction: Nocardiosis is a rare and a opportunistic infection caused by aerobic gram-positive bacteria. Skin and lungs are usually the main sites of localized lessions. The aim of this paper is to evaluate the role of ^{18}F-FDG PET/CT in the differential diagnosis of pulmonary nodules. We present the results of two patients. ***Materials and Methods:*** We reviewed records of two patients referred to our Nuclear Medicine Department with diagnosis of Nocardia infection: 41 years old woman with pulmonary nodules (no other importants diseases) and 71 years old male with trated lung cancer, abdominal abscess (nocardia culture positive) and pulmonary nodules (cytology negative). Whole body ^{18}F-FDG PET/CT and visual evaluation was performed and they had a follow up of two years. ***Results:*** Both cases presented moderate ^{18}F-FDG uptake in lung lessions, as well as in the intra-abdominal abscess describe in the male studies. During the follow up the patients underwent other whole body ^{18}F-FDG PET/CT study. Our first case show a rare opportunistic infection in no inmunocompromised patient, who underwent poor outcome during de follow up, with inadecuate antibiotic response. Control PET/CT study showed a slight increase in metabolism in the pulmonary nodules. In addition, PET/CT guided the biopsy (histopathological analysis did not show malignancy). The second patient, the male, did not show significant changes in the lesions described in the previous study, which supports an infectious origin (less likely recurrence of lung cancer given stability without treatment). ***Conclusion:*** Nocardiosis is a rare infection that we have Know, mainly in immunocompromise patients. In addition, ^{18}F-FDG PET/CT at baseline add information about disease extent and underlying malignancies, as well as follow up FDG-PET/CT could evidenciate the therapy response. However, bigger scale studies are needed to prove the optimal timeframes between both PET/TC studies.

Mean Parenchymal Transit Time measurement on Tc-99m EC Diuretic renography can help differentiate obstructed from non-obstructed kidneys

***N. Gupta*[1],** *M. Ponnusamy*[1], *K. K. G*[1], *P. Mathiyazhagan*[2];
[1]*Jawaharlal Institute of Postgraduate Medical Education and Research, Pondicherry, INDIA,*
[2]*Krishna Cancer Institute, Cuddalore, INDIA.*

Aim/Introduction: Diuretic renography is used to rule out pelviureteric junction obstruction (PUJO) in antenatally-detected hydronephrotic kidneys. In addition to Normalized Residual Activity at 20 minutes (NORA20) and Output Efficiency at 20 minutes (OE20), Mean parenchymal transit time (MPTT) measured through deconvolution analysis is a continuous quantitative parameter that can be used for follow up and for deciding intervention. The objectives of the study were to compare MPTT values obtained with Tc-99m EC diuretic renography in obstructed and non-obstructed hydronephrotic kidneys in children with suspected PUJO and to find the association with other transit time parameters. ***Materials and Methods:*** In a cross-sectional analytical design, this study analyzed data of Tc-99m EC diuretic renography performed in children under the age of 18 years and suspected to have PUJO. The renography data was transferred to MATLAB and values of NORA20, OE20, and MPTT were obtained using separate algorithms. The contralateral non-hydronephrotic kidney was considered normal for study purposes. Obstructed kidneys were identified based on the diuretic renography images and curve pattern by an experienced nuclear medicine physician. The MPTT values were compared between normal, hydronephrotic non-obstructed, and obstructed kidneys. In addition, association between values NORA20, OE20 and MPTT was studied. ***Results:*** In the interim analysis of data from 75 patients (143 renal units), the median MPTT in non-hydronephrotic (n=58), hydronephrotic non-obstructed kidneys (n=58), and obstructed kidneys (n=27) were found to be 3.18 minutes (IQR: 2.87, 3.57), 4.63 (IQR: 3.47, 6.06), and 10.15 (IQR: 8.78, 11.90) respectively. A significant difference was observed between the 3 groups ($p < 0.01$). The median values of NORA20 for hydronephrotic non-obstructed and obstructed kidneys were 0.66 (IQR: 0.39, 1.04) and 2.43 (IQR: 1.79, 3.08), while the values of OE20 were 83.04 (IQR: 69.86, 90.50) and 44.33 (IQR: 34.97, 55.25), respectively. There was a strong positive correlation between MPTT and NORA20 in obstructed kidneys (correlation coefficient: 0.76, $p=0.18$) but weak in the other two subgroups. There was a strong negative correlation between MPTT and OE20 in obstructed kidneys (correlation coefficient: -0.79, $p<0.05$) but weak in the other two subgroups. ***Conclusion:*** MPTT values obtained on Tc-99m EC diuretic renography showed a significant difference between the hydronephrotic non-obstructed and hydronephrotic obstructed kidneys, implying that MPTT can distinguish obstructed from non-obstructed kidneys. The values correlated with NORA20 and OE20 values.

EP-0574

Impact of kidney allograft infarction on renal transplant outcomes

R. Nunes, *R. Albergueiro, V. Alves;*
Unidade Local de Saúde de São João, Porto, PORTUGAL.

Aim/Introduction: Renal transplantation is the best choice of treatment for patients with end-stage renal disease as it is associated with the best survival rates and improved quality of life. However, various complications may occur in the post-operative period or during follow-up, resulting in graft dysfunction or in severe cases graft loss. Segmental infarction is one of the complications that may occur in the post-operative period. The aim of this study was to compare differences in time to allograft failure and 5-year post-transplant estimated glomerular filtration rate (eGRF) between patients either with or without allograft infarction immediately after transplant. ***Materials and Methods:*** An observational and retrospective study was carried out, which included adults that underwent renography with [99mTc]Tc-MAG3 or [99mTc]Tc-DTPA for assessment of perfusion and function of the kidney allograft in the early post-operative period in our institution between 2014 and 2017. Segmental infarction was reported when a persistent photopenic image in the allograft was seen in all phases of the dynamic study. Graft failure was defined as the need for renal replacement therapy or transplantectomy. eGFR was calculated using the MDRD equation. The hypothesis of differences in the time to allograft failure between both groups of patients was tested through Kaplan-Meier analysis and the Log-Rank test. For patients in whom allograft failure did not occur during the follow-up, the association between the diagnosis of infarction and the eGFR at 5 years post-transplant was tested with two sample t-test. ***Results:*** 50 patients were included and 29 were male (58%). Median age was 49.6 ± 11.7 years. 20 patients (40%) had one or more images suggestive of segmental infarction. In 10 patients (20%) allograft failure occurred during the follow-up, of which 3 needed to undergo renal replacement therapy and 7 transplantectomy. There was no statistically significant association between the occurrence of infarction and allograft failure (p=0.38) using Kaplan-Meier analysis and the Log-Rank test. In patients in whom allograft failure did not occur during the follow-up, we found a statistically significant association between the occurrence of infarction and a lower eGFR (t=2.97; p=0.005). ***Conclusion:*** This study suggests that the occurrence of kidney allograft infarction is not associated with higher rates of graft failure but it is related to a lower GFR in renal transplant recipients.

Total variation filter in dose reduction by improving image quality in Pediatric Scintigraphy

M. Arsénio[1], *R. Vigário[1], A. Mota[2];*
[1]Faculdade de Ciencias e Tecnologias, Universidade Nova de Lisboa, Lisboa, PORTUGAL, [2]Instituto Biofisica e Engenharia Biomédica, Faculdade de Ciências, Universidade de Lisboa, Lisboa, PORTUGAL.

Aim/Introduction: Currently, more than 300 million diagnostic pediatric examinations involving radiation are performed globally. In Pediatric Renal Scintigraphy (PRS), finding a balance between image clarity and minimal radiation exposure is critical for accurate diagnoses and patient safety. However, as the image noise inherent in low radiation can impair diagnostic accuracy, it is necessary to improve image quality without increasing the radiation dose. ***Materials and Methods:*** This work proposes a method based on the minimization of Total Variation (TV) of the data to mantaining the image quality standards in PRS examinations with lower radiation dose for the children. The public Database of dynamic renal Scintigraphy was used, specifically the drsbru dataset, which includes 100 99mTc-MAG3 dynamic renal studies carried out on children aged between 0 and 17 years. These studies cover cases of unilateral or bilateral uropathy, and were acquired in posterior projection, with a resolution of 128x128 pixels and captured in 10-second frames during a 20-minute acquisition. Before implementing the Total Variation minimization filter, a dose reduction of the sum of the 100 slices was simulated, so 75%, 50% and 25% of the slices were considered. Despite the reductions, we consistently used the combined image of all the slices for analysis. Subsequently, the TV filter was applied to the cases corresponding to the lowest dose simulations. Image quality was assessed by measuring the signal-to-noise ratio (SNR) and multiscale structural similarity (MS-SSIM), before and after applying the filter. ***Results:*** In this preliminary study, four cases within 0 and 1 year age range were selected. The SNR values in the kidneys exhibited a notable increase, with an average variation of 21% with 75% of the original dose, and 12% with 50% of the original dose post-filtering. The MS-SSIM in 50% of the slices after filtering with the TV filter had very high values of 0.984 on average (a variation of 1.59% on average). ***Conclusion:*** The increase in SNR values after filtering showed that it is possible to use lower doses (-50%) without compromising image quality, and the application of the filter in this dose reduction takes, on average, around 0.11 seconds. The low variation of MS-SSIM allows us to conclude that there is no deterioration in the definition of small structures in the image, i.e, the application of the TV filter can smooth out the noisiest areas of the PRS image, preserving the contours and details of the structure.

EP-0576

Prognostic power of prenatal pelvic anteroposterior diameter APD and residual functional area RFA to predict functional impairment and excretory alterations at renal sequential scintigraphy.

C. Olianti[1], *A. Vallario[1], A. Mantovani[2], L. Pasquini[1], G. La Cava[1];*
[1]University Hospital of Florence, Florence, ITALY,
[2]University Hospital Meyer, Florence, ITALY.

Aim/Introduction: The comparison between the functional and morphological alterations during prenatal sonography and the scintigraphic results after birth. ***Materials and Methods:*** 42 children with prenatal diagnosis of hydronephrosis (IDN) and hydroureteralnephrosis (IDUN) at 36weeks of gestational age, were evaluated with diuretic scintigraphy within 8 months from birth (mean 5 months). The kidney were classified considering the pelvis anteroposterior diameter APD on SIEOG classification as mild, moderate and severe in IDN and as specific cohort in IDUN. Effective renal plasma flow ERPF and the %excretion 20minutes after furosemide administration E% were considered for comparison with prenatal parameters. Functional residual area (FRA) is defined as the whole-kidney area minus the pelvic

area, evaluated on longitudinal view, and expressed as %. ***Results:*** In severe (14/20; 70%) IDN and IDUN (22/22) the median monolateral ERPF of pathologic kidney was lower 255 (range 190-290) ml/min/1,73 m2BSA) vs 299 found in mild (1/20; 0.5%) and in moderate (5/20; 25%) IDN (range 275-315) (p=0.038). Even if not significant (p=0.86) we found that the tracer excretion was insufficient (E% <40%) in 10 kidney with severe IDN (10/14;71%) and only in one with mild IDN (1/5; 20%) and 8 with IDUN (8/22; 36%). Ballon shaped pelvis (BP) was found in 29/42(69%) cases and associated to a poor excretion E%<40% in 16/29(55%) and only in 3/13(23%) in not-BP (p=0.093). Mean ERPF is reduced in BP, 237 ml/min/1,73 m2BSA (range 180-278), while it's 292 ml/min/1,73 m2BSA (range 251-308) in not-BP. A correlation between FRA and ERPF in all 56 pathologic kidneys showed two clusters: 5/56 (9%) with FRA <70% which had a mean ERPF of 70 ml/min/1.73m2BSA and displasia feature (uretral valves or major vescico-ureteral reflux) and 51/56 (91%) with meanERPF 286 ml/min/1.73m2BSA (range 245-312) always related to IDN or IDUN without displasia. Mild and moderate IDN have 78% and 42% probability of spontaneous resolution, 5% and 10% of urinary tract infection UTI, 0% and 8% surgical treatment, respectively. Only 25% needed further investigations. Severe IDN and IDUN have 5% and 24% probability of spontaneous resolution, 30% and 33% of UTI. 75% of IDN needed further examinations and 55% was operated for pelvic-ureteral stenosis. 24% of IDUN had spontaneous resolution and 24% was operated. ***Conclusion:*** For kidney with FRA >70% during prenatal echography we could expect a normal or only slightly reduced renal function. The proposed FRA cut-off, if confirmed as prognostic tool, could help for accurate risk assessment.

EP-0577

Comparison between diuresis renography protocols F0 and F+15 in the evaluation of hydronephrosis in children under 2 years old: a propensity score-matched analysis

R. Nunes, *R. Albergueiro, V. Alves;*
Unidade Local de Saúde de São João, Porto, PORTUGAL.

Aim/Introduction: Hydronephrosis is the most common abnormality of the urinary tract diagnosed in children. Diuresis renography provides information on relative renal function and drainage pattern of the excretory system, allowing identification of cases at risk for function loss that benefit from early intervention. Various furosemide administration protocols can be used. The F0 protocol decreases the exam duration compared to the F+15 protocol, but it results in a loss of information about the elimination of the radiopharmaceutical in basal conditions. Additionally, in children with immature kidneys, cortical clearance of the radiopharmaceutical is not useful to exclude obstruction. Few studies have compared the F0 and F+15 protocols, and none included only children under 2 years of age. The aim of this study was to compare positivity rates for obstruction between furosemide protocols F0 and F+15 of renography in children under 2 years old. ***Materials and Methods:*** An observational and retrospective study was conducted, including children under 2 years old with unilateral hydronephrosis who underwent either F0 or F+15 protocol of diuresis renography with [99mTc] Tc-MAG3 (both with late post-void imaging), in our institution between 2018 and 2024. Each renography was classified as having obstructive stasis or normal/non-obstructive stasis based on the most likely diagnosis assigned in the medical report. We also recorded the values of the relative renal function and time to peak of each renography, the anteroposterior diameter of the renal pelvis given by ultrassound and the reporting physician. The hypothesis of differences in positivity rates for obstruction between F0 and F+15 protocols was tested after adjusting for potential confounding factors by sequentially applying propensity score analysis, full matching and weighted logistic regression with g-computation on the matched data. ***Results:*** 52 children were included and 43 were male (83%). The median age was 7.3 ± 6.4 months. 30 children (58%) underwent renography with the F+15 protocol and 22 (42%) with the F0 protocol. Obstruction occurred in 6 children (20%) who underwent renography with the F+15 protocol and in 7 (32%) who underwent renography with the F0 protocol. There was no statistically significant association between the diuretic protocol type and the result of the renogram (odds ratio: 0.618; p-value: 0.455), after adjusting for relative renal function, anteroposterior diameter of the renal pelvis and reporting physician. ***Conclusion:*** This study suggests that F0 and F+15 protocols have similar accuracy for detection of upper urinary tract obstruction in children under 2 years old.

Impact of Renal Function on Texture Analyses of Kidney Uptake duringPeptide Receptor Radionuclide Therapy with^{177}Lu-DOTATATE

H. Wakabayashi[1], *K. Okuda[2], T. Konishi[3], H. Yoneyama[3], H. Mori[1], T. Hiromasa[1], N. Akatani[1], S. Watanabe[1], D. Kayano[1], T. Terashima[4], S. Kinuya[1];*
[1]Dept. of Nuclear Medicine, Kanazawa University Hospital, Kanazawa, JAPAN, [2]Hirosaki University, Hirosaki, JAPAN, [3]Radioisotope Division, Kanazawa University Hospital, Kanazawa, JAPAN, [4]Kanazawa University Advacned Preventive Medical Scienced Research Centre, Kanazawa, JAPAN.

Aim/Introduction: The kidney is a critical target organ for peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE for neuroendocrine tumor patients. The damage effects may differ between patients due to renal function. Although the effects have been mainly studied by radiation exposure dose, the accumulation features by texture analyses have not been reported. This study investigated whether renal accumulation features during PRRT are altered by renal function using LIFEx feature analysis software (ver 7.5.7). ***Materials and Methods:*** Patients underwent dosimetry with four imaging sessions at 4hr, 24hr, 72hr, and 120hr after 1st PRRT. Volumes of interest (VOI) of bilateral kidneys were manually delineated, and the VOI for analysis was set with a threshold of 40% of the upper limit. Kidneys near the tumor, in which the VOI setting was difficult to delineate, were omitted from the present study. Using the LIFEx texture analysis program, we extracted texture and specific features from the images. Then, we calculated the statistical significance of differences between parameters of patients with eGFR less than or more than 60 ml/min by an Analysis of Variance (ANOVA). All pairs were compared using Tukey-Kramer HSD tests. A linear relationship was analyzed between two variables. P<0.05 were considered as significant. ***Results:*** Twenty-one patients received dosimetry, and 34 kidneys were analyzed. For all kidneys, all texture features had no

differences, but other specific features had significant differences by ANOVA: VOIIntensity-based_AreaUnderCurve, Intensity-based_EnergyIBSI, Intensity-based_RootMeanSquareIntensity, Intensity-based_TotalLesionSomatostatinReceptorExpression, and Local_Intensity_Histogram_GlobalIntensityPeak. All five features were significantly different between the four scans for kidneys with eGFR of more than 60 but not with eGFR of less than 60. Tukey-Kramer HSD tests showed values decrease steadily and significantly. Absorbed and biologically effective doses for kidneys tended to increase depending on lower renal function. ***Conclusion:*** This study found no texture feature change between the four imaging sessions in the kidneys. As for the intensity features, they decreased depending on time, but it depended on renal function. A correlation between renal function and radiation dose was also observed. It is important to recognize that renal exposure dose may increase when renal function is decreased.

EP-0579

Evaluation of the efficacy of the Lu-177 DOTATATE Treatment in Inoperable/Metastatic Paraganglioma and Malignant Pheochromocytoma

C. Güneren[1], *L. Uslu Beşli[1], K. Şahin[1], O. E. Şahin[1], S. Özel Yıldız[2], L. Kabasakal[1], H. B. Sayman[1];*
[1]Istanbul University-Cerrahpasa Cerrahpasa Medical Faculty Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Istanbul University Istanbul Faculty of Medicine Deparment of Biostatistics, Istanbul, TÜRKIYE.

Aim/Introduction: Our aim is to assess the efficacy of Lu-177 DOTATATE peptide receptor radionuclide therapy (PRRT) in inoperable or metastatic paraganglioma and malignant pheochromocytoma patients who have limited systemic treatment options. ***Materials and Methods:*** We retrospectively analyzed 26 patients (14 paraganglioma, 12 pheochromocytoma) treated with at least two courses of Lu-177 DOTATATE between 2010 and 2024.Eligibility criteria included increased somatostatin receptor (SSTR) expression (Krenning score ≥2) on Ga-68 DOTATATE PET imaging.Patients received an average of six treatments (range 2-13) with an average Lu-177 DOTATATE dose of 6.1 GBq (range 4.0-7.6 GBq) at 8-16 week intervals.Response was evaluated 3-6 months post-treatment using Ga-68 DOTATATE PET and RECIST 1.1 criteria.Patients were divided into two groups based on whether they received 2-4 courses (n=13) or ≥5 courses (n=13) of treatment.Kaplan-Meier analysis was performed for progression-free survival (PFS) and overall survival (OS).The relationship between histopathology, patient demographic characteristics, or the number of PRRT courses and PFS was evaluated using Chi-square test.Continuous variables between the two groups were compared using the Mann-Whitney U-test, and categorical variables were compared using Fischer's exact T-test.All statistical analyses were performed using SPSS v.29, and $p<0.05$ was considered statistically significant. ***Results:*** Nine patients were stable and four had progressive disease in 2-4 courses group, one patient showed partial response, eight had stable disease, and four progressed in ≥5 courses group. Adverse events included myelodysplastic syndrome (1 patient, 13 courses) and Grade 3 thrombocytopenia (2 patients, 8 and 5 courses).Median PFS was 29 months (15 for 2-4 courses, 42 for ≥5). Median OS was 85 months.Significant associations were found between the primary tumor type and gender ($p=0.045$) and mean SUVmax value ($p=0.031$).Furthermore, a statistically significant relationship was found between the number of PRRT courses and total lesion count ($p=0.003$), while no significant differences were found among other variables. ***Conclusion:*** Our study revealed a 66% stable disease rate and 69% disease control rate, comparable to literature, but higher progression (31%) and low objective response (4%).Study limitations include imaging-only response assessment, small sample size, no biochemical response evaluation, and heterogeneous treatments pre/post-PRRT.PRRT appears safe and beneficial for these conditions, improving PFS. However, a personalized, multidisciplinary approach is essential. Larger, homogeneous prospective studies are required to further explore PRRT's survival impact. ***References:*** Satapathy S, Mittal BR, Bhansali A. 'Peptide receptor radionuclide therapy in the management of advanced pheochromocytoma and paraganglioma:A systematic review and meta-analysis'. EP-0580

Predictive parameters of response to [177Lu]Lu-DOTA-TATE in well-differentiated neuroendocrine neoplasms

S. Bondia-Bescós[1], *J. Vercher-Conejero[1], J. Martin-Marcuartu[1], G. Reynés-Llompart[2], M. Pudis[1], A. Rodriguez-Gasen[1], V. Carrero-Vasquez[1], P. Perlaza-Jiménez[1], B. Hervás-Sanz[1], J. Díaz-Moreno[1], M. Zamorano-Rivas[1], A. Bagán-Trejo[1], L. Rodriguez-Bel[1], I. Sanchez-Rodriguez[1], J. Robles-Barba[1], À. Teulé-Vega[3], M. Suárez-Piñera[1], J. Ruffinelli-Rodriguez[3], I. Peiro-Martínez[4], M. Cortés-Romera[1];*
[1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital, Barcelona, SPAIN, [2]Phisics Department, Institut Català d'Oncología, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN, [3]Medical Oncology Department, Institut Català d'Oncología, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN, [4]Nutrition Functional Unit, Institut Català d'Oncología, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN.

Aim/Introduction: To evaluate the response to peptide receptor radionuclide therapy (PRRT) with [177Lu]Lu-DOTA-TATE in patients with well-differentiated neuroendocrine neoplasms (wNEN) and somatostatin receptors (STTR) overexpression based on tumor characteristics (anatomopathological, morphological and functional) and previous treatments received. ***Materials and Methods:*** Retrospective analysis of patients diagnosed with wNNE treated with [177Lu]Lu-DOTA-TATE in our centre between March/2017-July/2023. The Response Assessment (RA) to PRRT was evaluated based on the degree of tumor differentiation (G), treatment line (L) and functional parameters [Total Tumour Volume (TTV), Total Tumour Activity (TTA), Liver Tumour Volume (LTV), Liver Tumour Activity (LTA), SUVmax] calculated on the PET/CT [68Ga]Ga-DOTA-TOC (PET-SSA) pre-PRRT. Statistical analysis was performed to evaluate whether these data had an impact on progression-free survival (PFS) and overall survival (OS). ***Results:*** Seventy patients were treated (31 women, mean 59.4 years). 14p did not complete PRRT due to progression/toxicity/other. Overexpression of STTR pre-PRRT was observed using [m99Tc]Tc-EDDA/HYNIC-TOC (24p/70p) and/or PET-SSA (36p/70p). In 10p there was no access to pre-PRRT imaging. 33p/36p with PET-SSA had liver involvement. In these, the TTV/TTA/LTV/LTA/SUVmax parameters did not significantly influence RA in the Wilcoxon test, nor were significantly modified according to G. However, a high TTV/LTV meant worse PFS/OS ($p<0.05$). RA did not vary significantly depending on G or L, although a positive trend towards greater PFS/OS was identified in wNEN-G1; and PRRT in ≤2L led to better PFS/OS ($p<0.05$). ***Conclusion:*** In our cohort, better survival after PRRT was observed in patients with ≤2L, as well as with lower TTV/LTV. Trends towards a better post-treatment outcome were observed in wNEN-G1 when comparing to wNEN-G2.

Our results suggest that using PRRT in earlier stages leads to better results. TTV and LTV calculated on the PET-SSA pre-PRRT could be biomarkers of response to [177Lu]Lu-DOTA-TATE.

EP-0581

Prognostic value of the volumetric parameters measured by SSTR PET/CT in patients with neuroendocrine tumors treated with long-acting somatostatin analogues as a first line therapy

M. Opalinska[1], *K. Morawiec-Sławek[1], W. Lenda-Tracz[2], A. Sowa-Staszczak[1], A. Hubalewska-Dydejczyk[1];*
[1]Departament of Endocrinology, Jagiellonian University, Krakow, POLAND, [2]Faculty of Health Sciences, Jagiellonian University, Krakow, POLAND.

Aim/Introduction: Somatostatin analogues (SSA) are the first treatment option (especially for disease control) for disseminated neuroendocrine tumors (NETs) with good expression of the somatostatin receptors. Despite significant progress in NET personalized management, searching for novel predictive and prognostic factors of response to systemic therapy in NET is crucial for more effective patient management including more accurate follow-up leading to better final outcomes. The aim of this study was to evaluate the predictive role of volumetric and standardized uptake values (SUVs) obtained from pre-treatment [68Ga]Ga-DOTA-SSA in the prediction of the response to SSA therapy in patients with NET. ***Materials and Methods:*** 42 patients (21 females, 21 males; age range: 46-84 years) with histologically proven metastatic NET (15 pancreas, 15 small intestine, 4 lung, 7 unknown, 1 cecum; WHO G1 13, G2 28, 1 unknown; median Ki-67 index 5%, range 1-16) receiving long-acting SSA as first-line treatment were included in the study All of them underwent [68Ga]Ga-DOTA-TATE PET/CT before receiving first dose of SSA. For each [68Ga]Ga-DOTA-TATE avid lesion, SUVmax and SUVmean were measured as well as TBR (SUVmean of tumours/metastases divided by SUVmean of normal spleen) was calculated. In addition, two volumetric parameters were counted: tumor somatostatin receptor expression volume (STV) and total lesion somatostatin receptor expression (TLD). Finally, the sum of STV (total STV, TSTV) and TLD (total TLD, TTLD) was calculated for each patient and used in the analysis. ***Results:*** At the time of analysis, 14 patients had stable disease (33.3%) and 28 patients had progressive disease (66.7%); among whom 12 died. Median progression-free survival (PFS) and overall survival (OS) were 26.5 and 46.5 months, respectively. The median SUVmax, SUVmean and TBR ratio were 38.5 (range 12.9-99.1), 21.4 (range 10.4-51.9) and 0.93 (range 0.38-3.29), respectively. The median TSTV was 41.4 cm3 (range 1.0-1446.7) and the median TTLD was and the median TTLD was 650.7 (range 10.6-16156.8). In the univariate analysis, the TBR ratio (HR=1.96, 95% CI 1.058-3.62, p=0.03) was the only parameter significantly associated with PFS. In patients with small bowel NETs, TSTV (HR=1.00, p=0.023) and TTLD (HR=1.00, p=0.026) were significantly associated with PFS in univariate analyses. No significant correlation was found between the measured volumetric parameters and OS. ***Conclusion:*** Volumetric parameters of pre-treatment 68[Ga]Ga-DOTA-TATE PET/CT may be potentially useful in prediction of the response to SSA therapy in patients with NET: higher TTLD was associated with worse outcome in patients treated with SSA in monotherapy.

EP-0582

External Exposure Dose to Carers and the Public During ^{177}Lu-PRRT for Neuroblastoma

Y. Sun, *X. Sun;*
Department of Nuclear Medicine, Shandong First Medical University and Shandong Academy of Medical Sciences, Shandong Cancer Hospital and Institute, Jinan, CHINA.

Aim/Introduction: To estimate the radiation dose to carers and the public from 177Lupeptide receptor radionuclide therapy (PRRT) for pediatric neuroblastoma patients and determine the duration of contact restrictions, aiming to provide a crucial reference for relevant radiation protection measures. ***Materials and Methods:*** A retrospective study was conducted to collect data from 18 pediatric neuroblastoma patients, aged (6.72±2.72) years, who received 177LuDOTATATE treatment at the Nuclear Medicine Department from June 2023 to July 2023. After administration, the dose rate (DR) around the patients was measured using a nuclear radiation monitoring dosimeter at 0, 0.1, 0.5, 1, and 2 meters from the patients at 1, 4, 24, 48, and 96 hours. And then, we delineated the wholebody ROI. Subsequently, curve regression fitting was performed using a biexponential function model. By incorporating hypothesized social contact durations, we estimated the cumulative radiation doses received by family members and the public through contact with patients. ***Results:*** The 177Lu-DOTATATE administration dose was (4353.42±1451.51) MBq. All patients were discharged 24 hours after 177Lu-DOTATATE administration. At discharge, patients had excreted (76.70±3.99)% of the administered activity, and DR at 0.1, 1, and 2 meters from the patients were (32.74±6.98), (4.07±1.45), and (1.22±0.51) μSv/h, respectively. After discharge, the radiation doses to carers from children aged 25 years and 513 years were (2.47±1.80) mSv and (0.88±0.47) mSv, respectively. The contact restriction period for sleeping with family members was 2 days, and 1 day for contact with other children. On the day of discharge, patients should limit their time on public transportation within 4 hours and do not need to restrict private transportation. ***Conclusion:*** To ensure that the total effective dose equivalent (TEDE) remains within the safety limits stipulated by current regulations, it is necessary to implement contact restrictions for patients' family members and the general public. After implementing preventive measures, 177LuDOTATATE emerges as a safe radionuclide therapeutic option.

EP-0583

^{177}Lu-Octreotide SPECT/CT Dosimetry in Predicting PRRT Efficacy and Adverse Reactions in Children with High-Risk Neuroblastoma

F. Zheng, *X. Sun;*
Shandong Cancer Hospital and Institute, Jinan, Shandong, CHINA.

Aim/Introduction: To establish dosimetry predictors for therapeutic response and adverse effects following 177Lu-labeled Peptide Receptor Radionuclide Therapy (PRRT) in pediatric patients with high-risk neuroblastoma, utilizing 177Lu-Octreotide SPECT/CT imaging. ***Materials and Methods:*** A prospective study enrolled pediatric patients with high-risk neuroblastoma scheduled for 177Lu-PRRT. Post-treatment, multi-timepoint whole-body imaging and 24-hour chest-abdomen SPECT/CT scans were performed. Hermes 3.0 software was utilized to measure the cumulative absorbed dose (CAD) in target lesions (up to 5 "hot" lesions) and critical organs. Therapeutic response was evaluated based on pre- and post-treatment 18F-SSTR PET imaging, while

adverse effects in critical organs were assessed using CTCAE 5.0 criteria. Logistic regression was applied to assess the correlation between dosimetry parameters, hematological indices, osseous tumor volume (OTV), and both therapeutic response and adverse effects. The predictive performance was evaluated using the area under the curve (AUC). ***Results:*** 25 patients received 1-2 cycles of 177Lu-PRRT, achieving a cumulative absorbed dose (CAD) of 2.79Gy in target lesions and ranging from 1.88 to 9.70Gy in critical organs. Therapeutic response was evaluated in 99 target lesions from 22 patients, revealing disease control rates of 54.54% for patients and 83.83% for lesions. The only adverse effect observed was myelosuppression. CAD in target lesions correlated with therapeutic response, and both CAD1cycle and CAD2cycles showed predictive value for treatment response (AUC=0.845 and 0.800, respectively). No association was found between bone marrow CAD and myelosuppression. Pre-treatment osseous tumor volume (OTV) and hemoglobin were identified as independent risk factors for grade 3-4 thrombocytopenia and anemia, with predictive accuracies of 0.793 and 0.813, respectively. ***Conclusion:*** Dosimetry measurements of CAD in target lesions post-177Lu-PRRT, combined with pre-treatment OTV and hemoglobin levels, effectively predict therapeutic response and adverse effects in pediatric patients with high-risk neuroblastoma receiving PRRT.

EP-0584

Safety and Dosimetry of [^{177}Lu]Lu-DOTA-TATE in Adolescent Patients With Somatostatin Receptor-Positive Gastroenteropancreatic Neuroendocrine Tumors or Pheochromocytomas and Paragangliomas

A. Giraudet[1], *D. Handkiewicz-Junak[2], R. Hladun[3], T. W. Laetsch[4], C. Sorge[5], R. Sparks[6], L. Xu[7], K. Perraud[8], G. Kollar[9], F. Khanshan[7], L. Blumenstein[10], F. Brouri[8], M. Gaze[11];*
[1]Centre Léon Bérard, Lyon, FRANCE, [2]Maria Skłodowska-Curie Memorial National Research Institute of Oncology, Gliwice, POLAND, [3]Hospital Vall d'Hebrón, Barcelona, SPAIN, [4]Children's Hospital of Philadelphia, University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA, [5]University of Kentucky, Lexington, KY, UNITED STATES OF AMERICA, [6]CDE Dosimetry Services Inc., Knoxville, TN, UNITED STATES OF AMERICA, [7]Novartis Pharmaceuticals Corp, East Hanover, NJ, UNITED STATES OF AMERICA, [8]Advanced Accelerator Applications International S.A., Geneva, SWITZERLAND, [9]Advanced Accelerator Applications S.A., Rueil-Malmaison, FRANCE, [10]Novartis Biomedical Research, Basel, SWITZERLAND, [11]University College London Hospitals NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: Adolescent patients with gastroenteropancreatic neuroendocrine tumors (GEP-NET) or pheochromocytomas/paragangliomas (PPGL) diagnosed with advanced disease have limited treatment options. The ongoing phase 2 NETTER-P study (NCT04711135) evaluates the safety and dosimetry of the radioligand therapy, [177Lu]Lu-DOTA-TATE (177Lu-DOTATATE), in adolescent patients with somatostatin receptor-positive (SSTR+) GEP-NET or PPGL. ***Materials and Methods:*** Enrolled patients were aged 12-17 years, with advanced, inoperable, SSTR+, GEP-NET (Grade 1 or 2) or PPGL. Treatment schedule was ≤4 cycles of 177Lu-DOTATATE (4×7.4 GBq) administered every 8±1 weeks. Amino acid solution was given for renal protection. Safety was assessed during treatment and follow-up. Dosimetry and pharmacokinetic assessments were performed during Week 1 after the first cycle (C1) of 177Lu-DOTATATE (or after C2 if not feasible after C1). Primary endpoints were incidence of adverse events (AE) and laboratory toxicities during C1 of 177Lu-DOTATATE, and absorbed radiation dose in target organs (kidney and bone marrow). ***Results:*** At the time of this analysis, 9 patients were treated (median age 15 years [range: 13-16]; GEP-NET, n=4; PPGL, n=5). Overall, 8/9 patients experienced ≥1 AE during C1 of 177Lu-DOTATATE (considered treatment-related in 7 patients). The most common AEs were headache (n=4) and fatigue (n=3). AEs of special interest during C1 were reported in 5/9 patients (hematotoxicities [n=3], nephrotoxicities [n=1], cardiovascular and electrolyte disorders [n=1]). All patients experienced ≥1 AE during the overall treatment period. Treatment-related AEs were reported in 8 patients; none were considered serious. No deaths or AEs leading to treatment discontinuation were reported. In patients evaluable for dosimetry (n=8), estimated mean (standard deviation [SD]) cumulative absorbed dose for 4 cycles of 177Lu-DOTATATE was 23 (8.5) Gy in the kidneys and 0.79 (0.16) Gy in the bone marrow (by blood). Estimated mean (SD) cumulative tumor absorbed dose was 76 (35) Gy in GEP-NET (n=8) and 27 (20) Gy in PPGL (n=6). 177Lu-DOTATATE blood pharmacokinetic analysis (n=9) showed a bi-exponential clearance with a rapid first phase until 24 hours and a slower second phase until 72 hours post-administration. Population pharmacokinetic model-derived parameters of 177Lu-DOTATATE in adolescents were comparable with those derived for adults with GEP-NET. All adolescent results, except tumor dosimetry, were consistent between GEP-NET and PPGL cohorts. ***Conclusion:*** No new safety signals were identified to date in 9 adolescents with SSTR+ GEP-NET or PPGL treated with 177Lu-DOTATATE. The estimated cumulative absorbed doses of 177Lu-DOTATATE were comparable with those observed in adults. Funded by Advanced Accelerator Applications, a Novartis company.

EP-0585

Real-world efficacy and safety of re-treatment with [177Lu]Lu-DOTA-TATE in patients with neuroendocrine tumors (NETs)

F. Velázquez[1], *A. García-Burillo[1], V. Pubul Nuñez[2], S. Asadurova[1], J. Hernando Cubero[1], N. Martínez-Lago[2], A. Calatayud Cubes[2], U. Anido Herranz[2], A. Garcia-Alvarez[1], J. De Matías Leralta[2], J. Echeverri Díaz[1], J. Suils Ramón[1], N. Calviño[1], T. Canela Coll[1], M. Marusso Fizzani[1], O. Hernández Cristancho[1], C. Gámez Cenzano[1], J. Capdevila[1];*
[1]Hospital Universitario Vall d´Hebron, Barcelona, SPAIN, [2]Complejo Hospitalario Universitario de Santiago de Compostela, Santiago de Compostela, SPAIN.

Aim/Introduction: The established efficacy and safety of [177Lu]-DOTA-TATE in metastatic gastroenteropancreatic neuroendocrine tumors (GEP-NETs) and bronchial NETs (G1, G2) have paved the way for exploration into re-treatment ([177Lu] RR-PRRT) safety and efficacy, an area with limited available data.This study aims to evaluate the safety and efficacy of [177Lu] RR-PRRT in patients with progressive GEP-NETs or lung NETs following standard-dose PRRT. ***Materials and Methods:*** A retrospective multicenter study conducted from July 2018 to October 2023 involved 31 patients. Tumor characteristics, treatment history, outcomes, and adverse events (AEs) were comprehensively analyzed. ***Results:*** The cohort comprised 61.3% males, with predominant tumor locations in the intestinal (58.1%), pancreatic (22.6%), and lung (16.1%) regions. NETgrades included 32.3% NET-G1, 51.6% NET-G2, and 16.1% NET-G3. Predominant metastatic locations were the liver (90.9%), lymph nodes (64.5%), bone (45.2%), peritoneum (35.5%), and lung (12.9%). Treatment lines varied, with 6.5% in the first, 41.9% in the second, 35.5% in the third, 6.5% in the fourth, and 9.7% in the fifth. Previous treatments included 90.3% somatostatin analogs (SSA), 25.8% everolimus, 22.6% chemotherapy, 16.1% tyrosine kinase inhibitors (TKI), and 6.5% other modalities. The overall response rate (ORR) to initial PRRT was 54.8% partial

response (PR) and 45.2% stable disease (SD), with 100% clinical benefit. Progression-free survival (PFS) post-PRRT was notable at 29.37 months (range 13.8-120.67). Notably, 19.3% received more than one line of treatment between PRRT and RR-PRRT. Response to RR-PRRT revealed an ORR of 4.5% and a disease control rate (DCR) of 59.1%. With a median follow-up of 25.8 months, PFS RR-PRRT was 11.5 months (95% CI, 9-14), and OS RR-PPRT was 27.7 months (95% CI, 14.7-40.6). RR-PRRT-associated AEs (grade 3-4) included thrombocytopenia (12.9%), lymphopenia (9.7%), anemia (6.5%), and leukopenia (3.2%). Importantly, no nephrotoxicity was observed during RR-PRRT. ***Conclusion:*** [177Lu] RR-PRRT in progressive GEP-NETs or lung NETs post standard-dose PRRT demonstrated favorable efficacy with manageable AEs.

EP-0586

Sequence of cancers - GEP NET

B. Schemmer, *M. Essler;*
Uniklinik Bonn, Bonn, GERMANY.

Aim/Introduction: With longer patient survival, secondary, tertiary, etc. neoplasms are increasingly relevant to patient care and quality of life. However, are there any specific neoplasms following or primordial cancers leading to GEP NETs that we should or could be aware of when treating patients? ***Materials and Methods:*** We searched the SEER Research Plus Data, 8 Registries, Nov 2023 Sub (1975-2021), released April 2024, based on the November 2023 submission. We limited our search to patients with a GEP NET at any time in their history regardless of sequence and considered any tumor during their lifetime. ***Results:*** A total of 4323 patients was included, median age 62 years, 2389 male, 1934 female. The most common site for the primary was the small intestine (1095), followed by the rectum (905), stomach (436), pancreas (423), appendix (221), cecum (150) and sigmoid colon (132). The most common secondary neoplasia's were prostate (546) and breast cancer (383) followed by recurrent NET in the small intestine (402), rectum (255), stomach (265) and pancreas (213) as well as lung and bronchial cancer (361) and kidney cancer (163) This pattern is similar for tertiary and quaternary cancers although on a significantly lower level: small intestine 86 and 8, stomach 76 and 22, prostate 103 and 27, breast cancer 129 and 30. Histologic variation was significantly lower when compared to other cancer with 8240/3 and 8140/3 being the type of about 90% of all neoplasia's considered. ***Conclusion:*** GEP NETs show little histologic variance with regard to consecutive cancers. They recur most commonly in the gastrointestinal tract. For most patients the GEP NET is their first primary, the secondary and consecutive tumors are either common place like breast and prostate cancer or recurrences of GEP NETs in a different location.

EP-0587

^{177}Lu-DOTATATE in patients with well-differentiated neuroendocrine tumors and skeletal metastases: A single-centre experience

S. Satapathy, *S. Ballal, M. P. Yadav, R. K. Sahoo, C. Bal;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE has emerged as a mainstay in the treatment of advanced well-differentiated neuroendocrine tumors (WD-NETs). Bone metastases have been known to portend a poor prognosis in patients with WD-NETs. However, there is scarce literature on the role of 177Lu-DOTATATE PRRT in such cases. Here, we report our institutional experience with 177Lu-DOTATATE in patients of WD-NETs with skeletal metastases. ***Materials and Methods:*** This was a retrospective, single centre study. Data of consecutive patients of advanced WD-NETs with skeletal metastases treated with 177Lu-DOTATATE, between 2014 and 2021, were collected and analyzed. The various outcome measures included objective response rate (ORR), disease control rate (DCR), and overall survival (OS). ***Results:*** Of the 310 patients treated with 177Lu-DOTATATE PRRT at our centre, 77 patients (median age: 62 years, range: 26-79) having WD-NETs with skeletal metastases were included in this study. Gastrointestinal NET was the most common site of primary (30/77, 39%), followed by pulmonary carcinoid (17/77, 22%) and pancreatic NET (12/77, 16%). 18 (23%) patients had unknown primaries. Tumor grades were available in 65 patients, of which, 25 (38%) patients had grade 1, 33 (51%) patients had grade 2, and 7 (11%) patients had grade 3 NETs. Apart from the skeletal involvement, liver and lung metastases were also seen in 62/77 (81%) and 38/77 (49%) patients, respectively. Prior treatments included somatostatin analogues in 57 (74%) patients, everolimus in 9 (12%) patients, and cytotoxic chemotherapy in 30 (39%) patients. The patients received a median cumulative activity of 16.7 GBq (range: 5.55-44.4) of 177Lu-DOTATATE over a median of 3 cycles (range: 1-7). Radiographic responses were available for 50 patients, of which 8 (16%) patients had partial response, 34 (68%) had stable disease, and 8 (16%) had progressive disease. The ORR was 16% while the DCR was 84%. The patients were followed up for a median duration of 26 months during which 28 (36%) patients expired. The median OS was estimated to be 45 months (95% CI: 40-50). ***Conclusion:*** 177Lu-DOTATATE PRRT showed clinically meaningful responses and survival in patients of WD-NETs with skeletal metastases, despite such patients having an adverse prognosis. With the advent of targeted alpha therapy having high linear energy transfer, future studies exploring the same are expected to result in better outcomes for such patients.

EP-0588

Safety and efficacy of ^{177}Lu DOTATATE Peptide Receptor Radionuclide Therapy (PRRT) in progressive gastro-entero-pancreatic (GEP) Neuroendocrine Tumour (NET)

***R. Alipour*[1],** *R. K. Karri*[1]*, E. Boehm*[1]*, K. Jewell*[1]*, M. Fahey*[1]*, J. Saghebi*[1]*, A. Cardin*[1]*, L. Neeson*[1]*, J. P. Buteau*[1]*, A. Ravi Kumar*[1]*, T. Akhurst*[1]*, M. Hofman*[1]*, M. Michael*[1]*, R. Hicks*[2]*, G. Kong*[1]*;*
[1]Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA,
[2]Melbourne Theranostic Inovation Centre, Melbourne, AUSTRALIA.

Aim/Introduction: Patients with GEP NET who retain adequate somatostatin receptor (SSTR) expression upon progression after initial response to PRRT are amenable to re-treatment PRRT (R-PRRT). We aim to assess the safety and efficacy of R-PPRT in progressive metastatic GEP NET. ***Materials and Methods:*** A retrospective analysis was performed in patients with GEP NET who received R-PRRT with 177Lu-DOTATATE for symptomatically and/or radiologically progressive disease. Renal and haematological parameters at 3 months post initial PRRT (I-PRRT) were compared to each subsequent R-PRRT to assess the safety defined by common terminology criteria for adverse events (CTCAE). Molecular imaging response was evaluated on 68Ga-DOTATATE (GaTate) PET/CT on pre-defined criteria. RECIST 1.1 measurements 3 months post R-PRRT were documented when available. ***Results:*** A total of 63 patients had R-PRRT (R1) with 177Lu-DOTATATE (1-2 cycles). Majority (76%) had G2 NET followed by G1 (14%). Of the 63, 55% had intestinal primary. A second R-PRRT (R2) course was administered in 20 patients and 6 patients had a third R-PRRT (R3) course. No worsening of renal function occurred following R1. Following R2, worsening GFR from CTCAE G2 to G3 was seen in 2/20, with no GFR deterioration following R3.

No G3/4 haematological toxicity was observed after R1 or R2, but 1 G3 thrombocytopenia occurred following R3. Myelodysplastic syndrome (MDS) was diagnosed in 3 patients 18, 23 and 36 months after I-PRRT while 1 patient developed AML 10 years post I-PRRT. After I-PRRT the overall evaluable RECIST 1.1 responses CR, PR, SD, and PD were observed in 2%, 45%, 49% and 4% of patients, respectively (disease control rate - DCR 96%). Following R1, this was 0%, 10%, 76%, and 14% (DCR 86%), respectively. DCR on GaTate PET/CT was 59/60 (98%) after I-PRRT and 52/58 (89%) post R1-PRRT. The risk difference was 9% (95% CI: -2, 20). Median overall survival (OS) from I-PRRT was 6.0 years (95% CI: 4.7,7.5). Median progression free survival (PFS) from R1-PRRT was 1.6 years (95% CI: 1.2-2.3). ***Conclusion:*** R-PRRT is feasible and efficacious upon progression of SSTR expressive GEP NET following response to I-PRRT without a significantly increased risk of toxicity.

EP-0589

The Clinical Utility of Receptor Metabolic Response Evaluation Based on Somatostatin Receptor Imaging (SRI), in Patients with Advanced, Non-resectable, Progressive GEP-NET after Combine Radioligand and CAPTEM therapy.

J. Cwikla[1], *A. Zrajkowska[1], M. Nowicki[2], J. M. Pałucki[3], M. Kempińska-Wróbel[1], A. Kolasińska-Ćwikła[3];*
[1]University of Warmia and Mazury, Olsztyn, POLAND, [2]Hospital Ministry of Internal Affairs and Administration, Warsaw, POLAND, [3]Maria Skłodowska-Curie National Research Institute of Oncology, Warsaw, POLAND.

Aim/Introduction: Prospective, single-arm, open-label, case series study with assessment of response using somatostatin receptor imaging (SRI) after combined radioligand (RLT) and CAPTEM in therapy of advanced, unresectable progressive GEP-NET (NCT04194125). The aim of the study was evaluation of utility of SST receptor (SSTR) metabolic response on combine therapy based on somatostatin receptor imaging (SRI) in follow-up studies. SRI locally assessed. ***Materials and Methods:*** Nineteen patients in group of 21 treated subjects between 18.02.2019 to 01.04.2024 included into analysis, two of them exclude due to rapid disease progression (DP). All patients with confirmation of GEP-NETs, as advanced, non-resectable, DP. Combine therapy RLT (177Lu DOTATOC) and CAPTEM used in all. NETG1=8, G2=10, G3=1. Disease status and treatment efficiency were evaluated by clinical assessment; biochemical response, ORR (RECIST) and also changes of SSTR expression based on cyclic SRI, which utilized standard SUV of TLR (Tumor to Liver Ratio) of combine therapy. The measurement was performed in target lesions the median TLR was calculated in each follow-up study up to clinical or imaging DP. ***Results:*** Pancreatic n=13, midgut n=6. During clinical and RECIST follow-up of 60 months 7 subjects had still partial response PR or stabilization SD; overall DCR=37%, rest of them had progression (DP). PFS for all subjects 31.5 months (IQR 16.0-nr), pancreas PFS=28.0 (14.0-nr), midgut PFS=31.5 (24.5-nr). Analysis of TLR as metabolic SSTR response indicated drop of activity compared to initial SRI (before therapy) TLR=7.7 (IQR 4.7-10.4) and first follow-up SRI after 3 Months TLR=3.3 (IQR 1.7-5.9). Subjects who developed DP were noted increase TLR=4.3 (3.4-7,9), compare to those who had DCR noted further drop of TLR=1.5 (1.0-3.6).The separate analysis in group of subjects who had DP the initial TLR=7.9 (IQR 4.9-11.3) after 3M of follow-up TLR=3.6 (3.1-6.4) and after documented DP further increase TLR=4.3 (3.8-7.9).In those with PR or SD (DCR) initial TLR=6.4 (IQR 4.7-10.1) vs. follow-up after 3M TLR=1.49 (IQR 1.2-5.9) and then TLR=1,47 (IQR 1.0-3.6), during whole follow-up with no increase of TLR indicate receptor metabolic SD or PR. ***Conclusion:*** Combine therapy is effective in advance pancreatic and midgut NET in terms of improvement of PFS. Receptor metabolic response could be potentially used when standard RECIST evaluation is difficult to assessed or the results of response are uncertain. In those subjects with DCR we noted decline of TLR from initial value in those with DP after initial drop of TLR further increase of TLR noted during follow-up.

EP-0590

Post-therapy Dosimetry in Patients with GEP-NETs Treated with ^{177}Lu-oxodotreotide: a Preliminary Evaluation

D. Maccora[1], *G. Iaccarino[2], S. Rea[1], A. Annovazzi[1], B. Cassano[2], S. Ungania[2], R. Sciuto[1];*
[1]Nuclear Medicine Unit, IRCCS Regina Elena National Cancer Institute, Rome, ITALY, [2]Laboratory of Medical Physics, IRCCS Regina Elena National Cancer Institute, Rome, ITALY.

Aim/Introduction: Radioligand therapy with lutetium-oxodotreotide (177Lu-RLT) is approved for patients with advanced, well-differentiated (G1-G2), gastro-entero-pancreatic neuroendocrine tumours (GEP-NETs) that progress on cold somatostatin analogues. The approved approach of using a fixed activity of 7.4 GBq infusions of 177Lu-RLT in four cycles is safe but not necessarily the most effective. This regimen is far from a personalized medicine and may lead to under or over treatments. The aim of the study was to perform a post-treatment dosimetry in a cohort of GEP-NET patients with a heterogeneous disease extension, treated with 177Lu-RLT. ***Materials and Methods:*** Twenty GEP-NET patients (12 females; median age: 64 years, range 36-81) who underwent a standard 177Lu-RLT regimen (7.4 GBq infusions every 8 weeks) were included. Post-therapy dosimetry based on EANM 2022 guidelines was performed after each 177Lu-RLT cycle. Absorbed dose (Gy) was calculated by convolution of cumulated activity with 177Lu-VSV kernel. MIM MRT SurePlan was used for dose calculation. Clinical response was evaluated with 68Ga-DOTATOC PET/CT 4-6 months after the end of the treatment and with a follow-up evaluation. ***Results:*** Among the included patients, 12 had liver metastases plus node metastases in 11 of them, 5 liver, node and bone metastases plus lung and brain lesions in one of them, 2 both liver and peritoneal lesions plus node metastases in one of them, while one only node metastases. None of the patients reported clinically relevant toxicity except one case of myelodysplasia. The median cumulative tumours absorbed dose was 108 Gy (range 25 -361), with 50% of patients receiving <100 Gy in most lesions. No patients reached the dose limits to bone marrow or kidneys. The clinical response rate was 50% of partial response, 30% of stable disease, and 20% of progressive disease. The median duration of response was 12 months (range 4-36). Two patterns of tumours adsorbed dose were identified: the first showing high adsorbed doses after the first 177Lu-administration, significantly reduced on the other cycles (associated to a better clinical response), and the second presenting initial low adsorbed doses and remaining low in the following cycles (with a worse clinical response). ***Conclusion:*** 177Lu-RLT is an effective and well-tolerated treatment for GEP-NET patients. However, there is a high heterogeneity in the tumours absorbed doses using the current standard regimen. A personalized dosimetry is crucial to optimize 177Lu-treatment strategy, increase the response rate and duration.

Navigating nephrotoxicity: insights from 4 years of [^{177}Lu]Lu-DOTA-TATE therapy at our institution

E. Sousa[1], *R. Sousa[2], D. Fraga[1], I. P. Carvalho[1], I. Vitorino[1], D. Rombo[1], J. Aço[1], P. Jorge[1], L. Salgado[1];*
[1]Instituto Português de Oncologia Francisco Gentil, Lisboa, PORTUGAL, [2]Hospital das Forças Armadas, Lisboa, PORTUGAL.

Aim/Introduction: Despite renal damage being described as a potential adverse effect of [177Lu]Lu-DOTA-TATE therapy, most research reported low nephrotoxicity. We conducted a single center, retrospective, observational study to assess potential renal damage in patients treated with [177Lu]Lu-DOTA-TATE. ***Materials and Methods:*** A total of 42 patients with neuroendocrine neoplasia (NEN) were submitted to therapy with [177Lu]Lu-DOTA-TATE from 2020 onwards were selected. Potential risk factors were evaluated (age >65 years, previous kidney disease, diabetes mellitus, arterial hypertension, previous chemotherapy or peptide receptor radionuclide therapy). Renal function assessment, including serum creatinine (Cr), blood urea nitrogen and eGFR (calculated using CKD-EPI Creatinine Equation - 2021) was performed before and 5-6 weeks after each cycle and, at least, >3 months after the last cycle. Every patient received an amino acid perfusion before each [177Lu]Lu-DOTA-TATE administration. Renal toxicity was graded according to the Common Terminology Criteria for Adverse Events (CTCAE v.5.0). ***Results:*** Of the 42 selected patients, 12 were excluded due to lack of access to clinical data, premature interruption of treatment on account of disease progression and non-kidney related complications. Of the included 30 patients, 16 were male and 14 were female. The mean age was 64 years (31-79 interval). The mean administered activity and number of cycles were 800mCi (600-1200mCi) and 4 cycles (3-6), respectively. At baseline, the mean Cr level was 0.815 (0.52-1.21) and the post-therapy mean Cr level was 0.825 (0.46-1.56). Of the 30 patients included, 6 had G1 (CKD) and 1 had G2 chronic kidney disease (CKD) at baseline. None of these had any meaningful deterioration in renal function, while 3 others developed G1 CKD. No other patient developed G2 or worse nephrotoxicity. ***Conclusion:*** Despite the limitations inherent to this study, namely its retrospective nature, low patient number and relying on eGFR, our results are consistent with previous research reported in the literature, showing minor renal toxicity associated to [177Lu]Lu-DOTA-TATE therapy, making it a safe and important therapeutic option managing patients with NEN. ***References:*** - Bergsma H, Konijnenberg MW, van der Zwan WA, et al. Nephrotoxicity after PRRT with (177)Lu-DOTA-octreotate. Eur J Nucl Med Mol Imaging. 2016;43(10):1802-1811. doi:10.1007/s00259-016-3382-9 - Baum RP, Fan X, Jakobsson V, et al. Long-term Nephrotoxicity after PRRT: Myth or Reality. Theranostics. 2024;14(2):451-459. Published 2024 Jan 1. doi:10.7150/thno.92487.

EP-0592

Analysis of factors associated with discontinuance of therapy with [^{177}Lu]Lu-DOTATATE in patients with tumors of neuroendocrine origin

A. Piñeiro[1], *A. Soldado Serrano[2], D. Maroto Morales[2], E. González Flores[2], M. Muros de Fuentes[1];*
[1]Nuclear Medicine Department, Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [2]Medical Oncology Department, Hospital Universitario Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: To identify patient-related factors or related to their clinical history, in addition to those related to the primary tumor that are associated with discontinuance of [177Lu]Lu-DOTATATE therapy in patients with neuroendocrine tumors (NETs). ***Materials and Methods:*** Retrospective study of 82 patients with NETs of various primary origins (32 gastrointestinal, 29 pancreatic, 13 pulmonary, and 8 of other origins) who have been treated with [177Lu]Lu-DOTATATE between 2015-2023. The variables analyzed were: age, grade, ki67, mitotic index, primary tumor location, functionality, lines of treatment previously received (surgery, somatostatin analogues, chemotherapy, everolimus, QUETA). Statistical analysis was performed by the chi square test. ***Results:*** 82 patients with TNEs treated with [177Lu]Lu-DOTATATE with a mean age 59.95±11,46 years; 53,7% male and 15,3% functionals. Sixty-five of these patients completed the 4 cycles of treatment versus the remaining 17 who had to discontinue treatment. Patient-related factors such as age, sex, years of evolution of the disease, did not show a statistically significant association with discontinuance of treatment with [177Lu]Lu-DOTATATE. Tumor-related factors including location of the primary tumor, grade, ki67, mitotic index or functionality did not show a statistically significant association with the interruption of therapy. More than 2 lines of treatment received before radioligand therapy was the only factor associated with an increased risk of discontinuance of [177Lu]Lu-DOTATATE therapy (OR: 4,81; p=0,034). ***Conclusion:*** The lines of treatment received before therapy with [177Lu]Lu-DOTATATE seems to be an important feature to determine the outcome of the therapy. Earlier administration of radioligand therapy with [177Lu]Lu-DOTATATE is associated with a lower rate of treatment interruption.

EP-0593

Hematologic toxicity in real life population of patients treated with 177Lu-Dotatate: incidence and dosimetric correlation.

V. Pirro[1], *E. Richetta[2], V. Garbaccio[1], M. Manfredi[1], M. Stasi[2], R. Pellerito[1];*
[1]AO Mauriziano Hospital, Nuclear Medicine, Turin, ITALY, [2]AO Mauriziano Hospital, Health Physics, Turin, ITALY.

Aim/Introduction: Hematologic toxicity (HT) in RLT is determined by irradiation of the bone marrow (BM) (aspecific binding or by skeletal metastases), renal function, gender, age, BM reserve and genetic. In NETTER1 study, predominantly mild and reversible HT (nadir 4-6 weeks after administration) was recorded. Grade 3/4 thrombocytopenia and/or leukopenia were observed in 2% and 1% of cases; long-term HT occurred with almost negligible frequency. This retrospective study compared HT incidence in real life with that of Netter1 study and evaluated the correlation between absorbed dose (AD) at BM and Spleen and HT incidence. ***Materials and Methods:*** Fifty-two patients (34M, 18F, mean age 64.4 ys, KPS>60, adequate renal, haepatic and BM functions) with metastatic or locally advanced unresectable GEP-NET G1-2 progressive during SSA, with high somatostatine receptor expression, have been treated. 177Lu-Dotatate was administered every 8 weeks (4x7.4 GBq); activity has been halved in 1 pt and infusion delayed in 2 pts. Treatment was discontinued in 2pts for nonhaematological serious adverse event. Blood count checks were performed: baseline, -7 days and +30 days from each administration, +90 days from the last administration, every 180 days in the FU (minimum duration 6 months). BM AD was calculated with the MIRD-Olinda Model (based on blood samples every 2h from administration to discharge and at 96h). Spleen AD was calculated with MIRD-Sphere Model (based on SPECT/CT at 24-48-96h). ***Results:*** HT occurred in 19% of cases; lymphopenia G1-2 5% and G3-4 0% (vs 1%) and thrombocytopenia G1-2 21%

and G3-4 0% (vs 2%). G3-4 HT observed frequency was lower than expected, probably due to the sample size. No statically significant difference was found in term of HT incidence, for each grade. In the two groups without and with HT (any G and duration) a significant difference is observed for AD at the Spleen (pzTE+ 22.5 Gy; pzTE- 15.7 Gy p=0.002) with a cutoff value at the ROC curve of 16.4 Gy, while not significant for the AD at the BM (pzTE+ 0.87 Gy; pzTE- 0.80 Gy p=0.06). ***Conclusion:*** HT in real-life population is confirmed rarely severe and transient; however the risk of lasting BM damage remains an attentioned topic in course of RLT, with a view to reprocessing, dose personalization, first line use for the possible reduction of BM reserve in anticipation of subsequent myelotoxic lines. A significant role could be played by Spleen AD in identifying patients at risk of HT.

EP-0594

DUONEN trial - step towards personalized treatment of neuroendocrine tumors - RLT based on the individual dosimetry.

Sowa-Staszczak*[2], *P. Cegła*[3], *A. Hubalewska-Dydejczyk*[2], *R. Mikołajczak*[5];
[1]Department of Endocrinology and Isotope Therapy, Military Institute of Medicine - National Research Institute, Warsaw, POLAND, [2]Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, POLAND, [3]Department of Endocrine Oncology and Nuclear Medicine, National Institute of Oncology - National Research Institute, Warsaw, POLAND, [4]Collegium Medicum, Jan Kochanowski University, Kielce, POLAND, [5]Radioisotope Center POLATOM, National Centre for Nuclear Research, Otwock, POLAND, [6]Faculty of Health Sciences, Jagiellonian University Medical College, Krakow, POLAND, [7]Department of Nuclear Medicine, Military Institute of Medicine - National Research Institute, Warsaw, POLAND.

Aim/Introduction: Radioligand therapy (RLT) is usually used as a second or third line of therapy for gastroeneropancreatic neuroendocrine tumors (GEP-NETs). Optimisation of RLT may include increasing efficacy and reducing side effects. Heterogeneity of tumor cells and different tumor burden may limit the effectiveness of standard, fixed-radioactivity RLT.Individualised RLT based on dosimetry seems to be a promising approach to increase its efficacy. ***Materials and Methods:*** Adult patients with advanced, unresectable, progressing, well-differentiated (G1/G2) GEP-NETs are randomized into four arms:- A: treated with [177Lu]Lu-DOTATATE with fixed radioactivity of 7400 MBq/cycle,- B: treated with a combination of [177Lu]Lu-DOTATATE and [90Y]Y-DOTATATE initially in a ratio of 3700:1850 MBq/MBq, and dosimetry-based modification of [90Y]Y-DOTATATE radioactivity in subsequent cycles,- C: treated with a combination of [177Lu]Lu-DOTATATE and [90Y]Y-DOTATATE like arm B, and dosimetry-based modification of [177Lu]Lu-DOTATATE radioactivity in subsequent cycles,- D: treated with [177Lu]Lu-DOTATATE initially with radioactivity of 7400 MBq, and dosimetry-based modification of [177Lu]Lu-DOTATATE radioactivity in subsequent cycles.In each case, the individual dosimetry of kidney and bone marrow is performed. Radioactivity adjustment in subsequent cycles is made to reach 23 Gy renal and/or 2 Gy bone marrow dose limits for a full four-cycle RLT. ***Results:*** To date, 40 patients (10 per arm) have been enrolled in the study and started RLT. Totally 97 RLT cycles were administered, including 59 fixed-radioactivity (i.e. the first administration in each arm and the subsequent administration in arm A).Of the 38 cycles requiring radioactivity adjustments, 17 were escalated and 21 were reducted.The mean kidney absorbed dose in cycles with fixed radioactivity of [177Lu]Lu-DOTATATE was 4.92 (± 1.3) Gy/cycle (i.e. 19.68 Gy/RLT) and in cycles with [177Lu]Lu-DOTATATE escalation was 5.78 (± 0.9) Gy/cycle (i.e. 22.26 Gy/RLT) which was close to the target value of 23 Gy/RLT.In patients in whom in the first cycle the combination of [177Lu]Lu-DOTATATE and [90Y]Y-DOTATATE was used the mean kidney absorbed dose was 8.86 (± 5.0) Gy/cycle (2.95 Gy from [177Lu]Lu-DOTATATE and 5.91 Gy from [90Y]Y-DOTATATE). The absorbed dose of 0.5 Gy/cycle in the bone marrow was exceeded only in one case (arm C). ***Conclusion:*** The individual dosimetry may identify patients (particularly those treated with [90Y]Y-DOTATATE) who are at higher risk of exceeding renal dose limits. In selected cases, RLT adjustment allows for higher radioactivity of radiopharmaceuticals, potentially increasing the efficacy of RLT. ***References:*** The study is funded by the Polish Medical Research Agency (Project number 2019/ABM/01/00077-00).

EP-0595

Use of ^{177}Lu-DOTATATE in the treatment of advanced Olfactory Neuroblastoma

***L. Flynt*[1],** *O. Ajuria Illarramendi, MD, PhD*[2];
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA, [2]Hospital universitario Ramon y cajal, Madrid, SPAIN.

Aim/Introduction: To determine if Lutathera could be an effective treatment of advanced Olfactory Neuroblastoma.Olfactory neuroblastoma (ON), also known as esthesioneuroblastoma, is a rare malignant neuroendocrine disease which arises from the olfactory epithelium and accounts for approximately 2% of all sinonasal tumors with an incidence of 0.4 per million population. In patients with locoregional disease, the standard treatment is with surgery, with best results using a combination of surgery and radiation. For patients with advanced and metastatic disease systemic treatment have been used, however, it remains unclear if systemic treatment improves outcomes. ON tumors are known to overexpress the somatostatin receptor type 2 (SSTR2), therefore, 68Ga-DOTATATE PET/CT is often used to evaluate extent of disease. Given these tumors express SSTR2 and demonstrate robust DOTATATE uptake on PET, it is hypothesized that these patients may respond to 177Lu-DOTATATE (Lutathera). ***Materials and Methods:*** Retrospective case review of patients with advanced metastatic ON with positive DOTATATE PET/CT scans, who then completed a full course of 4 cycles of Lutathera. ***Results:*** Out of 17 patients with positive DOTATATE PET scans, 10 patients went on to receive Lutathera, and 6 patients completed the full course of 4 cycle. For each patient, 4 target lesions were identified and used to measure SUVmax both before, and after, receiving the full course of Lutathera. SUVmax from target lesions was then recorded and normalized using background liver activity to give SUVc (SUVcorrected). Pre-treatment minus post-treatment mean SUVc was equal to 3.44 with a 95% confidence interval from 1.99 to 4.89. With n of 20, results of a paired t test yielded statistical significance with a p value of < 0.0001. ***Conclusion:*** Our findings show that treatment with a full course of Lutathera significantly reduced SUVc of target lesions in patients with 68GaDOTATE PET positive, advanced Olfactory Neuroblastoma. Therefore, Lutathera may prove to be an effective therapeutic in the treatment of advanced Olfactory Neuroblastoma. ***References:*** Cranmer, Lee D et al."Chemotherapy

EP-0596

Quantitative SPECT/CT is predictive of 6-month RECIST response in midgut neuroendocrine tumors treated with 177Lu-DOTATATE

I. Megherbi, *C. Hoog, D. Morland;*
Institut Jean Godinot, Reims, FRANCE.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) with radiolabeled somatostatin analogs, such as 177Lu-DOTATE, has become an established second-line treatment for patients with advanced small intestine neuroendocrine tumors (siNET). Treatment efficacy is often delayed and assessed 6-12 months after the end of treatment based on RECIST criteria. Posttherapeutic scintigraphy can be performed after each cycle but its usefulness in treatment follow-up has not been evaluated. The aim of this study is to assess whether quantitative posttherapeutic scintigraphy is of value in predicting response to treatment, focusing on the evolution of SUV between the first (C1) and the second (C2) cycle. ***Materials and Methods:*** All patients with siNET referred to our center for treatment with 177Lu-DOTATATE were analyzed. The SUVmax of the lesion with the greatest uptake was measured on the post-therapy quantitative SPECT/CT at C1 and C2. ΔSUVmax was calculated. The 6-month PRRT response was evaluated quantitatively using the RECIST 1.1 percentage. Linear regression between ΔSUVmax and RECIST percentage was used. ***Results:*** Twelve consecutive patients with progressive metastatic siNET were included. One patients was in partial response at 6 months (-32.0%), the other were considered as stable (percentage ranging from -15.0% to 18.0%). ΔSUVmax was strongly linked to 6-month RECIST percentage ($p<0.001$) with the following formula : 6-month RECIST = -0.05 + 0.36 x ΔSUVmax. Out of the 3 patients with a positive RECIST percentage at 6 months, 2 progressed on long-term follow-up. No progressive disease was reported if the 6-month RECIST percentage was negative. ***Conclusion:*** We report a significant link between ΔSUVmax on post PRRT quantitative SPECT/CT and 6-month RECIST percentage in patients with siNET. Quantitative imaging would thus make it possible to detect the long-term efficacy of PRRT as early as C2. This study needs to be confirmed on a larger population.

EP-0597

Safety of [^{177}Lu]Lu-oxodotreotide in gastroenteropancreatic neuroendocrine (GEP-NET) patients. Experience in our hospital.

L. Garcia Lama, *C. G. Franco Monterroso, M. A. Hernandez Fructuoso, C. Jimenez Pena, B. Santos Montero, L. Rey Sanchez, A. Garcia Burillo;*
Hospital Universitario Vall d´Hebron, Barcelona, SPAIN.

Aim/Introduction: [177Lu]Lu-oxodotreotide is a radiopharmaceutical indicated for the treatment of somatostatin receptor-positive neuroendocrine tumours (NETs).The aim of the study was to evaluate adverse drug reactions (ADRs) and the safety of this treatment during infusion and post-administration of the radiopharmaceutical in our centre.This study will allow us to incorporate a pharmacovigilance programme in our Unit. ***Materials and Methods:*** 77 patients were treated with [177Lu] Lu-oxodotreotide (52 males and 25 females; average age 60.5±13.8 years).25 patients had NETs pancreas (G1=1, G2=14, G3=10), 19 intestinal (G1=5, G2=12, G3=2), 15 ileal (G1=10, G2=5), 8 in lungs (5 atypical and 3 typical carcinoids), 3 patients had paraganglioma, 1 duodenal (G2), 1 rectum (G2), 1 had pheochromocytoma, 1 meningioma and 1 thymic.2 patients had NETs of unknown primary.All of these patients had SSTR-overexpressing, histologically confirmed neoplasm.The treatment regime consists of 4 infusions of 7.4GBq doses spaced 8 weeks apart.[177Lu]Lu-oxodotreotide was administered by slow intravenous infusion over approximately 30 minutes.For renal protection purpose, an amino acid solution was administered intravenously during 6 hours, 30 minutes prior to the start of [177Lu]Lu-oxodotreotide infusion.Adverse reactions for all patients were registered during, just after each administration and between each cycle. ***Results:*** 54 patients (70.1%) completed 4 cycles.23 did not complete treatment:11 due to progression (47.8%), 8 due to severe haematological toxicity (34.8%), 2 due to exitus (8.7%), 1 due to diarrhoea and vomiting (4.3%) and 1 (4.3%) decided to leave treatment.During and just post radiopharmaceutical administration 24 patients (31.2%) had ADRs.The most common ADRs were gastrointestinal (59%), followed by facial flushing (29.4%).The most common gastrointestinal ADRs were nausea and vomiting related to amino acid solution administration. Other less frequent were dizziness (5.9%), tachycardia (2.9%) and headache (2.9%).All of them were mild and self-limited.Between each cycle, the milder ADRs recorded were: asthenia (53.2%), nausea and vomiting (16.9%), diarrhoea (13%), alopecia (10.4%), abdominal pain (11.7%), weight loss (6.5 %), osteoarticular pain (5.2 %), decreased appetite (3.9 %), steatorrhea (2.6%), and fever (1.3%).The most severe ADR after treatment was haematological toxicity (19 patients) and resulted in discontinuation in 8 of them (10.4%). ***Conclusion:*** Acute and mild side effects of [177Lu]Lu-oxodotreotide were mainly related to amino acids administration and were self-limiting.Subacute side effects were related to the absorbed dose of radiation in the bone marrow.In most cases, they were reversible, and only 10.4% of patients required treatment suspension.Despite the observed side effects, the treatment is generally well tolerated by the majority of patients.

EP-0598

Predictive Parameters of a Worse Prognosis in Patients with G2 Neuroendocrine Tumors Treated with Peptide Radio Receptorial Therapy

J. Jandric[1], *A. Laffi[1], L. Muraglia[1], R. Zanca[1,2], M. Rodari[1], L. Evangelista[1,2];*
[1]IRCCS Humanitas Research Hospital, Rozzano, ITALY,
[2]Humanitas University, Pieve Emanuele Milano, ITALY.

Aim/Introduction: Peptide Receptor Radionuclide Therapy (PRRT) has significantly improved the prognosis of patients with neuroendocrine tumors (NET). However, a subset of patients experiences disease progression following PRRT. This study aims to identify prognostic predictors in patients with G2 NET who underwent PRRT. ***Materials and Methods:*** Between January 2011 and March 2023, we conducted a retrospective analysis of data from 142 patients (81 females, 57%; 61 males, 43%; median age: 59

years) diagnosed with G2 NET originating from the gastrointestinal tract (GEP-NET). We focused on patients who received PRRT (n=24, 17%). Clinical and histopathological data were collected for each patient. 68Ga-DOTATOC PET/CT scans were performed at the time of initial NET diagnosis and qualitatively analyzed using the Krenning score, which assesses SSTR ligand uptake (0=no uptake, 1=very low uptake, 2=uptake less than or equal to that of the liver, 3=uptake greater than the liver, and 4=uptake greater than that of the spleen). Additionally, the tumor burden liver score (0=no lesions; 1=25%, 2=25-75%, and 3=>75% of liver involvement) was evaluated on CT images obtained before PRRT. ***Results:*** Among the 24 patients (13 females, 54%; 11 males, 46%; median age: 62 years), 15 (63%) had pancreatic NET, and 9 (37%) had other types of NET. At baseline 68Ga-DOTATOC PET/CT, the Krenning score was 2 in 1 patient, 3 in 8 patients, and 4 in 15 patients. Thirteen (54%) out of 24 patients had liver involvement at the initial diagnosis. Moreover, all subjects received treatment with somatostatin analogs, and 11 (46%) also underwent targeted therapy. After PRRT, 9 (37%) patients experienced disease progression, while 15 (63%) did not. Only tumor liver burden and Krenning score showed significant differences between patients with and without disease progression (both $p < 0.05$). Following a median follow-up period of 52 months (range: 21-145), 6 patients (25%) died. Among these, three (50%) had progressive disease after PRRT. ***Conclusion:*** Among the patients who underwent PRRT, tumor liver burden and Krenning score emerged as significant predictors of disease progression. These results underscore the importance of assessing these factors to better stratify patients and optimize treatment strategies. Moreover, the study highlights the need for further research to refine prognostic indicators and enhance patient outcomes in this population.

EP-0599

Gastrointestinal NET tumors: The importance of Administered Activity and Absorbed Dose in Relation to Tumor Shrinkage During [177Lu]Lu-DOTA-TATE Treatment

A. Kistner[1,2], *T. Sadus[3,1], J. Nilsson[2,1], R. Altena[4,5], M. Larsson[2,6], C. Hindorf[2,1];*
[1]Dept of Nuclear Medicine and Medical Physics, Karolinska University Hospital, Stockholm, SWEDEN, [2]Karolinska Institutet, Stockholm, SWEDEN, [3]Dept of Neuroradiology, Karolinska University Hospital, Stockholm, SWEDEN, [4]Medical Unit Breast, Endocrine tumors and Sarcoma | Karolinska University hospital and Department of Oncology/Pathology | Karolinska Institutet, Stockholm, SWEDEN, [5]Dept of Oncology, Stockholm, SWEDEN, [6]Dept of Endocrinology and Diabetology, Karolinska University Hospital, Stockholm, SWEDEN.

Aim/Introduction: In a cohort of ileal and pancreatic NET (p-NET) with widespread disease, we aimed to determine if differences in absorbed dose (ABD, Gy) in lesions or administered activity (ADA, GBq) related to tumor response during treatment with [177Lu]Lu-DOTA-TATE. We also aimed to study differences in tumor response in relation to primary tumor site. ***Materials and Methods:*** 36 patients (47% men) were included. [177Lu]Lu-DOTA-TATE treatment was normally given as four cycles (7.4 GBq per cycle) with 6 - 10 weeks in between. [68Ga]Ga-DOTA-TOC-PET/CT or CT performed before and 3 months after last treatment were re-studied. Up to three target lesions were selected for evaluation in each patient, normally 2-3. Total ADA and mean ABD in target lesions were determined. Tumor response according to RECIST was estimated before and after treatment with the sum of largest diameter (SLD). Progressive disease (PD) was defined as at least 20% increase in the SLD of target lesions, taking as reference SLD recorded before treatment started or the appearance of new lesions. Partial response (PR); at least 30% decrease of SLD, stable disease (SD); neither partial response nor progressive disease. ***Results:*** The group consisted of patients with ileal NET (n=27) or p-NET (n=7), mean age (range) 65 (35-82) years. Two patients with lung carcinoids were studied seperately. 28% were NET grade 1, 58% NET grade 2 and 8 % NET grade 3, in two patients, grade was indetermined. Median (range) nr of treatments were 4 (1-7). Mean (+/- 95% CI) ABD was 23 (19-27) Gy per treatment and total ADA was mean (range) 26.7 (6.7-51.4) GBq. After treatment 17% had PR, 64% SD and 19% had PD. In the entire cohort total ADA (Bq) was inversely correlated with SLD-change (%) (—0.5, $p<0.01$); in patients with p-NET the inverse correlation was stronger ; r= —0.89, $p<0.01$, n=7. An inverse correlation was found between mean ADD and SLD-change ($p=0.34$, $p<0.05$).There was no significant correlation between ABD and SLD-change (r= —0.03, p=ns). In patients with a positive SLD-change an inverse relation was found between ABD and tumor shrinkage (r= —0.6, $p<0.001$, n=13). ***Conclusion:*** Total administered activity seems to be of greater importance for tumor response / shrinkage than absorbed dose. P-NET seems more sensitive to response to the total administered activity compared with ileal NET.

EP-0600

An evaluation of Progression-Free Survival (PFS) and Overall Survival (OS) in Patients with Advanced, Non-resectable, Progressive rectal NET Treated Using Radioligand therapy.

J. Cwikla[1], *A. Sankowski[2], J. Pałucki[3], N. Seklecka[4], A. Kolasińska-Ćwikła[3];*
[1]University of Warmia and Mazury, Olsztyn, POLAND, [2]Hospital Ministry of Internal Affairs, Warsaw, POLAND, [3]Maria Skłodowska-Curie National Research Institute of Oncology, Warsaw, POLAND, [4]Diagnostic and Therapy Center – "Gammed", Warsaw, POLAND.

Aim/Introduction: Retrospective, single-arm, open-label, case series study evaluating the efficacy of radioligand therapy (RLT) including 90Y or 177Lu DOTA-TATE and mix of both in advanced, unresectable progressive rectal NETG1/G2. The primary endpoint was local RECIST 1.1 progression-free survival (PFS). Secondary endpoints: overall survival (OS) and clinical response based on performance status. ***Materials and Methods:*** Twenty-four patients in group of 156 screened subjects with GEP-NET treated with RLT between Oct 2008 to Apr 2024 included. All patients with histopathologic confirmation of rectal NETG1/G2. All subjects with advanced, unresectable, progressive disease stage prior to RLT. RLT used 90Y; 177Lu DOTA-TATE or mixture of both in different regimens, first with 90Y and then with 177Lu DOTA-TATE and mixture of both. Mean age of subjects 58.8 +/-12.8, male/female ratio 10/14. NETG1=7 and G2=17. Disease status and treatment response were evaluated by clinical assessment; biochemical response, PFS based on local RECIST 1.1 assessment and OS during follow-up. Calculation of OS and PFS using standard KM estimator, differences between groups using T.Cox Mantel test. ***Results:*** All subjects had an average of 4.5 therapy sessions, range 2 to 9, and 1.5 therapy courses per patient, range 1-3. Initially 8 subjects were treated with 90Y, then 9 with 177Lu, the remainder had mixed 90Y and 177Lu with 50% of each. Median PFS for all subjects (IQR) 34.7 months (16.8-43.7), OS for all subjects 61.1 months (IQR 40-100.4).There was a significant difference in median OS between female OS=73.1 (IQR 48.9-114.0) vs. male OS=42.1 (26.5-53.4) ($p=0.02$), bulky liver disease >25% involvement OS=42.5 (23.9-

57.1) vs. less than 25% OS=100.8 (53.5-116.3); p=0.005. There was no significant difference in median OS including number of therapy courses, age (below or over 58.8, years), BMI (less or over 25.8), presence of bone and other mts also G1 vs. G2 tumors;Median PFS was only significantly different between bulky liver disease >25% PFS=19.3 months (IQR 14.3-23.4) vs. less than 25% liver involvement PFS=42.0m (25.5-45.0); p=0.04. There was no significant difference in median PFS including: female vs. male; number of therapy sessions, age (below or over 58.8 years), BMI (less or over 25.8), presence of bone and other mts also G1 vs. G2 tumors. ***Conclusion:*** Patients with advanced rectal NET1/G2 treated with different regimens of RLT are beneficial in terms of improvement of OS in group of female subjects and low volume liver involvement. In PFS only low volume liver involvement is predictor of PFS improvement.

EP-0601

Effectiveness and Safety of a Rechallenge PRRT in Patients With Progressing Neuroendocrine Tumors

M. Mattke[1], *H. Dittmann[1,2], F. Seith[3], L. Zender[4,2,5], C. la Fougère[1,2,5], N. Trautwein[1,2];*
[1]Department of Nuclear Medicine and Clinical Molecular Imaging, University Hospital Tuebingen, Tuebingen, GERMANY, [2]ENETS Center of Excellence, University Hospital Tuebingen, Tuebingen, GERMANY, [3]Department of Diagnostic and Interventional Radiology, University Hospital Tuebingen, Tuebingen, GERMANY, [4]Department of Medical Oncology and Pneumology (Internal Medicine VIII), University Hospital Tuebinge, Tuebingen, GERMANY, [5]DFG Cluster of Excellence 2180 'Image-Guided and Functional Instructed Tumor Therapy' (iFIT), University of Tuebingen, Tuebingen, GERMANY.

Aim/Introduction: Peptide receptor radionuclide therapy (PRRT) is an established treatment for patients with unresectable neuroendocrine tumors (NETs) G1-G3. PRRT is usually well tolerated and has demonstrated the ability to enhance progression-free survival (PFS). Currently only up to 4 cycles have been approved by EMA and FDA. As treatment options in NETs are limited, additional cycles of PRRT may improve PFS and open new opportunities for these patients. The benefits and side effects of a retreatment are poorly described. In this study, we evaluated treatment response and tolerability in patients undergoing a rechallenge of PRRT. ***Materials and Methods:*** Retrospectively, we analyzed 29 patients (15 women and 14 men) with NETs: n=25 with gastroenteropancreatic NETs, n=3 NETs of unknown origin and n=1 with a bronchopulmonary NET, G1: 13%, G2: 74% and G3: 13%. All patients were treated with an initial PRRT (median = 4 cycles) and showed a controlled disease for at least 6 months. Re-PRRT was carried out with at least 2 cycles. SSTR-PET/CT-scans and regular blood samples were performed for treatment monitoring. PFS was evaluated using RECIST 1.1 criteria. Hematotoxicity was graded according to CTCAE 5.0. ***Results:*** Following rechallenge PRRT, 79,3 % of patients presented stable disease, 3,4% achieved partial response while 17,3% showed progressive disease. The median PFS was 20 months. All patients showed some degree of anemia (19/29 Grade 1, 9/29 Grade 2 and 1/29 Grade 3). A decreased platelet count was observed in 13 of 29 patients (11/29 Grade 1, 1/29 Grade 2 and 1/29 Grade 3). 12 of 29 patients exhibited leucopenia (Grade 1: 5/29, Grade 2: 5/29 and Grade 3 2/29). Only a few patients had elevated AST and ALT (5/29 and 7/29 respectively), no severe nephrotoxicity was observed. ***Conclusion:*** Rechallenge PRRT seems to be an effective option for patients with unresectable NETs predominantly resulting in good tumor control. Only mild to moderate side effects were observed.

EP-0602

Therapeutic response with B-OT as a radiosensitizer after disease progression with TANDEM PSMA radioligand therapy (PRLT) - first case report.

C. Kramer, *A. Eismant, R. P. Baum;*
Curanosticum Wiesbaden-Frankfurt, Wiesbaden, GERMANY.

Aim/Introduction: PSMA-radioligand therapy (PRLT) with α- or β-emitting radionuclides has demonstrated efficacy in the therapy of metastatic castration-resistant prostate cancer (mCRPC). Nevertheless, certain patients are non-responders to initial PRLT or exhibit progression after successful PRLT with α- or β-emitting radioligands. The acquired resistance might be linked to alterations in the DNA repair system of the tumor cells. Benfo-oxythiamine (B-OT) is a prodrug that releases oxythiamine, a thiamine antagonist that interferes with the biochemical synthesis of ribose-5-phosphat (R5P), a substrate required for DNA-replication and -repair. The combination of PRLT with the radiosensitizer B-OT ('B-OT-PRLT') might overcome radiation resistance and achieve better efficacy of PRLT as decreased levels of R5P could diminish the repair rate of radiation-induced double-strand breaks. ***Materials and Methods:*** A 79-year-old mCRPC patient underwent radical prostatectomy (pT3ba pN0 (0/7) M0 L0 V0 R0 G3, Gleason 5+5=10, iPSA 4.05 ng/ml). Soon after radical prostatectomy, PSMA-PET/CT revealed lymph node metastases. Subsequent treatment lines included androgen deprivation therapy and radiotherapy, chemotherapy (with docetaxel), followed by the androgen receptor antagonist enzalutamide and 4 cycles of 177Lu-PRLT and 1 cycle of TANDEM-PRLT. Even after the resumption of chemotherapy, progress was observed. Due to the intense PSMA expression, PRLT was resumed. For cycles 6 to 9 (177Lu-PRLT), the patient was additionally treated with B-OT (B-OT-PRLT, 1-2 x 3 mg/d p.o., starting before PRLT, on 2-5 consecutive days). Total activity over 9 cycles was 67 GBq Lu-177 and 2.1 MBq Ac-225. ***Results:*** B-OT-PRLT was well tolerated. No significant changes in laboratory results (hematology, liver, kidney) were observed. Additionally, significant improvement in clinical symptoms was reported by the patient. Post-treatment 177Lu-PSMA SPECT-CT (7th cycle/after 2 cycles of B-OT-PRLT) revealed excellent regression of the metastases (compared to SPECT-CT after 6th cycle) and after former non-controllable disease progression, a mixed response was found in 68Ga-PSMA PET-CT (before 8th cycle). PSA showed a 50% decline from 264 to 132 ng/ml after one cycle with B-OT-PRLT. Although the patient had massive progression before the first B-OT-PRLT cycle, the patient survived a further 12 months. ***Conclusion:*** This case demonstrates exceptional effectiveness of B-OT-PRLT in overcoming radiation resistance in mCRPC not responding anymore to 177Lu- or 225Ac-PRLT alone. Even though the patient showed later progression after TANDEM-PRLT, a sustainable PSA decline and partial response/regression of metastases were observed after B-OT-PRLT. The combination was well tolerated. In summary, the potential of B-OT-PRLT needs to be explored in a larger patient populations.

EP-0603

Matched-pair analysis comparing 4-week and 6-week treatment intervals of prostate-specific membrane antigen targeted radioligand therapy in patients with metastatic castration-resistant prostate cancer

***A. Karimzadeh*[1],** *C. Hecker*[2], *M. Heck*[3], *R. Tauber*[3], *W. Weber*[2], *M. Eiber*[2], *I. Rauscher*[2];
[1]*Department of Diagnostic and Interventional Radiology and Nuclear Medicine, University Medical Cente, Hamburg, GERMANY,* [2]*Department of Nuclear Medicine, School of Medicine, Technical University of Munich, Munich, GERMANY,* [3]*Department of Urology, School of Medicine, Technical University of Munich, Munich, GERMANY.*

Aim/Introduction: This retrospective study evaluated the effects of 4-week versus 6-week intervals in prostate-specific membrane antigen targeted radioligand therapy (PSMA RLT) on treatment toxicity, prostate-specific antigen (PSA) response, PSA progression-free survival (PFS), and overall survival among cohorts of matched metastatic castration-resistant prostate cancer (mCRPC) patients. ***Materials and Methods:*** Forty-six mCRPC patients who received 7.4 GBq of PSMA RLT were analyzed retrospectively, divided equally into two groups based on treatment intervals (23 patients each in 4-week and 6-week intervals). Matching was based on clinical and laboratory data, including baseline LDH, prior treatments, and molecular imaging TNM classification. Treatment toxicity was monitored up to the final treatment cycle and compared with baseline values. Adverse effects were assessed using the Common Terminology Criteria for Adverse Events version 5.0. The efficacy was evaluated by measuring best PSA response and comparing PSA-PFS and overall survival between the two groups. ***Results:*** A significant decline in PSA (>50%) was noted in 47.8% of patients in the 4-week interval group versus 21.7% in the 6-week group (p=0.12). There was a non-significant trend towards longer PSA-PFS in the 4-week group (median 26.0 weeks) compared to the 6-week group (median 18.0 weeks; HR 0.6, p=0.2). Overall survival was not significantly different between groups (median OS, 15.1 months for 4-week vs. 18.4 months for 6-week; HR 1.3; p=0.5). The 4-week group also experienced significantly more substantial reductions in leukocyte and platelet counts (38.5% and 26.7% respectively) compared to the 6-week group (18.2% and 10.7%; p=0.047 and p=0.02). Severe adverse events were minimal in both groups. ***Conclusion:*** Shortening the interval of PSMA RLT from 6 weeks to 4 weeks showed some improvement in PSA response and PSA-PFS in mCRPC patients but did not significantly impact overall survival. The intensified regimen also led to more significant bone marrow suppression. The overall advantage of shorter treatment intervals is still unclear, calling for more prospective studies to fully evaluate the impacts on toxicity, treatment response, and efficacy.

EP-0604

Comparative Analysis of 177Lu-PSMA Radioligand Therapy Efficacy in Metastatic Castration-Resistant Prostate Cancer: Impact of Taxane Chemotherapy Precedence

A. Nazar, *D. Srivastava, M. ora, S. Barai, S. Gambhir, P. Pradhan, A. Arya;*
Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, INDIA.

Aim/Introduction: This study looks into the effectiveness of 177Lu-labelled prostate-specific membrane antigen (PSMA) radioligand therapy in treating metastatic castration resistant prostate cancer (mCRPC). The study focuses on evaluating the clinical outcomes of 177Lu-PRLT in two groups of patients: those who have undergone taxane chemotherapy (T-pretreated) and those who have not (T-naïve). ***Materials and Methods:*** In this study, a retrospective analysis was conducted on 35 patients who were diagnosed with metastatic castration resistant prostate cancer (mCRPC) and received at least 2 cycles of 177Lu-PRLT treatment between 2017 to 2022. Patients were categorised as either T-pretreated or T-naïve based on whether they had received chemotherapy before undergoing 177Lu-PRLT. The clinical outcomes of both groups were evaluated based on prostate-specific antigen (PSA) response rate. Univariate and multivariable analyses were performed to identify predictors of outcome for both groups. ***Results:*** Out of the total 34 patients who received 177Lu-PRLT treatment, 18 were T-pretreated and 16 were T-naïve. 11 out of 18 chemo pretreated patient responded to 177Lu-PRLT which was defines as decrease in S.PSA > 50 % from baseline while 7 were non responder. 9 out of 16 chemo-naive patients were responder while 7 were non responder. ***Conclusion:*** The use of 177Lu-PRLT as a treatment for mCRPC shows similar response rate and similar overall survival with observed in patients who were both treatment-naïve and treatment-pretreated. So 177Lu-PSMA can be taken as an option before starting chemotherapy. Hence reducing the toxicity and side effects of chemotherapy in the patients. However this results should be validated in a multicentric study on a larger number of patients.

EP-0605

The Patterns and Approach to Hyperprogression after Lutetium-177 PSMA-617: Semi-manual AI-based Analysis

T. Cengiz, *M. Crank, K. Cardenas, J. Sullivan, D. Grady, M. Benayoun, Y. Bradley;*
Atrium Health Wake Forest Baptist Hospital, Winston-Salem, NC, UNITED STATES OF AMERICA.

Aim/Introduction: Not all patients benefit from the Lutetium-177 PSMA-617 therapy, as some patients may experience significant progression of disease (more than 100% increase in disease burden). It is unknown which patients may experience "hyperprogression". This study aims to analyze the characteristics of hyperprogression and identify possible therapeutic approaches. ***Materials and Methods:*** All patients undergoing Lutetium-177 PSMA treatments were identified. Baseline and follow up F-18 DCFPyL (PSMA) PET/CTs were analyzed via a software to segment total, osseous and soft tissue volumes (all mm3) before and after the radioligand therapy. All patients had laboratory work at 4 weeks after treatment. Follow-up PSMA PET/CTs were done as needed basis if there was a significant increase in PSA. Patients were characterized as "hyperprogression" if they had more than %100 increase in total tumor volume compared to the baseline. All patient demographics and prior treatments were then analyzed. ***Results:*** 45 patients were identified. Ten patients had interim PET/CTs after a median of 3 cycles, of these 7 patients (16%) were in the hyperprogression group. Hyperprogression group predominantly had progression in the bones (7/7, 100%), with a median increase in bone tumor volume of 232 (vs -59 in others) and a decrease in soft tissue volume -26 (vs -0.8 in others). Hyperprogression patients had a higher median ALP 166 (vs 85), and a median PSA 51 (vs 78), both p >0.05. These patients had a median increase in PSA of 19.6 ng/mL and a median increase in ALP of 5. Despite a greater increase in PSA, ALP had a better correlation than PSA (spearman correlation 0.71 vs 0.59, p < 0.05) with the total tumor volume in the whole cohort. There was no difference in baseline and follow up SUVmax, SUVmean

and SUVmin. Patients who experienced hyperprogression were older (median age 79 vs 71, p=0.04), and had a greater median Gleason score (8.5 vs 8, p=0.04). Three patients elected to proceed with Radium-223 dichloride treatment, and two of these had subsequent decrease in ALP after their first Radium-223. One patient expired after the first dose of Radium-223. ***Conclusion:*** Hyperprogression throughout the Lutetium-177 PSMA-617 therapy is not uncommon, and predominantly occurs in the bone. Both PSA and ALP are important biomarkers to detect the hyperprogression, however given bone predominant progression pattern ALP may be a better biomarker than PSA. Radium-223 dichloride shows promise for further treatment in patients who had hyperprogression.

EP-0606

Prognostic parameters in ^{68}Ga-PSMA-11-PET-CT in mCRPC patients undergoing ^{177}Lu-PSMA-radiologand therapy

L. Rahbar Nikoukar, *R. Seifert, D. Ventura, P. Schindler, M. Bögemann, K. Rahbar, W. Roll;*
University Hospital Münster, Münster, GERMANY.

Aim/Introduction: Advanced, metastatic castration-resistant prostate cancer (mCRPC) has a poor prognosis. Use of PSMA-targeting radioligands has revolutionized the diagnostic and therapy of these patients. Many studies have aimed for establishing one or few prognostic and predictive parameters. The aim of this study was to compare the various published parameters in one cohort, in terms of progression-free (PFS) and overall survival (OS). ***Materials and Methods:*** In this study, the data of 68Ga-PSMA-PET-CT of 82 patients undergoing 177Lu-PSMA-RLT were analyzed. The studied parameters include total tumor volume (tumor volume), average SUVmean of all tumor lesions (SUVmean) and the quotient of mean of SUVmean of all tumor lesions to SUVmean of the parotid glands (tumor-parotid-ratio; TPR) and to SUVmean of kidneys (tumor-kidney-ratio; TKR). PFS was defined as the time to PSA increase of ≥ 25% above nadir (at least 2 ng/ml) and confirmation via a control test in 3 weeks according to PCWG3, OS was defined as time to death or time to last follow-up. ***Results:*** In this cohort a higher tumor volume is associated with worse prognosis (tumor volume < 290.6 ml, PFS: 4.2, OS: 13.2 months; tumor volume > 290.6 ml, PFS: 3.4 months, OS: 6.2 months (PFS: p = 0.01; OS p < 0.001)). Average SUVmean inversely correlates with survival, with an average SUVmean > 10.7 (PFS: 4.2 months, OS: 11.4 months) versus SUVmean < 10.7 (PFS: 1.6 months, OS: 5.0 months) (p <0.001). A TKR > 0.33 showed a PFS of 4.2 months vs 2.9 months for TKR < 0.33 (p-value = 0.009). But there was no significant difference regarding OS. There was also no significant relationship between TPR and PFS or OS. ***Conclusion:*** The present study confirms that PSMA-PET-CT can reveal prognostic factors, however the majority seems to be dependent on the study population, taking into account partly contradictory results in recently published studies . Prospective confirmation is warranted before implementation into clinical use.

EP-0607

Response to ^{177} Lu-PSMA-617 radioligand therapy of liver metastases in patients with metastatic castration-resistant prostate cancer (mCRPC)

A. Namazova, *S. Sager, H. B. Sayman;*
Istanbul University-Cerrahpasa, Istanbul, TÜRKIYE.

Aim/Introduction: Prostate cancer is one of the most common malignancies in men, with a significant portion of patients progressing to metastatic castration-resistant prostate carcinoma (mCRPC). Studies on the overall survival (OS) of patients diagnosed with mCRPC have shown that the worst median OS in those with liver metastasis. Recently, various studies have shown promising results of 177Lu-PSMA-617 radioligand therapy in advanced-stage mCRPC patients. However, limited information is available regarding the efficacy of this treatment specifically against liver metastases. Therefore, we conducted a retrospective study to assess the therapeutic effect of 177Lu-PSMA-617 RLT on patients with mCRPC and liver metastasis, as well as to evaluate the relationship between liver lesion response and OS. ***Materials and Methods:*** Patients diagnosed with mCRPC with liver metastases between 2015 and 2023 (mean age 66) who received at least 2 cycles of 177Lu-PSMA-617 radioligand therapy were retrospectively evaluated. Patients were initially planned to receive 4-6 cycles of treatment at 2-4 week intervals. The mean activity administered to patients was 6 GBq, with a cumulative activity of 20.5 GBq. Response assessment post-treatment was evaluated using the Solid Tumor PET Response Criteria (PERCIST 1.0) on 68Ga PSMA PET/CT imaging. ***Results:*** Evaluation of post-treatment 68Ga PSMA PET/CT images revealed partial response (PR) in liver lesions of 3 patients (27%), stable disease (SD) in 2 patients (18%), and progressive disease (PD) in 6 patients (55%). Median overall survival among patients exhibiting partial or stable response in liver lesions was 15 months (range: 7-16 months), while for patients evaluated as PD, the median overall survival was 5 months (range 3-7 months). Mean pre-treatment liver PSMA-positive tumor volume was 114.2 cm3, post-treatment was 261.3 cm3. The mean pre-treatment liver tumor SUVmax/Mediastinum SUVmax ratio was 19 and post-treatment was 32. Mean pre-treatment PSA levels measured 101.8 ng/ml and post-treatment was 286.2 ng/ml. ***Conclusion:*** Our findings highlight that liver lesion management was successful in 45% of patients treated with 177Lu-PSMA-617 radioligand therapy. However, to reach more robust statistically significant results, conducting larger-scale and comprehensive studies involving a broader patient cohort is needed.

Factors Influencing Clinical and Biological Response in Patients Treated with [177Lu]Lu-PSMA-617 under France's early access program.

V. Habouzit[1], *M. Claudin[2], F. Borrelly[3], C. Richard[4], C. Bailly[5], P. Schwartz[6], E. Mairal[7], S. Chêne[8], K. Hebert[9];*
[1]Centre Hospitalier Universitaire, Saint-Etienne, FRANCE, [2]Centre Hospitalier Universitaire, Nancy, FRANCE, [3]Centre Hospitalier Universitaire, Nîmes, FRANCE, [4]Institut Curie, Paris, FRANCE, [5]Centre Hospitalier Universitaire, Nantes, FRANCE, [6]Institut Bergonié, Bordeaux, FRANCE, [7]Centre Jean Perrin, Clermont-Ferrand, FRANCE, [8]Advanced Accelerator Applications, Rueil-Malmaison, FRANCE, [9]Institut du Cancer de Montpellier, Montpellier, FRANCE.

Aim/Introduction: The VISION study showed that [177Lu]Lu-PSMA-617 combined with best standard of care prolonged progression-free survival confirmed by imagery (rPFS), overall survival, and delayed time to worsening in health-related quality of life in patients with PSMA-positive mCRPC previously treated with at least one taxane-based chemotherapy and a novel hormonal therapy (NHT). Various factors related to patients, their disease, and the treatment sequence may impact the treatment's effectiveness. This retrospective analysis aims to evaluate the influence of these factors on the clinical and biological response of patients receiving [177Lu]Lu-PSMA-617 under France's early

access program. ***Materials and Methods:*** Between December 1, 2021, and April 30, 2023, 790 PSMA positive patients with mCRPC pretreated with 1-2 taxane chemotherapy and ≥1 NHT who received [177Lu]Lu-PSMA-617 under France's early access program were included. Among these, 685 patients were categorized into two groups: responders (experiencing reduced PSA levels and improved clinical symptoms) and non-responders (experiencing PSA progression and/or worsening clinical symptoms). Group characteristics were compared using bivariate analysis (Chi-squared test, Fisher's exact test, or Mann-Whitney test). Odd ratios (OR) and their 95% confidence interval [95CI] were calculated. A p-value <0.05 was considered statistically significant. ***Results:*** In our sample, 311 patients (39.4%) were classified as responders, and 374 as non-responders (47.3%). Responders had received more cycles of [177Lu]Lu-PSMA-617 (median 6 vs. 3; p<0.0001), more frequently showed uptake in all lesions on PSMA PET (85.2% vs. 69.5% of patients; OR 2.5 [95CI: 1.7, 3.7]; p<0.001), and more frequently received concurrent NHT (33.1% vs. 18.7%; OR 1.9 [95CI: 1.3, 2.7]; p<0.001). No significant differences (p>0.05) were observed between the responders and the non-responders with respect to patient age, ECOG score, initial PSA levels, metastasis locations, the number of previous NHT, the number of lines of taxane-based chemotherapy, and treatments received such as external radiotherapy, bisphosphonates, denosumab or immunotherapy. Additionally, Patients with PSMA PET uptake in all lesions experienced prolonged rPFS (median 7.9 vs. 5.5 months; p<0.001) and delayed symptom worsening (median 8.1 vs. 7.0 months; p=0.046). Previous treatment with 1 taxane was associated with delayed symptom worsening (8.2 vs 7.5 months; p=0.007). Concurrent NHT administration was also associated with a longer rPFS (median 8.3 vs. 6.1 months; p=0.0001) and delayed time to symptom worsening (median 8.6 vs. 7.4 months; p<0.001). ***Conclusion:*** The response to [177Lu]Lu-PSMA-617 may be influenced by the number of [177Lu]Lu-PSMA-617 cycles administered, PSMA-PET lesion positivity and concurrent NHT administration.

EP-0609

177Lu-PSMA in Metastatic Castration Resistant Prostate Cancer: Preliminary Analisys of Brazilian Multicentric Study

E. Etchebehere[1,2], *V. Heringer[1], J. Correia[3], J. Marin[4], C. Mosci[5], D. Anjos[6], P. Filho[7], G. Gomes[8], F. Villela-Pedras[9], F. Ribeiro[10], C. Buchpiguel[4], D. Bastos[4];*
[1]UNICAMP, Campinas, BRAZIL, [2]MND group, Campinas, BRAZIL, [3]São Carlos Clínica, Fortaleza, BRAZIL, [4]Hospital Sírio Libanês, São Paulo, BRAZIL, [5]Hospital Vila Nova Star, São Paulo, BRAZIL, [6]Hospital Santa Paula, São Paulo, BRAZIL, [7]Hospital Real Português, Recife, BRAZIL, [8]Núcleos, Brasília, BRAZIL, [9]Clínica Villela-Pedras, Rio de Janeiro, BRAZIL, [10]Bionuclear, Florianópolis, BRAZIL.

Aim/Introduction: Investigate 177Lu-PSMA therapy in Brazilian patients with metastatic castration resistant prostate cancer (mCRPC). ***Materials and Methods:*** Data for this retrospective multicentric study was collected from 9 Brazilian centers from 6 federative units (SP, PE, CE, RJ, SC and DF) that performed at least two cycles of 177Lu-PSMA therapy in mCRPC. Data with skewed distribution were reported as median (min-max). Primary outcome was overall survival. Secondary outcomes was the maximal PSA response and hematological adverse events (HAE). ***Results:*** A total of 100 males were included, median age = 74 years old (min-max: 54 - 96 years old). 177Lu-PSMA was the fifth (median) line of therapy (min-max 2-10). A total of 333 cycles were performed with a median of 4 cycles (min-max 1-10). The median overall survival was 16.9 months. Among the 72 patients with data available for the maximal PSA response at any time, 65% presented any PSA decline. 42% presented PSA decline ≥ 50% from baseline. 89% of patients did not present HAE or presented grades 1 or 2 HAE. Only 11% of patients presented grade 3 HAE. 0% of patients presented grade 4 HAE. ***Conclusion:*** 177Lu-PSMA therapy was effective and safe in the Brazilian population even with a median of 5th line of therapy (maximum 10th line). Overall survival and PSA decline ≥ 50% from baseline were similar to the literature data. Only 11% of patients presented grades 3 or 4 hematological adverse events. ***References:*** 1. Rahbar et al. Evaluating the response and side effects of Lu177-PSMA therapy in mCRPC patients, a single center experience from Iran

A. Aghaee, *S. Soltani, E. Askari, K. Aryana;*
Nuclear Medicine Research Center,Mashhad University Of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Investigation of clinical and laboratory findings of patients during treatment with lu177-PSMA in metastatic prostate cancer patients resistant to anti androgen therapy. ***Materials and Methods:*** In this cross-sectional study, all patients with metastatic prostate cancer resistant to hormone therapy who were referred to the nuclear medicine center of Ghaem Hospital for treatment with lu177-psma therapy between 2019 and 2021 were included in the study. During the treatment period, the patients were routinely monitored by a nuclear medicine specialist in one week, 4 weeks and 8 weeks intervals after the treatment.Laboratory tests including PSA, CBC, creatinine and liver tests were performed and recorded. Lu177-PSMA therapy repeated every 8-10 weeks and the treatment response was thoroughly evaluated after each cycle. ***Results:*** In this study, 133 patients with metastatic prostate cancer resistant to hormone therapy underwent a course of treatment with 177Lu-PSMA radiopharmaceutical. decline in PSA level was observed in 122 patients, of which 39 patients had a ≥50% PSA decrease after the first dose. Stabilization of the disease was observed in 79 patients and progression of the disease was observed in 24 patients. Out of 72 patients who had bone pain, pain improvement was seen in 81% of patients. 67% grade 1 hematological toxicity and 34% grade 2 hematological toxicity were observed. No kidney or liver complications occurred. ***Conclusion:*** According to the results, it seems that treatment with 177Lu-PSMA radiopharmaceutical in metastatic prostate cancer patients resistant to hormone therapy has a favorable therapeutic response with limited side effects.

EP-0611

Simple method for production and quality control of ^{225}Ac- PSMA-617 for the targeted alpha therapy of castration-resistant prostate cancer.

H. Khoshhosn, *M. Dayeni, M. Pirdadeh, M. Ghapanvari, Y. Tavakoli, M. Samizadeh, M. Mazidi, R. Nami, N. Soltani, H. Movahhed, A. Gravand, A. Sarabi, M. Davarpanah;*
Pars Isotope company, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Prostate cancer (PC) is the second most

common cause of cancer in men of all races [1]. Targeted alpha therapy (TAT) has a great potential for the treatment of metastatic castration resistant Prostate Cancer. Therefore, interest treatment of prostate cancer 225Ac-PSMA-617 for PSMA-Targeted a Radiation Therapy in nuclear medicine in all of the world is increasingly growing. After binding at the tumor cell surface, the PSMA ligands are internalized allowing radioisotopes to be concentrated within the cell and therefore, a suitable target for PC imaging and therapy [2]. An increasingly popular alternative can be the use of αemitting radionuclides for the therapy of PC patients such as Ac225, and Ra223 which have successfully been used to treat different tumors. Therefore a simple method without purification of 225Ac-PSMA-617 was evaluated. Labeling yield and radiochemical purity were >99%. ***Materials and Methods:*** For synthesis of 225Ac-PSMA-617 Radiopharmaceuticals, the Ac-225 radionuclide sample, dissolved in 0.1 M HCl in a 15R vial, was obtained from IPPE Co. PSMA-617 peptide was from Arian pazho Co. The 200 µl (250µCi) Ac-225 solution was transferred into the reaction vial which contains 0.9 mL of 1M sodium acetate buffer and 70 µg PSMA-617. The pH of the reaction mixture was determined to be 4.0- 5.0. The labeling was accomplished for 30 minutes at 95°C. Determine to the radiochemical purity of the 225Ac-PSMA-617 radiopharmaceuticals uses the ITLC method. ***Results:*** Based on the synthesis results, the production yield of 225Ac-PSMA-617 is usually around (95 %). The radiochemical purity of samples was at least 99%. The pH of the final product was 7.0. After QC, the final product could be used directly without need for a final purification step. ITLC analysis of the final product revealed no evidence of free 225Ac after 14 days in room temperature. ***Conclusion:*** According to the results, the possibility of safety form synthesizing 225Ac-PSMA-617 has been confirmed. This protocol allows a routine production for the treatment of patients with metastatic prostate cancer. ***References:*** 1. Ferlay J, Colombet M, Soerjomataram I, Dyba T, Randi G, Bettio M, et al. EP-0612

PACS-integrated, AI-based Monitoring of Body Composition in Patients with Metastatic Castration-Resistant Prostate Cancer undergoing Radioligand Therapy with [^{177}Lu]Lu-PSMA.

T. Ruhwedel, *J. Rogasch, M. Galler, C. Furth, S. Shnayien, J. Kolck, D. Geisel, H. Amthauer, N. L. Beetz;*
Charité - Universitätsmedizin Berlin, Berlin, GERMANY.

Aim/Introduction: Patients with metastatic castration-resistant prostate cancer (mCRPC) receiving radioligand therapy (RLT) are showing a variable response to the therapy. Prognostic factors that allow an estimation of the overall survival (OS) are required. Body composition (BC) describes the percentages of different body tissues as a measure of physical fitness and tumor cachexia. We evaluated the impact on OS of relative changes in BC parameters between baseline imaging before the start of RLT and interim staging after two cycles of RLT. ***Materials and Methods:*** This is an unicentric, retrospective analysis of 87 patients undergoing RLT with a median of 3 cycles (range 2 - 8 cycles) [177Lu]Lu-PSMA. Patients received baseline staging within 6 weeks before RLT and interim staging 6-8 weeks after the second RLT cycle. BC parameters were obtained from CT on the height of vertebrae L3 using an AI-based, PACS-integrated software tool. Relative BC changes were determined as the percentage deviation at interim staging from baseline. Cox regression was used to determine the prognostic value on OS. All variables with a p-value below 0.1 in univariable Cox regression were included in multivariable regression following stepwise inclusion (likelihood ratio). ***Results:*** During follow-up, 74 patients (85%) died. The median OS was 16.3 months, the median follow-up in survivors 25.2 months. In univariable Cox regression, 6 parameters representing relative changes in BC, previous treatment with Xofigo, higher number of previous chemotherapy lines, lymphonodal metastases, liver metastases, baseline PSA level, hemoglobin level and De Ritis ratio were significant predictors of OS (each $p<0.05$). In multivariable regression, higher relative decrease of the total fat area (TFA) (HR: 0.10; $p = 0.001$), higher number of previous chemotherapy lines (HR: 2.2; $p = 0.006$) and a higher baseline De Ritis ratio (HR: 1.4; $p = 0.001$) remained independent predictors of a shorter OS. Patients with high decrease in TFA (≤ -14%) had a median OS of 10.2 months compared to 18.5 months in patients with lower TFA decrease > -14% (logrank test: $p = 0.001$). In a separate Cox model, the TFA decrease predicted OS ($p < 0.001$) independent from the PSA trend after two RLT cycles ($p = 0.006$), and there was no interaction between the two (p=0.11). ***Conclusion:*** PACS-integrated, AI-based monitoring detects relative decrease of the TFA which was an independent predictor of shorter OS in this cohort of patients undergoing RLT.

EP-0613

Reduced total tumor volume on post-therapeutic SPECT - a cause for early treatment failure of patients undergoing PSMA-radioligand therapy?

L. Hempel[1], *Z. Ells[1,2], S. C. Kunte[1], M. Unterrainer[1,3], A. Holzgreve[1,2], M. J. Zacherl[1], G. T. Sheikh[1], M. Brendel[1], H. Ilhan[1,3], W. G. Kunz[4], J. Casuscelli[5], A. Delker[1], L. M. Unterrainer[1,2,6];*
[1]Department of Nuclear Medicine, LMU University Hospital, LMU Munich, Munich, GERMANY, [2]Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, University of California Los Angeles UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [3]Die RADIOLOGIE, Munich, GERMANY, [4]Department of Radiology, LMU University Hospital, LMU Munich, Munich, GERMANY, [5]Department of Urology, LMU University Hospital, LMU Munich, Munich, GERMANY, [6]BZKF, partner site Munich, Munich, GERMANY.

Aim/Introduction: 177Lu-PSMA-based radioligand therapy (RLT) in mCRPC patients is increasingly used since its FDA-approval. However, some patients comprise inferior treatment response despite comparable pre-RLT conditions. We could observe that pre-therapeutic total tumor volume on PSMA-PET (PSMA-TTV) partially differs from post-therapeutic TTV on SPECT-imaging (SPECT-TTV) after the first cycle. We aimed at comparing pre- and post-treatment TTV on PSMA-PET with SPECT-TTV after therapy cycle 1 and 2 in patients with early tumor progression during PSMA RLT. ***Materials and Methods:*** We conducted a retrospective study including 11 patients who received 2 cycles [177Lu]Lu-PSMA I&T and who showed early progressive disease after cycle 2 as defined by PSMA-PET and PSA. Pre-therapeutic PET-TTV on [^{18}F]F-PSMA-1007 PET was compared to SPECT-TTV at cycle 1. Similarly, PET-TTV after cycle 2 was compared to SPECT-TTV at cycle 2. Additionally, percentage TTV-changes on PET- and SPECT-imaging were assessed. For statistical analysis, paired t-tests were performed. ***Results:*** The patients (mean age 74.3 ± 7.6 years) received their first therapy cycle 27.3 ± 14.2 days after baseline PSMA-PET. Follow-up PSMA-PET was performed 45.0 ± 6.3 days

after cycle 2. PSA was significantly rising between the timepoint of pre-therapeutic PSMA-PET and the timepoint of PSMA-PET after cycle 2 (62.7 ± 62.9 ng/ml vs. 231.1 ± 247.3; p < 0.001). Also, PSMA-TTV was significantly increasing after cycle 2 compared to baseline PSMA-PET (181.8 ± 134.4 ml vs. 516.2 ± 263.0 ml, p < 0.001). In total, pre-therapeutic PET-TTV did not significantly differ from SPECT-TTV at cycle 1 (181.8 ± 134.4 ml vs. 178.0 ± 160.9 ml; p = 0.765). However, PET-TTV after 2 cycles was significantly higher than SPECT-TTV at cycle 2 (516.2 ± 263.0 ml vs. 178.9 ± 147.7 ml; p < 0.001). The percentage changes for PET-TTV, SPECT-TTV and PSA after second therapy cycle compared to baseline were 265.8 ± 208.0%, -7.3 ± 58.4% and 330.3 ± 363.6%, respectively. ***Conclusion:*** In this preliminary analysis, mCRPC patients with early progression after cycle 2 of PSMA-RLT showed a drastically lower tumor volume on post-therapy SPECT-TTV compared to PSMA-TTV. This suggests that a generally lower radioligand uptake on SPECT than on PSMA-PET might influence treatment failure and might allow early identification of non- responders. Analyses in a larger patient cohort, comparisons to patients with response to PSMA-RLT and correlation with the further disease are underway.

EP-0614

Radiomic ^{18}F-Fluorocholine PET/CT variables as stronger predictors of overall survival in patients with metastatic castration-resistant prostate cancer treated with^{223}Ra dichloride.

M. Montijano[1], *M. Amo-Salas[2], S. Guzman Ortiz[1], J. Bonilla Plaza[1], L. Garcia Zoghby[1], M. K. Meneses Navas[1], J. Cassinello Espinosa[3], V. Poblete García[4], A. García Vicente[1];*
[1]Hospital Universitario de Toledo, Nuclear Medicine Department, Toledo, SPAIN, [2]Universidad de Castilla la Mancha, Mathematics Department, Ciudad Real, SPAIN, [3]Hospital Universitario de Guadalajara, Oncology Department, Guadalajara, SPAIN, [4]Hospital Universitario de Ciudad Real, Nuclear Medicine Department, Ciudad Real, SPAIN.

Aim/Introduction: To determine the impact of prognostic factors in overall survival (OS) of metastatic castration-resistant prostate cancer patients (m-CRPC) treated with 223Ra-dichloride (223Ra). ***Materials and Methods:*** Multicenter, prospective, non-randomized study where all patients treated with 223Ra from January/15 to December/22 were collected. Baseline, interim, and end-treatment bone-scintigraphy (BS) and 18F-Fluorocholine PET/TC (FCH-PET/TC) scans were performed. Clinical and imaging variables were collected, including age, Gleason score, lactate dehydrogenase (LDH) or alkaline phosphatase (ALP) levels prior and during treatment, bone treatments and related events, lesions number on FCH-PET/TC, predominant activity, concordance between techniques, and treatment response both biochemically and by imaging, among others. Response assessment, concordance between techniques (Kappa=k) and OS relationship were analyzed using cross-tabulations and Log-Rank test, respectively. ***Results:*** 100 patients were included with a mean age of 72.7 years (±8.5). Gleason score was ≥8 in 45%. 56% did not complete 223Ra treatment, 92% died during follow-up. Median progression free survival and OS were 4 and 14 months, respectively. Concordance between techniques for interim was k=0,447 (p= <0.001) and for end-treatment k=0.211 (p=0.075). Clinically, statistically associated variables with increased OS were: ECOG status 0 (p=<0.001, χ2=23.3), non-pathological ALP (p=<0.001, χ2=12.5) and LDH levels (p=0.033, χ2=4.5) prior 223Ra, treatment completion (p=<0.001, χ2=29.1), PSA non-progression during treatment (p=0.004, χ2=8.5), bone events history during or after treatment (p=0.025, χ2= 4.9), receiving abiraterone (p=0.010, χ2=6.6) and/or enzalutamide (p=<0.001, χ2=11.3) thereafter. Regarding imaging variables, FCH-PET/CT findings were associated with lower OS such as >5 lesions (p=0.028, χ2=4.8) or superscan pattern (p=<0.001, χ2=16,7), axial lesion localization (p=<0.001, χ2=14.7), high tumor burden (p=0.003, χ2=9.0), bone marrow involvement (p=<0.001, χ2=27.2), uptake higher than liver (p=<0.001, χ2=13.1), non-blastic lesion on CT (p=0.047, χ2=3.9), soft-tissue involvement (p=0.048, χ2=3.9), and poor concordance between techniques (p=0.026, χ2=4.9). Regarding interim and end-treatment imaging techniques, interim non-progression in both BS and FCH-PET/CT showed statistical significance with OS (p=0.004, χ2=8.3 and p=<0.001, χ2=17.0, respectively). ***Conclusion:*** Characteristics like improved ECOG status, normal LDH and ALP levels pre-223Ra treatment, completing 223Ra, PSA non-progression during treatment, or receiving bone-protective therapy were associated with increased OS.Baseline and post-therapy FCH-PET/CT derived radiomics, including disease extent, metabolic activity and extraosseous involvement, were more robust than BS disease characteristics in the survival prediction.

EP-0615

[177Lu]Lu-PSMA selection criteria, PSMA SPECT TTV post-cycle and dosimetry: our LATAM experience.

D. Mena, *C. Carreras, J. Schalch;*
Hospital Angeles Lomas, CDMX, MEXICO.

Aim/Introduction: Theranostics is growing fast. New evidence around potential imaging biomarkers is available. Dosimetry is a powerful tool to evaluate noble organs and target lesions absorbed dose as a prognostic factor. Join together all pieces could be challenging. ***Materials and Methods:*** We present our proposal for an integral patient road. Our sample case is male, 73 years old, metastatic castration-resistant prostate cancer (mCRPC), treated before with novel-generation androgen, taxane and biochemical relapse. Even when FDG PET is not necessary according to VISION trial, we prefer when possible use TheraP criteria and FDG PET TTV (total tumor volume). We plan first cycle administration with dosimetry protocol that include first cycle SPECT/CT with 2 time points (24, 72 hours). For cycles 2 and 3 we do just 24 hours SPECT/CT. We use software tool to get cycle 2 and 3 dosimetry results using cycle 1 multi-point time activity curves. We also implement PSMA SPECT TTV post-cycle as a potential biomarker. ***Results:*** Our sample case had a PSMA PET uptake lesions over spleen ([18F]PSMA-1007) and many even above parotid uptake. Complementary FDG PET show complete match with PSMA PET, and FDG PET TTV was 84 mL (below 200 mL suggested prognostic biomarker). Cycle 1 multipoint dosimetry results (Gy mean dose): parotids: 0.7 Gy, kidneys: 0.6 Gy, tumor 1: 12.7 Gy, tumor 2: 37.3 Gy, tumor 3: 18.4 Gy and after 3 cycles accumulated absorbed dose were parotids: 1.8 Gy, kidneys: 3.2 Gy, tumor 1: 27.2 Gy, tumor 2: 119 Gy, tumor 3: 37 Gy. PSMA SPECT TTV results showed cycle 1: 2688 mL, cycle 2: 1812 mL and cycle 3: 665 mL with a delta between cycle 1 and 2 of 32% and cycle 1 and 3 of 75%. ***Conclusion:*** Guidelines describe selection criteria and follow up for [177Lu]Lu-PSMA but in latinamerica we should take consideration about local radiotracers availability. On the other hand, complementary FDG PET seems to be an interesting potential prognostic biomarker. New evidence about PSMA / FDG PETS discordance or PSMA SPECT TTV can be implemented in daily practice with technology with AI that simplify steps. Finally, 72 hours SPECT/CT is not always possible so multi-time point first cycle dosimetry for 24 hours single timepoint next cycle could be a solution. ***References:*** Emmett L et al. 177Lu-PSMA SPECT

Quantitation at 6 Weeks (Dose 2) Predicts Short Progression-Free Survival for Patients Undergoing 177Lu-PSMA-I&T Therapy. J Nucl Med. 2023 Mar;64(3):410-415.

EP-0616

Therapy-related Myeloid Neoplasms Following Lutetium-177 [^{177}Lu]Lu-PSMA Therapy in patients with Metastatic Castration-Resistant Prostate Cancer: A Case Series

M. Eifer[1,2,3], *D. E. K. Sutherland[1], I. Goncalves[4,5], J. P. Buteau[1,4], T. Akhurst[1], R. Alipour[1,4], L. Au[4,5], A. A. Azad[4,5], A. Cardin[1,4], D. Chen[1], B. Emmerson[1], L. Emmett[6], K. Jewell[1,4], G. Kong[1,4], R. Kashyap[1,4], L. Kostos[4,5], A. S. Ravi Kumar[1,4], E. M. Kwan[7], L. Macfarlane[1], E. Medhurst[1,4], J. Saghebi[1,4], S. Sandhu[4,5], B. Tran[4,5], A. [1]Molecular Imaging and Therapeutic Nuclear Medicine, Cancer Imaging; Prostate Cancer Theranostics and Imaging Centre of Excellence (ProsTIC), Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [2]Department of Diagnostics Imaging, Chaim Sheba Medical Center at Tel HaShomer, Ramat Gan, ISRAEL, [3]Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv, ISRAEL, [4]Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, AUSTRALIA, [5]Department of Medical Oncology, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [6]Department of Theranostics and Nuclear Medicine, St Vincent's Hospital, Sydney, NSW, Australia; Faculty of Medicine, UNSW Sydney, NSW, Sydney, AUSTRALIA, [7]Vancouver Prostate Centre, Department of Urologic Sciences, University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: [177Lu]Lu-PSMA therapy has a favourable toxicity profile in patients with metastatic castration-resistant prostate cancer (mCRPC). Therapy-related myeloid neoplasms (t-MN) are described following [177Lu]Lu-DOTATATE but have not yet been reported following [177Lu]Lu-PSMA. This case series describes five patients with mCRPC who developed t-MN following [177Lu]Lu-PSMA at our institution. ***Materials and Methods:*** In this single-centre retrospective analysis, we reviewed all patients with mCRPC treated with [177Lu]Lu-PSMA at a high-volume centre. Patients who developed biopsy-proven t-MN during or following [177Lu]Lu-PSMA treatments are summarised with descriptive statistics. ***Results:*** Between August 26 2015 and December 31 2022, 5 of 381(1.3%) patients treated with [177Lu]Lu-PSMA were subsequently diagnosed with t-MN. Their median age at cycle 1 (C1) was 78 years [range 65-80]. The median time from C1 to t-MN diagnosis was 32.4 [range 6.0-58.8] months. Previous treatments included docetaxel (n=5), external beam radiotherapy to metastases (n=5), abiraterone (n=4), enzalutamide (n=3) and cabazitaxel (n=3). On PSMA PET/CT, 4 (80%) patients had predominantly bone metastases and 1 (20%) had predominantly nodal metastases. They were treated with [177Lu]Lu-PSMA-617 (n=3) or [177Lu]Lu-PSMA-I&T (n=2). A median of 7 (range 4-12) cycles of [177Lu]Lu-PSMA was administered with a median total cumulative activity of 49.5GBq (range 31.3-60.4). Prostate-specific antigen (PSA) reduction ≥50% or ≥80% from baseline was seen in 5 (100%) and 4 (80%), respectively. All had PSA progression preceding t-MN diagnosis. t-MN diagnosis included: myelodysplastic syndrome with single-lineage dysplasia (MDS-SLD) (n=2), myelodysplastic syndrome with excess blasts-1 (MDS-EB1) (n=1), acute promyelocytic leukaemia (APML) (n=1) and AML (n=1). At t-MN diagnosis, all patients presented with ≥ grade 2 cytopenia and involving one or more blood cell lines. Marrow genetic analysis revealed unfavourable karyotype and/or mutation variants in all patients, including tumour protein 53 (TP53) mutations in two patients and MECOM rearrangement AML in one patient. Most patients transitioned to best supportive care once diagnosed with t-MN; induction therapy was initiated in the patient with APML. Survival was 8.1, 31.3, 43.0, 56.0 and 60.4 months from C1 and 1.8, 2.1, 6.8, 10.3 and 12.4 months from t-MN diagnosis. ***Conclusion:*** In the mCRPC population after chemotherapy, we describe a 1.3% incidence of t-MN following [177Lu]Lu-PSMA therapy. Ongoing follow-up is necessary to further define true incidence of t-MN or other unexpected delayed toxicities, particularly with earlier use of [177Lu]Lu-PSMA in the disease course.

EP-0617

The radium-223 in mCRPC with bone metastases: 6 years of experience in our center.

J. Echeverri Diaz, *A. García-Burillo, R. Morales, N. Calviño, M. R. Marusso Fizzani, O. Hernández Cristancho, F. M. Velazquez, T. Canela-Coll, S. Asadurova, J. Suils, C. Gamez Cenzano, J. Carles; Hospital universitario Vall d'Hebron, BARCELONA, SPAIN.*

Aim/Introduction: Radium-223 is an alpha emitter used as a palliative treatment for bone metastases in patients with metastatic castration-resistant prostate cancer (mCRPC), often administered after multiple other treatments have failed. This study aims to evaluate the outcomes, efficacy in pain control, and patient reality in our service after receiving Radium-223. ***Materials and Methods:*** We retrospectively reviewed medical records of 57 patients treated with Radium-223 from 2016 to 2023. Patient demographics, treatment history, dosage details, hematological toxicities, and pain control effectiveness were analyzed. ***Results:*** The average patient age was 73 years, ranging from 57 to 84 years. A majority had bone metastases at diagnosis (84%), and more than 50% had received medical treatment initially. Only 17.5% underwent surgery. Prior to Radium-223 treatment, 98% of patients had received at least one line of non-androgen hormonal (NAH) and taxanes treatments. Over 50% had more than 20 bone metastases identified via scintigraphy. 63% received 5 to 6 doses of Radium-223 intravenously every four weeks, 37 % had between 1-4 injections of radium-223, of wich 1 % died, 21% had progression disease, 7% had hematological toxicity (decrease platelet count) and 8% were suspended due to other reasons. 64% had adverse events during the treatment, wich were all hematological, including anemia (28%), decreased platelet (18%), neutropenia (2%) and lymphopenia (51%). Pain control improved significantly, with 70% of patients experiencing diminished pain or better management. The overall survival from the start of treatment was 7 months, extending to 12 months in patients who completed 5 to 6 cycles. ***Conclusion:*** Radium-223 demonstrates significant efficacy in controlling pain and managing bone metastases in mCRPC patients who have undergone extensive prior treatments. However, hematological toxicities remain a concern, highlighting the need for careful patient selection and monitoring during treatment to achieve finishing the 6 inyections of radium-223 in order to raise de overall survival.

EP-0618

A single-center experience in compassionate use of ^{177}Lu-PSMA-617 in advanced prostate cancer.

G. Crosta[1], *G. Argiroffi[2], A. Lorenzoni[2], M. Kirienko[2], G. Aliberti[2], F. Rubino[2], C. Chiesa[2], G. Procopio[3], V. Guadalupi[3], E. Verzori[3], M. Maccauro[2];*

[1]university of milan, milan, ITALY, [2]Nuclear Medicine Unit, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, milan, ITALY, [3]Medical Oncology Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, Milan, ITALY.

Aim/Introduction: Radioligand therapy (RLT) with 177Lu-PSMA-617 targeting the prostate-specific membrane antigen (PSMA) has emerged as an innovative and promising approach in the management of metastatic castration-resistant prostate cancer (mCRPC). This single-center observational study reports on the compassionate use of 177Lu-PSMA-617 for patients with advanced mCRPC at the Fondazione IRCCS Istituto Nazionale dei Tumori, Milan. ***Materials and Methods:*** The clinical protocol comprised up to four cycles of 177Lu-PSMA-617, administered every 6 weeks in patients affected by PSMA-positive mCPRPC showed at 68Ga-PSMA-11 PET/CT. Overall survival (OS), PSA response rates, and adverse events (AEs) were assessed. ***Results:*** A total of 24 men received 177Lu-PSMA-617 between October 2021 and June 2022, with a focus on evaluating efficacy, safety, and patient outcomes. Since compassionate use program eligibility required patients with advanced metastatic disease, RLT was dispensed after several prior treatments, including surgery, radiotherapy, antiandrogen therapy, and chemotherapy. The median activity administered was approximately 6.93 GBq (6.72-7.29) per cycle. Out of the 24 patients, 12 completed the full treatment protocol. The primary endpoint, overall survival (OS), revealed a median OS of 14 months for patients who completed the treatment. This result aligns with previous studies highlighting the potential benefits of 177Lu-PSMA-617 in a heavily pretreated mCRPC population. As a secondary endpoint, the study reported a median PSA reduction of 26.94% following the first RLT cycle, with 6 patients achieving a reduction of over 50%. In subsequent cycles, 4 additional patients showed similar reductions, and notably, in 3 cases, PSA levels decreased by more than 90%. While the treatment was predominantly well-tolerated, monitoring for adverse events based on the Common Terminology Criteria for Adverse Events (CTCAE) revealed that hematologic toxicities were the most frequent serious side effects, with 4 subjects experiencing toxicities at grade 3 or 4 levels. No other grade 3 or 4 toxicities have been documented. ***Conclusion:*** This study presents 177Lu-PSMA-617 as an effective option under compassionate use, providing crucial data on its application in a real-world setting. The findings suggest that 177Lu-PSMA-617 is a viable treatment option for patients with advanced mCRPC, especially those with limited alternative. Moreover, with the expectation of wide use of this treatment in the near future, the study highlights the importance of patient selection and the potential for radioligand therapy in mCRPC. This forward-looking perspective underscores the evolving paradigm towards more personalized and effective treatments in oncology.

EP-0620

Clinico-radiological factors determining progression free survival following 177Lu PSMA therapy in metastatic castrate resistant prostate cancer, an Indian scenario

S. Choudhury, *A. Agrawal, V. Rangarajan, S. Ghosh;*
Tata Memorial Hospital, Mumbai, INDIA.

Aim/Introduction: Introduction:177Lu PSMA radio ligand therapy is an established treatment modality for the management of metastatic castrate-resistant prostate cancer. However, in practice the effect of radio ligand treatment is often short-lasting. A variety of clinic-radiological factors affect response to PSMA radioligand therapy. The purpose of this study, was to to elucidate these factors in predicting progression-free survival in Indian patients treated with radioligand therapy. ***Materials and Methods:*** Methods: In this retrospective observational study total 52 patients of mCRPC treated with 177Lu PSMA therapy from the year 2019 to 2021 were included. Various patient specific characteristics like age, past history of treatment with chemotherapy, PSA value, baseline hemoglobin, combination therapy (novel androgen receptor pathway inhibitors(ARPI) like enazluatmide, abriratarone) with 177Lu PSMA, and various scan specific characteristics (on pre-therapy PSMA PET scan) such as SUVmax of the most avid lesion, number of bony lesions, presence of visceral metastasis, presence of PSMA negative soft tissue lesions were also recorded. Kaplan-meier method was used to assess cumulative PSA progression free survival(PFS) and log rank test was used evaluate prognostic value of various clinic-radiological factors. Cox proportional hazard model was used for multivariate analysis, to find independent prognostic factors. ***Results:*** Median PSA-PFS was 8 months (95% CI, 3.2,12.7). ROC analysis was done to find SUVmax cutoff of 29.025 for PSA-PFS 8 months or higher (AUC: 0.756, P value:0.002). In univariate analysis, only this SUVmax-based division was shown to be significant predictor for PSA-PFS (P value: 0.033). Of all the patient-specific variables only ARPI combination therapy was found to be significant predictor for PSA-PFS in univariate analysis (median PSA-PFS 3 vs 10 month, p value=0.027). In multivariate analysis, both combination therapy and SUVmax of most avid lesion was found to be independent prognostic factor for PSA-PFS (HR: 0.465, 95% CI 0.234,0.922, P: 0.028 and HR 0.478, 95% CI 0.247,0.925 P value: 0.029) . ***Conclusion:*** SUVmax > 29 of most avid lesion in pretherapy PSMA PET and combination therapy with ARPI were independent predictors of PSA-progression-free survival in mCRPC patients treated with 177Lu PSMA therapy. ***References:*** Gafita, A., Marcus, C., Kostos, L., Schuster, D. M., Calais, J., & Hofman, M. S. (2022). Predictors and Real-World Use of Prostate-Specific Radioligand Therapy: PSMA and Beyond. American Society of Clinical Oncology educational book. Evaluation of the therapeutic efficacy of ^{225}Ac-PSMA I&T in advanced prostate cancer: preliminary results

T. Budlewski[1], *A. Majkowska-Pilip[2], F. Bruchertseifer[3], A. Bilska-Sobecka[1], B. Irtych[1], R. Walczak[2], A. Morgenstern[3], J. Walecki[1];*
[1]1Isotope Therapy Department, National Medical Institute of the Ministry of the Interior and Administration, Warszawa, POLAND, [2]2Institute of Nuclear Chemistry and Technology, Centre of Radiochemistry and Nuclear Chemistry, Warszawa, POLAND, [3]Joint Research Centre, European Commission, Karlsruhe, GERMANY.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is a protein highly expressed on the surface of prostate cancer cells, making it an ideal target for therapy. The use of 225Ac-PSMA-617 to treat advanced prostate cancer has shown remarkable efficacy without significant side effects. The treatment relies on accurately delivering the radiopharmaceutical to cancer cells with elevated PSMA receptor expression, leveraging the potent impact of alpha radiation on tumor DNA. Our study aims to assess the efficacy and safety of 225Ac-PSMA I&T in patients with prostate cancer who have shown disease progression despite previous treatment modalities. ***Materials and Methods:*** Ten patients diagnosed with metastatic castration-resistant prostate cancer underwent a treatment regimen involving four cycles of 225Ac-PSMA I&T at 100 kBq/kg, administered at two-month intervals. All patients had previously received extensive chemotherapy and hormonal therapy before their enrollment. After each treatment cycle, urine and blood samples were collected at three-time points for up to 24 hours to assess the clearance rate. The prostate-specific antigen

(PSA) levels and blood cell counts were measured throughout the treatment regimen every four weeks. PET/CT using 68Ga-PSMA-11 was used for baseline staging and imaging control after treatment. The local research ethics committee approved the study. ***Results:*** Preliminary results from this ongoing study demonstrate the auspicious therapeutic efficacy of 225Ac-PSMA I&T in patients with progressive prostate cancer. The early evaluation shows favourable response rates, including significant reductions in PSA concentrations of 26.7% to 36.5% after the first dose of 225Ac-PSMA I&T and from 77.5% to 93.8% after the second dose compared to baseline. The 68Ga-PSMA-11 PET/CT images prove tumor regression compared to baseline scans. Importantly, the treatment is well-tolerated, with no significant treatment-related adverse events reported thus far. ***Conclusion:*** Targeted α-therapy with the use of 225Ac-PSMA I&T is very promising and provides the possibility of effective treatment of advanced-stage prostate cancer patients progressing on existing treatment lines. Additional research involving a larger cohort of patients is necessary to evaluate the efficacy and safety of the treatment comprehensively.

Yttrium-90 resin microsphere radioembolization-induced liver disease and associations with predictive dosimetry

***J. Fong*[1], *K. Chen*[2,3], *A. K. T. Tong*[1], *C. X. Y. Goh*[1], *H. Huang*[1], *K. S. H. Loke*[1,3], *S. X. Yan*[4], *D. Y. Y. Peh*[5], *T. S. K. Ong*[6], *E. Yeo*[6], *P. K. H. Chow*[3,7,8]; *[1]Department of Nuclear Medicine, Singapore General Hospital, Singapore, SINGAPORE, [2]Department of Gastroenterology and Hepatology, Singapore General Hospital, Singapore, SINGAPORE, [3]Duke-NUS Medical School, Singapore, SINGAPORE, [4]Department of Radiology/ Nuclear Medicine, UTSouthwestern Medical Centre, Dallas, TX, UNITED STATES OF AMERICA, [5]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, SINGAPORE, [6]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE, [7]Department of Surgical Oncology, National Cancer Centre Singapore, Singapore, SINGAPORE, [8]Department of Hepato-pancreatico-biliary Surgery, Singapore General Hospital, Singapore, SINGAPORE.*

Aim/Introduction: Hepatocellular carcinoma (HCC) is the sixth most frequent malignancy and fourth leading cause of cancer-related death worldwide. Yttrium-90 (Y90) is a high energy beta-emitter used for locoregional therapy of HCC, with secondary Bremsstrahlung photons and positrons that can be imaged for dosimetry calculations. Radioembolization-induced liver disease (REILD) is a potentially life-threatening complication post-Y90 radioembolization (RE). We report on cases of clinical REILD that developed after Y90 resin RE, with pre- and post- therapy dosimetry measurements. ***Materials and Methods:*** Data was extracted from a database of 472 patients who underwent Y90 resin RE at a tertiary centre between 2008 to 2019. REILD was defined as development of jaundice and ascites 4 to 8 weeks post-RE without tumour progression or bile duct obstruction. Pre-therapy planning dosimetry was obtained via artery-specific partition model based on medical internal radiation dose macrodosimetry. Post-therapy dosimetry was obtained using voxel-based MIM LiverY90 SurePlan Local Deposition Method. Visual agreement between pre- and post-RE scans were scored independently by three senior Nuclear Medicine Physicians. ***Results:*** 12 REILD cases were identified, all were BCLC stage C with portal vein thrombosis (PVT) at baseline. This represents 2.54% of the entire database, and 6.28% of BCLC C with PVT patients. 6 of the REILD cases had available for pre-therapy dosimetry and 7 had adequate scan data for post-therapy dosimetry. Visual assessment revealed that all pre- and post- Y90 scans had complete/ near complete or partial overlap. Median Y90 activity administered was 1.5 GBq. Both predicted and actual median absorbed doses to non-tumoral liver (41.5Gy and 33.0 Gy respectively) were within the recommended threshold for whole liver treatment of 40Gy. ***Conclusion:*** In our cohort, all patients that developed REILD post-Y90 were BCLC stage C with PVT at baseline. The median absorbed radiation to normal liver was within the recommended threshold, suggesting that a lower threshold for absorbed dose to non-tumoral liver may be required for patients with risk factors such as advanced BCLC stage.

EP-0623

Radioembolization as bridging therapy in the treatment of hepatocellular carcinomas in patients who are candidates to liver transplantation. Our experience.

C. Ruiz Corbalán, *A. De Agrela Serrao, A. Leiva Montejo, G. Martínez Gómez, M. Castellón Sanchez, A. Hernandez Martinez, T. Rodriguez Locarno, T. Moreno Monsalve, J. Contreras Gutierrez, L. Frutos Esteban, J. Navarro Fernández, N. Sanchez Izquierdo, M. Ibañez Ibañez;*
ARRIXACA, Murcia, SPAIN.

Aim/Introduction: A review of patients diagnosed with hepatocellular carcinoma (HCH) in our centre who underwent liver transplantation between January 2018 and December 2023 and who previously had received radioembolization with glass microspheres labelled with 90Y with the aim of stabilizing and, in some cases, achieving a downstaging of the disease to meet the Milan criteria for liver transplantation. ***Materials and Methods:*** Retrospective study of 8 patients, 7 men and 1 woman with a mean age of 63 ± 7 years with HCH on cirrhotic liver (2 ethanolic, 4 HCV and 2 HBV; 6 CHILD A, 1 B and 1 C) treated with radioembolization as a bridging therapy to transplantation (2 left and 8 right lobectomies). Until December 2023, clinical and radiological monitorization was pursued to assess treatment response and to meet the transplant criteria, as well as to assess progression-free survival (PFS) and overall survival (OS). ***Results:*** Before radioembolization, only 1 patient met the Milan criteria and after radioembolization, 5 patients. The dose administered to the liver was 185.87 ± 55.2 Gy. Partial response was obtained in 62% of patients, complete necrosis of the lesion in 13% and progressed in 25%. The size of the lesions was reduced by 37%. The PFS was 6.89 ± 7 months, and the waiting time between radioembolization and transplantation was 9.33 ± 7.3 months. OS was 38.1 ± 20.87 months. ***Conclusion:*** The preliminary results of our sample indicate that radioembolization is effective in reducing the size of liver lesions, achieving a downstaging of the disease that allows the patient to meet the Milan criteria and stabilizing it until the moment of transplantation.

EP-0624

Overall survival (OS) as function of tumor absorbed dose (T) in hepatocellular carcinoma (HCC) treated with Y-90 microspheres

***K. Knesaurek*[1],** *D. Mena*[2], *P. Casciato*[3], *C. Collaud*[3], *I. Hume*[3];
[1]*Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES OF AMERICA,* [2]*Nuclear Medicine World, CDMX, MEXICO,* [3]*Hospital Italiano de Buenos Aires, Buenos Aires, ARGENTINA.*

Aim/Introduction: The aim of our study was to investigate the relationships between mean absorbed tumor (T) dose, obtained from PET/CT post-therapy studies in hepatocellular carcinoma (HCC) treated with yttrium-90 microspheres (Y-90), and overall survival (OS) of treated patients. ***Materials and Methods:*** After treatment with Y-90 microspheres, 27 patients (10 female and 17 males, mean age 69.0± 7.8y), underwent PET/CT imaging. PET/CT studies were conducted with an acquisition time of 15 minutes, using the reconstruction matrix of 200x200x75 and voxel size 4.07x4.07x3.00 mm3. Low dose, non-diagnostic CT images were used for attenuation correction (1). PET/CT reconstructed images were transferred to a common platform and Y-90 dosimetry was calculated utilizing the local deposition method. Regions-of-interest (ROIs) for whole liver and tumor(s) were manually created for each patient, while the normal tissue ROI was automatically generated. Patients were categorized into two groups: Groupe 1with T less than 215 Gy and Groupe 2 with T equal or greater than 215 Gy, based on literature values for tumoricidal dose. Survival analysis was performed using Kaplan-Meier survival plot. ***Results:*** In Groupe 1, consisting of 13 patients, the range of T was 22Gy to 213Gy. For Group 2, comprising 14 patients, the range for T was 258Gy to 1370Gy. The mean and median OS for Group 1 were 16.1 and 9.0 months, respectively, while for Group 2, they were 24.1 and 18.0 months, respectively. ***Conclusion:*** Although the differences in mean and median OS were not statistically significant (p=0.2), the trend indicated that both values were higher for Group 2. Group 2 exhibited a mean OS longer by 8 months and a median OS longer by 9 months compared to Group 1. The limitation of the study is the relatively small sample size of 27 patients; with a larger number of cases, the mean and median OS differences between Groups 1 and 2 may become statistically significant and larger than observed in this study. ***References:*** 1.Knešaurek K, Tuli A, Kim E, Heiba S, Kostakoglu L. Comparison of PET/CT and PET/MR imaging and dosimetry of yttrium-90 (90Y) in patients with unresectable hepatic tumors who have received intra-arterial radioembolization therapy with 90Y microspheres. EP-0625

Lung dose verification after ^{90}Y-microsphere radioembolization treatments

S. Kappadath, *B. Lopez;*
University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: To estimate the delivered lung doses using post-therapy 90Y-SPECT/CT and 90Y-PET/CT imaging and to evaluate its concordance with doses predicted with pre-therapy 99mTc-macroaggregated albumin (99mTc-MAA) planar and SPECT/CT imaging. ***Materials and Methods:*** Thirty-five 90Y-microsphere therapy patients underwent pre-therapy 99mTc-MAA planar and SPECT/CT and post-therapy 90Y-SPECT/CT and 90Y-PET/CT imaging (as part of a prospective clinical trial, RAPY90D, NCT03896646). Lung shunt fractions (LSFs) were calculated by contouring lungs and livers on corresponding CTs and determining their volumes, masses, and either the mean SPECT count density or the median PET activity concentration. Appropriate techniques, based on previous techniques,1 to minimize biases from noise, respiratory-motion, and mis-registration were implemented. Lung doses (in Gy/GBq of administered 90Y) were calculated by multiplying LSFs by 49.7 Gy*kg/GBq and dividing by patient-specific lung mass. In cases with truncated lungs in the field-of-view (FOV) of hybrid scans, diagnostic chest CTs were used to calculate total lung masses and adjust net lung uptake determined from the hybrid scans.1 As typically done, 99mTc-MAA planar dosimetry was performed assuming 1 kg lung mass. ***Results:*** Estimated lung masses ranged (median) between 506-1567 (901) g, with only 17 (49%) cases containing the full lungs in >1 hybrid-CT FOV. There was good concordance between 90Y-SPECT (range 0.3-2.3 Gy/GBq) and 90Y-PET (range 0.1-4.1 Gy/GBq) based lung dose estimates, with a paired-difference mean ± SD of -0.1 ± 0.6 Gy/GBq and 92% of cases within 1 Gy/GBq of the verified dose. SPECT and planar MAA imaging over-estimated the verified lung dose by a mean ± SD difference of +0.1 ± 1.2 Gy/GBq and +0.9 ± 1.6 Gy/GBq, respectively, demonstrating good agreement in most cases. In the worst 2 cases, verified lung doses of 2.1 and 3.7 Gy were grossly over-predicted to be 12.1 and 18.6 Gy with 99mTc-MAA SPECT/CT and 22.9 and 28.1 Gy with 99mTc-MAA planar imaging, respectively. ***Conclusion:*** Good agreement between post-therapy 90Y-SPECT/CT and 90Y-PET/CT lung doses suggest high confidence in methodology developed to verify lung doses. While there was overall good correspondence, cases exist where over-estimated predicted lung doses could negatively impact current or future treatments. ***References:*** [1] Lopez et al. Calculation of lung mean dose and quantification of error for 90Y-microsphere radioembolization using 99mTc-MAA SPECT/CT and diagnostic chest CT. Med Phys 46(9):3929-3940, 2019.

EP-0626

Radioisotopic synoviorthesis as a treatment for refractory or relapsing chronic arthritis

***J. Villa-Palacios*[1,2,3],** *E. Triviño-Ibáñez*[1,2,3], *D. Rivas-Navas*[1,2,3], *A. Piñeiro-Donis*[1,2,3], *C. Ramos-Font*[1,2,3];
[1]*Hospital Universitario Virgen de las Nieves, Granada, SPAIN,* [2]*Servicio de Medicina Nuclear. Hospital Universitario Virgen de las Nieves, Granada, SPAIN,* [3]*Instituto de Investigación Biosanitaria ibs, Granada, SPAIN.*

Aim/Introduction: To evaluate the results of radioisotopic synoviorthesis (RSO) therapy in patients with chronic synovitis refractory to first-line therapy. ***Materials and Methods:*** This is an observational and retrospective study that included all RSO performed in our department, between September 2014 and 2023, in patients with large and/or medium-sized chronic inflammatory mono/oligoarthritis refractory to first-line treatment and with no or minimal cartilage or bone destruction. Pain, joint mobility/functionality and quality of life were assessed at 2, 6 and 12 months. ***Results:*** 35 patients (age: 51.06 ± 14.15, 57.1% male) underwent 41 therapeutic procedures (dose: 176.49 ± 35.2 MBq). The most frequent underlying pathology was autoimmune (51.4%) followed by proliferative arthritis (17.1%). 34.3% had received previous local treatment. 91.4% had local pain and 94.3% had limited mobility. 54.3% of patients had multifocal involvement. The most frequent location was the knee (91.2%) and left side (62.9%). At 2 months follow up, 80% of the patients had improved pain, 65.7% improved joint mobility and 60% improved quality of life. At 6 months, 45.7% of patients reduced analgesic treatment and 68.6% improved joint dynamics. At 12 months,

48.6% had a relapse of symptomatology. Retreatment occurred in 17.1% of our population. The probability of relapse was 27%, 38% and 45% at 3, 6 and 12 months, respectively. The only factor significantly associated with the likelihood of relapse was male sex (HR: 3.87, p=0.049). One patient showed an acute complication and none had chronic complications related to RSO. ***Conclusion:*** RSO is an effective and safe treatment in patients with chronic inflammatory synovitis refractory to first-line therapy. ***References:*** 1: Kampen WU, Boddenberg-Pätzold B, Fischer M, Gabriel M, Klett R, Konijnenberg M, Kresnik E, Lellouche H, Paycha F, Terslev L, Turkmen C, van der Zant F, Antunovic L, Panagiotidis E, Gnanasegaran G, Kuwert T, Van den Wyngaert T; EANM Bone & Joint Committee, the Dosimetry Committee, the Oncology & Theranostics Committee. EP-0627

Survival biomarkers of radioembolization with Yttrium-90 glass microspheres in metastatic colorectal cancer

J. Villa-Palacios[1,2], *E. Triviño-Ibáñez[1,2,3], E. González-Flores[1,4], G. Ruiz-Villaverde[1,5], A. Rodríguez-Fernández[1,2,3];*
[1]Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [2]Servicio de Medicina Nuclear. Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [3]Instituto de Investigación Biosanitaria ibs, Granada, SPAIN, [4]Unidad de Gestión Clínica de Oncología Médica. Hospital Universitario Virgen de las Nievesa, Granada, SPAIN, [5]Unidad de Gestión Clínica de Radiodiagnóstico. Hospital Universitario Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: To evaluate the prognostic factors and survival outcomes of colorectal cancer liver metastasis (lmCRC) treatment by transarterial hepatic radioembolization with yttrium-90 (TARE). ***Materials and Methods:*** Prospective longitudinal study, which included patients with colorectar liver metastases treated by TARE, between November 2015 and October 2023. The therapeutic response was evaluated at 3 and 6 months of the TARE (criteria RECIST1.1). Predictive biomarkers associated with survival was explored. ***Results:*** 48 TARE were performed in 39 patients (age 61.58 ± 8.56 years, 61.5% men). Ten patients (25.6%) underwent surgery for the primary tumor and 27 cases (69.2%) presented liver metastases synchronous with the primary tumor. Prior to TARE, 36 (92.3%) patients had received at least one line and 13 (33.3% patients) received at least 2 lines of QT. The most frequent type of TARE was lobectomy (74.4% cases) followed by segmentectomy and bilobar (12.8%). The average perfused volume was 922.15 ± 553.00 cm3, absorbed dose in the tumor tissue of 207.55 ± 113.90 Gy, and an average tumor-to-normal-liver ratio (TNR) of 27.76 ± 44.47. Median OS was 46 months (95%CI 29.77-62.23 months) from CRC diagnosis and 11 months (95%CI 8.03-13.98 months) from TARE. PFS was 5 months (95%CI 3.17-6.84). The factors associated with a lower OS were: synchronous metastases (HR: 3.329; p= 0.035), extrahepatic disease (HR: 4.730, p= 0.002), ascites (HR: 8.835, p= 0.012) , treatment with aflibercept (HR: 2.679, p= 0.039), baseline AST (HR: 1.026, p= 0.041), platelet-to-lymphocyte ratio (PLR) (HR: 1.01, p= 0.049), neutrophil-to-lymphocyte ratio (NLR) >4 (HR : 4.04, p=0.044), Y-90 activity (HR: 1.47, p<0.001), perfused volume (HR:1.001, p= 0.008), absorbed tumor Y-90 dose <150 Gy (HR: 3.24, p =0.014). After TARE, urea (HR: 1.02, p= 0.023), AST (HR: 1.02, p< 0.001), ALT (HR: 1.01, p 0.022), alkaline phosphatase (HR :1.01, p= 0.006), GGT (HR: 1.002, p< 0.001), total bilirubin (HR: 1.29, p< 0.001), lactate dehydrogenase (HR: 1.004, p< 0.001), NLR (HR: 1.04, p= 0.002), PLR (HR: 1.006, p= 0.001), and toxicity (HR: 4.35, p= 0.002) were associated with OS. 25 patients died (64.1%). ***Conclusion:*** TARE is a safe therapeutic procedure for the treatment of lmCRC. Prognostic biomarkers include biochemical parameters to factors related to tumor dosimetry.

Aim/Introduction: To analyze the efficacy and safety of treatment by hepatic transarterial radioembolization with yttrium-90 (TARE) of liver metastases from colon cancer (lmCRC). ***Materials and Methods:*** Prospective longitudinal study, which included patients with lmCRC treated by TARE, between November 2015 and October 2023. The therapeutic response at three and six months (RECIST1.1 criteria) by calculating objective tumor response rates (ORR) and disease control (DCR) and toxicities by Common Terminology Criteria for Adverse Events, version 5 were evaluated. ***Results:*** 48 TAREs were performed in 39 patients (age 61.58 ± 8.56 years, 61.5% men). Ten patients (25.6%) underwent surgery for the primary tumor and 27 cases (69.2%) presented liver metastases synchronous with the primary tumor. Prior to TARE, 36 (92.3%) patients had received at least one line and 13 (33.3% patients) received at least 2 lines of QT. The most frequent type of TARE was lobectomy (74.4% cases) followed by segmentectomy and bilobar (12.8%). The average perfused volume was 922.15 ± 553.00 cm3, absorbed dose in the tumor tissue of 207.55 ± 113.90 Gy, and an average tumor-to-normal-liver ratio (TNR) of 27.76 ± 44.47. At 3 months, 3 patients (7.7%) had a complete response (CR), 7 (17.9%) had a partial response (PR), 13 (33.3%) had stable disease (SD) and 16 (41%) patients progressed (PD). This represents an ORR of 25.6% and DCR of 59%. AT 6 months after TARE, there was no CR, 1 patient (2.6%) maintained PR, 8 (20.5%) had EE and 19 (48.7%) patients had PD. The ORR was 2.6% and the DCR was 23.1%. Only, 1 patient presented an acute complication (pain) after the procedure and 12 (30.8%) patients showed some degree of late toxicity, with hyperbilirubinemia being the most frequent toxicity (7 patients, 17.9%), grade 3-4 in 5 patients. (12.8%). ***Conclusion:*** TARE is a safe and effective therapeutic procedure for the treatment of liver metastases from unresectable colorectal carcinoma.

Radioembolization with Yttrium-90 glass microspheres in hepatocellular carcinoma: factors impacting survival

J. Villa-Palacios[1,2], *E. Triviño-Ibáñez[1,2,3], M. López-Garrido[1,4], P. Navarro-Vergara[1,5], A. Rodríguez-Fernández[1,2,3];*
[1]Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [2]Servicio de Medicina Nuclear. Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [3]Instituto de Investigación Biosanitaria ibs, Granada, SPAIN, [4]Unidad de Hepatologia, Servicio de Aparato Digestivo, Hospital Universitario Virgen de las Nieves,

Granada, SPAIN, [5]Unidad de Gestión Clínica de Radiodiagnóstico. Hospital Universitario Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: Transarterial radioembolization (TARE) with yttrium-90 microspheres is an established treatment option for patients with hepatocellular carcinoma (HCC). However, optimization of treatment as well as patient selection remains a challenge. Here we report on the effectiveness and prognostic factors, including dosing methods, associated with TARE for HCC in the prospective observational study. ***Materials and Methods:*** This prospective longitudinal study enrolled 43 consecutive patients with HCC between Jan 2022 and Sep 2023 treated with TARE (glass microspheres). Patient characteristics and treatment-related data were collected at baseline. Therapeutic response at three months (RECIST1.1 criteria) by calculating objective tumor response rates (ORR) and disease control (DCR) was evaluated. Kaplan-Meier and multivariate Cox regression were conducted to identify independent prognostic factors for overall survival (OS). ***Results:*** forty-three TAREs were performed (mean age, 71.52±9.56 years; 62.8% male). The median OS was 20.5 months, the median PFS was 16.1 months. At three months, the objective response rate (ORR) was 73% and the DCR 80%. OS was significantly associated with tumour-absorbed dose >300Gy (p=0.042), NIACE score (p=0.020), presence of cirrhosis (p = 0.007), radiation segmentectomy vs. lobectomy (p< 0.001), target volume <500 cm3 (p=0.008) and % perfuses volume (0.033). ***Conclusion:*** TARE is an effective treatment in patients with HCC. Target volume and tumor dosimetry impact on survival.

Assessment and Safety of High Pulmonary Uptake on Holmium-166 Scout Imaging

E. Vranken[1], *A. De Crop[1], V. Nuttens[2], R. Vandenbulcke[1], T. Dewaele[2], T. Ryckaert[1], J. Decaestecker[1], S. De Meulder[1], P. De Bondt[2];*
[1]AZ Delta, Roeselare, BELGIUM, [2]OLV Ziekenhuis, Aalst, BELGIUM.

Aim/Introduction: Lung shunt assessment during radioembolization (RE) work-up is essential for risk evaluation of radiation pneumonitis. Hereby, either Technetium-99m-macroaggregated-albumin (99mTc-MAA) or Holmium-166 (166Ho) microspheres are administered during hepatic angiography followed by thoraco-abdominal scintigraphy. Safety of use of 166Ho microspheres for scout imaging (166Ho-scout) has been demonstrated in a cohort study, but, to our notice, evaluation of its delivered lung dose has not been described so far. Therefore, a retrospective study in two centres was performed, covering all HCC patients referred for RE between 01/04/2021 and 31/12/2023. Presence of significant lung shunt and lung radiation dose was assessed. ***Materials and Methods:*** All work-up procedures were performed with 166Ho microspheres. Administered activity was based on angiographically determined perfusion territories not exceeding leaflet prescribed maximum activity of 250 MBq. Scintigraphic imaging consisted of planar imaging and tomographic imaging combined with computed tomography (SPECT/CT) covering thoraco-abdominal region. Based on planar and SPECT/CT-images, lung shunt fraction (LSF) was calculated. For patients with significant lung shunt, SPECT/CT assessment was applied to calculate actual and hypothetical maximum 166Ho-scout lung doses. ***Results:*** Twenty-nine HCC patients were evaluated. Twenty-two patients with favourable outcomes during work-up received subsequently 166Ho RE therapy. No significant post-therapy lung shunts were observed afterwards. Seven patients were excluded from 166Ho RE therapy of whom four based on excessive lung shunt. These four patients were suffering from large unresectable HCC (tumour diameter range 13 to 18 cm) in a non-cirrhotic liver without prior liver treatments. Planar LSF averaged 43% (range 29% - 69%). Range of SPECT/CT based LSF was between 10% and 41%. In 3 of these patients visual arteriovenous shunting was already observed during hepatic angiography and lung shunting was confirmed on scout imaging. One patient was identified with real lung shunting on scintigraphy (SPECT/CT based LSF 17%) despite no angiographic abnormalities. Based on effectively injected 166Ho-scout activity in these patients (range 100-200 MBq), mean lung dose of 0,43 Gy (range 0,11 - 0,66 Gy) was calculated. If maximum allowed activity of 250 MBq would have been administered, mean lung dose would be 0,74 Gy (range 0,29 - 1,38 Gy). No pulmonary adverse events related to 166Ho-scout were recorded in follow-up. ***Conclusion:*** This study supports the previously stated hypothesis that 166Ho-scout enables accurate assessment of post-therapy lung shunt and that 166Ho-scout is a safe alternative for 99mTc-MAA prior to SIRT. Despite significant lung shunt, acceptable low lung doses from 166Ho microspheres were demonstrated.

The Objective Response and Disease Control Rates in Patients with Breast Cancer: a Meta-analysis

N. Quartuccio[1], *S. Ialuna[1], V. Militano[2], M. Pappalardo[3], L. Filippi[4], O. Bagni[5], A. M. Moreci[1];*
[1]Nuclear Medicine Unit, Ospedali Riuniti Villa Sofia-Cervello, Palermo, ITALY, [2]Nuclear Medicine Unit, Azienda Ospedaliera "Pugliese-Ciaccio", Catanzaro, ITALY, [3]Division of Plastic Surgery, Università degli Studi di Modena e Reggio Emilia, Modena, ITALY, [4]Nuclear Medicine Unit, Department of Oncohaematology, Fondazione PTV Policlinico Tor Vergata University Hospital, Roma, ITALY, [5]Department of Nuclear Medicine, "Santa Maria Goretti" Hospital, Latina, ITALY.

Aim/Introduction: The aim of this study was to meta-analyze the clinical utility of radioembolization in patients with breast cancer (BC), based on the average objective response rate (ORR) and disease control rate (DCR). ***Materials and Methods:*** A comprehensive literature research through April 2024 in the PubMed/MEDLINE and CENTRAL databases was carried out to retrieve studies with 1) a study cohort or a subset of at least 20 BC patients treated with radioembolization and 2) adequate information on response assessment to derive ORR and DCR. The methodological quality of the studies was assessed by an investigator using the "Quality Assessment of Diagnostic Accuracy Studies" tool, v. 2 (QUADAS-2). Statistical analysis was performed on a per-patient basis; the ORR was calculated as the ratio between the number of patient with complete response (CR) or partial response (PR) over the total number treated with radioembolization; the DCR was calculated as the ratio between the number of patient with CR, PR or stable disease (SD) over the total number treated with radioembolization. The I2 statistic was used to measure the degree of inconsistency across the studies, with values of 25%, 50%, and 75% representing thresholds for low, moderate, and high heterogeneity. Interpretation of heterogeneity was carried out at a significance level of p=0.05. A random-effects model was used for statistical pooling. ***Results:*** Eighteen studies were eligible for the calculation of the OOR and DCR: 10 studies included resin spheres, 4 studies used glass spheres and the remaining studies used both types of spheres in their patient cohorts. The risk of bias resulted low in most of the studies. In the all patients group (n=650) ,ORR resulted 50.71% (95% C.I.: 40.04 - 61.36; I2: 87%); DCR resulted 88.37% (95% C.I.:

81.89 - 93.57; I2: 82%). Taking into account only resin spheres (395 patients), the ORR was 60.35% (95% C.I.: 46.55 - 73.36; I2: 87%) and the DCR was 92.73% % (95% C.I.: 87.17 - 96.80; I2: 71%). Considering glass spheres (144 patients), the ORR was 32.38% (95% C.I.: 18.43 - 48.16; I2: 72%) and the DCR was 82.69% % (95% C.I.: 59.29 - 97.26; I2: 90%). ***Conclusion:*** The present meta-analysis favors the use of radioembolization in patients with breast cancer. In patients with BC, radioembolization provides good ORR and DCR either with resin or glass spheres.

EP-0632

Selective Internal Radiation Therapy With Microspheres Labeled With Holmium 166 In Liver Tumors: Experience In Our Center

J. Deportos, *S. Lafuente-Carrasco, J. Sampere-Moragues, G. Tovar-Felice, V. Benito-Santamaria, D. Tovar-Felice, F. Pardo-Aranda, D. Balaguer-Paniagua, L. Layos, M. Bermudez-Ramos, S. Ruiz-Llama, L. Prats-Cabaces, R. Benito-Paredes, J. Cordero-Ramajo, G. Moragas;*
H.Germans Trias i Pujol, 08917, SPAIN.

Aim/Introduction: To assess the absorbed doses and tumor response in treatments with 166Ho-labeled microspheres (166Ho-microspheres) in patients with liver tumors. ***Materials and Methods:*** Between December 2018 and January 2024, 39 selective internal radiation therapies (SIRT) with 166Ho-microspheres were performed in 38 patients with liver tumors ; one of them received two treatments with 166Ho-microspheres (14 women / 24 men; 28 - 84 years; 15 cholangiocarcinomas, 18 hepatocellular carcinomas, 3 liver metastases from colon cancer, one liver metastasis from a neuroendocrine tumor and one giant hepatic adenoma). Treatment planning was carried out with albumin macroaggregates labeled with Technetium 99 or with 166Ho-microspheres. Planning images were acquired the day of the administration using a hybrid gamma camera. Treatment doses were calculated using a single-compartment model or personalized dosimetry. The images of the treatments with 166Ho-microspheres were acquired the day after administration and the dosimetries were evaluated using the dosimetric software. Follow-up was performed 3 and 6 months after treatment using CT and/or MRI. ***Results:*** Average absorbed doses in target volumes: 52 - 563 Gy. 7 patients presented lesion progression at 6 months. 8 patients presented extralesional progression at 6 months. 7 patients presented partial response or stable disease at 6 months and underwent surgery with curative intent. 4 patients presented partial response after 6 months. 1 patient presented complete response after 6 months. 1 patient presented stable disease at 6 months. 8 patients are waiting follow-up at 6 months. 2 patients lost follow-up at 6 months. ***Conclusion:*** SIRT with 166Ho-microspheres is a safe and well-tolerated technique as a bridge to surgery and/or to treat liver tumors.

EP-0633

Mean tumour absorbed dose in the response assessment of transarterial radioembolization with 90Y-resin microspheres

S. Bondia-Bescós[1], *J. Martín-Marcuartu[1], J. Vercher-Conejero[1], G. Reynés-Llompart[2], R. Martin-Vaello[2], A. Bagán-Trejo[1], B. Hervás-Sanz[1], J. Díaz-Moreno[1], M. Zamorano-Rivas[1], M. Pudis[1], L. Gràcia-Sánchez[1], P. Notta[1], C. Martínez-Ramos[1], E. Alba-Rey[3], J. Valcarcel-Jose[3], E. Serrano-Alcala[3], B. Gener-Laquidain[3], M. Cortés-Romera[1];*
[1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital, Barcelona, SPAIN, [2]Phisicist Department, Institut Català d'Oncología, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN, [3]Interventional Radiology Unit, Radiology Service, Bellvitge University Hospital, L'Hospitalet de Llobregat, Barcelona, SPAIN.

Aim/Introduction: Transarterial Radioembolization (TARE) is a locoregional radiation therapy for inoperable liver lesions that has demonstrated an embolic and biologic effects, but the clinical results have been variable between patients, therefore a better understanding of the dose-response is still necessary. The aim of this study was to evaluate the role of the mean tumour absorbed dose in 90Y-TARE as predictor of response and survival in benign and malignant neoplasms. ***Materials and Methods:*** Retrospective analysis of 20 patients affected by hepatocarcinoma (n=17) and colorectal metastasis (n=3) treated with 90Y-resin microspheres in our centre. Planification and treatment were carried out with m99Tc-MAA/90Y-resin. The activity and the absorbed dose (AD) were computed during planification (partition model) and after TARE (voxel-based model). Response assessment (RA) was obtained with morphological parameters. Statistical analysis was performed to evaluate the differences in mean tumour absorbed dose between the different responders [partial response (PR), complete response (CR)] with Wilcoxon test. Overall survival (OS) and progression free survival (PFS) were analysed, and a Cox regression was fitted using the tumour absorbed dose to obtain the hazard ratios (HZ). To obtain a dose threshold a binomial model was fitted and used in a receiver operating characteristic curve, and a threshold of 100% sensitivity for response was used as a criterion to find a minimum absorbed dose limit. Using this limit a Kaplan-Meier survival analysis (KP) was performed. The absorbed dose was log-transformed for fitting model assumptions. ***Results:*** The following values were recorded: Planned activity 3.47GBq[1.50GBq-9.00GBq], administered 3.03GBq[0.90GBq-9.27GBq]. AD planning vs treatment: tumour 395.84Gy[74.82Gy-1137.59Gy] vs 237.70Gy[50.78Gy-493.20Gy]; lungs 6.09Gy[0.1Gy-23.49Gy] vs 1.06Gy[0.00Gy-13.24Gy]. The RA observed were PR=14p and CR=6p. The mean tumour AD for PR and CR were 187±121Gy and 332±102Gy (p=0.002) respectively. An AD threshold of 183.5± 75 Gy was found. Kaplan-Meier analysis using the threshold showed a difference of mean progression time of 23 months for PR vs 34 months for CR (p = 0.052). ***Conclusion:*** Our experience confirms the efficacy of 90Y-resin microspheres in malignant tumours, obtaining high doses during planification and assuming high therapeutic doses. The mean AD was significantly different when comparing patients with PR and CR. In both cases, the mean AD was higher than others described in the literature. In our cohort, the optimal cut-off value for complete response and better survival was obtained for AD 332±102Gy. ***References:*** Weber M, Lam M, Chiesa C, et al. Eur J Nucl Med Mol Imaging. 2022;49(5):1682-1699

EP-0634

Ablative Trans-Arterial Radioembolization (TARE) of Hepatic Metastases with Yttrium (^{90}Y) Resin Microspheres

C. Schneider, *T. R. Baetens, L. W. van Golen, R. G. H. Beets-Tan, F. M. Gómez Muñoz, T. Helmberger, B. J. de Wit-van der Veen, E. G. Klompenhouwer;*
Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Aim/Introduction: Ablative TARE of hepatic metastases with 90Y glass microspheres is associated with high disease control rates and minimal toxicity. We evaluated the safety and initial efficacy of ablative TARE with Y-90 resin microspheres. ***Materials and Methods:*** This retrospective study, approved by the

institutional review-board, examined 15 patients with hepatic metastases treated in the Netherlands Cancer Institute. Patients were included if aimed tumor dose was ≥200 Gy, determined by partition dosimetry, and had a minimal follow-up of three months. Primary outcomes were target tumor response at three months using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1 and clinical and biochemical toxicity in the first three months after TARE using the National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) v5.0. Secondary outcomes were time to progression (TTP) of target lesions and overall survival (OS), estimated by the Kaplan-Meier method. ***Results:*** Fifteen patients underwent ablative TARE with a median target tumor dose of 200 Gy (range, 200-350 Gy). The median follow-up was 11 months (range 2-52 months). Nine (60%) patients had a liver tumour burden of <25% and six patients (40%) had a liver tumour burden of 25-50%. The median index tumor size was 6.5 cm (range 3.9-15.8 cm) and 23 target lesions were identified for response assessment. The median age was 59 years and hepatic metastases included metastases from colorectal cancer (80%), neuroendocrine tumors (13.3%) and breast cancer (6.7%). The most common clinical grade 1-2 toxicities were fatigue (53.3%), abdominal pain (46.7%) and nausea (40.0%). One (6.7%) patient experienced a clinical grade 3 toxicity of fatigue. Six (40%) patients experienced a grade 3-4 biochemical toxicity, of which one (6.7%) patient had a neutropenia and five (33.3%) patients had increased gamma-glutamyl transpeptidase (GGT). The disease control rate at 3 months follow-up was 93% (47% partial response, 47% stable disease, 7% progressive disease). The median OS was 25.0 months (95% CI 8.9-41.1) and the mean TTP was 26.4 months (95% CI, 22.0-30.9 months). ***Conclusion:*** Ablative TARE with 90Y resin microspheres shows a high disease control rate with clinically acceptable toxicity in the treatment of hepatic metastases. Further 90Y PET post-treatment dosimetry is required to investigate dose distribution and its effects on response and toxicity.

EP-0635

Inter- and intraobserver variability in tumor segmentation for selective internal radiation therapie (SIRT) using contrast-enhanced SPECT/CT: Implications for treatment planning and predictive dosimetry

***A. Fuchs*[1],** *F. Eilers*[2], *F. Schaeg*[1], *C. Duhme*[2], *A. Wegener*[3], *I. Asmus*[1], *P. Kies*[1], *M. Masthoff*[4], *K. Rahbar*[1], *X. Jiang*[2], *M. Köhler*[4], *L. Stegger*[1]; [1]*University Hospital Münster, Department of Nuclear Medicine, Münster, GERMANY,* [2]*University of Münster, Department of Computer Science, Münster, GERMANY,* [3]*University of Münster, Department of Mathematics, Münster, GERMANY,* [4]*University Hospital Münster, Department of Radiology, Münster, GERMANY.*

Aim/Introduction: Liver cancer poses a global challenge. Selective internal radiation therapy (SIRT) with 90Y-resin spheres is an established therapy for inoperable tumors. However, image-guided planning with 99mTc-MAA and predictive dosimetry needs segmentation of liver lobes and tumor manifestations. This process is error-prone, affecting achieved dose and thereby outcome. In this study, contrast-enhanced CT was used together with SPECT in order to optimize tumor visibility. The inter- and intraobserver variability of tumor segmentation was evaluated as well as its impact on the the resulting tumor dose. ***Materials and Methods:*** A cohort of 19 patients were evaluated for SIRT, each presenting with 1-14 liver tumor manifestations of diverse primary origins. Patients were injected with 99mTc-MAA particles via a catheter placed in the liver arteries or its branches. A biphasic contrast-enhanced CT of the liver was acquired together with the SPECT. Two experienced nuclear medicine professionals and one medical student segmented the tumors in both lobes using SurePlan Liver Y90TM (MIM Software Inc.). The student additionally performed a repeat segmentation after three months. For the analysis of the inter- and intraobserver variability of segmentation, the Dice Similarity Coefficient (DSC), twice the overlapping volume divided by the sum of the two individual volumes, was calculated for each segmentation pair. For all segmentations, the predictive dose for tumor and normal-liver was calculated using the partition model. The deviations in tumor dose, caused by segmentation mismatch, was calculated from this data in order to assess the impact of inter- and intraobserver segmentation variability. ***Results:*** Interobserver analysis revealed mean DSC values of 0.73, 0.74, and 0.75, the intraobserver analysis a mean DSC of 0.79, i.e. intraobserver segmentations overlapped more than interobserver segmentations without a clear difference between expert and beginner observers. In comparison to the observer with the highest achieved tumor dose, the segmentations of the other two observers lead to 11% less tumor dose on average. Interestingly, DSC did not correlate with dose deviation. ***Conclusion:*** Even when using biphasic contrast-enhanced CT for improved tumor visibility, a significant inter- and intraobserver variability in tumor segmentation was seen for both expert and beginner observers. The resulting differences in predicted tumor dose as observed in this study give an indication of the size of the error made during predictive dosimetry that is caused by inexact tumor delineation. This error should be kept in mind when deciding on injected activity on the basis of predictive dosimetry.

No Association of Preablation Thyroglobulin Antibody Positivity and Outcome in Patients with Diffuse Sclerosing Papillary Thyroid Carcinoma

L. Yang, *P. Dong, L. Xiao, L. Li;*
Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: This study was designed to evaluate the relationship between preablation thyroglobulin antibody (TgAb) positivity and clinical outcomes in patients with diffuse sclerosing papillary thyroid carcinoma (DS-PTC). ***Materials and Methods:*** In the period 2009-2023, all consecutive DS-PTC patients who underwent total thyroidectomy and radioiodine ablation at a tertiary hospital in southwestern China were retrospectively included. TgAb was measured before remnant ablation. Tumor characteristics and long-term outcomes were compared between TgAb-positive and TgAb-negative patients. ***Results:*** Forty-nine patients were analyzed. Preablation TgAb positivity was presented in 55.1% of patients. Tumor characteristics, lymph node metastases, and median duration of follow-up were similar between TgAb-positive and -negative patients. During follow-up, the percentage of patients with either surgical reintervention for lymph node metastases (3.7% vs 0.0%, P = 1.000) or repeated 131I therapy (14.8% vs 9.0%, P = 0.256) was similar between TgAb-positive and -negative patients. At the final follow-up visit, the rates of structural disease did

not differ between the two groups (11.1% vs 18.2%, P = 0.769). ***Conclusion:*** This study highlights no association of preablation TgAb positivity and clinical outcome in patients with DS-PTC.

EP-0637

Treatment Outcome ofAdjunctivePotassium Iodideinthe Radioactive IodineTreatment of Severe Hyperthyroidism. A Randomized Trial

J. Liu;
The First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: This study aimed to explore the application value of Adjunctive potassium iodide in the treatment of severe hyperthyroidism with Radioactive Iodine(131I). ***Materials and Methods:*** Sixty-two patients with severe hyperthyroidism who were to be treated with 131I were randomly divided into the experimental group (31 cases of oral potassium iodide group) and the control group (31 cases of oral antithyroid drugs [ATDs] group). The differences in serum free T3 (FT3) and free T4 (FT4) 1 month after 131I treatment, the side effects, and the prognosis were compared between the two groups. ***Results:*** Comparison results indicated an insignificant difference in serum FT3 and FT4 between the experimental and control groups (FT3: P = 0.647; FT4: P = 0.176). In 31 patients treated with potassium iodide, leukopenia, impairment of liver and kidney function, and anaphylaxis were not found, or preexisting but not worsening symptoms were found. In 31 patients treated with ATDs, There was 1 case of new leukopenia, 1 case of liver function impairment and 1 case of mild drug allergy. Leukopenia was observed in one patient before iodine-131 treatment and worsened after iodine-131 treatment with ATDs, One patient had liver function injury before iodine-131 treatment, and increased liver function injury after iodine-131 adjuvant MMI treatment. the remission rate between the experimental and control groups was insignificantly different (P = 0.059), and the effective rate was 100%. ***Conclusion:*** The effect of potassium iodide on reducing thyroid hormone level and prognosis in the treatment of severe hyperthyroidism with 131I was insignificantly different from that of ATDs. However, the side effects were less than those of ATDs, and potassium iodide played an important role in the radioactive iodine treatment of severe hyperthyroidism.

EP-0638

Relationship Between Factors in the Treatment Process of Xerostomia Developed Due to I-131 Therapy

R. Tokac[1], *A. Alakbarli[2], I. Durusoy Onmus[2], A. Akgun[2];*
[1]Ege University, Izmir, TÜRKIYE, [2]Ege University, İzmir, TÜRKIYE.

Aim/Introduction: I-131 therapy administered in patients with differentiated thyroid carcinoma (DTC) causes damage to the salivary glands. Approximately 40% of patients develop long-term xerostomia after treatment. In this study, we aimed to compare complaints related to salivary glands in patients who received I-131 therapy with gender, I-131 dose, use of chewing gum, lemon, and findings of I-131 whole-body scanning (WBS). ***Materials and Methods:*** Symptoms of salivary gland damage in 101 patients with DTC who received I-131 therapy between 2004 and 2021 were retrospectively queried, including dry mouth, taste disturbance, incresed water intake during meals, and presence of swelling in salivary gland areas. The use of chewing gum, and lemon during treatment was noted. WBS findings obtained post-therapy and at 9-12 months were evaluated, and asymmetric salivary gland uptake was considered positive. The relationship between patient complaints and gender, I-131 dose, use of chewing gum-lemon during treatment, and WBS findings were statistically evaluated. ***Results:*** The ages of the patients ranged from 9 to 72 years, with 79 females and 22 males. Patients received a cumulative I-131 dose ranging from 30 to 550 mCi (mean: 97.5 mCi ± 76.8). I-131 therapy was administered 1 to 3 times. During treatment, 53 (52.5%) patients had a history of chewing gum, and 50 (49.5%) had a history of lemon use. Complaints included dry mouth in 26 patients (25.7%), swelling in salivary gland areas in 17 patients (16.8%), incresed water intake during meals in 22 patients (21.8%), and taste disturbance in 21 patients (20.8%). Asymmetric uptake in salivary glands was found in 5 patients (4.9%) on post-therapy WBS and in 21 patients (20.8%) on WBS at 9-12 months. There was a significant correlation between post-therapy I-131 WBS findings and dry mouth ($p < 0.05$). There was no significant link found between WBS results and swelling in salivary glands, incresed water intake during meals, or taste disturbance complaints. Similarly, no significant associations were observed between total I-131 dose, chewing gum or lemon Usage, patient gender, and reported complaints. ***Conclusion:*** In this study, a relationship was demonstrated between dry mouth complaints and WBS findings, but no relationship was found between other xerostomia complaints and WBS findings. There is no relationship between the total I-131 dose and xerostomia findings. The recommended use of lemon and chewing gum during patient admission was found to be ineffective in preventing xerostomia development.

EP-0639

Evaluation of response to radioiodine therapy in thyroid oncocytic carcinoma patients, a single center experience from Iran

A. Aghaee, *S. Zakavi, E. Askari, F. Karamian;*
Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Thyroid oncocytic carcinoma, also known as Hürthle cell carcinoma (HCC), is a rare subtype of thyroid cancer with unique characteristics. Radioiodine therapy, while less effective for HCC due to poor radioiodine accumulation in tumors, has shown improved survival rates for tumors larger than 2 cm. Adjuvant radioiodine therapy is recommended in certain cases, particularly for older patients with a worse prognosis. ***Materials and Methods:*** This study reviewed data from 18 HCC cases compared to the overall patient population (OPP) at Qaem Hospital's nuclear medicine department. ***Results:*** The mean age at diagnosis was higher for HCC patients compared to OPP, with varying responses to therapy observed. Assessment of response to therapy after one year revealed 26.7%, 20%, 20%, and 33.3% of HCC patients with excellent, indeterminate, biochemical incomplete, and structural incomplete responses, which were 41.5%, 24.7%, 13%, and 20.7% in OPP, respectively. The Kaplan curve of patient survival showed an average of 100±13.5 months. ***Conclusion:*** Approximately 44% of HCC patients showed excellent survival outcomes after radioiodine therapy, highlighting its importance as a treatment option for HCC. Further research is needed to optimize treatment choices and improve patient outcomes in this less common subtype of thyroid cancer.

EP-0640

Long-term therapeutic morbidity in patients treated for Differentiated Thyroid Cancer

A. Savchenko[1], *E. Radzyshevska[2], G. Grushka[1];*

[1]V. N. Karazin Kharkiv National University, Kharkiv, UKRAINE,
[2]Kharkiv National Medical University, Kharkiv, UKRAINE.

Aim/Introduction: The standard strategy of special treatment of differentiated thyroid cancer (DTC) consists of surgery, radionuclide therapy and hormone therapy being sequentially applied. Theoretically, each component of the treatment process can cause adverse somatic consequences in future, the study of which can help to prevent and correct them. Our aim was to evaluate possible long-term effects of the treatment of DTC in the form of the therapeutic pathologies on the basis of follow-up data of long-term observation using sophisticated information technologies. ***Materials and Methods:*** The study was based on follow-up data of 157 individuals who were undergoing combination treatment of DTC at the Institute clinic from 1993 to 2015, received it in full and underwent regular screening examinations after treatment. The database created for the study contained, as much as possible, digitized arrays of follow-up data of paper case-records on the disease and its consequences in patients with a follow-up period exceeding 12 years after special treatment. Wiz Why packages (Data Mining category) and the general purpose software package STATISTICA were used to make hypotheses and test them. ***Results:*** According to a retrospective case-control analysis, it was found that in the long term after treatment of DTC the number of cases of coronary heart disease increased by 1.3 times. Provocative factors of this increase is radioiodine therapy and the duration of suppressive hormone therapy, which exceeds 6 months. Also, a comprehensive analysis revealed a statistically significant increase of urological system (US) disease cases within the period of 3.75 - 4.8 years after special treatment. It was shown that the total number of US pathologies was 2.04 times higher in comparison with US incidence before the special treatment. The total onset frequency of gallbladder, liver and pancreas disorders was increased by a factor of 1.6 in a statistically significant manner in DTC patients. Patients initially presenting gallbladder disorders received shorter cures of hormone therapy (4 versus 13 months), and lower levels of L-thyroxine in a context of uncompensated hypothyroidism (2.3 versus 3.5 mg/kg). A statistically significant relation was established between the total duration of breastfeeding in women presenting metabolic health disorders, and onset of liver pathology (essentially non-alcoholic steatohepatitis). ***Conclusion:*** The foregoing allows us to state that a reasonable element of post-treatment screening of patients who have undergone special treatment for DTC should be a mandatory comprehensive regular therapeutic study.

EP-0641

What is the optimal number of lymph nodes to resect in papillary thyroid carcinoma? - hints from the SEER database

B. Schemmer, *M. Essler;*
Uniklinik Bonn, Bonn, GERMANY.

Aim/Introduction: Radioiodine therapy is currently regarded as expendable by some, especially in lower tumor stages, and widely regarded as indispensable in metastasized disease.While we could already show that the side effects of radioiodine therapy are limited, we wondered whether its full potential is already being realized.Since surgery is one of the cornerstones of curative therapy we wanted to see whether there are improvements to be made in the interplay of surgical resection and radioiodine therapy.Here we focus on the optimal number of lymph nodes to resect. ***Materials and Methods:*** We searched the SEER Research Plus Data, 8 Registries, Nov 2023 Sub (1975-2021), released April 2024, based on the November 2023 submission. Included were papillary thyroid carcinomas with ICD-O-3 8260/3.Cause-Specific-Survival was calculated for Tumorsizes 0, 1-10, 10-20, 20-40 and 40+ mm respectively with examined vs. positive lymphnodes as X and Y axis. ***Results:*** Small tumors almost never have lymphnode metastasis, unless they do. Distant metastasized tumors almost always have lymphnode metastasis, unless they don't. The number of lymophnode metastasis is not easily determined by tumor size. There is however a correlation between the number of positive and examined lymphnodes where as if examined lymphnodes > positive lymphnodes prognosis is always better than if examined = positive nodes (true for positive lymphnodes < 6) hinting at the possibility that positive lymphnodes were missed initially. However even excessive resection of lymphnodes does not improve prognosis.In this dataset the resection of positive lymphnodes + 1 generally already leads to the best prognosis. Due to the small populations (at most 1435 patients) in every comparison the results are not significant, however the effect is consistent throughout the different tumor sizes. ***Conclusion:*** Removing healthy lymphnodes while leaving metastasis is likely detrimental to patient health- Removing an excessive amount of lymphnodes likely provides no advantage for the patient - It is unlikely that the correct number of lymphnode metastasis can be found by resection alone - In this dataset outcome for patients where metastasis + 1 lymphnode are removed is better than if all resected lymphnodes are positive - It seems reasonable that determining the optimal number of lymphnodes to be resected before actually doing so could provide the patient with a curative treatment - Determining the correct number of lymphnodes to be resected likely requires imaging, be it in the form of 124-I and FDG-PET/CT or 131-I therapy.

EP-0642

Evaluation of quality parameters in the clinical pathway of treatment with I-131 in differentiated thyroid cancer

C. Villaprado, *N. Cruz, A. Barrera, A. Alomar, I. Blanco, N. Rudic, P. Boya, F. Lozada, M. Ribelles, E. Goñi, A. Camarero, L. Paruta, N. Izcue;*
Hospital Universitario de Navarra, Pamplona, SPAIN.

Aim/Introduction: A clinical pathway (CPW) is a management tool that allows for periodic evaluation of the quality of care, improving the trasmission of information to the patient, their subjetive apreciation of the clinical process and safety, the optimization of resources and the updated training of professionals. The objective of a CPW is to reduce the variabiliity in care and help in decision making, based on a multidiciplinary approach in which the sequence of interventions of the healthcare professional involved is detailed. After the planning, development, and implementation of a CPW for the metabolic therapy with I-131 in differentiated thyroid cancer (DTC) at hospital, the aim was to meet the quality objectives in ≥ 80% of patients and to identify areas for improvement. ***Materials and Methods:*** During the implementation (2019-2024), data from the CPW and satisfaction surveys from all patients with DTC and an indication for post-surgical therapy with I-131 was analyzed. We evaluated the fulfillment of following time interval objectives: surgery to I-131 administration <4 months; Nuclear Medicine appointment to I-131 administration <2 months. Other objetives were median hospital stay 1-3 days and a global patient satisfaction index >8 (scale 1 to 10). ***Results:*** CPW of 170 patients were analyzed, 112 women (65.9 %) with a median age of 53 years. 154 (91%) had papillary carcinoma; 16 (9%) follicular carcinoma. 127 patients

(74.7%) stage 1, 30 patients (17,6%) stage 2, 5 (2.9%) stage 3, and 8 (4.7%) stage 4. The dose of 131-I administered was 1.11-7.4 GBq. The median surgery to I-131 administration was 115.28 days (27-460), meeting the objective in 159 patients (93.5%). The median Nuclear Medicine appointment to I-131 administration was 37.72 days (13-171), meeting the objective in 150 patients (88.2%). In pre-treatment appointment 24 patients (14.11%) presented variations in healthcare; being the most frequent due to concurrent clinical process and language barriers. During hospitalization 17 patients (10%), showed clinical variations, most due to the appearance of concomitant pathology. The median hospital stay was 2.04 days (1-8). Satisfaction surveys were collected from a total of 72 patients. Overall, 92% of patients assessed their care with 8-10 points. ***Conclusion:*** All the quality objectives met. Most frequent variability registered is inherent to the patient and therefore unavoidable.

EP-0643

Dynamic risk stratification and analysis of influencing factors in patients with differentiated thyroid cancer following radioiodine therapy

G. Sipka, *G. Fricz, S. Nagy, Z. Mikó, A. Bakos, T. Czékus, I. Farkas, L. Pávics, Z. Besenyi;*
University of Szeged, Department of Nuclear Medicine, Szeged, HUNGARY.

Aim/Introduction: Dynamic risk stratification, with tailored treatment and follow-up recommendations, is currently the cornerstone of thyroid cancer management. The aim of our study was to investigate and confirm known and novel factors that may have a prognostic impact by influencing risk assessment in the local patient population. ***Materials and Methods:*** In our retrospective study, we selected 139 patients with differentiated thyroid cancer (34 men, 105 women, mean age 50 years) who received high-dose radioiodine treatment between 2016 and 2021. These patients participated in a follow-up study at both 6 and 12 months after the initial treatment. In total, the effects of 35 different oncological and pathological factors were evaluated separately on biochemical and structural responses (ultrasound, iodine whole body SPECT/CT) and combined them to assess dynamic risk stratification. ***Results:*** Of the 139 patients, 120 had papillary, 15 had follicular, and 4 had oncocytic thyroid cancer. Significantly better prognosis was observed in patients with papillary type thyroid cancer (Chi-squared, p=0.005) and without lymph node metastasis (Mann-Whitney, p=0.0128). Primary histological thyroiditis, which is not part of conventional risk assessment, showed significant differences by tumour markers (Mann-Whitney; p<0.0001), and unexpectedly, anti-thyroglobulin was found to be more sensitive for monitoring disease progression (Wilcoxon test; p=0.002). Surprisingly, primary T-stage, lympho-vascular infiltration, and dose did not affect dynamic risk stratification. The overall success rate was over 75% in the low- and medium-risk groups and over 60% in the high-risk population. In low- and intermediate-risk patients, a significant, sustained improvement in therapeutic outcome was observed at 6 and 12 months; however, in high-risk cases, this sustained improvement was not seen after the 6-month mark. ***Conclusion:*** Our findings suggest that histological thyroiditis, a previously underrepresented factor, might play a significant role in both initial risk estimation and dynamic risk stratification. The prognostic potential of anti-thyroglobulin was notably superior to general tumour markers in cases of thyroid inflammation and among high-malignant-risk patients. Unlike primary tumour size, initial histology and metastatic tendency emerged as key prognostic factors. Moreover, the high-risk group exhibited a significantly lower rate of substantial improvement after 6 months compared to lower-risk patients, indicating the potential benefit of initiating alternative therapeutic interventions promptly after 6 months following radioiodine ablation in cases of incomplete response. This highlights the importance of time in high-risk cases and suggests that alternative interventions should be used earlier in non-responders.

EP-0644

The optimal thyroglobulin cut off for detecting FDG-avid disease in TENIS syndrome in a resource constrained setting

N. Ndlovu, *N. Madi, T. Nxasana, L. Gabela, L. Harry, S. Masikane, M. Patel, V. Pillay, B. Hadebe, M. Vorster;*
Inkosi Albert Luthuli Central Hospital (University of KwaZulu Natal), Durban, SOUTH AFRICA.

Aim/Introduction: Differentiated thyroid cancer (DTC) has a good prognosis, with a 10-year survival rate ranging from 85% to 99%. However, 20-30% of papillary and follicular thyroid cancers may de-differentiate and lose the sodium-iodine symporter (NIS) expression, leading to thyroglobulin-elevated negative iodine scintigraphy (TENIS) syndrome. Thyroglobulin (Tg) is a glycoprotein synthesized by thryocytes. ATA-guidelines postulate ,a postoperative Tg value greater than 10ng/ml suggests potential persistent or recurrent disease, metastases or unsuccessful I-131 ablation, requiring further evaluation. One of the investigations includes ^{18}F-FDG PET-CT. 18F-FDG PET-CT imaging is costly and not a feasible option for resource limited centers such as ours. The study aimed to assess the prevalence of TENIS syndrome in our setting and to determine the optimal thyroglobulin level for detecting FDG-avid disease in TENIS syndrome. ***Materials and Methods:*** A retrospective analysis of 62/70 patients with proven differentiated thyroid cancer (Papillary or follicular) who developed TENIS syndrome who underwent 18F-FDG PET/CT to rule out dedifferentiation from 2016-2024 was carried out. Patients had follow-up whole body Iodine scans and serum thyroglobulin tests were with TSH stimulation.8 patients were excluded from the analysis: medullary and anaplastic histopathology and anti-thyroid antibodies >20. T-test or Wilcoxon were used to assess the distribution between two independent groups, mean or median differences. To determine association between categorical variables, a Chi-Square test was used. Sensitivity and specificity analysis were used to determine optimal cut off points of numeric predictors of metastasis. ***Results:*** Sixtry-two patients had a median age of 59 range (14.0-81. years), 76% were females. 45%had follicular and 59% had papillary thyroid cancer. The use of ^{18}F-FDG PET-CT showed 38 patients (60%) with ^{18}F-FDG avid metastases suggesting dedifferentiation. 27% had lung metastases whilst 27% had cervical lymph node metastases. The median thyroglobulin level during the time of the ^{18}F-FDG PET/CT was 52ng/ml. 23 of the 38 patients with positive FDG had Tg > 30ng/ml. Thyrogloblin levels were significantly higher in patients with positive ^{18}F-FDG than patients with a negative PET, median(Q1-Q3) Tg 79.9(32.9-1080) ng/ml for ^{18}F-FDG positive and 34.3(16.5-73.9) ng/ml for ^{18}F-FDG negative p=0.035. The optimal cut-off point for detecting positive ^{18}F-FDG was 30ng/ml youden 0.213 with a sensitivity of 74% and specificity 48%. ***Conclusion:*** In this study, the probability of ^{18}F-FDG avid disease suggesting de-differentiated thyroid cancer is higher when thyroglobulin is >30 ng/ml. Therefore, in resource constrained settings, performing ^{18}F-FDG when Tg is more than 30ng/ml is advisable compared to the recommended 10ng/ml.

EP-0645

X2X2

V. Bingali, *S. Sundaram P;*
Amrita Institute Of Medical Sciences, Kochi, INDIA.

Aim/Introduction: The aim of this study was to validate the effectiveness of dynamic risk stratification (DRS) in predicting structural progression in patients with differentiated thyroid cancer (DTC). ***Materials and Methods:*** This is a retrospective cross-sectional study in which we evaluated 100 patients (M:F 26:74) for a median of 3 years having differentiated thyroid cancer after total thyroidectomy and radioactive iodine remnant ablation in our department. As part of the initial staging, patients were categorized into three ATA risk categories: low, intermediate, and high. This information was then compared to the outcomes of dynamic risk stratification based on therapeutic response after six to twelve months following radioiodine ablation and the most recent visit, including whole body radioiodine scan, thyroid ultrasonography, anti-thyroglobulin antibody, and thyroglobulin level. These measures allowed for the division of subjects into four groups: excellent response (ER), incomplete structural response (ISR), incomplete biochemical response (IBR), and indeterminate response (IR). The ATA and DRS risk classification results were compared with clinical outcome. ***Results:*** Twenty patients were classified as high-risk, 15 patients as intermediate-risk, and 65 patients as low-risk at baseline. After 6 to 12 months of radioiodine ablation, 64.6% of patients in the low-risk group showed signs of ER response, 7.6% showed IBR response, 6.1% showed ISR response, and 21.5% showed IR response. In the intermediate-risk group, the following responses were noted: ER in 46.6% of patients, IBR in 13.3%, ISR in 20%, and IR in 20%. In the high-risk group, 40% of patients had ER response, 55% had ISR response, 5% had IBR response, and none had IR response. At the time of the last visit, 15.3% of ATA low risk, 26.6% of intermediate, and 55% of high risk had persistent disease. whereas according to dynamic risk stratification, of people who had excellent responses, only 2.3 % of low risk and 12.5 % of high-risk had persistent disease, and none were in the intermediate risk group. The combined use of the ATA and the DRS systems was statistically significant to predict the persistent disease (P< 0.00001). ***Conclusion:*** The use of dynamic risk classification in the follow-up of patients with differentiated thyroid carcinoma has shown improved accuracy in predicting disease progression and tailoring individualized treatment plans. Furthermore, through the refinement of initial ATA risk estimations based on response evaluation to radioiodine therapy, a more precise dynamic risk assessment is achieved, enabling tailored and effective ongoing follow-up care.

EP-0646

Are Differentiated Thyroid Cancer patients presenting with biochemical only evidence of disease receiving additional radioiodine therapy doomed to develop structural disease in the future?

S. Ramos Barata[1], *M. S. Serranito[2], A. Albuquerque[1], G. Costa[1];*
[1]Nuclear Medicine Department, Unidade Local de Saúde de Coimbra/Hospitais da Universidade de Coimbra, Coimbra, PORTUGAL, [2]Endocrinology, Diabetes and Metabolism Department, Hospital Curry Cabral - ULS São José, Lisbon, PORTUGAL.

Aim/Introduction: Additional radioiodine therapy (RAI-Tx) may be considered in patients with differentiated thyroid cancer (DTC) who underwent first-line treatment with total thyroidectomy and RAI-Tx. However, evidence fails to definitively underscore the benefits of this decision in patients with positive tumour marker but without evidence of disease in the imaging procedures. This study aimed to access the DTC patient's outcomes (tumour marker evolution and occurrence of structural disease), presenting with negative imaging but receiving additional RAI-Tx due to biochemical evidence of disease and having negative post-treatment whole-body scan (ptWBS). ***Materials and Methods:*** This retrospective study included DTC patients, that underwent additional RAI-Tx between 02/2009 and 12/2022, after the first-line treatment. We selected patients with biochemical disease but in whom imaging procedures, including ptWBS, failed to identify the source of the tumor marker. Demographic data and thyroglobulin(Tg) and anti-Tg-antibody(TgAb) values before, at the time of treatment and 12 months after treatment were collected. The occurrence of structural disease during follow-up was documented. Statistical analysis was conducted using SPSS-Statistics v.27.0 software. P values<0.05 were considered statistically significant. ***Results:*** Fifteen patients (10 female; mean age: 51.07±11.79y) met the criteria for inclusion in the study. The median follow-up was 156 (IQR 130) months. For patients with high Tg and without positive TgAb (n=11), the median Tg was 4.70ng/mL (IQR 22.50, range 1.60-75.0). In the 4 patients with positive TgAb, the median TgAb was 538.0UI/mL (IQR 475.5, range 331.0-538.0). The median TSH stimulated Tg at treatment was 33ng/mL (IQR 142, range 3.1-780.0) in negative TgAb patients. At the 1-year follow-up, there was a median increase in Tg of 1.36ng/mL in negative TgAb patients, nevertheless, this change was not statistically significant (p=0.44). For patients with positive TgAb, a median reduction of 206.5UI/mL was noted, although, this was not statistically significant (p=0.273). Nine patients showed unequivocal imaging evidence of disease during the follow-up period, with detection occurring at a mean of 59.11±49.67 months after the additional RAI-Tx. Uncertainty regarding structural disease persisted in 2 patients. ***Conclusion:*** This study highlights the uncertainty regarding the benefits of empirical RAI-Tx in patients with biochemical disease not seen on imaging procedure. The detection of structural disease in a significant number of patients emphasizes the need for continued surveillance. Further studies with larger cohorts and comparative arms are warranted to validate these findings and elucidate optimal management strategies for these patients, namely, regarding the role of additional RAI-Tx.

EP-0647

Efficacy of Radioactive Iodine (131I) Therapy and Prognostic Factors in Pulmonary Metastases of Differentiated Thyroid Cancer: A 10-Year Follow-Up Study on 25 Patients

S. Azzouz, *A. Rahal, L. Benabed, M. Azzouz;*
CHU Bainem, Algiers, ALGERIA.

Aim/Introduction: Pulmonary metastases are the most common distant site of spread in patients with differentiated thyroid cancer (DTC). Following surgical resection of the thyroid gland, radioactive iodine (131I) therapy and thyroid hormone suppression therapy are pivotal in managing these metastases. This study aims to assess the effectiveness of iodine therapy and identify prognostic factors in patients with lung metastases from differentiated thyroid cancer. ***Materials and Methods:*** A retrospective analysis was conducted on 25 patients with pulmonary metastases from DTC, initially treated with complete thyroidectomy followed by 131I therapy. Based on 131I whole body scan results, metastases were categorized as iodine-avid or non-avid. Treatment response

was evaluated using serum thyroglobulin levels, chest computed tomography (CT), and post-therapeutic 131I whole body scan. Prognostic factors for favorable outcomes at 10 years were determined based on therapeutic response and patient survival. ***Results:*** Of the 25 patients, 22 were female with an average age of 45 years. Papillary carcinoma was the predominant histological type (76%), while follicular carcinoma accounted for 12% of cases. Iodine-avid metastases were observed in 68% of patients. Among those with iodine-avid metastases, 47% showed significant reduction in thyroglobulin levels and 47% experienced reduction in metastatic lesion size on CT. In contrast, patients with non-avid metastases demonstrated disease progression in 87.5% of cases based on thyroglobulin levels and 75% based on CT imaging. Sub-radiological or micro-nodular pulmonary metastases were more prevalent in patients under 40 years (92%), while macro-nodular lesions were more common in patients over 40 years (40%). Patients under 40 years with stable or favorable biological and radiological evolution constituted 90% of cases. ***Conclusion:*** Iodine avidity, micro or infra-radiological metastatic forms, and younger age are favorable prognostic factors associated with a positive response to iodine therapy and improved outcomes over a 10-year follow-up period.

EP-0648

Iodine-refractory thyroid cancer: A review of 9 cases.

A. Dewi[1,2], *Y. Tuti[1];*
[1]Dharmais Cancer Center - National Cancer Center, Jakarta, INDONESIA, [2]Universitas Padjadjaran, Bandung, INDONESIA.

Aim/Introduction: Small groups of thyroid cancer patients might have unfavorable outcomes during the course of the disease, with 10 year survival rate about 47%. More than half population of the patients with distant metastasis can develop iodine-refractory thyroid cancer (IR-TC). ***Materials and Methods:*** We report nine cases of thyroid cancer with distant metastasis who progress to IR-TC, based on American Thyroid Association Thyroid Nodule/Differentiated Thyroid Cancer Guidelines 2015 categories. ***Results:*** Only one case showed tumor inability to concentrate I-131 since the first therapy, and stay stable after an accumulating doses of 500mCi. While one case with I-131 uptake, on the neck and the lung, developed negative iodine bone metastasis during follow-up, other seven cases showed I-131 uptake on all of the lesions. Despite of the uptake, all showed biochemical progression, and only one cases without evidence of anatomical progression. No cases showed negative I-131 uptake after prior evidence of I-131 uptake. The characteristic of the subjects were assessed. Four subjects were male, and five were female. Most of the subject were papillary cancer, interestingly, only one subject with follicular type. The latest, showed T2 multifocal tumor without extra-thyroid extension and nodal metastasis, while those characteristic presented in others. Only two subjects with T2 tumor, while other with T3-T4 tumor. Stimulated pre-ablation thyroglobulin level, range 108-618 ng/mL in those with lung metastasis, and 3,250-328,800 ng/mL in those with bone metastasis. In subjects with I-131 uptake, five showed residual disease on the second post-therapy scan, four of those with biochemical progression. Following anatomical imaging of those subjects, denote disease progression. Three subjects were died during follow up, all showed biochemical progression. ***Conclusion:*** Early identification of factors related to IR-TC development can be a challenge. Patient characteristic, such as tumor size, extra-thyroid extension, multifocality, nodal metastasis, distant metastasis, and stimulated pre-ablation thyroglobulin level might provide incremental value for predicting IR-TC development. Moreover, proven residual disease, biochemical, and anatomical progression after second RAI might also be considered. ***References:*** 1.Haugen BR, Alexander EK, Bible KC, et al. 2015 American Thyroid Association Management Guidelines for Adult Patients with Thyroid Nodules and Differentiated Thyroid Cancer. EP-0649

Low dose 177Lu-EDTMP therapy for palliation of painful bone metastases.

R. Kumar[1], *R. R. Pandey[2], S. Taywade[1];*
[1]All India Institute of Medical Sciences, Jodhpur, Jodhpur, INDIA, [2]Tata Memorial Centre, Mumbai, INDIA.

Aim/Introduction: Multiple bone metastases is usually seen in later stages of cancer leading to pain in multiple bony sites. This increases the patient morbidity. They often require a range of non-opioid to opioid analgesics to control the pain in order to improve the quality of life. These analgesics also cause side-effects like constipation and loss of appetite. 177Lu-EDTMP at prescribed dosage of 1 mCi/kg has been found to be quite successful. But it often adds to the myelotoxicity of the ongoing chemotherapy in these patients. To minimize the toxicity a low therapeutic dose of 177Lu-EDTMP was planned and its efficacy and safety was assessed. ***Materials and Methods:*** Ethical clearance was obtained from Institutional Ethics Committee, AIIMS Jodhpur. Patients were prospectively recruited between the period of March 2021 to September 2022. A bone scan was done to establish the finding of multiple osteoblastic bone metastases. Subsequently a dose of 0.5 mCi/kg of 177Lu-EDTMP was administered intravenously to seven patients who consented for this therapy protocol. Visual Analog Score (VAS), Analgesic score (AS), Karnofsky Performance Scale (KPS), ECOG was documented at baseline and at 3 months while haematological parameters were documented at baseline and at 2, 4, 8 and 12 weeks post therapy. ***Results:*** The mean VAS score dropped from 8.00 + 1.52 at baseline to 3.00 + 3.41 at 3 months (p=0.006). The mean AS score dropped from 3.29 + 0.76 at baseline to 2.00 + 1.91 at 3 months (p=0.049). According to CTCAE grading of haematological toxicity, 1/7 patients had grade III anemia, 1/7 had grade II anemia and 2/7 patients experienced grade I anemia. 1/7 experienced grade I leukopenia. 2/7 patient experienced grade I thrombocytopenia. None of the patients required blood transfusion. No much difference was seen in KPS and ECOG scores between baseline and at 3 months. The reason being that the baseline scores were close to normal (Median KPS 80 and Median ECOG 1). Overall response rate was 71%, with complete response seen in 4/7 (57.14%) patients, partial response in 1/7 (14%) and no response in 2/7 (29%) patients. ***Conclusion:*** Low dose 177Lu-EDTMP therapy (0.5mCi/kg) is effective, safe and economical.

EP-0650

Initial Clinical Experience with ^{177}Lu-EB-FAPI Radioligand Therapy in Patients with End-StageMetastatic Cancers

H. Fu, *J. Huang, W. Guo, H. Wu, H. Chen;*
The First Affiliated Hospital of Xiamen University, Xiamen, CHINA.

Aim/Introduction: Fibroblast activation protein (FAP) is overexpressed in several solid tumors and therefore represents an attractive target for radiotheranostic applications. Here, we report the efficacy and safety of 177Lu-EB-FAPI radioligand therapy (RLT) in patients with various end-stage metastatic cancers. ***Materials and Methods:*** FAPI radioligand therapy included a fixed doses of 177Lu-EB-FAPI (3.2 GBq) per cycle using a combination of clinical and statistical expertise design, and intervals of 6 weeks were considered between each cycle. Up to four cycles of radioligand therapy were offered to patients with (i) progressive metastatic malignancy, (ii) exhaustion of approved therapies, and (iii) high fibroblast activation protein (FAP) expression, defined as SUVmax≥ 10 in more than 50% of tumors. Biodistribution and dosimetry were examined by planer whole-body scans. We applied the NationalCancer Institute Common Terminology Criteria for Adverse Events (version 5.0) to measure RLT-associated toxicity. The primary endpoint was the RECIST response after RLT. Secondary endpoints included overall survival (OS), dosimetry, and safety of FAP-RLT. ***Results:*** A total of 32 patients with advanced cancers with unresectable tumors, or tumors refractory to conventional therapies, were prospectively enrolled. These patients include thyroid cancer (n=18), breast cancer (n=3), lung cancer (n=2), colorectal cancer (n=2), sarcoma (n=2), renal cancer (n=1), prostate cancer (n=1), nasopharyngeal cancer (n=1), esophageal cancer (n=1), and gastric cancer (n=1). Eastern Cooperative Oncology Group (ECOG) ≥2 was observed in 69 % of the patients. The patients were treated between June 2020 and December 2023. Overall, 78 RLT cycles with 177Lu-EB-FAPI were performed, and 23 of 32 (72%) patients underwent repeat RLT. The therapy was well tolerated in almost all patients. By RECIST, disease control was confirmed in 17 of 32 patients [53%; 27/32 (84%) of evaluable patients]. There were five partial response (PR) and twelve stable diseases after RLT. Disease control was associated with prolonged OS ($P < 0.01$). Dosimetry was acquired in 30 (94%) patients. The mean absorbed dose was 6.7± 11.3 Gy/GBq in the tumor. Treatment-related grade 3 or 4 adverse events were observed in 9 (28%) patients with thrombocytopenia (n=9), leukopenia (n=2), and anemia (n=1) being most prevalent. ***Conclusion:*** FAP-targeted radioligand therapy with 177Lu-EB-FAPI was well tolerated, with a low rate of attributable adverse events. We observed signs of tumor response, but further studies are warranted to determine efficacy and the toxicity profile in a larger cohort.

EP-0651

First evidence of 64CuCl2 treatment efficacy in recurrent glioblastoma patients

D. Stanimirovic[1], *D. Milakovic[1], J. Mijatovic[1], I. Rakita[1], G. Vuleta[1], M. Basile[2], S. Valentini[2], G. Valentini[2];*
[1]University Clinical Center of the Republic of Srpska, Banja Luka, BOSNIA AND HERZEGOVINA, [2]A.C.O.M.-Advanced Center Oncology Macerata-S.R.L., Montecosaro (MC), ITALY.

Aim/Introduction: Glioblastoma (GBM) is a highly malignant brain tumor that in most cases unavoidably progresses or recurs after first line treatments. Due to the complexity of disease, the available therapeutic options are limited, often highly toxic and there is no consensus regarding the best treatment choice. Copper-64 Chloride (64CuCl2) has been tested as a theragnostic method to evaluate treatment preliminary efficacy. ***Materials and Methods:*** We conducted a phase I monocentric, open-label, 2-stages design study on recurrent/progressive GBM adult patients previously treated with standard treatments (surgery, radiotherapy, chemotherapy). Only patients with a positive 64CuCl2 PET/CT scan at diagnostic dosage were selected for treatment. Stage 1 let to determine the maximum tolerated dose (MTD) based on dose-limiting toxicity (DLT). Stage 2 (Expansion cohort) was useful to define the anti-tumor activity administering 64CuCl2 once a week for a total of 7 fixed doses. The primary objective was the response to treatment expressed as objective response and defined as stable disease, partial response (reduction), complete response (disappearance of lesions) or disease progression, measured by MRI and defined according to Response Assessment in Neuro-Oncology (RANO) criteria. ***Results:*** 21 patients were screened, 18 patients were treated with 64CuCl2 and 10 patients were evaluated for preliminary efficacy. All Stage 2 patients were evaluated after 7 64CuCl2 administrations (day 42) and MRI assessment showed that 7 patients resulted as responders to the treatment and 3 resulted as non-responders. Among the responder patients, 3 patients showed stable disease and 4 patients resulted as partial responders showing a reduction in the sum of product of perpendicular diameters of all measurable enhancing lesions ≥50% compared to baseline MRI examination. ***Conclusion:*** In the challenge of recurrent GBM management, considering the aggressiveness of the disease, 64CuCl2 treatment gave promising results to proceed with clinical investigations on recurrent glioblastoma patients.

EP-0652

FAP-Targeted Radiopeptide Therapy using ^{177}Lu-, ^{90}Y-, ^{225}Ac-labelled 3BP-3940 in 19 Different Advanced Malignancies: First-in-Humans Results

J. Zhang[1,2], *A. Mishra[3], A. Eismant[3], L. Greifenstein[3], A. Klega[3], C. Landvogt[3], C. Mueller[3], T. Zhao[1,2], D. Benz-Zils[3], O. Klein[4], B. Jaeschke[4], V. Jakobsson[1,2,5], R. P. Baum[3];*
[1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE, [2]Theranostic Center of Excellence, National University of Singapore, Singapore, SINGAPORE, [3]Curanosticum Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY, [4]Department of Oncology and Hematology, Helios DKD Klinik, Wiesbaden, GERMANY, [5]International Centers for Precision Oncology, Wiesbaden, GERMANY.

Aim/Introduction: Fibroblast activation protein (FAP) has emerged as a highly promising target for imaging and targeted radiopharmaceutical therapy of diverse malignancies. The purpose of this study was to determine the feasibility of using a novel FAP-targeted cyclic peptide, 3BP-3940, for peptide-targeted radionuclide therapy (PTRT) and present first-in-humans results using 177Lu, 90Y, and 225Ac labeled 3BP-3940. ***Materials and Methods:*** Seventy patients with 19 distinct malignancies were treated (Mar'21-Feb'24) using 3BP-3940 after exhaustion of all conventional therapy options. 16 had pancreatic ductal adenocarcinoma (PDAC), 8 lung, 7 breast, 5 rectum, 6 colon, and 28 other types of cancer. PET/CT imaging was done with 68Ga-3BP-3940 to select patients for treatment. CTCAE v.5.0 was used to grade toxicity. Treatment response was evaluated by PET/SPECT and morphological imaging. Overall survival (OS), defined from the start of PTRT, was calculated (Kaplan-Meier survival analysis). ***Results:*** Administrations of 177Lu-/90Y-/225Ac-3BP-3940 were

well tolerated (dose/patient and range: 177Lu, 15 ± 11 GBq; 90Y, 7 ± 5 GBq; and 225Ac 14 ± 10 MBq) Pain flare occurred in 9/70 (13%) patients, nausea in 11/70 (16%), vomiting in 6/70 (9%), headache in 2/70 (3%), partial alopecia in 7/70 (10%), and intensified fatigue in 4/70 patients (6%); no other clinically relevant adverse symptoms were reported by patients. Dosimetry results after 9.73GBq 177Lu-3BP-3940: PDAC 2200mGy, brain 37mGy, lungs 168mGy, liver 86mGy, pancreas 142mGy, kidneys 265mGy. Posttherapy SPECT/CT scans demonstrated very high tumour-to-background ratios and long retention in tumour lesions on delayed imaging (up to 7 days). Tumour responses after 2 cycles of PTRT according to molecular imaging criteria were complete remission in 1/44 (2%), partial remission in 14/44 (32%), mixed response in 11/44 (25%), stable disease in 2/44 (5%), and progressive disease in 16/44 (36%). For the entire cohort, the median OS was 7 months from the start of PTRT; in patients with refractory, heavily pretreated pancreatic ductal adenocarcinoma, the median OS was 7 months. ***Conclusion:*** 3BP-3940 PTRT is feasible with 177Lu/90Y/225Ac either alone or as TANDEM treatment in end-stage cancer patients. Treatments were relatively well-tolerated without serious adverse effects. 3BP-3940 PTRT demonstrated a very favorable biodistribution (especially very low renal accumulation), with significant uptake and long retention in tumor lesions. Objective responses in very advanced metastatic adenocarcinomas and sarcomas were noted (one CR in a patient with ovarian cancer lasting now for two years). The survival benefit for PDAC patients seems to be very promising. Further prospective randomized studies are warranted.

EP-0653

^{68}Ga/^{177}Lu-PSMA theranostics in recurrent high-grade glioma - First study results & future perspectives

A. Karlberg[1], *B. E. Vindstad[2], E. M. Berntsen[1], H. Johansen[1], T. M. Keil[1], O. Solheim[1], S. Kjærnes Øen[1], T. Skeidsvoll Solheim[1], L. Eikenes[2];*
[1]St. Olavs Hospital, Trondheim, NORWAY, [2]Norwegian University of Science and Technology, Trondheim, NORWAY.

Aim/Introduction: In this clinical study, 68Ga/177Lu-PSMA theranostics is evaluated as a treatment alternative for patients with recurrent high-grade glioma. The main goal is to improve existing diagnostic and therapeutic methods in glioma management, and introduce a novel treatment that possibly can increase the overall suvival and quality of life for patients with very poor prognoses and no standard of care today. Safety, tolerability and efficacy of 177Lu-PSMA therapy are evaluated and the pre-therapeutic tumor uptake of 68Ga-PSMA is compared to the tumor absorbed doses from 177Lu-PSMA to establish an appropriate indication for therapy. This is one of the first studies in the world exploring theranostics as a treatment alternative for patients with glioma. ***Materials and Methods:*** Patients with a positive 68Ga-PSMA-PET/MRI examination are eligible for 177Lu-PSMA treatment. The patients are carefully monitored during each treatment cycle (PET/MR, SPECT/CT, neurological tests, blood tests, and quality of life questionnaires). Two patients with CNS WHO grade 4 glioblastomas have been included in this ongoing study to date. Both patients received standard treatment with surgery, radiotherapy and chemotherapy prior to inclusion, and were left with no other treatment options at recurrence. 177Lu-PSMA (7.1-7.3 GBq) was administered intravenously (Patient A: 1 treatment, Patient B: 5 treatments) and SPECT/CT scans were performed for dosimetry. ***Results:*** 68Ga-PSMA-PET prior to treatment demonstrated tumor uptake in both patients (SUVmax_A:9.0 and SUVmax_B:4.4) as well as uptake in the parotid glands (SUVmax_A:21.8 and SUVmax_B:15.9). 68Ga-PSMA uptake in normal brain was low, yielding high TBR (TBRA: 136.0 and TBRB: 45.4). Post treatment SPECT/CT revealed a rapid wash-out of activity, resulting in low absorbed doses (A: Tumor 1.4 Gy, kidneys 2.0-2.1 Gy, parotid glands 1.1-1.4 Gy, B: Tumor 2.6-2.9 Gy, kidneys 3.2-3.7 Gy, parotid glands 1.7-3.1 Gy). The patients reported no subjective side effects of the treatment, apart from transient xerostomia. Based on radiological evaluation (MRI), both patients demonstrated stable disease during the treatment cycles. ***Conclusion:*** Despite low tumor doses, the radiological stability of disease in these two patients is promising. Boosting brain tumor doses could potentially result in better treatment effect, and an innovative approach to achieve this is to use intraarterial administration instead of intravenous administration. A change in the current study protocol will now be made to implement this method.

EP-0654

Efficacy, Safety and Cosmetic in an Elderly Population after 188Rhenium Brachytherapy in NMSC: Long Term Follow Up Data

L. Vetrone[1], *C. Baraldi[2], M. Chessa[2], C. M. P. Sgro[3], E. Greco[3], F. Zagni[4], L. Strigari[4], E. Dika[2], A. G. Morganti[5,6], B. M. Piraccini[2], S. Fanti[1,7], P. Castellucci[1];*
[1]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY, [2]Dermatology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY, [3]Nuclear medicine, Alma Mater Studiorum University of Bologna, BOLOGNA, ITALY, [4]Department of Medical Physics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY, [5]Radiation Oncology Department, IRCCS Azienda Ospedaliero-Universitaria di Bologna, BOLOGNA, ITALY, [6]Radiation Oncology, Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, ITALY, [7]Nuclear Medicine, Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, ITALY.

Aim/Introduction: Mohs'surgery is the best treatment for non-Melanoma-Skin-Cancers(NMSC). However, brachytherapy with 188Re-resin is an option in "difficult to treat" lesions. Our aim was to assess efficacy, early side effects and cosmetic results after long term follow up. ***Materials and Methods:*** Enrollment criteria were: histologically proven NMSC; thickness<3.0mm, lesions categorized as "difficult-to-treat" with surgery or contraindication/ refUNITED STATES OF AMERICAI of surgery. Early toxicity(ET) was assessed between 14-32days after treatment according to Common Terminology Criteria Adverse Events 5.0(CTCAE). Efficacy and cosmetics were evaluated with videodermoscopy and biopsy (if needed) and a clinical aesthetic evaluation according to RTOG scale. Patients were followed after 6-12-24 months and, if needed, during the period of the whole FU (mean37mo; range 3-77). In our population 53pts died for other causes during FU. ***Results:*** 168 lesions were treated (92/168 BCC; 70/168 SCC; 6/168 mixed SCC-BCC) in 115 patients(mean age 82yo). 73/92 BCC were nodular-subtype, 11/92 nodular-sclerodermiform, 8/92 sclerodermiform; 35/168 located on the scalp, 94/168 in the H-area(forehead, nose, ears, cheeks), 21/168 in the extremities, 16/168 in the thorax and 2/168 on the scrotum. Mean surface area was 6,4cm2 (1-60cm2), mean thickness 1,3mm (0.2-3mm), mean volume(TV) 1,3cm3 (0,05-15cm3); mean dose at 0,5mm depth was 50Gy, mean target dose 25Gy, mean dose-at-surface 161Gy, and mean treatment's time 85 minutes. In 95/168 Re-brachitherapy was the first treatment; in 37/168 was performed after other therapies failure (Criotherapy, Laser, Imiquimod, photodynamic), 22/168 after surgery, 14/168 after RT. Efficacy: We evaluated 164/168 lesions with at least 6mo

FU. During FU we observed: 10/164 relapses(7pts) in the TV (6mo 5/10; 12mo 1/10; 18mo 1/10; 24mo 2/10; 36mo 1/10) and 5/164 at the external margins of TV (6mo 1/5; 18mo 1/51; 24mo 2/5; 36mo 1/5). We did not observe any relapse after 36mo.Safety: CTCAE grades: G1=81/168; G2=75/168; G3=12/168. All G1-G2 lesions resolved completely within 32days(mean 24days); G3 resolved in up to 90days (mean 54days). 98/168 needed local therapy (hyaluronic acid, antibiotics, steroids); 70/168 needed just cleaning-disinfection of the wound. Cosmetic ***results:*** At 6mo, 113/164 were excellent=CS1; 46/164 good=CS2; 4/164 poor=CS3; one was not valuable. At 12mo, 117/158 excellent=CS1, 38/158 good=CS2, 3/158 poor=CS3. At 24mo 96/124=CS1; 25/124=CS2 and 3/124=CS3. No significant cosmetic differences have been observed after 24mo in the available population. ***Conclusion:*** Brachytherapy with 188Re-resin showed: excellent efficacy in terms of local control, few early side effects and excellent cosmetic results. So far we did not observe relapses after 36 months from treatment.

EP-0655

Initial clinical experience of Rhenium-188 Therapy for Keloids

K. Mokoala[1], *L. B. Nonjola[1], N. P. Mokgoro[1], M. Magwaza[2], S. Brown[3], G. Dahlhoff[3], M. M. Sathekge[1,4];*
[1]University of Pretoria, Pretoria, SOUTH AFRICA, [2]Tautomer / NATIVA, Pretoria, SOUTH AFRICA, [3]Oncobeta GmbH, Bavaria, GERMANY, [4]NuMeRI, Pretoria, SOUTH AFRICA.

Aim/Introduction: The current management options of keloids are limited. Although there are several recommended strategies as a first-line therapy, these treatments have variable rates of success with high recurrence rate. Inhibition of the proliferation of fibroblasts and prevention of the synthesis of collagen is essential for treatment of keloids. The purpose of this study is to provide initial clinical data on the effectiveness of non-sealed beta emitter rhenium-188 for the treatment of keloids. ***Materials and Methods:*** Twenty-eight patients with keloids were recruited between November 2019 and November 2023. Treatment with Rhenium-188 via a specialized unit was applied onto the keloid lesion. A personalized treatment time was calculated for every patient. Topical 188Rhenium delivered as a jelly like matrix containing an insoluble dirhenium-heptasulfide was applied to every target lesion in a single session. The goal was to deliver 30Gy to the lesion per session. Patients were followed up at 2 weeks, 1, 3, 6 and 12 months for side effects as well as clinical and cosmetic outcomes. Subjective assessment of treatment was performed using the Dermatology Quality of Life (QoL) questionnaire which was completed before and after the treatment. ***Results:*** A total of 28 patients with 58 lesions were treated. Majority of the lesions were in the head and neck region. Previous therapies included surgery, radiotherapy, intralesional steroids and cryotherapy. The commonest symptom was itchiness followed by cosmetic concerns. The smallest area for treatment was 0.25cm2 and the largest area treated was 46.52cm2. With the exception of four patients (2 sessions to the same lesion), all the other patients received a single session of therapy. The average activity administered was 256,7MBq (range: 35MBq - 663,50MBq). The treatment time averaged 6 hours. There was complete response in 80% of the lesions, while the remainder had partial response (reduction in size and height). Hypopigmentation was the commonest expected long term side effect. After a median follow-up period of 36 months (range: 7 - 53), there was a 15% recurrence rate. ***Conclusion:*** In patients with keloids, single therapeutic session with Rhenium-188 appears to be effective and safe. While in firmer and thicker keloids require more than a single session of therapy.

EP-0656

Safety and efficacy of radiosynoviorthesis: a prospective multicentre Canadian trial

M. Desaulniers[1], *M. Paquette[1], S. Dubreuil[1], H. Senta[1], É. Lavallée[1], J. C. Thorne[2], É. Turcotte[1];*
[1]Université de Sherbrooke, Sherbrooke, QC, CANADA, [2]University of Toronto, Toronto, ON, CANADA.

Aim/Introduction: Radiosynoviorthesis, an intra-articular radionuclide treatment, is approved in several European countries and in the United States of America to treat refractory synovitis in many inflammatory joint diseases, such as rheumatoid arthritis (RA), spondyloarthropathies and other arthritic joint diseases. Unfortunately, no radiopharmaceuticals for radiosynoviorthesis are currently approved and available in Canada. The aim of this Health Canada-approved clinical trial is to demonstrate the safety and efficacy of radiosynoviorthesis. ***Materials and Methods:*** Between July 2012 and November 2017, we conducted a Canadian multicentre prospective clinical trial (NCT01615991). Patients (n = 360) with various inflammatory joint diseases, including 6 paediatric patients, who had refractory synovitis to standard treatment, defined as failure after two intra-articular glucocorticoid injections, were included. All the patients included received radiosynoviorthesis, and it was possible to treat several joints during the same appointment. In the absence of improvement in the clinical signs of synovitis (pain, swelling and effusion) at six months, a joint could receive a second radiosynoviorthesis. They were followed up clinically, serologically and radiologically at 3, 6 and 12 months after radiosynoviorthesis. Outcome measures at each visit included adverse events (AEs) and clinical signs of synovitis measured with Health Assessment Questionnaire Disability Index (HAQ-DI), Disease Activity Score (DAS28) and Visual Analogue Scale (VAS 100 mm). ***Results:*** In the cohort, 30.6% (110/360) of patients suffered from spondyloarthropathies, 24.7% (89/360) from RA and 11.9% (43/360) from osteoarthritis. A total of 392 joints were injected, including 82.7% (324/392) of knees. 83.4% (327/392) of large joints were treated with 90Y and 10.0% (39/392) with 186Re for medium-sized joints. 34 joints required a second radiosynoviorthesis six months after the first attempt, of which 17.6% (6/34) were RA-related. 55 AEs of all types, most of them of low severity, occurred and resolved without sequelae and were not life-threatening. The incidence of radiosynoviorthesis-related AEs was 9.4% (34/360). The proportion of patients showing an improvement in synovitis symptoms after radiosynoviorthesis was significant at 3 months, and was maintained up to 12 months ($p<0.001$). A non-significant improvement in HAQ-DI ($p=0.3$) and DAS28 ($p=0.1$) from 3 months was observed. No significant change in VAS 100 mm was observed ($p=0.5$). ***Conclusion:*** This study confirms the safety of

radiosynoviorthesis in the treatment of various inflammatory joint diseases with refractory synovitis to standard treatment. There is evidence of sustained clinical efficacy at 12 months, suggesting that radiosynoviorthesis is an effective treatment for improving the symptoms of synovitis.

EP-0657

Radiosynovectomy with Lu-177 MAA in Patients with Inflammatory Knee Joint: Preliminary Results

K. Saglam, *M. S. Sağer, S. Bilgiç, E. Karayel, H. Pehlivanoğlu, A. Aygün, N. Yeyin, M. K. Özşahin, M. Özer, C. D. Davulcu, H. Botanlıoğlu, S. Asa, O. E. Şahin, R. L. Uslu Beşli, H. B. Sayman; Cerrahpasa Medical Faculty, Istanbul, TÜRKIYE.*

Aim/Introduction: Osteoarthritis is the most common chronic rheumatic disease characterized by destruction of joint cartilage. Different types of arthritis include osteoarthritis, rheumatoid arthritis, psoriatic arthritis, pigmented villonodular synovitis (PVNS), ankylosing spondylitis, and nonspecific chronic synovitis. Various treatment methods successfully are used for inflammatory arthritis including radiosynovectomy. Radiosynovectomy procedure carried out by intra-articular injection of suitable radionuclides in colloidal form. Yttrium-90, Lutetium-177 and Rhenium-188 can be used for radiosynovectomy. The aimof this study is to investigate the feasibility of radiosynovectomy with Lutetium-177, since commonly used radionuclide Yttrium-90 is expensive and has difficulties regarding its supply. Lutetium-177 radiosynovectomy is applied for pain palliation in patients with inflammatory joint disease. There is a possibility that this compound may reach extra-articular tissues in small amounts. The Lutetium molecule is 99.5% bound to the macro aggregate albumin and is too large (10-90 microns) in size to leak of the joint space. ***Materials and Methods:*** Patients diagnosed with PVNS by clinical, laboratory and imaging findings were prospectively selected. An average dose of 8-10 mCi of Lu177-MAA labeled radiopharmaceutical injected intra articularly. Knee arthro-scintigraphy and SPECT/CT imaging performed with a medium-collimator with gamma rays of the Lu-177 MAA radiopharmaceutical. If possible, patients were evaluated with the Knee Injury and Osteoarthritis Outcome Score (KOOS), control SPECT or MRI imaging. ***Results:*** Injection was performed in 9 patients. Distribution of the injected radsiopharmaceutical was checked by SPECT/CT. Two of the patients had 6-month and 3 of them had 3-month KOOS follow-ups. An average of 35% improvement in KOOS was observed after 3-6 month clinical evaluations. ***Conclusion:*** This study is an ongoing study. It is expected that with more patients being followed for longer periods, more data will be available to assess about the use of this radiopharmaceutical in PVNS patients. The results so far showed us that Lu-177 MAA is a promising radiopharmaceutical for radiosynovectomy applications.

EP-0658

Insights from radiosynoviorthesis in the treatment of haemophilic arthropathy: a retrospective analysis

P. Portilla Merino, *J. Cordero García, V. Jimenez Yuste, C. Encinas Ullan, Y. Abadi, L. Giraldo Gonzalez, J. Otero Gonzalez, S. Rizkallal Monzon, S. Rodado Marina, L. Dominguez Gadea; Hospital Universitario La Paz, Madrid, SPAIN.*

Aim/Introduction: Haemarthrosis and synovitis are frequent among patients with haemophilia despite optimal replacement therapy, compromising the quality of life of patients due to the pain and stiffness associated with synovial effusion, and representing a risk of severe haemarthropathy. Our centre, national reference in haemophilia management, has used radiosynoviorthesis (RS) as a localized treatment for persistent or recurrent synovitis over the past three decades, owing to its recognized safety and efficacy. In this study, we review the outcomes of radiosynoviorthesis in haemophilic arthropathy at our centre over 2010-2020. ***Materials and Methods:*** We retrospectively reviewed 39 patients with severe haemophilia A and B and chronic synovitis (55 joints) treated with RS between 01/2010-01/2020. We used 90Y (5 mCi) for the treatment of large joints, and 186Re (2mCi) for medium-sized joints. Evaluation of results included assessing clinical improvement in terms of haemarthrosis, pain reduction or improvement in joint range of motion. Repeat the treatment was indicated (RS2) when 2 or more joint effusions occurred within 6 months after the initial synoviorthesis. The mean follow-up period of the joints was 79 months (13-146 months). ***Results:*** We treated a total of 55 joints (20 elbows, 10 knees and 25 ankles) in 39 patients with haemophilia, with a mean age of 35 years (SD±13). The youngest patient was 11 years old. In 35 joints (64%) post-treatment cessation of haemarthrosis was achieved, with a mean rebleeding free interval (RFI) of 70 months (SD±43); 29 joints did not showed rebleeding during the follow-up. Of the remaining 20 joints (36%) with persistent symptoms, 12 underwent RS2, 1 synovectomy, 1 received a joint prosthesis, 1 is pending RS2, whilst 5 are pharmacologically managed together with intra-articular infiltrations. In the case of the 12 RS2, 5 (41.6%) showed cessation of haemarthrosis with a mean RFI of 42 months (SD±22). Four of the remaining patients received pharmacological treatment, and 3 were summited to new RS (3 or 4 RS), two of them requiring synovectomy. The other patient was lost to follow-up. Overall, remission of haemarthrosis was achieved in 40 out of 55 joints (73%) with one or two RS, achieving complete remission with just one RS in 52% of patients. ***Conclusion:*** RS proves to be safe, minimally invasive and well-tolerated procedure in patients with chronic haemophilic synovitis, achieving complete response or prolonged RFI in a significant amount of patients.

EP-0659

I-131 Thyrotoxicosis Therapy - Audit of Repeated Treatments

F. Bone, *L. Rowley, E. Aveyard, C. Low; University Hospital Coventry and Warwickshire, Coventry, UNITED KINGDOM.*

Aim/Introduction: Radioiodine treatment using I-131 is offered as a first-line definitive treatment for patients with hyperthyroidism at University Hospital Coventry, UK. Since 2019, patients are administered an activity of 400 MBq for their first therapy. EANM guidance states 'The range of activities currently prescribed, vary in the range 200-800 MBq', and ARSAC Notes for Guidance states 'total activity administered to be a matter of clinical judgement by the responsible licensed practitioner holder' [1,2]. An audit was conducted to investigate the rate of occurrence of repeat treatment, to see if improvements could be made, and evaluate the appropriateness of the initial administered activity. ***Materials and Methods:*** Data for the audit were extracted from the hospitals radiology information system between 2014 and 2024. The examined parameters were number of repeat treatments per patient, time between treatments, and the administered activities per treatment. ***Results:*** A total of 501 patients underwent I-131 thyrotoxicosis therapy between 1/1/2014 and 1/2/2024. Of these, 472 patients received an initial DRL activity of 400 MBq, 27 received 500 MBq, and 2 received 550 MBq. Patients treated for the first time between 1/2/2023 - 1/2/2024 were excluded (assuming

an average time to retreat of 1 year). Of the 467 patients to be considered; 38 received one further treatment, 1 received two additional treatments, and 1 received three further treatments. Forty patients (8.6%) underwent repeated thyrotoxicosis therapy. From the 40 repeat patients, all received an initial activity of 400 MBq, 32 received a second dose of 400 MBq, 1 received a second dose of 500 MBq, 7 received a second dose of 550 MBq, 2 patients had a third dose of 400 MBq, and 1 had fourth dose of 800 MBq. ***Conclusion:*** 8.6% of all I-131 thyrotoxicosis therapy patients between 1/1/2014 and 1/2/2023 underwent repeated treatment, corresponding well to previously published data [3]. In our centre, all patients will be treated with an initial activity of 400 MBq. If retreatment is necessary, patients should receive a second dose with a higher activity of 550 MBq. This reduces the probability of further retreatment and provides guidance on repeat therapies, without increasing the initial treatment activity. ***References:*** 1. Marcel et al. Optimizing Radioiodine Therapy: Investigating Distribution Factors and Half-Life Variability in Thyroid Autonomies

K. Hansen, *M. C. M. Gammel, V. Petrova, S. van Marwick, M. Eiber, S. G. Nekolla;*
Department of Nuclear Medicine, Klinikum Rechts der Isar, Technical University Munich, School of Medicine & Health, Munich, GERMANY.

Aim/Introduction: I131-radioiodine therapy is effectively used to treat benign thyroid disorders. Despite suppressed TSH levels, patients with autonomous adenomas frequently exhibit significant iodine uptake in residual thyroid tissue. We aim to analyze the quantitative distribution of I131 to autonomous adenomas vs. residual thyroid tissue and potential variations in the effective half-life. ***Materials and Methods:*** We studied 5 patients diagnosed with hyperthyroidism due to autonomous adenoma (n=3) and disseminated autonomy (n=2), all presenting with suppressed TSH levels (<0.1 µU/ml). Prior to therapy, a diagnostic radioiodine test was conducted 4 days earlier using 2.7 ± 0.3 MBq of Iodine-131. I131 scintigraphies were performed 24 and 72h before the therapy using a high-resolution small-field gamma camera with a 256 x 256 matrix over 10 mins. Following radioiodine therapy, post-therapeutic measurements were continuously conducted over 24-48h, accompanied by additional scintigraphic imaging. Regions of Interest were automatically delineated around the entire thyroid and the adenoma using an automatic region grow function. These were precisely superimposed on the pre- and post-therapeutic scintigraphy images. A distribution factor was calculated from every scintigraphy by dividing the counts in the adenoma by those in the residual thyroid tissue. A factor > 1 indicates the adenoma absorbs more radioactive iodine, while a factor < 1 suggests higher absorption in the remaining thyroid tissue. ***Results:*** In this preliminary analysis, two out of three patients with an unifocal adenoma demonstrated a post-therapeutic distribution factor of less than 1 (0.40 and 0.79), indicating a significant disseminated component of the remaining thyroid tissue that absorbs parts of the therapeutic dosage. Furthermore, the distribution factor changed within the first 72 hours, decreasing by approximately 5.67 percentage points. For the other cases where the distribution factor was greater than 1, it also decreased by an average of 6.3 percentage points. This suggests different effective half-lives between the focal adenoma and the disseminated autonomy. ***Conclusion:*** In conclusion, our preliminary results highlight the necessity of precise calculations in radioiodine therapy, aimed at selectively targeting the autonomous component while avoiding hypothyroidism from overtreatment. Further attention should be paid to the distribution factor and the differing half-lives revealed by our data. However, further analysis involving a larger patient cohort and additional post-therapeutic measurements at later timepoints for accurate dosimetry is required.

EP-0661

Polidocanol Instillation in Predominantly Cystic Thyroid Nodules - Introducing a Re-aspiration Protocol

D. Groener[1], *C. Happel[1], K. Klimek[1], C. Keskin[1], N. Mader[1], J. Richter[2], M. Kreissl[2], R. A. Werner[1], F. Grünwald[1], A. Sabet[1];*
[1]Goethe University Frankfurt, University Hospital, Department of Nuclear Medicine, Clinic for Radiology and Nuclear Medicine, Frankfurt, Germany, Frankfurt am Main, GERMANY, [2]Otto von Guericke University, Department of Nuclear Medicine, University Hospital Magdeburg, Germany, Magdeburg, GERMANY.

Aim/Introduction: Ultrasound-guided percutaneous polidocanol instillation (PPI) may provide an alternative to percutaneous ethanol instillation (PEI) in symptomatic cystic or predominantly cystic thyroid lesions. To minimize the risk of systemic side-effects, this study aims to investigate whether treatment efficacy of PPI can be maintained when applying a re-aspiration technique. ***Materials and Methods:*** Patients with recurrent symptomatic cysts or predominantly cystic thyroid lesions underwent ultrasound-guided PPI. As set out by protocol, cystic content was aspirated, the emptied cyst was flushed with saline (NaCl 0.9%), and a median of 8 (IQR 4-10) mL of polidocanol 1% was instilled. After a retention time of 4 minutes, the instilled polidocanol was re-aspirated and local pressure was applied to the intervention site for ≥15 minutes. Patients were clinically reassessed after 6 weeks. Re-instillation was carried out in case of symptomatic recurrence. Follow-up visits were planned at a 6-month interval. The subjective symptom score for local complaints was reported on a semiquantitative scale (0-10). Data were analyzed retrospectively. ***Results:*** Twenty-one consecutive patients (median 46 (IQR 37-52) years of age, 14 females) underwent PPI. Initial cystic volume was 21 (IQR 10-47) mL. All patients achieved complete resolution of initial complaints, 14/21 (67%) reached persistent remission after a single instillation session, while 7/21 (33%) received up to 2 repeat instillations after initial recurrence within 15 (IQR 5-26) days of the preceding treatment. The volume reduction rate (VRR) was 95 (IQR 87-98)% at the 6-month follow-up. No significant pain was reported during or after PPI (VAS 0 in 18/21, ≤2 in 2/21 patients). One patient had self-limiting intracystic hemorrhage following PPI and could be successfully retreated. The subjective symptom score was significantly reduced from 3.9 to 0.3 ($p<0.001$). ***Conclusion:*** Based on findings from this pilot cohort, PPI can be carried out in predominantly cystic thyroid nodules with a re-aspiration technique maintaining good efficacy and safety results.

EP-0662

Does the therapeutic dose of 131I, based on a single measurement of iodine uptake, affect the effectiveness of radioiodine treatment for Graves' disease

A. Dyczka, *E. Salomon-Krekora, Z. Adamczewski;*

Nuclear Medicine Department Medical University of Lodz, Lodz, POLAND.

Aim/Introduction: Radioiodine therapy using 131I is widely recognized as an effective form of treatment for Graves' hyperthyroidism. The efficacy is determined by achieving euthyroid state or inducing hypothyroidism in approximately 80% of cases. However, within the hyperthyroid patient population, around 15% exhibit rapid iodine turnover, leading to a shortened effective half-life due to a limited iodine reserve in the thyroid gland (small pool syndrome). This phenomenon is more prevalent in patients with recurrent hyperthyroidism and/or in those undergoing long-term antithyroid medication treatment. In such cases, calculations of radioiodine doses can be inaccurate, leading to a possible underestimation of the 131I dose. To accurately calculate radioiodine dose, it is helpful to conduct additional iodine uptake measurements within 3 to 7 days after administering the diagnostic dose to determine the effective half-life. The aim of this study was to evaluate the impact of calculating the therapeutic dose of 131I based on a single iodine uptake measurement on the efficacy of Graves' hyperthyroidism therapy. ***Materials and Methods:*** We retrospectively analysed 339 patients (274 female, 65 male) with Graves' hyperthyroidism who underwent 131I treatment at the Nuclear Medicine Department Medical University of Lodz between 2018 and 2023. Prior to radioiodine therapy, patients underwent thyroid ultrasonography and measurement of TSH, T3, T4, and TRAb levels. Qualification for 131I treatment was based on thyroid scintigraphy results, with a single iodine uptake measurement taken 24 hours after administering the diagnostic dose. Treatment effectiveness was considered based on achieving euthyroidism or hypothyroidism within 6 to 12 months post-treatment. ***Results:*** After administering the therapeutic dose of 131I (ranging from 296 to 740MBq), determined from a single iodine uptake measurement, euthyroidism was observed in 44 patients (13%) - 33 females and 11 males - while hypothyroidism developed in 256 patients (75%) - 210 females and 46 males. Thirty-nine out of 339 patients (12%) either remained hyperthyroid or there was insufficient follow-up data due to missed appointments. The overall effectiveness of the treatment reached approximately 88% in the study group. ***Conclusion:*** This study demonstrates that administering the therapeutic dose of 131I based on a single iodine uptake measurement (24 hours after the diagnostic dose) for treating Graves' disease hyperthyroidism does not decrease the effectiveness of this therapy.

Initial Comparative Analysis of Lung Shunt Fraction Assessment via Planar Imaging and SPECT/CT in ^{90}YRadioembolization: A Pathway to Optimized Dosimetry

S. Kheruka, *A. Al Balushi, N. Al Maymani, N. Al Makhmari, H. Al Saidi, S. Al Rashdi, K. Al Riyami, A. Jain, R. Al Sukaiti; SQCCCRC, Muscat, OMAN.*

Aim/Introduction: This research sought to assess the differences in lung shunt fractions (LSFs) measured by Planar imaging compared to Single Photon Emission Computed Tomography/ Computed Tomography (SPECT/CT) in patients receiving 90Y radioembolization treatment. The study aimed to comprehend the influence of these differences on dosimetric planning, with a specific focus on the use of SPECT/CT for precise LSF evaluation when levels are above 10%. ***Materials and Methods:*** A retrospective analysis was performed on nine patients who were scheduled for 90Y radioembolization. Planar and SPECT/CT imaging were used to evaluate Lung Shunt Fraction (LSF). The statistical significance of the differences between the two modalities was assessed using a paired t-test. ***Results:*** The study's findings revealed notable disparities in LSF measures between Planar imaging (ranging from 2.0 to 8.7) and SPECT/CT imaging (ranging from 1.30 to 5.86), as shown by a p-value of 0.0018, suggesting significant variations. Even though all patients included in this research had LSF values below 10%, the results emphasize the significant importance of SPECT/CT in effectively evaluating LSF for prospective adjustments in 90Y dosimetry, particularly when levels are above 10%. ***Conclusion:*** The findings of this research demonstrate significant disparities in lung shunt fraction (LSF) measures when comparing Planar and SPECT/CT imaging before 90Y Radioembolization, underscoring the need for standardised evaluation techniques. The results emphasise the significance of SPECT/CT in accurately assessing and adjusting the dose for LSF when it exceeds the limit (10%) since all recorded LSF levels are below 10%. Exclusively relying on Planar imaging may result in inaccurate dosimetric planning for individuals with increased LSF. This necessitates more investigation to authenticate these first findings, formulate comprehensive imaging methodologies, and augment the accuracy and safety of 90Y therapies. This study establishes a foundation for future endeavors aimed at enhancing dosimetric planning and therapeutic results in radioembolization. It emphasizes the need to enhance imaging methods to get more precise measurements of the LSF.

EP-0664

Validation of Tc-99m and Lu-177 quantification parameters for a SIMIND Monte Carlo modelled gamma camera

S. Kamrani[1], *P. Sheikhzadeh[2], A. Kamali-Asl[1], A. Rahmim[3,4], A. Akhavanallaf[5], S. Aghamiri[1], F. Darvishi[1];*
[1]Department of Medical Radiation Engineering, Shahid Beheshti University, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Nuclear Medicine, Imam Khomeini Hospital Complex, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Departments of Radiology and Physics, University of British Columbia, Vancouver, BC, CANADA, [4]Department of Integrative Oncology, BC Cancer Research Institute, Vancouver, BC, CANADA, [5]Department of Radiology, University of Michigan, Ann Arbor, Michigan, MI, UNITED STATES OF AMERICA.

Aim/Introduction: Simulation of medical image acquisition using voxel-based anthropomorphic phantoms with known activity uptake provides a method to determine quantitative accuracy in patient geometries. In modern nuclear medicine, the absolute quantification of SPECT images is fundamental for providing an estimate of the activity in a patient and, consequently, the absorbed dose to each organ for diagnostic assessments and therapeutic decisions. SIMIND Monte Carlo modeling techniques can assess the quantitative accuracy of both planar and SPECT Nuclear Medicine images, leading to internal dosimetry optimization. We aimed to determine if the SIMIND MC code accurately simulates emission images measured with a

Discovery NM/CT 670 system for Tc-99m and Lu-177. ***Materials and Methods:*** The validation focused on performance tests comparing MC simulation to phantom experiment results using the LEHR (Low Energy High Resolution) collimator for Tc-99m and Lu-177. The system energy resolution, system spatial resolution, system sensitivity, and SPECT image quality were studied. The geometries used for 2D planar imaging were (1) Petri dish and (2) capillary source, while for 3D volumetric imaging, it was (3) Carlson image quality phantom. For quantitative assessment, we computed the standard deviation and percentage differences for the tests between each simulation and experimental measurements. ***Results:*** The resulting energy spectra present similar peaks for the gamma energy of Tc-99m and Lu-177. The system energy resolution of Tc-99m for the simulation was calculated to be 9.57%±0.13% and 9.44%±0.21% from the experimental data. The system energy resolution of Lu-177 for 113keV photopeak was 9.92%±1.2% and 10.12%±1.01% for the experimental and simulation data, respectively. Similarly, for 208 keV photopeak of Lu-177, it was 5.37%±0.8% and 5.50%±0.51% for the experimental and simulation data, respectively. The difference in sensitivity between simulation and experimental values for Tc-99m and Lu-177 was 5.1% and 3.2%, respectively. The experimental planar spatial resolution was 7.73±0.01 mm for Tc-99m and 8.10±0.12 mm for Lu-177. The simulation planar spatial resolution for Tc-99m was 8.03±0.09 mm, while for Lu-177 it was 7.69±0.01mm. Images obtained from the Carlson phantom, experimentally and by simulation, showed similarity in contrast and resolution. ***Conclusion:*** The results indicated that the simulation and experimental data agreed rather well. These findings illustrated that SIMIND could simulate Discovery NM/CT 670 successfully and, therefore, can be used with confidence to model Lu-177 and Tc-99m images.

EP-0665

Personalized CT scan range in parathyroid scintigraphy can reduce CT radiation dose

A. Thostrup[1], *J. Frederiksen[1], N. Bebbington[2], H. Zacho[1];*
[1]Aalborg University Hospital, Aalborg, DENMARK,
[2]Siemens Healthcare A/S, Ballerup, DENMARK.

Aim/Introduction: Parathyroid SPECT/CT is performed before surgery to localize potential adenomas. Parathyroid SPECT/CT protocols vary between departments, including variation on single or dual scanning timepoints. Furthermore, the CT scan range varies from default full SPECT-FOV CT to CT only covering the thyroid bed and then elongating the CT scan range, if the SPECT suggests ectopia. We aimed to investigate which of the two methods to determine CT scan range are the most optimal considering CT radiation dose and the risk of missing ectopic adenomas. ***Materials and Methods:*** 40 patients with primary hyperparathyroidism were included. All patients had a dual time point 99mTc-Sestamibi parathyroid SPECT/CT performed with full SPECT-FOV CT (standard examination), with a scan range from 29,0-41,7 cm depending on camera type. Two observers (technologist and junior doctor) retrospectively reviewed the non-attenuation corrected SPECT at three different time points (early, late in combination with early, and only late) and determined personalized CT scan range based on the SPECT. Scan range was measured with a software ruler and a comparison between the personalized scan range and standard examination was conducted. The reports from the standard examination were used as reference to investigate whether potential adenomas were missed when using personalized CT scan range. If the patient had undergone surgery, the report from surgery was used additionally. ***Results:*** Standard parathyroid SPECT/CT showed adenomas in 26 out of the 40 patients, the position of the adenomas was described as posterior of, just inferior to, or within the thyroid gland. Overall, similar reductions in CT range were observed independent of timepoint (range: mean percentage CT scan range reduction 58%-63%). The mean CT scan range was reduced by 21.2 cm, 21.4 cm and 22.4 cm at the early-, late with early- and late- timepoints for the junior doctor and 21.0 cm, 21.8 cm and 20.4 cm for the technologist, respectively. Comparing the personalized CT scan range to our reference showed that no adenomas were missed for any of the two observers. 11 out of the 40 patients had undergone surgery at the time of follow up, one had an ectopic adenoma (which was not detected on the standard examination). ***Conclusion:*** Personalized CT scan range in parathyroid SPECT/CT determined by either a technologist or a junior doctor can reduce scan range with 59-65% without missing (ectopic) adenomas enabling a reduction of the radiation dose without missing clinically relevant findings.

EP-0666

Advancing Precision in Radioembolization: A Comparative Analysis of Lung Shunt Fraction Estimation Through Planar Imaging, SPECT/CT, and Y90 PET/CT (Post Therapy)

A. Al-Balushi, *S. Kheruka, N. Al-Maymani, N. Al-Makhmari, H. Al-Saidi, S. Al-Rashdi, K. Al-Riyami, R. Al-Sukaiti;*
Sultan Qaboos Comprehensive Cancer Care Center (SQCCCRC), Muscat, OMAN.

Aim/Introduction: Radioembolization for hepatic malignancies often carries the risk of radiation-induced complications, such as pneumonitis and sclerosis, arising from hepatopulmonary shunting of 90Y microspheres. This study investigates the comparative accuracy and precision of lung shunt fraction (LSF) estimates derived from 99mTc macroaggregated albumin (99mTc-MAA) using planar, SPECT/CT, and Y90 PET/CT imaging modalities. ***Materials and Methods:*** Eight patients scheduled for radioembolization therapy were administered 99mTc-MAA and subjected to LSF measurement using planar and SPECT/CT imaging techniques. These pre-therapy LSF values were subsequently compared with post-therapy measurements from Y90 PET/CT to evaluate the precision and reliability of each imaging method. Statistical analyses were employed to quantify differences among the modalities. ***Results:*** Data analysis revealed a consistent overestimation of LSF by planar imaging in comparison to SPECT/CT and Y90 PET/CT. For example, LSF values for a typical patient (#4) were reported as 8.7% (Planar), 5.86% (SPECT/CT), and 5.512% (Y90 PET/CT). Statistically, planar imaging significantly overestimated LSF values relative to SPECT/CT and Y90 PET/CT ($p < 0.01$), underscoring the superior accuracy and agreement of SPECT/CT and Y90 PET/CT in post-therapy assessments. ***Conclusion:*** This study highlights the limitations of planar imaging in estimating LSF accurately and endorses the use of SPECT/CT as a more reliable method for pre-therapy lung shunt estimation. The findings advocate for a revision of imaging protocols to incorporate SPECT/CT, enhancing therapeutic planning and potentially improving patient outcomes in hepatic radioembolization.

EP-0667

Diagnostic Accuracy of SPECT/CT Images and SUV Values in Cardiac Amyloidosis

B. Bozca[1], *A. Erdem[1], A. Inanir[1], A. Cinar[1], N. Aydinbelge Dizdar[1], N. Altun Yologlu[1], S. Demirtas Senlik[1], D. Cayir[1,2], B. Kalayci[3], N. Coskun[4], O. Ozmen[1,2];*
[1]Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]University of Health Sciences, Ankara, TÜRKIYE, [3]Ankara Etlik City Hospital, Department of Cardiology, Ankara, TÜRKIYE, [4]Ankara City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Cardiac amyloidosis (CA) diagnosis typically involves heart-to-contralateral lung ratio (H/CL) calculations from planar images at 1-hour and visual evaluation from SPECT/CT images at 3-hours. This study aims to evaluate the impact of planar and SPECT/CT images, along with SUV values, on diagnostic accuracy. ***Materials and Methods:*** The H/CL ratio was computed by dividing counts on areas of interest in planar images at 1 and 3-hours. Visual grading was performed on SPECT/CT images taken at 1 and 3-hours, and SUVmax and SUVmean values were obtained from the 3-hour images. Spearman correlation analysis compared the H/CL ratios, while Mann-Whitney U test evaluated quantitative data, considering $p<0.05$ statistically significant. ***Results:*** Seventy patients suspected of ATTR-CA were included. Using H/CL cutoff values of 1 and 1.5 on planar images at 1 hour, 9 patients were negative, 51 suspicious, and 10 positive. Upon combined visual and quantitative assessment, the median 1 and 3-hour H/CL ratios for negative patients (n=58) were 1.17 and 1.15, while for positive patients (n=12), they were 1.57 and 1.68, respectively. Strong correlation was observed between 1-hour and 3-hour H/CL ratios in positive and negative patients ($p<0.001$). The 1-hour H/CL cutoff value for distinguishing positive and negative patients was determined as 1.4 (83.33% sensitivity and 89.66% specificity), while the 3-hour cutoff value was 1.33 (83.33% sensitivity and 87.93% specificity). On 3-hour SPECT/CT images, patients were graded as Grade-0 (n=38), Grade-1 (n=20), Grade-2 (n=4), and Grade-3 (n=8). SUVmax and SUVmean cutoff values for distinguishing positive and negative patients were 4.35 and 2.92. There was a statistically significant difference in SUVmax and SUVmean values between Grade 0-1 and Grade 2-3 groups in the myocardium, sternum, ribs ($p<0.05$) and myocardial, atrium, aorta, thorax, sternum, and rib SUVmax values between Grade 0-1 and Grade 2-3 ($p<0.05$). When combining 3-hour H/CL (>1.33) and 3-hour myocardial SUVmax (>4.35) cutoff values, a sensitivity of 66.6% and specificity of 96.5% were achieved in distinguishing positive and negative groups. Planar quantitative assessment resulted in 23 patients in the suspected group reclassified as negative using SPECT/CT, thus preventing false positives. ***Conclusion:*** Planar imaging at 1 or 3-hours is recommended for diagnosis of CA. Strong correlation was found between 1-hour and 3-hour H/CL ratios in positive and negative patients. In cases of time and equipment constraints, 3-hour imaging alone may be sufficient for diagnosis. 3-hour SPECT/CT images and derived SUV parameters may reduce the number of suspected/false positive patients.

EP-0668

Fast and Furious: Optimizing Clinical Blood Pool SPECT

L. Raes[1,2];
[1]Universitair Ziekenhuis Brussel, Brussels, BELGIUM, [2]Vrije Universiteit Brussel, Brussels, BELGIUM.

Aim/Introduction: Imaging the blood pool activity imaging allows to demonstrate inflammation associated with osteomyelitis, yet traditional planar imaging methods present challenges in accurately identifying focal regions of increased activity. Integrating SPECT imaging into bone scintigraphy protocols would enhance localization accuracy and eliminate superposition artifacts. Therefore, we aimed to optimize a fast SPECT imaging acquisition specifically tailored for blood pool imaging. ***Materials and Methods:*** A Jaszczak phantom filled with 550MBq of 99mTc-MDP, a standard activity for bone scintigraphy, was scanned using various SPECT acquisition setups. The standard bone scintigraphy SPECT consisting of 60p (projections per detector head) of 18 seconds and a matrix size of 128x128 served as baseline. Setup variations included: 30p x 18s, 30p x 9s, 12p x 30s, 12p x 18s, and 8p x 30s. All acquisitions were processed using OSEM iterative reconstruction. The same reconstruction parameters of the baseline SPECT were maintained with 8 iterations and 8 subsets, utilizing a Gaussian filter of 9mm FWHM. ***Results:*** The acquisitions of 30 projections demonstrated good performance in discerning hot rods, while those based on 8 or 12 projections struggled to delineate the hot rods clearly. Cold sphere contrast was reduced notably. A balance between acquisition time and image quality was achieved with 30 projections of 9 seconds, resulting in a total acquisition time of 4.5 minutes. ***Conclusion:*** A SPECT protocol suitable for blood pool imaging was obtained, showcasing a preference for acquiring more projections using shorter acquisition times over a limited number of projections. The protocol offers improved accuracy in localizing inflammatory sites over traditional planar imaging, while still being able to image the blood pool activity. Because of this, the protocol was introduced in clinical routine.

EP-0669

Comparison of "Step and Shoot" vs. "Continuous" mode of SPECT imaging with ^{99m}Tc regarding resolution and contrast

C. Happel, *B. Leonhäuser, B. Bockisch, R. A. Werner;*
Goethe University Frankfurt; University Hospital; Department of Nuclear Medicine; Clinic for Radiology and Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: SPECT-examination may be performed either by continuous movement of the detector heads (Continuous Motion (CM)) or by step-by-step acquisition in single angels (Step-and-Shoot mode (SnS)). Aim was to evaluate the influence of the acquisition mode regarding tomographic resolution and contrast for 99mTc-SPECT. ***Materials and Methods:*** SPECT-acquisition was performed with a gamma camera (IRIX, Philips) using a Jaszczak phantom filled with a total of 5,540 ml H2O and a 99mTc-activity of 45 kBq/ml in the hot regions (square pillars; volume: 13, 54 and 105 ml) and 15 kBq/ml in the surrounding volume. Beside the acquisition mode the number of views in SnS and the radius of the orbit were varied. The reconstructed transaxial slices were evaluated. An equal decay corrected examination time was used for comparison. ***Results:*** In SnS the number of views varied between 40 and 120. Tomographic resolution was not significantly impaired when using a small number of views (40). However, examination time was reduced obtaining the same net acquisition time. On the other hand, contrast was improved especially for the small pillar due to an increased number of counts per image. Concerning the acquisition mode, no significant influence in resolution and contrast of the hot regions was detected. The best results concerning contrast and resolution were obtained using a patient

contour orbit, but the deviation of image quality for the smallest possible circular orbit (22cm) and the patient contour orbit were not statistically significant (p>0.05). Further increase of the radius resulted in a decrease of contrast and resolution of up to 50% depending on acquisition mode and number of views. However, the negative correlation between orbit radius and image contrast is associated with an increased study time due to the radial motion of the detector heads during acquisition that lasted up to 120s depending on the number of steps and the transversal shape of the patient. ***Conclusion:*** Because of no significant disadvantage in image quality and its increased convenience especially for claustrophobic patients CM is the preferable acquisition mode. The number of views can be reduced to 40 to obtain an increased number of counts per view and therefore enhance tomographic contrast. Only a small improvement of image quality can be achieved with a patient contour orbit compared to the smallest circular orbit. However, the increased gross acquisition time and the radial movement of the detector heads may be unpleasant especially for the claustrophobic patients.

EP-0670

A phantom study to optimize BSREM 3D-ring cadmium-zinc-telluride SPECT/CT reconstruction parameters for sentinel node imaging of head neck melanoma

C. P. W. Cox*, A. A. Harteveld, M. Segbers;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Sentinel node (SN) detection of head and neck melanoma may benefit from the use of a 3D-ring cadmium-zinc-telluride (CZT) SPECT/CT due to its superior sensitivity in comparison with conventional dual head SPECT/CT. Furthermore using block sequential regularization expectation maximization (BSREM) as reconstruction algorithm may also improve SN detection. Thus far, SN imaging in head and neck melanoma has not been investigated for BSREM 3D-ring CZT SPECT/CT. The aim of this phantom study is to determine the optimal BSREM parameters for 3D-ring CZT SPECT/CT SN imaging in head and neck melanoma and compare the optimal reconstruction with a conventional SPECT/CT scan. ***Materials and Methods:*** To simulate one SN and two in-plane higher echelon nodes three Eppendorf tubes with each 2MBq [99mTc]Tc-pertechnetate were positioned in the neck area of an anthropomorphic Alderson phantom. On top, 1cm tissue equivalent material was placed on which four Eppendorf tubes with each 10MBq were attached lateral from the SN to simulate injection sites. SPECT scans with 20 minutes acquisition time were performed on a conventional and 3D-ring CZT SPECT/CT. 3D-ring CZT SPECT/CT scans were reconstructed using BSREM with resolution recovery, attenuation correction, dual energy window scatter correction, bySens and 2.46mm voxels. To determine to optimal number of iterations, 10, 20 and 30 iterations with 10 subsets were reconstructed using a default factory protocol with β=0.05 and γ=2. The optimal number of iterations was used for reconstructions with β between 0.01-0.5 and γ between 1-4 to optimize β. After which γ was further optimized using values between 5-11. After a visual assessment for artefacts, optimal parameters were determined by highest SN contrast-to-noise ratio (CNR) and recovery coefficient (RCmax) values. SN detection between the optimal and conventional reconstruction was compared using SN peak to background valley ratio. Peak and valley values were determined with a line profile over the SN and background between SN and injection site. ***Results:*** Highest CNR (13.6) and RCmax (1.1) were obtained with 30 iterations. Whereas, the optimal reconstruction parameters β=0.05 and γ=10 resulted in stabilized CNR (201.2) and RCmax (1.7) values without visible artifacts. Comparison with the conventional SPECT/CT reconstruction resulted in an increase in SN peak to background valley ratio from 3.8 to infinite as the valley of the optimal reconstruction was zero. ***Conclusion:*** SN detection in head and neck melanoma improved with BSREM 3D-ring CZT SPECT/CT. Further investigation is needed to validate and optimize the results in patients.

EP-0671

High Image Quality at Reduced Time per Bed Position - an Evaluation of Posttreatment ^{177}Lu-PSMA-617 scans Using the StarGuide CZT-based SPECT/CT system

H. Duan, *V. Ferri, J. Shah, H. Song, P. Castaneda, T. Visser, K. Luong, A. Iagaru;*
Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Single photon emission computed tomography/computed tomography (SPECT/CT) imaging post targeted radionuclide therapy is important for assessing uptake in tumor lesions, dosimetry, and identification of possible extravasation. However, whole-body SPECT/CT is constrained by long image acquisition times with respective low patient compliance, and relatively low sensitivity. We have shown that fast whole-body post-therapy SPECT/CT is feasible using the StarGuide (GE Healthcare), a next-generation multi-detector Cadmium-Zinc-Telluride (CZT) SPECT/CT system (1). In this study, we assessed the image quality of post 177Lu-PSMA-617 SPECT/CT scans with reduced time per bed position (pBp) of 1 minute and 2 minutes, and compared them to standard 3 minutes per bed position. ***Materials and Methods:*** We retrospectively analyzed SPECT/CT scans from 50 patients who received 177Lu-PSMA-617 as part of standard of care. Post-treatment whole-body SPECT/CT images were routinely acquired for 3 minutes pBp and were retrospectively reconstructed to be equivalent to 2 minutes and 1 minute pBp. Three readers independently evaluated image quality for each reconstruction using a 5-point Likert scale (1 non-diagnostic, 2 suboptimal image quality, 3 acceptable image quality, 4 good image quality, 5 excellent image quality). We assessed interreader agreement and calculated the difference of proportion of high quality image between each pair of comparison. ***Results:*** Mean image quality across all readers was nearly excellent for standard 3 minutes pBp at 4.75±0.51 (range, 2-5). The reconstructed 2 minutes pBp yielded in good image quality at 4.33±0.77 (range, 2-5) while the 1 minute acquisition pBp was acceptable at 3.05±0.95 (range, 1-5). The interreader agreement, however, was low. The per-reader analysis showed no significant difference between 3 minutes and 2 minutes for Reader 1 and 3 (P=1 and P=0.5, respectively) while for Reader 2, 3 minutes pBp showed 39% higher image quality than 2 minutes (P=<0.001). The image quality of scans acquired at 1 minute pBp was significantly lower than that of 2 minutes and 3 minutes across all three readers (P=<0.001, respectively). ***Conclusion:*** Our preliminary data showed that fast acquisition times of as low as 2 minutes per bed position for whole-body post-treatment SPECT/CT yielded in high image quality using the new StarGuide SPECT/CT system. Further evaluation in larger cohorts are needed to validate our findings. ***References:*** Song H, Ferri V, Duan H, et al. SPECT at the speed of PET: a feasibility study of CZT-based whole-body SPECT/CT in the post (177)Lu-DOTATATE and (177)Lu-PSMA617 setting. Eur J Nucl Med Mol Imaging. 2023;50:2250-2257.

EP-0672

Optimization of Collimator Design in HiReSPECT II: a Monte Carlo Study

***M. Mirdoraghi*[1],** *B. Teimourian Fard*[2], *O. Kochebina*[3], *H. Mahani*[4], *M. Ay*[1];
[1]*Department of Medical Physics and Biomedical Engineering, School of Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Research Center for Molecular and Cellular Imaging, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [3]*Université Paris-Saclay, Inserm,CNRS, CEA, Laboratoire d'Imagerie Biomédicale Multimodale (BioMaps), Orsay, FRANCE,* [4]*Radiation Applications Research School. Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Small animal imaging has an extensive variety of applications, including the design and optimization of novel imaging devices. Monte Carlo (MC) simulations are enhanced due to their high accuracy. The purpose of this investigation was to validate the MC code for a preclinical SPECT known as HiReSPECT II machine and also optimize different collimator materials and geometries for sensitivity and spatial resolution. ***Materials and Methods:*** The validation of a small animal SPECT scanner furnished with lead hexagonal parallel-hole collimator, CsI(Na) pixelated crystal and SiPM photodiodes was performed by comparing experimental results with Geant4 Application for Emission Tomography (GATE) simulation data. In the next step, the optimization appraisals for both spatial resolution and sensitivity on the collimator material and hole diameter were carried out using GATE. The experimental and simulated sensitivities were obtained using a cylindrical phantom at collimator-source distance (SCD) of 3 cm. Moreover, a line source was applied to assess the spatial resolution in the simulated and experimental environments at different SCDs. ***Results:*** The discrepancy between experimental and simulated sensitivities was less than 8%. In addition, the differences between simulated and experimental spatial resolutions were less than 12%. Also, the sensitivity for TuCu, Au, Pb and Tu was studied. Besides, the spatial resolution values of Au, Tu and Pb was close to each other and better than Tu+Cu. ***Conclusion:*** The best spatial resolution-sensitivity tradeoffs for parallel-hole collimators are observed in Au with hole diameter of 1.2 mm and Pb with hole diameter of 1.2 mm. However, lead is preferred over gold because it's considerably cheaper than gold. Additionally, the spatial resolution-sensitivity tradeoff greatly depends on the hole diameter and collimator material. Increasing the hole diameter augments the sensitivity and decreases the spatial resolution.

EP-0673

Fabrication of a patient-specific metastasized lumbar vertebra phantom with realistic attenuation properties

L. Pieper, *A. Theisen, M. Laßmann, M. Salas Ramirez, J. Tran-Gia;*
Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY.

Aim/Introduction: 177Lu SPECT/CT imaging is essential for bone marrow dosimetry. However, not much is known about its accuracy in bone sites, where imaging is particularly challenging due to low count rates in combination with high photon attenuation. The aim of this work was to produce and validate a phantom of a metastasized lumbar vertebra with realistic attenuation properties in cortical bone, spongiosa, and metastasis. ***Materials and Methods:*** The phantom consisted of a two-compartment lumbar vertebra (healthy spongiosa and metastasis) and a single-compartment right kidney, fitted inside a Jaszczak cylinder. Both inserts were segmented on the CT of a pretherapeutic [18F]F-PSMA-1007 PET/CT scan of a patient suffering from metastatic castration-resistant prostate cancer. While a clear resin with density similar to soft tissue was used for the kidney (HU: 121[1]), a high-density resin was used to replicate the higher density of cortical bone (HU: 813[1]). The kidney was filled with a [177Lu]LuCl3 solution of activity concentration 310kBq/ml dissolved in 0.1M HCl with 216mg/ml non-active LuCl3*6H2O. The stock solution for the denser bone compartments was prepared based on[2]. Here, a method was presented to determine the K2HPO4 concentration required for a stock solution of a given HU in a low-dose CT. The target HUs (spongiosa: 200, metastasis: 500) were obtained from the CT of a peritherapeutic SPECT/CT acquisition of the same patient after [177Lu]Lu-PSMA-I&T therapy. Both stock solutions were prepared by mixing K2HPO4 with H2O and adding a separately prepared solution of H2O, DTPA and 33kBq/ml (healthy spongiosa) or 0.95Mbq/ml (metastasis) of [177Lu]LuCl3. SPECT/CT imaging was performed with a clinical low-dose protocol (MELP, 20s-per-projection, 256x256 matrix, 1.95cm voxel-size, 130kVp, 20mAs). ***Results:*** Visually, the phantom CT exhibited a noticeably higher density than the surrounding water. The HU histogram showed three peaks, corresponding to the densities of the materials used. Cross-sections through the attenuation maps of patient and phantom showed comparable density profiles of water, cortical bone, spongiosa, and metastasis. Despite the similarities, the integral along a central line through the vertebra showed a higher attenuation in the phantom than in the patient. ***Conclusion:*** This study shows that realistic attenuation properties in bone sites can be achieved by a combination of denser 3D printing resins and stock solutions when measuring with hollow phantoms. This represents an important step towards the validation of quantitative SPECT/CT imaging in bone sites. ***References:*** [1] Kalidindi Y et al. Micromachines 14(10);2023:1928, [2] Pieper L et al. EP-0674

Subdiaphragmatic artefacts in myocardial perfusionm scintigraphy

***K. Kovacevic-Kusmierek*[1],** *M. Chwascinski*[2], *Z. Adamczewski*[1];
[1]*Nuclear Medicine Department Medical Uniwersity of Lodz, Lodz, POLAND,* [2]*Medical Uniwersity of Lodz, Lodz, POLAND.*

Aim/Introduction: Myocaridal perfusion imaging aids in assessing coronary artery disease. During image acquisition, subdiaphragmatic artifacts may occur, hindering the accurate evaluation of the conducted study. Several methods exist to reduce the occurrence of these artifacts. The aim of this study was to evaluate the quantity of examinations repeated due to these artifacts at the Department of Nuclear Medicine, Medical University of Łódź. ***Materials and Methods:*** Study included 139 patients (67females, 72males) aged 35-91 years, BMI 18.8-48.8 [kg/m2]. 103 patients (74%) were classified as overweight (BMI ≥ 25). The analyzed studies were conducted between IX-XII 2022, encompassing a complete set of myocardial perfusion scans (rest (RS) and stress(SS): exercise - 86 patients or pharmacological tests - 53 patients). Studies were performed using GE Discovery 530c semiconductor gamma camera and GE Infinia Hawkeye 4 scintigraphic gamma camera. ***Results:*** Subdiaphragmatic artifacts occurred in 27/139 SS (19.4%) and 44/139 RS (31.7%). In 17 cases, they occurred in both SS and RS of the same patient (12.2%). Incidence of these artifacts was significantly lower in SS compared to RS (19.4% vs. 31.7%; $p = 0.009$). Among 53 patients who underwent pharmacological stress tests, artifacts occured in 15 cases (28.3%), while in 86 patients who underwent exercise tests

they occured in 12 cases (14%). Incidence of subdiaphragmatic artifacts after excercise stress tests was significantly lower than after pharmacological stress tests (14% vs. 28%; p = 0.038). No significant relation between age, sex and BMI of the patients and incidence of subdiaphragmatic artifacts was observed. ***Conclusion:*** Recommendation that patients walk moderately intensively (in the designated area of the Department) between radiopharmaceutical administration and image acquisition on a gamma camera may reduce the occurrence of subdiaphragmatic artifacts in rest studies and studies after pharmacological stress tests.

The Role of Ga^{68}-PSMA PET/CT in Biochemical Recurrent Prostate Cancer

C. Dündar Çaglayan, *G. G. Bural, A. Boz;*
Akdeniz University Hospital, Antalya, TÜRKIYE.

Aim/Introduction: The aim of study was to investigate the the diagnostic performance of PSMA PET/CT performed for restaging in subjects with biochemical recurrent prostate carcinoma after curative treatment either with radical prostatectomy (RP) or Radiation Treatment (RT). ***Materials and Methods:*** 58 prostate cancer patients (Age 73±8) with biochemical recurrent prostate carcinoma after curative treatment who underwent Ga68-PSMA PET/CT between December 2015 and August 2022 were retrospectively analyzed.PSMA uptake levels were grouped as posivite or negative.Positive disease locations were classified as prostate/prostate bed,pelvic lymph node,abdominal lymph node,supradiaphragmatic lymph node,bone,visceral organ.SUVmax values were recorded for positive disease sites.According to PSMA PET/CT findings, the extent of disease was decided (pelvis limited and distant metastatic). Gleason score,ISUP grade (International Society of Urological Pathology)),PSA,PSAdt,PSAvelocity and pathological SUVmax values were recorded and compared in PET positive and negative subjects and also in RT and RP groups.Findings were correlated with histopathological results and/or radiological, clinical and laboratory findings. ***Results:*** PSMA PET/CT was positive in 33 patients,negative in 25 patients.The sensitivity,specificity,positive predictive value and negative predictive value of PSMA PET/CT were calculated as 73.2%,78.6%,90.9%,50%,respectively.Patient-based detection rate was found to be 57%.Detection rate was 24% when PSA level was <1 ng/ml,69% when PSA level was between 1-4 ng/ml and 81% when PSA level was above 4 ng/ml.A statistically significant correlation was found between PSMA PET/CT positivity and age,Gleason score,ISUP grade and PSA level.PSA value was found to be significantly higher in PET-positive patients. The threshold value in the ROC analysis for PSA was calculated as 1.0050 ng/ml,and was statistically significant (p= 0.06).In the presence of bone involvement,Gleason score average and PSA were found to be higher.A statistically significant relationship was found between visceral involvement,supradiaphragmatic LN involvement and bone involvement and ISUP Grade categories.A statistically significant strong positive correlation was observed between PSA and bone SUVmax.PSA value was observed to be significantly higher in patients with distant metastases.It was noted that the PSAdt value was shorter, especially in cases with extensive metatatic disease.The uptake in local recurrence site was higher in subjects who had RT than in subcets with RP.No difference was noted for both groups in other metastatic disase sites. ***Conclusion:*** Ga68-PSMA PET/CT has shown reliable performance in locating recurrence sites of prostate cancer.This performance is better when the PSA serum level is above 1 ng/mL.Ga68-PSMA PET/CT imaging should be considered and used as the first-line imaging modality for biochemical recurrence in prostate cancer patients who had curative treatment.

EP-0676

The impact of various patient hydration protocols on physiological $^{[18F]}$FDG uptake in the urinary bladder on PET/CT

A. Khalimon, *A. Nikiforuk, M. Khodzhibekova, A. Leontyev;*
P. Hertsen Moscow Oncology Research Institute – branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: To assess the impact of volume and route of hydration, forced diuresis (furosemide 10mg IV) and the time of diuretic administration, prehydration (before $^{[18F]}$FDG administration) on physiological $^{[18F]}$FDG uptake in the urinary bladder on PET/CT. ***Materials and Methods:*** Prospective single-center randomized trial included 140 patients who underwent $^{[18F]}$FDG PET/CT. Scans were performed according to the standard EANM proposed protocol, 60 minutes after the IV administration of $^{[18F]}$FDG. Patients were divided into 7 groups (n=20 for each group), based on the hydration protocol: (#1) 1000ml orally post $^{[18F]}$FDG injection (p/i); (#2) 1000ml orally p/i + furosemide 10mg IV (60 minutes before PET); (#3) 1000ml orally p/i + furosemide 10mg IV (30 minutes before PET); (#4) 500ml orally p/i + furosemide 10mg IV (30 minutes before PET); (#5) 1000ml IV p/i + furosemide 10mg IV (30 minutes before PET); (#6) 500ml IV p/i + furosemide 10mg IV (30 minutes before PET); (#7) 500ml IV before and 500ml IV within 30 minutes p/i + furosemide 10mg IV (30 minutes before PET). $^{[18F]}$FDG uptake in the urinary bladder was quantified using SUVmean (Mean Standardized Uptake value), measured within a spherical VOI with a fixed volume of 2.5cm3 delineating the bladder boundaries. Intergroup differences were assessed for statistical significance using the nonparametric Mann-Whitney U test. ***Results:*** The urinary bladder SUVmean for each group were as follows: (#1) - 15.4 [9.0;36.1]; (#2) - 5.4 [4.1;10.5]; (#3) - 2.8 [2.3;3.9]; (#4) - 5.0 [3.7;6.4]; (#5) - 3.1 [2.6;3.5]; (#6) - 4.8 [3.6;7.2]; (#7) - 3.3 [3.1;4.0]. Significantly lower SUVmean ($p<0.001$) were observed in the groups (#4) and (#6) compared to the groups (#3) and (#5), respectively. Patients in all other groups also exhibited significantly lower SUVmean compared to the group (#1) ($p<0.001$ for each group). Additionally, SUVmean was significantly lower ($p<0.0001$) in the group (#3) compared to the group (#2). No significant differences in SUVmean were found between the groups (#3) and (#5) ($p=0.46$), groups (#4) and (#6) ($p=0.98$), as well as between the groups (#5) and (#7) ($p=0.095$). ***Conclusion:*** A larger volume of hydration, forced diuresis and a 30-minutes time interval between furosemide administration and the start of PET acquisition significantly reduced both the level and variability of $^{[18F]}$FDG uptake in the urinary bladder. Prehydration and the route of hydration in the same volume did not affect $^{[18F]}$FDG uptake in the urinary bladder.

EP-0677

Phantom-based evaluation of yttrium-86 quantification using a conventional and a digital PET system: impact of prompt gamma coincidence correction

A. Syka[1,2], *M. Teimoorisichani[3], J. Ráliš[4], D. Kersting[5,6], P. Costa[5,6], F. Zarrad[5,6], K. Herrmann[5,6], O. Lebeda[4], M. Conti[3], W. Jentzen[5,6];*
[1]University Hospital RWTH Aachen, Aachen, GERMANY, [2]University Hospital Essen, Essen, Germany, GERMANY, [3]Siemens Healthineers, Molecular Imaging, Knoxville, TN, UNITED STATES OF AMERICA, [4]Nuclear Physics Institute of the CAS, Prague, CZECH REPUBLIC, [5]University Hospital Essen, Essen, GERMANY, [6]University of Duisburg-Essen, Essen, GERMANY.

Aim/Introduction: In theranostic approaches, the diagnostic and therapeutic radionuclide should ideally be the same element. For example, the beta-emitting yttrium-90 is often used for therapeutic applications; the corresponding diagnostic yttrium isotope is the positron-emitting yttrium-86. However, yttrium-86 has a complex decay scheme emitting a large amount of prompt gammas that impair PET image quantification. In this phantom study, the quantitative performance of yttrium-86 will be evaluated. Yttrium-86 images reconstructed with and without prompt gamma coincidence correction (PGC correction) are compared with reference level results of fluorine-18. ***Materials and Methods:*** A PET NEMA phantom (with a lung insert) was scanned using two PET/CT scanners, a conventional Biograph mCT and a digital Biograph Vision 600. A clinical relevant acquisition time of 240 s for yttrium-86 and 67 s for fluorine-18 (positron-branching ratio-adapted) were selected. Images were reconstructed with time-of-flight option, once with PSF and once without and with and without application of PGC correction. Four performance metrics were used: sphere signal recovery coefficient, sphere contrast recovery coefficient, background recovery coefficient, and residual lung bias. ***Results:*** For all metrics, images without PGC correction yielded inferior output, particularly unacceptable results for the conventional scanner. Applying the PGC correction improved considerably all metrics. Sphere signal and sphere contrast recovery coefficient values of yttrium-86 were underestimated (≤ 15%) compared to fluorine-18 reference levels. The images with PGC correction provided residual lung bias values comparable to those of fluorine-18. Nevertheless, images with PGC correction achieved a background recovery of 85%. ***Conclusion:*** This study reveals necessity of PGC correction in the image reconstruction of yttrium-86. Involving the PGC correction resulted in quantitative performance comparable across both PET/CT systems. Despite observed improvements, additional advancements of PGC correction are desirable.

EP-0678

Misregistration correction of 650 PET/CT scans with data-driven gated CT

T. Pan, *D. Luo;*
The University of Texas, M.D. Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Misregistration caused by irregular respiration can compromise the quantification and localization accuracy of PET/CT. Repeat PET/CT can be a solution, but it takes > 5 mins to repeat 1-bed position on a 25-cm axial field of view PET/CT. We have developed a data-driven gated (DDG) CT, whose CT radiation dose is 35% of a repeat PET/CT and whose scan time is < 1 min. We evaluated the efficacy of DDG CT for misregistration correction of 650 PET/CT scans. ***Materials and Methods:*** All PET/CT scans were reviewed for data integrity in the last bed position. When misregistration is identified, a low-dose cine CT scan over the misregistration area is initiated during the transition from PET to CT to patient release. The cine CT scan protocol is 120 kVp, 5-sec cine duration, 0.8-sec gantry rotation cycle time, noise index = 70, and 10 ≤ mA ≤ 20. The cine CT takes < 1 min and the radiation dose is 1.3 mSv, 35% of a repeat PET/CT. The overlap region of the misregistered CT with DDG CT is replaced with the DDG CT for attenuation correction of the PET data. The DDG CT was derived from the changes in the lung CT numbers and body outlines to respiration and was applied for misregistration correction of 650 PET/CT scans from January 1, 2023, to April 17, 2024. ***Results:*** The 650 scans constituted only 3% of the total PET/CT scans. Three cine CT scans (< 0.5%) failed due to patient motion or loss of landmark position between PET and cine CT. The remaining 647 scans (> 99.5%) were all improved with DDG CT for quantification and registration. Of the 650 scans, 49%, 30%, and 18% were 18F-FDG, 18F-PSMA-PYL, and 68Ga-Dotatate scans, respectively; and 308 scans (47%) had ≥ one lesion in the misregistration area and benefited from correction. Of these 308 scans which had ≥ one lesion in the misregistration area, 70%, 8% and 22% were 18F-FDG, 18F-PSMA-PYL, and 68Ga-Dotatate scans, respectively. There was no impact on patient throughput as the misregistration correction was applied during the acquisition of the next PET scan. ***Conclusion:*** The efficacy of DDG CT for misregistration correction has been demonstrated on 650 scans. The DDG CT was effective for misregistration correction, particularly for the 18F-FDG and 68Ga-Dotatate scans. Misregistration correction of the 18F-PSMA-PYL scans may not be necessary as there is usually no lung or liver lesion.

EP-0679

Additional value of the acquisition of PET with ^{18}F-FDG in inspiration to the conventional PET/CT protocol, in the metabolic assessment of lung nodules.

M. Casallas Cepeda, *S. Salcedo Cortés, J. Alonso Farto, I. Gomez Fernandez, J. Montalva Pastor, E. Ardila Manjarrez, L. Reguera, j. Ardila Mantilla;*
Hospital General Universitario Gegorio Marañón, Madrid, SPAIN.

Aim/Introduction: To determine the impact of the acquisition of PET in inspiration, in addition to the conventional ^{18}F-FDG PET/CT protocol, in the metabolic assessment of pulmonary nodules. ***Materials and Methods:*** We analyzed 53 patients (median 68 years; 24 Women and 29 Men) referred for evaluation of one or more lung nodules previously identified in previous radiological studies. The acquisition was performed with PET/CT (GE Discovery Gen 2 5-ring) on an empty stomach, for at least 4 hours, checking basal blood glucose, after administration of ^{18}F-FDG. Whole body and chest images were acquired on inspiration (both PET and CT) with multiparametric visual analysis, as well as quantitative analysis of the maximum standardized uptake index (SUVmax). ***Results:*** 85 nodular lesions (size 0.3-3cm) were analyzed. We performed a visual assessment of which 58 were suspicious of malignancy, 25 suspected of benignity and 2 undetermined. An SUVmax > 2.5 was also defined as a suspicious cut-off point, evaluating them both in the usual acquisition and in inspiration, 41 nodules evaluated with the usual acquisition obtained an SUVmax > 2.5, while those evaluated with PET in inspiration were 63 with a median increase in SUVmax of 0.59. Similarly, the SUVmax decreased in 22 nodules and increased in 58 nodules. ***Conclusion:*** The acquisition of PET/CT in inspiration is very useful to determine the malignancy of lung nodules, not only from a semi-quantitative point of view, but also significantly impacting the visual assessment. Therefore, the acquisition of PET in inspiration added to the usual protocol allows it to be a useful tool for correct assessment, staging

and, consequently, adequate medical-surgical management. ***References:*** 1. Lamare, F et al. "PET respiratory motion correction: quo vadis?." EP-0680

Evaluation of the optimal imaging protocol for [18F] PSMA PET-CT to detect bone metastases in prostate cancer patients

D. Ventura[1], *L. Bredensteiner[1], P. Rassek[1], M. Schäfers[1], M. Bögemann[2], P. Schindler[3], M. Weckesser[1], K. Rahbar[1], W. Roll[1];*
[1]Department of Nuclear Medicine, Münster, GERMANY,
[2]Department of Urology, Münster, GERMANY,
[3]Department of Radiology, Münster, GERMANY.

Aim/Introduction: PSMA-PET is a commonly used diagnostic tool for patients with prostate cancer (PC). However, it is important to consider the indications and acquisition time due to the limited availability of PET scanners and associated costs. The objective of this investigation was to determine if a PET scan from the head to the proximal femur is sufficient to detect the presence of relevant bone metastases. ***Materials and Methods:*** A retrospective analysis was carried out on 1050 consecutive [18F]PSMA-1007-PET-CT scans, acquired from the head to the proximal lower leg. PET scans were classified based on the presence and quantity of bone metastases: (1) 1-5, (2) 6-19 and (3) ≥20. The PET scans were also evaluated for the presence of bone metastases distal to the thigh. The imaging results were compared to patients PSA values. ***Results:*** Bone metastases were present in 391 PSMA-PET scans. In 37.3% (n=146) the PET scan also revealed distant bone metastases in the femur and/or proximal tibia. The majority of distant bone metastases was found in patients with more than five bone metastases (second and third subgroups). Only one patient with five metastases in total (subgroup one, 0.7%) presented with a distant bone metastases. No solitary distant metastasis was detected. PSA values increased significantly with a higher number of bone metastases (first vs third subgroup, $P < 0.001$). The ROC analysis indicated that a PSA value of 11.15 ng/mL is the most effective cut-off for detecting distal bone metastasis, with an AUC of 0.919 (95% CI: 0.892 - 0.945), sensitivity of 87%, and specificity of 86%. ***Conclusion:*** PSMA-PET acquisition protocols from the head to the proximal femur may be sufficient for accurate detection of bone metastatic disease in PC. PSA values can be used to support decision making regarding individual PET acquisition protocols.

EP-0681

When do Ki images benefit lesion detection by SUV images

D. Cai, *Y. He, H. Yu, Y. Zhang, H. Shi;*
Zhongshan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: To compare using Ki or SUV images. ***Materials and Methods:*** Patients with a histopathological diagnosis who received a weight-based 18F-FDG injection and underwent 60-min total-body PET/CT dynamic imaging were included in this retrospective study. SUV images were reconstructed using data collected from the last 10 minutes of the scans. Ki images were generated using the Patlak methods with data from minutes 12-60. The background SUVmax, SUVmean, SUVSD, Kimax, Kimean, and KiSD values were recorded. The signal-to-noise ratios of the SUV (SUVSNR) and Ki (KiSNR) images were calculated. The lesion detection rate and sensitivity of the SUV and Ki images were evaluated. ***Results:*** The study included 134 patients with 244 pathologically confirmed lesions (200 malignant and 44 benign). The lesion-detection rates were 97.7% (214/219) and 99.5% (218/219) for the SUV and Ki images, respectively ($p = .22$). Five false-negative lesions on the SUV images were true-positive on the Ki images. The sensitivity (94.0% vs. 96.0%, $p = .22$), specificity (41.9% vs. 41.9%, $p > .99$), accuracy (84.4% vs. 86.1%, $p = .61$), positive predictive value (87.9% vs. 88.1%, $p = .94$), negative predictive value (60.0% vs. 69.2%, $p = .47$), and the area under the curve [.68 (95% confidence interval, .61-.73) vs. .69 (95% confidence interval, .62-.74)] were similar in the SUV and Ki images (all $p \geq .10$). ***Conclusion:*** SUV images play an important role in lesion detection. Sometimes, particularly for lesions in organs with high radiotracer background, Ki images enhance the detection ability of the SUV images.

EP-0682

Brain-Only Imaging on Long Axial Field-of-View PET/CT

J. Khan, *T. Willson, N. Davis, B. F. Holman, B. Ferreira, D. McCool, J. Edwards, T. Szyszko, T. Wagner;*
Royal Free London NHS Foundation Trust,
London, UNITED KINGDOM.

Aim/Introduction: Brain-only PET/CT studies are crucial for diagnosing brain malignancies and Alzheimer's disease. They are typically performed over one bed position centred on the brain, with the CT providing attenuation correction (AC). The Royal Free Hospital recently received the UK's first long axial field-of-view (LAFOV) PET/CT system, boasting a 106 cm axial length and 20 times higher sensitivity than current-generation scanners. This system offers significantly improved image quality and contrast recovery. However, for single-organ studies like brain imaging, it poses the question of optimal patient positioning to balance sensitivity and CT dose. Should the brain be centred in the FOV for maximum sensitivity but higher CT dose, or positioned at the edge for lower dose but noisier images? This study seeks to optimize brain-only PET/CT scans by evaluating patient positioning, image quality, and CT dose. ***Materials and Methods:*** The need for CT attenuation correction was assessed to determine if it could be omitted from the imaging study. All initial brain imaging studies using the LAFOV system were retrospectively reconstructed with and without CT-based attenuation correction. Additionally, a reconstruction using the Chang filter was created. Two experienced nuclear medicine practitioners reviewed the images to assess whether CT attenuation correction was required. Phantom data were also acquired using a brain phantom placed at the centre and the edge of the FOV. CT scans were performed with varying quality reference mAs from 7 to 300 to optimize the CT dose while identifying the optimal patient position. ***Results:*** LAFOV non-attenuation-corrected (NAC) brain images were deemed acceptable if a recent high-quality brain CT or MRI was available. In this case, imaging the brain at the centre of the FOV was considered optimal. If no high-quality CT or MRI was available, imaging the brain near the edge of the FOV with a CTAC scan at 60 mAs provided a reduced dose while achieving a diagnostically

appropriate image. This mAs value was the lowest that could be used without photon starvation and still provided a suitable quantitative image. ***Conclusion:*** Brain-only imaging on a LAFOV PET/CT system is optimized by either centering the brain in the FOV with no attenuation correction if a high-quality CT/MRI is available or positioning the brain at the edge with a low-dose CTAC. This flexibility allows for a reduction in CT radiation burden while maintaining diagnostic image quality.

EP-0683

Impact of Different Coincidence Strategies on Image Quality in [18F]FDG PET: A Phantom Study

Y. Liu[1], *X. Li[1], Y. Cheng[2], Q. Xie[1,2], X. Zhou[3];*
[1]Wuhan National Laboratory for Optoelectronics, Wuhan, CHINA, [2]Department of Electronic Engineering and Information Science, University of Science and Technology of China, HeFei, CHINA, [3]Department of Biomedical Engineering, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: In PET/CT imaging, image quality is a critical factor for evaluating and optimizing scanning protocols, and it is directly influenced by count rate performance. Considering this relationship, we focuses on exploring whether applying different coincidence strategies to the same raw scan data affects image quality, as quantified by recovery coefficients (RC). Accurate RC values are essential for effective clinical diagnosis and scientific research. ***Materials and Methods:*** This study employed a fully digital clinical PET/CT system, which utilizes multi-voltage threshold (MVT) technology to directly digitize scintillation pulses, thereby facilitating post-acquisition coincidence sorting with various Coincidence Sorting Methods (CSMs) via software. We conducted four 10-minute scans of an Image Quality (IQ) phantom at hourly intervals, yielding 48 images utilizing 12 distinct coincidence strategies. The initial PET/CT scan of the phantom commenced with a background-to-lesion ratio of 1:10, where the lesion activity concentration was 19.13 kBq/ml. Each coincidence strategy was incorporated with a unique pairing policy dictating the management of coincident events within a 5 ns timing window. These policies (1), which ranged from the most restrictive ("killAll") to the least restrictive ("takeAllGoods"), were evaluated in both multi-window and single-window modes. All images were processed under identical reconstruction parameters (OSEM+PSF, 2 iterations, 12 subsets). Using ANOVA, we assessed the effects of different coincidence strategies on the mean and maximum recovery coefficients (RCmean and RCmax) for hot spheres varying from 10 mm to 37 mm in diameter, aiming to evaluate their potential impact on image quality. ***Results:*** The ANOVA results indicated no statistically significant differences in RCmean and RCmax across different coincidence strategies ($P > 0.9999$), suggesting that under the test conditions used, the choice of coincidence strategy does not significantly impact recovery coefficients. ***Conclusion:*** The findings demonstrate that different coincidence strategies do not significantly affect RCmean and RCmax when using the digitalized PET/CT system on an IQ phantom, thereby providing flexibility in clinical and research applications. Future research should explore the impact of varying reconstruction parameters and different imaging time intervals on quantitative image parameters to deepen understanding of the stability and reliability of quantification under different settings. ***References:*** (1) OpenGATE GATE user's guide version 9.4 openGATE. http://www.opengatecollaboration.org/.

EP-0684

Lesion conspicuity by size in [18F]FDG long-axial field-of-view PET/CT

C. Mingels[1,2], *L. Weissenrieder[1], K. Zeimpekis[1], H. Sari[1,3], R. Seifert[1], F. Caobelli[1], L. Nardo[2], A. Rominger[1], T. Pyka[1];*
[1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [2]Department of Radiology, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [3]Siemens Healthineers International AG, Zürich, SWITZERLAND.

Aim/Introduction: To compare lesion quantification with [18F]FDG long-axial field-of-view (LAFOV) PET/CT to simulated short-axial field-of-view (sSAFOV) PET/CT. ***Materials and Methods:*** In this retrospective evaluation of 57 oncologic patients who underwent [18F]FDG LAFOV PET/CT, 160 malignant lesions (melanoma, lung cancer, lymphoma, breast cancer) were evaluated. Lesions were divided into different subgroups by their largest diameter based on the coregistered CT (<8mm: n=22, 8-10mm: n=32, 11-20mm: n=48, .20mm: n=58). LAFOV PET/CT was acquired in list-mode for 360s in maximum ring difference (MRD) 322. For sSAFOV PET, data were reconstructed in MRD 85 with 120s acquisition time. Image evaluation was performed by two nuclear medicine physicians. Image noise were characterized by liver's mean standardized uptake value (SUVmean) and signal-to-noise ratio (SNR). Tumor uptake was compared by using SUVmax/SUVpeak. Tumor-to-background ratio (TBR) was calculated by SUVmax/SUVpeak (TBRpeak). Image quality was assessed by SUVpeak tumor-to-noise ratio (TNRpeak) and a new independent image quality criterion (IQ: TBRpeak x TNRpeak). Paired t-test ($p<0.05$) was used to identify statistically significant differences between LAFOV and sSAFOV reconstructions. ***Results:*** Background noise level was impacted by LAFOV PET/CT reconstructions. While liver SUVmean did not change significantly between both analyzed reconstructions ($p=0.08$), SNR was significantly lower in sSAFOV compared to LAFOV PET (7.71±1.22 vs. 14.98±3.81). SUVmax was significantly higher for sSAFOV PET/CT in all lesion sizes compared to LAFOV PET/CT ($p<0.05$). TBR by SUVmax was significantly higher for sSAFOV to LAFOV PET/CT ($p<0.05$). However, TBR by SUVpeak was not significantly different between sSAFOV and LAFOV reconstructions. All LAFOV reconstructions showed increased image quality criteria compared to sSAFOV PET/CT. TNRpeak was significantly higher in all analyzed subgroups (<8mm: 8.12±3.79 vs. 16.22±9.74 $p<0.0001$; 8-10mm: 11.18±5.70 vs. 21.09±12.67 $p<0.0001$; 11-20mm: 17.92±13.68 vs. 35.02±28.63 $p<0.0001$ and >20mm: 31.85±21.26 vs. 63.78±45.01 $p<0.0001$). Subsequently, IQ was significantly higher in LAFOV PET compared to sSAFOV PET (<8mm: 10.44±11.80 vs. 22.00±29.13 $p<0.01$; 8-10mm: 18.07±18.31 vs. 34.89±39.51 $p=0.0001$; 11-20mm: 66.04±101.66 vs. 131.76±210.50 $p=0.0001$ and >20mm: 194.75±281.29 vs. 392.77±567.79 $p<0.0001$). ***Conclusion:*** Given the improved sensitivity and spatial resolution of next generation LAFOV PET/CT, here we present the first semi-quantitative data comparing LAFOV and sSAFOV PET/CT. LAFOV PET/CT showed not only increased tumor uptake values, but also superior image quality compared to sSAFOV PET/CT even in small size lesions (<8mm). This could be used to characterize early tumor stages or small metastases, not only morphologically by CT but also with reliable metabolic information by PET.

EP-0685

Performance Evaluation of a High-Sensitivity Preclinical PET/CT Scanner

***Y. Cheng*[1],** *T. Hu*[1], *X. Li*[2], *L. Zeng*[2], *S. Zhang*[2], *A. Li*[2], *Y. Hua*[3], *Q. Xie*[1,2], *X. Zhou*[2];
[1]*University of science and technology of china(USTC), HeFei, CHINA,* [2]*Huazhong University of Science and Technology, WuHan, CHINA,* [3]*Institute of Artificial Intelligence, Hefei Comprehensive National Science Center, HeFei, CHINA.*

Aim/Introduction: The next generation preclinical PET/CT incorporates multi-voltage threshold (MVT) readout technology. This system is equipped with LYSO detector blocks, each comprising 1 × 4 detection heads. A light guide connects a 13 × 13 array of LYSO crystals coupling to a 6 × 6 SiPM array. The dimensions of each crystal are 13.0 mm in length and 1.89 × 1.89 mm^2 in cross-sectional area, with a 2.00-mm pitch in both axial and transaxial directions. The system includes 48 detector sectors arranged in two contiguous rings, offering transaxial field of view (FOV) of 160 mm and axial FOV of 200 mm, enableing the dynamic imaging of various organs in experimental animals. This study aims to assess the performance of the E180 system in accordance with the National Electrical Manufacturers Association (NEMA) NU4-2008 standard. ***Materials and Methods:*** Spatial resolution, sensitivity, image quality (IQ), and count rate performance were assessed in accordance with the NEMA standard. Spatial resolution was further evaluated using a Derenzo phantom. Finally, high-throughput performance was tested by simultaneously scanning 2-4 IQ phantoms and four mice. The resulting images were then compared with those from single phantom/mouse scans. ***Results:*** Employing 2D-filtered back projection (FBP) reconstruction, the system achieved full-width at half maximum (FWHM) values of 1.69 mm, 1.69 mm, and 1.46 mm in the radial, tangential, and axial directions, respectively, at the centre of FOV. Derenzo phantom imaging clearly resolved 1.2 mm-size features. The peak absolute sensitivity was 7.58% in a 350-650 keV energy window. Scatter fractions were 18%, 28%, and 47%, and peak noise-equivalent counting rates (NECRs) achieved 1340 kcps@129MBq, 727 kcps@94MBq, and 100 kcps@114MBq for mouse-, rat-, and monkey-like phantoms, respectively. In IQ phantom studies, recovery coefficients (RCs) for 1-5 mm rods ranged from 10.99% to 113.84%, with image uniformity at 7.0% and spill-over ratio (SOR) of 5.11% and 4.20% for the water- and air-filled regions, respectively. Dynamic scanning of a single mouse yielded images of excellent quality. Concurrent imaging of two and four IQ phantoms, alongside four mice, demonstrated the system's capability for multi-target imaging. ***Conclusion:*** The E180 preclinical PET/CT system exhibits superior count rate performance, high sensitivity, and the ability to capture high-quality images of multiple mice simultaneously. These features render it exceptionally suitable for high-throughput dynamic imaging of experimental animals in preclinical studies.

EP-0686

Is Breath-Hold PET/CT Comparable with Cutting-Edge Technology for Evaluation of Pulmonary Nodules?

O. Kodaz, *G. Kaya, P. Ozgen Kiratli;
Hacettepe University Department of Nuclear Medicine, Ankara, TÜRKIYE.*

Aim/Introduction: FDG PET/CT is recommended for the evaluation of pulmonary nodules. However, blurring of the image due to respiratory movement may reduce the signal of the nodule and cause faulty interpretation. There are some software programmes which solve respiratory blurring problem but they are not available in every imaging center. The aim of our study is to reveal the role of breath-hold PET/CT imaging (BH) in the evaluation of pulmonary nodules. ***Materials and Methods:*** Patients aged 18-years and older with pulmonary nodules referred for FDG PET-CT scanning were included. All had undergone whole body imaging as well as BH and late free respiration imaging. In this retrospective single center study, the diagnostic performances of late imaging with free-respiration, immediate 30 second-BH, digital-motion-correction (MC) were analyzed. From OSEM and Bayesian Penalised Likelihood (BPL) images; SUVmax, SUVmean, Tumor-to-background ratio (TBR) as well as CT derived findings (nodule size, shortest distance from the lesion to nearest pleura, solid or subsolid nodules etc) were investigated. ***Results:*** Thirty-four patients (17 female) were included into the study. The mean age was 65.9 (±1.4) years. Imaging was performed 71.6 (±2) min post injection. Predominantly the nodules were solid (18) and were located in the upper lobes (53%) with a mean size of 19.3 (±1.1) mm. All nodules were FDG avid except 5 and all imaging parameters were concordant regarding FDG avidity. The median SUVmax of the nodules on standard, BH, late and MC were 1.99 (0-18), 2.45 (0-19.6), 1.94 (0-19.5) and 2.71 (0-18.8), respectively. Median TBR values for standard, BH and late imaging were 5.62 (1.65-57.3), 12 (1.8-92.7), 4.7 (1.7-71.9), respectively. TBR values were the highest in the BH group ($p<0.001$) which led improved confidence among the readers. Similarly, the proximity of the nodule to the pleura cause difficulty in interpretation on standart imaging which is accomplished by BH and MC images. The SUVmax values of BH images are strongly correlated with MC images (Spearman's correlation value: 0,968, $p<0.001$). ***Conclusion:*** Breath-hold images are comparable with motion correction algorithms and this may improve reader confidence independent from nodule localization, texture and distance from the pleura. Breath-hold PET-CT imaging can be a part of routine pulmonary nodule evaluation in daily settings.

Aim/Introduction: We generate attenuation maps for positron emission tomography (PET). These more accurate attenuation maps will be applied to the BrainPET insert developed in-house for a human 7T MR scanner to improve PET quantitation accuracy for typical neuroscientific applications as activation studies and neuroreceptor imaging. ***Materials and Methods:*** Firstly, an accurate transformation from Hounsfield units (HU) to linear attenuation coefficients for 511 keV gamma photos is needed to provide accurate attenuation correction maps for quantitative PET. Spectral CT systems allow to reconstruct virtual monochromatic

images (VMI) from the inherently multiple polyenergetic data sets of CT. VMIs can be used to obtain virtual non-contrast (VNC) images and bone mineral density measurements. Currently, CT-derived PET attenuation maps are based on conversion schemes from conventional CT scanners with polyenergetic X-ray spectra and it is known that the conversion from polyenergetic spectra to the monoenergetic energy of 511 keV introduces systematic errors in the attenuation coefficients for PET. Inaccuracies in the transformation will also propagate into attenuation maps for hybrid MR-PET devices, if the attenuation correction is based on CT images, e.g., using template method. In our approach, we plan to use angiographic spectral CT scans with administration of iodinated contrast agents and to compute VNC images from the obtained dataset. For improving the measured bone mineralization accuracy, which is of high relevance for gamma attenuation, we combine the VNC images with bone mineral density measurements. So, we segmented all bone values from the bone mineralization image and replaced the corresponding image voxel values in the VNC image. ***Results:*** The resulting combined monochromatic CT image (at 67 keV) is converted to linear attenuation coefficients at 511 keV. The conversion scheme from monochromatic CT images to linear attenuation coefficients was obtained by acquiring spectral CT data for different tissue types using the electron density phantom developed for spectral CTs and a photon-counting CT scanner. We will present conversion schemes from HU to attenuation coefficients for different tube voltages (120 kV and 140 kV) virtual monochromatic energies (64, 67, 76, 80, and 100 keV). Further, we will evaluate the accuracy of the conversion scheme using previously acquired angiographic CTs. ***Conclusion:*** Spectral CT allows to minimize the systematic error when converting HU values to linear attenuation coefficients for 511 keV gamma rays using virtual monochromatic images. Further, VNC images allow to compute these attenuation coefficients from CT angiographic images after administration of iodinated contrast agents.

EP-0688

Low dose CT for attenuation correction of LAFOV PET body imaging

T. Willson, *H. Natarajan, J. Khan, D. McCool, B. F. Holman;*
Royal Free London NHS Foundation Trust,
London, UNITED KINGDOM.

Aim/Introduction: Adding additional filtration to the X-ray tube reduces the tube output whilst increasing the average energy of the X-ray beam. This may be desirable for low dose CT scanning, since a higher energy beam may better penetrate the patient and avoid artefacts even when the tube current is significantly reduced. Considerable dose reductions have been achieved by authors applying a tin filter for this purpose.[1,2] Low dose CT is particularly desirable in the context of LAFOV PET, where the whole of the PET field of view must undergo CT in order to produce an attenuation corrected PET reconstruction. Previous work has typically examined dose reductions possible for standard sized phantoms. In this study we sought to create a LDCT workflow that would produce adequate imaging for PET attenuation correction, including larger patients and those who must be scanned with their arms down. ***Materials and Methods:*** A NEMA image quality phantom was prepared with 7 and 36.7 kBq/ml 18F in the background and lung regions respectively. The lung insert additionally contained an iodinated contrast solution (23.6 mgI/ml) to approximate the Hounsfield units of bone. The phantom was imaged with and without additional scatter and attenuation material added to simulate a larger patient scanned with their arms down. The phantom was scanned using the manufacturer's low dose CT workflow, tin filter workflows using CarekV and a range of quality reference (QR)mAs settings, and our existing clinical PET/CT workflow. PET reconstructions were created using each CT scan, and volumes of interest were drawn on the lung insert and background regions. SUV deviation was assessed relative to the clinical scan. ***Results:*** Photon starvation artefacts were observed in the arms-down configuration, which became increasingly severe as the QRmAs were reduced. Both the manufacturers low dose workflow and the tin filter workflow with a QRmAs of 200 produce a PET reconstruction with <2 percentage points SUV difference in the background region to reference, whilst incurring CT doses of <20% of our current workflow. Larger SUV discrepancies were measured in the lung insert. Further dose reduction is possible, but only by accepting larger SUV discrepancies inside and in proximity to highly attenuating structures. ***Conclusion:*** The manufacturers default low dose CT workflow and the tin filter workflow using 200 QRmAs both achieve significant dose reductions whilst achieving adequate image quality, even when performing arms-down scanning of large patients. ***References:*** 1.Bebbington et.al, DOI:10.1186/s40658-023-00585-0 2.Mostafapour et.al, DOI:10.1002/mp.16862

EP-0689

PET Image Quality in a Weight-Based Activity Regime: A Prospective Study

L. Davies, *S. Chicklore, J. John, P. Marsden, J. Mackewn;*
King's College London & Guy's and St Thomas'
PET Centre, London, UNITED KINGDOM.

Aim/Introduction: Scaling PET radionuclide administered activity with patient weight is recommended in EANM-endorsed guidelines [1], and weight-based dose scaling is common clinical practice in the UK[2]. For fixed activity, PET image quality typically reduces among heavier patients, reducing the diagnostic power of images. Research informing the EANM guidelines is scanner-specific, and the literature largely does not originate from prospective studies, notably not with patients whose weights are high. EANM guidelines scale from 75 kg, a weight which is greatly exceeded by many patients in the clinic. A prospective study was performed on two lutetium-based scintillator PET-CT scanners to investigate the relationship between PET tracer activity and image quality in larger patients. It is expected that higher tracer activity improves image quality via higher signal to noise ratio. However, higher activity can result in image degradation due to dead time and randoms effects. Patients of weight well above 75 kg were injected with increased activity, and images were compared against patients of the same weight injected with standard, lower activity. ***Materials and Methods:*** 27 patients with unspecified indications weighing between 120 kg and 140 kg were injected and scanned with 510 ± 20 MBq 18F-FDG. 27 patients in the same weight range were scanned with 350 ± 50 MBq 18F-FDG. Qualitative and quantitative measurements were made to compare image quality between the two cohorts . Mean and standard deviation in standard uptake value (SUV) in the uniform liver was measured and compared for every patient. A subset of 9 weight-based activity patients were matched with a standard activity patient based on height, weight, and arm positioning for visual comparison by a PET-CT clinical consultant. ***Results:*** Patients scanned with higher activity exhibited a 22% reduction in mean noise in the uniform liver. The consultant rated weight-based images as much better than standard activity in 11% of pairs, slightly better in 56%, equivocal in 22%, slightly worse in

11%, and much worse in 0%. ***Conclusion:*** Increasing the tracer activity from 350 ± 50 MBq to 510 ± 20 MBq 18F-FDG produces less noisy images for patients weighing 120-140 kg scanned on a lutetium-based scintillator PET-CT scanner. Weight-based scaling of 18F-FDG for patients in this range is advisable, and the reduced noise brought about by the higher activity is not negated by dead time effects. ***References:*** [1] Eur J Nucl Med Mol Imaging (2015) 42:328-354; [2] Nuc Med Commun (2023) 44(6):p 518-56.

EP-0690

Assesment of the use of central venous catheter with out-injector for the administration of ^{18}FDG in PET-TC studies

D. Ovejero, *N. Manso, M. Rubio, S. García, A. Prieto, B. Sanchez, I. Salcedo;*
Hospital Universitario Puerta de Hierro, Madrid, SPAIN.

Aim/Introduction: Our Nuclear Medicine department performs an average of thirty PET-CT scans per day for oncological or inflammatory/infectious diagnoses. Since March 2023, the injection [18F]FDG is conducted using automatic injection system. Oncology patients often have difficult peripheral venous access, which with the rapid injection flow, leads to frequent extravasation of peripheral catheters, requiring re-cannulation, patient discomfort and occasionally loss of dose. These patients often have central venous catheters (CVC), which the management is undertaken by expert nursers. Despite the lack of evidence, the clinical guidelines do not support the use of CVC for [18F]FDG administration. The aim of this study was to describe the use of CVCs in the administration of [18F]FDG by auto-injector and to assess whether it has a negative influence on the quality of PET-CT. ***Materials and Methods:*** Descriptive study with prospective data collection of all PET-CT procedures in patients with CVC attended at the Nuclear Medicine Unit of a tertiary hospital of Madrid Health Service since January 1st 2024 (continued). Standard injection procedure consists of removal of the anti-reflux valve, permeability check, injection of [18F]FDG and flushing with 50 ml of saline with Intego-Bayer© injector at 0.5-1ml/s and subsequent sealing. Image acquisition is performed after 50-90min according to oncological or inflammatory indications. The equipment used is Siemens Biograph Vision Syngo VG80x PET/CT scanner. The studies are reviewed and reported by a specialist in Nuclear Medicine with more than 12 years of experience.Variables collected: patients (sex, age, diagnosis); CVC (type: PICC, Hickman, reservoir, central line; location; duration); procedure (indication); quality of the study (dependant variable). ***Results:*** Preliminary data up to April 2024 are presented. Forty-nine procedures were included in 48 patients (52.1% female), mean age 64.1; mean CVC duration 54 days (range 1-378); 68.8% PICC (n=33); diagnostic reason: oncological 60.4% vs. inflammatory 39.6%. Of all procedures, [18F]FDG uptake was observed in 57.1%. In 16,3% PET were considered as low quality and in one procedure (2%), the administration of [18F] FDG using CVC interfered with clinical interpretation, leading to a repeat study through peripheral access route. ***Conclusion:*** Despite the uptake on CVC caused by the administration of [18F]FDG on many cases, only a small faction are considered of low quality and may interfere with the clinical interpretation. However, given the possibility of uptake, further studies are needed to assess the impact of [18F]FDG administration by CVC. ***References:*** GELTAMO. Guía de PET-TC en Linfomas. [Online]. Available on: https://www.geltamo.com/descargas/documentos-publicos/115-guia-de-pet-tc-en-linfomas-de-geltamo/file.

EP-0691

^{18}F-FDG conventional digital PET/CT imaging: Does a higher dosage always entails superior image quality?

R. Yang, *Y. Lin, Z. Zheng, Y. He, H. Gao, H. Shi;*
Department of Nuclear Medicine, Zhongshan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: The EANM has established a minimum range of administered radioactivity, below which achieving the desired image quality would require extended acquisition time. However, the full clinical potential of the latest digital PET/CT scanners may not have been fully explored within that range. Therefore, our study aimed to investigate whether high-normal-dose 18F-FDG digital PET/CT imaging could yield superior image quality and improved lesion detectability compared to full-dose imaging. ***Materials and Methods:*** 37 patients who underwent a conventional digital PET/CT scan following a high-normal-dose 18F-FDG injection (5.5 MBq/kg) were included to assess the overall image quality, abbreviated as high-normal-dose IQ cohort. Among these, 32 patients with pathologically diagnosed malignant tumors formed another cohort, abbreviated as high-normal-dose LD cohort, to evaluate lesion detectability. In the subsequent matched-pair study, 37 patients (full-dose IQ cohort) who received a full-dose 18F-FDG injection (3.7 MBq/kg) were retrospectively selected from our database. These patients were well-matched in terms of age, gender, weight, height, BMI, blood glucose level and uptake time with the 37 subjects in high-normal-dose IQ cohort. Additionally, another 32 patients (full-dose LD cohort) were selected to match with the pathology features, including histological typing and grading, of those in high-normal-dose LD cohort. Objective image quality in IQ cohorts was evaluated using SUVmean, SUVSD and signal-to-noise ratio (SNR= SUVmean/SUVSD). Lesion detectability in LD cohorts was compared by calculation of SUVmax and tumour-to-background ratios(SUVmax of lesion/SUVmax of backgrounds). Liver, mediastinal blood pool and gluteus maximus muscle were utilized as backgrounds for the semi-quantitative analysis. ***Results:*** Both SUVmean and SUVSD of all backgrounds in high-normal-dose IQ cohort were lower than those in full-dose IQ cohort, with the corresponding SNR being slightly higher in the former. However, the differences in SUVSD and SNR between the two cohorts were not statistically significant. In contrast, SUVmax of the lesions and all backgrounds in high-normal-dose LD cohort were all lower than those in full-dose LD cohort. Significant differences in SUVmax were observed across all backgrounds between these two cohorts, while SUVmax of the lesions did not exhibit. Consequently, the tumor-to-background ratios were all higher in high-normal-dose LD cohort than those in full-dose LD cohort, with a significant difference observed across all backgrounds. ***Conclusion:*** In comparison to full-dose 18F-FDG digital PET/CT imaging, high-normal-dose 18F-FDG digital PET/CT imaging provides slightly improved SNR and significantly enhanced tumor-to-background ratio, which can be utilized when striving for higher image quality and improved lesion detection rate.

EP-0692

Pathologic Response Prediction Value of ^{18}F-FAPI PET/CT inEsophageal Squamous Cell CarcinomaTreated with Neoadjuvant Camrelizumab and Chemotherapy: A phase II clinical trial

Y. Wei, *Y. Dong, J. Yu;*
Shandong Cancer Hospital and Institute, Jinan, CHINA.

Aim/Introduction: The neoadjuvant chemotherapy and

immunotherapy have brought safer and more effective treatment for locally advanced esophageal squamous cell carcinomas (LA-ESCC) patients, but there are still 55% to 83% of patients with poor curative effect. This study was a single-center, single-arm, phase II trial (ChiCTR2100050057), evaluating the predict value of 18F-FAPI PET/CT in camrelizumab plus chemotherapy in the neoadjuvant treatment for LA-ESCC patients. ***Materials and Methods:*** This study included thirty-two patients with newly diagnosed LA-ESCC who underwent 18F-FAPI PET/CT at baseline and after 2 cycles of neoadjuvant camrelizumab and chemotherapy (nCC). PET parameters including SUV, tumor-to-background ratio (TBR), metabolic tumor volume (MTV) and total lesion FAP expression (TLF), as well as the variables of SUV and TBR, were recorded. Patients were classified as major or minor pathologic responders (MPR or MiPR) according to postoperative pathology findings. We compared the PET parameters between the 2 pathologic response groups and analyzed their predictive performance for tumor pathologic response. ***Results:*** 50.0% (16/32) achieved an MPR, and 50.0% (16/32) was MiPR. SUVs, including maximum, peak, mean and TBRs, decreased significantly after nCC, all P values <0.05. MPR found lower SUVs than MiPR, all P values <0.05, but TLF and MTV found no difference. For Patients with MPR, the variables of SUVs were also significantly higher than those in MiPR, all P values <0.05, but variables of TLF and MTV found no difference. Maximum (AUC, 0.87; P=0.0026), peak (AUC, 0.89; P=0.0017), mean (AUC, 0.88; P=0.0021), TBRmax (AUC, 0.86; P=0.0031) and TBRmean (AUC, 0.88; P=0.0021) after nCC were significantly parameters for prediction of pathologic response to nCC, and the predictive sensitivity and specificity were 63.64% and 100%, 81.82% and 83.33%, 81.82% and 83.33%, 81.82% and 91.67%, 81.82% and 91.67%, respectively. Variables of maximum (AUC, 0.81; P=0.0116), peak (AUC, 0.82; P=0.0097), mean (AUC, 0.81; P=0.0116) and TBRmean (AUC, 0.74; P=0.0489) were significantly parameters for prediction of pathologic response to nCC, and the predictive sensitivity and specificity were 81.82% and 83.33%, 72.73% and 83.33%, 81.82% and 75.0%, 63.64% and 91.67%, respectively. ***Conclusion:*** In this study, SUVs after and variables of nCC in patients with LA-ESCC may be better predictors to nCC.

EP-0693

Fabrication of Zirconium-89 solid phantoms for PET using 3D Printing

S. Seeger[1], *E. Elmoujarkach[1], F. P. Schmidt[2,3], G. Nachimuthu[2], C. Schmidt[4], J. Mannheim[2,5], M. Rafecas[1];*
[1]Universität zu Lübeck, Institute of Medical Engineering, Lübeck, GERMANY, [2]Werner Siemens Imaging Center, University of Tübingen, Tübingen, GERMANY, [3]Department of Preclinical Imaging and Radiopharmacy, University of Tübingen, Tübingen, GERMANY, [4]Universität zu Lübeck, Isotopenlabor der Sektion Naturwissenschaften, Lübeck, GERMANY, [5]Cluster of Excellence iFIT (EXC 2180) "Image Guided and Functionally Instructed Tumor Therapies", University of Tübingen, Tübingen, GERMANY.

Aim/Introduction: In immuno-PET, radiolabelling with 89Zr (t1/2=78.4 h) allows non-invasive tracking of monoclonal antibodies as well as longitudinal studies, and enables theranostic approaches for cancer treatment. Dedicated characterization, evaluation and quality assurance (QA) of 89Zr-PET conventionally requires scanning 89Zr-filled phantoms. However, the metallic nature of 89Zr makes it adhere to the phantom walls, resulting in non-uniform distributions unsuitable for QA and performance studies. By direct 3D-printing of 89Zr mixed with resin, we have previously shown1 that this problem can be avoided. Here we investigate the suitability of two 89Zr 3D-printed phantoms for high-resolution small-animal PET. ***Materials and Methods:*** We modified our method for 18F-FDG2 to produce a full-size micro-PET image quality (IQ) phantom3 (0.20 MBq/ml) and its 50%-scaled-down replica (0.21 MBq/ml). The original resin tank and the print bed of an Anycubic-Mono SLA 3D-printer were replaced by smaller ones to achieve a high activity concentration. After printing, the phantoms were washed and cured for 5 min under UV light. The full-size phantom was measured in a MEDISO nanoScan PET/CT for 20 min. For reference, a standard IQ phantom filled with 89Zr (0.18 MBq/ml) was scanned using the same acquisition parameters. The scaled-down phantom was scanned for 40 min. Evaluation was done following the NEMA protocol3. ***Results:*** Neither observable printing defects nor large air bubbles affected the 3D-printed phantoms. The image of the printed IQ phantom showed 5.4% higher mean contrast recovery values compared to the filled one. In both images, 4 out of 5 rods were clearly visible. The relative standard deviation in the uniform region were approx. 16% (filled) and 17% (printed). The downscaled phantom also showed a homogeneous distribution of 13%. ***Conclusion:*** 3D-printing of 89Zr mixed with resin is a flexible alternative to filled phantoms enabling longitudinal performance and QA studies. The method was suitable to 3D-print customized shapes as well as radioactive submillimetre structures with homogeneous activity distributions. The procedure will be applied to enhance performance evaluation studies of high-resolution scanners for 89Zr-immuno-PET. ***References:*** 1Elmoujarkach et al., Trans. Evaluation of F^{18} FDG PET/CT According to Mandard Classification in Locally Advanced Rectal Cancer Patients Receiving Neoadjuvant Chemotherapy

F. Aras[1], *M. Parvizi[2], O. A. Nalbant[3], V. Ozkol[4], E. Kut[5];*
[1]Manisa Celal Bayar University Medical Faculty, Manisa, TÜRKIYE, [2]Department of Radiation oncology, Manisa City Hospital, Manisa, Turkey, Manisa, TÜRKIYE, [3]Department of Pathology, Manisa City Hospital, Manisa, Turkey, Manisa, TÜRKIYE, [4]Department of Nuclear Medicine, Manisa City Hospital, Manisa, Turkey, Manisa, TÜRKIYE, [5]Department of Medical Oncology, Manisa City Hospital, Manisa, Turkey, Manisa, TÜRKIYE.

Aim/Introduction: In this study, the relationship between PET/CT with ^{18}F-FDG parameters and Mandard's tumor regression grade (TRG) used in the evaluation of response to treatment in Locally Advanced Rectal Cancer Patients Receiving Neoadjuvant Chemotherapy was evaluated. ***Materials and Methods:*** Our study is a retrospective study. The study included patients diagnosed with locally advanced rectal cancer, receiving neoadjuvant chemotherapy, operated after neoadjuvant chemotherapy, and those who received a complete response (TRG1) and did not receive a complete response (TRG2-5) according to the pathological preparation examination according to the Mandard Classification, F18 FDG PET/CT scans before treatment. Patients with socio-demographic findings, tumor characteristics and post-operative data of the patients were compared. ***Results:*** 151 patients were included in the study. The median age of the patients was 62 (28-85). The groups were similar in terms of age and gender (p>0.05). There was a statistically significant difference between TRG1 and TRG2-5 in terms of family history (p=0.034). There was a statistically significant difference between TRG1 and

TRG2-5 in terms of carsinoembryonic antigen (CEA) tested at diagnosis, Ca19-9 checked after radiotherapy, and the presence of concurrent chemotherapy (CT) (p=0.002, p=0.045, p=0.004, respectively). There was a statistically significant difference between TRG1 and TRG2-5 in terms of perforation, lymphovascular invasion (LVI), perineural invasion (PNI), and post-op CEA during and after surgery (p=0.045, p=0.023, p=0.031, p=0.001, respectively). There was no significant difference between the groups in terms of maximal standardized uptake value (SUVmax), total lesion glycolysis (TLG), and metabolic tumour volume (MTV) (p>0.05). While 86.3% of the patients in the TRG1 group were alive, 47.6% of the patients in the TRG2-5 group were alive. There was a statistically significant difference between TRG1 and TRG2-5 in terms of survival status, disease-free survival time, and overall survival time (p=0.001, p=0.001, p=0.001, respectively). The risk factors were found to be significantly associated with complete response (TRG1) in the logistic regression analysis included family history, post-RT CEA, post-op CEA, perforation, LVI, and PNI (p<0.05). The risk factors were found to be significantly associated with survival in the logistic regression analysis included Mandard (TRG1), histopathological diagnosis, and perforation (p<0.05). ***Conclusion:*** Our results showed that there was no correlation between initial [18F] FDG-PET parameters and Mandard's tumor regression grade. However, family history, Post-RT CEA, Post-op CEA, perforation, LVI, and PNI variables predicted TRG1. Additionally, TRG1 histopathological diagnosis and perforation predicted survival.

PSMA PET vs. Pelvic MRI in Localized Biochemically Recurrent Prostate Cancer

V. Murthy[1], *I. Sonni[1], R. Mehta[1], A. Chung[1], L. Unterrainer[2], M. Hotta[2], A. Farolfi[2], C. Benitez[3], W. Armstrong[2], S. Doddipalli[1], A. Bandara[1], L. Valle[3], A. Kishan[3], M. Benz[1], S. Raman[1];*
[1]Department of Radiological Sciences, David Geffen School of Medicine at UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [2]Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine at UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [3]Department of Radiation Oncology, David Geffen School of Medicine at UCLA, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: After primary definitive therapy of localized prostate cancer with either radical prostatectomy or radiation therapy, up to 50% of patients will experience biochemical recurrence (BCR) of disease. Both PSMA PET/CT and pelvic MRI can provide useful information about the location of disease, which can guide more tailored management of these patients. The objective of this descriptive, retrospective analysis is to compare the performance of PSMA PET/CT and pelvic MRI in BCR and investigate the added value of their combined use in this patient population. ***Materials and Methods:*** Patients with localized BCR who underwent PSMA PET/CT and pelvic MRI within three months of each other at the University of California, Los Angeles with available imaging and follow-up data were included in our retrospective analysis. Two board-certified nuclear medicine physicians blinded to clinical information interpreted the PSMA PET/CT scans independently and described up to three positive findings. A third nuclear medicine physician resolved any disagreements (2:1 majority rule). In a similar framework, two radiologists interpreted the pelvic MRIs with a third radiologist serving as a tiebreaker. Data on disagreements between clinical PSMA PET/CT and pelvic MRI reads, disagreements between blinded and clinical PSMA PET/CT and pelvic MRI reads, and subsequent management based on findings from clinical PSMA PET/CT and pelvic MRI were collected. ***Results:*** 10/84 (12%) patients had a negative clinical pelvic MRI and positive PSMA PET/CT, with 33% of these lesions noted to be in the lymph nodes, while 8/84 (10%) patients had a negative clinical PSMA PET/CT and positive pelvic MRI, with 100% of these lesions noted to be in the prostate or prostate bed. In 10/84 (12%) patients, the blinded PSMA PET/CT reads were negative while the clinical PSMA PET/CT reads were positive, and in 7/84 (8%) patients, the blinded pelvic MRI reads were negative while the clinical pelvic MRI reads were positive. 51% of patients underwent radiation as a next step in management, 26% underwent biopsy, 17% underwent follow-up imaging, and 6% underwent other focal or systemic therapy. ***Conclusion:*** In this retrospective, descriptive analysis of 84 patients with localized BCR, there was good agreement between PSMA PET/CT and pelvic MRI, although pelvic MRI may overcall lesions in the prostate and prostate bed and miss nodal metastases. Most patients with localized BCR underwent radiation therapy or biopsy following PSMA PET/CT and pelvic MRI, with a minority of patients undergoing follow-up imaging, systemic therapy, or focal therapy.

EP-0696

CT recon optimisation on Long Axial Field-of-View PET/CT scanner

B. Ferreira, *J. Edwards, B. Holman, A. Pritchard, H. Shirsavar, A. Leite, M. Nathan, A. Partiphun, T. Wilson, T. Wagner;*
Royal Free London, NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: The Nuclear Medicine department of the Royal Free Hospital has recently installed a long axial field-of-view (LAFOV) PET/CT scanner. As expected, a significant image quality improvement has been noticed when comparing images from previous standard PET/CT system. Given the different CT system in use, work was done to optimise CT images. ***Materials and Methods:*** A cohort of 30 patients that underwent a ^{18}F-FDG PET/CT scan using the new LAFOV PET/CT scanner were selected randomly, making sure a wide range of BMI was captured. Thus, only scans performed with patients' arms elevated and without any detectable motion artefact were included, or any other type of artefact that could potentially affect image quality. CT images were reconstructed using different recon kernels, slice reconstruction thickness and different SAFIRE strength levels. The baseline CT reconstruction parameters chosen were selected to provide an image quality similar to the one provided by the previous conventional PET/CT system. A proforma was distributed to 3 Nuclear Medicine consultants to compare the different reconstructions parameters. Reporters were also enquired if further reconstructions were desired (e.g. bone window). ***Results:*** The three consultants have preferred sharper images compared with baseline reconstructions, obtained by the use of recon kernels between Br34 and Br38. Preference was given to 2 mm slice thickness, even though 1 mm was also deemed with good image quality by one of the consultants. Images with 1 mm slice thickness were considered noisier despite being sharper. Although there was no significant difference between SAFIRE strength levels, agreement was reached to a value of 3. ***Conclusion:*** Despite not agreeing completely with all the reconstruction parameters, Nuclear Medicine consultants have preferred sharper CT reconstruction compared to baseline ones. Despite a dedicated reconstruction for a bone window was considered as potentially useful, this was deemed as not needed. ***References:*** Comparison

of image noise and image quality between full-dose abdominal computed tomography scans reconstructed with weighted filtered back projection and half-dose scans reconstructed with improved sinogram-affirmed iterative reconstruction (SAFIRE*), S Choy et al, Abdominal Radiology, Volume 44 (355-361).

EP-0697

Performance of PET-choline in the pre-surgical localization of benign parathyroid pathology (adenoma/hyperplasia) in patients with clinical primary hyperparathyroidism and previous negative 99mTc-MIBI scintigraphy

B. Jaramillo Lopez, *M. García Aragón, R. Zambrano Infantino, J. Gómez Hidalgo, N. Álvarez Mena, F. Sebastián Palacid, M. González Soto, C. Gamazo Laherran, R. Ruano Pérez;*
Hospital Clinoco Universitario De Valladolid, Valladolid, SPAIN.

Aim/Introduction: To evaluate the importance of performing ^{18}F Choline in patients exhibiting a high clinical suspicion of benign parathyroid pathology (adenoma/hyperplasia) as the underlying cause of primary hyperparathyroidism, particularly those with prior negative findings on 99mTc-MIBI scintigraphy. ***Materials and Methods:*** 51 patients with negative 99mTc-MIBI scintigraphy. who underwent surgery between January 2020 and March 2024 due to suspicion of pathological parathyroid gland, either based on positive ^{18}F Choline PET (group A, 26 cases) or positive ultrasound, CT, or MRI (group B, 25 cases), were included. The data were compared with respect to the pathological anatomy results after surgery. ***Results:*** In group A, pathological parathyroid tissue was confirmed in 20/26 patients (76%): 2/25 (7%) had hyperplasia and 18/26 (69%) had adenoma. In 5/26 patients (19%), the parathyroid tissue was reported as normal, while in 1 case parathyroid tissue was not found. In group B, pathology was confirmed in 17/25 cases (68%), 15/25 (60%) had parathyroid adenoma, 2/25 (8%) had other lesions with pathological reports of thyroid cancer in one case and Whartin's tumor in another. In 8/25 cases (32%), pathological anatomy indicated normal parathyroid tissue. ***Conclusion:*** In patients with primary hyperparathyroidism and surgical criteria, including PET ^{18}F Choline as a complementary test after a negative 99mTc-MIBI gammagraphy increases the probability of locating the responsible pathological parathyroid gland. Compared to other imaging localization techniques, PET ^{18}F Choline was superior in the successful treatment of primary hyperparathyroidism.

EP-0698

Optimizing Malignant Lung Lesion Detection: A Comprehensive Evaluation of PET Reconstruction Methods

N. Ben Fekih[1], *C. Mhiri[2], K. Ben Ahmed[3], R. Ghannem[1], S. Charfeddine[4,5], I. Jardak[4,5], K. Chtourou[5];*
[1]Faculty of Medicine of Monastir, Monastir, TUNISIA, [2]Faculty of Medicine of Tunis, Tunis, TUNISIA, [3]Faculty of Medicine of Sousse, Sousse, TUNISIA, [4]Faculty of Medicine of Sfax, Sfax, TUNISIA, [5]Habib Bourguiba's Hospital Sfax, Sfax, TUNISIA.

Aim/Introduction: The maximum standardized uptake value (SUVmax) is the most common parameter used to quantify tumor metabolic uptake in F^{18}-fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT), but it is largely influenced by image reconstruction and its different methods. The aim of this study was to analyze the association of SUVmax deviations related to point spread function (PSF) and time-of-flight (TOF) reconstruction with tumor-to-background ratios (TBR) in pulmonary metastatic nodules. ***Materials and Methods:*** Thirty pulmonary metastatic nodules from different malignant tumors were included retrospectively. FDG-PET/CT imaging was performed on a Siemens Biograph mCT 64 followed by image reconstruction using 3D-ordered subset expectation maximization (3D-OSEM) or 3D-OSEM with PSF modeling both with (UltraHD) and without TOF information. Image quality was evaluated by the mean of coefficient of variance (CV) calculated by divising liver standard deviation by SUVmean of the liver. Tumor to ratio background (TBR) was obtained by devising nodule's SUVmax by background's SUVmean. Different TBR and CV values were compared and analyzed using the Friedman test and Wilcoxon test for paired non-parametric data. ***Results:*** The TBR median was highest with UltraHD reconstruction (20,25), followed by TOF (16,63) then by PSF only (14,45). The lowest TBR median value was seen with 3D-OSEM. There was a significant difference between the median TBR obtained with UltraHD and all the other methods, between the median TBR obtained with 3D-OSEM and all the other methods (p=0,0001), but no significant difference found in TBR values with PSF and TOF (p=0,861). As for quality of image, the lowest median value of CV, meaning the best quality, was seen in images reconstructed with PSF (7,81), followed by UltraHD (10,68) and 3D-OSEM (13,3). The highest was obtained by using TOF alone (14,54), with significant difference between all these methods (p 0,0001). ***Conclusion:*** Our results suggest that the different reconstruction methods cause significant alteration of pulmonary nodules's SUVmax. UltraHD provided the highest SUVmax increase with better TBR without altering image quality. ***References:*** ADDIN ZOTERO_BIBL {"uncited":[],"omitted":[],"custom":[]} CSL_BIBLIOGRAPHY 1. Rogasch JM, Steffen IG, Hofheinz F, Großer OS, Furth C, Mohnike K, et al. The association of tumor-to-background ratios and SUVmax deviations related to point spread function and time-of-flight F^{18}-FDG-PET/CT reconstruction in colorectal liver metastases. EP-0699

Primary hyperparathyroidism: ^{18}F-fluorocholine PET/CT and related semiquantitative parameters.

F. Linguanti, *V. Rossi, M. Agnolucci, V. Vergura, A. Baldoncini;*
Nuclear Medicine Department, Ospedale
San Donato, Arezzo, ITALY.

Aim/Introduction: This retrospective study aimed to explore the utility of ^{18}F-fluorocholine (FCH) positron emission tomography/computed tomography (PET/CT) as a tool for localizing parathyroid adenoma (PTA) in patients with biochemical primary hyperparathyroidism and analyze the potential role of semiquantitative PET parameters to aid in the interpretation of scans. ***Materials and Methods:*** Thirteen patients (24-75 years old, mean: 57) with biochemical primary hyperparathyroidism (PTH mean 120 pg/ml, Calcium mean 11.2 mg/dl) who underwent FCH PET/CT, US and dual-phase ^{99}mTc-MIBI imaging were evaluated. Only patients treated with surgery were included. FCH PET/CT were performed one hour after injection of radiopharmaceutical (from 100 to 300 MBq), according to EANM guidelines. After a visual interpretation of images, lesion SUVMax was measured by assigning a spheric VOI to the suspect area of uptake. Thyroid SUVMean was assessed by placing a spheric VOI inside the contralateral thyroid lobe and SUVratio (SUVr) was calculated using lesion SUVmax and this background region. Also, metabolic tumor volume (MTV) was evaluated. The relationship between biochemical parameters and semiquantitative parameters and consequently its impact on management was evaluated. The Sensitivity (SE), positive predictive value (PPV) and accuracy of

each method were calculated. Finally, the percentage difference of biochemical parameters before and after surgery was computed. ***Results:*** 12 parathyroid lesions were histologically confirmed as adenoma and among them, 10 PTA with chief cells, 1 oxyphil cell PTA and 1 atypical PTA were detected. One histopathological evaluation proven hyperplastic glands. FCH PET/CT showed significantly higher sensitivity than ^{99}mTc-MIBI scintigraphy and US in detection of PTA. SE, PPV and accuracy of FCH PET/CT were 100%, 92% and 92%. The corresponding values for MIBI were 50%, 100% and 54% and for US were 86%, 86% and 50%. The mean value of SUVmax, SUVmean, SUVr and MTV in PTA was 7.1, 4.3, 3.9 and 1.3 . The mean value of Thyroid SUVMean was 1.9. Pearson's test showed a significant correlation between PTH values and SUVmax and SUVmean ($p<0.05$, $r= 0.58$ and $r=0.62$ respectively). No significant correlation with SUVr was found. After parathyroidectomy, biochemical parameters showed reduction of 60% for PTH values and of 14% for Calcium. ***Conclusion:*** F^{18} fluorocholine PET/CT shows superior accuracy over the conventional imaging modalities in patients with primary hyperparathyroidism. Semi-quantitative PET parameters closely correlate with PTH, highlighting their potential role in the characterization of parathyroid adenoma.

EP-0700

Evaluation of a 24 cm-axial field of view PET/CT system using ^{18}F/^{68}Ga NEMA phantoms emulating different patient BMI

F. Bisello[1], *C. Macis[1], G. Della Gala[1], M. Santoro[1], F. Zagni[1], S. Strolin[1], S. Civollani[1], M. Maccagnani[1], S. Fanti[2], L. Strigari[1];*
[1]Department of Medical Physics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,
[2]Department of Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: Image quality and activity quantification depend on used radiopharmaceutical, reconstruction algorithm and patient body mass index (BMI). This work aims to assess the optimal parameters for four combinations of reconstruction algorithms and post-processing filters available for a 24 cm long field of view PET/CT recently installed in our centre, according to radionuclide and patient BMI. ***Materials and Methods:*** Two NEMA Image Quality phantoms were filled with 18F and 68Ga, respectively, with 8:1 spheres-to-background activity ratio. Five-minute acquisitions were collected in list mode, and reconstructed at 1, 1.5, 2, 3, 5 minutes, and 2, 3 and 5 minutes, for 18F and 68Ga, respectively. Phantoms images were acquired using the standard setup, and with one or two in-house-built water belt rings, to mimic patients with three BMIs (19, 36 and 46 kg/m2, respectively). Investigated algorithms included: iterative (alg1), iterative with noise suppression (alg2) for 18F and 68Ga, the deep process iterative method (alg3) and iterative with deep learning-based noise post-processing correction (alg4) for 18F. (SUVbw)maxbg, i.e., the maximum SUVbw (SUV body weight) over the average background SUVbw, and (SUVbw)maxth, i.e., the mean SUVbw over the theoretical SUVbw were calculated for each sphere to assess the percentage deviation of resulting values compared to the expected ones. ***Results:*** Our analysis revealed that 0.4 and 0.85 are optimal reconstruction parameters for alg2, for 18F and 68Ga respectively, independently of BMI-mimicking phantoms and that this algorithm outperforms the alg1. For 18F phantoms, the disagreement of median (SUVbw) maxbg values increase with BMI, within 20% for all the algorithms and configurations. The (SUVbw)maxbg disagreement, according to sphere dimensions tends to slightly be reduced moving from alg1 to alg3 (i.e. from 55% to 40%) among all phantoms and considering reconstruction time from 1 to 5 minutes. For 68Ga phantoms, the disagreement of median (SUVbw)maxbg values decrease with BMI, being within 10% for all the algorithms, with improved accuracy for larger BMI-mimicking phantoms. The (SUVbw)maxbg disagreement, according to sphere dimensions tends to stay about equal, as in the 18F acquisitions (i.e., from 42% to 57%). ***Conclusion:*** Performance evaluation is mandatory as a new PET/CT scanner become available for clinical practice. BMI variability does impact PET/CT image quantification. This should be considered, during harmonization and standardization procedure for its potential impact in clinical practice.

EP-0701

Impact of image reconstruction algorithm and acquisition time for ^{90}Y NEMA phantom acquisitions for radioembolization treatment on a 24 cm-axial field of view PET/CT

C. Macis[1], *F. Bisello[1], G. Della Gala[1], M. Santoro[1], F. Zagni[1], S. Strolin[1], S. Civollani[1], M. Maccagnani[1], S. Fanti[2], L. Strigari[1];*
[1]Department of Medical Physics, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY,
[2]Department of Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: After 90Y radio-embolization, PET/CT acquisitions allow verification of the distribution of 90Y resin or glass micro-sphere as a tool for post-treatment internal dosimetry. This work investigates the optimal parameters of three image reconstruction algorithms available for a 24 cm field of view PET/CT recently installed in our centre and not yet reported in literature. ***Materials and Methods:*** A NEMA Image Quality phantom was filled with 90Y chloride (90YCl3), with 8:1 spheres-to-background activity ratio [1], and a concentration of 900 kBq/ml in hot spheres, for a total activity of 1.2 GBq. Phantoms images were acquired using the standard setup and with one or two in-house-built water belt rings to mimic patients with three BMIs (19, 36 and 46 kg/m2, respectively). Thirty-minute acquisitions were collected in list mode, and reconstructed at 5, 8, 10, 15, 20 and 30 minutes. Investigated algorithms included iterative with a Gaussian filter of 3-mm FWHM (alg1), with a Gaussian filter of 8-mm FWHM (alg2) applied during the image post-processing, and iterative with three levels of noise suppression (alg3). For a total of eighty-one reconstructions, the contrast recovery (CR) background variability (BV) (CRBV) index, simultaneously considering contrast recovery and background variability as CR * (1 - BV) [2], was calculated. ***Results:*** Alg3, with the highest level of noise suppression (1.0), performed better than alg1 and alg2, considering a minimum reconstruction time of 10 minutes. The CRBV metric was analysed using the same reconstruction algorithm (alg3) and varying the reconstruction time. In this case, among all sphere sizes for NEMA standard setup, CRBV ranged from 0.29 to 0.67, and from 0.26 to 0.69, for 10- and 30-minute reconstruction, respectively. Images of phantoms mimicking overweight patients showed a significantly increased noise level and lower CRBV values, i.e. with a maximum CRBV ranging from 0.2 to 0.3. ***Conclusion:*** Our phantom study indicates that, for the investigated PET/CT system, alg3 with the highest level of noise suppression and a minimum reconstruction time of 10 minutes are necessary to enable post-treatment 90Y dosimetry. Longer acquisition times are necessary for overweight patients. ***References:*** [1] D'Arienzo M. et al., "Phantom validation of quantitative Y-90 PET/CT-based dosimetry in liver radioembolization". EP-0702

The evaluation of image quality of Four-ring Discovery DMI vs. Discovery 710 PET/CT using F^{18} and Ga68

L. Ghadhanfer[1], *Z. Alqallaf[2], M. Al-Qabandi[3], F. Marafi[4];*
[1]Department of Radiologic Sciences, Kuwait University, Kuwait, KUWAIT, [2]Mubarak Al-Kabeer Hospital, Nuclear Medicine Department, Kuwait, KUWAIT, [3]Department of Nuclear Medicine, College of Medicine, Kuwait University, Kuwait, KUWAIT, [4]Sheikh Jaber Al Ahmad Al Sabah for Nuclear Medicine and Molecular Imaging Center, Kuwait, KUWAIT.

Aim/Introduction: Positron Emission Tomography/Computed Tomography (PET/CT) is a sensitive, accurate, non-invasive diagnostic tool that remarkably evaluates physiological and pathological processes. PET modality has been increasing in detecting tumours, infections, or inflammation. The appropriate PET system and radioisotope choice for certain investigations has to be based on deep knowledge to obtain the desirable diagnostic outcome. This study compares PET/CT systems (DMI & D710), and radionuclides (F^{18} and Ga68, the most prominent pharmaceuticals currently used for imaging and differentiating lesions), in terms of image quality and the ability to detect the most minor lesions. ***Materials and Methods:*** Jaszczak Deluxe Flangeless phantom was filled F^{18} and Ga68 with different sphere-to-background ratios 4:1 and 8:1 of 7.2kBq/mL and 14.2kBkq/mL, respectively. PET/CT scans were performed using Digital DMI and Discovery D710 PET/CT. Five minutes of acquisition time were acquired and used to get partial data of different times (4,3,2.5, 2,1.5, 1,0.5). Images were reconstructed using OSEM + TOF + PSF. SUV max contrast, Spatial resolution, COV, and NECR were investigated. The Q.clear + TOF parameter was used for DMI, with different β values, ensuring a comprehensive approach. The statistical analysis was conducted with the utmost rigour, employing Mann-Whitney U, Wilcoxon Signed-Rank, and Kruskal-Wallis tests to provide a robust validation of the findings. ***Results:*** The most minor detected lesion in 4:1 DMI and D710 images for F18 was 12mm and 16mm, respectively, at 1.5 min/bed position and was 16mm for both systems at 2 min/bed position for Ga68. The spatial resolution at 2min/bed images in DMI and D710 for F18 was 6.4 mm and 7.9mm, respectively, and for Ga68 was 7.9mm and 9.5mm, respectively. Overall, no significant changes have been shown regarding SUVmax at different times/beds in both systems. The COV on both systems was ≤ 20%, with DMI having significantly lower COV and noise than D710 ($p < 0.05$). The NECR at 14.2kBq/mL for F18 was 108.1 kcps and 84.7 kcps in DMI and D710, respectively and was 98.3kcps and 69.7kcps for Ga68, respectively. Q.Clear images showed improved image quality using β=600 for both radionuclides with an SNR gain of 1.3. ***Conclusion:*** This study has demonstrated that the new-generation Digital MI PET/CT system has improved the detectability of small lesions at different times per bed. F18 offers better image quality and spatial resolution with different activity concentration ratios than Ga68.

Dynamic profiles of early biological responses to predict the treatment efficacy of proton therapy in liver cancer assessing with in vivo PET/MRI

Y. Chung[1], *C. Weng[2];*
[1]Chang Gung Memorial Hospital, Tao-Yuan, TAIWAN, [2]Chang Gung University, Tao-Yuan, TAIWAN.

Aim/Introduction: Proton beam therapy (PBT) is an advanced treatment for patients with unresectable hepatocellular carcinoma (HCC). However, evaluating the response to treatment based on tumor size alone may not be sufficient. Hence, this study used dynamic $^{[18F]}$FDG PET and diffusion-weighted MR imaging (DWI) to monitor the biological response to PBT in HCC mice, to assess treatment efficacy. ***Materials and Methods:*** Mice with orthotopic HCC received 20 Gy of PBT with a FOV of 15 mm2. The dynamic $^{[18F]}$-FDG PET was performed with a two-compartment kinetic model and T2/DWI at baseline and post-PBT days 1, 3, 7, and/or 10. The tissue histopathological and in vitro $^{[18F]}$-FDG cellular uptake studies were conducted for validation. ***Results:*** The study found that tumors with PBT within 7 days had constant relative SUVs (0.80 ± 0.16, 0.92 ± 0.20 and 0.76 ± 0.29 for post-PBT day 1, day 3 and day 7) and increased trend in K1 values (1.23 ± 0.38, 1.60 ± 0.70 and 1.70 ± 0.38 for post-PBT day 1, day 3 and day 7) compared to those who did not receive PBT. This is in line with an increased CD 31 expression on PBT day 7. Meanwhile, the tumor's relative ADC values significantly increased post-PBT days 3 (1.2 ± 0.11) and 7 (1.19 ± 0.10). Significantly decreased proliferation rate and cellular density on day 1 and/or day 3 and rebound on day 7 corresponding with increased vessel expression and inflammation by ex vivo IHC were consistent with the imaging parameters. However, no significant changes in tumor size were found between the PBT and non-PBT groups on post-treatment until day 7. ***Conclusion:*** Dynamic $^{[18F]}$-FDG PET/DW-MRI techniques are feasible and promising approaches for assessing tumor response in the early stages of PBT treatment and for predicting the treatment response.

EP-0704

The MERMAID Project : Pioneering PET Imaging for Small Aquatics Animals

S. Seeger[1], *H. Vo[1], E. Elmoujarkach[1], C. Schmidt[2], M. Rafecas[1];*
[1]Universität zu Lübeck, Institute of Medical Engineering, Lübeck, GERMANY, [2]Universität zu Lübeck, Isotopenlabor der Sektion Naturwissenschaften, Lübeck, GERMANY.

Aim/Introduction: Zebrafish and other small aquatic animals have become important model organisms in biomedical research. However, there is currently no dedicated PET system for such animals. Our Multi-Emission Radioisotopes - Marine Animal Imaging Device (MERMAID) aims to bridge this gap by providing dedicated solutions for imaging, animal handling and tracer application. The PET device has been now upgraded with an improved data acquisition software, a dedicated image reconstruction framework, and has been characterised using various point sources and phantoms. ***Materials and Methods:*** The improved prototype comprises two detector heads, with two

detector modules per head. Within each module, a LYSO crystal matrix (16x8) is directly coupled to two silicon photomultiplier arrays (SiPMs). The heads rotate around the object with a variable number of steps (typically 3 steps, diameter 33 mm). For an accurate energy calibration, we modelled the SiPM behaviour1 using data from 133Ba, 22Na, and 137Cs point sources. Coincidences were sorted based on a 2-ns time window and an energy window of 450-550 keV. The reconstruction relies on a dedicated list-mode implementation of penalized maximum likelihood. For characterization, we employed point sources and 3D printed radioactive phantoms. Towards future PET of living fish, preliminary animal trials were conducted with focus on handling, fixation in a water-filled chamber, and tracer application (e.g., radiolabelling of fish food with 18F-FDG). ***Results:*** Due to the limited pixel count per detector channel, the SiPMs response saturated at high photon energies. The mean energy resolution was 21,6% for 18F-FDG data. The reconstructed images of the point sources and phantoms show a high spatial resolution, reaching approximately 0.74 mm along the x-axes for a 22Na point source. A noticeable shrinkage (about 9%) affected the reconstructed sizes of extended objects, probably due to an insufficient compensation of parallax effects through the system model used in the reconstruction algorithm or number of rotation steps. The animal studies showed that MERMAID's imaging chamber provides efficient immobilization of anesthetized zebrafish for extended periods—up to 40 minutes—with a continuous supply of fresh water. Radiolabelling of fish food promised better performance as radiotracer delivery via surrounding water. ***Conclusion:*** Efforts will be devoted to improve radiotracer administration and compensation of parallax errors. By combining high-resolution PET with efficient immobilization and anaesthesia methods for in-vivo imaging, MERMAID opens up new possibilities for biomedical research. ***References:*** 1S. EP-0705

Design and Construction of a Head Phantom with Internal Carotid Flow for Image-Derived Input Function with 7T MR-BrainPET Studies

U. Khalid[1,2], *J. Scheins[1], L. Tellmann[1], P. Lohmann[1,3], H. Herzog[1], N. Shah[1,4,5], C. W. Lerche[1], C. Régio Brambilla[1];*
[1]Forschungszentrum Jülich GmbH, Jülich, GERMANY, [2]FH Aachen University of Applied Sciences, Department of Chemistry and Biotechnology, Jülich, GERMANY, [3]Department of Nuclear Medicine, University Hospital RWTH Aachen, Aachen, GERMANY, [4]Institute of Neuroscience and Medicine (INM-11), Jülich Aachen Research Alliance (JARA), Forschungszentrum Jülich GmbH, Jülich, GERMANY, [5]Department of Neurology, University Hospital RWTH Aachen, Aachen, GERMANY.

Aim/Introduction: Quantitative brain studies with positron emission tomography (PET) often require an arterial input function (AIF), which can be derived from the radiotracer transition through the internal carotid arteries (ICAs). However, PET data obtained from regions of interest over the ICAs often suffer from partial volume effects (PVE). This effect can be corrected using magnetic resonance imaging (MRI) to show the structure of the ICA. The described combination of PET and MRI data is optimal in combined PET/MR scanners, such as a 7T MR-Brain PET. To achieve accurate AIFs, the Iida head phantom [1], containing grey matter (GM), white matter (WM) and skull structures, was used as a starting point for the design and construction of a realistic head imaging phantom that incorporates ICA structures and allows dynamic flow simulation through the phantom. Here, we report on the present state of this project. ***Materials and Methods:*** The initial phantom model was generated using a set of CT/MR images acquired from the Iida head phantom [1]. The images were processed using PMOD v4.3. Segmentation of GM, WM, and skull structures was performed using 3D Slicer v5.4.0 with a combination of manual and semiautomatic thresholding techniques. Additionally, 3D Slicer v5.4.0 was utilized to extract the anatomical structure of the ICA from an MR angiography of a healthy volunteer. This extraction process involved applying specific threshold values to isolate the ICA from the surrounding structures. The segmented data were then exported to 3D computer-aided design (CAD) software for further editing. The GM, WM, and ICA compartments were designed to contain radioactive solutions. ***Results:*** The GM and WM are clearly demarcated by a distinct boundary, while the bone component is crafted from a solid material to replicate bone attenuation properties accurately. The Standard Triangle Language (STL) file will be utilized in the next step to obtain a first prototype using 3D printing technology. ***Conclusion:*** This work is currently in the development phase, and further optimization of materials for 3D printing is required to mimic realistic head properties. Furthermore, the new dynamic 3D phantom requires validation to confirm that it accurately reflects images from PET acquisitions with ICA flow. ***References:*** [1] Iida, H., et al 2013. EP-0706

Diagnostic value of PET/MR biomarkers in patients with gynaecological malignancies

P. G Shinkar[1], *H. Latha[1], Z. Khan[1], D. Kumar[2], P. Wadhwa[2];*
[1]Omega Hospital, Hyderabad, INDIA, [2]United Imaging Healthcare, Delhi, INDIA.

Aim/Introduction: PET/MRI has a capability to provide the molecular and metabolic information using PET biomarkers along with anatomical and functional information using MRI biomarkers [1]. The purpose of this study is to evaluate the correlation between PET/MRI biomarkers and histopathology in patients with gynecological malignancies and further evaluate its importance. ***Materials and Methods:*** This is a retrospective study and a total of 25 patients diagnosed with gynaecological malignancies including cervical, endometrial, vulvar and uterine cancer were studied. All the patients included in this study were referred for diagnosis and staging and underwent regional [18F]FDG PET/MR scan on 3T MRI scanner (uPMR790, United Imaging Healthcare, Shanghai, China) at Omega hospital, Hyderabad. The operable cases underwent hysterectomy, and the histopathology reports were collected. Inoperable cases underwent radiotherapy. 148-185 MBq of radiotracer was administered and the scanning was done 60 minutes after the injection and with an empty bladder. A precise MR scan was conducted for patient comfort with 15 min scan time and the protocol including following sequences: Dixon, T2-weighted, T2-FatSat, DWI. PET/MRI biomarkers that were measured include the ADCmin, ADCmean and ADCmax calculated from DWI images, SUVmax, TLG and MTV and correlated with the histopathology. ***Results:*** Tumours were segregated in squamous cell carcinoma (SCC), adenocarcinoma (AdC), endometrial carcinoma (ECa) and leiomyosarcoma (LMS). In more aggressive SCC (poorly differentiated SCC), SUVmax was high (18.6-23.9), whereas, for less aggressive SCC (SCC-in-situ), the SUVmax was as low as 3.9 showing a direct correlation between SUVmax and the tumor grade. Further, ADC values are lower in poorly differentiated SCC and higher in SCC-in-situ. Leimyosacroma also demonstrates the same pattern as SCC-in-situ and has low SUVmax values and high ADC values. There is also a significant inverse correlation between SUVmax and ADCmean values (r=-0.53). TLG and MTV values demonstrate a direct correlation with the tumor grade

only for endometrial carcinoma. ***Conclusion:*** This study shows that simultaneous PET/MRI biomarkers can provide an alternative to histopathological findings in gynaecological malignancies and demonstrates the importance of PET/MR in gynaecological cases. ***References:*** 1. Shih IL, Yen RF, Chen CA, Cheng WF, Chen BB, Chang YH, Cheng MF, Shih TT. PET/MRI in Cervical Cancer: Associations Between Imaging Biomarkers and Tumor Stage, Disease Progression, and Overall Survival. J Magn Reson Imaging. 2021 Jan;53(1):305-318. doi: 10.1002/jmri.27311. Epub 2020 Aug 14. PMID: 32798280.

EP-0707

Discrepanciesand calibrationof Aβ protein threshold in ^{18}F-florbetaben PET imaging acrossdifferent scanners

H. Lin, *C. Zuo;*
Deparment of Nuclear Medicine / PET Center, Huashan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: Standardization methods like standardized uptake value ratio (SUVR) and the centiloid scale are crucial for analyzing amyloid beta (Aβ) positron emission tomography (PET) images. However, variations in scanners, such as PET/CT and PET/MRI, can affect Aβ thresholds. This study aims to investigate the differences in Aβ threshold on 18F-florbetaben (18F-FBB) PET imaging between PET/CT and PET/MRI scanners, and propose a correction method. ***Materials and Methods:*** A total of 137 subjects with Alzheimer's disease, mild cognitive impairment, dementia with Lewy bodies, posterior cortical atrophy, multiple system atrophy, Parkinsonism syndrome, or subjective cognitive impairment underwent 18F-florbetaben PET/CT (N=48) or PET/MRI (N=79, huashan hospital, Shanghai, China; N=10, xuanwu hospital, Beijing, China) imaging. SUVR values were transformed into Centiloid units. Receiver operating characteristics analysis established cutoff values and sensitivity/specificity for amyloid PET imaging. Correction for scanner differences was performed using data from the Global Alzheimer's Association Interactive Network (GAAIN) website. The calibration method for scanner differences was verified in the PET/MRI data of Xuanwu Hospital. ***Results:*** PET/CT and PET/MRI (Huashan hospital) scanners revealed SUVRs of 1.032±0.109 and 1.489±0.200 for negative Aβ, and 1.186±0.176 and 1.736±0.271 for positive Aβ in the global cortical target (CTX), respectively. The SUVR thresholds for 18F-FBB PET/CT and PET/MRI (Huashan hospital) were 1.140 and 1.401, respectively, resulting in sensitivities/specificities of 96.30%/85.71% and 92.86%/89.47%, respectively. The threshold of 18F-FBB on PET/CT in our cohort aligned with the standard threshold observed on the GAAIN website, whereas the threshold of 18F-FBB on PET/MRI was notably higher than that on PET/CT. After calibrating the whole cerebellum (calWC) reference using the formula calWC = 1.365 × WCsuv - 260.5 with standard data from the GAAIN website, the PET/MRI threshold was adjusted to 1.132, yielding a sensitivity/specificity of 92.86%/89.19%. Following the calibrating formula of calWC, the PET/MRI (xuanwu hospital) received SUVRs of 0.91±0.109 for negative Aβ, and 1.186±0.176 for positive Aβ in the global cortical target (CTX), respectively. ***Conclusion:*** Variations in Aβ thresholds between 18F-FBB PET/CT and PET/MRI scanners may be due to differences in whole cerebellum attenuation. Correction using whole cerebellum reference improved consistency across scanners, allowing SUVR values on PET/MRI to be converted into CL units using a standard equation. Further research is needed to validate these findings and establish standardized protocols for amyloid PET imaging.

EP-0708

Evaluation of dose reduction for [^{11}C]PHNO: how does it affect the binding potential non-displaceable (BP_{ND})?

D. Ribeiro[1], *W. Hallett[2], O. Howes[3], R. McCutcheon[3], M. Nour[4], S. Husbands[1];*
[1]University of Bath, Bath, UNITED KINGDOM, [2]Invicro, A Konica Minolta Company, London, UNITED KINGDOM, [3]King's College London, London, UNITED KINGDOM, [4]University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: [^{11}C]PHNO has been used in psychiatric studies investigating disease aetiology and drug development, due to its binding to D2 and D3 brain receptors. This radiopharmaceutical has the potential to be used in prospective studies investigating the hypothesis of a genetic neurodevelopmental continuum between childhood neurodevelopmental disorders and psychiatric conditions. This project aims to evaluate dose reduction for [^{11}C]PHNO Positron Emission Tomography (PET)-Magnetic Resonance (MR) imaging, to reduce the radiation burden for future research participants. ***Materials and Methods:*** Ten in vivo datasets, belonging to ten healthy volunteers who received 134.2±20.3 MBq of [^{11}C]PHNO and were scanned on a General Electric SIGNA PET-MR, were reconstructed once with the full administered dose and 7 times with different simulated low doses. The low dose simulations were obtained by undersampling the time frames and represented 1⁄2, 1⁄3, 1⁄4, 1⁄5, 1⁄6, 1⁄10,1⁄15 of the full dose. An OSEM algorithm with time-of-flight was used with 6 iterations, 16 subsets, a 5mm filter (xy-axis). Regions of interest were drawn in the accumbens, substantia nigra, caudate, globus pallidus, putamen, striatum and thalamus. A simplified reference tissue model was used to investigate the binding potential non-displaceable (BPND) for each structure, per reconstruction. Coefficient of variation (CV) and bias were investigated. The two-way ANOVA and Kruskal-Wallis tests were used for group comparisons between the low dose and the full dose datasets. ***Results:*** The substantia nigra (20.55%) and thalamus (39.90%) presented the highest CV, for the full dose datasets. When comparing the full dose CV and the highest CV from the low dose datasets, differences ranged between 0.67%-4.36% for the accumbens, caudate, globus pallidus, putamen, striatum and thalamus. For the substantia nigra, the difference was 22.92%. The 1⁄2 and 1⁄3 low dose datasets produced the lowest bias for all structures except, the putamen and striatum. The 1⁄10 and 1⁄15 low dose datasets produced the highest bias, for all structures. Apart from the putamen and striatum, no significant differences were found between the 1⁄2, 1⁄3, 1⁄4, 1⁄5, 1⁄6 low dose and full dose datasets. The putamen and striatum showed significant differences between the 1⁄2, 1⁄10, 1⁄15 low dose and the full dose datasets however, visual assessments of the time-activity curves indicate there may be an image artefact/bias in the 1⁄2 low dose dataset. ***Conclusion:*** Whilst the data indicates that reducing the [^{11}C]PHNO may be possible, current statistical differences suggest further work is needed before low dose is a suitable approach.

EP-0709

Impact of surface coil interposition on attenuation correction in preclinical^{18}F-fluorodeoxyglucose (FDG) positron emission tomography-magnetic resonance imaging (PET/MRI): a phantom study

H. Rida[1], *M. Guetlin[1,2], M. Naveau[3], M. Joubert[1,2], A. Manrique[1,4];*
[1]Cyceron UR4650 PSIR, Université Caen Normandie, Caen, FRANCE, [2]Diabetology, CHU de Caen, Caen, FRANCE, [3]UAR3408/US50 Cyceron, CNRS, INSERM, Université Caen Normandie, Caen, FRANCE, [4]Nuclear Medicine, CHU de Caen, Caen, FRANCE.

Aim/Introduction: 23Na MR imaging has lower signal strength due to a lower gyromagnetic ratio and tissue abundance of 23Na. In PET/MRI imaging, resonators enhance proton imaging, while surface coils increase 23Na sensitivity. However, using a surface coil can disrupt the PET signal. In this study, we compared the PET images acquired using a resonator or a surface coil. ***Materials and Methods:*** To evaluate the impact of a surface coil interposition on attenuation correction in a 7T preclinical PET/MRI (Bruker BioSpin), we developed a dedicated cradle (DC) incorporating a surface coil, and then we integrated the attenuation map into the PET reconstruction process. To validate this attenuation correction, we compared it to that obtained using a conventional cradle (CC) and a resonator. A NEMA (National Electrical Manufacturers Association) NU-4 2008 phantom, a homogeneous phantom, and a resolution phantom filled with 18F fluorodeoxyglucose (FDG) (3.7 MBq) with the two cradles were used. Various image quality metrics (recovery coefficients (RC), non-uniformity (%STD), spillover ratio (SOR)) were calculated for NEMA phantoms according to the NEMA standards. The images were reconstructed using Maximum A Posteriori algorithm. ***Results:*** The RC calculated for rods of 1, 2, 3, 4 and 5 mm diameters were respectively 0.12, 0.43, 0.78, 0.94 and 0.92 for CC and 0.08, 0.50, 0.86, 0.89 and 1.03 for DC. The RC values using the DC was slightly higher than that of the CC. The %STD increased with the number of iterations until it converged, starting with 15 iterations. However, the %STD was lower with the CC (3.29 ± 0.53) vs. the DC (5.07±0.18, p=0.0023). The SOR was consistent between the two cradles for both air and water. The number of iterations also affected the Contrast-to-Noise Ratio (CNR) values, a convergence occurring after 20 iterations. There was no effect of scatter correction, but there was an increase in RC when using partial volume correction and the point spread function for both cradles. The CC - CD image subtraction demonstrated an overestimation of the PET signal on the surface coil side and an underestimation on the opposite side. The spatial resolution value was similar with the two cradles. ***Conclusion:*** The dedicated cradle with a surface coil increased the RC but also the non-uniformity compared to a conventional cradle with a resonator coil. This could impact quantitative PET imaging when using a surface coil in PET/MRI with 23Na imaging.

EP-0710

Time resolution and sensitivity including triple coincidences of a UHF-MRI compatible BrainPET insert

D. Niekämper[1,2], *J. J. Scheins[1], B. Weissler[3,4], D. Schug[3,4], J. L. Herraiz[5], N. J. Shah[1,6,7], C. Lerche[1];*
[1]Forschungszentrum Jülich GmbH, Institute of Neuroscience and Medicine 4, Jülich, GERMANY, [2]Department of Physics, RWTH Aachen University, Aachen, GERMANY, [3]Hyperion Hybrid Imaging Systems GmbH, Aachen, GERMANY, [4]RWTH Aachen, Physics of Molecular Imaging, Experimental Molecular Imaging, Aachen, GERMANY, [5]Nuclear Physics Group, EMFTEL and IPARCOS, Complutense University of Madrid, Madrid, SPAIN, [6]Institute of Neuroscience and Medicine 11 (INM-11), Forschungszentrum Jülich GmbH, Jülich, GERMANY, [7]Department of Neurology, RWTH Aachen University, Aachen, GERMANY.

Aim/Introduction: The BrainPET-7T is a new high-performance PET insert for brain imaging combined with Ultra-High-Field MRI [1]. With its state-of-the-art detector technologies and enhanced data processing methods, it is expected to achieve good timing resolution and high sensitivity. For this system, the standard processing of coincidence events is extended for triple coincidences to increase the sensitivity with reduced loss of accuracy. Additionally, the identification of triple coincidences when using isotopes that emit additional prompt gammas after the positron emission could be used for dual-isotope [2] and positronium lifetime imaging [3]. ***Materials and Methods:*** The scintillator blocks of the BrainPET-7T consist of LSO scintillator arrays in three staggered layers with a readout by 12x12 digital Silicon photomultipliers (operating temperature 18°C, second photon trigger) providing high-resolution time stamps [4]. The skews between timer components and scintillation location are calibrated systemwide on block and die level and considering depth of interaction [5]. We determine the timing resolution of the system after skew correction and investigate the noise level and the sensitivity for double coincidences and triple coincidences of prompt gamma emitters with the simulator PeneloPET [6] as well as with measurements using 124I, 22Na and 68Ge sources. ***Results:*** Preliminarily, a timing resolution <850ps was achieved. The sensitivity at the iso-center in comparable simulations using point-sources was 17% for double coincidences of 18F and 2.3% for triple coincidences of 22Na. The measured peak sensitivity of the BrainPET-7T for double prompt coincidences including those caused by triple coincidences for a 18F line-source at the iso-center was ≈12% leading to an expected triples sensitivity of ≈1.6% for 22Na. ***Conclusion:*** The simulated sensitivity for double coincidences from 18F was 7.4 times larger than the sensitivity for triple coincidences from 22Na. Reliable identification of true and random triple coincidences of different nuclides could be shown allowing for a more accurate quantification for pure positron and prompt gamma emitters. ***References:*** [1] C. Generating synthetic CT volumes for PET/MR attenuation correction using machine learning

A. Hoseinipourasl[1,2], *G. Hossein-Zadeh[3], P. Sh.Zadeh[4], H. Arabalibeik[5], S. Karimi Alavijeh[1], M. Ay[1,2];*
[1]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging (RCMCI), Advanced Medical Technologies and Equipment Institute (AMTEI), Tehran University of Medical Sciences (TUMS), Tehran, IRAN, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]School of Electrical and Computer Engineering, College of Engineering, University of Tehran, Tehran, IRAN, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Nuclear Medicine Department, IKHC, Faculty of Medicine, Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Tehran University of Medical Sciences, Research Center for Biomedical Technologies and Robotics, IK Hospital Complex, Keshavarz Blvd, Tehran, IRAN, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Achieving accurate quantitative PET images in neurological studies requires proper attenuation correction. PET/MR systems pose a challenge in this regard due to the dependence of MR signals on proton density and tissue relaxation times rather than electron density. In this study, we proposed a novel machine learning-based approach to generating synthetic CT volumes with continuous HU values. This method can quickly generate synthetic CT volumes to create accurate attenuation correction maps for brain PET data. ***Materials and Methods:*** We acquired MR images from ten healthy volunteers using

IR-PETRA and VIBE-DIXON techniques with a 3T MR scanner and a 20-channel head/neck coil after providing their written consent. Following the bias magnetic field correction and MR-CT registration, we extracted 3D voxel-based radiomics feature maps from these MR volumes using the Pyradiomics library. After scaling the features and performing feature selection, we employed LightGBM, an advanced gradient-boosting framework, to predict synthetic CT volumes from unseen folds. Furthermore, the LightGBM Hyperparameters were optimized using the Optuna library. Lastly, we assessed the ten synthetic CT volumes against the Ultra-low dose CT volumes as reference images using various voxel-wise and volume-wise evaluation metrics. ***Results:*** Based on our experimentation, we found that training the LightGBM model using a 9-fold train dataset on a system equipped with a Core i7 CPU and 16 GB RAM took approximately 60 minutes. Also, generating a synthetic CT volume with continuous HU values from the test fold took less than 1 minute. To ensure accuracy, we used a 10-fold leave-one-out cross-validation technique, which allowed us to generate ten synthetic CT volumes from MR volumes. After comparing these volumes with reference ultra-low dose CT volumes, the findings revealed an average mean absolute error of 60.75±8.8 HU, an average structural similarity index of 88±2%, and an average Pearson correlation coefficient of 95±1%. These results are comparable to those reported in the literature. Further histogram-wise and slice-wise evaluations also revealed high correlation and similarity between synthetic and reference CT volumes. ***Conclusion:*** Significant differences were discovered between CT and synthetic CT images in the ear regions and the patients' head surfaces, possibly due to ear positioning variations during different scans or MR-CT registration errors. Quantitative assessments indicated promising correlations and similarities between Reference CT and LightGBM-generated CT images. Furthermore, the cross-validation results demonstrated the possibility of generating accurate synthetic CT volumes for PET/MR attenuation correction with lower computational time using CPU-based processors.

EP-0712

^{18}F-FDG PET/MRI Imaging in the Differential Diagnosis Between Progressive Recurrence and Radionecrosis in the Ccontext of Ccerebral Metastatic Lesions

D. Darejan Bessac[1,1], *A. Kaseb[2], S. Baloglu[3], I. Namer[2], C. Bund[2]; [1]ICANS, Strasbourg, FRANCE, [2]ICANS, Strasbourg, FRANCE, [3]CHU Strasbourg, Strasbourg, FRANCE.*

Aim/Introduction: Brain metastases are the most common intracranial tumours, and their incidence is increasing. While the improved overall survival of oncology patients contributes to this rise, it does not fully explain the trend. Radiotherapy is a frequently used treatment for brain metastases. However, during post-treatment follow-up, it is often difficult to distinguish between radionecrosis and tumour recurrence. Radionecrosis lacks specific imaging features on MRI sequences. The combination of anatomical and functional (PET/MRI) imaging can help overcome this diagnostic challenge and enhance the ability to differentiate between radionecrosis and tumour progression. The aim of our study was to assess the contribution of ^{18}F-FDG PET/MRI in differentiating between radionecrosis and recurrence of brain metastases in patients who had undergone brain radiotherapy. ***Materials and Methods:*** : We analysed 72 patients with the input from five doctors, including three nuclear physicians and two radiologists. The results were subsequently compared with clinical and radiological findings. ***Results:*** The diagnostic performance of ^{18}F-FDG PET, MRI, and PET/MRI was evaluated separately. The sensitivity was 97.9%, specificity was 100%, and the NPV was 98.9% for ^{18}F-FDG PET combined with a T1 MRI sequence in distinguishing recurrence from radionecrosis. PET/MRI resolved misclassifications in 17% of patients initially misclassified by PET/MRI alone. Late acquisition allowed for the calculation of a retention index at 4 hours, which enhanced the diagnostic performance of PET. ***Conclusion:*** Combining PET with brain MRI remains crucial for detecting new lesions, especially micro-lesions, and demonstrating lepto-meningeal dissemination. Technological advancements, such as PET/MRI, allow for the integration of the strengths of both techniques while improving patient comfort. Simultaneous PET/MRI acquisition provides compelling and clinically relevant additive diagnostic value for the most complex cases, that necessitate precise alignment of morphological and functional information.

Fully integrated handheld gamma camera compared to conventional gamma camera for detection and localisation of sentinel lymph nodes in breast cancer

F. Gelardi[1,2], *A. Sagona[2], A. Chiti[1,3], M. Rodari[2], L. Leonardi[2], S. Petrozza[2], R. Massari[4], A. D'Elia[4], A. Soluri[4], L. Antunovic[3,2]; [1]Università Vita-Salute San Raffaele, Milano, ITALY, [2]IRCCS Humanitas Research Hospital, Rozzano (MI), ITALY, [3]IRCCS Ospedale San Raffaele, Milano, ITALY, [4]Institute of Biochemistry and Cell Biology (IBBC), National Research Council of Italy (CNR), Monterotondo Scalo, ITALY.*

Aim/Introduction: Preoperative lymphoscintigraphy is the gold standard for sentinel lymph node biopsy (SLNB) in breast cancer (BC) patients. However, conventional gamma camera imaging is prone to operator variability and time consuming in the nuclear medicine department workflow. This study aims to validate the performance of the Pocket Gamma CAM (PGC), a handheld gamma camera, in detecting and locating sentinel lymph nodes (SLNs) during the preoperative and intraoperative phases in BC patients compared to conventional gamma camera imaging. In addition, we evaluated the manoeuvrability and intrinsic instrument sensitivity of both devices. ***Materials and Methods:*** Adult female patients with histologically confirmed BC candidates for surgery and SLNB were enrolled in this prospective open-label clinical trial. All patients underwent pre- and intra-operative assessment using both the PGC and conventional lymphoscintigraphy. The performance of the two devices was compared using the Poisson regression model for incidence rate ratios (IRRs). The intrinsic sensitivity of the devices was compared using the Wilcoxon Ranked Sign Test. The manoeuvrability of the devices was defined as low-moderate-high. ***Results:*** Sixty-eight patients (median age 50 years, BMI 21.4) were enrolled, including one patient with bilateral breast cancer who underwent two SLNBs. The PGC demonstrated superior preoperative lymph node detection (IRR 8.01, 95% CI 6.11-10.50; p<0.0001) and intrinsic device sensitivity (299 versus 56.5 counts per second; p=0.0003) compared to the

conventional gamma camera. Intra-operative assessment with PGC was performed in 64 patients and no additional lymph nodes were visualised. However, the conventional gamma camera demonstrated superior manoeuvrability ($p<0.0001$). ***Conclusion:*** The PGC handheld gamma camera has potential for preoperative sentinel lymph node assessment in patients with BC. Its limited manoeuvrability may hypothetically increase inter- and intra-operator variability. However, appropriate training and frequent use of nuclear medicine and surgical equipment could overcome this limitation.

EP-0714

PET/MRI Mixed Reality for Intraoperative Localization of Sentinel Lymph Nodes in Head and Neck Melanoma

H. Duan, *B. L. Daniel, F. M. Baik, D. Anders, A. M. Dreisbach, D. Holley, B. L. Franc;*
Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Patients with malignant melanoma undergo surgical sentinel lymph node (SLN) resection to determine stage of disease. Pre-surgical SLN single-photon emission computed tomography (SPECT)/computed tomography (CT) is currently used to visualize the first draining lymph node with subsequent use of the neoprobe to detect the node intraoperatively. As the neoprobe registers the amount of radiation, it can only give an estimate to where the SLN is located in tissue. In this study, we evaluated whether mixed reality (MR) that projects pre-surgical SLN imaging onto the patient can aid the surgeon localize and extract the SLN. ***Materials and Methods:*** Molecular sieves with a diameter of 3 mm were incubated with fluorine-18 (18F) in order to simulate lymph nodes and were implanted in fresh cadavers. Imaging with positron emission tomography (PET)/magnetic resonance imaging (MRI) was performed instead of SPECT/CT. Virtual renderings of the PET/MRI scans were generated and projected onto the cadaver using a commercially available MR headset (HoloLens 2). Standard surgery was performed on one side of the neck while on the contralateral side, surgery with the MR headset was performed. Surgeons received a questionnaire asking about their overall experience. ***Results:*** Six cadavers were scanned with 4 implanted SLN per side, respectively. All surgeons (n=11) reported that AR has helped determining where to set the first incision for retrieving the SLN. However, the AR depth perception was limited and was therefore not helpful in guiding how deep the lymph node is located in tissue. The surgeons found that wearing the AR headset was comfortable and not distracting; they believed unisono that AR has added value for the intraoperative detection of the SLN. The alignment of the hologram onto the cadaver was time intense, however with the introduction of new QR code based fiducial markers, this might improve in the near future. ***Conclusion:*** MR visualization of PET/MRI data in 3D improved the surgeons' confidence in where to set the first incision for removing the SLN and might be able to reduce overall time spent in the operating room.

EP-0715

SFoV Imaging Using a Hybrid Optical-Gamma Camera (HGC): Specifications and First Clinical Result

I. Md Musidek[1], *A. Ng[1], M. Md Shah[1], C. Yeong[2], A. Perkins[3];*
[1]Faculty of Medicine, Universiti Malaya, Kuala Lumpur, MALAYSIA, [2]Faculty of Health and Medical Sciences, Taylor's University, Subang Jaya, MALAYSIA, [3]Radiological Sciences, School of Medicine, University of Nottingham, Nottingham, NG7 2UH, UNITED KINGDOM.

Aim/Introduction: A portable small field of view (SFoV) high resolution gamma camera designed for small organ has been developed. Four integrated pinhole collimators (1, 2, 3 and 5 mm diameter) can be software selected in seconds to optimise image resolution and acquisition speed. A microcolumnar CsI(Tl) crystal scintillator converts gamma to optical photons for detection by a semi-conductor. An in-built optical camera with the same field of view, allows real-time display of gamma image acquisition streaming mapped to surface anatomy. ***Materials and Methods:*** Following characterisation and performance measurements, pilot studies were undertaken in the clinical setting as part of research ethics committee (REC) approved clinical studies. Imaging was undertaken in patients undergoing standard of care imaging and the investigational images compared with the standard gamma camera images. ***Results:*** Characterisation results indicate that spatial resolution, spatial linearity, and uniformity values exceed those of large field of view (LFoV) gamma cameras. Sensitivity and count rate capability were comparably lower, due to the smaller size of the device. This is partially compensated by the ability to position the small camera head (< 15 cm diameter) very close to the region of interest. A range of patients have been studied and images from the first clinical investigations will be presented. The compact nature of the camera allows use with the patient in a small-sized room. A 60° field of view allows the operator to assess larger or smaller regions by altering the camera distance from the region of interest. Automated pinhole collimator change allows rapid change between 'higher sensitivity' and 'higher resolution' settings. These studies demonstrated that the camera is highly suited to SFoV imaging applications such as thyroid and parathyroid using Tc-99m and I-131, sentinel node localisation studies and bone spot views. However there is a learning curve for the operator to establish the optimum combination of camera positioning and collimator selection for each case. Investigation of further clinical applications using different radionuclides are underway to determine how the fusion of the gamma and visible images can be used to best effect. ***Conclusion:*** Use of a hybrid SFoV camera complements the LFoV imaging and in some applications may provide a solution for small organ imaging without the use of the larger, more expensive systems. The portability of the device offers the potential to integrate scintigraphy within clinical pathways outside of the nuclear medicine department such as surgical and intensive care settings.

EP-0716

Verification of pharmacopoeia TLC procedure of method C used for separation between medronate and oxidronate. Technetium (^{99m}Tc) medronate injection (01/2016:0641)

U. Karczmarczyk[1], *M. Nemtusiak[1], M. Ochman[2], P. Garnuszek[1];*
[1]Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND, [2]University of Wrocław, Faculty of Chemistry, Wrocław, POLAND.

Aim/Introduction: Technetium (99mTc) medronate injection produced under GMP requirements must assure quality based on

the European Pharmacopeia (Ph.Eur.) monograph 0641.The direct implementation of the pharmacopoeial method C (thin-layer chromatography) for medronate identification was associated with several inconveniences that had to be eliminated, including the lack of visible spots for sodium oxidronate, the long drying time of the developed plate (at least 14 h) and the multiple application of samples for analysis. Based on the recommendations in Ph. Eur. chapter 5.26 Implementation of pharmacopoeial procedures, we verified method C and obtained reliable and reproducible results for the test product. ***Materials and Methods:*** The following parameters of the method C were modified: the concentration of reference solution (a) of sodium oxidronate increased by 15 times, and the concentration of reference solution (b) and test solution of medronic acid increased by five times. The sample application was changed from 5 µL in 1 µL portions to 1 or 2 µL in one portion. The drying in-air procedure has been drastically reduced from 14 hours to at least 20 minutes. Other method parameters, such as mobile phase, development and detection, remained unchanged. The method was investigated using three types of plates with cellulose for chromatography as the coating substance: 5552 MERCK (aluminium-backed), 1.05730 MERCK (glass-backed), and 1.05577.0001 MERCK (plastic-backed). ***Results:*** We successfully verified the pharmacopoeial TLC method by increasing the concentration of the reference and test solutions and applying them once. These modifications showed clearly visible spots due to the test solution and the reference sodium oxydronate sample developed using glass and plastic-backed chromatographic plates. At the same time, we demonstrated that shortening the drying time of the plates after development does not affect the final result. ***Conclusion:*** Implementing changes to the Ph. Eur. method allowed to obtain reliable results under our laboratory conditions. Furthermore, we have shown that reducing the plate drying time to 20 minutes allows the entire analysis (identity) to be completed in up to 4 hours. The implementation of the verified analytical method for identification of the medronate will allow the biodistribution test to be removed from the specification, which is in line with the 3Rs principle. ***References:*** 1. Ph.Eur. monograph 06412. Ph.Eur. General text 5.26. Implementation of pharmacopoeial procedures.

Artificial high- and low-density materials in bone mineral densitometry using dual-energy X-ray absorptiometry: A GATE Monte Carlo simulation of "Black-hole" artifact

M. Qutbi;
Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: To evaluate the effect artificial high- and low-density materials on BMD scans in dual-energy X-ray absorptiometry (DXA) method and emergence of so-called black-hole artifact through GATE Monte Carlo simulation. ***Materials and Methods:*** A GATE Monte Carlo code is utilized to simulate the artifact encountered in clinical scans acquired by HOLOGIC® bone densitometer. Two simplified phantoms are designed. The first one is a rectangular box with 6 smaller cubes inside and second one is body torso. Materials of cubes are spine bone, PMMA, barium sulfate suspension in water, stainless steel, titanium alloy and gold. Torso phantom contains objects of 5 vertebrae, bowel and 3 small spherical objects near the surface of torso as piercing objects on the abdominal wall, each overlying the vertebrae. Using 100 and 140 kVp, spectral X-rays are generated to simulate DXA. For both phantoms, two simulations are conducted. The pair of projections acquired for each phantom are then subtracted and analyzed by curve plotting. ***Results:*** Except for spine bone, in which radio-opacity decreases with increasing spectral X-ray energy (from 100 to 140 kVp), other squares exhibit little changes over different energies. PMMA shows consistently very low radio-opacity. For four other materials (barium sulfate in water, stainless steel alloy, titanium alloy and gold), all attenuate the X-ray photons substantially. Except for spine bone, and other materials are barely noticeable in pairwise subtracted images. In torso phantom, piercing objects are visualized as "holes" in vertebrae. ***Conclusion:*** Both artificial high- and low-density materials, compared to bone, are eliminated during subtraction of dual-energy X-ray profiles and therefore, can create black-hole artifact.

EP-0718

Optimizing PET dose in adult imaging: striking a balance between patient safety and optimal image quality. From our daily clinical experience to the existing literature.

P. Guglielmo[1], *A. Filice[2], F. Chierichetti[3], S. Panareo[4], G. Rovera[5], V. Frantellizzi[6], R. Laudicella[7], A. Iudicello[4], F. Stracuzzi[8], L. Burroni[9], AIMN HTA Study Group;*
[1]Veneto Institute of Oncology IOV - IRCCS, Padua, ITALY, [2]Azienda USL-IRCCS of Reggio Emilia, Reggio Emilia, ITALY, [3]S Chiara Hospital, Trento, ITALY, [4]University Hospital of Modena,Modena,Italy, Modena, ITALY, [5]University of Turin,Turin,Italy, Turin, ITALY, [6]Sapienza University of Rome,Rome,Italy, Rome, ITALY, [7]University of Palermo,Palermo,Italy, Palermo, ITALY, [8]University of Messina,Messina,Italy, Messina, ITALY, [9]Ospedali Riuniti Hospital,Ancona,Italy, Ancona, ITALY.

Aim/Introduction: Since the development of hybrid scanners combining a Positron emission tomography (PET) and an X-ray computed tomography (CT), the use of PET/CT has rapidly increased worldwide. However, radiation exposure can be a thoughtful concern. A proper PET/CT procedure should achieve the clinical purpose, without compromising the objective evaluation of the PET/CT study, while maintaining radiation dose "as low as reasonably achievable" (ALARA principle). In fact, PET/CT results in considerable medical radiation exposure (up to 25 mSv in older systems, and approximately 7-10 mSv at modern state-of-the-art CT), which is somewhat higher than in multidetector contrast material-enhanced CT (depending on the examination protocol). Thus, especially for young patients who potentially require repeated follow-up studies, the imaging modality with the lowest possible absorbed radiation dose per examination is desired.Aim of our study is to collect all the adopted measures in our clinical daily practice to reduce the patient dose at different steps (injected activity, CT protocol, reconstruction methods, etc.) and to compare them to the current evidence in literature. ***Materials and Methods:*** A comprehensive search of relevant articles was conducted in medical databases (i.e. Embase, Scopus, Web of Science and Medline), using the keywords: dose optimization, computed tomography, PET, radiopharmaceutical, PET/CT, PET/MRI, DRL. Only English and full-text articles were included, without limitations on the publication year. After the screening, 58 articles were selected considered eligible for the analysis. ***Results:*** The methods used for dose optimization include: improving reconstruction algorithms; reducing the injected radiotracer activity but increasing the acquisition times, especially in new digital PET scanner; using long-axial field of view (LAFOV) PET/CT tomographs; and modulating CT radiation dose

by using artificial intelligence tools. All these approaches are in line with those implemented in our departments. Furthermore, the future trend is prioritizing data collection, in accordance with international guidelines, to better understand PET/CT dose discrepancies while also striving to optimize radiation doses without compromising the quality of PET images. ***Conclusion:*** Several optimization methods have been developed and implemented to reduce the dose delivered to the patients who undergo PET/CT or PET/MRI examination; in recent years, the advent of digital PET and LAFOV scanners represent an important step in the evolution of molecular imaging and dose optimization and are also experiencing an increasingly widespread adoption in clinical practice. ***References:*** Al-Fatlawi M et al. Optimization of the Acquisition Time and Injected Dose of ^{18}F-Fluorodeoxyglucose Based on Patient Specifications for High-Sensitive PET/CT. WJNM.2023;22(3):196-202.

EP-0719

Introducing Risk Management into the IAEA Quality Management Program

A. Brink[1], *M. Marengo[2], S. Rubow[3], M. Dondi[1], F. Giammarile[1], E. Minoshima[1], B. Arends[4], K. Pathmaraj[5], L. Torres[6], D. Paez[1];*
[1]IAEA, Vienna, AUSTRIA, [2]University of Bologna, Bologna, ITALY, [3]Stellenbosch University, Stellenbosch, SOUTH AFRICA, [4]Catharina Ziekenhuis, Eindhoven, NETHERLANDS, [5]Austin Health, Melbourne, AUSTRALIA, [6]CENTIS, Havana, CUBA.

Aim/Introduction: Risk management strategies aim to effectively identify and prevent risks and mitigate their possible effects. The expected outcomes for a medical organization include an improved capacity for achieving the desired level of quality and safety in care and creating a safer work environment for staff. The overall goal of a new IAEA project is to help Nuclear Medicine departments in Member States to develop a risk management culture where all staff members and stakeholders are aware of the importance of prospectively evaluating and then monitoring and managing risk. ***Materials and Methods:*** A committee of NM professionals with experience in QM, auditing, and risk assessment, discussed strategies to promote and support risk management as a tool in Nuclear Medicine departments. The group reviewed literature and experience in various fields within Nuclear Medicine to establish the range of aspects in which risk management should be implemented. Failure Modes and Effects Analysis (FMEA), was selected as a suitable tool applicable in our discipline. In FMEA, the level of risk R of an activity or operation is calculated semi-quantitatively based on the probability P of occurrence of a fault, the grade of severity S of the consequences and the detectability D of the specific fault. These variables are scored on a 5-level scale. A model Excel spreadsheet was used to capture the steps for each of a few example procedures and their possible failures, calculating the risk score for each step. Possible causes and preventive or corrective measures were provided in the spreadsheets. ***Results:*** Selected Nuclear Medicine procedures were used to prepare examples of implementing FMEA. Each procedure was broken down into a series of individual steps, for which possible failures were considered. An initial set of FMEA spreadsheets was prepared, covering situations such as injection of radiopharmaceuticals; thyroid cancer therapy with 131I; and labeling of kits with 68Ga. More examples are being developed. ***Conclusion:*** The IAEA promotes the practice of risk management in Nuclear Medicine. The adoption of FMEA as a prospective method will facilitate setting up more robust SOPs, and a system of checks, graduated according to the risk and tailored to the needs. Tools, like an FMEA spreadsheet, that can be easily adapted according to local needs, and a library of examples will shortly be available on the IAEA's Human Health Campus. This further extension of the QUANUM portfolio will help improve quality and safety in patient care.

EP-0720

Can IRT replace ^{18}F-FDG PET/CT scan in the assessment of Brown Adipose Tissue activation?

M. Jensen[1], *S. Andersen[2,3], C. E. Almasi[4];*
[1]Department of Clinical Medicine, Aalborg University, Aalborg, DENMARK, [2]Department of Geriatrics, Aalborg University Hospital, Aalborg, DENMARK, [3]Department of Clinical Medicine, Aalborg Univserity, Aalborg, DENMARK, [4]Department of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK.

Aim/Introduction: Brown Adipose Tissue (BAT) has the potential to combat obesity and metabolic diseases. Hence, it has been a field of abundant research since the confirmation of BAT presence in adult humans by PET/CT. PET/CT has since been considered as the gold-standard for BAT assessment (1). PET/CT scans are relatively expensive and expose research participants to ionising radiation. In contrast, infrared thermal imaging (IRT) is an inexpensive, easy, and non-invasive alternative method that has the potential to assess BAT activity without radiation exposure. In BAT research, IRT measures the skin temperature in the supraclavicular region, where the largest, superficial depot of BAT in humans typically is located. IRT measures a direct outcome for BAT activity, as the main function of BAT is thermogenesis. Studies have observed an overlap of the region with maximal temperature on IRT with the area of maximal fluorodeoxyglucose (18F-FDG) uptake on PET/CT. However, only few studies validate IRT compared PET/CT scans or similar imaging techniques. In studies that have measured BAT activity with PET/CT and IRT, there is discrepancy in the correlation of FDG-uptake and the supraclavicular temperature. We aim to validate IRT for BAT assessment by standardized methods. We examine the correlation between supraclavicular temperature measured with IRT and BAT activity quantified by different PET-parameters in the supraclavicular region. ***Materials and Methods:*** Recommendations for standardised BAT assessment and analysis are followed (1,2). PET/CT scans are performed on 20 healthy participants at two separate visits: A cooling visit and control visit. To activate BAT, participants are exposed to an individualised 2-hour cold exposure with cooling blankets. 18F-FDG will be injected after the first hour of cooling. PET/CT scans will be performed after 2 hours cooling. During the cold exposure, IRT images are obtained from the beginning and every 15 minutes until the PET/CT scan is performed after 120 minutes. We assess the relationship of BAT activity and volume by measuring the correlation of outcome from the two methods: the maximal supraclavicular temperature from IRT and different PET-parameters in the supraclavicular region including maximal standardized uptake volume adjusted for lean body mass (SULmax), BAT metabolic volume (BMV) and total BAT glycolysis (TBG). ***Results:*** Data will be ready for presentation at the conference. ***Conclusion:*** Awaiting data analyses. ***References:*** 1. Chen KY et al. Cell Metabolism. Cell Press; 2016 2. Kim K et al. Journal of Visualized Experiments; 2019.

EP-0721

Impact of ^{18}F standard PET EARL-harmonization on functional volume measurement: a pilot single-center phantom study

G. Khamadeeva, *A. Khalimon, A. Nikiforuk, S. Onishchenko, M. Khodzhibekova, A. Leontyev;*

P. Hertsen Moscow Oncology Research Institute – branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: To assess the impact of 18F-based PET EARL-harmonization on the variability of functional volume measurements (FVM). ***Materials and Methods:*** A 5 rings BGO PET/CT system certified according 18F standard 2 EARL accreditation program and NEMA IEC Body Phantom Set NU2-2018 were used in the study. The volume of the each sphere of the phantom was previously measured. The phantom filling and scanning procedure was performed in accordance with the recommendations of EARL 18F standards [1]. The study included 40 image reconstructions: 20 EARL2-harmonized (EARL2) (10 - 3D OSEM+PSF, 10 - BSREM) and 20 non-harmonized (10 - 3D OSEM+PSF, 10 - BSREM), as control group. The volume of the each sphere on PET were measured using two segmentation tools: a 41% of the maximum voxel value 3D isocontour (41%ISO) and the adaptive iterative algorithm (AIA). For each of six spheres the volume recovery (VR) value was calculated, which corresponds to the ratio of measured PET volume to the true volume, similar to EARL's recovery coefficient [2]. Mean VR (MVR) value was calculated for each reconstruction, then coefficients of variation (CoV) of MVRs were calculated across EARL2 and control group (6 CoVs for each group) depending on reconstructive algorithm (3D OSEM+PSF or BSREM) and segmentation tool. ***Results:*** CoVs of EARL2 were lower in comparison to control group independently of the reconstruction algorithms and the segmentation approaches used: for the AIA tool 6.7% vs 20.4% in the total, 6.9% vs 15.1% for 3D OSEM+PSF, 6.0% vs 21.9% for BSREM; for the 41%ISO tool 4.4% vs 11.5% in the total, 4.0% vs 14.5% for 3D OSEM+PSF, 0.7% vs 4.7% for BSREM. The CoVs were lower when using EARL2 BSREM in comparison to 3D OSEM+PSF independently of the segmentation tool, the lowest one (0.7%) was achieved among the EARL2 for BSREM algorithm using 41%ISO tool. 41%ISO tool consistently yielded lower CoVs irrespective of harmonization status or the reconstructive algorithm. ***Conclusion:*** Preliminary results suggest that EARL harmonization, alongside reducing interscanner SUV variability, may also contribute to decreased interscanner FVM variability in 18F-based PET, utilizing widely available segmentation tools. It is necessary to conduct a multicenter study to verify obtained results on different PET-systems. ***References:***

EP-0722

The Color of Radiation: Evaluating and Advocating for Improved Colormaps in Nuclear Medicine

M. C. M. Gammel[1], *S. G. Nekolla[1], B. M. Gammel[2];*
[1]Department of Nuclear Medicine, Klinikum rechts der Isar, Technical University Munich School of Medicine and Health, Munich, GERMANY, [2]Infineon Technology AG, Munich, GERMANY.

Aim/Introduction: Strict quality guidelines for monitors and room classes are in place to ensure high-quality image analysis. Frequent sources of artifacts such as the human eye and Colormaps (CMAP) are often overlooked. A translation table comprises guidelines for image generation by transforming a sequence of numbers into respective pixels, with each numeral in the sequence being converted into a pixel of a distinct color. An optimal translation table allows for the undistorted visual representation of measurements and would e.g. aid in the detection of perfusion abnormalities and reduce the likelihood of mistakenly classifying artifacts as pathological findings in myocardial perfusion SPECT. Societies like ASNC and EANM recommend linear and thus perceptionally uniform CMAPs to prevent effects like pseudo-contouring. However, an equidistant color spacing has not yet been considered, which significantly affects the undistorted representation of measurements. Furthermore, dichromacy, led by deuteranomaly (5% of the male population), is a common condition that can lead to misinterpretations with some CMAPs. ***Materials and Methods:*** The common 16 CMAPs of the Cedars Cardiac Suite QPS/QGS were examined for a linear luminance curve in the CIE L*a*b* color space, which is device-independent and perception-based, thus perceived independently of the origin or reproduction technique under standard lighting conditions. Furthermore, the CMAPs were examined for equidistant color spacing. ΔE00, as defined by the standard CIEDE2000 (ISO/CIE 11664-6), serves as a metric for the visual distance between two colors. Based on the CIE L*a*b* color model, it considers differences in luminance (L*) as well as variations in the chroma components a* and b*. With simulated deuteranomaly, protanomaly, and tritanomaly through the Matpack C++ Numerics and Graphics Library, we checked whether transitions between colors are still noticeable. ***Results:*** Only 1/16 CMAP (thermal) had a nearly linear luminance curve in the CIE L*a*b* color space. The remaining 15 are thus susceptible to erroneous evaluations due to pseudo-contouring. None of the CMAPs have a uniform equidistant color spacing, thus distorting the representation of the measurements. With deuteranomaly, 13/16 color transitions are difficult to differentiate, with protanomaly 13/16, and with tritanomaly 5/16. ***Conclusion:*** None of the tested CMAPs met the societies' recommendations regarding perceptional uniformity. Additionally, equidistance should be considered. Further, Common CMAPs and current recommendations do not account for individuals with dichromacy and can therefore lead to misinterpretations. Since ensuring image quality requires considerable effort, including financially, CMAPs should be included in quality assurance and take dichromacies into account.

EP-0723

Multi-site comparison of imaging protocols for quantitative 99mTc SPECT-CT

S. F. W. Shearer[1,2,3], *A. J. Gemmell[1,2,4], R. Gillen[1,5,2], C. Reilly[1,4,2], H. J. Wallace[1,2,4];*
[1]Department of Clinical Physics & Bioengineering, NHS Greater Glasgow and Clyde (GGC), Glasgow, UNITED KINGDOM, [2]College of Medical, Veterinary & Life Sciences, University of Glasgow, Glasgow, UNITED KINGDOM, [3]Chief Scientist Office, Scotland, UNITED KINGDOM, [4]NHS Education for Scotland, Scotland, UNITED KINGDOM, [5]Institute of Nuclear Medicine, University College London, London, UNITED KINGDOM.

Aim/Introduction: Quantitative SPECT-CT is available from several Gamma Camera vendors, as well as vendor neutral applications. Implementation in clinical practice remains piecemeal and inconsistent, though recent EANM guidelines attempt to address this[1]. There are a range of SPECT-CT systems across six hospitals in NHS Greater Glasgow and Clyde and some variation remains in clinical adoption of quantification. This work aims to investigate variations in [99mTc] quantification between SPECT-CT systems with a view to establishing harmonised quantification protocols. ***Materials and Methods:*** Calibrations of seven SPECT-CT systems were performed for [99mTc] using a uniform SPECT phantom and resulting calibration factors were compared. A NEMA-IEC-2012 phantom was adapted to include

a 60mm diameter sphere, filled to give a sphere-to-background ratio of 5:1 and imaged on each system. Standardised set-up instructions, acquisition protocols and vendor neutral reconstruction protocols were developed and applied to ensure cross-site consistency. Background recovery, based on 60mm diameter spherical VOIs, was assessed. Recovery Coefficient (RC) curves (derived from Max, Mean and Peak measurements in hot spheres) were analysed visually and compared numerically using Mean Contrast Recovery (MCR). Multiple NEMA phantom acquisitions were performed on one system to assess repeatability and reproducibility. This variation was consistent with a ±10% range, hereafter used as an acceptable benchmark for cross-system consistency. ***Results:*** Calibration factors ranged from 78.9-96.2 cps/MBq over the seven systems assessed. Background recovery matched the expected activity concentration to within 6% and was comparable between systems with a maximum difference of 7% (range 0.94-1.01). The RC curves approached maximal recovery with the addition of the 60mm sphere, demonstrating minimisation of partial volume effect with this larger sphere size and reducing uncertainty for RC curve fitting [2]. RC curves from all seven systems fell within the acceptable range derived from the single system repeatability and reproducibility measurements; demonstrating cross-system consistency for standardised acquisition and reconstruction protocols. MCR averages and ranges were found to be comparable between systems [MCRMax: 0.785(0.737-0.815), MCRMean: 0.540(0.507-0.562) and MCRPeak: 0.733(0.646-0.916)]. ***Conclusion:*** RC curves for standardised [99mTc] acquisition and reconstruction protocols demonstrated acceptable cross-system consistency. The addition of a 60mm diameter sphere improved RC curve fit and minimised partial volume effects. Ongoing work will assess city-wide consistency using clinical protocols, including vendor specific reconstructions. ***References:*** [1]Dickson.JC; Armstrong.IS; Gabiña. EP-0724

Development of Harmonised Quantitative Imaging as a First Step to a Pan-Scotland Dosimetry Service for ^{177}Lu

***M. Ulyatt*[1,2],** *A. J. Gemmell[1,2,3], S. Small[1,2,3];*
[1]Nuclear Medicine, Gartnavel General Hospital, Glasgow, UNITED KINGDOM, [2]Department of Clinical Physics and Bioengineering, NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM, [3]College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, UNITED KINGDOM.

Aim/Introduction: The Scottish national service for [177Lu] Oxodotreotide therapies is provided at Gartnavel General Hospital (GGH), delivered as a fixed protocol of four 7.4 GBq fractions. Post-therapy imaging acquired each fraction 24 hours post-administration assesses radiopharmaceutical distribution within the patient. Personal dosimetry has the potential to improve patient outcomes, but is not currently performed at GGH due to the requirements of the fixed protocol. The multi-timepoint quantitative imaging required for optimal personalised dosimetry is not currently practical for patients outwith Glasgow: we aim to set up a pan-Scotland dosimetry service, by imaging patients at more practical local Nuclear Medicine sites. Factors involved in identifying suitable sites include location, camera capabilities, legislative requirements and staffing levels. ***Materials and Methods:*** Three gamma cameras at GGH, Aberdeen Royal Infirmary (ARI) and New Victoria Hospital (NVH) were chosen as pilot sites and calibrated for 177Lu. Prior to phantom preparation, radionuclide calibrator calibration factors at each site were determined for 177Lu using sources traceable to the National Physical Laboratory via the secondary standard radionuclide calibrator at GGH. Locally optimised clinical acquisition parameters were used as standard across all sites. SPECT-CT data were reconstructed using a standardised reconstruction on vendor neutral software. Planar sensitivity factors were determined using a small flat-bottomed flask. SPECT-CT sensitivity factors were determined using a cylindrical uniformity phantom. An image quality phantom adapted to include spheres of diameter 10 to 60 ml, to allow full contrast recovery to be approached, was filled with a 177Lu solution to give a sphere-to-background ratio of 5:1. Mean Recovery coefficient (RC) curves were characterised using Mean Contrast Recovery (MCR), curvature and absolute error, as suggested by Kaalep et al[1]. ***Results:*** Planar calibration factors ranged from 16.3-17.6 cps/MBq. SPECT-CT calibration factors ranged from 20.4-21.4 cps/MBq. Visual appearance of the mean RC curves were similar. Percentage range of MCR, curvature and absolute error of the mean RC curves were 23.3%, 33% and 22.3%, respectively. ***Conclusion:*** Planar and SPECT-CT calibration factors for all cameras were comparable. RC curve analysis has demonstrated similar gamma camera performance. The foundations for harmonised quantitative imaging as part of a pan-Scotland 177Lu dosimetry service have been established; further work using this standardised calibration and imaging protocol will establish calibration factors for gamma cameras at additional sites and trial multi-timepoint imaging and dosimetry of patients. ***References:*** Kaalep.A; Sera.T; Rijnsdorp.S. et al. Feasibility of state of the art PET/CT systems performance harmonisation. EurJNuclMedMolImaging(2018). https://doi.org/10.1007/s00259-018-3977-4.

EP-0725

^{99m}Tc-efficacy of a well-counter - evaluation of different approaches

C. Happel, *B. Leonhäuser, T. Walger, B. Bockisch, R. A. Werner;*
Goethe University Frankfurt; University Hospital; Department of Nuclear Medicine; Clinic for Radiology and Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: The efficacy of a well counter is defined as the ratio of the actual activity in kBq and the measured count rate in cpm of a radioactive sample. The biannual verification of the 99mTc-efficiacy is a regulatory requirement in Germany. Aim of this investigation was to compare different approaches to calculate the 99mTc-efficacy regarding accuracy, managability and radiation protection. ***Materials and Methods:*** Three different approaches (10 series of measurements respectively) were evaluated: 1. a dilution series of 1:1000 in 1 ml H2O in three steps; 2. Dilution of 1:1000 by addition of a volume of 1 ml 99mTc to 999 ml H2O and 3. Preparation of an appropriate 1 ml 99mTc-sample by decay. In each approach, a concentration of 5 kBq/ml (2% deadtime of the well-counter) was aimed for. A well-counter with connected multi-channal-analyser (Dr. Westmeier GmbH) and a dose-meter (ISOMED 2020; MED) were used. Measuring time was 60s in each case. 99mTc efficacy was calculated as the ratio of background corrected count rate (energy window 140 keV ± 20%) and decay corrected 99mTc activity. Results were statistically compared by calculating mean and standard deviation within the three measurement series.

Results: The first method showed a mean 99mTc-efficacy of 48,302 cpm/kBq ± 6.6%. Mean 99mTc-efficacy of the second method was 47,220 cpm/kBq ± 1.9% and the third method showed a mean 99mTc-efficacy of 46,696 cpm/kBq ± 1.1%. Maximum deviation of the three approaches were 13% (1. Approach), 2.4 % (2. Approach) and 2.1 % (3. Approach). ***Conclusion:*** Due to its easiest practical implementation, the lowest risk of contamination and the highest accuracy, method 3 should be favored over the other two methods. In addition, the preparation and implementation is quicker compared to the other methods. Method 2 has the highest potential for contamination and is inferior in terms of handling and preparation time. Method 1 is the most error prone.

EP-0726

The impact of the operator and the software in gated equilibrium radionuclide angiography processing.

R. Silva[1], *H. Martins[1], R. Albergueiro[2], M. Sofia[1], L. Costa[1];*
[1]Unidade Local de Saúde de Santo António, Porto, PORTUGAL,
[2]Unidade Local de Saúde de São João, Porto, PORTUGAL.

Aim/Introduction: Gated Equilibrium Radionuclide Angiography (ERNA) allows for optimal measurement of ventricular volumes and the evaluation of left ventricle ejection fraction (LVEF) during the course of chemotherapy with potential cardiotoxicity. An accurate LVEF quantification is essential, since a significant serial decrease may dictate the interruption of ongoing chemotherapy. This study aims to evaluate the impact of intraoperator, interoperator and intersoftware variability in LVEF estimation. ***Materials and Methods:*** Retrospective study including all ERNA performed between September 2023 and February 2024 in a tertiary referral hospital. All ERNA with non-standard technical imaging parameters were excluded. Each ERNA was semi-automatically processed three times by 3 independent operators (OP), using two different softwares (FUGA Gated Heart Analysis v6 [Hermes] e MUGA syngo MI Applications VA46C [Siemens]). Statistical Package for the Social Sciences (SPSS) v27 was used for statistical purposes. ***Results:*** One hundred and twenty-six ERNA were included in the final sample and 28 ERNA were excluded. The final sample comprised an oncological population with 94 females (75%) with a mean age of 59 years. The most common cancer was breast cancer (63%), followed by leiomyosarcoma (n=7). Intraoperator measurements were consistent between themselves (ICC > 0,90).Hermes and Siemens ICC were 0.962 (95%CI 0,949-0,972) and 0.983 (95%CI 0,978-0,988), respectively, revealing excellent reproducibility. However, both softwares revealed significant differences between operators, which were higher in the Hermes group: there were significant LVEF differences between OP1-OP3 (mean difference -1,728%) and OP2-OP3 (mean difference +2,071%). In the Siemens group, there were LVEF differences between OP1-OP3 (mean difference +0,738%). The average LVEF estimated by Siemens was significantly higher than the one calculated by Hermes (61,59±8,77 vs. 60,41±8.86%; p-value 0,015). ***Conclusion:*** Although having excellent interoperator repeatability and interoperator reproducibility, there seems to exist some degree of operador-dependency. The higher differences between operators using Hermes software may be explained by higher erroneous region-of-interest (ROI) segmentations than in the Siemens group, inducing more operator-dependent ROI marginalization. The LVEF differences between softwares may be explained by different processing algorithms applied in both softwares. Different algorithms may contribute to unequal ROI segmentations used for LVEF estimation - left ventricle end-systolic and end-diastolic ROI and the background ROI. Therefore, it seems reasonable to include the software used for ERNA processing in medical reports. The current study also highlights the importance of uniformizing the algorithms applied in the different ERNA processing software, in order to make the LVEF a reliable value, operator- and, possibly, software-independent.

EP-0727

Implementation of EARL ^{177}Lu Quantitative SPECT Accreditation on 360° CZT SPECT-CT Camera

A. Dumouchel, *A. Koudia, M. Francois, P. Bohn, A. Dieudonne;*
Centre Henri Becquerel, Rouen, FRANCE.

Aim/Introduction: The aim was to apply the SPECT-CT 177Lu accreditation protocol to our new-generation 360° CZT camera, which is not included in the EARL recommendations, in comparison with our standard NaI two-head gamma camera. ***Materials and Methods:*** Radionuclide calibrator was calibrated by a metrology laboratory. The gamma cameras were calibrated for 177Lu, in accordance with the manufacturers' recommendations. The first fantom was a cylinder filled with 400MBq of 177Lu, in order to measure quantitative accuracy for large volumes. The second was an IEC Body NEMA, without the lung insert, whose spheres contained a concentration of 2MBq/mL of 177Lu, in order to measure the spatial resolution, and whose volumes are: Sphere1=27.36cm3, Sphere2=11.24cm3, Sphere3=5.52cm3, Sphere4=2.41cm3, Sphere5=1.20cm3.Acquisitions were carried out on the 2 gamma cameras according to the protocol recommendations: 7 million counts for the 1st phantom, 3 million counts for the second. The reconstructions on the standard gamma camera followed the recommendations of the protocol (CT Attenuation Correction (CTAC), Resolution Modelling (RM), TEW Scatter Correction (TEWSC), 25iterations 2subset (25it2s) and no filtering). For the CZT gamma camera, several parameters were tested in order to obtain results close to that of the NaI camera: Clinical reconstruction: CTAC, 4it8s, convolution filter 0.125mm and High Peak Correction (HPC) 0.2 EARL reconstruction: CTAC, 25it2s, convolution filter 0.125mm. ***Results:*** Quantitative accuracy, measured with a circular volume of interest (VOI) with a diameter equal to 85% of the diameter of the activity distribution in the cylinder gave SUVs at 1.04 for standard camera and 1.05 for CZT camera, with the same phantom filled with 393 MBq of 177Lu. Spatial resolution was assessed by the recovery coefficient (RC) of each sphere. The same phantom, with 2MBq/mL in each sphere, was used.For the standard camera, the RC were 0.97 (sphere1), 0.97 (sphere2), 0.93 (sphere3), 0.93 (sphere4) and 0.59 (sphere5). For CZT camera:Clinical reconstruction: 0.99 (sphere1), 0.85 (sphere2), 0.81 (sphere3), 0.72 (sphere4) and 0.35 (sphere5) EARL reconstruction: 1.01 (sphere1), 0.89 (sphere2), 0.87 (sphere3), 0.82 (sphere4) and 0.39 (sphere5). ***Conclusion:*** The EARL protocol was successfully applied on a CZT 360° gamma-camera with comparable results to a NaI gamma-camera. The same protocol will be tested with the 6 cm sphere replacing the smallest sphere as recommended by EARL.

EP-0728

Evaluation of surface activity detection efficiency for different contamination meters, decay modes and sizes of contaminated area

M. Hakulinen, *H. Gröhn;*
Diagnostic Imaging Center, Kuopio
University Hospital, Kys, FINLAND.

Aim/Introduction: Use of open sources in nuclear medicine facilities demand for reliable contamination measurements.

General threshold values for contaminated areas are set to very low surface activity (SA), i.e. from 0.4Bq/cm2 up to 40Bq/cm2. Our aim was to measure and evaluate the sensitivity of two different contamination meters to detect such threshold values with radionuclides with different decay modes. In addition, effect of contaminated area size to sensitivity and quantitative accuracy (Bq/cm2) was evaluated. ***Materials and Methods:*** Two types of contamination meters were measured using four radionuclides with different decay modes: 223Ra, 177Lu, 99mTc and 18F. All the measurements were done for two different distances (2cm and 10cm) and surface areas (1cm2 and 16cm2). Average values over approximately 5s measurement time were used. Accurate SA values were determined based on known activity concentration measured in standard vial geometry using metrologically traceable Secondary Standard Calibrator and prepared with known volumes measured with high accuracy pipettes. Quantitative accuracy was calculated as a difference between measured and known SA values. ***Results:*** Only preliminary results are presented. For 2 cm distance and surface area of 16cm2, lowest detectable SA of 5Bq/cm2 were observed with alpha and beta decay modes, whereas only 1kB/cm2 SA was detected with 99mTc. With 18F, corresponding lowest SA was 12.5Bq/cm2. Quantitative accuracy was the highest for 177Lu with SA between 5-12.5Bq/cm2, ranging from 1.1% to 20.9%. Interestingly, for all radionuclides (99mTc excluded) the most accurate quantitative values were observed with SA of 12.5Bq/cm2.On the other hand, with surface area of 1cm2, the detectable SA was substantially higher (1MBq/cm2) with 99mTc whereas only the highest threshold value of 40Bq/cm2 was detected with 223Ra, 177Lu and 18F. ***Conclusion:*** Sensitivity and accuracy of the contamination measurements are highly dependent on decay mode of radionuclide as well as size of the contaminated area. In practice, small, concentrated contaminations (e.g. 1cm2) can be detected but only with higher SA, whereas lower SA can be detected only in larger contaminated areas. Importantly, optimal performance of contamination meters was observed with alpha and beta emitters, which are the most important decay modes in terms of contamination risks. Use of alpha channel in contamination meters provided only information about the presence of alpha radiation. With positron emitters, the performance of contamination meters was sufficient for clinical settings whereas the detection of low SA was challenging for gamma emitters.

EP-0729

Achieving EARL Accreditation on a Long Axial Field-of-View (LAFOV) PET/CT System

B. Holman, *T. Willson, B. Ferreira, N. Davis, D. McCool;*
Nuclear Medicine, Royal Free Hospital,
London, UNITED KINGDOM.

Aim/Introduction: European Association of Research in Nuclear Medicine (EARL) guidelines aim to standardise PET imaging, particularly in clinical research, but were developed primarily for conventional PET/CT systems. Recent studies at the University Medical Centre Groningen explored a method to adapt EARL standards for long axial field-of-view (LAFOV) systems using high sensitivity (HS) static mode. This study extends the scope by examining ultra-high sensitivity (UHS) configurations and continuous bed motion (CBM) to determine EARL compliance. ***Materials and Methods:*** The NEMA IEC image quality phantom was filled with ^{18}F-fluorodeoxyglucose at a 10:1 spheres: background ratio. The phantom was scanned at five locations along the 106cm LAFOV PET/CT system: at 1/4, 1/3, 1/2, 2/3, and 3/4 of the axial length. Images were acquired in static mode for 5 minutes and with CBM at 2.2 mm/sec, simulating a 5-minute static acquisition. Reconstructions were performed in HS and UHS modes using 3D ordered subset expectation maximization (OSEM) with 4 iterations and 5 subsets, with time-of-flight (TOF) and point spread function (PSF) corrections. Matrix sizes were 220×220 with Gaussian filtering of 4, 5, 6, and 7mm, and 128×128 with filtering of 3, 4, 5 and 6mm. The contrast recovery curves for each sphere were compared against the EARL standards. ***Results:*** Images met EARL standard specifications in both HS and UHS static modes, as well as UHS with CBM. Optimal reconstructions used 3D TOF OSEM with 4 iterations, 5 subsets. For EARL 1, HS static, UHS static and UHS with CBM required matrix sizes and Gaussian filtering of 220×220 and 7mm, 128×128 and 2mm and 128× 128 with 6mm respectively. For EARL 2 UHS static and CBM matrix and Gaussian filters were 220×200 with 4mm and 128×128 with 3mm respectively. Additionally, the improved performance of the LAFOV system meant that the recovery profiles were flat making EARL2 complicated to achieve without significantly reducing image quality. ***Conclusion:*** The study demonstrates that both EARL 1 2 standards are achievable with a LAFOV PET/CT system. This compliance allows these systems to participate in clinical trials that require harmonization with conventional PET/CT cameras, enhancing flexibility in research and clinical practices. ***References:*** Van Sluis J, Van Snick JH, Brouwers AH, Noordzij W, Dierckx RAJO, Borra RJH, Slart RHJA, Lammertsma AA, Glaudemans AWJM, Boellaard R, Tsoumpas C. EARL compliance and imaging optimisation on the Biograph Vision Quadra PET/CT using phantom and clinical data. Eur J Nucl Med Mol Imaging. 2022 Nov;49(13):4652-4660. doi: 10.1007/s00259-022-05919-1.

EP-0730

Dynamic Imaging and Accuracy of Kinetic Analysis on a Long Axial Field-of-View PET/CT System

B. Holman, *T. Willson, A. Chowdhury, B. Ferreira, N. Davis, D. McCool;*
Nuclear Medicine, Royal Free Hospital,
London, UNITED KINGDOM.

Aim/Introduction: Dynamic PET/CT imaging and kinetic analysis hold promise for enhancing patient diagnosis, staging, and treatment planning. However, these techniques have yet to be widely adopted in clinical settings due to extended acquisition times, suboptimal image quality from shorter scans, and the requirement for specialized expertise. New long axial field-of-view (LAFOV) PET/CT systems with sensitivity 20 times higher than conventional scanners, coupled with integrated kinetic analysis software and AI-derived input functions, could reduce acquisition times and bring dynamic imaging and kinetic analysis into mainstream clinical practice. This study explores the image quality of dynamic images using a parsley plant and evaluates the accuracy of kinetic analysis with a phantom. ***Materials and Methods:*** Freshly cut parsley was placed in a cup of water containing 12 MBq of ^{18}F-FDG. A dynamic PET acquisition was performed over 8 hours, and reconstructed using 8-minute time intervals, with an additional reconstruction using 24×5-second frames at 6h to evaluate image quality for shorter scans. Images were analysed qualitatively to assess the uptake pattern and plant movement. For the kinetic analysis, a 500 mL saline bag was placed at the centre of the field of view on the bed and connected to a syringe with 13 MBq of ^{18}F-FDG in 30 mL. An infusion pump delivered the tracer at a rate of 100 mL/hr. Dynamic images were acquired every 30 seconds for 20 minutes. Kinetic analysis was performed using a 1-tissue irreversible compartment model to estimate K1, representing the infusion rate into the bag. Patlak analysis was

also used to confirm the accuracy of the kinetic analysis. ***Results:*** Dynamic images from the parsley plant demonstrated uptake in the stems and leaves over the entire acquisition. In 5-second reconstructions, uptake and movement were clearly observed, demonstrating the high sensitivity of the LAFOV system and potential for accurate kinetic analysis. The kinetic analysis, using both proprietary software and user-defined calculations, accurately estimated the rate of change in activity, confirming the system's reliability for these measurements. ***Conclusion:*** LAFOV dynamic imaging provides exceptional image quality due to its 20-fold sensitivity increase. This study introduces a straightforward method to test proprietary kinetic analysis software before patient use. The potential for these systems to support more accurate and shorter dynamic PET/CT studies in clinical settings is indicated. This improved capability could facilitate broader adoption of dynamic imaging and kinetic analysis in nuclear medicine.

EP-0731

Optimisation of Ga-68 DOTATATE Imaging on a Long Axial Field-of-View PET/CT

B. Holman, *O. Walford, N. Davis, T. Willson, B. Ferreira, D. McCool, S. Navalkissoor, T. Wagner;*
Nuclear Medicine, Royal Free Hospital,
London, UNITED KINGDOM.

Aim/Introduction: Ga-68 DOTATATE is a radiopharmaceutical used in PET/CT imaging to detect and localise neuroendocrine tumours (NETs) and other tumours expressing somatostatin receptors. Patients are typically injected with 100-200 MBq of Ga-68 DOTATATE and imaged at 3 minutes per bed position on a standard PET/CT system. Due to the technical expertise and time required to produce Ga-68 DOTATATE, and associated costs, the supply of this essential radiotracer is limited, leading to high demand and long waiting lists. Long axial field-of-view (LAFOV) PET/CT scanners, with 20 times the sensitivity of conventional scanners, offer the opportunity to reduce injected activity and acquisition times, increasing throughput, reducing waiting times, and improving patient outcomes. This study aims to optimise the imaging regime to keep injected activity low while maintaining minimal acquisition times. ***Materials and Methods:*** Images of 25 patients undergoing Ga-68 DOTATATE studies on the LAFOV PET/CT as part of standard care were analysed. Patients received 100-200 MBq of Ga-68 DOTATATE and were imaged in static mode, acquired in ultra high sensitivity (UHS) configuration. To explore reduced activity, shorter image acquisition times were tested. Images were reconstructed with 10-minute acquisition (no filter), 5-minute acquisition (no filter), 5-minute acquisition with a 2mm Gaussian filter, and 5-minute acquisition with a 5mm Gaussian filter. All reconstructions utilised OSEM with 4 iterations, 5 subsets, a 440x440x708mm matrix, point spread function (PSF), and time-of-flight (TOF) corrections. Experienced nuclear medicine radiologists evaluated the images based on the number of lesions seen, number of liver lesions, overall diagnostic quality, and liver diagnostic quality using a 5-point scale: seriously inadequate, inadequate, marginally adequate, definitely adequate, and more than adequate. Quantitative noise measurements were taken from the liver. ***Results:*** Images acquired with a 5-minute acquisition and no filter were diagnostic but noisier compared to the 10-minute acquisition. The addition of a Gaussian filter reduced noise, with the 2mm filter considered optimal to avoid over-smoothing. Quantitative noise measurements indicated that the 5-minute acquisition with a 2mm Gaussian filter had equivalent noise to the 10-minute acquisition. These findings suggest that reducing injected activity by up to 50% while maintaining a 10-minute scan duration can yield diagnostic-quality images, allowing patient throughput to double. ***Conclusion:*** Ga-68 DOTATATE throughput can be doubled by reducing injected activity by half and imaging for 10 minutes on a LAFOV PET/CT scanner. This optimisation provides a significant opportunity to reduce waiting times and increase efficiency while maintaining diagnostic image quality.

EP-0732

Acceptance Testing of a Long Axial Field-of-View PET/CT Scanner

T. Willson, *A. Chowdhury, N. Davis, J. Khan, O. Walford, H. Natarajan, D. McCool, B. F. Holman;*
Royal Free London NHS Foundation Trust,
London, UNITED KINGDOM.

Aim/Introduction: The Royal Free Hospital has acquired the UK's first Long Axial Field-of-View (LAFOV) PET/CT scanner, providing greater sensitivity and broader coverage (106cm axial FOV) compared to standard PET/CT scanners. This study aims to characterise the performance of this scanner, including new modes of acquisition such as ultra-high sensitivity (UHS) with a maximum ring distance (MRD) of 322 and continuous bed motion (CBM), alongside traditional high-sensitivity (HS) mode with an MRD of 85. ***Materials and Methods:*** Standard performance testing was conducted according to the National Electrical Manufacturers Association (NEMA) NU2-2018 guidelines and compared to manufacturer specifications. Additional tests were performed to characterise performance across the entire FOV, including extended sensitivity measurements and NEMA scatter and accuracy with lengths greater than the axial FOV. Spatial resolution tests, image quality assessments using the NEMA IEC phantom, and SUV validation measurements were performed at ¼, 1/3, ½, 2/3 and ¾ of the FOV with both static and CBM acquisitions to identify any variations. ***Results:*** Performance metrics were evaluated for HS and UHS modes, as well as for static and CBM . In UHS mode, sensitivity measurements showed a 20-fold increase over standard PET/CT scanners, and contrast resolution improved by 30% on average across the FOV. Spatial resolution also improved, with no significant differences observed between static and CBM modes in UHS configuration. Noise equivalent count rate (NECR) increased by 15 times compared to standard scanners. Variations in contrast recovery were noted between static and CBM in HS mode, while UHS mode displayed consistent results across both acquisition methods. ***Conclusion:*** The adaptation of current NEMA testing protocols to evaluate LAFOV PET/CT scanners presents challenges, but the results indicate substantial benefits in terms of sensitivity, contrast resolution, and spatial resolution. The consistency in spatial resolution between static and CBM modes in UHS configuration suggests versatility for clinical applications. The findings underscore the robust and adaptable performance of the LAFOV PET/CT scanner, offering a reliable solution for clinical imaging with expanded coverage and increased sensitivity. ***References:*** Prenosil et. al,. Artifacts caused be the spillover effect in dynamic SPECT studies - prevalence and preliminary assessment of possible methods of elimination

***P. Cichocki*[1],** *A. Plachcinska*[2], *Z. Adamczewski*[1];
[1]*Nuclear Medicine Department, Medical University of Lodz, Lodz, POLAND,* [2]*Department of Quality Control and Radiological Protection, Medical University of Lodz, Lodz, POLAND.*

Aim/Introduction: Calculation of myocardial blood flow (MBF) and myocardial flow reserve (MFR) in dynamic PET and SPECT studies requires applying certain corrections taking into account such factors as partial volume effect and spillover effect. Two models used in such calculations - net retention (RET) and one compartment (1CM), apply these corrections in different ways. RET applies constant correction for the whole myocardium, while 1CM relies on more detailed corrections calculated for each segment separately. During assessment of dynamic SPECT studies in 1CM model, in certain patients we observed spots of abnormally high activity on high resolution blood flow polar maps (reaching max level on the default color scale), that clearly stood out from activity in adjacent segments and ware not visible in RET model. These spots are most likely artifacts caused by the spillover effect and can potentially affect MBF and MFR values, so assessing their prevalence was considered necessary. ***Materials and Methods:*** High resolution blood flow polar maps generated by Corridor 4DM software (v2024) from dynamic SPECT studies of 107 patients with coronary artery disease were analyzed retrospectively. ***Results:*** Spots of abnormally high activity were found in approximately half of the assessed patients (52/107), most often in the vicinity of the apical part of the inferior wall and basal part of the septum. These areas are mostly assigned to the RCA vascular territory. In G-SPECT studies, these areas often appeared in the vicinity of myocardial segments with poor contractility and/or thickening, like membranous part of the septum or post-infarction scars. Methods of eliminating or minimizing these artifacts are the subject of an ongoing research, but our preliminary findings indicate that they can be reduced by correcting heart motion and improving the fit of activity in left ventricle cavity to the edges of its contour. Also, influence of manual heart motion correction on the extent of these artifacts may be one of the factors causing lower interobserver repeatability of MBF and MFR values in 1CM model, that we observed in our studies (especially in RCA territory). ***Conclusion:*** Artifacts caused by spillover effect can be observed on high resolution blood flow polar maps in 1CM model. This may be a useful information for study quality control, as our preliminary observations suggest that manual heart motion correction can reduce their extent. Influence of these artifacts on MBF and MFR values and potential methods of their elimination will be further investigated.

EP-0734

Evaluation of NEMA performance of two 3D ring-design digital SPECT/CT systems

***T. Noponen*[1],** *H. Gröhn*[2], *M. Hakulinen*[2], *L. Kääriä*[1], *M. Seppänen*[3];
[1]*Department of Clinical Physiology, Nuclear Medicine, Turku PET Centre and Medical Physics, Turku University Hospital and Wellbeing Services County of Southwest Finland and University of Turku, Turku, FINLAND,* [2]*Diagnostic Imaging Center, Kuopio University Hospital and Wellbeing Service County of North Savo, Kuopio, FINLAND,* [3]*Department of Clinical Physiology, Nuclear Medicine, Turku PET Centre, Turku University Hospital and Wellbeing Services County of Southwest Finland and University of Turku, Turku, FINLAND.*

Aim/Introduction: Recently, ring-design general-purpose whole-body CZT digital SPECT/CT systems have been developed for clinical use. The systems consist of 12 narrow digital detectors arranged in a 3D ring geometry. They could potentially be an alternative for conventional dual-head analog SPECT/CT systems. In this study, the performance of two 3D digital SPECT/CT systems from different vendors were evaluated in accordance with vendors' NEMA instructions and NEMA NU 1-2018 publication. ***Materials and Methods:*** Both systems contain tungsten parallel-hole collimators registered with the CZT detector pixels of 2.46 mm. The systems have axial field-of-views (FOV) of 27.5 and 31.4 cm and sweeping/swiveling motion of detector heads enables the coverage of entire transaxial FOV. In addition, detector and collimator design between the systems includes differences. Our NEMA tests focus on the SPECT imaging performance of the systems. The following tests were carried out; energy resolution, flood field uniformity, count rate performance in air, SPECT reconstructed spatial resolution without and with scatter, system volume sensitivity (SVS), and tomographic contrast and absolute quantification accuracy. The tests were performed using 99mTc nuclide and the stopping conditions, energy window settings, detector motion settings, test equipment and source activities were attempted to be standardized between the two systems in all the tests. SPECT data were reconstructed in both systems using a basic iterative OSEM algorithm with 10 iterations, 15-16 subsets and CT-attenuation correction. Data were analysed according to NEMA instructions using a same vendor-neutral software for both systems, except vendor provided code for energy resolution. ***Results:*** According to the preliminary analysis, mean energy resolution for 99mTc over all 12 detectors was 5.1 and 5.4% for the different systems. The count rate in air decreased highly linearly with the decreasing activity, showing no dead-time in the digital CZT detectors. SPECT reconstructed spatial resolutions without scatter ranged between 2.7-3.9 mm and 2.9-5.3 mm for the different systems. Corresponding results with scatter ranged between 3.5-5.1 mm and 3.1-5.2 mm. Calculated SVS was 523.7 kcps/(MBq/cm3) and 798.0 kcps/(MBq/cm3) for the two systems. ***Conclusion:*** Other system showed a better performance in energy resolution. There were some small differences in reconstructed spatial resolution between the systems. However, both systems showed slightly lower spatial resolution values than previously reported maybe due to differences in the reconstruction parameters. SVS was higher in the other system. These performance differences may be caused by differences in detector and collimator design.

Medicine, Department of Radiological Sciences, AOU delle Marche, Ancona, ITALY, [7]Nuclear Medicine Unit, ASL BA - Di Venere Hospital, Bari, ITALY, [8]Veneto Institute of Oncology IOV-IRCCS, Padua, ITALY, [9]Nuclear Medicine Unit, Oncology and Haematology Department, University Hospital of Modena, Modena, ITALY, [10]Department of Biomedical Sciences, Humanitas University, Milan, ITALY, [11]Nuclear Medicine Unit, Azienda Unità Sanitaria Locale-IRCCS di Reggio Emilia, Reggio Emilia, ITALY.

Aim/Introduction: Fully digital PET (dPET) systems with solid state detectors have several technical advantages over analog PET (aPET) systems with photomultiplier tubes, holding potential for more accurate quantification and earlier disease localization. This review aimed to summarize the current literature evidence about the clinical advantages offered by dPET technology. ***Materials and Methods:*** The PubMed/MEDLINE and Embase databases were sistematically searched according to PRISMA guidelines. The methodological quality of full-text articles was independently assessed by four authors using the Critical-Appraisal-Skills-Programme (CASP) Diagnostic Study checklist. ***Results:*** 81 articles on both oncological (n=42) and benign diseases (n=39) were included. In early-recurrent prostate cancer (PCa) (PSA range <0.5 and 0.5-2.0 ng/ml), PSMA dPET has shown a significantly higher detection rate compared to aPET especially in smaller lesions, with excellent interrater reliability. These results mirror the experience from an Italian center on 440 Pca patients, with higher dPET detection rate for both PSA 0.2-0.5 ng/ml (39.0% vs 25.2%) and 0.5-1.0 ng/ml (63.2% vs 40.8%). dPET higher image quality and lesion detectability was also confirmed in other mixed-cohorts oncological FDG studies, where metabolic TNM upstaging occurred in up to 32% of cases compared to aPET. Improvements thanks to dPET technology were also reported in the localization of in-transit metastases in melanoma, the staging of oral squamous cell carcinoma, 68Ga-DOTA-TATE imaging in NET patients and 124I imaging in differentiated thyroid carcinoma recurrence. The enhanced sensitivity of dPET can however increase the risk of false positive findings (e.g., unspecific bone uptake in PSMA-1007 imaging) and the variability of SUVmax and radiomic features in multi-scanner studies. In non-oncological diseases, dPET achieved a significantly higher positivity rate in localizing hyperfunctioning parathyroid glands (91% vs 69%), especially subcentimetric. dPET was also shown to improve the sensitivity of semiquantitative analysis in neurodegenerative diseases, as well as the accuracy of 82Rb myocardial blood-flow quantification thus further advancing the diagnostic and prognostic role of molecular imaging in coronary artery disease. Finally, dPET allowed the optimization of imaging protocols by reducing administered activities and/or scan times. A 3/3.5-fold reduced scan time was proven feasible in FDG/DOTA/PSMA imaging, thus allowing to limit radiation exposure (especially in younger patients), lower imaging costs and increase patient throughput. ***Conclusion:*** dPET has shown a diagnostic advantage over aPET in a variety of oncological and benign settings, where the earlier and more accurate disease localization and characterization could have relevant implications for optimal patient management.

Validation under simulated analytical conditions of PETKinetiX, software for 4D PET voxelwise kinetic modeling at the whole FOV level

F. Besson[1,2], *C. COMTAT[2], S. Faure[3,4];*
[1]AP-HP, Le Kremlin-Bicêtre, FRANCE, [2]CEA / Inserm / CNRS / Université Paris Saclay, BioMaps, Orsay, FRANCE, [3]Laboratoire de Mathématique d'Orsay, CNRS, Université Paris Saclay, Orsay, FRANCE, [4]INRIA, Orsay, FRANCE.

Aim/Introduction: The performance of a new academic software for fast parametric 4D-PET imaging, called PETKinetiX (1), is validated under simulated analytical conditions on a digital phantom. ***Materials and Methods:*** 4D-PET thoracic data were simulated from a reference digital phantom (XCAT) and realistic time-activity curves (TACs). These TACs, of whom the parameters K1, k2, k3 and Vb are known (groundtruth), were extracted from real-life practice 18F-FDG 4D-PET data (SAFOV PET/MR device). A total of 100 analytical simulations have been reconstructed using CASToR, an open-source software for tomographic reconstruction : without noise and with noise fulfilling the clinical characteristics of two available SAFOV and LAFOV PET systems. All these data were processed with PETKinetiX (IDIF approach) to generate kinetic parametric maps of 18F-FDG according to the simplified Patlak model (Ki and Vb) and the irreversible two-compartment model (2TCM: k1, k2, k3, Vb and Ki= k1 *k3/(k2+k3)). For each simulation, regions of interest were drawn within several organs of interest and the mean bias of PETKinetiX was computed as follows : Bias (%) = |(PETKinetiX – Ground truth) / Ground truth|×100. For data simulated with clinical noise, biases were compared to those observed in corresponding SUV data. ***Results:*** When applied to noise-free data, PETKinetiX provided kinetic parametric maps with biases less than 4% for all estimated kinetic parameters (Patlak and 2TCM). On the noisy data, the biases observed on the parametric maps generated with PETKinetiX diverged by 4 to 26% compared to the intrinsic variability observed in corresponding SUV data. This level of bias was at least two-times lower for LAFOV images than for SAFOV images, depending on the organ, and similarly impacted PETKinetiX parametric maps and SUV data. ***Conclusion:*** PETKinetiX generates robust kinetic modeling parametric maps, validating its performance under controlled noise-free and noisy simulated conditions. The magnitude of biases is similar to these observed with standard SUV data. ***References:*** (1) PET KinetiX-A Software Solution for PET Parametric Imaging at the Whole Field of View Level. J Imaging Inform Med. 2024 Apr;37(2):842-850. doi: 10.1007/s10278-023-00965-z. Epub 2024 Jan 10.

EP-0737

STANDARDIZATION IN PRE-IMAGING PROTOCOLS IN FOLLOW UP ^{18}FDG PET/CT STUDIES IN LYMPHOMA PATIENTS; REASONS BEYOND BENCHMARK

N. Fatima[1], *M. u. Zaman[2];*
[1]Aga Khan University, Karachi, PAKISTAN, [2]Section of NM and PET/CT imaging, Dept of Radiology, Aga Khan University Hospital, Karachi, PAKISTAN.

Aim/Introduction: The standardization is necessary for the utilization of quantitative ^{18}FDG PET/CT as an imaging biomarker. Routine assessment by regular clinical audits of facilities performing ^{18}FDG PET/CT are crucial for ensuring compliance with standardized pre-imaging protocols and minimizing deviations from established benchmarks. Objectives: Determine the compliance with standardized pre-imaging protocols for follow-up ^{18}FDG-PET/CT studies in lymphoma patients and to determine the deviation(s) beyond established benchmarks. ***Materials and Methods:*** This is a retrospective study that was conducted at PET/CT section of Radiology department of Aga Khan University (AKU) and duly exempted from review by the ethical review committee in February-2023. The 52 lymphoma patients had undergone baseline and interim ^{18}FDG PET/CT from timeframe of 2021-2022 were included. The demographics and pre-imaging protocols,

including the ^{18}FDG dose, hepatic SUVmean (Standardized uptake value) and uptake time were retrieved. The compliance of standardized imaging protocol in the follow-up ^{18}FDG PET/CT was calculated against 85% benchmark as one of the key performance indicators (KPIs) in the department of set for JCIA (Joint Commission International Accreditation) standards. Any significant deviations in compliance from KPI were analyzed. ***Results:*** In follow-up ^{18}FDG-PET/CT studies, no significant differences were observed in demographic and pre-imaging parameters. The compliance rates for ^{18}FDG dose and hepatic SUVmean were 86%, surpassing the 85% benchmark as per institutional KPI. Conversely, there was a deficiency in adherence to the institutional benchmark for uptake time, with a compliance of 80% compared to the required 85%. ***Conclusion:*** The study findings indicate commendable adherence to standardization in pre-imaging protocols of ^{18}FDG dose and hepatic SUVmean for serial ^{18}FDG PET/CT examinations in accordance with international and institutional benchmarks. However, sub-standardization in compliance was observed in uptake time between ^{18}FDG injection and scanning beyond institutional KPI, especially delays associated with the positioning of bed-bound and unplanned prolonged radiation planning patients.

Performance evaluation of a high-resolution, dual-head animal SPECT system (HiReSPECT II) based on the NEMA NU1-2018 standard

M. Samizadeh[1,2], *F. Yousefzadeh[2], B. Teimourianfard[2], M. Ay[1,2];*
[1]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging (RCMCI), Advanced Medical Technologies and Equipment Institute (AMTEI), Tehran University of Medical Sciences (TUMS), Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Animal SPECT imaging is crucial in developing radiopharmaceuticals and researching disease treatments in the preclinical phase. For this purpose, the "HiReSPECT II" was developed in our center based on pixelated crystal and SiPM. ***Materials and Methods:*** The "HiReSPECT II" has two detectors, each detector consisting of a 95.2*95.2*5 mm3 pixelated CsI (Na) crystal (consisting of a 68*68 array with a pixel size of 1.4*1.4 mm2) with a 3mm light guide glass coupled to four SiPM modules with dimensions of 50.4*50.4 mm2 (each SiPM includes 12*12 photodiodes with dimensions of 3 mm and 4.2 mm pitch). Since HiReSPECT II is designed for SPECT imaging of small animals, it benefits from a suitable field of view (FOV) for imaging both mice and rats. Due to the use of SiPM photodiodes, the system is provided with higher resolution compared to similar systems with PSPMTs. Considering that no standard has been provided to measure the performance of the animal SPECT device, a series of protocols were designed based on the modified NEMA NU1-2018 clinical standard and have been used to measure the system's parameters. All of the physical parameters mentioned in NEMA were assessed with custom-made phantoms to match the detector's small dimensions. For example, the planar performance of the system was investigated by different phantoms such as a special lead mask to evaluate the intrinsic special linearity, and a point source to assess the intrinsic energy resolution. The system's sensitivity was evaluated employing a cylindrical phantom and the system's spatial resolution was measured by a capillary tube respectively, in terms of different distances. ***Results:*** The results show that the intrinsic absolute linearity is about 0.04 mm and the intrinsic differential linearity is 0.2 mm. The integral uniformity after correction is 2.9% in UFOV and 2.8% in CFOV. The differential uniformity after correction is 2.3. System sensitivity was 1.2 cps/μCi. Tomographic spatial resolution is ~4 mm in 30mm ROR. Note that the data shown here comes from a LEAP collimator, with ongoing measurements being conducted for the LEHR collimator. ***Conclusion:*** This study presents a modified protocol based on NEMA for performance evaluation of pixelated gamma cameras. Our pixelated animal SPECT tested with recent protocol and realized that the camera is suitable for preclinical research. ***References:*** NEMA NU 1-2018 Performance Measurements of Gamma Camera. EP-0739

Y-90 quantification in PET-CT: mini-phantom experiment with induced respiratory motion

S. Pekkarinen[1], *T. Ihalainen[2], T. Miettinen[1], O. Sipilä[2], M. Tenhunen[1], V. Reijonen[1];*
[1]HUS Comprehensive Cancer Centre, Helsinki University Hospital and University of Helsinki, Helsinki, FINLAND, [2]HUS Diagnostic Center, Helsinki University Hospital and University of Helsinki, Helsinki, FINLAND.

Aim/Introduction: Yttrium-90 is used in molecular radiotherapy, and it is notoriously difficult to measure. Post-therapy imaging for dosimetric quantification is often performed with PET-CT. In this work, we aimed to study partial volume effect (PVE) in small volumes of interest (VOI; V<20 ml) using activity concentrations (~1 MBq/ml) encountered in patient treatments. PVE rises from the finite resolution of the imaging system, but post-processing factors may contribute as well; also, patient-related matters such as respiratory motion may add to it. ***Materials and Methods:*** We 3D-printed three spherical mini-phantoms (MP) and filled them with Y-90 chloride solution: MP1 inner diameter d=15 mm and activity A=1.7 MBq, MP2 d=20 mm and A=3.4 MBq, and MP3 d=30 mm and A=10.2 MBq. Activity was determined using precision scale and double-checked using radionuclide calibrator. The MPs were placed inside a liver insert of a dynamic anthropomorphic phantom with surrogate breathing platform. The images of the phantom were then acquired with PET-CT using patient protocol for Y-90 post-therapy imaging: first without motion, and secondly with breathing-like motion: with optical respiratory gating technique and without it. The images were reconstructed and analyzed to determine the activities in the MPs. ***Results:*** Firstly, we determined the activity in a large VOI (1500 cm3) drawn around the whole liver insert on the static image: 15.1 MBq, matching very closely (-2%) to the sum of the activities in the MPs. When VOIs were drawn to contain the liquid volume in each MP, the results were: MP1 0.49 MBq (-71%), MP2 1.5 MBq (-55%), and MP3 6.3 MBq (-39%), matching recovery coefficient curves in literature [1]. For breathing-like motion (sequence: cos6θ, amplitude 10 mm, period 5 s), the activities appeared MP1 0.30 MBq (-82%), MP2 0.95 MBq (-72%), and MP3 5.3 MBq (-47%). When respiratory gating was applied, MP1 0.49 MBq (-71%; -1% difference compared to the static case), MP2 1.5 MBq (-56%; -5%), and MP3 6.8 MBq (-33%; +9%). We plan to present more measurement data using different breathing patterns, and to perform imaging with PET-MRI and Bremsstrahlung-SPECT-CT for comparison. ***Conclusion:*** Breathing adds up to the already high-level partial volume effect in PET-CT Y-90 imaging. In this work, we studied how well resolution can be recovered using optical respiratory gating technique: the results were within ±10%. To assess the level of reliability, more data is needed. ***References:*** 1. Van, B.J., Dewaraja, Y.K., Sangogo, M.L. et al. EJNMMI Phys 8, 45 (2021).

EP-0740

Verification of quantitative performance of a preclinical PET-CT system for ^{89}Zr.

A. Fenwick[1], *A. Robinson[1], S. Paisey[2], C. Marshall[3];*
[1]National Physical Laboratory, Teddington, UNITED KINGDOM, [2]Wales Research and Diagnostic PET Imaging Centre, Cardiff, UNITED KINGDOM, [3]Wales Research & Diagnostic PET Imaging Centre, Cardiff, UNITED KINGDOM.

Aim/Introduction: Pre-clinical imaging of various 89Zr labelled mAbs in animals has been particularly widespread in recent years [1]. Many of the studies have highlighted the advantages of 89Zr over shorter lived radiometals such as 68Ga or 18F [2]. It allows the tracking of mAbs over extended periods of time, and thus the development of a better understanding of uptake and long-term residency times. This study investigated the quantitative accuracy of a preclinical PET-CT camera for 18F and 89Zr using readily available calibration objects. ***Materials and Methods:*** The system was initially calibrated following the manufacturer's recommended protocol using traceable solutions of 18F. Verification measurements using traceably filled syringes and quality control phantoms with both 18F and 89Zr were made. Measurements were made over several half lives to test system stability and establish accuracy over a range of activities. Daily QC measurements were preformed to monitor system stability over the measurement period. ***Results:*** The system was found to have a stability of 1.2 %. The system was able to resolve the activity in an 18F syringe to within 0.1 % of the calibrated activity with results for 89Zr showing a 4 % positive bias. An estimate of the overall uncertainty on the activity in the recovered images was 5.3 %. Recovery coefficient curves were generated for both radionuclides and showed good comparisons to other published works[3]. ***Conclusion:*** The study demonstrated that activity recovery for two radionuclides was accurate to within 4 % for measurements between 10 MBq and 5 kBq (total object activity). A detailed study into activity recovery for lower activities gave quantifiable limits of detection for objects below certain size. An uncertainty assessment was made and some critical components were assessed, however further work is required in this area to build a more robust uncertainty assessment for reconstructed PET images. ***References:*** 1. Me, Myself and My calibrator: An update to the NPL good practice guide for calibrator operation and quality assurance

A. Fenwick;
National Physical Laboratory, Teddington, UNITED KINGDOM.

Aim/Introduction: Radionuclide Calibrators are the backbone of any nuclear medicine department, providing accurate activity measurements for virtually all procedures in the department. Their maintenance and quality assurance should be a high priority for any nuclear medicine team to ensure patient safety and diagnostic or therapeutic accuracy. From trainee to consultant level, everyone should take a vested interest in the maintenance of these devices and thankfully it does not need to be an onerous task! ***Materials and Methods:*** The UKs National Physical Laboratory (NPL) has recently revitalised its good practice guide (known as GPG93) which provides a protocol for establishing and maintaining the calibration of medical radionuclide calibrators and their quality control. ***Results:*** The guide includes comprehensive descriptions of how a calibrator operates and covers the daily use and maintenance of radionuclide calibrators. The guide also includes extensive information relating to acceptance testing, daily and annual quality tests and special measurement processes such as the appropriate use of copper filters. ***Conclusion:*** The guide is available now and is accompanied by an online training course and both can be used as training materials for new (or experienced) staff. Both the guide and online course are free to download and have already been used by more than 500 students globally. ***References:*** 1. EP-0742

Value of single-harmonic Fourier curve fitting analysis on myocardial wall thickening signal for extraction of phase and amplitude of myocardial wall contraction during synchrony assessment by myocardial perfusion imaging

M. Qutbi;
Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: To evaluate the effect of single- or first-harmonic Fourier curve fitting in the enhancement of temporal resolution and consequently estimation of phase and amplitude of myocardial wall thickening curve for different levels of frame rate and phase shift. ***Materials and Methods:*** A typical signal of myocardial wall thickening spanning between two consecutive R waves or one cardiac cycle is generated. The original reference signal is shifted circularly to various amounts in time (0°, 2.8125°, 5.625°, 11.25°, 22.5°, and 45.0° from a 360-degree cardiac cycle). The non-shifted and shifted signals are resampled in 8, 16, 32, 64, and 128 intervals. In addition to raw noisy data, smoothed data are also created. The raw noisy and smoothed data are fitted to a first- or single-harmonic Fourier curve-fitting model and amplitude and phase of each one are calculated. ***Results:*** The estimated values of amplitude based on noisy raw data are relatively the same for all amounts of shift (0° to 45°) in all frame rates. Conversely, based on temporally-smoothed data, the amplitude is remarkably underestimated in 8-frame sampling in all amounts of shift and gradually approaches the true value

of amplitude. Likewise, the estimation of phase closely depends on frame rate. As the frame rate increases from 8 to 128, the curve approaches the actual value of shift. This pattern is almost consistent for all amounts of shift. The highest amount of error is for frame rate of 8. The value of amplitude is properly estimated for noisy raw data for all frame rates but is slightly underestimated in temporally-smoothed data, more prominently in frame rate of 8. The estimated value of phase, in 8-frame sampling, is highly variable. However, in frame rates of 16 or higher, the estimation shows a consistent pattern from no shift to 45° shift. ***Conclusion:*** The lowest accuracy in the estimation of phase was for frame rate of 8 and then 16. Smoothing of data profoundly worsens the estimates and is discouraged. In estimation of amplitude, for all frame rates, a good level of accuracy is observed. For frame rate of 16, using this method enhances the estimation of phase to a resolution, on average, of frame rate 1/32. For frame rate 32, good agreement is present between estimated and actual phases and thus is the preferable option in phase analysis if feasible for local SPECT facility.

EP-0743

Image quality evaluation in brain study when varyingreconstruction parameters by using a Digital PET/CT in Costa Rica

E. Mora Ramirez, *J. Monge Cerdas, J. Campos Mendez; Cyclotron and PET/CT Laboratory, University of Costa Rica, San Pedro, San Jose, COSTA RICA.*

Aim/Introduction: The the first digital PET/CT has been installed in Central America, at the University of Costa Rica. Then, it's fundamental to understand its capabilities for different studies by using ^{18}F-FDG. In Costa Rica this device is used for oncologic diagnosis, but there is an increase motivation from different neurology departments that this equipment can also be used for brain studies. Brain images can be affected by noise when different reconstruction parameters are employed. Then, depending on reconstruction method applied the signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), background variability (%BV) and image roughness (%IR) are degraded. ***Materials and Methods:*** One brain protocol from the Biograph Vision 450 PET/CT was selected. The Striatal RSD phantom is used where the putamen and left caudate nucleus function as high uptake regions and the brain shell as a background region. One bed acquisition with times 1, 2, 3, 4, 5 min were employed. For all case one bed image was employed. Reconstruction method is performed in combination with the following parameters: iterations of 1,4,6,10,20,30,40, 5 subsets, gaussian filters of 3mm,5mm,10mm and all pass filter, matrix size 880 x 880. SNR, CNR, %BV, %IR are evaluated by creating several regions of interest from the generated images. Fiji software was employed to study those images. ***Results:*** SNR increases as the number of iterations increases. SNR decrease when increasing the gaussian filters. When Gaussian filter of 10 mm is used, SNR does not change from 10 iterations onwards. SNR is not affected by acquisition time. CNR decrease as the number of iterations increases. The highest CNR occurs for the highest gaussian filter. CNR increases when acquisition time increases.%IR increases as the number of iterations increases. %IR decreases as the Gaussian filter increases. If all pass filter is used, %IR increases importantly. %IR decreases as the acquisition time increases.%BV increases as the number of iterations increases. %BV decreases as the gaussian filter increases. If all pass filter is used, %BV increases importantly. %BV decreases as the acquisition time increases. ***Conclusion:*** An initial evaluation of the effect of reconstruction parameters in brain studies protocols using a digital PET/CT was carried out. Further studies will occur with to assess the "best imaged quality" according to reconstruction parameters employed and also by using the Hoffman Brain Phantom. ***References:*** Tong, S., Alessio, A., & Kinahan, P. (2010). Noise and signal properties in PSF-based fully 3D PET image reconstruction: an experimental evaluation. doi.org/10.1088/0031-9155/55/5/013.

EP-0744

A novel two-step unsupervised machine learning clustering strategy for the identification of PET/MR-based biomarkers in arrhythmogenic cardiomyopathy. Preliminary study

B. Ponsi[1], *H. Necib[1], L. Marteau[1], A. Monnet[2], T. Carlier[1], T. Eugène[1], J. Serfaty[1], N. Piriou[1];*
[1]University hospital of Nantes, Nantes, FRANCE, [2]Siemens Healthineers France, Courbevoie, FRANCE.

Aim/Introduction: Tissue characterization by magnetic resonance (MR) late-gadolinium enhancement (LGE) is a major diagnostic criterion in arrythmogenic cardiomyopathy (AC), assessing myocardial fibrosis, but it suffers from the inherent limitation of being only qualitative. Studies have shown the complementary value of PET in identifying markers of myocardial inflammation which is a prevalent aspect in patients with AC and a poor prognostic marker in cardiomyopathy. This preliminary study aims to demonstrate the potential of simultaneous PET/MR and inter-patient data linkage in the discovery of novel regional markers of AC, overcoming the inherent limitations of qualitative sequences. ***Materials and Methods:*** Two-step clustering was applied to T1 and T2 maps, LGE and 18F-FDG-PET images of 14 patients genetically diagnosed with AC pathogenic variants. Left ventricular (LV) myocardial segmentation was performed semi-automatically on the LGE images. Images were z-scored, summed and clustered into supervoxels using SLIC, a k-means based algorithm, independently for each patient. Abnormal supervoxels with extreme relaxation times were excluded. Data from all patients within the LV were then pooled and Box-Cox transformed. Twenty-five inter-patient groups of supervoxels were obtained by spectral clustering. The ratios of each cluster per patient were then used to hierarchically group patients into different profiles. Additionally, an "abnormality" score was assigned to each cluster for each modality, calculated as a distance from its median compared to a "healthy" reference cluster. These scores were then used to visualize the abnormal, likely diseased areas on each patient's imaging data, and to generate health reports for each patient, which were compared with the physicians' reports using balanced accuracy (BA). ***Results:*** The reports generated by clustering allowed for an accurate representation of the proportions of hyper-signal combinations per patient, while identifying most of the cardiac imagers observations (BA=0.65). Furthermore, the identified abnormal clusters closely matched their visual observations, facilitating the identification of varying degrees of fibrosis or inflammation intensity on the images. ***Conclusion:*** This framework provides a new approach to visualizing and quantifying diseased areas within the LV of AC patients. Through its inter-patient nature, this method overcomes the non-quantitative aspects of LGE, bringing new perspectives to the analysis of PET/MR images in AC. It then provides an encouraging first step towards identifying clusters of prognostic value through supervised clustering and the identification of specific patient profiles. Future plans include evaluating the approach in a larger cohort. ***References:*** Hansen et al. EXPERT SYST APPL (2021). Protonotarios, Wicks, Int. J. Cardiol. (2023).

Aim/Introduction: Patients with dementia symptoms struggle to remain still during PET examinations, necessitating motion compensation in brain PET imaging to ensure the high image quality needed for diagnostic accuracy. This study validates a novel data-driven motion-compensated (MoCo) PET brain image reconstruction algorithm that corrects head motion by integrating the detected motion frames and their associated rigid body transformations into the iterative image reconstruction. Validation was conducted using phantom scans, healthy volunteers, and clinical patients. ***Materials and Methods:*** We conducted a technical validation of the method with Hoffman brain phantom filled with $^{[18F]}$FDG and scanned on a PET/CT scanner (26.3cm FOV, 214ps TOF) during a series of controlled movements. Then, we did two blinded reader studies assessing image quality between standard uncorrected images and MoCo images in 38 clinical patients undergoing dementia scans with $^{[18F]}$FDG, $^{[18F]}$N-(3-iodopro-2E-enyl)-2beta-carbomethoxy-3beta-(4'-methylphenyl)-nortropane, or $^{[18F]}$flutemetamol, and a group of 25 elderly subjects scanned with $^{[18F]}$fluoroethoxybenzovesamicol for a research project. ***Results:*** The technical validation showed that the algorithm detected and corrected for even minimal movements, 1-mm translations and 1^0 rotations, applied to the phantom. In the clinical cohort whose standard images were deemed to be of suboptimal or non-diagnostic quality, all MoCo images were classified as having acceptable diagnostic quality. In the research cohort, MoCo images consistently matched or surpassed the image quality of standard images even in cases with minimal head movement, and the MoCo algorithm never led to degraded image quality. ***Conclusion:*** The PET brain MoCo reconstruction algorithm was robust and worked well for four different tracers with markedly different uptake patterns. Moco Images enhanced diagnostic accuracy for patients who were unable to lie still during a PET examination and obviated the need for repeat scans. Thus, the method was clinically feasible to use and had a clear clinical impact.

^{11}C-CFT PET brain imaging in Parkinson's Disease using a total-body PET/CT scanner

X. Sun, *X. Tan, Q. Zhang, L. Jiang;*
Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, CHINA.

Aim/Introduction: This study aimed to evaluate the feasibility of and explore the optimal scan duration to guide the clinical practice. ***Materials and Methods:*** Thirty-two patients with Parkinson's disease (PD) performing 11C-CFT PET/CT brain imaging using a total-body PET/CT scanner were retrospectively enrolled. The PET data acquired over a period of 900 s were reconstructed into groups of different durations: 900-s, 720-s, 600-s, 480-s, 300-s, 180-s, 120-s, 60-s, and 30-s (G900 to G30). The subjective image quality analysis was performed using 5-point scales. Semi-quantitative measurements were analyzed by SUVmean and dopamine transporter (DAT) binding of key brain regions implicated in PD, including the caudate nucleus and putamen. The full-time images (G900) were served as reference. ***Results:*** The overall G900, G720, and G600 image quality scores were 5.0±0.0, 5.0±0.0, and 4.9±0.3 points, respectively, and there was no significant difference among these groups (P>0.05). A significant decrease in these scores at durations shorter than 600 s was observed when compared to G900 images (P<0.05). However, all G300 image quality was clinically acceptable (≥3 points). As the scan duration reduced, the SUVmean and DAT binding of caudate nucleus and putamen decreased progressively, while there were no statistically significant variations in the SUVmean of the background among the different groups. Moreover, the changes in the lesion DAT binding (ΔDAT-binding) between the full-time reference G900 image and other reconstructed group G720 to G30 images generally increased along with the reduced scan time. ***Conclusion:*** Sufficient image quality and lesion conspicuity could be achieved at 600-s scan duration for 11C-CFT PET brain imaging in PD assessment using a total-body PET/CT scanner, while the image quality of G300 was acceptable to meet clinical diagnosis, contributing to improve patient compliance and throughput of PET brain imaging.

EP-0747

Impact of Partial Volume Correction on Dopaminergic Network Parameters

I. Miederer[1], *G. Gonzalez-Escamilla[2], G. Guo[1], S. Groppa[2], M. Schreckenberger[1];*
[1]Department of Nuclear Medicine, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, GERMANY, [2]Department of Neurology, University Medical Center of the Johannes Gutenberg University Mainz, Mainz, GERMANY.

Aim/Introduction: In positron emission tomography (PET) studies, partial volume effects lead to a biased signal. This affects outcome parameters such as the binding potential (BPND) of high-affinity D2-like radioligands (Smith et al., 2019) and consequently further analyses, such as network analyses of brain connectivity. The Müller-Gärtner algorithm (Müller-Gärtner et al., 1992) for partial volume correction (PVC) involves mathematical convolution and deconvolution to correct for white matter spill-in and grey matter spill-out. The goal of this study was to investigate the effect of PVC on global and local parameters of the dopaminergic network. ***Materials and Methods:*** In a $^{[18F]}$fallypride PET study, 19 subjects (age: 30 ± 7.2 years) were examined with 175 ± 12 MBq and magnetic resonance imaging. After pre-processing of the data (motion correction, spatial normalisation and PVC), regions of the dopaminergic network were defined and time-activity curves extracted. Using the simplified reference tissue model 2 (reference region: cerebellum), the BPND was calculated without and with prior PVC. For both methods, graph theory was used to compare the topological organisation of the dopaminergic network based on the similarity of the regional binding across participants. The networks were computed in a density range of 0.3-0.9 in 0.01 steps. ***Results:*** PVC increased BPND values within the dopaminergic network compared with those calculated from uncorrected $^{[18F]}$fallypride uptake. Differences between methods (without and with PVC) were found for network measures of integration, segregation, centrality and

others. With PVC, global efficiency decreased ($p < 0.0001$), while the network was strengthened in terms of modularity ($p < 0.025$), betweenness centrality ($p < 0.0001$) and small world ($p < 0.0001$). In addition, regional betweenness centrality changed for several brain regions. ***Conclusion:*** Correction for partial volume effects should be performed to account for age- or neurodegeneration-related effects in PET studies with [18F]fallypride. Further analysis needs to consider the effect of PVC on network parameters. PVC has been shown to improve the stability of dopaminergic network analysis and increase the robustness of network parameter analysis. ***References:*** Smith CT et al. PET-only method for quantification of [18F]florbetaben scans and its relationship with histopathology, visual assessment, and longitudinal clinical progression from Mild Cognitive Impairment to Alzheimer's disease

G. Domingues Kolinger[1], *J. Lee[2], S. Kang[2], S. A. Shin[2], N. Koglin[1], S. Bullich[1];*
[1]Life Molecular Imaging GmbH, Berlin, GERMANY,
[2]Brightonix Imaging Inc., Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: The quantification of amyloid brain Positron Emission Tomography (PET) scans has recently increased in importance on research, clinical trials of Alzheimer's disease (AD) modifying drugs, and clinical routine as adjunct to visual read (VR) of PET images. Given differences in image processing pipelines1, there's the need to compare quantitative results of every available software with histopathology and clinical assessment. Therefore, in the present work, quantitative results from a PET-only pipeline have been compared with brain Aβ histopathology, visual interpretation from five independent readers, and longitudinal clinical status from Mild Cognitive Impairment (MCI) to AD in a span of four years. ***Materials and Methods:*** A total of 673 amyloid PET scans acquired with [18F]florbetaben were quantified with Centiloid (CL) values using BTXBrain2 (Brightonix Imaging Inc) with the whole cerebellum as reference region and a composite region as target. 91 scans correspond to brains which had post-mortem histopathology confirmation of presence or absence of Aβ in the brain and were used as standard of truth for the definition of a positive Aβ quantitative cut-off. To define a cut-off indicating absence of Aβ, 122 scans of healthy volunteers with a consensus negative VR were assessed. Furthermore, the agreement between VR and quantification was established with an independent set of 386 scans assessed visually by five readers. At last, a 4-year clinical follow-up was carried out in 45 MCI patients to evaluate the relationship between their clinical status progression and baseline CL value. ***Results:*** There was a strong agreement between quantification and histopathology with a sensitivity and specificity of 0.93[0.82-0.98] and 1.00[0.90-1.00], respectively, with a cut-off point of CL = 41.5 for Aβ positivity. This cut-off also had a 93.8% (362/386) agreement with the majority VR in an independent set of images. A cut-off of CL = 25.6 defined the absence of Aβ at the 95% quantile of the CL distribution from healthy controls with negative VR. In the 4-year longitudinal assessment, no individual with CL<41.5 progressed to AD while 87.5% (21/24) of individuals with quantitative Aβ positivity did progress to AD. ***Conclusion:*** Centiloid quantification of [18F] florbetaben PET scans with the BTXBrain PET-only pipeline can provide reliable and valuable results for adjunct assessment to VR of brain amyloid imaging. ***References:*** [1] Jovalekic, et al. EP-0749

Diagnostic Performance Of Myocardial Perfusion SPECT/CT With Attenuation Correction

S. Mammeri[1], *F. Mansouri[2];*
[1]Hospital Military of Constantine ALGERIA, Constantine, ALGERIA, [2]Hospital university of Constantine ALGERIA, Constantine, ALGERIA.

Aim/Introduction: Myocardial perfusion single-photon emission computed tomography (SPECT) is one of the basic tools used for the purpose of diagnostic of coronary artery disease (CAD), prognosis of its unfavorable consequences,and evaluation of therapy effectiveness.However, its efficacy is compromised by a relatively low specificity of detection of perfusion defects, which is attributed to attenuation of gamma rays inside the patient's body, causing artefacts erroneously taken for perfusion defects.it is expected that attenuation correction (AC) could eliminate such artefacts.The aim of the present study was to evaluate whether computed tomography based-attenuation correction (CT-AC) provides any advantage over non -attenuation corrected(NAC) images for qualitative and quantitative analysis of SPECT myocardial perfusion imaging (MPI). ***Materials and Methods:*** We prospectively evaluated data of 85 patients who underwent stress rest MPI SPECT/CTas per standard protocol. Angiography done within +/- 3 months of MPI was taken as reference standard.two readers independently evaluated CT-AC and NAC images.Receiver operating characteristics curve analysis was done using ≥70%stenosis as cutoff. ***Results:*** AC increased the specificity of detection of (CAD) in the whole groupe of patients from 51% to 88%($p \leq 0.0001$), with a reduction in sensitivity from (96%to 86%) ($p=0.002$), with improved specificity was also noted in subgroups of male ans females patients and subgroups of obese and non- obese patients.Accuracy in the whole group of patients increased from 77% to 87% ($p=0.001$).CT-AC images had significantly lower sensitivity for detecting right coronary artery disease compared with NAC (from 79%to 91%) ($p=0.02$); but also high specificty from 67% for NAC to 98% dor AC ($p=0.001$),there was no significant difference in sensitivity and specificity in the left anterior descending artery (LAD) and left circumflex (LCX) between CT-AC and NAC images. ***Conclusion:*** In our study , the CT -based AC improved significantly the specificity especially in the right coronary artery but decreased sensitivity leading despite that to an improvement in overall diagnostic accuracy of tc99m sestamibi/MPI. ***References:*** 1. Integration of imaging and non-imaging data for risk prediction in cardiac amyloidosis using machine learning

***C. Spielvogel*[1],** *D. Haberl[1,2], K. Kluge[1], J. Hennenberg[3], J. Yu[1], J. Ning[1,2], K. Kumpf[4], Y. Lutz[5], F. Hofer[6], K. Mascherbauer[6], T. Traub-Weidinger[1], J. Mascherbauer[7,8], A. Kammerlander[6], C. Hengstenberg[6], M. Hacker[1], R. Calabretta[1], C. Nitsche[6];*
[1]Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Christian Doppler Laboratory for Applied Metabolomics, Vienna, AUSTRIA, [3]Division of Neuroradiology and Musculoskeletal Radiology, Medical University of Vienna, Wien, AUSTRIA, [4]IT4Science, Medical University of Vienna, Wien, AUSTRIA, [5]Division of Nuclear Medicine, Vienna General Hospital, Vienna, AUSTRIA, [6]Division of Cardiology, Medical University of Vienna, Vienna, AUSTRIA, [7]Karl Landsteiner University of Health, St Poelten, AUSTRIA, [8]Department of Internal Medicine 3, University Hospital St Poelten, St Poelten, AUSTRIA.

Aim/Introduction: The recent arrival of various disease-modifying amyloid-targeting therapies(1-3) has led to an increasing interest in the characterization and risk stratification of patients with transthyretin cardiac amyloidosis (ATTR-CA) to guide treatment decisions and assess treatment response. While the current diagnostic approach relies on visual interpretation of 99mTc-scintigraphy, risk assessment is largely based on a combination of blood, clinical, and imaging parameters from various modalities. The aim of this study was to evaluate machine learning-based integration of scintigraphy, echocardiography, and non-imaging parameters for the diagnosis, characterization, and risk stratification in patients with CA. ***Materials and Methods:*** This study included all consecutive patients who underwent [99mTc]Tc-DPD scintigraphy at the Vienna General Hospital between 2010 and 2023. Two machine learning models were created and the predictive importance of their parameters were assessed: 1) a model designed to identify patients displaying CA-suggestive uptake (Perugini grade 2/3) in [99mTc]Tc-DPD scintigraphy scans; 2) a model developed to predict the risk of future heart failure hospitalization (HFH) in patients with CA-suggestive uptake. Overall, 58 features were extracted from electronic health records including echocardiography, blood, demographic parameters, and comorbidities. Scintigraphy imaging features were extracted using a deep convolutional autoencoder. A random survival forest machine learning model was employed for HFH prediction and was validated using 100-fold stratified Monte Carlo cross-validation. ***Results:*** In total, 12 380 consecutively enrolled patients were included, of which 279 (2.3%) were affected by CA-suggestive uptake. The machine learning model performed well for the detection of CA (AUC 0.96 [95% CI 0.95-0.97], sensitivity 0.78 [95% CI 0.77-0.80] and specificity 0.99 [95% CI 0.99-0.99]. For the prediction of HFH, the machine learning model demonstrated good performance (C-index 0.71 [95% CI 0.68-0.75]). The most predictive parameters in the time to HFH analysis were right ventricular diameter, previous diagnosis of chronic heart failure and creatine kinase. ***Conclusion:*** Detection of patients with cardiac amyloidosis using machine learning is feasible with high performance while imaging features play a major role. Integration of imaging and non-imaging parameters can aid in the risk estimation of patients with cardiac amyloidosis, potentially guiding novel approaches for assessing disease progression and treatment response. ***References:*** 1.Maurer,-M.-S.-et-al.-Tafamidis-Treatment-for-Patients-with-Transthyretin-Amyloid-Cardiomyopathy.-N.-Engl.-J.-Med.-379,-1007-1016-(2018).2.Maurer,-M.-S.-et-al.-Patisiran-Treatment-in-Patients-with-Transthyretin-Cardiac-Amyloidosis.-N.-Engl.-J.-Med.-389,-1553-1565-(2023).3.Gillmore-Julian-D.-et-al.-Efficacy-and-Safety-of-Acoramidis-in-Transthyretin-Amyloid-Cardiomyopathy.-N.-Engl.-J.-Med.-390,-132-142-(2024).

EP-0751

Comparison Between Two Software Programs of the Left Ventricular Ejection Fraction Obtained from Dedicated Cardiac CZT Camera

B. Lima, *F. A. Mourato, C. A. Almeida, M. A. Almeida, A. L. G. Leal, F. M. Sasaki, A. F. F. Sales, J. C. A. Almeida, P. J. Almeida Filho;*
Real Hospital Português de Beneficência em Pernambuco, Recife, BRAZIL.

Aim/Introduction: To compare the left ventricular ejection fraction (LVEF) during stress and rest phases of myocardial perfusion scintigraphy (MPS) acquired with a CZT cardiac scintillation camera, using two different software programs: software of common use for MPS (Software 1) and software dedicated for MPS analysis on CZT (Software 2). ***Materials and Methods:*** A retrospective study analyzing myocardial perfusion scintigraphy with Sestamibi-99mTc performed on a CZT cardiac scintillation camera in 2023 and 2024, involving 1523 consecutive patients. A nuclear physician experienced with both software programs performed the image processing and analysis, determining the LVEF for both phases in each patient. Cases where the LVEF could not be calculated by either program were excluded. LVEF values were described using median and interquartile ranges (IQR). The non-parametric Wilcoxon test was conducted to check for significant differences between the programs. The concordance correlation coefficient was also obtained, considered weak when less than 0.9; moderate between 0.9 and 0.95; substantial between 0.95 and 0.99; and perfect above 0.99. Analyses also included Bland-Altman plots (described as the difference between the means of the methods, as well as upper and lower limits) and Mountain-plots. In these analyses, Software 1 was considered the reference program. ***Results:*** Out of the 1523 patients analyzed, 1490 were included. The median LVEF obtained by Software 1 was 62.0% (IQR: 53.0-70.0%) and 60.0% (IQR: 51.0-67.0%) for rest and stress, respectively. In the Software 2 program, the median was 59.0% (IQR: 51.0 - 65.0%) and 58.0% (IQR: 50.0 - 64.0%). The Wilcoxon test showed a significant difference between the methods in both phases ($p<0.01$ for both). The Bland-Altman plots showed an average difference in ejection fractions of 3.4%, with a lower limit of -6.4% and an upper limit of 13.2% for rest. For stress, the average difference was 2.8%, with a lower limit of -6.3% and an upper limit of 12.0%. The correlation coefficient for the stress phase between the programs was 0.92 (Pearson $\rho = 0.94$ and Bias correction factor $Cb = 0.98$) and 0.90 (Pearson $\rho = 0.93$ and Bias correction factor $Cb = 0.97$) for rest. ***Conclusion:*** The LVEF obtained by the Software 1 and Software 2 programs had a moderate degree of agreement, with an average difference between methods of 3.4% for rest and 2.8% for stress. The comparison between the software also showed great precision and accuracy.

EP-0752

Prognostic Value of SPECT MPI Parameters in different sexes patients with ischemic heart disease

Y. Li, *R. Wang, Y. Zhao, Y. Hu, Y. Wang, X. Diao, S. Li;*
First Hospital of Shanxi Medical University, Taiyuan, CHINA.

Aim/Introduction: There are obvious gender differences in risk factors for ischemic heart disease (IHD) due to differences in physiologic anatomy and lifestyle habits. Single photon emission computed tomography (SPECT) myocardial perfusion imaging

(MPI) is important for the diagnosis and risk stratification of IHD. However, multiple studies have concluded that focusing on the same parameters and applying uniform thresholds between the sexes reduces the diagnostic and prognostic accuracy of the disease. This study aimed to investigate the prognostic value of traditional cardiovascular risk factors and SPECT MPI parameters in different genders IHD patients. ***Materials and Methods:*** Patients diagnosed with IHD who underwent resting gated SPECT MPI at the First Hospital of Shanxi Medical University from 2016 to 2021 were included and followed up. The study endpoints were major adverse cardiovascular events (MACE). The effects of traditional cardiovascular risk factors, total perfusion defect (TPD), left ventricular ejection fraction (LVEF), peak filling rate (PFR), eccentricity index (EI) and entropy on the prognosis of patients with IHD in different sexes were analyzed by univariate and multivariate Cox regression. The Youden index was used to select optimal thresholds for predictors, and the survival curve was plotted by Kaplan-Meier method. ***Results:*** A total of 1475 patients were included, including 1058 males (59.17±12.94 years old) and 417 females (63.84±11.29 years old). Compared with female, the proportion of traditional cardiovascular risk factors and partial drug use in male patients was higher (all p<0.05). During the follow-up period [3.05(1.71-4.97) years], there was no statistically significant difference in the incidence of MACE between the sexes (male: 40.9%, female: 36.2%, p=0.095). Multivariate Cox analysis showed: age [HR=1.016 (95% CI: 1.008-1.023)], prior myocardial infarction [HR=1.888 (95% CI: 1.547-2.303)], hypertension [HR=1.405 (95% CI: 1.151-1.714)], diabetes [HR=1.263 (95% CI: 1.034-1.542)] and EI [HR=0.002 (95%CI: 0.004-0.133)] were independent prognostic factors in males, and the optimal threshold of age and EI were 58.5 and 0.84 respectively. Age [HR=1.030 (95% CI: 1.014-1.047)], hypertension [HR=1.668 (95% CI: 1.106-2.516)], PFR [HR=0.621 (95% CI: 0.459-0.840)] were independent prognostic factors for women, and the optimal thresholds for age and PFR were 66.5 and 1.42 respectively. ***Conclusion:*** The prognostic value of traditional cardiovascular risk factors and MPI parameters in IHD should be fully considered in terms of gender. The male population should focus on the elderly, prior myocardial infarction, diabetes, hypertension and cardiac pathological remodeling (EI<0.84) patients; In female, the focus was on the elderly, hypertension, and diastolic dysfunction (PFR<1.42).

Dopamine Transporter SPECT Imaging in Patients with Parkinsonian Symptoms. Comparison of Visual Assessment and Semiquantitative Analysis with a Normal Database

V. Valotassiou[1], *G. Xiromerisiou[2], D. Psimadas[3], C. Tzavara[3], A. Diakakis[1], K. Sakellariou[3], G. Angelidis[3], E. Theodorou[3], C. Tzioumerka[3], C. Ziangas[3], I. Tsougos[4], E. Dardiotis[2], P. Georgoulias[1]; [1]Dpt of Nuclear Medicine, Faculty of Medicine, University of Thessaly, University Hospital of Larissa, Larissa, GREECE, [2]Dpt of Neurology, Faculty of Medicine, University of Thessaly, University Hospital of Larissa, Larissa, GREECE, [3]Dpt of Nuclear Medicine, University Hospital of Larissa, Larissa, GREECE, [4]Dpt of Medical Physics, Faculty of Medicine, University of Thessaly, University Hospital of Larissa, Larissa, GREECE.*

Aim/Introduction: 123I-ioflupane SPECT is used for the evaluation of nigrostriatal degeneration in patients with movement disorders. The assessment of studies is based on visual interpretation and semiquantification of tracer uptake in basal ganglia. Comparison with normal subjects' database is also available in several centers. The aim of this study was to compare the results of visual and semiquantitive evaluation with those obtained after comparison with a normal database and set optimal cut-offs in semiquantification. ***Materials and Methods:*** We studied 560 patients with movement disorders, mean age 67 years (SD=10.7) and median disease duration 24 months (IQR: 12-48 months). All patients underwent a brain SPECT 3 hours after the i.v. administration of 185 MBq 123I-ioflupane. Drugs known to interfere with tracer uptake were discontinued and oral Lugol's solution was given for thyroid protection. SPECT studies were evaluated by two experienced nuclear medicine physicians who rated images of the whole right(R) and left(L) striatum, R-L putamen and R-L caudate as normal or abnormal-reduced uptake. Semiquantitive evaluation was performed selecting the three slices with the most intense tracer uptake and drawing ROIs over the L-R striatum, L-R putamen, L-R caudate and occipital cortex. For the comparison, we used the normal subjects' database of Parkinson's Progression Markers Initiative-PPMI. ***Results:*** Compared with the results of PPMI normal database, visual assessment had a sensitivity ranged from 83.3% (for L-caudate) to 99.5% (for L/R putamen). Specificity ranged from 75% (for L-striatum) to 88.9% (for R-caudate). PPV ranged from 46.9% (for L-caudate) to 76.8% (for R-putamen) and NPV from 97.2% (for L-caudate) to 99.7% (for L/R striatum and putamen). Moreover, semiquantitative measurements had significant prognostic value [AUC ranged from 0.91 to 0.96, with p<0.001]. The optimal cut-off for L-striatum was ≤2.49 (sensitivity 89.2%, specificity 86.2%) and for R-striatum was ≤2.31 (sensitivity 89.5%, specificity 92.2%). For L-putamen the optimal cut-off was ≤2.39 (sensitivity 93.8%, specificity 87.6%) and for R-putamen the optimal cut-off was ≤2.47 (sensitivity 91.9%, specificity 83.8%). For L-caudate the optimal cut-off was ≤2.40 (sensitivity 87.1%, specificity 88.8%) and for R-caudate the optimal cut-off was ≤2.52 (sensitivity 89.7%, specificity 86.7%). ***Conclusion:*** Comparison with the normal database resulted in the identification of the optimal cut-offs in semiquantitive analyses, which would be particularly useful for the more accurate evaluation of SPECT studies in departments lacking the appropriate normal databases. ***References:*** Morbelli et al. Striatal dopamine transporter SPECT quantification: head-to-head comparison between two three-dimensional automatic tools. EJNMMI Res. 2020 7;10(1):137.

EP-0754

Long-Term Prognostic Value of Expert Scoring, Combined with Automated Measurements, in Nuclear Cardiology: Comparisons with the Angiographic Score

G. Angelidis, *S. Giannakou, V. Valotassiou, I. Tsougos, C. Tzavara, K. Sakellariou, D. Psimadas, E. Theodorou, C. Ziangas, J. Skoularigis, F. Triposkiadis, P. Georgoulias; University of Thessaly, Larissa, GREECE.*

Aim/Introduction: Myocardial perfusion imaging (MPI) has a crucial role in the non-invasive investigation of coronary artery disease (CAD). The interpretation of MPI studies is mainly based on the visual evaluation of the reconstructed images, while the automated analysis of the studies has been also incorporated into clinical practice. We aimed to investigate the role of expert reading of summed stress score (SSS), summed rest score (SRS), and summed difference score (SDS), combined with the automated measurements of these parameters, as long-term prognostic markers of cardiac events, in comparison to the prognostic value of the angiographic score. ***Materials and Methods:*** The study was conducted at the Nuclear Medicine Laboratory of the University of Thessaly, in Larissa, Greece. 378 consecutive patients

with known or suspected CAD were enrolled. All participants were referred to our laboratory for the performance of stress/rest myocardial perfusion single photon emission computed tomography. Automated measurements of SSS, SRS, and SDS were obtained by Emory Cardiac Toolbox (ECTb (Version 3.0), Emory University, Atlanta, GA, USA), Myovation (MYO, Xeleris version 3.05, GE Healthcare, Chicago, IL, USA), and Quantitative Perfusion SPECT (QPS Version 4.0, Cedars-Sinai Medical Center, Los Angeles, CA, USA) software packages. Coronary angiographies were scored according to a 4-point scoring system (angiographic score; O: normal study, 1: one-vessel disease, 2: two-vessel disease, 3: three-vessel disease). Follow-up data were recorded after phone contacts, as well as through review of hospital records. All participants were followed up for at least 36 months. ***Results:*** The sample consisted of 378 patients (61.9% males) with mean age 63.8 years (SD=9.6 years). Any cardiac event was recorded in 36.5% of the participants. Median angiographic score was 1 (IQR: 0-2). The prognostic value of the angiographic score was significant (AUC=0.71; 95% CI: 0.65-0.76) with an optimal cut-off point equal to 0.5. The prognostic value of expert scoring was also significant (AUC=0.88; 95% CI: 0.84-0.91), and significantly greater in comparison to the angiographic score (p<0.001). The prognostic value of expert scoring, combined with the prognostic ability of the three software packages, was also significant (AUC=0.91; 95% CI: 0.88-0.94) and significantly superior compared to the angiographic score (p<0.001). ***Conclusion:*** Based on our results, in patients with known or suspected CAD, the prognostic ability of expert reading, combined with the automated measurements of SSS, SRS and SDS, is superior to the prognostic value of the angiographic score.

EP-0755

Generation of an Age-dependent and Resolution-adaptive ^{18}F-FDG Brain-PET Atlas using High Sensitivity Short-Axial FOV PET/CT System

L. Fu[1], *L. Yin[1], Z. Zhou[2], S. Yang[1];*
[1]Department of Nuclear Medicine, China-Japanese Friendship Hospital, Beijing, CHINA, [2]Department of Neurology, China-Japanese Friendship Hospital, Beijing, CHINA.

Aim/Introduction: 18F-FDG Brain PET is crucial for the clinic and neuroscience research. However, PET scanner advancements have led to various spatial resolution and gray-to-white matter contrast recovery, causing quantitative errors when higher resolution data is interpreted with lower-resolution atlas,or vice versa. This study aimed to create a high-resolution FDG-PET brain atlas stratified by different ages and harmonize it with a lower-resolution atlas to generate an adaptive 18F-FDG brain atlas for various PET/CT scanners. ***Materials and Methods:*** The study retrospectively enrolled 160 subjects receiving whole-body and brain 18F-FDG PET/CT scan for staging of tumor, aged from 10 to 90 years, in groups of 20 per 10 years of age. Subjects with benign tumors or with malignant tumors staged as T1N0M0 were included. Sixty minutes after 18F-FDG administration for each participant, static data acquisition (matrix:440×440, OSEM, TOF=214ps, PSF, Iterations:6, Subset:5, Zoom:2, all-pass filter) with a duration of 4-min were performed. The 18F-FDG brain PET were normalized to the simulated BigBrain FDG activity map with FWHM=4.0mm smoothness and corresponding gray matter probability map. Spatial normalization was conducted in MNI space with 1.00mm isotropic resolution using ANTs toolkits with SyNRA registration algorithms for each subject. Cortical-to-cerebellum SUV ratios (SUVRs) were calculated and underwent 3D gaussian filter (FWMH 1.0mm to 12.0mm, 1.0mm interval). Age-dependent and gaussian-kernel-size-dependent atlases were generated by averaging the corresponding SUVRs in each group. Pearson correlation of the SUVR variations with age and kernel size was performed on frontal, temporal, parietal, occipital lobes, striatum and cerebellum gray matter respectively. ***Results:*** An array of atlases spanning ages from 10 to 90 years in 10-year interval, with gaussian filter FWMH sizes ranging from 1.0mm to 12.00mm, were generated for public research use as requested. The frontal, temporal, parietal, occipital lobes, striatum showed significant negative correlations with age for all kernel sizes (r = -0.72, -0.70, -0.71, -0.51, -0.61, respectively), while the correlation for cerebellum gray matter was 0.01. SUVRs in all regions significantly correlated with kernel size, with r value of -0.68, -0.67, -0.68, -0.83, -0.77, -0.97 for frontal, temporal, parietal, occipital lobes, striatum and cerebellum gray matter, respectively. ***Conclusion:*** Age-dependent, resolution-adaptive FDG Brain PET Atlases were created from high-resolution and high TOF PET/CT scanner to accommodate various spatial resolutions and gray-white matter contrast recovery, demonstrating age-related FDG uptake decline in cortical regions and striatum, and illustrating kernel size's impact on FDG uptake statistics.

EP-0756

A Potential Problem and Its Solution with the Algorithm for Calculating Washout Rate in Myocardial Single-Photon Emission Computed Tomography: Comparison of Total Count Washout Rate and Arithmetic Mean Washout Rate

H. Miyauchi[1], *R. Ono[1], T. Iimori[2], K. Sawada[2], Y. Kobayashi[1];*
[1]Chiba University Graduate School of Medicine, Chiba, JAPAN, [2]Chiba University Hospital, Chiba, JAPAN.

Aim/Introduction: Washout rate (WR) analysis is commonly used in nuclear cardiology to assess cardiac pathophysiology. WR is defined as the percentage of the difference in tracer counts between the early and time-decay-corrected late images relative to the tracer counts in the early image. The calculation of WR in myocardial single-photon emission computed tomography involves the use of dedicated software that calculates the arithmetic mean of the WR values for each pixel unit within a given region of interest (ROI) as the WR value for the ROI. The resulting value is called the arithmetic mean washout rate (AMWR). However, in patients with areas of decreased tracer uptake in early images, such as extensive myocardial necrosis, the WRs are calculated to be low using the AMWR algorithm. Therefore, we formulated a new algorithm to calculate WR, the total count washout rate (TCWR), based on the total count of the ROI and evaluated its clinical validity. ***Materials and Methods:*** We compared the AMWR and TCWR of iodine-123-beta-methyl-p-iodophenylpentadecanoic acid (^{123}I-BMIPP) in patients with various diseases associated with fatty acid and triglyceride metabolism. Participants included individuals with no cardiovascular disease detected (normal) (n = 11), CD36 deficiency (n = 6), triglyceride deposit cardiomyovasculopathy (TGCV) (n = 14), TGCV with old myocardial infarction (TGCV with OMI) (n = 17), and non-TGCV with OMI (n = 10). ***Results:*** The AMWR and TCWR values were not significantly different in the following groups: normal, 27.4 ± 8.5 and 27.3 ± 8.5% (p = 0.97); CD36 deficiency, -3.2 ± 6.5 and -4.1 ± 7.4% (p = 0.81); TGCV, 2.4 ± 6.3 and 2.2 ± 6.3% (p = 0.93); and TGCV with OMI, -0.9 ± 7.6 and -3.7 ± 8.4% (p = 0.32). However, the AMWR showed a significantly lower WR than the TCWR in non-TGCV with OMI (4.8 ± 8.7 and 18.9 ± 6.7%, p = 0.0008). This finding suggests that the AMWR may underestimate the WR in non-TGCV with OMI, potentially leading to misdiagnosis; a decreased WR (<10%) of ^{123}I-BMIPP is an essential criterion for the diagnosis of

TGCV. ***Conclusion:*** Our study demonstrated the superiority of the TCWR algorithm over the AMWR algorithm in differentiating TGCV from other cardiovascular diseases with extensive necrosis. Furthermore, the concept of TCWR has significant implications for quantitative analysis methods in imaging studies. ***References:*** National University Corporation Chiba University. International Publication Number: WO 2024/053646.

EP-0757

A novel method on the harmonization of brain PET in PET studies using paired PET/CT and MRI images

L. Fu, *L. Yin, S. Yang;*
Department of Nuclear Medicine, China-Japanese Friendship Hospital, Beijing, CHINA.

Aim/Introduction: Multi-center brain PET studies require the harmonization to minimize heterogeneity across PET/CT scanners. The more acceptable method is to use 3D Hoffman phantom scan to harmonize the imaging protocols used in multi-center studies. The Effective Image Resolution (EIR) based on 3D Hoffman phantom is the newly proposed method by AMYPAD Consortium, and can significantly reduce the image quality variability while minimally affecting quantitative accuracy. However, the implementation of 3D Hoffman phantom experiment is often challenge, which requires special skills to fill the phantom. In this study, we proposed a simple method using paired PET/CT and T1W MRI images, which is often acquired clinically, to provide a 2nd option in the case of 3D Hoffman phantom experiment is not easily carried out. ***Materials and Methods:*** The study retrospectively enrolled 3 subjects receiving 18F-FDG PET/CT and MRI scans. The total acquisition for brain PET was 4 minutes and its reconstruction were followed as, matrix:440×440, OSEM, TOF=214ps, PSF, Iterations:6, Subset:5, Zoom:2, and all-pass filter. The processing pipeline consisted of 1) the rigid alignment of T1W MRI images to PET/CT images in subject's space; 2) the deformative transformation of BigBrain T1W and its corresponding FDG activity map in MNI space into subject's space; 3) the calculation of EIR by identifying the lowest difference between the measured FDG and the smoothed activity map, which is generated by gaussian smoothing the transformed initial FDG activity map created from BigBrain project. All alignment and deformative transformations are conducted using ANTs toolkits. In the step 3), the gaussian FWHM was used and ranged from 1.0 to 12.0mm with 0.1mm as steps. ***Results:*** The EIR identified for 3 subjects were 5.4, 5.7 and 6.0, and the site digital reference object's (DRO) EIR was recommended within 5.0 - 6.0mm. The recommended site DRO EIR is in between 5.0 to 6.0mm, which was in accordance with the one measured using 3D Hoffman phantom. ***Conclusion:*** We proposed a simple method to calculate the Site DRO EIR for brain PET harmonization using paired PET/CT and MRI images as a 2nd option to the 3D Hoffman phantom experiment. The proposed method is more accessible in clinical environments, and more suitable for multi-center studies.

EP-0758

Predicting abnormal Myocardial Perfusion, stress Blood Flow and Flow Reserve from Calcium Scoring and coronary CT Angiography in hybrid Coronary Artery Disease Imaging using machine learning approaches

T. Lima[1], *J. A. Montoya-Zegarra[2], U. Bhure[1], H. Grünig[1], M. Bossard[1], J. E. Roos[1], K. Strobel[1];*
[1]Luzerner Kantonsspital, Lucerne, SWITZERLAND, [2]Lucerne University of Applied Sciences and Arts, Lucerne, SWITZERLAND.

Aim/Introduction: To evaluate the accuracy of using data-driven models based on machine learning approaches to predict myocardial ischemia, myocardial stress blood flow (sMBF) and myocardial flow reserve (MFR) from coronary artery calcium scoring (CAS) and coronary CT angiography (CCTA). ***Materials and Methods:*** A total of 184 patients (42% female, average age: 66.2 +/- 10.3 years (range: 36 - 86) underwent a hybrid protocol combining Rb-82 myocardial perfusion PET and CCTA. Ischemia score, sMBF, MFR were categorized in four grades (0-3), calcium score (CAS) and CAD-RADS scores for coronary stenosis grading were assessed by doubly board certified nuclear medicine physicians/radiologists. Correlation between the categories were evaluated and used to develop a data-driven model with machine learning to predict cardiac perfusion and flow scores from CAS and CCTA categories. For the evaluated models, we reported both the mean model accuracy and f1_weighted score with respective standard deviations. ***Results:*** 83% of the patients had no ischemia, 73% had normal sMBF and 76% normal MFR, 20% CAS score 0 and 22% CADRADS score 0. The model that presented the best results was based on XGBoost (eXtreme Gradient Boosting) using a k-fold cross-validation. Accuracy for this model varied from 70.3 +/- 5.1 % (corresponding f1_weighted score of 64.7 +/- 4.7 %) to 89.1 +/- 4.5 % (f1_weighted score 89.4 +/- 4.2 %), respectively for prediction of ischemia, sMBF and MFR using the CCTA scores. ***Conclusion:*** Our data allowed the evaluation of different CAD parameters in patients who underwent a hybrid Rb-82 PET/coronary CT angiography . The data-driven model can predict low-risk cardiac perfusion PET scores with over 80% accuracy from CAS and CAD-RADS score obtained by CCTA. This evidence has the potential to stratify patients more effectively by using CCTA as a gatekeeper before PET perfusion imaging.

EP-0759

Multicenter study on the use of Supervised Clustering for TSPO PET imaging

A. Da Costa[1], *C. Tauber[2], B. Sarton[1,3], V. Camus[2,4], S. Silva[1,3], J. Vercouillie[2], A. Salabert[1,3], J. Cottier[2,4], A. Hitzel[3], M. Ribeiro[2,4], P. Payoux[1,3];*
[1]Université Toulouse 3 , Inserm, ToNIC Toulouse NeuroImaging Center, Toulouse, FRANCE, [2]UMR 1253, iBrain, Université de Tours, Inserm, Tours, FRANCE, [3]Toulouse University Hospital, Toulouse, FRANCE, [4]Tours University Hospital, Tours, FRANCE.

Aim/Introduction: Supervised Cluster Analysis (SVCA) (10.1007/s00259-021-05309-z, 10.1038/jcbfm.2012.59) is a widely used approach for quantifying 18-kilodalton translocator protein (TSPO) in PET studies. While effective, this method requires for each clinical centre and camera access to both TSPO PET and MRI images of healthy subjects to generate typical kinetic classes. Such data isn't always available in research protocols. In this study, we evaluate the use of SVCA classes generated in one centre for the application of supervised clustering in another centre, to facilitate quantification of TSPO in studies were SVCA classes could not be generated with local data. ***Materials and Methods:*** This multicentre study was conducted between Toulouse and Tours on healthy high affinity binders subjects from two different studies: COMA3D (n=12, age range 22-75) and NIDECO (n=4, age range 56-76). PET images were acquired using a Siemens Truepoint HD scanner in Toulouse and a Philips Ingenuity PET scanner in Tours. $^{[18F]}$DPA-714 PET images were acquired in 32 frames for 60 minutes in Toulouse and in 31 frames for 59 minutes in Tours. Two sets of SVCA classes were generated independently for each centre. A temporal resampling was used to convert each set of classes to the framing of the other centre. The SVCA approach was used to

generate two reference activity curves on each PET image, using the local set of classes and the resampled set from the other centre. PET image quantification (BPnd) was performed using SRMT2 algorithm on Pmod (10.1007/s00259-014-2895-3). A run test for randomness of residuals between the two reference time activity curves (TACref) was performed (10.1007/s00228-006-0179-y). Paired t-tests were conducted to compare mean BPnd values in several regions. Significance was considered at p<0.05. ***Results:*** The run tests lead to random residuals between the two TACref, with Z=-1.623 ±0.623 on coma3d subjects and Z=-1.059±1.428 on nideco subjects. We obtained non-significant p-values when comparing the use of the two set of classes to generate the BPnd in all ROIs, with average differences of 0.0014±0.0164(p<0.734) in whole brain, 0.0003±0.0161(p<0.936) in white matter, 0.0039±0.0345(p<0.655) in thalamus and 0.0037±0.0169(p<0.39) for grey matter. ***Conclusion:*** On our multicentre dataset, no significant differences were found on the parametric values generated using SVCA classes from the other centre. The TACref were coherent. While the study should be extended to more centres and cameras, our results suggest that it could be possible to quantify correctly TSPO using the SVCA approach with classes from another centre.

EP-0760

Non-MRI Supervised Clustering for TSPO PET imaging

A. Da Costa[1], *P. Payoux[1,2], B. Sarton[1,2], S. Silva[1,2], A. Salabert[1,2], M. Ribeiro[3,4], P. Peran[1], A. Hitzel[2], C. Tauber[3];*
[1]Université Toulouse 3 , Inserm, ToNIC Toulouse NeuroImaging Center, Toulouse, FRANCE, [2]Toulouse University Hospital, Toulouse, FRANCE, [3]UMR 1253, iBrain, Université de Tours, Inserm, Tours, FRANCE, [4]Tours University Hospital, Tours, FRANCE.

Aim/Introduction: Supervised Cluster Analysis (SVCA) (10.1007/s00259-021-05309-z, 10.1038/jcbfm.2012.59) was developed to quantify the 18- kDa translocator protein (TSPO) in PET studies. While powerful, this approach usually requires the use of T1 MRI images to define the region used for normalization, which are not always available in research studies. In this study, we evaluated an alternative normalization method where MRI is only needed for the generation of SVCA classes but not required in future studies. ***Materials and Methods:*** 22 healthy control subjects (20-75 years old) from the Coma3d study (NCT03482115 DOI: 10.1093/brain/awae045) were considered, including 12 high-affinity binders and 10 mixed-affinity binders. All subjects underwent 18F-DPA-714 PET and MRI (T1) scans on a Philips 3T MRI scanner and a Siemens Truepoint HD PET. For the classical SVCA procedure, denoted SVCAMRI, all MRI images were segmented using Freesurfer and co-registered to PET images. The MRI segmentation was used for normalization and to generate the SVCA set of classes and the reference activity curve for all subjects. Alternatively, all MRI and PET images were registered to MNI space and the whole brain was segmented in the PET image using SPM12. In this process, denoted SVCAMNI, the classical SVCA approach was used except for the normalization step which was based on the brain ROI obtained from the PET image. Pmod implementation of SRMT2 algorithm (10.1007/s00259-014-2895-3) was used to obtain Binding Potential (BPnd) maps from the reference regions obtained with SVCAMRI and SVCAMNI. The residuals between the two reference curves of each PET image were calculated and a run test for randomness of residuals was performed (DOI: 10.1007/s00228-006-0179-y). A paired t-test was conducted to compare mean BPnd values in several regions. Significance was considered at p<0.05. ***Results:*** The run tests lead to having random residuals between the reference curve generated with SVCAMRI and SVCAMNI, with Z=-0.712±1.491. The BPnd values obtained with SRTM2 were not significantly different in all considered regions, with the following illustrative results. The BPnd differences were 0.0127±0,2113(p<0.78) in whole brain, -0.0006±0.2155(p<0.99) in white matter, 0.0137±0.3732(p<0.87) in thalamus, and 0.0249±0.2078(p<0.58) in grey matter. ***Conclusion:*** Our results suggest that an alternative normalization can be used in the SVCA approach. With this approach, MR images acquisitions are only required for the generation of the SVCA classes of the camera. Such results should facilitate the use of the SVCA approach for the quantification of TSPO in dynamic PET acquisitions when no MRI is available.

EP-0761

Quantification of [^{11}C]PIB amyloid in 3xTg-AD mice using reference tissue models

M. Avila-Rodriguez, *S. Burgos-Puentes, A. Avendaño-Estrada, D. Garduño-Torres, H. Lopez-Valdes, H. Martinez-Coria, E. Ramirez-Hernandez;*
National Autonomous University of Mexico, Ciudad Universitaria, Cdmx, MEXICO.

Aim/Introduction: The aim of this work was to perform a quantitative analysis of microPET images acquired with the radiopharmaceutical [^{11}C]Pittsburg Compound-B ([^{11}C]PIB) in a triple-transgenic model of Alzheimer's disease (3xTg-AD) to determine accumulation of beta-amyloid (Aβ) plaques using two reference tissue models. ***Materials and Methods:*** Five 3xTg-AD male mice of 8, 12, 13, 14 and 15 months of age and one wild-type (WT) mouse (8 months of age) were included in this study. Imaging was performed in a Focus 120 microPET scanner. [^{11}C]PIB (18 ± 3 MBq) was intravenously administered as a bolus via the tail vain while animals were under anesthesia (2.4% isoflurane). Dynamic microPET scans of 16 frames of increasing length (4x30s, 3x60s, 5x180s, 4x600s; 60 min in total) were acquired. Images were reconstructed with a 2D ordered subset expectation maximization algorithm (2D-OSEM). Quantitative analysis was performed with PMOD software using the simplified reference tissue model (SRTM) [1] to calculate BPND, and the Logan reference tissue model (LRTM) (Logan et al., 1996) [2] to calculate DVR-1. LRTM analysis was done using the efflux constant (k2') calculated with SRTM. In both models cerebellum was used as reference region. ***Results:*** The values of BPND and DVR in the cerebral cortex of transgenic animals showed an increasing trend as a function of the age, consistent with the accumulation of Aβ in the 3xTG-AD model. The WT control showed similar quantitative values as the transgenic animal of the same age (8 months), so both animals could be considered as controls. The average percentage increase in DVR in the cerebral cortex of the transgenic animal group, compared to control animals, was on the order of 20%. DVR (BPND+1) values obtained with both reference tissue models were equivalent for the evaluated brain structures and a linear correlation analysis between the DVR values obtained with LRTM and SRTM gave correlation coefficients in the range of 0.924 to 0.996 for of 3xTg-AD animals of 8 and 15 months of age, respectively. ***Conclusion:*** SRTM and LRTM using cerebellum as reference region provide parametric images that appear qualitatively similar, and equivalent quantitative values for [^{11}C]PIB amyloid in 3xTg-AD mice. This research was supported by UNAM-DGAPA PAPIIT-IT201623. ***References:*** [1] Lammertsma & Hume, 1996, NeuroImage, 4:153-158. [2] Logan et al., 1996, J. Cereb Blood Flow and Metab, 16:834-840.

EP-0762

Blood transcriptomic biomarker of disease progression in Parkinson's Disease

R. Lee[1], *J. Seok[2];*
[1]Chung-Ang University Gwangmyeong Hospital, Seoul, KOREA, REPUBLIC OF, [2]Chung-Ang University Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Parkinson's disease (PD) is a neurodegenerative disorder characterized by progressive loss of dopaminergic neurons, resulting in motor and non-motor symptoms. Early and accurate detection of disease progression is crucial for timely intervention and management. The purpose of this study is to identify blood-based biomarkers that relate to disease progression in PD. ***Materials and Methods:*** This study used RNA-seq data of participants with PD and healthy controls (HC) from the Parkinson's Progression Markers Initiative (PPMI) database. Contrastive principal component analysis (cPCA) was applied to unveil enriched temporal patterns in a diseased subjects and derive gene expression-pseudotimes, which reflect the individual proximity to the pathology-free state. Gene expression-pseudotimes were correlated with progression of various clinical variables including DAT scan findings, Hoehn and Yahr Scale, and several proven progression milestones. ***Results:*** A total of 582 participants (PD 393, HC 189) were included in this study. The cPCA deriven gene expression-pseudotime was significantly higher in PD patients than HC (0.39 ± 0.25 vs. 0.06 ± 0.02, $P < 0.001$). The obtained pseudotime showed significant predictive associations with progression of mean striatal DAT binding (0.41 ± 0.25 vs. 0.26 ± 0.25, $P < 0.001$), Hoehn and Yahr Scale (0.35 ± 0.25 vs. 0.23 ± 0.25, $P < 0.001$), and progression milestones, including activities of daily living (0.39 ± 0.26. Vs. 0.27 ± 0.25, $P < 0.001$), autonomic dysfunction (0.36 ± 0.26 vs. 0.26 ± 0.25, $P < 0.001$), cognition (0.38 ± 0.25 vs. 0.25 ± 0.25, $P < 0.001$), functional dependence (0.38 ± 0.25 vs. 0.25 ± 0.25, $P < 0.001$), motor complications (0.41 ± 0.24 vs. 0.25 ± 0.25, $P < 0.001$), walking and balance (0.38 ± 0.26 vs. 0.26 ± 0.25, $P < 0.001$), and any domain (0.37 ± 0.27 vs. 0.21 ± 0.22, $P < 0.001$). ***Conclusion:*** Our study presents a peripheral biomarker signature that holds promise for predicting and monitoring disease progression in PD. The development of a reliable and minimally invasive biomarker assay based on these findings could significantly enhance clinical management strategies for PD patients, facilitating early intervention and personalized treatment approaches.

EP-0763

Visual Reading and Centiloid Scaling for the Evaluation of Brain Amyloid PET Imaging in Patients with Mild Cognitive Impairment: Impact on Conversion to Alzheimer´s Disease Dementia

K. Hirschmüller[1], *E. Prieto[1], F. Mínguez[1], R. Fahmi[2], E. F. Guillen[3], R. Cuevas[1], F. Pareja[1], A. Fernández[1], B. Echeveste[1], M. Riverol[1], J. Arbizu[1];*
[1]Clínica Universidad de Navarra, Pamplona, SPAIN, [2]Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA, [3]Clínica Universidad de Navarra, Madrid, SPAIN.

Aim/Introduction: In clinical routine, amyloid Positron Emission Tomography (A-PET) is important for diagnosing Alzheimer´s disease (AD). Centiloid (CL) scale is a standardized metric for quantifying A-PET acquired with different tracers. The aim of this study was to investigate the agreement of Centiloid scale with visual reading and progression of disease. ***Materials and Methods:*** 162 patients (69 females, 93 males) aged 71.3±6.2 years with Mild Cognitive Impairment (MCI) who underwent an A-PET (22 18F-florbetaben, 52 18F-flutemetamol, 88 18F-florbetapir) on a Biograph mCT scanner (Siemens Healthineers) at our institution were retrospectively reviewed. PET images were reconstructed iteratively using time-of-flight and point-spread-function (3 iterations, 21 subsets, 2mm Gaussian filtering). Patients were classified as "positive" or "negative" by consensus between two trained nuclear medicine physicians using visual reading procedures. Images were processed using a commercially available solution to calculate composite standard uptake value ratios (SUVR) using tracer-specific "target/reference" regions, which were then converted to the Centiloid scale using appropriate SUVR-to-Centiloid conversion equations. A receiver operating characteristic analysis (ROC) was performed to discriminate patients in agreement with the visual reading, and the optimal Centiloid cut-off value was calculated as the value that maximized the Youden's J Index of the ROC curve. Using the ROC, the Centiloid values were categorized into "clearly negative", "grey zone", and "clearly positive" ranges based on the sensitivity and specificity values. Cox regression analysis was conducted to study the rate of conversion to AD dementia during the follow-up. ***Results:*** The percentage of concordance between readers was 95% and the eight discordant cases were excluded from the ROC analysis. 107 (66%) subjects were visually classified as "positive" with CL=60.8±28.1, while 55 (34%) subjects were visually classified as "negative" with significantly lower CL=-7.5±20.5 ($p<0.05$). The ROC analysis yielded excellent agreement with visual-based classification with an area under the ROC curve of 0.9872, and a corresponding optimal CL cut-off value of 26 (sensitivity 92.0%, specificity 96.3%). A Centiloid "grey zone" range of 11 to 39, was determined where both sensitivity and specificity are less than 100%. The Cox regression analysis showed that patients classified as "positive", either visually or using Centiloids, converted more rapidly to AD dementia, but those in the Centiloid "grey zone" converted slower than "positive" (Table 1). ***Conclusion:*** Centiloid scale is a promising quantitative tool in the clinical routine to harmonize SUVR data across different A-PET tracers, with different progression patterns related to AD dementia conversion in MCI subjects.

Open-source MATLAB code for the identification of spatial covariance patterns in neuroimaging data

D. Peretti[1], *S. K. Meles[2], D. Vállez García[3], G. Carli[2], H. J. van der Horn[2], K. L. Leenders[2], R. J. Renken[4,2];*
[1]University of Geneva, Geneva, SWITZERLAND, [2]University Medical Center Groningen, Groningen, NETHERLANDS, [3]Amsterdam University Medical Center, Amsterdam, NETHERLANDS, [4]University of Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Positron emission tomography (PET) imaging offers in-vivo insights into brain pathology, which may improve diagnostic accuracy, allow for disease staging, and assess disease-modifying treatment. While univariate approaches are widely used in research, they do not consider spatial correlations between voxels. This limitation is addressed by multivariate analyses, such as the Scaled Subprofile Model using Principal Component Analysis (SSM/PCA). SSM/PCA is particularly well suited for studying conditions that involve dysfunction in brain networks. Moreover, it provides a disease-specific spatial covariance pattern (DP) that can be used to computer subject-specific expression scores, informing clinicians about disease progression and treatment effects. The aim of this work is to introduce a new open-source

MATLAB-based code for the SSM/PCA analysis of imaging data in neurological disorders. ***Materials and Methods:*** We developed an SSM/PCA software to evaluate spatial covariance patterns using PET data to create a DP. First, a mask is applied to exclude non-informative voxels (either by an intensity threshold or using a pre-defined mask), which is followed by a data-driven intensity normalisation (at subjects and group levels, yielding a "Scaled Subprofile"). Then PCA is applied to reduce data dimensionality, and components that together explain up to a certain variance of the data are included in the analysis. Subsequently, a stepwise logistic regression model is used to select and combine principal components in an optimal way to differentiate between healthy individuals and patients. This generates a disease-specific DP. This DP can then be used to evaluate the expression of a specific disease in the image of a new individual. ***Results:*** Different DPs have been generated to assess a variety of disorders. Metabolic patterns using ^{18}F-FDG have been identified for Alzheimer's disease, Parkinson's disease, spinocerebellar ataxia type 3, mild cognitive impairment, and others. Pathology-specific patterns for amyloid and tau accumulation in Alzheimer's disease using 11C-PIB and ^{18}F-Flortaucipir have been described. Furthermore, a serotonin DP using 11C-DASB in dystonia has been identified. Finally, a cerebrovascular reactivity DP in Parkinson's disease has also been detected. These patterns have been successfully used to differentiate patients from controls. ***Conclusion:*** Our SSM/PCA software offers an open-source code that is easy to apply to different radiotracers and disorders. This software has been successfully applied to a variety of neurological disorders and it is now available for download and research use.

Image-derived input function for (-)-[18F]Flubatine using a long axial field of digital PET system

L. Barth[1], *G. A. Becker[1], M. Rullmann[1], S. Hesse[1], P. M. Meyer[1], A. Schildan[1], B. Sattler[1], F. R. Zientek[1], P. Schönknecht[2], M. Leitzke[1,3], O. Sabri[1];*
[1]Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, [2]Department of Psychiatry and Psychotherapy, University of Leipzig, Leipzig, GERMANY, [3]Department of Anesthesiology, Helios Clinics, Leisnig, GERMANY.

Aim/Introduction: Long axial field of view (FOV) PET-CT systems enable dynamic data acquisition throughout their entire axial FOV. That opens up the possibility of pharmacokinetic analysis and modeling simultaneously involving all body regions covered by the axial FOV, including the brain based on large blood pools, i.e. parts of the aorta. The partial volume effect, a known limitation of image-based input function derivation, is further mitigated by cutting edge, highly sensitive PET systems with improved spatial resolution compared to state-of-the-art standard digital PET systems with shorter axial FOVs. Furthermore, the use of (-)-[18F] Flubatine, a tracer with a comparatively low metabolic degradation targeting the alpha4beta2* nicotinic acetylcholine receptors [1], simplifies the otherwise complex radiometabolite correction. ***Materials and Methods:*** Within 26 days two whole-body PET-CT scans were performed with continuous measurement for the first 90 minutes in ultra-high sensitivity mode and a total imaging time of 360 minutes (0-90min, 195-225min, 330-360min p.i.). The scans were conducted after a bolus injection of ~300 MBq of (-)-[18F]Flubatine in a patient presenting with Long COVID. Metabolites, plasma to whole blood ratios, and tracer binding to plasma proteins ratios were determined by taking arterial blood samples, which served as the gold-standard. The image-derived input function was extracted from the aortic arch based on the segmentation of the thoracic aorta AC-CT-data. Kinetic modeling of the body including the brain was performed based on arterial as well as image-derived input functions. Kinetic analyses with various compartment models and graphical approaches (Logan plots) were employed for the evaluation of the data. ***Results:*** The image-derived input function shows small differences (1st scan: 0.43 ± 0.92 kBq/ml, 2nd scan: 0.20 ± 1.29 kBq/ml, n=29) with lower values observed for the arterial input function, which can be partially attributed to the ratio of plasma to whole blood. The results of the two investigations were found to be similar in this regard. ***Conclusion:*** (-)-[18F]Flubatine is a tracer that seems suited for kinetic modeling using an image-derived input function. Further studies are warranted to validate the clinical utility of long axial field of view PET-CT image-derived input functions for this tracer instead of arterial blood sampling and analysis. ***References:*** [1] Patt et al., Nucl Med Biol 2014; 41:489-94.

Comparative analysis of tumour segmentation methods in positron emission tomography (phantom study)

G. Khamadeeva, *S. Onishchenko, A. Khalimon, M. Khodzhibekova, A. Leontyev;*
P. Hertsen Moscow Oncology Research Institute – branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: In nowadays different tumour delineation approaches exists on PET. That leads to incomparable results in studies which utilize volume PET-metrics. A choice of segmentation tool should be based head-to-head comparative analysis. The aim of present study was to compare repeatability and accuracy of six segmentation approaches. ***Materials and Methods:*** Two phantoms were used: NEMA IEC Body Phantom Set NU 2-2018 (NEMA-Ph) and in-house designed phantom (Ph2) which have 10L total volume and internal 235ml irregular shaped fillable insert (with less suffer from partial volume effect). Various target-to-background (TB) ratios were used: 1.5, 3, 4.5, 6, 7.5, 10 and 15 with [18F]FDG solution. Phantoms were scanned on 5 ring PET/CT system (Block Sequential Regularized Expectation Maximization, β=400, 3min p/b). Fixed threshold-based (SUVmax41% and SUV2.5), background subtraction (BSV) [1], gradient [2], adaptive threshold (AT) [3], adaptive iterative algorithm (AIA) [4] were analyzed. ***Results:*** Direct comparison of methods were possible within TB ratios range from 7.5 to 15, since at lower TBs some approaches (except AT, AIA) failed to perform delineation. The repeatability of all methods, except BSV, correlated with an object size (the highest for the Gradient ($r=-0.886$, $p<0.05$). Coefficient of variation (%) of AT, AIA, Gradient, BSV, SUVmax41%, SUV2.5 measurements were 0.21, 1.27, 16.98, 25.15, 0, 0, respectively. The average error (% (95-%CI)) of NEMA-Ph measurements were -4.23 (-12.4; 3.95) for SUVmax41%, 33.37 (26.51; 40.22) for SUV2.5, -79.23 (-95.05; -63.41) for Gradient, 39.27 (23.83; 54.73) for BSV, -3.68 (-7.11; -0.24) for AT, 5.44 (-1.88; 12.75)

for AIA. For Ph2 errors were 20.79 (-5.07; 46.65) for SUVmax41%, -16.88 (-82.94; 49.18) for SUV2.5, -9.92 (-11.49; -8.34) for Gradient, 31.26 (25.1; 37.4) for BSV, -1.63 (-5.96; 2.71) for AT, -6.67 (-8.1;-5.23) for AIA. A systematic underestimation of the volumes for both NEMA-Ph and Ph2 for Gradient (p=0.0127) and overestimation for BSV (p=0.0208) was revealed. ***Conclusion:*** The repeatability of measurements (except BSV) had inverse relationship with measured volume. A systematic misestimation of the volume by the Gradient and BSV was observed both on the NEMA-Ph and Ph2. The AT and AIA methods had the most optimal characteristics (wide TB range of applicability, high repeatability, comparatively small measurement error). ***References:*** 1. Burger IA. ^{18}F-PSMA 1007 PET/CT metrics for Assessment of Whole-Body Tumor Burden in Patients with Metastatic Prostate Cancer

S. Moustafa[1], *A. Rayan[2];*
[1]Clinical oncology and nuclear medicine department, Assiut Uinversity, Assiut, EGYPT, [2]clinical Oncology department., assiut, EGYPT.

Aim/Introduction: A prostate-specific membrane antigen (PSMA) ligand PET/CT may be applied to provide PSMA-derived SUVs, yet individual lesion SUVs may be inadequate to determine the overall response. On the way of the vision of the measurement of the whole-body tumor burden in patients with metastatic prostate cancer, and to standardize the evaluation of treatment-related changes; we unmet a quantitative imaging biomarker reflecting the whole-body tumor burden based on the size, number, and precise activity of tumor lesions, as well as being easily applicable in clinical practice for lesions. PSMA-derived volumetric parameters such as PSMA-total volume (PSMA-TV) and PSMA-total lesion parameters (PSMA-TL) that are calculated by multiplying the respective TV and mean SUV are hypothesized to be a tool for quantification of whole-body tumor burden in patients with metastatic prostate cancer. We aim to investigate PSMA ligand PET/CT volumetric parameters as a measure of whole-Body tumor burden, in comparison with PSA levels as a surrogate marker of tumor load. ***Materials and Methods:*** We enrolled 39 patients with prostate cancer and had PSMA avid metastatic lesions, from all suspected pathological lesions (n = 313), the mean and maximum SUV (SUV mean, SUVmax) and the tumor volume of each lesion were determined in VOIs with isocontours set at 41% of the maximum uptake within the respective focus; that is called PSMA-TV and finally, PSMA-TL calculated by multiplying the respective TV and mean SUV. ***Results:*** Whole body PSMA parameters (SUVmax, PSMA-TV, SUV mean, PSMA-TL) exhibited significant correlations with PSA (r=0.55 & p=0.001, r=0.31& p=0.05, r=0.6 & p=<0.001, r=0.6 &p<0.001 respectively) as well as with Gleason score (r=0.4 & p=0.03, r=0.4 & p=0.02, r=0.3 &p=0.046, r=0.4& p=0.006 respectively) Interestingly, when we analyzed only metastatic osseous lesions we found, osseous PSMA parameters (SUVmax and SUVmean) lost their association for the current population with PSA, but significant positive correlations between PSA and TV PSMA & TL-PSMA with P value (p=0.024 and p=0.02) respectively. ***Conclusion:*** PSMA-TV and PSMA-TL are considered promising parameters defining the lesions size and intra-lesional PSMA expression and providing a quantitative imaging biomarker of real volumetric assessment and total tumor burden. Moreover, PSMA-TV and PSMA-TL could refine better stratification of patients into low- and high-volume metastatic disease in clinical trials; that is recently of paramount use in precision appropriate treatment strategies of metastatic prostate cancer and subsequently an utmost tool in predicting metastatic cure.

EP-0768

Feasibility of Shortening the FDG Patlak Scan Time in a High Sensitivity Short-Axial FOV PET/CT System for Oncological Studies Using Deep Learning Denoising Algorithms

L. Wang, *L. Fu;*
China-Japan friendship hospital, beijing, CHINA.

Aim/Introduction: This study aims to investigate the clinical acceptability of 18F-FDG Patlak imaging in a high-sensitivity short-axial PET/CT scanner by comparing various Patlak protocols and employing a deep learning-based denoising algorithm. ***Materials and Methods:*** This study involved 15 patients who received a dual-time injection of 18F-FDG (80% of the dose administered at the first injection and the remaining 20% administered at the second injection starting at 80 min post-injection). Four protocols were generated to account for different arterial input functions (AIF), and whole-body passes (3, 4, 5, 6, 7 passes × 5 min/pass) obtained between 40 and 75 minutes after the injection were used for Patlak fitting after denoising. ANOVA was used to compare the four AIF protocols in Ki values in FDG-avid lesions and to analyze the effect of the number of whole-body passes on differences in Ki values. Additionally, Pearson correlation of Ki values between abbreviated protocols and the standard protocol (Protocol-1 with 7×5 min/pass) was performed. ***Results:*** Twelve out of 15 participants completed the entire protocol, and 12 FDG-avid lesions were manually contoured. Compared to the image-derived input function of the standard protocol, the abbreviated protocols exhibited a relatively lower area-under-curve. Ki values demonstrated good agreement and high correlation between different protocols, with R-squared values ranging from 0.8992 to 0.9999. In comparison to the estimation obtained from Protocol-1, the population-based input function (PBIF)-based Protocol-4, with 20 minutes of PET (i.e., 55 to 75 min post-injection), yielded <5% bias and <15% precision error for Ki in tumor lesions. The acquired Ki images using different protocols were visually comparable. ***Conclusion:*** The findings suggest that abbreviated protocols can provide acceptable Patlak Ki estimation from short-axial PET/CT systems. The 20-minute PBIF-based abbreviation protocol, enhanced by a deep learning-based denoising algorithm, holds promise for the potential application of Ki analysis in both scientific and clinical settings.

EP-0769

Recovery coefficients as an estimate of effective spatial resolution in SPECT

W. Claeys[1], *K. Baete[1,2], M. Koole[1];*
[1]KU Leuven, Leuven, BELGIUM, [2]UZ Leuven, Leuven, BELGIUM.

Aim/Introduction: While there are many ways to measure the spatial resolution of a SPECT camera, determining the effective resolution of reconstructed SPECT images remains challenging. Due to the depth dependent resolution, non-circular detector rotation and resolution recovery (RR), the effective resolution is different from the system resolution and spatially variant. Since

recovery coefficients (RCs) are a measure for the partial volume effect, which is in turn determined by the resolution, these could be used to estimate the effective resolution. Therefore, our aim was to develop and evaluate a RC-based resolution calculation method. ***Materials and Methods:*** For an idealized SPECT system with a fixed full width at half maximum (FWHM), the RC of a sphere with diameter D is given by RC(d)=erf(d)+1/√π[(e^(-d2)-3)/d-2(e^(-d2)-1)/d3] where d=1.665*D/FWHM. Using this formula, the effective image resolution can be calculated directly from the RCs of spherical objects. This approach was tested by measuring a NEMA IEC body phantom containing 6 spheres filled with 99mTc on a SPECT/CT system (Siemens Intevo Bold) using low and medium energy collimators. The data were reconstructed with and without RR using MIM software. For each image, the RC-based resolution was determined and evaluated against two image-based methods: fitting a theoretical edge profile to each sphere and finding the Gaussian filter required to optimally match a smoothed template of the phantom with the SPECT image. ***Results:*** For the reconstructions without RR, the RC-based resolution matched the system resolution at the average sphere depth (14.3mm and 18.8mm at 25i2s for the low and medium energy collimator respectively), in line with the fitted profile (13.9mm and 18.8mm) and the matched filter methods (15.1mm and 19.6 mm). In the reconstructions with RR, the RC-based resolution was better (9.9mm and 11.4mm at 25i2s), in line with the matched filter method (9.5mm and 10.4mm), and continued to improve with increasing number of iterations. Meanwhile, the fitted profile method to failed due to Gibbs artifacts. The RC method also allowed to estimate the resolution for each individual sphere to investigate variations in effective resolution. Without RR, the resolution was position-dependent, with RR the resolution proved to be size-dependent. ***Conclusion:*** The RC-based resolution calculation method is a robust tool to assess the effective spatial resolution in reconstructed SPECT images and can be used to quantify local resolution variations.

EP-0770

Motion-Resolved Parametric Imaging for Short-Dynamic PET

A. Artesani[1], *J. van Sluis[2], L. Providência[2], J. van Snick[2], R. Slart[2], W. Noordzij[2], C. Tsoumpas[2];*
[1]Humanitas Mirasole SPA, Rozzano, ITALY, [2]University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: [18F]Fluorodeoxyglucose (FDG) Positron Emission Tomography (PET) is currently conducted in a single time-point static acquisition mode, 60 minutes post injection. However, this clinical routine provides reduced information about the distribution of the radiotracer within the body over time, limiting the capability to distinguish cancer from inflammatory processes or perfusion effects, especially in assessing therapy response. This study explores the added value of parametric imaging in short-dynamic total body PET/CT scans to quantify time-dependent glucose metabolic rate and blood flow for enhancing our understanding of physiological processes. ***Materials and Methods:*** Four patients with malignant lymphoma underwent a 15-minute total body FDG PET scan for therapy evaluation. Parametric imaging framework was developed, incorporating population-based input function derived from retrospectively selected patients who underwent full dynamic FDG PET acquisition. Misalignments between PET and CT due to subtle patient motion were corrected with AI-based registration methods [1],[2]. ***Results:*** The motion correction process demonstrates significantly reduced mismatches between tomographic images without changing the voxel intensity values (variations below 1-2%). Post-therapy, two patients showed persistent malignancies in mediastinal and axillary lymph nodes, characterized by an average net influx rate of 0.13-0.25 ml/100ml/min that exceeded ten times the background. Overall, tissue-to-background ratio evaluated for the influx rate parameter was twice as high as the one for the SUV. This improved lesion readability in parametric images was particularly beneficial in delineating small size lymph nodes. Furthermore, the parametric representation exhibited more heterogeneous behavior of the lymph nodes with respect to the SUV mean. Notably, where SUV suggested an extended malignancy, the influx rate detected a reduced volume of the tumoral tissue, indicating potential contribution of perfusion or inflammation within the same region. ***Conclusion:*** The implementation of short-dynamic PET and parametric imaging offers valuable insights into kinetic responses of tissues, with additional advantages of removing motion effects in the parametric analysis framework, a step frequently overlooked in commercial software. ***References:*** [1] J. Development of a real-word-data-based indicator system to evaluate the use of PET/CT and other major imaging equipment: A Delphi study

Y. Xiong[1], *Y. Ma[2], L. Li[2], T. He[3], F. Yang[4], X. He[5], F. Cui[1], H. Wang[3], Y. Liu[4], W. Lu[5], R. Tian[1], X. Sun[2], Q. Li[1];*
[1]Department of Nuclear Medicine, West China Hospital, Sichuan University, chengdu, CHINA, [2]Chinese Evidence-Based Medicine Center, Cochrane China Center, and MAGIC China Center, West China Hospital, Sichuan University, Chengdu, Sichuan, China, chengdu, CHINA, [3]Department of Nuclear Medicine, Panzhihua Central Hospital, Sichuan, China, Panzhihua, CHINA, [4]Department of Nuclear Medicine, Ya'an People's Hospital, Sichuan, China, Ya'an, CHINA, [5]Department of Nuclear Medicine, Guangyuan Central Hospital, Sichuan, China, Guangyuan, CHINA.

Aim/Introduction: With increasing applications of PET/CT and other major imaging equipment in patient care, we aim to develop an indicator system to evaluate their use in routine clinical practice, using real-world data as the source. ***Materials and Methods:*** We first searched PubMed, CNKI, Wanfang Data, five national and international government websites (such as the US FDA and WHO website), and Microsoft Bing for studies and administrative documents that evaluated the use of major radiological imaging equipment (i.e., PET/CT, PET/MR, CT, and MRI), and collected indicators for evaluation. The accessibility of indicators was determined using electronic health records from four hospitals. A Delphi consensus process was then conducted involving a convenience sample of 17 experts to vote for indicators to construct the final system. These participants were invited from 9 provinces in China and from various specialties, including nuclear medicine, radiology, relevant clinical specialties, and methodology. Each indicator was rated for importance

and accessibility on a 5-point Likert scale (0 for complete disagreement; 5 for complete agreement). The first round of Delphi was completed and a second round is ongoing. ***Results:*** All experts approached returned their survey. The expert authority coefficient was greater than 0.7, and the coordination coefficients of experts in the total index were 0.309 (for importance) and 0.246 (for accessibility, both P<0.001). A preliminary three-level indicator system was developed for evaluation of the use of major radiological imaging equipment (i.e., PET/CT, PET/MR, CT, and MR) in routine clinical practice (Table 1). First-level indicators include clinical use, equipment and staff, and other efficiencies. Second (and third) level indications include: appropriateness of use (rate of appropriate use and of positive results), efficiency of use (number of examinations per day, annual number of examinations per equipment, annual days of operation, average time of a single examination, and annual rate of operation), safety (radiation exposure dose of patients and staff), reporting quality (completeness of reporting), equipment condition (year of service), staffing status (number of staffs), economic efficiency (annual income), and research efficiency (number of representative publications per equipment). ***Conclusion:*** This is the first real-world data-based indicator system for the evaluation of the use of PET/CT and other major imaging equipment in routine practice. This indicator system provides an efficient and objective approach of evaluation given its utilization of real-word-data as the source, and will help promote high-quality use of imaging equipment in patient care.

EP-0772

Health Economic Models to Assess Response to Therapy with Positron Emission Tomography in Oncology Care: A Methodological Review

***S. van Mossel*[1,2]**, *R. E. de Feria Cardet*[3], *L. de Geus-Oei*[1,2,4], *D. Vriens*[5], *H. Koffijberg*[2], *S. Saing*[2];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*University of Twente, Enschede, NETHERLANDS,* [3]*University of Sydney, Sydney, AUSTRALIA,* [4]*Delft University of Technology, Delft, NETHERLANDS,* [5]*Radboud University Medical Center, Nijmegen, NETHERLANDS.*

Aim/Introduction: This methodological review addresses model-based cost-effectiveness studies assessing response to systemic therapy with positron emission tomography (PET) for various cancer diseases. This review aims to identify the modelling methodologies used and to include a systematic assessment of the assumptions made, the extent of structural uncertainty and consequences on cost-effectiveness outcomes. The objective is to provide recommendations for future decision-analytic models assessing the cost-effectiveness of therapy response monitoring with PET in oncology care. ***Materials and Methods:*** Information sources included electronic bibliographic databases, reference lists of review articles and contact with experts in the fields of nuclear medicine, health technology assessment and health economics. Eligibility criteria included peer-reviewed scientific publications and published grey literature. Literature searches, screening and critical appraisal were conducted by two reviewers independently. The Consolidated Health Economic Evaluation Reporting Standards were used to assess the methodological quality. The Bias in Economic Evaluation checklist was used to determine the risk of bias in the included publications. ***Results:*** The search results included 2,959 publications. The number of publications included for data extraction and synthesis was ten, representing eight unique studies. These studies addressed patients suffering from lymphoma, advanced head and neck cancers, brain tumours, non-small cell lung cancer and cervical cancer. All studies studied response to chemo(radio)therapy. Most studies positioned PET as an add-on modality within the considered care pathways and a single study positioned PET as a replacement modality for conventional imaging. Three studies reported decision-tree structures, four studies reported cohort-level state-transition models and one study reported a partitioned survival model. No patient-level models were reported which was surprising given the heterogeneity observed in many of the patient populations. The simulation time horizons adopted by the studies ranged from one year to lifetime. Most studies reported probabilistic analysis, whereas two studies only reported deterministic analysis. Multiple studies did not adequately discuss model-specific aspects of bias. Most importantly and regularly observed was a high risk of structural assumptions bias, limited simulation horizon bias and wrong model bias. ***Conclusion:*** The reasons for selecting a specific modelling methodology were rarely discussed. Modelling approaches with event history analysis which considers time-to-events were absent. Future studies require more patient-level evidence, and flexible patient-level models are highly recommended. This also means that more time should be available to develop such flexible models and to increase validation efforts (linked to the development of more complex models).

EP-0773

Usefulness of Free Image Analysis Software in Appropriate Amyloid PET Imaging: A Multicenter Study for Site Accreditation Program in Japan

***S. Isogai*[1],** *H. Daisaki*[1], *M. Sato*[1], *M. Shiga*[1], *K. Kishi*[2], *M. Shimizu*[3], *T. Iizuka*[3], *H. Fukushima*[4], *T. Mino*[5], *K. Osakabe*[6];
[1]*Gunma Prefectural College of Health Sciences, Maebashi, JAPAN,* [2]*Gunma University Hospotal, Maebashi, JAPAN,* [3]*Fujioka General Hospital, Gunma, JAPAN,* [4]*Gunma Prefectural Cancer Hospital, Gunma, JAPAN,* [5]*Tomioka General Hospital, Gunma, JAPAN,* [6]*Maki Hospital, Gunma, JAPAN.*

Aim/Introduction: Currently in Japan, the Japanese Society of Nuclear Medicine is certifying PET imaging facilities (J-PEQi) to ensure the appropriateness of amyloid PET. In J-PEQi, image quality evaluation of Hoffman and cylindrical phantom is performed using PMOD software. However, few Japanese facilities own PMOD software, and it is difficult for each facility to evaluate image quality in advance to optimize PET imaging conditions for J-PEQi site accreditation. Recently, free image quality analysis software PETquactIE (Nihon Medi-Physics Co., Ltd.) has been developed and is being used in various facilities in Japan [1]. The purpose of this study was to determine the effectiveness of image quality analysis using PETquactIE in the optimization of amyloid PET imaging. ***Materials and Methods:*** Hoffman and cylindrical phantom imaging was obtained according to J-PEQi phantom procedure manual [2] using six different PET/CT scanners at five facilities. Image reconstruction was performed by 3D-OSEM method without PSF correction with 60-80 iterative updates, followed by smoothing using a Gaussian filter at 1mm intervals between none and 5mm. These PET images were analyzed using PETquactIE and PMOD to compare image reconstruction conditions that satisfied contrast (%contrast≥55%), image noise (CV≤15%), and uniformity (SDΔuROI≤0.0249). After 15 sets of PET images with 135s were reconstructed under optimized imaging conditions, image quality was evaluated and differences in analysis values between analysis software were examined. Statistical significance was compared by t-test. ***Results:*** For contrast, PETquactIE analysis was significantly higher than PMOD analysis (p<0.01), but the difference was within

3% for all scanners. There was no significant difference between the CVs of PMOD and PETquactIE for the two scanners, but for the three scanners. However, as with %contrast, the difference in CVs was within 3% for all scanners. The imaging conditions for a Gaussian filter that could achieve a CV≤15% were the same for both analysis software. The slight difference in %contrast analysis is likely due to the automatic alignment of ROI templates in PMOD, whereas PETquactIE is manually aligned. The slight difference in CVs may be due to the manual alignment between ROI template and PET images in both analyses. ***Conclusion:*** Image analysis using PETquactIE at each institution can help optimize PET images that meet the image quality criteria set by J-PEQi, but a margin of about 3% should be considered. Automation of ROI template alignment is important to obtain image quality assessment with higher agreement. ***References:*** [1] https://www.nmp.co.jp/member/hiroba/[2] Ikari Y,et al. EJNMMI Phys. 2016 Dec;3(1):23.

Quantitative PET/MR imaging for hepatic portal vein input function measurements: a phantom study

Z. Chalampalakis[1], *M. Ortner[1], M. Almuttairi[1], M. Bauer[2], E. G. Tamm[3], A. I. Schmidt[3], O. Langer[2], R. Frass-Kriegl[3], I. Rausch[1];*
[1]QIMP Team, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Clinical Pharmacology, Medical University of Vienna, Vienna, AUSTRIA, [3]High-field MR Center, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Precise pharmacokinetic modelling in PET relies on obtaining an accurate input function, ideally non-invasively from imaging data. In hepatic pharmacokinetic modelling, it is crucial to consider two input functions to accommodate the blood supply from both the hepatic artery and portal vein. However, obtaining image-derived measurements of the portal vein poses challenges due to its small size and respiratory motion induced blurring. In this study, we aim to demonstrate how a dedicated PET/MR protocol can address these challenges and showcase accurate input function measurements of the portal vein by approximating the clinical setup using a dedicated liver phantom. ***Materials and Methods:*** A liver PET/MR phantom with fillable compartments, fabricated using 3D printing, was developed to replicate the anatomy of the human liver and the portal vein. PET/MR scans were conducted with simulated respiratory motion induced by a non-magnetic piezoelectric motor. The fillable liver and portal vein compartments were filled with FDG activity concentration of 4.1 kBq/cc and 78.8 kBq/cc respectively. The proposed PET/MR protocol involved acquiring high-resolution anatomical MR images of the portal vein, followed by a 4-minute PET scan parallel to a motion-tracing MR sequence. Motion tracking and deformation data were extracted from both MR and PET scans. The data was used to reconstruct motion compensated dynamic PET series. Anatomical MR images were employed for correcting partial volume effects in the input function measurements, obtained from the motion-corrected PET series. ***Results:*** With motion-compensated reconstruction the resulting dynamic series of PET frames were nearly motion-free, facilitating accurate time activity measurement of the portal vein input function. Following partial volume correction of these measurements, the resulting values demonstrated a close approximation of the true activity in the portal vein compartment, with maximum deviation of 5.1%. ***Conclusion:*** The suggested protocol showcases the clinical applicability of PET/MR imaging for pharmacokinetic investigations of the liver, ensuring precise quantification of the portal vein input function. This is demonstrated by successfully addressing the challenges in PET imaging and quantification related to respiratory motion and partial volume effects.

EP-0775

Parametric Images and Clinically Accepted Glucose Metabolism: A Validation Analysis

K. Tehlan[1,2,3], *F. De Benetti[3], R. Bundschuh[2], T. Wendler[1,2,3];*
[1]University Augsburg, Augsburg, GERMANY, [2]Universitätsklinikum Augsburg, Augsburg, GERMANY, [3]Technical University of Munich, Munich, GERMANY.

Aim/Introduction: Deriving pharmacokinetic parametric images from dynamic ^{18}F-FDG PET has become possible using physiology-aware neural networks [1]. The kinetic parameters of the 2-tissue reversible compartment model, namely K1 (mL/cm3/min), k2 (1/min), k3 (1/min), and k4 (1/min), describe the perfusion and the metabolic processes of glucose. Comprehensive literature on the expected values of the kinetic parameters is scarce, and parametric images are not conventionally used in clinical research. In this work we show that the generated parametric images are consistent with the current clinical knowledge of the metabolic pathways of glucose. ***Materials and Methods:*** The dataset included 23 oncological patients with heterogeneous tumour types. Dynamic ^{18}F-FDG PET scans were acquired using a long axial FOV (LAFOV) PET/CT scanner [2].The parametric images are generated by the neural network proposed by De Benetti et al. [1], using 18 patients for training and validation, and 5 for testing (including 3 patients with lymphoma, one with breast cancer and one melanoma). ***Results:*** The plausibility of the resulting parametric images was confirmed by an experienced nuclear medicine physician, and the kinetic parameters values per organ are consistent with [2].The predicted parametric images show high perfusion in the kidneys (K1=0.96, k2=1.30), and the liver (K1=0.58, k2=0.73). Brain and kidneys have a high phosphorylation rate (k3=0.30 and k3=0.07, respectively). We report high k1, k2, and k3 in the perfused regions of cancerous lesions, whereas they are absent in the cysts or in the necrotic regions of the tumours. Mediastinal glucose uptake (k3) was notably high in lymphoma patients. As expected [3], gluconeogenesis is observed in the liver (k4=0.25), the kidneys (k4=0.18), and intestines (due to patients fasting prior to imaging). ***Conclusion:*** The use of parametric images provides a novel method to non-invasively measure the perfusion and glucose metabolism throughout the body at a voxel level. Specifically, it facilitates the analysis of the kidney glucose metabolism, which is challenging with static PET images and has previously led to an underestimation of the kidneys' contribution to overall gluconeogenesis. In addition, the voxel-wise analysis of the k3 and k4 parametric images can give insights about the different regions of the kidneys with glucose uptake and gluconeogenesis, respectively. The agreement of the predicted parametric images with the current understanding of the glucose metabolism paves the way for a wider use of parametric images in clinical practice. ***References:*** [1] De Benetti, 2023. Report on respiratory motion amplitude in PET/CT

H. Zeng, *L. Shi, C. Sun, Y. Li, Y. Zhao, Y. Lu;*
United Imaging Healthcare, Shanghai, CHINA.

Aim/Introduction: The degradation of image quality due to patient respiratory motion has become a primary concern in clinical PET imaging. Despite the growing attention paid to respiratory motion (RM) correction methods, there lacks reports of the amplitude of RM at organ level. This study aims to bridge

this gap by assessing the motion amplitudes of internal organs affected by RM. ***Materials and Methods:*** A cohort of one hundred subjects (55/45 M/F,58.4±15.5 years old,64.8±12.1 kg,166.0±8.0 cm, Chinese population) underwent whole-body 18F-FDG (6.79±1.30 mCi) scans. The motion amplitude of each organ was estimated as follows: data-driven RM signal was extracted using centroid-of-distribution (COD), which followed by RM gated reconstructions. Attenuation correction (AC) was performed using deep learning-based attenuation map to avoid AC artifacts. Non-rigid registration was performed between inspiration and expiration gate, where the yielded deformation field (DF) was used as the RM amplitude estimate for each voxel. N=49 organ volumes of interest (VOIs) were generated using AI-based segmentation methods based on CT. The mean and standard deviation (SD) values of DF within each VOI were calculated. ***Results:*** The mean value of RM amplitudes within the VOIs ranged from 0.5-12.0 mm (SD,0.6-5.1 mm). The liver dome region exhibited the largest amplitude among all organs (12.0±3.8 mm), followed by pancreas (10.5±1.9 mm), right kidney (9.9±2.5 mm), left kidney (9.1±2.5 mm), stomach (9.9±2.7 mm), spleen (8.9±2.6 mm), heart (7.3±1.8 mm), aorta arch (3.3±1.4 mm), bladder (2.0±1.2 mm), while the right lung lower lobe (9.2±5.1 mm), right lung middle lobe (6.9±2.8 mm), left lung lower lobe (6.2±3.8 mm), left lung upper lobe (2.9±1.1 mm) and right lung upper lobe (2.5±1.9 mm). The chest and abdominal walls show amplitudes of 3.1±3.0 mm and 5.5±3.0 mm, respectively. Males exhibit 7.5% in average higher motion amplitude than females. ***Conclusion:*** This study provides a quantitative evaluation of the motion amplitudes of internal organs affected by RM in a PET dataset of 100 subjects among Chinese population.

Detection of cancer-associated cachexia in lung cancer patients undergoing whole-body [18F]FDG-PET/CT imaging

D. Ferrara[1], *E. Abenavoli[2], T. Beyer[1], S. Gruenert[3], M. Hacker[3], S. Hesse[4], L. Hofmann[4,5], S. Pusitz[3], M. Rullmann[4], O. Sabri[4], P. Sandøe[6], R. Sciagrà[2], L. K. Shiyam Sundar[1], A. Tönjes[7], H. Wirtz[5], J. Yu[1,3], A. Frille[4,5];*
[1]QIMP Team, Medical University of Vienna, Vienna, AUSTRIA, [2]Division of Nuclear Medicine, Azienda Ospedaliero Universitaria Careggi, Florence, ITALY, [3]Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [4]Department of Nuclear Medicine, University Hospital Leipzig, Leipzig, GERMANY, [5]Department of Respiratory Medicine, University Hospital Leipzig, Leipzig, GERMANY, [6]University of Copenhagen, Copenhagen, DENMARK, [7]Department of Endocrinology, University Hospital Leipzig, Leipzig, GERMANY.

Aim/Introduction: Cancer-associated-cachexia (CAC) is a metabolic syndrome that substantially decreases the quality of life and survival of oncology patients. We aim to assess the potential of whole-body [18F]FDG-PET/CT imaging for providing metabolic imaging readouts indicative of CAC in lung cancer patients. ***Materials and Methods:*** 347 lung cancer patients (LCP) underwent [18F]FDG-PET/CT imaging for clinical staging. Using the body mass index (BMI)-adjusted weight loss (WL) grading system (WLGS), LCPs were stratified into three metabolic phenotypes: "No CAC" (WLGS-0/1 at baseline and first follow-up: N=159, 52F/107M), "Dev CAC" (WLGS-0/1 at baseline and WLGS-3/4 at follow-up: N=90, 34F/56M), and "CAC" (WLGS-3/4 at baseline: N=98, 31F/67M). Abdominal organs, muscles, subcutaneous and visceral adipose tissue were segmented automatically from PET/CT images [1]. Organ volumes and standardized uptake values (SUV) normalized to aorta uptake (SUVaorta) were calculated and compared statistically across the three cohorts. A correlation analysis was conducted to study inter-organ connectivity using Spearman correlations. A machine-learning model was trained to classify the LCP in "No CAC", "Dev CAC" or "CAC". SHapley Additive exPlanations (SHAP) analysis was employed to identify the parameters that primarily contributed to CAC for each patient. ***Results:*** Mean SUVaorta were highest in "CAC" patients in most regions ($p<0.05$), except liver and kidneys; the corresponding organ volumes were smaller than in the other two cohorts. In "CAC" patients, a strong negative Spearman correlation ($\rho=-0.8$) was identified between mean SUVaorta and volumes of the fat regions. Machine-learning based classification into "CAC" and "No CAC" was 81% accurate, while classification into "No CAC" or "Dev CAC" was low (54%). SHAP analysis identified SUVaorta of the spleen, pancreas, liver, and fat as the key parameters for the prediction of CAC. ***Conclusion:*** Whole-body [18F]FDG PET/CT imaging reveals elevated uptake levels in multiple organs associated with the metabolic disease. Metabolic patterns in LCP with CAC were distinct for LCP without CAC. "Dev CAC" prediction was not possible given the variability of metabolic profiles and requires further analysis on larger cohorts. ***References:*** [1] L. K. Shiyam Sundar et al. Using machine learning and advanced filtering for denoising of simulated low-dose O-15 water PET sinograms to assess potential dose reduction in activation studies

M. Voskamp[1,2], *F. Büther[3], M. Mamach[4,2], J. Lücke[5,6], S. Salwig[5], H. Mousavi[5], F. Bengel[1], T. Lenarz[7,2], G. Berding[1,2];*
[1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Cluster of Excellence "Hearing4all", Hannover, GERMANY, [3]Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY, [4]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY, [5]Department of Medical Physics and Acoustics, Carl von Ossietzky University Oldenburg, Oldenburg, GERMANY, [6]Cluster of Excellence "Hearing4all", Oldenburg, GERMANY, [7]Department of Otolaryngology, Hannover Medical School, Hannover, GERMANY.

Aim/Introduction: Using radioactive tracers, positron-emission-tomography (PET) enables the assessment of increased neuronal activity with precise spatial assignment. In this regard, O-15-water is a useful tracer which allows statistical inferences on regional activations. As a basis to reduce the radiation exposure for future PET scans we simulated low-dose scans and evaluated the usefulness of machine learning (ML) to denoise sinograms. ***Materials and Methods:*** We included O-15-water-PET activation studies of five patients with different types of auditory implants in the cochlear (CI, n=1), brainstem (ABI, n=2) or midbrain (AMI, n=2). Patients were scanned in a full-ring PET/CT (LSO-Duo) during quiet and speech stimulation[1]. To simulate the application of lower radioactive doses we randomly reduced the number of coincidence events by different factors of the power of two. Normalised and corrected sinograms were used for reconstruction directly or after denoising with a Gaussian mixture-model-based machine-learning algorithm (GMM) or the advanced-filtering algorithm BM4D[2]. The outcome was assessed by computing (i) the signal-to-noise-ratio (SNR) in the reconstructed images, and (ii) the number of significantly-activated voxels in the auditory

cortices based on statistical-parametric-mapping (SPM). For the latter analyses, the number of available scans was also incorporated in the reduction level. ***Results:*** While reducing the scans without denoising led to a significant decrease in the SNR values on every reduction level compared to original scans ($p<0.05$), denoising with either BM4D or GMM was able to avoid a significant decrease in SNR up to a reduction factor of 32 and 64, respectively. Moreover, GMM was performing significantly better than BM4D when compared directly ($p<0.05$). In the SPM analyses of non-denoised data a reduction of coincident counts on every level led to a significant decrease in the number of detected activated voxel compared to the original (100% counts). Denoising with GMM was able to sustain the number of activated voxels up to a reduction factor of eight, while BM4D could sustain the same up to a factor of four. ***Conclusion:*** The present data indicates that the outcome in important parameters of activation studies could be sustained by suitable denoising if the patient would have been administered a significantly lower amount of radioactivity. We expect that denoising the sinograms with a GMM-based algorithm enables a dose reduction up to a factor of eight when being applied on the same PET system. ***References:*** [1]Berding G et al. Intra-subject and inter-group variability of whole-body [18F]FDG PET/CT imaging of healthy controls

D. Ferrara[1], *Z. Chalampalakis[1], Z. Chen[2], B. K. Geist[3], S. Gutschmayer[1], M. Hacker[3], S. Kinuya[2], K. Kluge[3], W. Langsteger[3], I. Rausch[1], L. K. Shiyam Sundar[1], S. Takeda[4], J. Taki[4], H. Wakabayashi[2], J. Yu[1,3], T. Beyer[1];*
[1]QIMP Team, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Nuclear Medicine, Kanazawa University Hospital, Kanazawa, Ishikawa, JAPAN, [3]Department of Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [4]PET Center, Kanazawa Advanced Medical Center, Kanazawa, Ishikawa, JAPAN.

Aim/Introduction: Whole-body [18F]FDG-PET/CT imaging is a clinically viable method for managing oncology patients. To investigate disease-associated inter-organ aberrations of metabolic profiles, a normative database of Standardized Uptake Values (SUVs) is needed. This multi-centre study assessed test-retest variabilities of mean SUV body weight (SUVBW) of key organs at different time intervals (90 min, 1 month, and 1 year) in healthy cohorts. ***Materials and Methods:*** This study included three cohorts of healthy controls undergoing test/retest whole-body or total-body [18F]FDG-PET/CT imaging, with the following different time lapses between the test and retest scans: 90 min for 19 volunteers (10M/9F, 76±17 kg) scanned in Austria (AUT_90min, uptake-time: 71±5 min), 1 month for 25 controls (13F/12M, 74±13 kg) imaged with a total-body system in Austria (AUT_1m, uptake-time: 58±6 min), and 1 year for 49 participants (8F/41M, 69±13 kg) scanned in Japan (JPN_1y, uptake-time: 61±1 min). CT images were automatically segmented into volumes-of-interest (VOIs) for the key organs: brain, myocardium, kidneys, liver, pancreas, spleen, lung, skeletal-muscle, and subcutaneous-fat using the MOOSE software [1]. Mean SUVBW and volumes were extracted from each VOI. Intra-control differences and distributions across the centres were assessed using relative percentage differences (%D) between test and retest, and t-tests. ***Results:*** In the AUT_90min, mean SUVBW exhibited significant intra-subject variation only in brain (%D=-3%, p=0.01) and heart (%D=-16%, p=0.02). AUT_1m did not exhibit test-retest mean SUVBW variations in any region. In JPN_1y, intra-control mean SUVBW differences were significant only in kidneys (%D=-3%, p=0.05). Liver uptakes on AUT_90min and JPN_1y data were comparable (%D<5%, p=0.66). In all 3 cohorts, weight changes of the subjects between test and retest were not significant. Overall, participants in JPN_1y had smaller muscle and fat volumes than AUT_90min and AUT_1m cohorts ($p<0.05$). ***Conclusion:*** Differences in mean SUVBW in the test-retest studies of healthy controls were minimal, particularly in less perfused organs, suggesting that building a normative database of FDG- SUVBW is plausible. However, confounders, such as differences in demographics and uptake time, may contribute to variations in mean SUVBW distributions and should be addressed. ***References:*** [1] L.K. Shiyam Sundar et al. "Fully-automated, semantic segmentation of whole-body [18F]FDG-PET/CT images based on data-centric artificial-intelligence". In: J Nuc Med (2022).

EP-0780

Impact of Delay Calculation Methods in LAFOV PET Kinetic Analysis

L. Providencia, *C. W. J. van der Weijden, P. Mossel, J. Somsen, G. Salvi De Souza, G. Luurtsema, R. A. J. O. Dierckx, A. A. Lammertsma, C. Tsoumpas;*
University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Large axial field-of-view (LAFOV) PET scanners enable whole body parametric imaging using image derived input functions (IDIF). However, whole-body kinetic analysis faces challenges, such as the need to correct for delay between tissue and IDIF tracer arrival [1]. The conventional approach, joint estimation, fits the delay as an additional parameter in the tissue compartment model, which is computationally demanding at a voxel-level. The leading edge (LE) method has been proposed as a efficient alternative, but its validation is limited to [18F]FDG bolus injections [2]. This study assesses the LE method for estimating delay in both bolus and non-bolus injections of [15O]H2O and [18F]MC225, respectively, and evaluates its impact on kinetic parameter estimation. ***Materials and Methods:*** Four LAFOV PET scans were performed: two 10 minutes scans after a 5 seconds [15O]H2O bolus injection (500 MBq) and two 60 minutes scans after an extended 60 seconds [18F]MC225 injection (143-200 MBq). IDIFs were extracted from the ascending aorta. For tissue activity curves, eight regions of interest (ROIs) were segmented using Total Segmentator (brain, kidneys, spleen, pancreas, gluteus, myocardium). The delay between IDIF and the ROIs was calculated using the joint estimation (JE) and LE methods [1]. Kinetic modelling was performed using a reversible single compartment model ([15O]H2O) and two-tissue compartment model ([18F]MC225), using the delays obtained with both methods. Delay values and kinetic parameters estimated using LE were compared with those obtained using JE. ***Results:*** For the [15O] H2O bolus injection, an average difference of 2.88±1.27 seconds was found between the delays estimated using LE and JE (R2=0.94). K1 and volume of distribution (VT) derived with both delays showed, on average, a relative difference of 3.6 ± 5.3% and 1.7±2.0%, respectively (Table 1). For the [18F]MC225 non-bolus injection, an average difference of 9.25±3.26% seconds was found between the delays estimated using LE and JE (R2=0.66), resulting in a relative difference of 10.19 ± 3.30% and 15.72 ± 14.11% for estimated K1 and VT, respectively (Table 2). ***Conclusion:*** For a [15O]H2O bolus injection, the LE method shows very good agreement with the traditional JE method, for both delay and kinetic parameters. For the slow [18F]MC225 injection, delay and

kinetic parameters obtained using the LE method showed a poorer agreement with the JE method, indicating that the LE method may not be the optimal approach in case of non-bolus injections. ***References:*** 1.Li EJ et al.,J Nucl Med. 2022 Aug;2.Wang Y et al.,J Nucl Med. 2023 Jul.

EP-0781

Optimization of Platelet Kinetic Calculations Using a Comprehensive Programmed Spreadsheet

E. Miñana Olmo, *Á. Alonso García, T. Chivato Martín-Falquina; Unidad de Radiofarmacia. Hospital General Universitario Santa Lucía, Cartagena, SPAIN.*

Aim/Introduction: Autologous radiolabelled platelets are used to assess platelet kinetics in patients with immune thrombocytopenic purpura (ITP), characterized by low platelet count in an otherwise healthy individual. Platelet kinetic and scintigraphic parameters can establish the pattern of platelet destruction, which is predictive of splenectomy success as second-line treatment. Data processing of samples tipically involves a combination of spreadsheets, statistical software and manual calculations. We aim to unite all those tools into a single software solution. ***Materials and Methods:*** Platelet kinetics were studied in 10 ITP patients, following Thakur et al.'s method [1]. Counting rates from the standard and blood samples at 30 minutes, 2, 3, 4, 24, 48 and 72 hours post-injection were input into a Microsoft Excel 2013 spreadsheet, along with patient sex, height, weight and platelet count. The spreadsheet was programmed for regression by linear, exponential and multiple-hit method. Multiple-hit variables were optimized using Excel VBA and the Solver add-in. Results were validated against those from RStudio and the COST program [2]. ***Results:*** The program calculates mean counts per minute for each blood sample, charting them as a percentage of total platelet activity. Platelet recovery, mean survival time and turnover are automatically reported and compared to reference values. Results showed no difference compared to validated software. Reggresion residuals are displayed, and users can choose wether to calculate mean survival time by weighted mean or multiple-hit method, the latter being recommended by the International Council for Standardization in Haematology (ICSH) as it provides the closest fit to data. ***Conclusion:*** We have developed a useful tool to analize and report platelet kinetics in a single validated spreadsheet providing instantaneous results. Removing manual calculations and reducing the programs involved have two main benefits: decreased risk of error and faster analysis. The software is available upon request to the authors. ***References:*** [1] Mathew L. Thakur, Lisa Walsh, Harry L. Malech, Alexander Gottschalk. Impact on SUV measurements of extravasation resulting from an intra-arterial administration of 2-[18F] FDG

V. de Sousa, *I. C. Ferreira, M. R. Victor, A. I. Santos; Hospital Garcia de Orta, E.P.E., Almada, PORTUGAL.*

Aim/Introduction: Standardized uptake value (SUV) is widely used as a PET semiquantitative parameter and can be calculated as the ratio between activity concentration (MBq/mL) and administered dose (MBq) multiplied by the patient's weight, corrected taking into consideration the delay between injection time and the scan start time. An extravasation event may occur during radiopharmaceutical administration, making the SUV value less accurate since the administered activity is not entirely distributed.The purpose of this study was to evaluate the impact on SUV measurements of an arterial administration followed by radiopharmaceutical extravasation, in a 2-[18F]FDG PET/CT scan. ***Materials and Methods:*** We evaluated a PET/CT scan in which extensive extravasation was observed in the right forearm and hand, after an inadvertent intra-arterial injection of 2-[18F]FDG. The administered activity was corrected based on activity and time of calibrated dose, time of injection and residual activity. Volumes of interest (VOI) were drawn using isocontour in three hypermetabolic lesions in the pancreatic region and the extravasation site (right forearm). Activity retained in the administration site was then estimated by multiplying the activity concentration by the volume of the extravasation site. Corrected SUV values were estimated based on the extravasation corrected administration activity and relative differences were calculated. ***Results:*** Administered activity was 223.48 MBq at time of injection. The images were acquired 82 minutes after and SUVmax was found to be 7.79 g/ml, 7.48 g/ml and 4.73 g/ml in lesions 1, 2 and 3 with volumes of 69.41 cm3, 12.17 cm3 and 8.71 cm3, respectively. The extravasation site had 452.65 cm3 and a SUVmax of 184.59 g/ml, resulting in an injection site activity of 69.20 MBq. The corrected distributed activity calculated was 154.28 MBq. Absolute relative differences between initial SUVmax and estimated SUVmax based on distributed activity were in the range of 44.86% to 46.85%. ***Conclusion:*** It was observed that inadvertent intra-arterial injection and significant extravasation can alter substantially SUV values. This could be of critical clinical importance for both an initial diagnosis and therapy response assessment PET/CT. Extravasation should thus be reported to avoid false interpretations when using SUV values.

EP-0783

Comparison of Relative Renal Function with ^{99}mTc-DMSA from Planar Imaging and 360-degree CZT SPECT/CT

B. Lima, *F. A. Mourato, C. A. Almeida, M. A. Almeida, A. L. G. Leal, A. F. F. Sales, J. C. A. Almeida, P. J. Almeida Filho; Real Hospital Português de Beneficência em Pernambuco, Recife, BRAZIL.*

Aim/Introduction: To compare the relative uptake of 99mTc-DMSA in renal scintigraphy obtained from planar imaging and 360-degree CZT SPECT/CT. ***Materials and Methods:*** Patients who underwent both imaging modalities on the same day were first included and those with functional DMSA exclusion or solitary kidney were excluded from analysis. The minimum, maximum, and mean relative uptake (with standard deviation) for each kidney using both methods were calculated. Relative uptake was categorized as follow: 45-55% (normal), 35-45% (mild reduction), 25-35% (moderate reduction), and <25% (marked reduction). Concordance between methods was assessed using the Bland-Altman test and the intraclass correlation coefficient for both kidneys. ***Results:*** To date, 24 patients have been analyzed. For the right kidney, the planar images showed a minimum uptake of 4.90%, a maximum of 97.10%, and a mean of 51.64% (SD 21.953); the left kidney showed a minimum of 2.90%, a maximum of 95.10%, and a mean of 48.61% (SD 22.032). With 360-degree CZT SPECT/CT, the right kidney showed a minimum

uptake of 2.50%, a maximum of 97.80%, and a mean of 50.41% (SD 22.370); the left kidney showed a minimum of 9.10%, a maximum of 97.50%, and a mean of 50.41% (SD 49.70). Regarding renal function classification, planar images revealed that 20.8% of patients had normal function, and 33.3%, 25.0%, and 20.8% had mild, moderate, and marked reductions, respectively. For CZT SPECT/CT images, 29.2% showed normal function, and 33.3%, 8.3%, and 29.2% had mild, moderate, and marked reductions, respectively. The Bland-Altman analysis showed a concordance between methods for the right kidney with limits of agreement from -8.0% to +5.5%, and for the left kidney from -8.2% to +11.8%. The intraclass correlation coefficient indicated good reliability, with a value of 0.8710 (95% CI: 0.7267-0.9419). ***Conclusion:*** The analysis demonstrates that the relative renal function measurements obtained from 360-degree CZT SPECT/CT are reliable and comparable to those obtained from planar imaging. Further patients are being enrolled in this analysis.

EP-0784

Enhancing Blood-Brain Barrier Penetration Prediction with Machine Learning and Explainable Artificial Intelligence

C. Spielvogel[1], *N. Schindler[1], S. L. Stellnberger[2], L. Papp[3], M. Hacker[1], C. Schröder[4], V. Pichler[2], C. Vraka[1];*
[1]Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Pharmaceutical Sciences, Division of Pharmaceutical Chemistry, University of Vienna, Vienna, AUSTRIA, [3]Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA, [4]Department of Computational Biological Chemistry, University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Predicting the penetration of the blood-brain barrier (BBB) is pivotal for the development of central nervous system (CNS) drugs and one of the bottlenecks of successful clinical phase I studies. In this study we employ traditional methods based on physico-chemical properties derived using experimental measurements and in silico methods. We enhance these molecular properties by machine learning (ML) integration to identify radiolabeled molecules capable of penetrating the BBB. ***Materials and Methods:*** For a dataset of 110 radiolabeled molecules previously measured in vivo for BBB penetration, we collected a total of 24 calculated and experimental molecular parameters such as molecular weight, polar surface area (PSA), logP values, hydrogen bond characteristics, and published values or prediction rules. Additionally, we enhanced these with novel in silico 3D calculations of non-classical polar surface area. Based on the collected data, we trained various ML models employing a 100-fold Monte Carlo cross-validation framework. Explainable artificial intelligence methods such as Shapley additive explanations (SHAP) and surrogate modeling were integrated to interpret the influence of individual molecular parameters on BBB penetration predictions. ***Results:*** The machine learning approach outperformed traditional predictive parameters, with the random forest model achieving the best performance for predicting binary BBB penetration (AUC 0.88, 95% CI: 0.87-0.90) and multiclass efflux transporter versus CNS positive and CNS negative prediction (AUC 0.82, 95% CI: 0.81-0.82). SHAP analysis identified the problem as highly multifactorial further emphasizing the benefit of multivariate models over single predictive parameters where novel and established parameters play important roles. A comparison with existing scoring systems like the CNS MPO (AUC 0.58) and BBB (AUC 0.67) scores (1,2) demonstrated the superior predictive capability of the ML model, while additionally allowing for the identification of efflux transporter substrates. ***Conclusion:*** Our integrated ML approach utilizing in vivo measurements and novel in silico approaches significantly enhances the prediction of BBB penetration, potentially reducing reliance on extensive experimental measurements and animal testing. This advancement not only accelerates CNS drug development but also offers a standardized database and hence a methodologically transparent approach through the application of explainable AI. ***References:***

Total-body Organ Metabolic Analysis for Patients with Different Intensities of Smoking using uEXPLORER

H. Wang[1,2], *Z. Huang[2], Y. Wu[3], Z. Liu[2], W. Li[2], M. Wang[3], G. Mok[1], Z. Hu[2];*
[1]University of Macau, Macau, CHINA, [2]Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Shenzhen, CHINA, [3]Henan Provincial People's Hospital & People's Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: Smoking history has always been an important indicator in lung cancer screening. We all know common sense that smoking damages lung function. However, whether smoking is harmful to other organs of total-body and what abnormalities may occur among various organs have not yet been studied. Moreover, it is also limited by the fact that previous scanners cannot simultaneously image the total-body. Until the emergence and development of total-body PET/CT (uEXPLORER), we can capture the metabolic status of organs throughout the body at the same time. This advanced technology facilitates the exploration of the correlation between abnormal metabolism among various organs of total-body. This work takes a group of lung cancer patients as an example and introduces the factor of smoking intensity to observe the metabolic abnormalities between organs and systems in different smoking groups. ***Materials and Methods:*** 18F-FDG PET and CT images from 60 anonymized subjects with 40 lung cancer patients and 20 healthy controls (HCs) are scanned from uEXPLORER PET/CT. Among lung cancer patients, smokers of varying intensities were surveyed (non-smokers: light smokers: heavy smokers = 21:4:15). For each scan, 17 regions of interests are outlined as total-body organs. To analyze the abnormal metabolism of different smoking groups, we construct individual abnormal metabolism networks and group abnormal metabolism networks, and establish a reference network based on HCs, inspired by the work of Sun et al[1]. ***Results:*** For the individual abnormal metabolism analysis, the proportion of smokers with significant abnormal metabolism is obviously higher than that of non-smokers. Besides, heavy smokers have a substantially greater proportion of metabolic decline compared with others for some organs like lungs, heart, kidneys and esophagus. In addition, for the group abnormal metabolism analysis, the abnormal metabolism of the lungs, esophagus and gland thyroid increases significantly as the intensity of smoking higher, and between the nervous system and other systems also show stronger abnormal metabolism. ***Conclusion:*** This work explores the impact of smoking intensity on total-body organ glucose metabolism in lung cancer. The proposed analysis method has the potential to be applied to other systemic diseases in the future. ***References:***

metabolic abnormities from a systemic perspective using whole-body PET imaging," European Journal of Nuclear Medicine and Molecular Imaging, vol. 49, no. 8, pp. 2994-3004, 2022.

EP-0786

Interrogating wastewater data for insight into medical radionuclide usage in the UK

A. Adrych-Brunning[1], *L. Sasi[2], N. Smith[1], J. Scuffham[2], R. Nutbrown[1];*
[1]TUV SUD Nuclear Technologies, Warrington, UNITED KINGDOM, [2]Royal Surrey County Hospital NHS Foundation Trust, Guildford, UNITED KINGDOM.

Aim/Introduction: The supply of medical radionuclides to the UK is integral for delivering healthcare for diagnosis and treatments. It is known that there is geographic variability on the quality of healthcare received [1], with the supply of medical radionuclides being limited in some areas. Understanding the quantity of radionuclides used in different areas of the UK will demonstrate which areas are underserved. However, getting access to the number of procedures performed per hospital is difficult considering data restrictions and different procedural recordings. As part of UK law, the discharge of radionuclides in aqueous waste must be estimated using assumed patient excretion factors and reported to the Environment Agency (EA) for monitoring purposes. We investigated whether the publicly available EA waste data inventory [2] could be used to show regional Usage of medical radionuclides. ***Materials and Methods:*** The total emission of all radionuclides via wastewater was interrogated from 2019 until 2022 using Python. The healthcare sites (both private and public) were separated from universities and other research sites to focus on just the radionuclides used in healthcare. For each radionuclide, the activity collated by the EA was divided by the recommended excretion factor [3] to get a total activity before administration at each of the healthcare sites. This total activity was cross-checked against detailed data of procedures performed with Tc-99m at the Royal Surrey, UK. ***Results:*** An interactive map was created that can interrogate the amount of radionuclides used at healthcare sites across the UK. The EA data when cross-checked with the detailed procedural data was on average consistent by 90%, providing confidence in the method applied. ***Conclusion:*** Estimates of environmental discharge of radionuclides can be utilised to understand the radionuclide usage in the UK. The map of radionuclide usage demonstrates clear geographic discrepancy in the amount of radionuclides used in the South compared with the North of the UK, which could be linked to healthcare deprived areas in the UK. The same methodologies could be applied in other nations where there are similar datasets available. ***References:***

New autoradiography image analysis tool combining overlain microscopy and histology in Carimas multimodal DICOM image analysis software

M. Miner[1,2], *S. Piirola[3,2], E. D. Atencio Herre[1], H. Liljenbäck[1], R. K. Aarnio[1,2], M. Ståhle[1], A. Roivainen[1,2,4];*
[1]Turku PET center, University of Turku, Turku, FINLAND, [2]Turku PET Center, Turku University Hospital, Turku, FINLAND, [3]Turku PET Center, University of Turku, Turku, FINLAND, [4]InFLAMES Research Flagship, University of Turku, Turku, FINLAND.

Aim/Introduction: Autoradiography is an essential tool for the many different stages of radiopharmaceutical development. It is often used in the assessment of thin layer chromatography (TLC) of synthesis products, metabolite products and can directly measure ex vivo tissues (whole and sections) with high spatial resolution. A new autoradiography analysis module was built into Carimas medical image analysis software to improve workflow and move closer to an all-in-one radiopharmaceutical image suite for in vitro, in vivo, and ex vivo studies. This new program was rigorously tested against existing software to examine its comparability and validity with existing workflows. ***Materials and Methods:*** Comparative testing of Carimas (Turku PET Centre) versus commercially available software (AIDA and TINA; Raytest) was done via practical methods and pixel-by-pixel testing in random clusters. First, fluorine-18-containing samples were exposed to phosphor imaging plates for 4 hours and scanned with a Fujifilm BAS-5000 using different encoding and resolution settings (8- and 16-bit depth as well as 25 µm and 50 µm resolution). Segmentation was performed on macro regions, pixel-by-pixel in random 6-by-3 clusters, and small 3×3 pixel areas extracting photo-stimulated luminescence (PSL) values. ***Results:*** All small region analyses were identical (after adjusting for a 1 pixel shift present in TINA) in PSL and PSL/mm2 output suggesting that the same quantification equation is employed in all three software suites. Macro regional analyses varied only by an average (n = 72 regions from 4 images and all analysed in each 3 software programs) of 0.084% ± 2.163, which was attributed to subtle differences in manual region drawing. A single factor ANOVA test suggested no significant differences between the three programs ($P = 0.999$, $F = 0.001$). ***Conclusion:*** The results showed no significant difference in data output between programs. Carimas was demonstrated to be an accurate program for analysing autoradiography image data and includes the ability to overlay histology images to conveniently guide segmentation.

EP-0788

Optimised model for elimination of baseline imaging for bile acid malabsorption tests

L. Perry[1], *R. Konstandelos[2], E. Souza[1], L. Bates[3], Z. Win[1];*
[1]Imperial College Healthcare NHS Trust, London, UNITED KINGDOM, [2]University College London Hospitals NHS Foundation Trust, London, UNITED KINGDOM, [3]NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM.

Aim/Introduction: Bile acid malabsorption tests commonly consist of a baseline intrinsic gamma camera image 15mins-3hours following oral administration of a 400kBq 75-Selenium tauroselcholic acid tablet.The image is repeated at 7days and retained activity calculated.The baseline data captures the administered activity attenuated by patient tissues and published literature reports this can be replaced by a mathematical model based on administered activity,patient height and weight[1] or body mass index[2].The gamma camera model used in our centre

was not used in these studies.We hypothesised patient age and sex could affect tissue distribution and attenuation and including these factors may improve model performance.The aim of this project was to evaluate the optimal model to replace baseline imaging for the gamma camera model in our institution. ***Materials and Methods:*** 152 consecutive studies were included in this audit. Patient height,weight,sex,age,administered activity and counts in baseline and day7 images were recorded.Baseline,background-corrected,geometric-mean counts were normalised to measured capsule activity.Multiple regression analysis was performed for combinatoins of height,weight,BMI,age and sex for 108 studies forming the development group.The adjusted R2 was used to rank the models.The best three models were tested on the remaining 44 studies forming the validation group and retained activity compared between modelled and acquired data using a 15% cut-off between normal and abnormal studies. ***Results:*** The best three models had adjusted R2values (and variables in model) of 0.822(height,weight,sex), 0.814(height,weight) and 0.787(BMI) for the development group with identical sensitivity(100%) and specificity(97.8%) across all models.For the validation group the sensitivity was 92% and specificity was 100% for the models based on height and weight and height,weight and sex.These values decreased to 88% and 95% respectively for the model based on BMI.The calculated retained activity was not statistically significantly different if modelled or acquired data was used. ***Conclusion:*** For the gamma camera at our centre the optimised model used patient height,weight and age to calculate baseline image data for bile acid malabsorption testing.However in the validation group this model had identical performance to the model based only on patient height and weight.Including patient sex did not improve the accuracy of the models.The simpler model based on height and weight is recommended for use. ***References:*** [1]Smout A, Scuffham J, Hinton P.Single scan SeHCAT studies:a model for the prediction of the 3-h counts.Nucl Med Commun 2021;42:1209-1216[2]Duchstein L, Haedersdahl C, Nielsen J, Flensborg A.Replacing the 3 hours imaging in 75Se-SehCAT bile acid malabsorption investigations with a calculated value.Eur J Nucl Med Mol Imaging46(Suppl1), p333(2019).

A New Innovative Tool for Estimating Radionuclide Demand for Diagnostic Medical Imaging at a National Level

A. Eisner[1], *N. A. S. Smith[2], R. Jena[3], R. F. Nutbrown[2];*
[1]School of Clinical Medicine, University of Cambridge, Addenbrooke's Hospital, Cambridge, UNITED KINGDOM, [2]TÜV SÜD UNITED KINGDOM, Warrington, UNITED KINGDOM, [3]University of Cambridge Department of Oncology, Cambridge, UNITED KINGDOM.

Aim/Introduction: For the 3 million people diagnosed with cancer in the UK annually, radionuclide imaging is an element of agreed diagnostic protocols. We hypothesise that utilisation of radionuclide falls below the levels expected by our national cancer burden. We therefore designed a mathematical model to estimate demand for radionuclide incidence assuming all patients are imaged according to best evidence. We present initial insights based on prostate cancer and lymphoma. ***Materials and Methods:*** We implemented a discrete event simulation whereby incidence data for a specific clinical indication can be inputted and fed through a series of calculations to produce radionuclide specific demand values (measured as number of scans required) which can then be compared to the baseline (actual number of scans performed). We used data for England in 2019. This model is composed of 3 main components. 1. Cancer registration data is stratified by stage and deprivation level. 2. Stage specific scan burden is determined from best evidence (national guidelines, published protocols and expert clinical consensus). 3. Division of scan burden by radionuclide type using the Administration of Radioactive Substances Advisory Committee guidelines and diagnostic imaging datasets. ***Results:*** We calculated an increase in demand from the baseline of 86% for prostate cancer, and 265% for lymphoma, according to best practice. We then split total demand by radionuclide type, resulting in an increased demand of 1319% for F^{18} and Ga-68 for prostate cancer, and of 264% for F^{18} for lymphoma. Additionally, analysis of incidence data demonstrated a disparity in cancer staging at diagnosis between the most and least deprived areas. For prostate cancer, in the least deprived areas, 39% are diagnosed at stage 1 and 18% at stage 4, compared to 35% at stage 1 and 23% at stage 4 in the most deprived areas. ***Conclusion:*** Our results highlight that we are not providing the appropriate number of scans required to adequately diagnose prostate cancer and lymphoma according to best practice. The degree of disparity between the baseline and the best practice models is significant. Additionally, the most deprived areas are disproportionally affected by the insufficient number of scans performed, resulting in worse patient outcomes. Going forward, this model will be utilised to calculate true demand for additional cancer types and other clinical indications, both at a national and regional level.

Local Distortion by Hot Object during Iterative MLEM Tomographic Reconstruction: Lessons from Myocardial Perfusion Imaging and Solution for Artifact Resolution

M. Qutbi;
Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: To assess performance of MLEM iterative reconstruction in presence of a hot spot or object in myocardial perfusion images and to visualize the artifact and quantify extent of involvement of adjacent and other more distant myocardial walls. Then, a technique for artifact resolution is proposed. ***Materials and Methods:*** A cardiac NCAT phantom is constructed that is used as "control" in which no nearby hot spot or highly intense object exists. Four other phantoms are generated by creating a lung lesion close to lateral wall of LV, with the goal of producing a hot spot with spot-to-myocardium ratio (S/M Ratio) of 0.5, 1, 2, and 4. Another uniformly-thick 3D ellipsoid phantom of LV with adjacent lesion is created in the direction of z-axis and lesion is located along the x-axis. Then, the entire phantom is rotated 90° along the y-axis and x-axis. Sinograms of phantoms are created by forward projection along z-axis and Poisson noise is added. An in-house MLEM algorithm is implemented and utilized for tomographic reconstruction. Images are reoriented along LV long axis. Slices are segmented and normalized to maximum pixel value of LV. Each image is subtracted from control image

to form error images. Circumferential profile curves are plotted. All computations are conducted in MATLAB software. ***Results:*** Tomographic image of control phantom reveals an almost uniform intensity in lateral wall. However, as S/M ratio increases, the distortion worsens. In the S/M ratio of 4, a remarkable artifactual defect and non-uniformity are seen along the lateral wall. The circumferential curves of all walls are almost superimposed except for the wall close to the object (or lateral wall of the LV), where the gap between curve of control and curves of other phantoms widens. For second phantom (hot object along the x-axis of LV), when phantom is rotated 90° along y-axis, hot spot is situated along z-axis, therefore, no defect is visualized in adjacent LV wall. ***Conclusion:*** Presence of a hot spot or object creates artifactual defect in adjacent region of organ-of-interest (LV wall close to the hot lesion) during reconstruction by MLEM algorithm. The severity and extent of defect are related to the relative intensity of hot spot and LV myocardial wall. A solution to prevent this artifact from occurring is rotating the volume before reconstruction in a way that the hot spot and the organ-of-interest (LV) are situated along z-axis on which reconstruction is performed.

EP-0792

Evaluation of post-reconstruction filters applied on Methionine brain PET

S. Yie[1,2,3], *D. Pigg[4], K. Kim[1,2,3], H. Choi[3], J. Eo[5], M. Kim[6], B. Spottiswoode[4], J. Lee[1,2,3];*
[1]Interdisciplinary Program in Bioengineering, Seoul National University, Seoul, KOREA, REPUBLIC OF, [2]Integrated Major in Innovative Medical Science, Seoul National University, Seoul, KOREA, REPUBLIC OF, [3]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [4]Siemens Medical Solutions UNITED STATES OF AMERICA Inc., Knoxville, TN, UNITED STATES OF AMERICA, [5]Department of Nuclear Medicine, Korea University Guro Hosptial, Seoul, KOREA, REPUBLIC OF, [6]Research Collaboration, Siemens Healthineers Ltd., Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Iterative reconstruction methods in nuclear medicine allows the reconstructed images to reflect the observed data and the data acquisition process. However, it suffers from low count rate and intrinsic system noise. To mitigate the noise in reconstructed images and better quantitative analysis of lesions, post-reconstruction filters such as Gaussian filters are utilized. Previously, we have shown that non-local mean (NLM) filter with entropy-based regulation can be effective to prevent blurring which is prevalent in Gaussian filters. This allows better delineation of lesions or anatomical structures. On the other hand, deep learning(DL)-based image filtering is known to be effective in automated feature extraction and generation. By proper design of unsupervised learning, the DL network can learn to denoise nuclear medicine scans without external dataset. In this work, we evaluate post-reconstruction filters based on reader studies. ***Materials and Methods:*** We acquired list-mode 11C-Methionine brain PET data (20 minutes post-injection) of 50 subjects using Biograph mCT40 and mCT64 PET/CT scanner. From each list-mode data, we reconstructed with full-, half-, and quarter-time of events. For each reconstructed image, we generated 4 types of image with filters; No filter, Gaussian, NLM, and DL. For DL filter, we used a network consisted of only 3-dimensional convolutional layers and leaky rectified linear unit activation functions. The network was trained for each subject with mean absolute error as fidelity and total variation as regularization. The scans were evaluated by two nuclear medicine physicians. The scans were graded in a 4-scale grade based on definition of lesion, definition of cortex, and noise in background. ***Results:*** In terms of definition of lesion, the grades were higher in order of Gaussian, DL, NLM and no filter for full count, and DL, Gaussian, NLM, no filter in lower counts. In terms of definition of cortex, the grades were unanimously higher in order of DL, Gaussian, NLM and no filter. For the background noise, the mean grades were higher in order of DL, Gaussian, NLM and no filter for full and quarter count, and DL, NLM, Gaussian and no filter for half count. The evaluators showed at least a fair correlation, and the highest correlation on definition of lesions. ***Conclusion:*** The DL filter was most effective and the NLM was limited in denoising the PET scan overall. The DL filter shows promise at removing image noise while preserving important features in brain.

EP-0793

Development of dedicated prostate TOF-PET based on ProVision detection concept: Initial image performance study

H. Vo[1], *T. Williams[2], K. Doroud[2], C. Williams[2], M. Rafecas[1];*
[1]Institute of Medical Engineering, Universität zu Lübeck, Lübeck, GERMANY, [2]Picotech SAS, Saint-Genis-Pouilly, FRANCE.

Aim/Introduction: The ProVision scanner is a dedicated prostate PET system with dual-head configuration; it employs a new detector technology that provides high intrinsic resolution as well as depth-of-interaction (DOI) and time-of-flight (TOF) information. This study aims to develop a flexible image reconstruction framework for limited-angle TOF-DOI-PET to study the image performance of the current (V1) and proposed upgrade (V2) versions of the ProVision scanner. ***Materials and Methods:*** The ProVision detectors1 consist of four crystal layers which provide discrete DOI information (Y). Each layer contains six 30 mm-long crystals axially oriented, with a crystal pitch of 2.8 mm x 4.4 mm. Dual-ended shared readout yields timing resolution of 170 ps and intrinsic resolution of 8.24 mm (Z) and 1.88 mm (X) (FWHM). V1 and V2 consist of 2x2 and 3x4 detectors per head, respectively. The head-to-head distance is variable; the minimum distance of 19.5 cm is used in this study. A limited translational motion is possible, but no rotation. Using V1 experimental data of point sources, we explored the effects of a small translational head offsetting on the mitigation of truncation artifacts. For image reconstruction, we have extended the list-mode Maximum-A-Posteriori (One-Step-Late) with Total-Variation regularisation to include TOF information. The system matrix and sensitivity include models for detector attenuation and position uncertainty via multi-ray sampling2. Building upon that investigation, the image performance of the forthcoming V2 was studied using Monte-Carlo simulations (GATE) and different phantoms. ***Results:*** For point sources V1 experimental data shows a 38% reduction in elongation (FWHM) through head offsetting. V2 with translational motion (±8.04 cm) achieves FWHM of 1.27 mm (X), 4.42 mm (Y) and 3.49 mm (Z) (FWHM). Elongations caused by the limited angular coverage distort the reconstructed images despite the availability of TOF and DOI information. Nonetheless, V2 setup yields positive results compared to other systems with similar configurations3,4 and the field-of-view is large enough to cover the whole prostate. ***Conclusion:*** The innovative ProVision detector concept shows promising outcomes for inexpensive stand-alone PET. Further improvements in the reconstruction and in timing resolution, together with the use of artificial intelligence, should contribute to reduce the elongation artefacts. ***References:*** 1K Doroud et al 2019 JINST 14 P01016 2J E Gillam et al 2013 PMB 58 2377 3J Stiles et al 2022 Sensors 22 4678 4A Sanaat et al 2024 Ann. Nuc. Med. 38 31-70.

EP-0794

Improving image quantification in dynamic whole-body PET-CT: BSREM vs. OSEM

S. Springer[1], *J. Basset-Sagarminaga[2], T. van de Weijer[1,2], V. B. Schrauwen-Hinderling[2,1,3], W. H. Backes[1,4,5], R. Wierts[1];*
[1]Department of Radiology and Nuclear Medicine, Maastricht University Medical Centre, Maastricht, NETHERLANDS, [2]Department of Nutrition and Movement Sciences, Maastricht University, Maastricht, NETHERLANDS, [3]Institute for Clinical Diabetology, German Diabetes Center, Leibniz Institute for Diabetes Research at Heinrich Heine University, Düsseldorf, GERMANY, [4]School for Mental Health and Neuroscience, Maastricht University, Maastricht, NETHERLANDS, [5]School for Cardiovascular Disease, Maastricht University, Maastricht, NETHERLANDS.

Aim/Introduction: Dynamic whole-body PET-CT is a powerful tool for in-vivo glucose metabolic rate assessment in tissue. However, in conventional short-axis field-of-view PET-CT systems, typically short frame durations are used, resulting in relatively high noise levels. This necessitates higher administered 18F-FDG activity and, consequently, higher patient radiation dose. Block sequential regularized expectation maximization (BSREM) reconstruction methods suppress noise and lead to better signal-to-noise ratios in static PET-CT than the widely used standard ordered subset expectation maximization (OSEM) reconstruction method. This study aims to investigate whether the accuracy and precision of the net 18F-FDG influx rate (Ki) in dynamic whole-body PET-CT is improved with the use of BSREM compared to standard OSEM. ***Materials and Methods:*** Dynamic whole-body PET-CT data of five patients scanned under insulin stimulation and hyperglycemia were utilized. These data consisted of a ten minute dynamic scan of the thoracic region followed by six whole-body passes. All data were reconstructed using both OSEM and BSREM according to EARL2 standards. Regions of interest (ROIs) were delineated for the myocardium, quadriceps, hamstring, liver, subcutaneous adipose tissue (SAT), and the descending aorta for the arterial input function. ROI noise levels were calculated for both reconstruction methods. Time activity curves (TACs) for tissues with varying 18F-FDG influx rates (Ki = 0.01-0.06 ml (cm3min)-1) were computationally simulated. Noise was added to the TACs to determine the effect of BSREM and OSEM on the accuracy and precision of Ki calculated with Patlak analysis as a function of ROI size. Patient images were similarly analyzed to calculate Ki in all ROIs, along with the precision and relative bias of both reconstruction methods as a function of ROI size. ***Results:*** The noise in all ROIs was 40-55% lower for whole body passes reconstructed with BSREM ($p<0.05$). Simulations showed no systematic bias in Ki with either reconstruction method. Ki precision decreased with decreasing ROI size, with that of BSREM being superior compared to OSEM at smaller ROI sizes. The patient data corroborated these results, with BSREM providing the best precision for small ROIs of 0.55 cm3 in the quadriceps, hamstring, SAT and liver ($p<0.05$). ***Conclusion:*** BSREM reconstruction of dynamic whole-body PET-CT data yields more precise Ki values, especially for smaller ROIs, compared to standard OSEM. The improvement in precision, particularly for smaller ROIs, suggests the potential of BSREM to enhance the detection and characterization of metabolic activity of small tumors in oncological settings, which needs further confirmation.

EP-0795

Preliminary results from a PET-derived synthetic CT for attenuation correction of FDG brain studies

I. Armstrong[1], *A. Coates[1], L. Partin[2], R. Fahmi[2], C. Hayden[2], J. Schaefferkoetter[2], B. Spottiswoode[2], S. Muthu[1];*
[1]Manchester University NHS Foundation Trust, Manchester, UNITED KINGDOM, [2]Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Attenuation correction (AC) in an essential component of PET-CT for accurate quantification that is performed using CT. For brain studies, the CT is for AC purposes only and hence offers no additional use in image interpretation. Recently, deep learning has been utilised to produce either synthetic CT or attenuation maps from emission data that can be used for AC. This potentially alleviates the need for a CT. This study presents preliminary comparison data of true CT and synthetic CT for AC of FDG brain scans in adult patients. High performance time-of-flight (TOF) has been shown to reduce the data inconsistencies - even in non-AC images and hence this approach may be especially suited to state-of-art PET systems. ***Materials and Methods:*** A 3D U-net was trained to produce a synthetic CT (SynCT) image using 100 non-AC FDG brain TOF PET images from 100 adults suspected of dementia, acquired on a SiPM PET-CT with 214ps TOF resolution. An independent testing set of 15 adult cases was separately acquired with attenuation corrected images produced from the CT and SynCT, derived from the 15-minute non-AC FDG PET images. Images were reconstructed with 3D iterative reconstruction using 8 iterations, 5 subsets, no post-filter and included TOF and resolution modelling. For AC PET voxels within the brain, the root mean squared error (RMSE) and mean voxel ratio (MVR) (SynCT-AC / CT-AC) were calculated for SynCT. Paired, but blinded, AC PET images were assessed visually in synchronised 3-plane orthogonal views using a matched "Spectrum" colour scale, by an experienced nuclear medicine physician to identify any clinically relevant discrepancies in FDG distribution between the paired images. ***Results:*** The mean and standard deviation of RMSE across the 15 patients was 350 ± 110 Bq/ml and the MVR was 0.985 ± 0.016. Visual review found no perceivable differences in FDG distribution in all but one case. This case showed a minor difference in basal-to-frontal intensity in the vertex region which would not impact clinical interpretation. One other case showed appreciable motion blur in the PET, but the synthetic CT generation was sufficiently robust that no difference was observable between the two AC images. ***Conclusion:*** This work has demonstrated that PET-derived synthetic CT can be used for AC of FDG brain scans with no impact on clinical interpretation. Further work involving comparison with normal databases is planned.

EP-0796

Real-life sensitivity gain with time-of-flight PET considering faster convergence of iterative reconstruction

K. O'Connor[1], *N. A. Bebbington[2], I. S. Armstrong[3];*
[1]Aalborg Universityhospital, Nuclear Medicine Department, Aalborg, DENMARK, [2]Siemens Healthcare A/S, Aarhus, DENMARK, [3]Manchester University NHS Foundation Trust, Manchester, UNITED KINGDOM.

Aim/Introduction: Classical Time-of-Flight (TOF) PET theory describes a gain in contrast-to-noise ratio (CNR), that can be considered an effective sensitivity gain. An additional benefit of TOF is the improved convergence rate of iterative reconstruction, requiring fewer updates to achieve comparable or superior levels

of convergence. This work aims to establish real-life sensitivity gain (RLSG) by studying the CNR differences between TOF and non-TOF when reconstruction has converged. ***Materials and Methods:*** The NEMA image quality phantom, filled with a 10:1 ratio with ~83MBq F^{18}-Fluourodeoxyglucose, was scanned on a photomultiplier tube (PMT)-based PET-CT system (22.1cm axial field-of-view (AFOV), 540ps timing resolution), and then on a silicon photomultiplier (SiPM) PET-CT (26.3cm AFOV, 214ps timing resolution) for 30 min. Using CT attenuation correction and 3mm Gaussian post-filter, TOF and non-TOF reconstructions were made with a range of updates. Volumes-of-interest were assigned to the background and 10mm sphere. Curves of maximum activity concentration recovery (ACR) for the 10mm sphere were plotted against updates for all reconstructions. The number of updates at which the ACR curves plateaued, considered as convergence, were determined for non-TOF and TOF reconstructions from each system. For converged reconstructions, CNR for 10mm sphere:background were calculated. RLSG was defined as the additional acquisition time that would be required for the non-TOF reconstructions to achieve comparable CNR to TOF reconstructions on both systems. ***Results:*** Convergence was reached at 20, 42, 70 and 72 updates for SiPM TOF, PMT TOF, SiPM non-TOF and PMT non-TOF reconstructions, respectively. For the PMT system, TOF produced a RLSG factor of 1.9 compared with non-TOF. The SiPM TOF produced a RLSG factor of 8.4 compared with PMT non-TOF. These RLSG values are 81-82% of the effective sensitivity gain reported for these systems according to classical TOF theory. The SiPM TOF had a RLSG of 4.4 times that of PMT TOF, which matches the 4.3 times reported difference in effective sensitivity between these two systems. SiPM TOF demonstrated a RLSG of 3.4 times that of SiPM non-TOF, although this value is subject to bias from TOF information being used to enhance accuracy of corrections also for non-TOF reconstructions on this system. ***Conclusion:*** Considering the TOF effect on noise reduction, through faster convergence, it is shown that the RLSG is close to the estimates from the effective sensitivity value. This information allows clinically valid comparison of scanner performance for determining feasible scan time or dose reductions with newer systems.

EP-0797

Improving deep learning synthetic attenuation map generation by incorporating anatomical context from both early and late frame images in myocardial perfusion PET

I. Armstrong[1], *C. Oldfield[1], L. Partin[2], C. Hayden[2], J. Schaefferkoetter[2], B. Spottiswoode[2], M. Memmott[1], P. Arumugam[1]; [1]Manchester University NHS Foundation Trust, Manchester, UNITED KINGDOM, [2]Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA.*

Aim/Introduction: Attenuation correction (AC) is an integral part of cardiac PET but can be challenging to register the heart position in a fast CT with PET data acquired over several respiratory cycles. We have previously demonstrated the utility of synthetic attenuation maps in rubidium-82 PET, generated using deep learning from non-AC PET in the late "uptake" portion of the image acquisition. While most cases showed good agreement to CT-derived attenuation maps, several examples showed discordant features in the synthetic maps: primarily missing pericardial fat (PCF) and vascular structures in the thorax. Pleural boundaries and vascular structures are more readily visible during the early frames, so this work evaluates an updated algorithm trained on dual PET image input: early blood-pool and late uptake to determine whether this resolves these discrepancies. ***Materials and Methods:*** A 3D U-net was trained using dual non-AC rubidium-82 input images: 0-120 second "blood-pool" and 120-300 second "uptake" to generate synthetic attenuation map (SynAC-D). Data originated from 100 routine rubidium-82 patients, with a 5-minute acquisition on a SiPM PET-CT. Fifteen independent cases were evaluated with the single input synthetic map (SynAC-S) and CTAC map. A visual comparison was performed by synchronised scrolling of these three maps. Discrepancies in anatomical structures were noted, using the CTAC map as reference. ***Results:*** PCF was noted on 5/15 of the CTAC maps and was well matched on the SynAC-D map but absent (n=2), reduced (n=2) and matched (n=1) on SynAC-S map. A large and highly tortuous descending aorta was observed in one case that was completely absent on SynAC-S but well matched on SynAC-D. A mismatch in size and position of aortic arch was seen in three SynAC-S maps, but well matched in SynAC-D maps. Liver and diaphragm positions were similar on the synthetic maps but differed in several cases compared with the CT. This was noted in previous work and attributed to the CT capturing the diaphragm at the extreme positions of the breathing cycle. ***Conclusion:*** Our preliminary work has demonstrated that dual time-point, deep-learning algorithm PET derived synthetic attenuation maps are closer to the ground truth CT derived maps than a single point attenuation map. This is likely due to improved anatomical detail of the vascular structures visible during the first-pass of the tracer infusion. Further work is planned to compare, both quantitatively and clinically, the impact on the AC of the PET image using this updated algorithm.

EP-0798

Sinogram-based Deep Learning Partial Volume Correction for Lu177-PSMA-SPECT

T. Kaprélian, *A. Extebeste, D. Sarrut; Université de Lyon, CREATIS; CNRS UMR5220; Inserm U1044; INSA-Lyon; Université Lyon 1; Centre Léon Bérard, France., Lyon, FRANCE., Villeurbanne, FRANCE.*

Aim/Introduction: SPECT-based dosimetry is an essential tool for Lu177-PSMA treatment optimization but quantification is limited by Partial Volume Effects (PVE) [1] due to collimator response. Resolution Modeling (RM) correction applied during reconstruction helps but is still insufficient and anatomy-based methods such as iterative Yang (iY) rely on a segmentation. We propose a segmentation-free Deep-Learning-based method for Partial Volume Correction (PVC) on SPECT sinograms, to be applied before reconstruction. ***Materials and Methods:*** 15 patient CTs were automatically segmented and used to generate 5,000 Lu177 activity maps with lesion-to-background activity ratios set stochastically. In addition, inhomogeneity was included in various organs, and lesions were randomly placed and shaped. Each map was forward-projected with the RTK [2] Software: once with Point Spread Function (PSF) modeling during projection (PPVE sinogram) and once without (PnoPVE sinogram). The PSF was obtained from Monte-Carlo (MC) simulations with Gate [3] of the Siemens-Symbia-Intevo with Medium-Energy collimator. Poisson noise was applied to PPVE to obtain PPVE/noisy. The PVCNet framework contained two consecutive networks: the denoising network h1 taking PPVE/noisy as input and trained with PPVE as target; the deconvolution network h2 taking the output of h1 as input and PnoPVE as target. Both networks used the projected attenuation map and the sinogram obtained after a preliminary reconstruction (OSEM, 8 subsets, 10 iterations) followed by a forward-projection as additional input channels. h1 and h2 were 3D-Unets with 3 encoding/decoding layers. The

PVCNet method was evaluated with two experiments: a real Lu177 IEC phantom acquisition (6 spheres, target-to-background ratio of 13) and a MC simulation of a patient with Lu177 activity in kidneys, spleen, urinary bladder and three lesions. Three PVC methods were compared: RM, iY (applied after RM) and PVCNet applied before image reconstruction. All images were reconstructed with the OSEM algorithm (8ss, 20it). ***Results:*** On the IEC acquisition, Recovery Coefficients (RCs) on the three larger spheres were better with PVCNet (0.52/0.58/0.67) than with RM (0.36/0.43/0.60) but still lower than with iY (0.66/0.66/0.83). This results was expected since iY uses the CT segmentation, making the comparison with PVCNet unfair. On patient simulation, RCs on lesions with PVCNet (0.44/0.47/0.67) were also higher than with RM (0.28/0.26/0.44) and lower than iY (0.47/0.53/0.77). Finally, the global Mean Absolute Error on the image corrected with PVCNet was lower than with iY (0.51/0.52 respectively). ***Conclusion:*** PVEs on SPECT images can be reduced by a deep-learning framework trained on simulated data. ***References:*** [1]Erlandsson, 2012[2]Rit, 2014[3]Sarrut, 2022.

EP-0799

Optimal reconstruction algorithm for FDG-PET tests using CaLM with application of NLM filters

K. Tsuda[1], *S. Takemoto[2], K. Onuki[3], K. Tanimoto[2], S. Kimura[2], K. Murakami[2];*
[1]Juntendo University, 3-2-12 Hongo, Bunkyo-Ku, Tokyo 113-0033, JAPAN, [2]Juntendo Hospital, 3-1-3 Hongo, Bunkyo-Ku, Tokyo 113-8431, JAPAN, [3]Juntendo Tokyo Koto Geriatric Medical Center, 3-3-20 Shinsuna, Koto-Ku, Tokyo 113-0033, JAPAN.

Aim/Introduction: The FDG-PET test is useful in the diagnosis and management of patients with various types of cancer. However, as the quality of PET images is affected by the reconstruction algorithm and acquisition method used, it is critical to select the optimal reconstitution algorithm. In recent years, the Clear Adaptive Low-Noise Method (CaLM), a new noise reduction method that applies Non-Local Means (NLM) filters, has been developed, which can be used to reduce static noise without affecting image contrast. This study investigated the optimal reconstruction algorithm when using CaLM in clinical FDG-PET imaging. ***Materials and Methods:*** Twenty-two patients who underwent FDG-PET tests (Celesteion, Canon) between April 2019 and March 2021 were included in this study. All the patients showed accumulation of FDG in the head and neck region that was not affected by respiratory movement. The acquisition time was set to 150 sec. The acquired image data were reconstructed using TOF-OSEM algorithms (PSF(-), Iteration: 3, Subset: 10), and these images represented normal images. The target image was reconstructed using three CaLM parameters (Mild, Standard, and Strong) for the acquired image data. All the obtained images were investigated quantitatively and visually. Quantitative assessment involved calculation of maximum SUV (SUVmax), coefficient of variation (CV), and contrast-to-noise ratio (CNR), after setting regions of interest on the lesions. The effects of reduction of static noise on these quantitative indices were statistically analyzed using Dunnett's test. A p-value of less than 0.05 was considered significant. ***Results:*** Quantitative assessment revealed that the SUVmax of target images with all three CaLM parameters (Mild, Moderate, and Strong) was equivalent to that of normal images. The CV of target images (Standard and Strong) was significantly reduced by 17% and 27%, respectively, as compared to normal images. The results also showed a significant improvement in CNR of the target images (Strong) by 71% as compared to normal images. Visual assessment revealed that target imaging using the Strong parameter allowed for better detection of lesions and had higher image quality than normal images. ***Conclusion:*** The results of our clinical study demonstrate that target imaging using the Strong parameter facilitated better detection of lesions and image quality in FDG-PET tests than normal images. This suggests that it is useful to apply the Strong parameter in the reconstruction algorithm when using CaLM.

Continuous Bed Motion (CBM) for Short Range Axial Scans in Long Axial Field of View (LAFOV) Scanners

V. Panin;
Siemens Medical Solutions USA, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: CBM ideally achieves uniform axial sensitivity in imaging. Its effectiveness has been demonstrated in Short Axial Field of View Siemens scanners, where there is a transition from Step and Shoot (S&S) multi-bed acquisition time to equivalent quality CBM bed speed. However, CBM's efficiency diminishes due to the discarding of lower sensitivity data during reconstruction, a disadvantage exacerbated in LAFOV. Nevertheless, in applications such as reducing CT scan dose to specific axial regions of interest (ROI) in LAFOV scanners, S&S becomes similarly inefficient. Here, CBM emerges as a competitive alternative, offering physiological benefits as patients are not required to remain stationary at the center of the scanner for prolonged periods. Additionally, CBM reduces the influence of highly attenuated oblique data by emphasizing direct plane data. ***Materials and Methods:*** Attenuation modeling was performed using an infinitely long cylinder phantom with a 20 cm diameter. The measured normalization of a Siemens Vision Quadra scanner was utilized to assess scanner sensitivity. These components were used to model patient axial sensitivity for CBM and S&S scans. The relationship between CBM speed and S&S acquisition time was derived to achieve maximum sensitivity matching for both scan modes. CBM and S&S acquisitions were also performed using a daily Quality Control (QC) phantom (30 cm long, 20 cm diameter) to verify image quality through assessment of phantom central plane roughness. ***Results:*** To achieve the best quality match with stationary bed imaging, CBM speed can be reduced by 40% through proper sensitivity modeling of patient scans. For instance, a CBM speed of 0.88 mm/s with an idealistic triangular sensitivity profile increases to 1.22 mm/s with a measured sensitivity profile to match S&S at 10 minutes per bed. By restricting the Maximum Ring Difference (MRD) from Quadra Ultra High Sensitivity (UHS) to 40 degrees, CBM sensitivity diminishes by only 2%, whereas S&S sensitivity drops by 9%. In High Sensitivity (HS) mode (18 degrees), CBM sensitivity drops by 54%, while S&S demonstrates a noticeable drop of 92%. These theoretical considerations are supported by measured phantom data. ***Conclusion:*** The analysis demonstrates that CBM benefits in LAFOV scanners by reducing the weighting of highly oblique data, resulting in CBM acquisition times that are significantly closer to static bed acquisition for short axial ROI applications. CBM favors direct data and smaller MRD use, thereby reducing potential issues associated with modeling of unknown attenuation maps beyond CT-measured ROIs.

EP-0801

Comparative Assessment of MRAC Techniques in Brain ^{18}F-FDG-PET Imaging: Atlas vs. ZTE Reconstruction on Integrated PET/MR

M. Wang, *X. Wang, C. Ruan, Y. Dai, G. Lu, Y. Miao, R. Wu, Z. Wang; Department of Nuclear Medicine,General Hospital of*

Northern Theater Command, Shenyang, CHINA.

Aim/Introduction: This study evaluates the impact of two MR-based attenuation correction (MRAC) methods, Atlas-based and ZTE-based(zero echo time), on brain PET imaging within an integrated PET/MR system. ***Materials and Methods:*** Retrospective analysis included 12 cases of 18F-FDG PET/MR and PET/CT imaging on 6 male and 6 female patients aged 41-58 years. PET/MR scans used Atlas-AC and ZTE-AC methods for 18F-FDG-PET reconstruction with PET/CT CT images as the gold standard AC-map. SUVr values for 116 AAL brain regions were computed using whole-brain references. Statistical analysis involved Spearman correlation and paired nonparametric tests. ***Results:*** Comparing PET images reconstructed with ZTE-AC and Atlas-AC to the gold standard CTAC, ZTE-AC exhibited significantly lower deviations. Correlations between brain region SUVr values from Atlas-AC and CTAC were 0.978, while for ZTE-AC, they reached 0.995. In the cerebellar region, correlations were 0.980 for Atlas-AC and 0.987 for ZTE-AC. The frontal lobe showed the lowest correlation in lobe analysis at 0.909 for Atlas-AC and 0.969 for ZTE-AC. Analysis of brain regions indicated that deviations under ZTE-AC were notably smaller than those under Atlas-AC, especially in regions like the hippocampus and posterior cingulate gyrus, where only 1.7% of brain regions exhibited over 5% absolute deviation with ZTE-AC compared to 6.4% with Atlas-AC. Inter-individual analysis confirmed that ZTE-AC reconstruction induced lower bias than Atlas-AC. ***Conclusion:*** PET images reconstructed with ZTE-AC exhibited reduced SUVr deviations compared to those reconstructed using Atlas-AC, relative to CTAC as the reference standard.

EP-0802

BPL vs OSEM FDG PET-CT; Which One to Choose?

G. Kaya, *H. Pala, M. Tuncel, Ö. Uğur;*
Hacettepe University Medical School Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Bayesian penalized-likelihood(BPL) iterative PET reconstruction algorithms were new field players. Decreased noise and improved lesion detection were the benefits of these algorithms. However, which algorithm must be used to hold standards in daily clinical settings is still controversial. This study investigated the clinical contribution of the BPL and digital motion correction(MC) vs OSEM algortihms. ***Materials and Methods:*** Patients who underwent FDG PET-CT reconstructed by OSEM, BPL, and BPL+MC for malignancy were included in this retrospective-single-center study. Clinical contributions of BPL algorithms were evaluated. Visual improvements in lesion conspicuity and detection of additional malignant lesions were noted. SUVmax and SUVmean of the liver, lesions under 10 mm (Group A) and lesions larger than 25 mm(Group B) by OSEM, BPL, and BPL+MC algorithms were assessed. ***Results:*** The study included 1503 images of 501 patients (F/M: 255/246). Median age was 58 (min-max: 4-87). Median BMI was 26 (range: 5.7), and median injected FDG activity was 233 MBq (min-max: 96-362). 235 group A lesions and 254 group B lesions were investigated. The majority of the evaluated lesions were located at lymph nodes(168), lung lesions(75), and liver(45). BPL reconstruction increased reader confidence for 16 patients in five liver lesions, three lungs (eg. OSEM-SUVmax: 1.9; BPL-SUVmax: 5.5), three adrenal, and five others. Only in two patients was an additional lesion detected in the liver and lung that was not visible in OSEM reconstructed images. However, no statistically significant difference or clinical contribution was observed between BPL methods with or without motion correction. The liver's mean SUVmean values were not statistically significant (2.2 for OSEM, BPL and BPL+MC). Median SUVmax of lesions for the group A were 2.7(0.6-14.4) for OSEM and 3.8 for BPL algorithms (increased 40% $p<0.001$) and also for group B 11.2 for OSEM and 11.8 for BPL algorithms (increased 5% $p<0.001$). ***Conclusion:*** ΔSUVmax of small lesions at BPL images were significantly higher than large lesions compared to OSEM. While reporting SUVmax values one must use same reconstruction algorithms especially for the smaller lesions. We recommend the usage of BPL algorithms for smaller lesions to increase reader confidence especially for liver.

EP-0804

Enhanced Diagnostic Imaging in Prostate Cancer: Evaluating the Impact of TOF and PSF Integration in 68Ga-PSMA PET/CT

S. Kheruka[1], *N. Al Makhmari[1], N. Al Maymani[1], S. AL Rawahi[2], A. AL Subhi[2], H. AlSaidi[1], S. Al Rashdi[1], A. Al Balushi[1], A. AL Jabri[2], K. Al Riyami[1], R. AlSukaiti[1];*
[1]SQCCCRC, Muscat, OMAN, [2]SQU, Muscat, OMAN.

Aim/Introduction: Prostate cancer poses considerable difficulties in diagnosis, requiring the use of accurate imaging tools. The use of PET/CT with Gallium-68 labelled Prostate-Specific Membrane Antigen (68Ga-PSMA) has greatly changed the way prostate cancer is found and categorised, making it more accurate and sensitive. Additional advancements, such as Time-of-Flight (TOF) and Point Spread Function (PSF), have enhanced the resolution of images. This is important for accurately identifying and outlining tumors, as well as making informed decisions about therapy. ***Materials and Methods:*** The current study conducted a comparison between conventional TOF and TOF coupled with PSF in PET/CT images of patients with prostate cancer. The analyzed metrics were Signal-to-Noise Ratio (SNR), Contrast-to-Noise Ratio (CNR), Metabolic Tumour Volume (MTV), Total Lesion Glycolysis (TLG), and Contrast Recovery Coefficient (CRC). The statistical study used paired t-tests to identify disparities and evaluate concordance between the approaches. ***Results:*** The results of our study indicate that the use of TOF+PSF led to notable improvements in both SNR and CNR. These gains were statistically significant, as shown by t-tests of -11.03 and -11.19 for SNR and CNR, respectively, with p-values less than 0.05. In contrast, the CRC analysis showed that there was no statistically significant difference between the two approaches, as demonstrated by p-values greater than 0.05. The TLG and MTV analyses demonstrated significant but subtle differences, indicating the nuanced advantages of TOF+PSF in metabolic evaluation and lesion characterization. ***Conclusion:*** The use of TOF and PSF greatly improves the quality of PET/CT imaging, which is crucial for achieving greater accuracy in diagnosing and managing prostate cancer. Although CRC demonstrated only little improvement, the progress in SNR, CNR, TLG, and MTV highlights the possibility of TOF+PSF to enhance therapeutic outcomes by improving imaging accuracy. ***References:*** Fanti, S., et al. EP-0805

Segmentation of active lesions in breast cancer from 3D whole-body PET/CT scans using the MONAI framework

G. Giovacchini, *E. Giovannini, C. Bachi, A. Milano, C. Aschele, A. Ciarmiello;*
S. Andrea Hospital, La Spezia, ITALY.

Aim/Introduction: Breast cancer is the second leading cause of cancer death worldwide. PET/CT could provide useful information for defining patient-specific treatment strategies. Operator-dependent assessment of total disease burden from PET/CT images is a time-consuming process hardly feasible in a clinical setting. In this study we present an unsupervised segmentation method of FDG-PET/CT active lesions in breast cancer based on the 3D U-Net architecture from the MONAI framework. ***Materials and Methods:*** The tumor was manually segmented from 121 PET/CT images by two expert radiologists. Patients were splitted into training/test subsamples of n = 97 and n = 24 patients respectively.Primary tumor manual annotation was performed on fused PET/CT under PETVolume Computerized Assisted Reporting (PETVCAR version 2.0). PETVCAR uses an adaptive iterative volume delineation algorithm able to automatically segment the target volume from background tissue using a SUVmax threshold of 2.5 and a 3D isocontour of 41% of the maximum voxel value measured in the target lesion Automatic segmentation model used a variant of the Medical open network for AI (MONAI) library called DynUnet. MONAI provides a library of deep learning algorithms specifically designed to support diagnostic models based on medical images. The network was implemented with five layers each composed of two convolutions with $3 \times 3 \times 3$ kernels. Network output layer has a soft-max activation and a threshold of 0.5, which generates a binary image corresponding to the predicted structure. A dice similarity coefficient (DSC)-based loss function and the Adam optimizer were used during training. DynUnet was trained for 300 epochs. DCD index was used to assess the performance metric by measuring the degree of regional overlap between manual and unsupervised segmentations on test dataset. ***Results:*** The train loss progressively decreases, indicating the stability and accuracy of the optimization algorithm. The Dice index reaches the best performance with a plateau at epoch 266. At this epoch the model shows values of 0.27 and 0.61 for train loss and Dice index respectively. ***Conclusion:*** These results show that the presented segmentation technique has the potential to automatically identify lesions with high glucose metabolism in breast cancer.

EP-0806

Effects of Deep Learning-Based Image Quality Enhancement on a New-generation Digital-BGO PET System, Omni Legend 32 for ^{18}F-FDG Whole-Body Examination

K. Miwa[1], *S. Yamagishi[2], S. Kamitaki[2], K. Anraku[2], T. Yamao[1], N. Miyaji[1], K. Wachi[1], S. Mashiko[1], K. Oguchi[2];*
[1]Fukushima Medical University, Fukushima, JAPAN, [2]Aizawa Hospital, Nagano, JAPAN.

Aim/Introduction: The digital BGO PET/CT system, Omni Legend 32 (GE HealthCare), incorporates BSREM image reconstruction and a deep learning-based time-of-flight (TOF)-like image quality enhancement process (Precision DL, PDL). This study aimed to define the fundamental characteristics of PDL using clinical images. ***Materials and Methods:*** Thirty clinical whole-body 18F-FDG PET/CT examinations acquired on the Omni Legend 32 PET/CT system were included. All PET/CT examinations were performed with an acquisition time of 90 sec per bed position, with a matrix size of 384×384. Images were reconstructed using the OSEM+PSF and the BSREM at β values of 200, 300, 400, 500, and 600, combined with three different PDL strength levels (Low, Medium, High). Liver noise levels, mean SUV (SUVmean), and the tumor signal-to-noise ratio (SNR), signal-to-background ratio (SBR) and maximum SUV (SUVmax) were evaluated. ***Results:*** Noise levels decreased as a function of increasing β values in the BSREM, resulting in a higher SNR, but lower SBR. Combining PDL with BSREM, all β values produced better results in terms of noise, SNR, and SBR compared with OSEM. The stronger the application of the PDL method (High > Medium > Low), the higher the noise levels and SBR observed. The effect of PDL intensity on SNR varied among patients. The liver SUVmean did not significantly differ between the reconstruction methods, but tumor SUVmax was higher with BSREM than OSEM, and further increased with PDL. ***Conclusion:*** The combination of BSREM and PDL significantly enhanced the SUVmax of tumors and image quality compared with OSEM. The intensity of PDL modestly impacted tumor detectability, although it varied among patients. The β value influenced image quality and tumor detectability more than the intensity of the PDL, suggesting that the intensity of the PDL should be determined after setting β values. ***References:*** Shin Yamagishi*, Kenta Miwa*, Shun Kamitaki, Kouichi Anraku, Shun Sato, Tensho Yamao, Hitoshi Kubo, Noriaki Miyaji, Kazuhiro Oguchi. Performance characteristics of a new-generation digital-BGO PET/CT system Omni Legend 32 according to NEMA NU2-2018 standards, 2023, J Nucl Med, 64(12), 1990-1997. (*Contributed equally).

Validation of Dynamic Stochastic Resonance (DSR) for converting a low-count nuclear medicine (NM) image into a high-count image: a Phantom Study

A. Pandey[1], *S. Kumar[1], J. Chaudhary[1], P. Kumar[1], P. D. Sharma[2], C. Patel[1], R. Kumar[1];*
[1]All India Institute of Medical Sciences, New Delhi, INDIA,
[2]SGTB Khalsa College, University of Delhi, New Delhi, INDIA.

Aim/Introduction: In DSR, a controlled amount of noise is added to the image itself, to improve the signal-to-noise ratio. In brief, It can be explained using motion dynamics of a particle oscillating in a bistable double-well system, in the presence of a weak periodic signal, and noise, the double well gets tilted back and forth asymmetrically following the equation: xn+1= xn+δt [axn-bxn3+Signal+Noise], where Signal is the image and Noise is the internal noise of the image. We optimized the value of number-of-iterations and δt while keeping a = 0.5, and b = 0.185 as constant in the above equation to validate the role of DSR in converting a low-count NM image into a high-count image. ***Materials and Methods:*** A phantom was made of patient tubing (used for intravenous administration) and plastic box. 88.8 MBq of Tc-99m pertechnetate was administered in the phantom and then dynamic study of the phantom was acquired at 0, 3.3, 6.10, 8.54, 10.07, 20.45, 23.55 and 26.19 hour in 256 X 256 image matrix, and 30 seconds per frame for 10 minutes duration. High-count image was formed by summing all the frames of that study. Each low-count image (first frame of the study) after processing with DSR was compared with gold standard image (high-count image from 0 hour study). A MATLAB script was written for reading and processing the low count image using DSR iterative equation. At each value of δt = (0.1, 0.2,0.3,0.4,0.5, 1.0, 2.0, 2.5, 3.0, 4.0, 5.0, 5.5, 6.0, 7.0, 8.0, 9.0, 10.0, 10.5, 15.5, and 25.5), 30 iterations were performed that resulted in 30 high-count images (each iteration yielding one image). DSR processed images were subjectively and objectively (using SSIM metric) compared with high-count

gold standard image. ***Results:*** The optimized value of number-of-iterations and δt were found to be 30 and 0.4, for converting a low-count nuclear medicine image into a high-count image; the SSIM value of transformed low-count images was around 0.9923. The DSR transformed image (for 0 hour study) visually looks identical to high-count gold standard image. However, DSR transformed image (for 26.19 hour study, low-count image was having minimum counts) visually did not look identical to high-count gold standard image. ***Conclusion:*** The application of DSR algorithm can transform low-count NM image into a high-count image, whether the transformed high-count image will look identical to high-count gold standard image depends on the quality of the input low-count image.

EP-0808

Data Driven Head Motion Detection, Tracking and Correction in FDG Brain Positron Emission Tomography

V. Dao[1,2], *E. Mikhaylova[3], R. Aykroyd[2], J. van Sluis[1], C. Tsoumpas[1,2]; [1]University Medical Centre Groningen, Groningen, NETHERLANDS, [2]University of Leeds, Leeds, UNITED KINGDOM, [3]Positrigo, Zurich, SWITZERLAND.*

Aim/Introduction: In this study, we perform motion detection, tracking, and correction on simulated brain FDG PET scans using a dedicated brain scanner. ***Materials and Methods:*** A motion-free frame (300s) [jv1] [VD2] from one FDG patient (injected with 2MBq per kg) and corresponding CT was used to simulate tracer distribution using the open-source GATE software and exported as listmode. Bottom-up segmentation (BUS), a method that start with lots of time points where motion is assumed to occur then slowly remove all the incorrect time points, apart from the time points where motion probably occurred. Using BUS method, we can test for temporal and spatial sensitivity of motion detection, respectively, using the following simulation:1. In the first simulation we displaced the image (from left to right ear) every 10 seconds first by 3mm and gradually reducing the displacement by 1mm until reaching 0.5mm. This is for the spatial sensitivity of detecting motion.2. In the second simulation a fixed displacement of 3mm with an initial 10-second interval, repeated for ten cycles, reducing the interval by 2 seconds each cycle.A final simulation applied motion (10mm in each direction and rotation of 10 degrees in left to right ear and 10 degrees in chin to forehead every 150 seconds). Each [jv3] [VD4] frame, generated from BUS, is reconstructed using expectation maximization maximum likelihood estimation (EMML) with attenuation and scatter correction (via Single Scatter Simulation) using open-source software STIR with no post-filters. Rigid motion was estimated using a software called NiftyReg and motion correction was done using re-weighted average transform. For the evaluation, we use root mean square error (RMSE, measured in second for motion detection and tracking). A comparison static (no motion), non-motion-corrected (non-MoCor) and motion corrected image (MoCo) using visual analysis. ***Results:*** Simulation 1.) BUS method consistently detected motion up to 2mm. Simulation 2.) The BUS method consistently detected motion up to 6 seconds interval. The root mean squared error (RMSE) for motion tracking is [jv1] no more than 4mm. The MoCo images shows improvements over the non-MoCo but not as good as static. ***Conclusion:*** BUS method can detect motion and produce motion free frame for image reconstruction but better method for motion tracking is required to observed further improvement in image quality.

EP-0809

Impact of parameters in Block sequential regularized expectation maximization reconstruction with relative difference penalty for quantitative bone SPECT imaging using a ring-shaped CZT SPECT

K. Wagatsuma[1,2,3], *H. Matsushita[1], Y. Sato[4], Y. Toda[2], T. Hirakawa[1], K. Miwa[5], H. Sato[4], K. Yamaguchi[3]; [1]Kitasato University, Sagamihara-shi, JAPAN, [2]Kitasato University Graduate School of Medical Sciences, Sagamihara-shi, JAPAN, [3]St. Marianna University School of Medicine, Kawasaki-shi, JAPAN, [4]St. Marianna University Hospital, Kawasaki-shi, JAPAN, [5]Fukushima Medical University, Fukushima-shi, JAPAN.*

Aim/Introduction: The block sequential regularized expectation maximization (BSREM) reconstruction algorithm, which incorporates a relative difference penalty (RDP) and is known as Q.Clear™, has been integrated into the StarGuide system, marking its debut in single photon emission computed tomography (SPECT) systems. Although BSREM is well established in positron emission tomography imaging, its impact on SPECT imaging remains to be determined. The aim of the present study was to optimize reconstruction parameters such as update number, gamma factor, and beta value in BSREM to obtain quantitative bone SPECT images. ***Materials and Methods:*** A thoracic spine phantom was employed to replicate the thoracic region of a standard Japanese person. The vertebral body, normal spine, and simulated tumor were filled with a mixed 99mTc and K2HPO4 solution to simulate bone density. Activity concentrations were set at 8, 50, and 300 kBq/mL for the main body, vertebral body and normal spine, and simulated tumor, respectively. The phantom was scanned for five minutes under clinical conditions using the StarGuide. Reconstruction parameters were fine-tuned in the order corresponding to 100 - 200 iterations × subset (I×S) with/without scatter correction (SC) based on dual energy window method, 2 - 25 gamma factor with/without SC, and 0.90 - 1.10 beta value from manufacturer recommended conditions (I×S, 10×10; gamma factor, 2; beta value, 1.00). The %contrast in simulated tumor and reference region and background (BG) variability (%) were evaluated for each parameter setting. ***Results:*** The %contrast remained unchanged by update number, regardless of the presence or absence of SC. The reference region's %contrast was overestimated when SC was employed. The BG variability remained below 7.0% at fewer than 40 subsets but increased with higher subsets. The %contrast improved with a higher gamma factor but decreased with a higher beta value. Conversely, the BG variability decreased with a higher beta value. The BG variability was lower with SC than without. ***Conclusion:*** A limit cycle was observed at 40 or more subsets. A higher gamma factor enhanced %contrast by preserving edges. Beta value reduced image noise when using SC. %contrast with SC was overestimated due to attenuation correction errors. The optimal settings were determined as 100 (5×20) iterations × subsets and a gamma factor of 15 for SC and 10 without SC for quantitative bone SPECT imaging. Visual evaluations using clinical bone SPECT images are required to determine optimal beta value.

EP-0810

Impact of Reconstruction Algorithms on Digital PET/CT: Evaluating Small Pulmonary Nodules

R. Albergueiro, *P. Soeiro, P. Dias, A. L. Carvalho; Unidade Local de Saúde de São João, E.P.E, Porto, PORTUGAL.*

Aim/Introduction: Quantitative Positron Emission Tomography (PET) plays a crucial role in the detection and assessment of

pulmonary nodules, which is a challenging structure due to the increased number of small size nodules and respiratory motion's influence. The partial volume effect (PVE) often underestimates radiotracer uptake in small lesions due to limited spatial resolution1. This study compares various methods of PET/CT reconstructions by determining contrast and activity recovery coefficients (CRCs and ARCs). PVE correction was also applied in the lesions mean and maximum Standardized Uptake Values (SUV). ***Materials and Methods:*** A NEMA phantom was scanned on a digital PET/CT system and reconstructed using ordered subset expectation maximization (OSEM) with time of flight (TOF), OSEM with TOF and point spread function (PSF), and Q.Clear with varying β values (350-850). CRCs and ARCs were calculated and compared with Wilcoxon tests, fitting ARCs to sphere volume and diameter1. Fifteen adult patients were randomly selected for pulmonary nodule evaluation using consistent equipment, with scans reconstructed using identical algorithms. Exclusion criteria included undefined nodules, larger than 3 cm, semi-solid, cystic, or ground glass nodules. Mean and maximum SUVs of small pulmonary nodules were measured, PVE-corrected, and compared using Friedman tests, with ΔSUVmean and ΔSUVmax calculated for PVE correction percentage increase. ***Results:*** Phantom results showed that Q.Clear produced higher CRCs and ARCs values compared with other methods (p=0.03). Multiple Q.Clear reconstructions showed decreasing ARCs with higher β, indicating uptake underestimation, however without statistical significance. ARCs data showed a good fit to both functions for all reconstructions (R2=0.98). Patients' nodules had a mean diameter of (12±5) mm. Both mean and maximum SUV lesions with Q.Clear illustrated significant differences from those reconstructed with other algorithms (p<0.003). After PVE correction, highly significant differences (p<0.003) still existed in the SUV values measured by Q.Clear compared with those measured by the other two algorithms. ΔSUVmean were 114.1%, 113.9%, 78%, and 104% for OSEM TOF, OSEM TOF-PSF and Q.Clear (β=350 and β=850), respectively. ***Conclusion:*** The Q.Clear algorithm improved PET/CT accuracy towards the true uptake in both phantom and clinical studies, enhancing quantification of the ARC and CRC values. This could have a significant impact on the early diagnosis of small malignant pulmonary lesions before they grow to 8 mm. ***References:*** 1. Zhifang Wu, Binwei Guo, Bin Huang et al. Phantom and clinical assessment of small pulmonary nodules using Q.Clear reconstruction on a siliconphotomultiplierbased timeofflight PET/CT system.Sci Rep 11, 10328 (2021).doi: https://doi.org/10.1038/s41598-021-89725-z.

EP-0811

Examining a Deep Learning Algorithm for Generating Time-of-Flight (TOF) Images from Non-TOF Low-Activity [18F]FDG PET Data

A. Lazar[1], *M. Olivieri[1,2], G. Matassa[2], D. Tosoni[3,4], A. Del Vecchio[4], M. Sollini[1,2], A. Savi[2], A. Chiti[1,2];*
[1]Vita-Salute San Raffaele University, Milan, ITALY, [2]Nuclear Medicine Department, IRCCS San Raffaele Hospital, Milan, ITALY, [3]University of Milan, Milan, ITALY, [4]Medical Physics Department, IRCCS San Raffaele Hospital, Milan, ITALY.

Aim/Introduction: Time-of-flight (TOF) PET imaging offers advantages in sensitivity gain, notably improving image quality. Acknowledging these benefits has led to alternative methods for non-TOF PET systems, such as integrating deep neural networks to generate TOF-like images. In this study we evaluate the effectiveness of various deep learning (DL) configurations when applied to non-TOF [18F]FDG PET datasets acquired over different acquisition times to simulate reduced-activity (1.6-2 MBq/kg) scans, aiming at identifying parameters that can optimize image quality and diagnostic accuracy. ***Materials and Methods:*** Our protocol for whole-body [18F]FDG PET/CT includes an administration of 2.5 MBq/Kg and an acquisition time of 1.5 min/bed. List mode data from 35 [18F]FDG PET scans acquired on a BGO-based PET/CT system (axial field-of-view=32 cm) were sorted to sinograms using varying time durations to simulate studies with 20%-33% activity reduction, and then reconstructed through block-sequential-regularized-expectation-maximization(BSREM) techniques. Regularization parameters(β) of 850, 600, and 450 were assigned to low (1 minute), medium (1.2 minutes), and high (1.5 minutes) count statistics, respectively. DL algorithms were applied with low-, medium-, and high-precision settings, resulting in six algorithm configurations: 1minβ850, 1minβ850-LPDL, 1.2minβ600, 1.2minβ600-MPDL, 1.5minβ450, and 1.5minβ450-HPDL. Standardized uptake values (SUV) and standard deviations(SD) both in target lesions and normal liver tissue were measured. Image quality was assessed by calculating Noise, as SDliver/SUVmean-liver, and signal-to-noise ratios(SNR), as SUVmax-lesion/Noise. Two nuclear medicine physicians rated the images based on a five-point scale (1-5, where 1-optimal) regarding noise, target-to-background contrast(TBC), sharpness, and diagnostic confidence(DC). Mean values and SDs were reported, and interobserver agreement was assessed using Cohen's kappa. ***Results:*** In quantitative evaluation, images with DL configuration showed better performances in all considered parameters. Mean SUVmax values were 2.30±0.84, 3.12±1.10 and 4.08±1.48 for 1minβ850-LPDL, 1.2minβ600-MPDL and 1.5minβ450-HPDL, respectively. Regarding image quality, all DL reconstructions displayed reduced noise levels, with a similar range of values: 0.11±0.02, 0.12±0.02 and 0.12±0.01 for 1minβ850-LPDL, 1.2minβ600-MPDL and 1.5minβ450-HPDL, respectively. The highest SNR was calculated for 1.5minβ450-HPDL (33.18±11.6), followed by 1.2minβ600-MPDL(27.25±10.13). In qualitative evaluations, DL configurations demonstrated superior noise performance, with 1minβ850-LPDL (1.61±0.75,κ=0.697,p<0.01) and 1.2minβ600-MPDL (1.70±0.71,κ=0.661,p<0.01) presenting the lowest noise levels. 1.5minβ450-HPDL exhibited the highest visual scores regarding TBC (1.73±0.76,κ=0.775), sharpness (1.79±0.70, κ=0.858), and DC (1.47±0.79,κ=0.882), p<0.01 for all. ***Conclusion:*** Our study demonstrates that integrating DL into non-TOF PET imaging significantly enhances image quality and diagnostic accuracy in low-activity [18F]FDG examinations. This enhancement needs a balanced trade-off between injected activity or scan/bed duration, and DL configuration, to optimize imaging characteristics.

EP-0812

Investigation of photopenic artifact in pet imaging due to arms motion: effect of scatter in a phantom experiment

R. Cuevas Jurado, *E. Prieto Azcárate, P. Echegoyen Ruíz, K. Hirschmüller, J. Martí-Climent;*
Clínica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: Assess the accuracy of different scatter correction techniques used in PET imaging when photopenic artifacts appear due to patient's arm movement. ***Materials and Methods:*** To simulate the patient, two 68Ge/68Ga cylindrical phantoms were used, the first one (thorax_phantom) with 9.6kBq/ml, and the second one (abdomen_phantom) with 4.1kBq/ml. In order to mimic the arms alongside the body, two 1-litre bottles, containing a concentration of 18F similar to that of the abdomen_

phantom, were placed on either side of the thorax_phantom. After motion-free CT and PET acquisition (matched_PET/CT), the bottles were moved at a slight angle (≈10°) and a second PET scan (mismatched_PET/CT) was performed simulating the movement of the patient's arms between CT and PET. Each acquisition was reconstructed four times, with each available scatter correction technique: SC_Relative (standard method for clinical studies), SC_WB_Relative, SC_Absolute, SC_WB_Absolute. Both visual and quantitative analyses were conducted. For quantitative analysis, a circular region of interest (ROI) was delineated in each of the central slices of the thorax_phantom, and the mean standard uptake value deviation (Δ(SUVmean)) in each ROI was assessed (Pmod package). Values of Δ(SUVmean)<5% were accepted. ***Results:*** In the matched_PET/CT with clinical reconstruction, a photopenic artifact was observed in the slices around the end of the bottles (axial extent of 45mm, maximum Δ(SUVmean)=-12%). This first image was used as a reference to isolate the effect of motion. In the mismatched_PET/CT, the use of either SC_Relative or SC_WB_Relative makes the photopenic artifact wider in the axial direction, particularly, up to 132.5mm and 147.5mm, respectively, and more pronounced (maximum Δ(SUVmean)=-20% and -21%, respectively). Applying SC_Absolute and SC_WB_Absolute were found to eliminate the photopenic artifact, although an overestimation was observed across the entire thorax_phantom, regardless of the presence of the mismatch. The deviations for mismatched_PET/CT, along the thorax_phantom range from +4% to +14% (mean value of +9.4%) for SC_Absolute, and from +2% to +11% (mean value of +7.6%) for SC_WB_Absolute, which are similar to the matched_PET/CT. ***Conclusion:*** SC_Relative and SC_WB_Relative showed a photopenic artifact when there is arm movement between CT and PET. Conversely, absolute correction methods eliminated this artifact but produced an overestimation in all image slices, being this overestimation lower for SC_WB_Absolute. It follows that the absolute corrections techniques are more robust in case of arm movement, as long as it is taken into account that the quantification will not be entirely correct.

EP-0813

The effect of image reconstruction on DAT tracer distribution in an anatomical brain phantom: a preliminary SPECT study

***A. De Maggi*[1],** *F. Bergesio[1], M. Lio[2], M. Balma[3], V. Liberini[3], L. Mansi[4], M. Pirozzi[5], B. Alfano[6], M. Quarantelli[7], S. Chauvie[1];*
[1]Medical Physics Divisions of Santa Croce e Carle Hospital (Cuneo), Cuneo, ITALY, [2]Univeristy of Turin, Cuneo, ITALY, [3]Nuclear Medicine Divisions of Santa Croce e Carle Hospital (Cuneo), Cuneo, ITALY, [4]CIRPS, Interuniversity Research Center for Sustainability, Rome, ITALY, [5]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, ITALY, [6]Human Shape Technologies S.r.l., Naples, ITALY, [7]Institute of Biostructures and Bioimaging, National Research Council, Naples, ITALY.

Aim/Introduction: An innovative anthropomorphic brain phantom, StepBrain(Human Shape Technologies S.r.l, Naples, Italy),was developed to characterize and standardize acquisition and reconstruction parameters in PET/CT.Here, we used the phantom in a SPECT/CT setting. ***Materials and Methods:*** StepBrain is a 3D-printed phantom derived from an MRI of a healthy volunteer.It replicates the real anatomy of three separate brain compartments to allow simultaneous simulation of the in-vivo activity distribution of gray matter(GM), white matter(WM), and dorsal striatum (DS).The phantom was created from a dataset of 1.5T MRI images of a 38-year-old normal volunteer. The volumes of the fillable inserts are 14.6, 407,and 714ml for STR,WM,and GM, respectively.The DS,WM, and GM compartments of the phantom were filled with Tc-99m pertechnetate and 123-I-Iofluopane with an activity concentration at acquisition times of 140,31, 46 kBq/ml and 70,17, 33kBq/ml, respectively.The phantom was then placed in an automatic shaker to homogenize the diffusion of the tracer for 40minutes.The phantom was acquired on an Infinia Hawkeye3/8" gamma camera with a fan-beam and a Low Energy-High Resolution (LEHR) collimator.Attenuation correction (AC) was obtained using the Hawkeye onboard X-ray tube. Images were reconstructed with filtered-back-projection,iterative reconstruction IR with 10subset and 2iteration applying progressively noAC,ChangAC with a coefficient of 0.07,measured AC, scatter correction, and varying the iteration number subset-product (ITSU 30-120)and the 10-power-low-pass filter threshold(0.55-0.89 mm).Analysis was performed considering fixed ROIs of 3cm2 conformed on the right and left DS.A 20% maximum threshold was applied to the images encompassing DS.DS/background ratio was calculated. ***Results:*** The average (± st.dev.)of DS counts with LEHR and FB collimators were stable with no significant changes among FBP and IR scatter, corrected but without AC (signal increasing factor of 1.01).However, it increased by a factor of 2.07 applying AC and remained stable varying the ITSU.Higher low pass filters led with LEHR to variation of st.dev up to 10%, but did not show a significant impact on FB.In particular, the average DS counts/background ratio with LEHR was 90/32 and 316/134 in FBP compared to 91/33 and 307/135 on OSEM noAC for Tc-99m pertechnetate and 123I-Iofluopane respectively. Average DS counts with FB collimator for Tc-99m pertechnetate was 903± 205 in FBP compared to 1055±214 on OSEM. Deeper quali-quantitative analysis is undergoing. ***Conclusion:*** According to preliminary findings, it is possible to measure the impact of various parameters on image quality using this new 3D-printed anthropomorphic brain phantom, which could help optimize the acquisition technique for comparative purposes in multicenter studies.

EP-0814

Preliminary Investigation of Enhancing FDG Brain PET Image Quality and Lesion Detection via MR-Guided Reconstruction in an integrated PET/MR

***H. Shao*[1],** *J. Hao[2], Q. Xue[2], J. Liu[1];*
[1]Department of Nuclear medicine, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA, [2]Central Research Institute, UIH Group, Shanghai, CHINA.

Aim/Introduction: Integrated PET/MR systems provide an opportunity to enhance PET image quality by incorporating anatomical information. Although various techniques utilizing anatomical prior information have been proposed over the past decade, clinical experience with their application in brain tumors, including as diffuse large B-cell lymphoma (DLBL), remains limited. In this study, we aimed to explore the application of the algorithm in improving the quality of brain FDG PET images for patients with and without brain tumors based on an integrated PET/MR. ***Materials and Methods:*** Thirty patients without brain tumors and two patients with DLBL were retrospectively enrolled in this study. All patients underwent 18F-FDG PET/MR imaging on an integrated PET/MR system. The PET images were reconstructed using two distinct methods: MR-guided PET reconstruction and conventional OSEM method. For the MR-guided PET reconstruction, we employed the parallel level sets (PLS) method, and 3D T1-weighted MR images were used as prior input [1]. For patients without brain tumors, we compared key metrics

such as contrast-to-noise ratio (CNR), coefficient of variance (CV) and edge sharpness. Meanwhile, for patients with DLBL, we focused on analyzing the signal-to-background ratio (SBR), signal-to-noise ratio (SNR), contrast-to-background ratio (CBR) and contrast-to-noise (CNR) of the lesions. Wilcoxon signed-rank test was utilized for statistical significance analysis. ***Results:*** For patients without brain tumors, the utilization of the MR-guided PET reconstruction led to a noteworthy enhancement in CNR by 35.6%±29.5%, a substantial improvement in edge sharpness by 33.8%±30.8% and a reduction in the CV by 21.8%±13.7%, all in comparison to the conventional OSEM algorithm. In the case of the two patients diagnosed with DLBL, a total of 10 lesions were detected. Remarkably, all four quantitative metrics of the lesions exhibited significant improvements when using the MR-guided PET reconstruction (SBR enhancement of 15.0%±8.6%, SNR enhancement of 86.0%±18.7%, CBR enhancement of 13.0%±6.6% and CNR enhancement of 81.0%±13.0%). ***Conclusion:*** The MR-guided PET reconstruction algorithm exhibited substantial advantages in image quality, surpassing the conventional OSEM algorithm, for both patients with and without brain tumors. Consequently, it is anticipated that this algorithm will gain broader adoption in the integrated PET/MR system, thereby enhancing image quality and optimizing the diagnosis and treatment process for patients. ***References:*** [1] Ehrhardt, M.J., et al., PET Reconstruction with an Anatomical MRI Prior using Parallel Level Sets. EP-0815

Feasibility of ultra-low-dose PET scan protocols with LSO-TX-based attenuation correction using a long axial field-of-view PET/CT scanner

H. Sari[1], *M. Teimoorisichani[2], R. Seifert[1], M. Viscione[1], K. Shi[1], M. Morris[3], E. Siegel[3], B. Saboury[3], T. Pyka[1], A. Rominger[1];*
[1]Bern University Hospital, Bern, SWITZERLAND, [2]Siemens Medical Solutions, USA Inc, Knoxville, TN, UNITED STATES OF AMERICA, [3]Institute of Nuclear Medicine, Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Long axial field-of-view (LAFOV) positron emission tomography (PET) scanners, with their enhanced system sensitivity, are making it possible to significantly reduce the administered tracer activities while maintaining clinically feasible scan durations, Whole-body CT scans performed for PET attenuation correction can significantly increase the total radiation exposure in these examinations. In this work, we investigate the viability of an ultra-low-dose PET protocol and evaluate the performance of a CT-less PET attenuation correction (AC) method with low count PET data. ***Materials and Methods:*** Four healthy subjects (75-98 kg) were scanned using an ultra-low-dose 18F-FDG protocol (injected activity: 6.7-9.0 MBq) using a LAFOV PET scanner. PET emission data were acquired for 90 minutes, and PET images were reconstructed using different frame durations. Whole-body CT scans were also performed for PET attenuation correction. A separate set of PET reconstructions were also performed using a CT-free AC method which utilizes Lu176 background radiation (LSO-TX) found in the PET detectors. We assessed image quality using signal-to-noise (SNR) in the liver and contrast-to-noise (CNR) in the brain. We also compared regional mean SUV values in PET images reconstructed with CT- and LSO-TX-based methods. ***Results:*** Visual evaluation of PET images showed that 20 minutes of PET data with activities under 10 MBq 18F-FDG might yield high quality PET images. The SNR of PET images reconstructed with the CT-based AC was 8.5 ± 2.7 at 90 minutes, 6.8 ± 2.3 at 40 minutes and 5.1± 1.5 at 20 minutes scan duration. The SNR of PET images reconstructed with the LSO-TX-based AC was 9.0 ± 2.5 at 90 minutes, 6.8 ± 2.3 at 40 minutes and 5.1± 1.5 at 20 minutes scan duration. The average absolute difference in brain grey matter SUV values in PET images, using CT- and LSO-TX-based attenuation correction, was 2.2±1.9% at 90 minutes, 5.9±1.3% at 40 minutes, and 6.9±1.6% at 20 minutes. ***Conclusion:*** The preliminary results of this work suggest that LAFOV PET scanners can produce images with good visual image quality with at least 20 minute-long 18F-FDG scans for activities under 10 MBq. The LSO-TX-based AC method produced images with comparable quality to CT-based AC method in such protocols. These initial results indicate the feasibility of ultra-low-dose 18F-FDG scans in certain settings, possibly extending the utility of PET scans beyond its current applications.

EP-0816

Reducing Time and Radiation in Dynamic PET: A Deep Learning approach with Total-body PET

H. Wang[1,2], *W. Ding[2], G. Chen[2], X. Qiao[2], R. Guo[1], B. Li[1], Q. Huang[1,2];*
[1]Department of Nuclear Medicine, Ruijin Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA, [2]School of Biomedical Engineering, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: With the advent of total-body positron emission tomography (PET), its extended axial field of view enables single-pass total-body dynamic scans. Additionally, significant enhancements in system sensitivity now allow for low-dose scans that reduce radiation exposure for patients. Dynamic parametric PET images, representing kinetic parameters, offer more comprehensive insights into disease processes compared to static images. However, these benefits are countered by longer scan durations. Furthermore, dynamic PET scans typically require larger injection doses of radiotracer to ensure a sufficient signal-to-noise ratio for accurate data analysis, which poses a challenge in reducing the required dosage of radiotracers while maintaining image quality. This study aims to address these issues by implementing a deep learning-based approach for rapid, low-dose dynamic scanning using total-body PET, reducing both scan duration and the dosage of radiotracers required. ***Materials and Methods:*** 68 patients who underwent a 65-minute dynamic FDG PET scan with the United Imaging uExplorer. We developed a novel 3D Image Space Shuffle U-Net (ISSUnet) model that incorporates 3D shuffle/unshuffled layers into the well-known U-Net architecture. This modification aimed to reduce training time and GPU memory usage without performance compromise. Dynamic kinetic parametric images, considered as the gold standard, were derived from the last 30 minutes of data using the Patlak model. The last 5 minutes of static SUV images, including full-dose images and low-dose images reconstructed with dose reduction factors (DRF) of 5, 10, and 20, were considered as training inputs for predicting dynamic parametric images. Image quality was assessed using Mean Absolute Error (MAE), Peak Signal-to-Noise Ratio (PSNR), and Structural Similarity Index (SSIM). ***Results:*** Preliminary results indicate a high degree of accuracy in the correspondence between the parametric images predicted from different dose SUV images and ground-truth images. The ISSUnet model outperformed traditional U-Net and GAN models across all dose levels (DRF1, 5, 10, 20) in terms of MAE, PSNR, and SSIM, demonstrated superior capability in generating precise parametric images at varied dosage levels with a 5- minute scan. ***Conclusion:*** The proposed 3D ISSUnet has proven effective in accurately and rapidly generating kinetic parametric images

from a low-dose 5-minute static SUV image. This method could potentially reduce the required 65-minute dynamic scanning time to 5 minutes, with effective performance even at 1/20th of the standard dose. Combined with Total-body PET, this approach could effectively enhance the feasibility of dynamic scans in clinical diagnostics, aiding in disease assessment.

EP-0817

A Novel Method for Rebinning in 3D PET Reconstruction on XTRIM PET

***M. Ghorbanzadeh*[1],** *T. Zare*[2,1], *M. H. Farahani*[1], *S. Hariri Tabrizi*[1], *A. H. Alikhani*[1], *B. Teimourian Fard*[1], *M. R. Ay*[2,1]; [1]*Research Center for Molecular and Cellular Imaging (RCMCI), Advanced Medical Technologies and Equipment (AMTEI), Tehran University of Medical Sciences (Tums), Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Fully 3D image reconstruction algorithms such as 3DRP, or 3D iterative algorithms in 3D PET scanners are accurate, but is very time consuming and computationally complex. Rebinning algorithms have been introduced to increase the speed of reconstruction algorithm. In the rebinning algorithms sinograms are sorted into a stack of 2D data. Unfortunately, rebinning algorithms distort the reconstructed image and degrade image quality. In order to increase the image quality in preclinical PET imaging, this study aims to introduce and assess the impact of the weighted multi-slice rebinning (W-MSRB) algorithm in Xtrim-PET scanner. Furthermore, the performance of the W-MSRB algorithm was compared with the single-slice rebinning (SSRB) and multi-slice rebinning (MSRB) approaches. ***Materials and Methods:*** SSRB assigns oblique LOR measurements to the middle axial slice, while MSRB assigns them to each traversed axial slice with equal weighting. The W-MSRB approach is a variant of the MSRB method where the weight assigned to oblique LORs varies based on their ring difference. This study was evaluated by Monte Carlo simulation of two phantoms in Xtrim_PET scanner using GATE (V9.1). This scanner is composed of 10 detector blocks and each block consists of a 24×24 array of 2×2×10 mm3 LYSO scintillators. The axial length of the scanner is 50.4 mm. A uniform phantom (80 mm diameter, 25.85 mm height) was simulated as its surface was in the middle of the axial field of view (FOV). In addition, two-rod sources (1.2 mm diameter, 20 mm height) were centered at (0, +40, +12) mm and (0, -40, -12) mm coordinations, respectively. The rods were positioned perpendicular to the central axis of the scanner. The rebinned sinograms were reconstructed with a 2D MLEM algorithm (20 iterations) using an in-house software. ***Results:*** In the uniform phantom analysis, the axial Coefficient of Variation (COV) parameter was 45%, 31%, and 10% for SSRB, MSRB, and W-MSRB methods. Edge Spread Function (ESF) parameters were obtained by drawing an axial profile line, measuring 9.45 mm for MSRB (30-80% peak) and 3.76 mm for W-MSRB, representing a 60% improvement over MSRB. For the Rod phantom, SSRB images showed distortion and curved Rod structures, while MSRB and WMSRB yielded excellent Rod images. ***Conclusion:*** The W-MSRB method demonstrates a noteworthy improvement in uniformity, SNR, and axial resolution. Furthermore, it exhibits a substantial reduction in distortions, indicating its superior performance compared to the SSRB and MSRB methods.

EP-0818

Comparative Analysis of Forward Projection Algorithms in Tomographic Imaging: A Study on Siddon, Perfect Siddon, Rotate and Sum, and Radon Transform Forward Projection Methods

***A. Dareyni*[1,2],** *A. AliKhani*[2], *M. Farahani*[2], *B. Teymourian*[2], *M. Ay*[1,2]; [1]*Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Research Center for Molecular and Cellular Imaging (RCMCI), Advanced Medical Technologies and Equipment (AMTEI), Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: The process of forward projection in tomographic imaging involves mathematically modeling the acquisition of physical data. Alongside back projection, forward projection constitutes a foundational element in iterative image reconstruction. Proper implementation of forward projection is a critical consideration for achieving optimal speed and accuracy in iterative reconstruction. In this study, our objective was to implement and assess the performance of different forward projection methods in terms of efficiency and accuracy. ***Materials and Methods:*** In this study, we implemented various algorithms in Python for tomographic image reconstruction. Siddon's algorithm efficiently traverses rays emitted from detector cell centers, accurately determining intersection points and calculating intersection lengths. These lengths are used as weighting factors in forward modeling to ensure appropriate voxel contributions to the final projection. The Perfect Siddon method emits multiple rays from each detector cell toward the voxelized object to enhance accuracy, albeit at a higher computational cost. Rotate and Sum involves incrementally rotating the image around a fixed axis in discrete steps, computing projections along rays passing through the detector array at each angle. The Radon transform, available in Python's Scikit image library, computes line integrals along rays. We applied these methods to reconstruct images from the Shepp-Logan phantom using the MLEM iterative reconstruction algorithm with 20 iterations. Finally, we evaluated the reconstructed images using metrics like MSE and PSNR. ***Results:*** In Perfect Siddon, increasing the number of emitted rays per detector cell resulted in a decrease in MSE and an increase in PSNR. Under identical conditions (image matrix size, MLEM reconstruction with 20 iterations), Perfect Siddon exhibited the lowest MSE and the highest PSNR among the methods evaluated. The performance of Siddon was comparable to that of Perfect Siddon in terms of MSE and PSNR. Rotate and Sum showed the highest MSE and the lowest PSNR, while the Radon function in Python exhibited performance characteristics intermediate between Siddon and Rotate and Sum. ***Conclusion:*** The Siddon and Perfect Siddon algorithms operate similarly, but Perfect Siddon achieves greater accuracy by emitting more rays per detector cell compared to Siddon. However, this increased accuracy requires more computational resources. The Rotate and Sum method demonstrates lower accuracy mainly due to interpolation during each rotation step. Additionally, our analysis indicates that the Radon algorithm in Scikit-image provides higher accuracy than Rotate and Sum but slightly less than Siddon and Perfect Siddon methods.

EP-0819

Longitudinal Multi-modality Correlation-based PET Enhancement for Reducing Radiation Accumulation

***X. Qiao*[1],** *H. Wang*[1], *W. Ding*[1], *G. Chen*[1], *B. Li*[2], *Q. Huang*[1]; [1]*School of Biomedical Engineering, Shanghai Jiao*

Tong University, Shanghai, CHINA, [2]Department of Nuclear Medicine, Ruijin Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: Lymphoma patients undergo multiple PET/CT scans throughout the diagnostic and treatment process, which are crucial for effectively monitoring disease progression and timely adjusting treatment plans. However, the cumulative radiation from these repeated PET/CT examinations cannot be disregarded. Although deep learning has been widely used for enhancing low-dose PET images, the quality of these enhanced images at ultra-low doses often remains suboptimal. These images may lack detail and, in some cases, even introduce non-existent anatomical structures, thereby compromising clinical reliability. This study addresses these challenges by using full-dose PET images from the baseline examination to enhance low-dose PET images at follow-up examinations, reducing radiation exposure, improving image quality, and ensuring clinical usability. ***Materials and Methods:*** Our study involved 119 patients who underwent total-body PET/CT scans using the United Imaging uExplorer. Among them, 11 patients had baseline full-dose PET/CT scans and follow-up real low-dose (10%) PET/CT scans. The remaining 108 patients had full-dose PET scans at both baseline and follow-up, with low-dose PET images generated by subsampling a portion of the full-dose PET. We proposed a longitudinal multi-modality correlation-based method for PET image enhancement, utilizing the high-quality baseline full-dose PET/CT image to learn patient-specific anatomical structure information in the non-lesion region and employing follow-up low-dose PET images to guide the lesion uptake recovery. The global quality of enhanced PET images was assessed by PSNR, NRMSE, and SSIM, with further evaluation through different total-body organs segmentation. Regional image quality was determined by the SUVmax of the largest lesion and the SUVmean of the liver. ***Results:*** Preliminary results indicate that referencing baseline full-dose PET/CT images can significantly improve follow-up low-dose PET image quality across different dose levels (1%, 2%, 5%, 10%, 25%), showing reduced noise and enhanced structural details. In the case of ultra-low-dose (lower than 10%), more details are recovered in enhanced PET images, achieving higher PSNR and SSIM and smaller NRMSE. Additionally, there is promising performance in enhancing real-low-dose PET images. ***Conclusion:*** The quality of follow-up low-dose PET images is significantly enhanced by referencing baseline full-dose PET/CT images. As the number of examinations increases, this approach notably reduces the cumulative radiation dose experienced by patients. This method holds clinical significance for lymphoma diagnosis, providing patients with safer and more accurate imaging evaluations, and is poised to be widely applied in clinical practice.

EP-0820

Spatial Resolution Enhancement in Dedicated Brain PET Scanner Using an Analytic System Matrix

T. Zare[1,2], *M. Ghorbanzadeh[2], S. Hariri Tabrizi[2], M. H. Farahani[2], B. Teimourian Fard[2], A. Rahmim[3], P. Sheikhzadeh[1,4], P. Ghafarian[5,6], M. R. Ay[1,2];*

Aim/Introduction: The spatial resolution in dedicated brain PET scanners is one of the most important factors in evaluation of brain metabolic process, neurotransmitter activity and early detection of diseases such as Alzheimer's. Resolution in PET is influenced by several factors such as crystal size, positron range and noncollinearity. Also in dedicated brain PET scanners, like whole-body PET scanners, the resolution is degraded by moving from the center to the edges of the transverse field of view (TFOV) due to the parallax error. The main objective of this study is to improve resolution in TFOV of our proposed dedicated brain PET scanner using Monte Carlo simulation and new analytic system matrix. ***Materials and Methods:*** The proposed dedicated brain PET scanner was simulated using Monte Carlo (GATE (V9.1)). This scanner configuration comprises 22 detector blocks in the transverse direction and 4 blocks axially. Each block is composed of a 23×23 array of 2×2×15 mm3 LYSO scintillators. Four cylindrical point sources (1.2 mm in diameter and 1 mm in height) filled with ^{18}F-FDG were positioned at the center of the TFOV and moved radially at 4 cm intervals. Image reconstruction was carried out using the OSEM algorithm via an in-house software. The full width at half-maximum (FWHM) of the point sources was determined in accordance with NEMA standards and subsequently utilized to compute an analytical system matrix employing a Gaussian function for resolution recovery enhancement. ***Results:*** The FWHM of point sources located at distances of 0, 4, 8, and 12 cm from the center of the TFOV without resolution recovery were determined to be 1.75, 1.96, 2.83, and 4.19 mm, respectively. By incorporating resolution recovery, the FWHM for these sources improved to 1.53, 1.49, 2.12, and 2.27 mm, respectively. The findings indicate that this resolution recovery technique has the capacity to enhance resolution by 12% and 45% for sources positioned at the TFOV center and 12 cm from the TFOV center, respectively. Therefore, implementing a resolution recovery algorithm with an analytical system matrix can result in more uniform spatial resolution in the TFOV. ***Conclusion:*** Utilizing data obtained from Monte Carlo simulations, an analytic system matrix was generated, demonstrating the capability of resolution recovery at various radial distances of TFOV. If the geometry of PET scanners and the FWHM of point sources at different TFOV radial distances are available, this method can potentially be modified to resolution recovery in other scanners.

Quantitative Accuracy of Reconstruction Methods in Preclinical PET and Effects on Kinetic Modelling

V. Turmacu[1], *G. Salvi de Souza[1,2], L. Garcia-Varela[3], J. Doorduin[1], G. Luurtsema[1], C. Tsoumpas[1];*
[1]Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, [2]School of Medicine, PUCRS, Porto Alegre, BRAZIL, [3]Nuclear Medicine and Molecular Imaging Group, Health Research Institute of Santiago de Compostela (IDIS), University Hospital Santiago de Compostela, Santiago de Compostela, SPAIN.

Aim/Introduction: The selection of PET scanning mode and reconstruction method can influence quantification and image interpretation. Analytical methods, such as filtered-back-projection

(FBP) and reprojection (RP), are fast, but compromise image quality (IQ) [1]. Iterative ordered-subset-expectation-maximization (OSEM) can mitigate these issues, but may introduce bias [2]. This study assesses the effects of reconstruction algorithms on IQ and quantification of activity concentration in phantom and animal experiments. ***Materials and Methods:*** An IQ phantom filled with [18F]FDG solution (179.87kBq/cc) was scanned for 20 minutes with a preclinical PET scanner. The data was histogrammed into: (1) a static and (2) dynamic scans with different time-frames (40 frames of 30s and 10 frames of 120s). Reconstruction was conducted with FBP2D, RP3D, and OSEM2D, each using 128x128 matrix size, 1.898mm pixel size, and 0.796mm slice thickness. Additional high resolution OSEM2D (HR-OSEM2D) reconstructions were performed using 256x256 matrix size and 0.633mm pixel size. IQ metrics (activity concentrations, noise, spillover-ratios (SORs)) were extracted and analysed to establish a gold standard reconstruction protocol. Furthermore, dynamic scans of two Wistar rats injected with 34MBq of [18F]MC225, with blood sampling, were acquired with the same scanner and reconstructed using the aforementioned protocols [3]. Whole-brain tissue time-activity curves (TAC) were fitted to a 1-tissue compartment model (1TCM) and using metabolite-corrected plasma, K1 and k2 were derived. ***Results:*** In the phantom study, either OSEM2D exhibited similar and superior performances across IQ metrics with minimal activity concentration error, ranging from 0.03% to 1.02%, and the lowest noise levels and SORs, ranging from 2.40% to 3.18% and 0.04 to 0.18, respectively. For the rat scans, a strong correlation across reconstruction methods was observed for TACs ($r=0.943$, $p<0.001$). However, significant differences across kinetic parameters were found for one of the two rats, mainly between OSEM2D and FBP2D ($p=0.013$). Model-fit analysis showed that 1TCM fit best on HR-OSEM2D, as indicated by standard error of estimated kinetic parameters, ranging from 1.12% to 3.21% and Akaike information criterion (AIC=252.32 for HR-OSEM2D and AIC=309.88 for FBP2D). ***Conclusion:*** In preclinical static and dynamic scanning, OSEM2D and HR-OSEM2D performed similarly and outperformed the other reconstruction methods. However, the reconstruction does not affect the TACs and only inconsistently affects kinetic parameters. Additionally, the 1TCM fits best on HR-OSEM2D reconstructed images. Further investigation with varied sample size, reconstruction methods, and tracers is essential to optimize quantification and kinetic analysis. ***References:*** 1. Boellaard et al., 2001 2. Predicting Treatment Response in Esophageal Cancer Patients Using ^{18}F FDG PET/CT Texturel Features Parameters

***G. Mutevelizade*[1,2]**, *O. Duran*[3], *N. Aydin*[2], *M. Erdugan*[3], *A. Suner*[4], *E. Sayit Bilgin*[2];
[1]*Manisa Celal Bayar University Hospital, MANISA, TÜRKIYE,* [2]*Celal Bayar University Hospital Department of Nuclear Medicine, Manisa, TÜRKIYE,* [3]*Celal Bayar University Hospital Department of Radiation Oncology, Manisa, TÜRKIYE,* [4]*Dokuz Eylül University School of Medicine Department of Public Health, Izmir, TÜRKIYE.*

Aim/Introduction: Radiomics, a rapidly growing research field focused on the numerical properties of medical imaging, holds promise for personalized medicine's future. It aims at identifying characteristics that effectively predict clinical conformity and treatment response. Our study investigates the relationship between tumoral ^{18}F-FDG PET/CT Tissue Analysis Parameters and tumor localization, histopathological type, lymph node metastasis, mortality, and treatment response in esophageal cancer patients undergoing curative chemoradiotherapy (CRT). ***Materials and Methods:*** We retrospectively evaluated imaging findings of esophageal cancer patients diagnosed at our center, who underwent staging and treatment response assessment with ^{18}F-FDG PET/CT following CRT. Using the LIFEx version 7.3.0 software, we derived 105 different metabolic and tissue analysis parameters of the primary tumor. Statistical analyses were performed using IBM SPSS 26.0. The Kruskal Wallis H and Mann-Whitney U tests were employed for group comparisons. ***Results:*** A total of 39 patients (24 males, 15 females; age 65.5 ± 9.7 years) were included in the study. The mean survival time was 23.5±25.2 months. The tumor morphology was squamous cell carcinoma in 31 patients (79.5%) and adenocarcinoma in 8 patients (20.5%). Lymph node metastasis was present in 20 patients (51.3%). The tumor was located in the proximal esophagus in 8 (20.5%), mid esophagus in 21 (53.8%) and distal esophagus in 10 (25.7%) patients. According to treatment response, 13 (33.3%) patients were categorized as complete response, 22 (56.4%) as partial response and 4 (10.2%) as progressive disease. Nine patients (23.1%) died during the follow-up period.Significant statistical differences were found between groups in terms of 47 radiomic parameters for tumor histologic sub-type and 45 for tumor localization ($p<0.05$). Gray Level Co-occurrence Matrix (GLCM)_InverseVariance parameter was significantly higher in the progressed group than in the complete and partial response group ($p=0.036$). 13 first order radiomics parameters and Gray-Level Size-Zone Matrix (GLSZM)_SmallZoneLowGreyLevelEmphasis parameter were significantly different according to the presence of lymph node metastasis ($p<0.05$). GLCM_ClusterShade, GLSZM_ZoneSizeVariance and INTENSITY-HISTOGRAM_MaximumHistogramGradient parameters were significantly higher in dead patients compared to survivors ($p=0.042$, $p=0.013$, $p=0.047$, respectively). ***Conclusion:*** Our study highlights the potential utility of the GLCM_InverseVariance parameter, an indicator of local homogeneity, in predicting treatment response in esophageal cancer patients. Various radiomic parameters are related to tumor histologic sub-type, localization, lymph node metastasis presence, and mortality. We conclude that the textural features of primary esophageal tumors could serve as prognostic biomarkers for identifying patients with poor prognosis and warrant further investigation in prospective studies with larger patient cohorts.

Is F^{18} FDG PET/CT Based Radiomics Features Useful for Prediction of PD-L1 Expression in Non-small Cell Lung Cancer?

S. Kim, *W. Ko;*
Pusan National University, Yangsan, KOREA, REPUBLIC OF.

Aim/Introduction: This study investigated the diagnostic test accuracy of F^{18} FDG PET/CT based radiomics features for prediction of PD-L1 expression in non-small cell lung cancer (NSCLC). ***Materials and Methods:*** A systematic search was performed in PubMed and EMBASE (last updated in 31 March 2023). Studies evaluating diagnostic performances of F^{18} FDG PET/CT based

radiomics features for prediction of PD-L1 expression in NSCLC. We determined the sensitivities and specificities across studies, calculated positive and negative likelihood ratios (LR+ and LR-), and estimated pooled area under curve (AUC). ***Results:*** The pooled sensitivity of F^{18} FDG PET/CT was 0.75 (95% CI; 0.64-0.83) and a pooled specificity of 0.66 (95% CI; 0.52-0.78) for prediction of >1% expression of PD-L1. For prediction of >50% expression of PD-L1, the pooled sensitivity of F^{18} FDG PET/CT was 0.77 (95% CI; 0.67-0.85) and a pooled specificity of 0.61 (95% CI; 0.55-0.66). For >1% expression of PD-L1, the pooled AUC of fixed effects was 0.791 (95% CI; 0.771-0.811) and of random effects was 0.783 (95% CI; 0.722-0.845). For >50% expression of PD-L1, the pooled AUC of fixed effects was 0.735 (95% CI; 0.718-0.751) and of random effects was 0.766 (95% CI; 0.706-0.825). ***Conclusion:*** Analysis of the available studies indicated that F^{18} FDG PET/CT based radiomics features showed a moderate diagnostic performances for prediction of PD-L1 expression in NSCLC. However, future studies would be necessary for standardization of the method for prediction of PD-L1 expression in NSCLC using F^{18} FDG PET/CT based radiomics features.

EP-0824

Evaluating the impact of the Radiomics Quality Score: A systematic review and meta-analysis

N. Barry[1,2], *J. Kendrick[1,2], K. Molin[1], J. Li[1,3], P. Rowshanfarzad[1,2], G. M. Hassan[1], M. A. Ebert[1,2,3];*
[1]School of Physics, Mathematics and Computing, University of Western Australia, Crawley, AUSTRALIA, [2]Centre for Advanced Technologies in Cancer Research (CATCR), Perth, AUSTRALIA, [3]Department of Radiation Oncology, Sir Charles Gairdner Hospital, Nedlands, AUSTRALIA.

Aim/Introduction: The radiomics quality score (RQS) has become the de facto quality appraisal tool for radiomics studies, consisting of 16 criteria which reward/penalise studies based on methodological approach (range, -8 to 36). However, an encompassing meta-analysis of its application within the literature is yet to be undertaken. Here we report a systematic review and meta-analysis on the impact the RQS has had on radiomics studies to date and to assess if adherence to its 16 criteria is improving over time. ***Materials and Methods:*** A systematic search was conducted from January 1, 2022, to December 31, 2023, for systematic reviews which implemented the RQS (CRD42024493843). Articles prior to 2022 were taken from a previous review. Data extracted from each included article were (where available) mean RQS, the RQS of individual radiomics papers, criteria scores, and multiple reader data. Date of publication of respective radiomics studies were matched with their assigned RQS from reviewers. Average score, average adherence (score>0) and inter-observer variability were evaluated for the 16 criteria. Correlation of quality scores and criteria scores with time were assessed using Pearson correlation. Errors in application of the RQS criteria were noted and corrected in systematic reviews which provided criteria scoring data. ***Results:*** A total of 130 systematic reviews were included for analysis, with mean RQS 130/130 (100.0%), quality scores of individual radiomics studies 117/130 (90.0%), criteria scores 97/130 (74.6%), and multiple reader data 24/130 (18.5%) extracted. A total of 3247 quality scores were extracted from radiomics studies with respective date of publication. Overall mean RQS was 9.89±3.87. Analysis of individual quality scores over time were positively correlated (Pearson R=0.32, p<0.001) and significantly higher after publication of the RQS (before publication, 5.58±6.16; after publication, 10.17±6.10; p<0.001). Only 233/3247 (7.18%) scores were ≥ 50% of the maximum RQS. The average percentage of the maximum score and adherence achieved ranged from -2.20% to 70.86% and 1.12% to 89.06%, respectively. Median Cohen's kappa ranged from 0.36 to 1.00. Correlation analysis revealed that ten, four, and two of the criteria had a significant positive correlation, no significant correlation, and significant negative correlation with time, respectively. Errors in criteria scoring were discovered in 38/97 (39.2%) of articles which provided criteria scores. ***Conclusion:*** Methodological approaches in radiomics studies are increasingly adhering to the criteria outlined by the RQS. However, current progress is still lacking for clinical translation of radiomics models in the future.

EP-0825

Evaluation of Endometrial Cancer Subtypes Metabolic, Volumetric, and Tumor Heterogeneity Parameters Obtained from F^{18} FDG PET/CT Imaging

S. Yagci[1], *E. Erdemoglu[2], S. S. Sengul[1];*
[1]Suleyman Demirel University, Faculty of Medicine, Department of Nuclear Medicine, Isparta, TÜRKIYE, [2]Suleyman Demirel University, Faculty of Medicine, Department of Gynecologic Oncology, Isparta, TÜRKIYE.

Aim/Introduction: The study's aim is to examine the relationship between endometrial cancer subtypes and lymph node metastasis status and texture parameters reflecting metabolic, volumetric, and tumor heterogeneity of the primary tumor obtained from F^{18} FDG PET/CT images. ***Materials and Methods:*** The study comprised 159 patients who had F^{18} FDG PET/CT imaging for staging after being diagnosed with endometrial cancer. Age, BMI, primary tumor subtypes, grades, and lymph node metastasis status of the cases were determined. Cases were first grouped into high- and low-grade subtypes according to their primary tumor subtypes. The same patient group was then divided into groups with and without lymph node metastasis. Images were evaluated in the LIFEx program. The primary tumor was segmented and texture features reflecting metabolic, volumetric and tumor heterogeneity were obtained. The relationships between these parameters and the groups were examined. ***Results:*** Patients with high-grade endometrial cancer had higher were older ages and had higher BMIs. When metabolic and volumetric parameters are measured, MTV, TLG, SUVmax, SUVmean, and SUVmin values were higher in patients with high-grade endometrial cancer. When these parameters were analyzed using logistic regression analysis, SUVmin was found to be the most efficient parameter on high-grade endometrial cancer. TLG had the highest value, with an AUC of 0.724. Cut-off values were found as 13.0368 cm3 for MTV, 5.00566 for SUVmin, 7.97611 for SUVmean, 15.48811 for SUVmax, and 100.4407 for TLG in ROC analysis. SUVmin and TLG levels were higher in patients with lymph node metastases than in those without. When ROC analysis was applied to these parameters between the groups with and without lymph node metastases, TLG had the highest value, with an AUC of 0.745. The cut off values obtained were 10.496 cm3 for MTV, 3.29881 for SUVmin, 9.15647 for SUVmean, and 121.7133 for TLG. There was no significant AUC value for SUVmax. Considering the texture parameters, while the parameters reflecting heterogeneity are observed to be high in high-risk endometrial cancers and patients with lymph node metastases, the parameters reflecting homogeneity are found to be high in low-grade endometrial cancers and patients without lymph node metastases. ***Conclusion:*** In our study, we showed that metabolic and volumetric parameters of the primary tumor obtained from F^{18} FDG PET/CT imaging and radiomics data reflecting tumor heterogeneity can contribute to distinguishing

endometrial cancer types and predicting lymph node metastasis ***References:*** https://pyradiomics.readthedocs.io/en/latest/, https://www.lifexsoft.org/.

Radiomic Features Extracted from PET Images Aid in Identifying Cachexia in Cancer Patients

Y. Jiang, *X. Peng;*
Southeast University School of Medicine, Nanjing, CHINA.

Aim/Introduction: Cancer-associated cachexia severely impairs the quality of life of cancer patients and is difficult to reverse in advanced stages of the disease. Therefore, early prediction of cachexia is crucial. The objective of this study was to investigate radiomic features extracted from PET images for the detection of cachexia in cancer patients who underwent [18F]fluoro-2-deoxy-D-glucose ([18F]FDG) positron emission tomography (PET)/computed tomography (CT) scans. ***Materials and Methods:*** Cancer patients who received [18F]FDG PET/CT scans between October 2017 and October 2020 were retrospectively enrolled for analysis. Radiomic feature extraction and model development were executed utilizing the FeAture Explorer Pro (FAE, Ver. 0.5.3) on PET scans encompassing volumes of interest, including the liver, pancreas, visceral and subcutaneous fat, as well as the psoas and sacrospinal muscle. We utilized pearson correlation analysis, analysis of variance, and logistic regression in the process of feature selection and construction of the radiomics model. Univariable and multivariable logistic regression were employed to identify variables independently associated with cachexia, facilitating the construction of both clinical and clinical-radiomic models. The discriminative ability of the models was assessed using the area under the curve (AUC), and statistical differences in AUC values between different models were compared using the DeLong test. ***Results:*** A total of 390 patients were included in this study, with 273 individuals in the training set and 117 in the testing set. In the training set, the AUC values for the clinical model, radiomic model, and clinical-radiomic model were 0.752, 0.746, and 0.782, respectively. The AUC value of the clinical-radiomic model was significantly higher than that of the radiomic model (P = 0.018). In the testing set, The AUC value of the clinical-radiomic model was significantly higher than that of the clinical model (0.754 vs 0.701, P = 0.049), while there was no statistical significance observed between the clinical-radiomic model and the radiomic model (0.754 vs 0.741, P = 0.617). ***Conclusion:*** Radiomic features extracted from [18F]FDG PET/CT scans hold significant utility in distinguishing cachexia among cancer patients.

EP-0827

Effects of Q.Clear reconstruction algorithm on predicting distant metastasis of non-small cell lung cancer from ^{18}F-FDG PET/CT images

J. Liu, *R. Wang;*
The First Affiliated Hospital of Zhengzhou University, zhengzhou, CHINA.

Aim/Introduction: This study aim to compare the effects of Bayesian penalized likelihood (Q.Clear) and ordered subset expectation maximization (OSEM) reconstruction algorithm on texture feature derived from ^{18}F-FDG PET/CT images and further clarify the advantages of the Q.Clear reconstruction algorithm for predicting distant metastasis for non-small cell lung cancer (NSCLC) PET/CT omics-related machinelearning (ML) modeling. ***Materials and Methods:*** A prospective multicenter study was conducted, including a total of 239 NSCLC patients from three hospitals. PET/CT data were reconstructed using both Q.Clear and OSEM reconstruction algorithms. A total of 125 image features were extracted based on each reconstruction algorithms, and eight ML methods were employed to build predictive models and evaluate their impact on prediction capabilities. Ten-fold cross-validation was performed to evaluate the reliability of ML models on training sets, which were subsequently validated on testing sets. The predictive performance of each model was assessed using receiver operating characteristic (ROC) curves, area under the ROC (AUC) values, decision curveanalysis (DCA) curves, and calibration curves. ***Results:*** The AUC values demonstrated that the Q.Clear algorithm exhibited superior predictive accuracy and reliability compared to the OSEM algorithm across all eight ML models, regardless of whether in the training or testing sets. Specially, in the training sets, significant differences in AUC values between Q.Clear and OSEM algorithms were observed for the k-nearest neighbors (KNN, r: 0.0406), random forest (RF, r: 0.0470), and support vector machine (SVM, r: 0.0404) models. Similarly, in the test sets, significant differences in AUC values between the Q.Clear and OSEM algorithms were observed for the KNN (r: 0.0496), RF (r: 0.0487), and SVM (r: 0.0492) models. Additionally, the ROC, DCA, and calibration curves further supported the superior performance of the KNN, RF, and SVM models when usingthe Q.Clear algorithm. ***Conclusion:*** The Q.Clear algorithm showed superior predictive accuracy and reliability in predicting distant metastasis of NSCLC using PET/CT radiomics compared to the OSEM algorithm. This improved performance may be attributed to the Q.Clear reconstruction algorithm providing more valuable information in PET/CTimages obtained.

EP-0828

3D Printed Radioactive Phantoms for the Validation of Texture Features in PET Radiomics

A. Zounek[1], *F. Lindheimer[1], A. Zatcepin[1,2], G. Palumbo[1], F. J. Gildehaus[1], A. Bollenbacher[1], P. Bartenstein[1,2], N. L. Albert[1,3,4], S. Ziegler[1], L. Kaiser[1];*
[1]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, [2]German Center for Neurodegenerative Diseases (DZNE), Munich, GERMANY, [3]German Cancer Consortium (DKTK), Partner Site Munich, German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [4]Bavarian Cancer Research Center (BZKF), Erlangen, GERMANY.

Aim/Introduction: Image textures are clinically relevant biomarkers and can be quantified with radiomics analyses. It is therefore important to investigate whether underlying structures are reliably detected. 3D printing allows the use of clearly defined activity distributions with complex geometries. The aim of this study was to validate radiomic texture features in PET imaging using phantom measurements with 3D-printed radioactive components. ***Materials and Methods:*** A homogeneous sphere and three heterogeneous radioactive objects were produced using a stereolithographic 3D printer [1]. The structure chosen for the heterogeneous objects was a cuboid with a chessboard-like cross-section in fine patterns of different scales (2/4/6mm). High-resolution PET/CT image data were acquired with a Mediso NanoScan system. Binary images were generated from the CT data to obtain ground truth (GT) activity distributions. Texture features were extracted for comparison between ground truth and PET radiomics. ***Results:*** The texture feature glcm_Contrast (C) was very low for the homogeneous sphere (GT: Csphere=0.34; PET: Csphere=0.45). The ground truth contrast was lowest for the coarsest textured object (C6mm=0.7) and highest for the finest object (C2mm=177.4), while the values were inverse for the PET

images (C6mm=8.6; C2mm=1.1). A similar trend was observed for other texture features such as ngtdm_Complexity and firstorder_Uniformity. ***Conclusion:*** The results confirm that heterogeneous structures can be successfully produced and characterized using 3D printing. The difference between the ground truth and PET data indicates that quantification is strongly influenced by parameters such as resolution. 3D-printed radioactive phantoms can potentially be used to validate radiomics texture features and facilitate the optimization of image parameters. ***References:*** 1. Gillett D, Marsden D, Ballout S, Attili B, Bird N, Heard S, et al. 3D printing ^{18}F radioactive phantoms for PET imaging. EJNMMI Physics. 2021;8(1).

EP-0829

Enhancing Prediction of Neoadjuvant Chemotherapy Response in Locally Advanced Breast Cancer Through [18F]FDG PET-Based Radiomics

***C. Bachi*[1],** *E. Giovannini[1], G. Giovacchini[1], N. Yosifov[1], A. Milano[2], C. Aschele[2], A. Ciarmiello[1];*
[1]Nuclear Medicine OU, Sant'Andrea Hospital, La Spezia, ITALY, [2]Oncology U, Sant'Andrea Hospital, La Spezia, ITALY.

Aim/Introduction: Machine learning and radiomics present exciting opportunities to enhance the clinical management of locally advanced breast cancer patients eligible for neoadjuvant chemotherapy (NAC). These technologies can provide valuable insights and potentially improve treatment outcomes for these patients. ***Materials and Methods:*** In this retrospective study, 71 breast cancer patients underwent PET/CT imaging with [18F] FDG as part of initial staging before neoadjuvant chemotherapy. By analyzing 87 textural features extracted from PET/CT scans and incorporating patient age, we identified predictive features using a LASSO regression approach. This methodology allowed for the selection of the most relevant features, enhancing the predictive accuracy of outcomes for these patients. ***Results:*** Five variables, including textural features (NGTDM_STRENGTH, GLCM_CORRELATION, GLSZM_LZHGE and GLSZM_HGZE) and age, were selected by LASSO regression analysis. These variables were used to create a radiomic model, which was related to three categorical variables of patients' response to NAC (Complete Response, CR; Partial Response, PR; No Response, NR). The AUCs obtained for these three variables were respectively 81.50% (NR), 73.0% (CR) and 69.0% (PR). ***Conclusion:*** These findings suggest that a predictive model incorporating radiomic features from PET/CT scans along with patient age can significantly enhance the accuracy of identifying non-responders to neoadjuvant chemotherapy (NAC). This integrated approach holds promise for more precise patient stratification and tailored treatment strategies in breast cancer care.

In Ga-68 PSMA PET/CT Treatment Response Evaluation in Prostate Cancer; the Effect of Tissue Heterogeneity on Treatment Response

***M. Avci*[1],** *M. Erdogan[2], M. Yildiz[2], S. S. Sengul[2];*
[1]Isparta City Hospital Departmant of Nuclear Medicine, Isparta, TÜRKIYE, [2]Suleyman Demirel University Faculty of Medicine Departmant of Nuclear Medicine, Isparta, TÜRKIYE.

Aim/Introduction: We aimed to investigate the relationship between lesion-based volumetric and texture parameters obtained from pre-treatment Ga-68 PSMA PET/CT images and treatment response in patients with prostate adenocarcinoma. ***Materials and Methods:*** Between December 2018 and November 2022, 226 patients with prostate cancer who underwent Ga-68 PSMA PET/CT imaging both before and after treatment were included in the study. A total of 452 Ga-68 PSMA PET/CT images were analyzed retrospectively and comparatively. Baseline and post-treatment blood parameters of 97 patients with mixed response according to treatment response evaluation were recorded. Images were re-evaluated according to the PSMA expression status of the lesions. In 82 patients with mixed response (bone, lymph node), 1148 metastatic lesions (1012 bone and 136 lymph node) were divided into two groups according to the increase and decrease of PSMA expression. Images were evaluated in the LIFEx program. Metastatic bone lesions and lymph nodes were drawn with a 40% threshold and volumetric and textural features were obtained. The relationship between these data and the change in PSMA expression was analyzed. ***Results:*** In bone lesions, SUVmax, SUVmean and SUVmin values were lower in lesions with decreased PSMA expression (reference values: 6.51, 4.71 and 2.49, respectively). PSMA-TV was higher (reference value: 8.92 cm3). No significant difference was observed in the TL-PSMA value. In logistic regression analysis, TL-PSMA and PSMA-TV affected the change in PSMA expression by -0.007 and 0.056 folds, respectively. In lymph nodes, SUVmax and SUVmin values were lower in lesions with decreased PSMA expression (reference values: 5.40 and 3.58, respectively). No significant difference was observed in SUVmean, PSMA-TV and TL-PSMA values. In logistic regression analysis, SUVmax was -0.953-fold and SUVmean was 1.74-fold influential on the change in PSMA expression. When texture parameters are analyzed, intensity-based parameters such as kurtosis, GLCM-Entropy, GLCM-Contrast, GLCM-Dissimilarity and GLSZM-ZS. ENTR were higher in lesions with increased PSMA expression, while parameters such as intensity histogram-uniformity, GLCM-Angular second moment, GLCM-Inverse difference, GLCM-Inverse difference moment and GLSZM-LZHGE were lower. ***Conclusion:*** In this study, we demonstrated that when texture parameters obtained from Ga-68 PSMA PET images are evaluated on a lesion basis, they may play a role in predicting treatment response by showing the heterogeneity of lesions. ***References:*** https://www.lifexsoft.org/https://pyradiomics.readthedocs.io/en/latest/index.html.

EP-0831

Prediction of Response to TARE Treatment with Y90 Glass Microspheres in Patients with Colorectal Cancer Metastatic to the Liver Using Artificial Intelligence-Assisted FDG PET Radiomics Model

***T. Kissa*[1],** *S. Azamat[2], F. Cagliyan[1], W. Noortman[3], K. Niftaliyeva[1], Z. Balaban Genc[1], S. Cetin[1], A. Eroglu[1], E. Soydemir[1], O. Kostek[1], E. Ozturk Isık[1], T. Y. Erdil[1], T. Ones[1], F. Dede[1];*
[1]Marmara Univercity, Istanbul, TÜRKIYE, [2]Bogazici Univercity, Istanbul, TÜRKIYE, [3]Univercity of Twente, Istanbul, NETHERLANDS.

Aim/Introduction: Transarterial Radioembolization (TARE) plays a crucial role in treating metastatic colorectal cancer. To enhance decision-making, radiomics-based analyses have gained prominence alongside existing biomarkers. While morphological images like CT and MRI are commonly used, studies exploring metabolic radiomics features from FDG PET scans are still limited. Challenges in FDG PET-based radiomics studies include heterogeneous study groups (encompassing both primary liver tumors and liver metastases) and lack of stratification based on resin or glass microspheres. In this single-center study, we focused on metastatic colorectal cancer patients treated with glass microspheres, aiming to predict treatment response using pre-TARE FDG PET radiomics modeling. ***Materials and Methods:***

We evaluated treatment response using PERCIST criteria. Lesions were categorized as responders (complete/partial regression) or non-responders (stable/progressive disease). Target lesion segmentation was performed using 3D Slicer on PET images (Voxel size 3.64x3.64x3.26 mm^3, bin size 0.5 g/mL). Radiomics features (RF) were extracted using PyRadiomics. Data were split into training and testing sets (80:20 ratio). Standardization of features was achieved with StandardScaler (mean = 0, standard deviation = 1), and principal component analysis (PCA) reduced feature dimensionality. ***Results:*** A total of 107 RFs were found in the analysis of 82 treated lesions (n:56/26; responders/non-responders). ICC (intraclass correlation coefficient) and PCA reduced the RF to 7. Among the 3 different PCA threshold combinations of 11 classifier models, the 4 best combinations (70.6% accuracy) were found. Among these 4 models, "AdaBoostClassifier with PCA threshold of 0.99" had the highest sensitivity and accuracy. ***Conclusion:*** In this study, it was found that treatment response could be predicted with 70.58% accuracy using PET radiomics model before TARE. Clinical features are planned to be added to these models in the next phase and it will be tested whether the ideal threshold of 80% accuracy can be reached.

EP-0832

Prediction of Amyloid PET Positivity from FDG PET: a Machine Learning-Based study

Y. Zhang, *H. Shao, G. Huang, C. Zhang, Y. Wang, J. Liu; Department of Nuclear Medicine, Institute of Clinical Nuclear Medicine, Ren Ji Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.*

Aim/Introduction: Amyloid positron emission tomography (Aβ PET) serves as a pivotal diagnostic tool in the diagnosis of Alzheimer's disease (AD). However, not all patients could undergo this examination. With this limitation in mind, we aimed to develop a model utilizing fluorodeoxyglucose positron emission tomography ([18F]FDG PET) as a means to predict Aβ PET outcomes. ***Materials and Methods:*** A total of 155 patients who underwent [18F]FDG PET, [18F]AV45 PET, and T1-weighted magnetic resonance imaging (T1WI) were enrolled in the study. Of these, 70 patients were Aβ PET positive and 85 were negative. PETSurfer was employed to automatically segment brain regions, and standardized uptake value ratio (SUVR) values were extracted. SUVR values and the ratios of SUVR values between brain regions were utilized as separate features. Feature selection was performed using mutual information, Pearson's coefficient, and Boruta. The selected features were then used to train a logistic regression model, which was then evaluated on a separate test set to assess its performance. This process was repeated 100 times for stability. ***Results:*** When using SUVR values alone as features, our model demonstrated a noteworthy performance in the test set, achieving an area under the curve (AUC) of 72.68% ± 5.49%, an accuracy of 72.34% [70.21%, 76.60%], a sensitivity of 77.43% ± 7.26%, a specificity of 67.93% ± 10.92%, a positive predictive value(PPV) of 74.43% ± 7.96%, and a negative predictive value(NPV) of 71.67% ± 8.90% in the test set. However, when incorporating the ratios of SUVR values across different brain regions as features, the model's performance was further enhanced, attaining an AUC of 76.23% ± 7.20%, an accuracy of 76.60% [70.21%, 80.85%], a sensitivity of 80.12% ± 8.55%, a specificity of 72.34% ± 11.77%, a PPV of 78.08% ± 8.98%, and an NPV of 74.67% ± 10.90%. Statistical analysis revealed significant differences between the two methods across all evaluated metrics (including AUC and accuracy, $p < 0.001$; specificity and PPV, $p < 0.01$; sensitivity and NPV, $p < 0.05$). ***Conclusion:*** We introduce a machine learning model leveraging [18F]FDG PET data to forecast Aβ PET outcomes, potentially offering an alternative for patients without Aβ PET access. Utilizing ratios of SUVR values across brain regions as features significantly improves performance over using original SUVR values, likely due to effectively capturing complex inter-regional relationships.

EP-0833

Multicentric whole-body 177Lu-PSMA-SPECT Total Metabolic Tumor Volume (TMTV) extraction for predicting PSA change in 177Lu-PSMA therapy

R. Eduardo[1,2], *L. Vergnaud[3], T. Laitinen[4], L. Imbert[5], C. Boursier[5], T. Zaragori[6], H. Gröhn[4], T. Laitinen[4], H. Mikko[4], A. Dieudonné[7], D. Tonneler[7], A. Edet-Sanson[7], P. Verra[7], P. Decazes[7], J. Badel[1,3], D. Sarrut[1];*
[1]Creatis, Lyon, FRANCE, [2]Siemens Healthcare, Paris, FRANCE, [3]Centre Léon Berard, Lyon, FRANCE, [4]Department of Clinical Physiology and Nuclear Medicine, Kuopio University Hospital, Kuopio, FINLAND, [5]Department of Nuclear Medicine, CHU–Nancy, Nancy, FRANCE, [6]CIC-IT, CHU-Nancy, Nancy, FRANCE, [7]Department of Nuclear Medicine, Centre Henri-Becquerel, Rouen, FRANCE.

Aim/Introduction: An automated method to extract Total Metabolic Tumor Volume (TMTV) from 177Lu-PSMA-SPECT images is proposed. It is used to assess the predictive potential of SPECT images for PSA change. ***Materials and Methods:*** This study involves 4 hospitals using the VERITON SPECT/CT system (Nancy, Kuopio, Rouen, Lyon) and will gather +150 patients. To date, 50 patients who completed 1 to 6 cycles of 177Lu-PSMA have been analyzed. Patients were categorized into 'responders' and 'non-responders' based on PSA nadir (difference between the initial PSA and the lowest PSA value observed throughout the course of treatment). Whole body SPECT/CT images acquired 24hrs after injection of the first cycle were analyzed. To obtain the TMTV, lesion uptake was separated from physiological uptake automatically segmented from the CT images using a deep learning method, followed by application of a threshold based on the mean uptake in physiological areas. Mean uptake in TMTV regions was plotted against response status. A subset analysis focused on bone lesions (TMTVbones) and was automatically extracted by selecting uptake voxels belonging to bones. The Wilcoxson-Mann-Whitney test was employed to analyze the distribution disparities between responders and non-responders. ***Results:*** Statistical analysis revealed significant differences in TMTV between responders and non-responders for 177Lu-SPECT's TMTV and TMTVbones (p-value 0.026 and 0.016 respectively). ***Conclusion:*** Automated TMTV extraction from 177Lu-PSMA-SPECT confirms the potential for prediction of PSA change. These findings underscore the importance of intra-treatment imaging modalities in guiding personalized therapy decisions and optimizing patient outcomes.

EP-0834

Radiomics analysis of 64CuCl2 PET in muscle-invasive bladder cancer: correlation of the primary tumour textural features with the disease extension

F. Fiz[1], *G. Rosari[2], A. Piccardo[1];*
[1]Ospedale Galliera, Genova, ITALY,
[2]University of Rome, Rome, ITALY.

Aim/Introduction: 64CuCl2 is a tracer of cancer metabolism with exclusive hepatic excretion; for this reason, it represents a promising tool in the PET imaging of muscle-invasive bladder cancer (MBC). However, uptake of this tracer within the cancer tissue can be heterogeneous, reflecting intrinsic

MBC characteristics that may be linked with its aggressiveness. We tested this hypothesis by applying a radiomics analysis to the 64CuCl2 PET images in a cohort of MBC patients. ***Materials and Methods:*** We prospectively enrolled patients referred to our institution for pathology-confirmed MBC staging/re-staging between September 2021 and January 2023. All patients underwent a whole-body 64CuCl2 PET/CT; the primary tumour was identified on both series, and volumes of interest were drawn manually. Radiomics features were extracted using LifeX®. Differences in these features between patients with or without nodal (N+ and N-) and distant (M+ and M-) were tested via a univariate analysis, applying Bonferroni correction. Stratification of the features according to the T stages was also tested. ***Results:*** In the PET images, four parameters had a significantly higher value in M+ patients than in M-: Intensity (p=0.0007), metabolically active volume (p=0.0007), GLCM_InverseVariance (p=0.0008) and GLRLM_RLNU (p=0.0009). In the CT datasets, eight parameters were higher in M+ patients than in M-; the most significant were volume (p=0.0008), energy (p=0.000056), GLRLM_RLNU (p=0.0009), and GLZLM_LZE/LZLGE/LZHGE (p=0.0007). Across all parameters, only GLCM_ Normalised InverseDifference in PET was higher in N+ patients than in N-. Entropy, GLCM_Entropy, GLZLM_GrayLevel/ZoneSize_NonUniformity were higher in T3/T4 tumours than in T1 (p<0.001). ***Conclusion:*** Texture analysis identifies a specific pattern in MBC with distant localisations: they are larger, present higher metabolic activity, and have a prevalence of large homogenous areas in the CT texture, possibly corresponding to necrotic or homogenously hypervascular areas. Conversely, no specific pattern identifies MBC with local nodal spread. Radiomics may represent a non-invasive biological characterisation in MBC. Tumours with relevant local extension (T3/T4) have markedly increased heterogeneity than the superficially confined (T1) forms.

EP-0835

Decoding recurrence in Prostate Cancer: Insights from ^{68}Ga-PSMA PET/CT radiomics features

N. Kumar[1], *S. Shamim[1], S. Jaswal[1], A. Mehndiratta[2], G. Arora[1], E. Kayal[2], H. Gupta[1];*
[1]All India Institute of Medical Sciences, New Delhi, India, New Delhi, INDIA, [2]Indian Institute of Technology (IIT) Delhi, New Delhi, INDIA.

Aim/Introduction: The recurrence of prostate cancer (PCa) remains a significant concern despite advances in diagnosis and treatment. Tumor heterogeneity poses a challenge in accurately predicting recurrence risk and tailoring management strategies. 68Ga-PSMA, a PET tracer recently introduced for the imaging of patients with PCa at diagnosis, staging/restaging and to assess the patients with any post-treatment biochemical failure. However, PET/CT has also a limitation to characterize subtle tissue variation and tissue or tumor heterogeneity. This study aims to explore the utility of 68Ga-PSMA PET/CT imaging combined with radiomics features by assessing spatial heterogeneity in tumors through mathematical analysis of texture features in predicting PCa recurrence in patients those achieved post-treatment complete metabolic response (CMR). ***Materials and Methods:*** We ambispectively reviewed PCa patients who underwent 68Ga-PSMA PET/CT to know the disease status. Patients were evaluated based on post-treatment CMR and recurrent disease based on PSMA expression on 68Ga-PSMA PET/CT. Using the MRIcron software (https://www.nitrc.org/projects/mricron), the region of interest (ROI) for CMR and recurrent disease areas were delineated over 2-4 slices on fused PET/CT images with the help of experienced Nuclear Medicine Physician. Haralick texture features were evaluated using a custom-built texture analysis toolbox in MATLAB (v. 2018; MathWorks, Natick, MA, USA). ROC curve analysis was done on significant parameters to estimate the cut-off values along with corresponding sensitivity and specificity. All the analysis was done using SPSS software v22.0. ***Results:*** A total of 31 PCa patients those achieved post-treatment CMR, mean age 63.96±7.62 years were included for the tumor recurrence prediction. The mean duration of CMR with treatment to recurrence was 11.2 ± 4.2 months. A total of 29 texture parameters [9 Gray Level Co-occurrence Matrix (GLCM), 8 histogram & 12 Run Length Matrix (RLM)] were assessed. Of 29 texture parameters, 23 were found to have statistical significance, comprising 8 out of 9 GLCM, 5 out of 8 histogram, and 10 out of 12 RLM features. The determination of concordance and discordance in texture parameters was based on post-treatment CMR as the reference standard. For GLCM parameters, energy, contrast and autocorrelation, showed highest diagnostic accuracy of 82.26%; mean, median, mode showed highest diagnostic accuracy of 90.32% among histogram features and SRHGE and GLV demonstrated the highest diagnostic accuracy of 80.26% among RLM texture features to predict the tumor recurrence. ***Conclusion:*** This approach could facilitate early detection of recurrence and optimize treatment planning, ultimately improving patient outcomes in PCa management.

EP-0836

Exploring the Impact of ^{68}Ga-PSMA PET/CT Radiomics Features to distinguish between normal prostate tissue vs malignant prostate Cancer

N. Kumar[1], *S. Shamim[1], S. Jaswal[1], A. Mehndiratta[2], G. Arora[1], E. Kayal[2], H. Gupta[1];*
[1]All India Institute of Medical Sciences, New Delhi, India, New Delhi, INDIA, [2]Indian Institute of Technology (IIT) Delhi, New Delhi, INDIA.

Aim/Introduction: The known heterogeneous nature of tumor on both gross and cellular levels, genetic and phenotypic levels might affect tumor diagnosis and prognosis thereby impacting the treatment. PET/CT based radiomics features is being applied to study the spatial heterogeneity in tumors that involve the application of various mathematical methods to analyse the relationship between the grey level intensity of pixels or voxels and their position within an image, thereby providing an objective, quantitative assessment of tumour heterogeneity. Present study is aimed to explore the potential of texture parameters extracted from 68Ga-PSMA PET/CT scans in distinguishing between normal prostate tissue vs malignant prostate cancer (PCa). ***Materials and Methods:*** We ambispectively reviewed PCa patients who underwent 68Ga-PSMA PET/CT to know the disease status. Patients were categorized into normal prostate tissue and malignant PCa patients based on PSMA expression on 68Ga-PSMA PET/CT. Using the MRIcron software (https://www.nitrc.org/projects/mricron), the ROI over normal and malignant prostate areas were delineated over 2-4 slices on fused PET/CT images with the help of experienced Nuclear Medicine Physician. Haralick texture features were evaluated using a custom-built texture analysis toolbox in MATLAB (v. 2018; MathWorks, Natick, MA, USA). All the analysis was done using SPSS software v22.0. ***Results:*** A total of 426 biopsy proven (300 malignant; 126 normal) patients with mean age of 67.78±7.17 years were evaluated in retrospective as well as prospective manner. A total of 29 texture parameters [9 Gray Level Co-occurrence Matrix (GLCM), 8 histogram & 12 Run Length Matrix (RLM)] were assessed. All Haralick texture parameters were

found significantly different among PCa and normal prostate tissue ($P < 0.05$). The concordance and discordance of texture parameters was determined based on the Gleason score as reference standard. Among GLCM parameters, dissimilarity and autocorrelation emerged as the top performers in differentiating PCa from normal prostate tissue with AUROC curve of 94.2% and 95.1% with sensitivity, specificity of 91.67%, 92.06% and 90.33%, 95.24%, respectively and having diagnostic accuracy of 91.78%. Similarly, in the context of histogram parameters, mode demonstrated highest diagnostic accuracy of 87.09% with AUROC curve of 93.8%, and sensitivity, specificity of 81.67%, 100%, respectively. For RLM texture parameters Long Run Low Grey-Level Emphasis (LRHGE) showed highest diagnostic accuracy 91.08% with AUROC curve of 94.8%, and sensitivity, specificity of 89.33%, 95.24%, respectively. ***Conclusion:*** Our study findings suggest the feasibility of employing radiomics-based approaches as adjuncts to PET/CT for improved diagnosis and treatment planning in PCa patients.

EP-0837

^{18}F-FDG PET/CT Radiomics features in distinguishing normal kidney from Renal Cell Carcinoma (RCC)

N. Kumar[1], *S. Shamim[1], H. Gupta[1], A. Mehndiratta[2], G. Arora[1], E. Kayal[2], S. Jaswal[1];*
[1]All India Institute of Medical Sciences, New Delhi, India, New Delhi, INDIA, [2]Indian Institute of Technology (IIT) Delhi, New Delhi, INDIA.

Aim/Introduction: Conventional imaging (CT/MRI) are fundamental for staging primary tumors during the initial diagnosis of Renal cell carcinoma (RCC). 18F-FDG PET/CT is a useful adjunct to conventional imaging in establishing metastatic disease in lesions detected by CT, MRI or bone scan. Although F-18 FDG PET/CT is not recommended for diagnosis and staging of RCC based on national and international guidelines. Also, high background of renal pelvis from physiological excretion of FDG limits the evaluation of small primary RCC. The utilization of radiomics features, holds the promise to explore the subtle differences in metabolic activity and tissue characteristics between normal kidney and malignant renal masses by scrutinizing the heterogeneity and complexity of lesions. Thus, the present study is aimed to distinguish between normal kidney vs RCC using 18F-FDG PET/CT radiomics features. ***Materials and Methods:*** This study included 62 histopathologically confirmed RCC patients (50 males; 12 females) with a mean age of 55.46 ± 11.02 years in a retrospective and prospective manner. Using the MRIcron software (https://www.nitrc.org/projects/mricron), the region of interest (ROI) for normal renal parenchyma and RCC mass was delineated within the same patient. Experienced nuclear physicians assisted in delineating ROIs over 2-4 slices on fused PET/CT images. The texture analysis was conducted using a custom-built texture analysis toolbox in MATLAB (v. 2018; MathWorks, Natick, MA, USA). Further, all analyses were conducted using SPSS v22.0 software from IBM Corporation. ***Results:*** A total of 29 texture parameters [9 Gray Level Co-occurrence Matrix (GLCM), 8 histogram & 12 Run Length Matrix (RLM)] were assessed. Eighteen (18) Haralick texture parameters including 8 GLCM, 2 Histogram and 8 RLM parameters were found significantly different among RCC and normal renal parenchyma ($P < 0.05$). The concordance and discordance of texture parameters was determined based on the SUVmax as reference standard. Among GLCM parameters, entropy emerged as the top performers in differentiating RCC from normal renal parenchyma with AUROC curve of 91% with sensitivity, specificity and diagnostic accuracy of 87.1%. Similarly, in the context of histogram parameters, entropyA demonstrated highest diagnostic accuracy of 76.61% with AUROC curve of 81%, and sensitivity, specificity of 58.06 %, 95.16 % respectively. For RLM texture parameters Short Run Low Grey-Level Emphasis (SRLGE) showed highest diagnostic accuracy 88.71% with AUROC curve of 93%, and sensitivity, specificity of 88.7%. ***Conclusion:*** The texture analysis enhances diagnostic accuracy, potentially allowing for earlier and more precise identification of RCC.

EP-0838

The importance of textural analysis of metabolically active thyroid nodules incidentally detected in PET/CT studies

K. Slusarz[1], *M. Buchwald[2], A. Szczeszek[2], J. Partyka[2], S. Kupinski[2], J. Pukacki[2], R. Czepczynski[1];*
[1]Nuclear Medicine Center, Affidea, Poznan, POLAND, [2]Poznan Supercomputing and Networking Center, Poznan, POLAND.

Aim/Introduction: With the growing popularity of PET/CT examinations, the number of accidentally detected metabolically active thyroid nodules is increasing. The nature of these nodules cannot be determined solely on the basis of conventional parameters used in everyday clinical practice. Textural analysis may be helpful, as it allows us to characterize features invisible to the physician with the naked eye. ***Materials and Methods:*** Radiomic features were extracted from PET images of 50 patients utilizing the PyRadiomics Python library. Subsequently, after selecting 20 features with the largest and 20 with the lowest regression coefficients, a logistic regression model for malignancy classification was created. A leave-one-patient-out cross-validation was used to evaluate three types of input variables: clinical data, clinical and radiomic data, and radiomic data only. The results of the textural analysis were correlated with the cytological results of the biopsy or histopathological results in the case of thyroidectomy. ***Results:*** In the cohort of 50 studied patients, 11 were diagnosed with malignant thyroid cancer (60 ± 11 years, female: N=5), and 39 had benign thyroid nodules (58 ± 11 years, female: N=34). An area under the receiver operating curve (AUC) for leave-one-out cross-validation with 20 radiomics features for logistic regression was: 0.89 (95% CI, 0.74-1.00), for support vector machine (SVM): 0.84 (95% CI, 0.67-1.00), and for gradient-boosted decision tree models (XGBoost) it was: 0.77 (95% CI, 0.62-0.92). ***Conclusion:*** Radiomics features may contribute to better characterization of incidentally detected metabolically active thyroid nodules.

EP-0839

A Prognostic PET Radiogenomic Signature for Non-Small Cell Lung Cancer

P. Taheri[1,2], *A. Golden[1];*
[1]Physics, School of Natural Sciences, University of Galway, Galway, IRELAND, [2]School of Mathematical and Statistical Sciences, University of Galway, Galway, IRELAND.

Aim/Introduction: Positron emission tomography (PET) has emerged as a significant imaging modality for diagnosis and treatment response assessment. Radiomics extracts quantitative imaging biomarkers from medical images and non-invasively provides valuable insights into tumor development and likely prognosis [1]. Simultaneously, clinical genomics plays a pivotal role in selecting personalized management strategies [2]. This study aimed to evaluate the integrative value of a prognostic PET-radiomic signature and tumor genomic characteristics obtained from transcriptomics analysis in non-small cell lung

cancer patients. ***Materials and Methods:*** Radiomic features, RNA sequencing data, and clinical risk factors from several NSCLC datasets were assessed in this study. The most significant features and genes were selected using Cox-univariate analysis and the least absolute shrinkage and selection operator (LASSO). Prognostic multivariate signatures were then developed to predict overall survival (OS) and categorize patients into risk groups using each model. To evaluate the association between radiomic risk cohorts and transcriptomic, we performed genomic analyses related to immunomodulator molecules, immune cells, and oncogenic signaling pathways. A multi-omics nomogram was constructed by integrating radiomics, genomics, and clinical data. ***Results:*** We independently developed three predictive models: a PET-radiomic signature (C-Index, 0.71; 95%CI: 0.67, 0.75) (Table 1), a genomic signature (C-Index, 0.82; 95%CI: 0.78, 0.86), and a clinical model (C-Index, 0.65; 95%CI; 0.61, 0.69). Each of these models significantly stratified patients into high- and low-risk groups. Our analysis revealed significant correlations between the radiomic risk score and various subcategories of clinical factors (such as TNM stages, age, and gender), immune cell types, and oncogenic pathways (p<.01). The high-risk cohort exhibited characteristics associated with tumorigenesis, while the low-risk cohort indicated anti-tumor immunity. The integrated nomogram significantly improves predictive performance. ***Conclusion:*** PET radiomic features demonstrate significant potential as non-invasive tools, aiding in risk assessment and providing valuable information on the biological characteristics of NSCLC. The fusion of radiomics and genomics insights in such radiogenomic analyses holds immense promise for advancing personalized NSCLC management. ***References:*** [1] J. J. Van Griethuysen, A. Response Prediction to Chemotherapy in DLBCL patients using dissemination feature Dmax derived from Baseline ^{18}F FDG PET scan

K. Mathiazhagan, *K. J. Das, J. K. Meena;*
NCI Jhajjar, Haryana, INDIA.

Aim/Introduction: DLBCL is the most common type of NHL, which is a more aggressive tumour. Dmax is a simple 3D feature that represent the maximal distance between the two farthest hypermetabolic PET lesions. Despite their heterogeneity, most studies showed a significant prognostic role of Dmax in predicting progression free survival and overall survival in DLBCL. In this study we aim to predict the metabolic response to first line chemotherapy in accordance with Deauville score in patients with biopsy proven DLBCL by using Dmax radiomics feature. ***Materials and Methods:*** 36 biopsy proven DLBCL patients (20 men and 16 woman, median age of 49 (13-76) years) were retrospectively analysed from march 2022 to march 2024. All of these patients underwent ^{18}F-FDG PET/CT scan before treatment and after 3 to 4 courses of chemotherapy. Their height were measured during the time of scan.These patients were followed up for a median period of 6 (3-17)months. The Dmax was calculated automatically using the LifeX software and were analysed by using Mann Whitney U Test (independent). ***Results:*** Of those 36 patients, 12 shows disease progression/ relapse, 13 shows complete metabolic response and 11 shows partial response to chemotherapy. The distance between the two farthest lesions (Dmax) of the baseline ^{18}F-FDG PET/CT were calculated. The mean of Dmax in the treatment response group is 26.73cm and the progression group is 48.74 cm respectively. It shows significant difference in Dmax between the progression and the treatment response group, with p value of 0.007 (p<0.05). However, no significant difference in the height of the patients between the progression and the treatment response group were observed (p valve of 0.934). ***Conclusion:*** This study concludes that the patients with high Dmax has more likely to have disease progression/relapse than patients with low Dmax.

Revolutionizing Colorectal Cancer Evaluation: A Comparative Analysis of AI-Driven and Conventional PET Imaging Techniques

S. Kheruka, *A. Jain, S. Usmani, N. Almaymani, N. Al Makhmari, K. Al Riyami, R. AlSukaiti;*
Sultan Qaboos Comprehensive Cancer Care and Research Centre, muscat, OMAN.

Aim/Introduction: AI in medical diagnostics is a paradigm change, especially in cancer diagnosis. Colorectal cancer, a major cause of cancer deaths, requires new diagnostic methods to improve therapy. This study studies how AI improves metabolic tumour assessments in colorectal cancer using PET imaging. To show how AI can consistently identify and measure tumour metabolic activity, we compare Syngo Via software with an AI-based platform. This might revolutionize cancer diagnosis. ***Materials and Methods:*** We conducted a study that included comparing a group of 15 individuals who had been diagnosed with colorectal cancer. The ^{18}F-FDG PET/CT scan was performed on every patient, and the analysis was conducted using both the regular SyngoVia software and the AI-enhanced RECOMIA platform. Our primary objective was to assess SUVmax, SUVmean, MTV, and TLG, which are crucial parameters for assessing tumour metabolism. The purpose of this comparative method was to evaluate the efficacy and precision of AI in tumour assessment, emphasizing the capacity of AI-powered platforms to enhance diagnostic accuracy. ***Results:*** The findings of the comparison investigation revealed notable disparities between the conventional and AI-driven assessments, namely in the SUVmean, MTV, and TLG measures. The RECOMIA platform, which is powered by artificial intelligence, demonstrated a significant advantage in accuracy. The mean differences observed were -0.87±1.81 for SUVmax (p=0.188), 7.49±6.94 for SUVmean (p=0.0119), -59.60±56.16 for MTV (p=0.0129), and -368.97±595.61 for TLG (p=0.1002). The aforementioned results highlight the enhanced sensitivity and accuracy of artificial intelligence (AI) in identifying small metabolic alterations inside tumours, surpassing conventional diagnostic techniques. ***Conclusion:*** Our work concludes that AI is a powerful tool for assessing colorectal cancer metabolism. AI's better SUVmean, MTV, and TLG metrics analysis supports RECOMIA's use in clinical diagnoses. Integration into

tumour metabolism might improve colorectal cancer therapy by enhancing therapeutic tactics and patient outcomes. This study enables AI-driven cancer diagnoses, advancing precision medicine. ***References:*** 1. 1.Bergstrom M, Muhr C, Lundberg PO, Langstrom B. Feasibility of deep progressive learning reconstruction (DPR) method in ^{18}F-FDG PET/MR for bone lesion diagnosis

S. Zhang[1], *Y. Dong[1], X. Su[2], Y. Yang[2], X. Du[1], H. Feng[1]; [1]First Affiliated Hospital of Dalian Medical University, Dalian, CHINA, [2]Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA.*

Aim/Introduction: Bone metastasis commonly occurs during tumor progression. However, the limited spatial resolution of PET imaging may impede the detection of microlesions. The advent of deep progressive learning reconstruction (DPR) method, leveraging convolutional neural networks (CNN), presents a novel approach [1]. We hypothesize that the DPR algorithm will improve the image quality and focal lesion detection of 18F-FDG PET images. This study aims to utilize DPR to optimize 18F-FDG PET/MR imaging and demonstrate its feasibility for bone lesions diagnosis. ***Materials and Methods:*** We examined ten patients using a PET/MR clinical system. PET images were reconstructed with both the DPR and the conventional ordered-subset expectation-maximization (OSEM) algorithms. The DPR method employs a denoising network (CNN-DE) to eliminate noise from the input image and an enhancement network (CNN-EH) to map a low-convergence image to a high-convergence image. Both networks were trained through a custom-designed feedback network [2]. Quantitative analyses were conducted measuring the standard uptake value (SUV) of bone lesions, the target-to-background ratio (TBR), and the signal-to-noise ratio (SNR). Additionally, three experienced radiologists independently conducted qualitative assessments, rating noise levels, lesion conspicuity, and overall image quality using a five-point Likert scale. They also evaluated diagnostic performance by identifying the number of bone lesions using both magnetic resonance (MR) morphological criteria and abnormal 18F-FDG uptake. ***Results:*** The DPR reconstructions exhibited increases of 48%, 44% and 21% in SNR, SUVmax and TBR, respectively, compared to the conventional group (all $p < 0.01$). On the five-point Likert scale, the DPR group received significantly higher scores for noise level (median score, 4 vs 3), lesion conspicuity (median score, 4 vs 3), and overall image quality (median score, 4 vs 3) (all $p < 0.01$). Moreover, radiologists reported a significantly higher incidence of bone lesions in the DPR group (15.8 ± 1.4) versus the conventional group (12.5 ± 1.6, $p < 0.01$). ***Conclusion:*** The DPR method appears promise in markedly enhancing the quality of bone imaging over standard imaging reconstructions. The improved SNR achieved with the DPR technique enables the detection of small bone lesions that may be masked by noise in conventional reconstructions, thus potentially improving the diagnostic accuracy of 18F-FDG PET/MR imaging for bone lesions. ***References:*** 1. EP-0843

PSMA-positive prostatic volume prediction with deep learning based on T2-weighted MRI

R. Laudicella[1,2,3], *A. Comelli[3], M. Schwyzer[4], A. Stefano[5], E. Konukoglu[6], M. Messerli[1], S. Baldari[2], D. Eberli[7], I. A. Burger[1,8]; [1]Department of Nuclear Medicine, University Hospital Zürich, University of Zürich, Zürich, SWITZERLAND, [2]Nuclear Medicine Unit, Department of Biomedical and Dental Sciences and Morpho-Functional Imaging, University of Messina, Messina, ITALY, [3]Ri.MED Foundation, Palermo, ITALY, [4]Institute of Diagnostic and Interventional Radiology, University Hospital Zürich, Zürich, SWITZERLAND, [5]Institute of Molecular Bioimaging and Physiology, National Research Council (IBFM-CNR), Cefalù, ITALY, [6]Computer Vision Lab, ETH Zürich, Switzerland, Zürich, SWITZERLAND, [7]Department of Urology, University Hospital of Zürich, Zürich, SWITZERLAND, [8]Department of Nuclear Medicine, Cantonal Hospital Baden, Baden, SWITZERLAND.*

Aim/Introduction: High PSMA expression might be correlated with structural characteristics such as growth-patterns on histopathology, not recognized by the human eye on MRI images. Deep structural image analysis might be able to detect such differences and therefore predict if a lesion would be PSMA positive. Therefore, we aimed to train a neural network based on PSMA PET/MRI scans to predict increased prostatic PSMA uptake based on the axial T2 weighted sequence alone. ***Materials and Methods:*** All patients undergoing simultaneous PSMA PET/MRI for PCa staging or biopsy-guidance between April 2016 and December 2020 at our institution were selected. To increase the specificity of our model, the prostatic beds on PSMA PET scans were dichotomized in positive and negative regions using an SUV threshold greater than 4 to generate a PSMA PET map. Then a C-ENet was trained on the T2 images of the training cohort to generate a predictive prostatic PSMA PET map. ***Results:*** 154 PSMA PET/MRI scans were available (133 [68Ga]Ga-PSMA-11 and 21 [18F]PSMA-1007). Significant cancer was present in 127 of them. The whole dataset was divided into a training cohort ($n = 124$) and a test cohort ($n = 30$). The C-ENet was able to predict the PSMA PET map with a dice similarity coefficient of 69.5±15.6%. ***Conclusion:*** Increased prostatic PSMA uptake on PET might be estimated based on T2 MRI alone. Further investigation with larger cohorts and external validation is needed to assess whether PSMA uptake can be predicted accurately enough to help in the interpretation of mpMRI.

Development of a Radiopharmaceutical Verification System using Smart Device and Mixed Reality

M. Shiga, *M. Sato, H. Daisaki, S. Isogai; Gunma Prefectural College of Health Sciences, Maebashi, JAPAN.*

Aim/Introduction: One of the most serious accidents is the misadministration of radiopharmaceuticals used in nuclear medicine examinations. There have been reports of the occurrence of misadministration and its causes [1,2]. To prevent such misadministration, radiologists take measures such as checking drugs every morning and labeling patients scheduled for administration. After all, the possibility of human error still exists because of human management. Therefore, in this study, we developed a deep learning model to classify radiopharmaceuticals using mixed reality device in hospitals. Furthermore, we

attempted to develop a system that can easily classify the type of radiopharmaceuticals by displaying the results on a hologram. ***Materials and Methods:*** Images of radiopharmaceuticals were captured using a mixed reality device. There were 15 types of radiopharmaceuticals to be captured. The images were taken in a radiopharmaceutical administration room in a hospital. These images were used as training data, and the pre-trained GoogLeNet of ImageNet was used for transfer training. A total of 12464 images were prepared, and 10-fold cross-validation was performed. In addition, Grad-CAM was applied to provide a basis for classification. ***Results:*** Accuracy of 99.98% was achieved. Observation of GradCAM also revealed that the classification was based on the shape of the radiopharmaceutical container, mainly the radiopharmaceutical label. Although some of the images showed the effects of over-learning, they can be used as a double-check. ***Conclusion:*** A system for matching radiopharmaceuticals has been developed. In the future, by developing and combining face recognition technology for patients, it will be possible to determine whether a drug can be administered by taking a picture of the drug with a smart terminal in the hospital, such as a mixed reality device. In other words, it will be possible to prevent incorrect administration. In addition, because a camera attached to a mixed reality device captures a radiopharmaceutical in the hand simply by bringing it into their view, it is possible to classify radiopharmaceuticals with more natural movements and to take measures that are more visually comprehensible, such as adding annotations to the real space. ***References:*** [1] Bogner, M. S., Human Error in Medicine, CRC, Press, pp. 179-196 (2018) [2] Marks, P., Pressures of the day can lead to misadministration of radiopharmaceuticals within an Aus- tralian setting, J. Nucl. Med., 57(supplement 2), 2659 (2016).

Deep learning-based classification and segmentation of whole-body ^{18}F-FDG PET/CT examinations using manually generated segmentation masks

D. Steube[1], H. Hillenhagen[1], S. Stilgenbauer[2], A. J. Beer[3], M. Beer[1], M. Götz[1], W. Thaiss[4], ***G. Glatting[5];***
[1]Department of Diagnostic and Interventional Radiology, University Hospital of Ulm, Albert-Einstein-Allee 23, 89081 Ulm, GERMANY, [2]Comprehensive Cancer Center Ulm, Albert-Einstein-Allee 23, 89081 Ulm, GERMANY, [3]Department of Nuclear Medicine, University Hospital of Ulm, Albert-Einstein-Allee 23, 89081 Ulm, GERMANY, [4]Department of Diagnostic and Interventional Radiology, University Hospital of Ulm, Albert-Einstein-Allee 23, 89081 Ulm, Germany; Department of Nuclear Medicine, University Hospital of Ulm, Albert-Einstein-Allee 23, 89081 Ulm, GERMANY, [5]Department of Nuclear Medicine, Ulm University, Albert-Einstein-Allee 23, 89081 Ulm, GERMANY.

Aim/Introduction: As convolutional neural networks (CNNs) are demonstrating progressive benefit in various medical specialties, we aimed to implement a medical image analysis tool for the automated classification and segmentation of integrated whole-body 18F-Fluorodeoxyglucose (FDG) Positron Emission Tomography/Computed Tomography (PET/CT) scans. The objective was to prospectively reduce medical misdiagnosis and oversights, enhance reporting efficiency, and facilitate easier access for unexperienced professionals. To address this aim, we primarily evaluated the performance of a CNN in classifying individual transverse PET/CT slices as either physiological or pathological. Subsequently, we programmed a CNN to delineate areas of increased uptake using the same images. ***Materials and Methods:*** The initial training dataset consisted of 262 individual whole-body PET/CT studies (152 male, 58.2 ± 14.8 years; 110 female, 59.1 ± 15.8 years), acquired at our institution between 2015 and 2021. These studies were primarily categorized as diseased (n = 98) and healthy (n = 164). All patients in the diseased group underwent manual segmentation and annotation for pathological and physiological regions. Due to technical constraints, only 76 of the diseased studies were available for training after preprocessing. Additionally, 15 random patients of the healthy group were selected and underwent physiological segmentation to create an independent testing dataset. To ensure diverse training, various approaches were conducted, such as generating different-sized image patches, varying the number of input layers, and overlaying CT and PET in different opacities. This resulted in 72 independent experiments for binary classification using a DenseNet121-based CNN and 60 for segmentation using a U-Net-based CNN. ***Results:*** The leading classification model for categorizing individual PET/CT layers achieved a predictive accuracy of 0.986 ± 0.029. Related F1-score, sensitivity and precision were 0.985 ± 0.029, 0.986 ± 0.029 and 0.987 ± 0.025, respectively. Regarding pathological segmentation, the best model obtained a Dice coefficient (DSC) of 0.659 ± 0.016 and a Hausdorff distance (HD) of 13.619 ± 2.624. For physiological segmentation, the corresponding DSC and HD were 0.800 ± 0.023 and 12.957 ± 1.737. Applied to the independent test dataset, the same models achieved an accuracy of 0.916 ± 0.036 for classification and a DSC of 0.522 ± 0.019 and a HD of 27.883 ± 1.230 for segmentation. ***Conclusion:*** Despite a relatively small dataset, especially the classification CNN models showed promising results for future integration into clinical practice. Therefore, additional training data augmented with supplementary information and multiple independent tests are required in follow-up studies to ensure reliability.

EP-0846

Performance Clinical Deep Learning Reconstructions applying Half dose FDG PET/CT protocols

E. Marino[1,2], *G. A. Peña[1], H. Liu[3];*
[1]FUESMEN (Fundación Escuela de Medicina Nuclear), Mendoza, ARGENTINA, [2]CNEA (Comisión Nacional de Energa Atómica), Buenos Aires, ARGENTINA, [3]Hebei University, Hebei, CHINA.

Aim/Introduction: FUESMEN installed a new digital SiPM PET/CT system, which enables high-speed scanning through its advanced AI iterative reconstruction engine. The AI reconstruction is a CNN-based iterative reconstruction which uses a pre-trained neural network to predict low noise PET images and improve image contrast[1]. This new system doubles the number of patients scanned each day and reduces the injected doses by half compared to the previous BGO PET/CT system. The aim of this study is to evaluate the image quality of Deep Progressive Reconstruction (DPR) compared to the standard OSEM in FDG scans of patients administered with half the injected standard dose. ***Materials and Methods:*** Image quality was evaluated in one hundred oncology patients injected with 2.035 MBq/kg to reduce the radiation dose by optimizing FDG PET/CT protocols. Two PET reconstructions were applied: standard OSEM (2 iter, 20 subsets) and AI recon (DPR ST1).Volumen of interest (VOI) in the liver, blood pool and muscle were located. For the VOIs measurement were obtained SUV max, SUV mean and standard deviation (SD). Image quantitative analysis applying coefficient of variation percentual (COV) in the liver (COVliver) were compared between OSEM and DPR reconstructions. Normal physiological biodistribution in liver, muscle and blood pool were compared, a T-student test was performed to establish the relationship. For

each overall image quality was subjectively rated by the referring physician on a 4-point scale (IQ score: 1 excellent, 2 good, 3 poor but interpretable, 4 poor not interpretable). SUVmax measurements and anatomic axial size were obtained from 92 malignant lesions. ***Results:*** Normal physiological distribution values were SUVmean-liver-OSEM= 2.414 and SUVmean-liver-DPR= 2.438, T-student test found a statistically significant relationship between SUVmean OSEM and SUVmean DPR [p = 0.006 (95% CI) values and pearson coefficient of 0.98 and high linear correlation R2= 9,65(Figure 1). In the image quantitative analysis values in the liver were COV-DPRmean = 6.98 and COV-OSEMmean = 11.39, obtaining 40.29 % of high reduction noise(Figure 3). The size range of the metastatic lesions was from 4 mm to 82 mm. The SUV max values presented a linear correlation with a determination coefficient of 0.871 (Figure 3). For half dose image quality score evaluation 92 % for PET OSEM were IQ good and for DPR were IQ Excellent. ***Conclusion:*** DPR reconstructions present a promising tool in PETCT protocols, offering excellent image quality with half the activity injected per patient. ***References:*** [1] Amirhossein,Isaac,Hosseini,Ismini,René,Habib. Deep-learning based classification of [18F]FDG PET/CT images for the diagnosis of neurodegenerative diseases

D. Kim[1], *S. Lee[1], H. Lim[1], D. Kim[2,3], K. Choo[1], H. Han[4], J. Lee[4], S. Seo[2], S. Baek[2], C. Yu[5], M. Yun[2];*
[1]Yonsei University, Seoul, KOREA, REPUBLIC OF, [2]Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF, [3]Hallym University College of Medicine, Anyang, KOREA, REPUBLIC OF, [4]Ewha Womans University, Seoul, KOREA, REPUBLIC OF, [5]Severance Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: ^{18}F-Fluorodeoxyglucose (FDG) PET/CT has been proven to be an effective biomarker of neurodegeneration, aiding the diagnosis of various diseases such as Alzheimer's disease. Recently, convolutional neural network (CNN) has been widely adopted to classify FDG PET/CT scans into various diseases, such as Alzheimer's disease. Extending on previous studies, this study aims to explore whether CNN is capable of classifying FDG PET/CT images to detect persons with normal condition (NC), Alzheimer's disease (AD), multiple system atrophy (MSA), progressive supranuclear palsy (PSP), and Lewy-body disease (LBD). ***Materials and Methods:*** This retrospective study involved 243 patients (mean age: 67.0±9.4, 132 male) who underwent FDG PET/CT examinations at Severance Hospital from 2015 to 2023. Labels were assigned on the consensus of two experts, one nuclear medicine physician and one clinician. ^{18}F-FP-CIT PET/CT examinations had been performed for the diagnosis of MSA and PSP. For external validation, 198 FDG PET/CT scans (mean age: 75.5±7.7, 109 male) were collected from Alzheimer's Disease Neuroimaging Initiative (ADNI). All scans were spatially normalized to the Dementia-Specific [18F]-FDG PET template1. Intensities of the scans were normalized by 99.9th percentile voxel intensity and clipped between [0, 1]. Out of a total of 441 data from Severance and ADNI, 332 scans were used for training and validation (136 NC, 88 AD, 45 MSA, 44 PSP, 19 LBD), and 109 scans were left out for test (38 NC, 44 AD, 11 MSA, 11 PSP, 5 LBD). DenseNet was implemented for classification, and model performance was evaluated by accuracy for general performance and AUROC for class-specific performance. ***Results:*** The accuracy of the model was 0.878 for in-house and 0.867 for external test set. For in-house test set, the AUROC of each class versus others was 0.970, 0.998, 0.914, 0.967, and 1.000 for NC, AD, MSA, PSP, and LBD respectively. For external test set, the AUROC was 0.956 and 0.949 for NC and AD. The confusion matrices for in-house and external dataset are provided in the table below. ***Conclusion:*** Experimental results demonstrate that convolutional neural network can robustly perform multi-class classification of ^{18}F-FDG PET/CT scans into NC, AD, LBD, MSA, and PSP. Future work should involve FDG scans from different institutes to further validate our findings. ***References:*** 1. Della Rosa, Pasquale Anthony, et al. TB-GAN: A new developed Deep Learning Framework for SPECT Myocardial Perfusion Image Denoising

S. Entezarmahdi[1], *A. Karimi[2], R. Faghihi[2], S. Ghasempoor[1], T. Ghaedian[1];*
[1]Shiraz University of Medical Sciences, Shiraz, IRAN, ISLAMIC REPUBLIC OF, [2]Shiraz University, Shiraz, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: In the field of single-photon emission computed tomography (SPECT) myocardial perfusion imaging (MPI), image denoising is a critical issue as it can impact clinical decision. This paper introduces an innovative deep neural network approach aimed at improving the quality of SPECT myocardial perfusion images by minimizing noise. ***Materials and Methods:*** This study was conducted on 407 individuals using a dual head gamma camera. Myocardial perfusion SPECT was performed with a projection time of 26 seconds to acquire images with standard noise levels. Immediately following the SPECT imaging, a 180-second planar scan was initiated (anterior and lateral views). This latter scan served as the high-quality, low-noise ground truth. The deep network structure proposed in this study, referred to as TB-GAN (Two-branches generative adversarial network), is composed of two encoder paths and one decoder section. One encoder network is responsible for computing the noise features, while the other extracts the signal features. The output features from these two encoders are combined and fed into a decoder to reconstruct a low-noise image. A discriminator network is employed as the adversarial objective function.The results obtained from this method were compared with those from the traditional noise-to-clean U-Net GAN framework. Quantitative evaluation was carried out using the peak signal-to-noise ratio (PSNR), structural similarity index (SSIM), and root mean square error (RMSE). ***Results:*** The quantitative assessment revealed a statistically significant enhancement in both PSNR and SSIM when utilizing the proposed framework. Specifically, PSNR increased from 34.74 to 41.95 and SSIM from 0.805 to 0.949 when comparing TB-GAN to the traditional GAN. Although the traditional GAN network produced outputs with a slightly lower RMSE than TB-GAN, the difference was not statistically significant (RMSE=0.116 for GAN vs. 0.159 for MV-GAN). Furthermore, both visual and count profile analyses demonstrated the superior performance of the proposed network. ***Conclusion:*** The newly proposed deep neural network structure named as TB-GAN, designed for enhancing image quality in SPECT myocardial perfusion images, has demonstrated superior noise reduction results compared to the traditional noise-to-clean U-Net GAN framework.

EP-0849

The impact of introducing deep learning based [18F] FDG PET denoising on EORTC and PERCIST therapeutic response assessments in digital PET/CT

K. Weyts, *J. Lequesne, A. Johnson, H. Curcio, A. Parzy, E. Coquan, C. Lasnon;*
Centre François Baclesse, Caen, FRANCE.

Aim/Introduction: [18F]FDG PET denoising using deep learning artificial intelligence (AI) was previously found to induce slight modifications in lesion and reference organs' quantification and in lesion detection. As a next step, we aimed to evaluate its clinical impact on solid tumour treatment response assessments in PET, while comparing "standard PET" to "AI denoised half-duration PET" ("AI PET") during follow-up. ***Materials and Methods:*** 110 patients referred for baseline and follow-up standard digital [18F]FDG PET/CT were prospectively included. "Standard" EORTC and, if applicable, PERCIST response classifications by 2 readers between baseline standard PET1 and follow-up standard PET2 as a "gold standard" were compared to "mixed" classifications between standard PET1 and AI PET2 (group 1; n=64), or between AI PET1 and standard PET2 (group 2; n=46). Separate classifications were established using either lean body mass standardized uptake values (SUL) from "ultra-high definition (UHD)" PET reconstruction (± AI-denoising), or EANM research limited version 2 (EARL2)-compliant Gaussian filtered SUL in standard PET and using the same filter in AI PET. ***Results:*** Overall, pooling both study groups, in 11/110 (10%) patients at least one EORTCUHD or EARL2 or PERCISTUHD or EARL2 mixed vs standard classification was discordant, with 369/397 (93%) concordant classifications, unweighted Cohen's kappa = 0.86 (95% CI: 0.78-0.94). These modified mixed vs standard classifications could have impacted patient management in 2% of patients. ***Conclusion:*** Although comparing similar PET images is preferable for therapy response assessment, the comparison between a standard [18F]FDG PET and an AI denoised half-duration PET is feasible and seems clinically satisfactory.

EP-0850

3D Automatic Segmentation of Colorectal Liver Metastases Detected in FDG PET Images Using Deep Learning

S. Asa, *S. E. Biyikoglu, K. Şahin, S. Sager, H. B. Sayman;*
Istanbul University-Cerrahpasa Cerrahpasa Medical Faculty Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: This study aims to utilize deep learning algorithms for the automatic three-dimensional segmentation of liver metastases in PET images of patients with colorectal cancer. ***Materials and Methods:*** Twelve patients diagnosed with at least one liver metastasis were included. Intestinal and renal activities were removed from three-dimensional PET images using 3D Slicer, isolating the liver for creating ground truth and test images. Two models were trained and tested using the Monai Label extension package and Python (version 3.11.5). The accuracy of these models in detecting lesions was evaluated. Additionally, their effectiveness in segmentation was assessed using Dice scores. ***Results:*** The first model was trained on a patient with three lesions (15 mm to 68 mm), and the second model was trained on the same patient plus another with nine lesions (5 mm to 29 mm). Testing involved ten patients with 79 lesions, 21 of which were under 10 mm. The first model accurately segmented 58.2% of lesions, and the second segmented 69.6%. Excluding smaller lesions, segmentation accuracies were 79.3% and 89.6%, respectively. Average Dice scores were 0.76 and 0.80. ***Conclusion:*** Deep learning algorithms appear to be effective for the automatic 3D segmentation of liver metastases in FDG PET images. The second model, trained with more lesions, demonstrated higher accuracy. This indicates that the quantity and diversity of lesions used in training significantly affect model performance. ***References:*** 1) Pieper, S., Halle, M., & Kikinis, R. (2004, April). 3D Slicer. Deep Learning FDG PET only CT-Free organ segmentation using nnU-NET.

Y. Salimi, *Z. Mansouri, H. Zaidi;*
Division of Nuclear MEdicine and Molecular Imaging, Geneva University Hospital, Geneva, SWITZERLAND.

Aim/Introduction: Automated and reliable organ segmentation is useful in various applications in nuclear medicine. A number of studies used reregistered CT images to segment healthy organs using deep learning (DL). However, CT used for attenuation correction (CTAC) are usually low-dose or ultra-low dose, thus affecting the performance of models. Besides, the high prevalence of mismatch between CT and PET images is another limitation (1), impacting the relevance of the approach. Moreover, this approach is not applicable to CT-less attenuation and scatter corrected PET images (2). The aim of this study was to develop a DL-based segmentation pipeline using only PET emission images. ***Materials and Methods:*** A total of 1487 total-body and whole-body ^{18}FDG PET/CT images were collected. Overall, 22 organs were segmented from co-registered CTAC images using previously developed models (3). Pairs of PET and CT images and their segmentations were visually assessed and 947 cases presenting with mismatch between CT and PET images due to respiratory motion, or bulk motion were excluded. The remaining 540 images were visually evaluated and used to train a nnU-Net model (4) employing uncorrected PET images as input and segmentation masks as target in a five-fold data split scheme. The organs were divided into two subgroups, namely (i) bones plus brain and eyeballs (8 organs) and (ii) soft-tissue and lung (14 organs). Training was continued for 2000 epochs and the average five-fold Dice coefficient was reported. ***Results:*** The average Dice coefficients achieved were 0.90±0.03, 0.76±0.06, 0.80±0.06, 0.63±0.23, 0.86±0.09, 0.94±0.02, 0.92±0.12 , 0.60±0.13, 0.73±0.12, 0.90±0.07, 0.85±0.15, 0.80±0.10, 0.84±0.11, 0.93±0.02, 0.83±0.11, 0.90±0.06, 0.89±0.03, 0.71±0.09, 0.88±0.03, 0.86±0.03, 0.96±0.03, 0.77±0.07 for Aorta, Colon, Oesophagus, Gall Bladder, Kidneys, Liver, Lungs, Adrenal Glands, Pancreas, Rectus Abdominus Muscle, Spleen, Stomach, Urinary Bladder, Heart, Eyeballs, Femoral Heads, Iliac, Rib Cage, Sacrum, Vertebrae, brain, and clavicle, respectively (Table 1). Overall, a Dice coefficient of 0.82 on average over all organs was obtained. ***Conclusion:*** We developed a deep learning-based pipeline for automated segmentation of 22 organs from uncorrected PET images. This pipeline is capable of segmenting multiple organs with high accuracy in cases where the co-registered CT or MRI segmentation is either not available or not reliable owing to either mismatch or low performance achieved due to noisy CT images. ***References:*** 1.Shiri I, Salimi Y, et al. EP-0852

Feasibility study of low-dose PET/MR imaging based on deep learning

Y. Xu;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: Reconstructing the low-dose PET (L-PET) images to the high-quality full-dose PET (F-PET) ones based on deep learning is an effective way that both reduces the radiation exposure and remains diagnostic accuracy. ***Materials and Methods:*** The imaging of L-PET was simulated by reconstruction with 10% of the original data. A total of 9000 slices of (^{18}F-FDG) PET date in 30 patients with malignancy. we propose a resource-efficient deep learning framework for L-PET reconstruction and analysis, referred to as transGAN-SDAM, to generate F-PET(100%) from corresponding L-PET(5%). The transGAN-SDAM consists of two modules: a transformer-encoded Generative Adversarial Network (transGAN) which generates higher quality F-PET images, and a Spatial Deformable Aggregation Module (SDAM) which integrates the spatial information of a sequence of generated F-PET slices to synthesize wholebody F-PET images. Another 20 PET date in patients with malignancy were used as validation objects. The average peak signal-to-noise ratio (PSNR), structural similarityindexmeasurement(SSIM), andvoxel-scalemetabolic difference (VSMD) were adopted to quantitatively evaluate the generated F-PET slices vs. original F-PET slices. We compared the proposed transGAN-SDAM with 6 state-of-the-art models that were specially designed for L-PET reconstruction or medical image synthesis: uNet, dNet , CycleGAN, fpGAN, BiGAN, and 3D Cycle-GAN. An experienced nuclear medicine doctor evaluates the image quality of the original image and the reconstructed F-PET image, and gives the diagnostic results. ***Results:*** The transGAN-SDAM framework significantly outperformed all of the com-peting models with the highest PSNR (30.1±3.8), SSIM (0.930±0.05), and the lowest VSMD (0.048±0.042), indicating that the quality of generated F-PET images by transGAN-SDAM is closest to the ground-truth F-PET images. TransGAN and transGAN-SDAM can produce richer and more accurate structural and metabolic details than other approaches. TransGAN-SDAM achieved the smallest voxel-scale difference to the ground-truth F-PET images. Quantitative analysis from the Bland- Altman and paired t-test show that wholebody F-PET image generated by transGAN-SDAM has smaller 95% limits of agreements (from -0.21 to 0.21), smaller 95% CI (from - 0.020 to 0.0120) and stronger correlation coefficient (0.815) than that from transGAN(Fig.3). These results showed that SDAM can optimize the whole-brain SUVR analysis and achieve more comparable results.There was no significant difference in image quality score and diagnostic results between the reconstructed F-PET image and the original image($P<0.05$). ***Conclusion:*** The transGAN-SDAM can be as a resourceefficient framework for L-PET(10%) reconstruction and accurate wholebody quantitative analysis. This framework is likely to become an effective method to reduce radiation dose in PET examination in the future.

EP-0853

Can Deep Learning Techniques Bridge the Disparity in Image Quality between Low and High-Performance PET Scanners

Y. Sun[1], *O. Mawlawi[2];*
[1]Rice University, Houston, TX, UNITED STATES OF AMERICA, [2]MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: PET images from scanners with high sensitivity and resolution are usually of better quality than those from lower performing systems. In this work, we present a diffusion model-based pipeline to improve the quality of PET images from low performing (LP) PET scanners and compare the results to high performing (HP) systems. ***Materials and Methods:*** Our pipeline consists of a modified U-Net encoder in addition to a conventional image-conditioned denoising diffusion probabilistic model. An input image from a LP scanner is first encoded into a feature image in the modified U-Net model in order to account for misalignment/pixel-size/field-of-view differences between the LP and HP images. The feature image is then concatenated with a randomly noisy ground truth PET image (HP) before inputting the results into the diffusion model. To train this model, F^{18} FDG brain PET scans from 10 patients were acquired on a Siemens Quadra scanner (HP) and a GE DMI-5 Rings scanner (LP). Data was acquired (HP/LP) for 6/3 min and reconstructed using OSEM with $440 \times 440 \times 180$ and $1.62 \times 1.62 \times 2$ mm3/ $256 \times 256 \times 119$ and $2.73 \times 2.73 \times 2.8$ mm3 respectively. Datasets from HP and LP scanners were then registered using MIM software before input into the model. For each patient dataset, we selected an average of 55 2D axial slices. All models were fine-tuned using the ADAM optimizer on the PyTorch platform and executed on NVIDIA A100 GPUs. We compared the performance of our model with the ground truth (HP) using visual inspection and line profiles as well as calculating PSNR and SSIM. ***Results:*** Visual inspection of the resultant images show that our model produces similar image quality compared to the ground truth. Average PSNR/SSIM results over 10 non-continuous slices for LP with respect to HP were 28.25dB/0.966 while those from our model were 29.62dB/0.971 respectively. ***Conclusion:*** Our model has the capacity to improve the quality of LP scanners thereby bridging the disparity with respect to HP scanners. Future work is to extend the current 2D model to a 3D version and validate the results on a full size patient datasets.

A pilot study of structuring radiology reports of FDG-PET/CT using LLM followed by SUVmax-based voxel identification algorithm

K. Hirata[1], *A. Katsuki[2], S. Watanabe[1], J. Takenaka[1], N. Wakabayashi[3], T. Yoshimura[1], M. Tang[1], K. Minami[1], N. Uetake[2], K. Kudo[1];*
[1]Hokkaido University, Sapporo, JAPAN, [2]GE HealthCare Japan, Tokyo, JAPAN, [3]Hokkaido Cancer Center, Sapporo, JAPAN.

Aim/Introduction: We previously demonstrated that using SUVmax values described in FDG-PET/CT reports enabled the identification of voxel locations on images by matching of SUVmax values [1]. Locating lesions enables the chronological comparison of their progression and efficient creation of datasets for supervised learning. Compared to traditional natural language processing (NLP) methods, recently developed large language models (LLMs) are expected to extract information more efficiently from report texts. This pilot study is designed to explore the potential of using LLM to extract "site and SUVmax" data from reports and to assess the feasibility of determining lesion coordinates by identifying voxel locations on images. ***Materials and Methods:*** In this IRB-approved study (#23-0128), we reviewed patients who underwent FDG-PET/CT examinations at our institute from 2009 to 2023. A total of 100 patients were randomly selected for the analysis. All reports were written in Japanese. The LLM used was Llama2-based "ELYZA-japanese-Llama-2-13b". The reports were input into the LLM with a prompt that ask to return a JSON-format text like {site: "pancreas", SUVmax:

"3.141"}. The ground truth was determined by consensus of two nuclear medicine physicians. The LLM's accuracy was evaluated using the Dice similarity coefficient (DSC). The voxel having the exact value of SUVmax was scanned in the image. ***Results:*** From the reports of 100 cases, an average of 2.64 (range 0-10) pairs of site-SUVmax per report were annotated by physicians. The DSC was 0.631 ± 0.365 (mean ± SD) with 34 (34%) cases of perfect match (DSC=1). In some instances, so-called hallucinations were observed, i.e., the creation of SUVmax values not described in the original report text. Of 264 SUVmax values in the ground truth, 173 (66%) were correctly extracted by the LLM. Among the 173, by referring the corresponding image, the coordinates of voxel that had the SUVmax were uniquely determined in 87 (50%). When restricted to cases of SUVmax with three decimal places (e.g., 3.141) or SUVmax greater than 5, the unique identification was achieved in 49 out of 66 cases (74%). ***Conclusion:*** Combining LLM-based report structuring with voxel identification algorithm using SUVmax as a lesion identifier enabled the construction of a multi-modal system of lesion localization, although accuracy is expected to be further improved by refining the LLM prompts. ***References:*** 1. Hirata K, et al. A Preliminary Study to Use SUVmax of FDG PET-CT as an Identifier of Lesion for Artificial Intelligence. Front Med (Lausanne). 2021 Apr 28;8:647562.

EP-0855

Automated Deep Learning-based Segmentation of Cardiac PET Images: Addressing Challenges in PET/CT Mismatch and Low Dose CTAC Scans

Y. Salimi, *Z. Mansouri, H. Zaidi;*
Division of Nuclear MEdicine and Molecular Imaging, Geneva University Hospital, Geneva, SWITZERLAND.

Aim/Introduction: Quantitative cardiovascular PET/CT imaging is useful in the diagnosis of multiple cardiac pathologies. Methodologies were developed for deep learning-assisted segmentation of cardiac substructures on CT images (1, 2). However, in most of the cases, there is a mismatch between PET and CT images and the performance of these models is not consistent over low-dose CTAC images commonly used in clinical practice, thus leveraging the need for robust PET image segmentation methodology to address these challenges effectively. ***Materials and Methods:*** This study included 406 cardiac PET images from 147 patients (43 ^{18}F-FDG, 329 13N-NH3, and 37 82Rb images). Previously trained models were used to segment heart cavities, including the left myocardium (LM), left ventricle (LV), and right ventricle (RV) from CT images. The segmentations were resampled to PET resolution, after visual assessment of the first 50 images, only 8 cases presented with good registration accuracy between the CT LV myocardium and corresponding PET uptake, and as such correction of the segmentation output was necessary. The segmentation masks were corrected using a combination of thresholding on PET images (empirical threshold of 1.3 SUV) and dilation of the CT segmentation mask with multiple conditions for image processing. All images were visually checked and edited if necessary. The refined PET and segmentation pairs were fed to a nnU-Net model (3) in a five-fold data split strategy making sure that multiple images from the same study (stress and rest) are all in the train or test split. Dice coefficients were calculated to evaluate the segmentation performance. ***Results:*** The average Dice coefficient was 0.86 ± 0.01, 0.79 ± 0.13, and 0.86 ± 0.08 for LV myocardium, LV cavity, and RV, respectively (Table 1). The Dice coefficient was consistent over all folds and there was no statistically significant difference between the Dice values for the three radiotracers. ***Conclusion:*** We developed an automated deep learning-based segmentation pipeline to segment cardiac PET images from various radiotracers with acceptable accuracy in terms of achieved Dice coefficient. Initial visual assessment on some cases indicated reduced potential for CT cardiac segmentation in the context of cardiac PET quantification. This methodology is particularly suited for CT-less PET imaging or hybrid PET/CT imaging where there is significant misregistration between CT and PET images. ***References:*** 1.Wasserthal J, et al. EP-0856

Evaluating 2D and 3D nnU-Net auto-segmentation performance on metastases in differentiated thyroid carcinoma patients from FDG-PET/CT images.

Y. Li[1], *K. Hirata[1,2,3], J. Takenaka[1,2], H. Endo[1], M. Tang[1], S. Watanabe[1,2,3], R. Kimura[1,4], K. Kudo[1,4];*
[1]Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, Japan., Sapporo, JAPAN, [2]Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, Japan, Sapporo, JAPAN, [3]Global Center for Biomedical Science and Engineering, Faculty of Medicine, Hokkaido University, Sapporo, Japan, Sapporo, JAPAN, [4]Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, Japan, Sapporo, JAPAN.

Aim/Introduction: Differentiated thyroid carcinoma (DTC) is one of the most common malignant tumors of the endocrine system. Whole-body FDG-PET/CT is an important tool for diagnosing DTC, and accurate segmentation of tumor is a key part for the subsequent treatments. However, manual segmentation of tumors on FDG-PET/CT is a task that is time-intensive and subject to variation between different observers. Although deep learning (DL)-based methods for automated segmentation are currently widely investigated, specialized DL methods are needed to build for each research. For general application, we used nnU-Net, which refers to a robust and self-adapting framework based on 2D and 3D vanilla U-Nets, to automated segmentation of metastatic lesions in DTC patients from FDG PET/CT images. In addition, compare the segmentation performance of the 2D and 3D nnU-Net models. ***Materials and Methods:*** We retrospectively analyzed 169 patients (Age ranging 8-86 years, male:female = 66:103) who had DTC and showed FDG-avidity before undergoing I-131 treatment at Hokkaido University Hospital from 2009 to 2022. Ground truth masks were manually obtained from a researcher who used Metavol software to segment FDG-avid metastatic lesions (SUV>3) on FDG-PET/CT, and the segmented lesions were modified and confirmed by an experienced nuclear medicine physician. The dataset was used for training using a 5-fold cross validation scheme. All PET images in DICOM image files transformed and saved as NIfTI image files. We trained the 2D and 3D nnU-Net models via Python. All available ground truth masks were cropped, resampled, and normalized into multiple types of voxel size (2-4 x 4 x 4 mm3). The pre-processing of nnU-Net included cropping, resampling, and normalization. The training parameters were as follow: optimizer stochastic gradient descent with momentum (Momentum SGD), maximum training epochs 200, mini-batch size 250. The segmentation performance was assessed by the Dice similarity coefficient (DSC). ***Results:*** The mean DSC (± standard deviation) of the 2D nnU-Net model in the validations dataset was 0.68±0.28, while that of the 3D nnU-Net model was 0.64±0.32. For the sub-analysis, the 2D and

3D nnU-Net models each accounted for 53% and 47% of DSC >0.75, respectively, which did not reach statistical significance (P=0.33). ***Conclusion:*** The nnU-Net is a promising tool for auto-segmenting the metastatic lesions of DTC patients on FDG PET/CT images. Additionally, the 2D nnU-Net model achieved a relatively higher DSC compared to the 3D nnU-Net model, although more data are necessary to improve the accuracy of nnU-Net model.

Development of Quality Assurance System for Amyloid PET using Artificial Intelligence for Anomaly Detection

M. Sato[1], *H. Daisaki[1,2], S. Isogai[1], M. Shiga[1], Y. Ikari[3,2], K. Tsuda[4,2], K. Hirata[5,2], U. Tateishi[6,2], K. Mori[7,2], H. Fujii[8,2], JSNM PET Imaging Site Qualification Program (J-PEQi);*
[1]Gunma Prefectural College of Health Sciences, Maebashi, JAPAN, [2]JSNM PET Imaging Site Qualification Program (J-PEQi), Tokyo, JAPAN, [3]Kobe City Medical Center General Hospital, Kobe, JAPAN, [4]Juntendo University, Tokyo, JAPAN, [5]Hokkaido University, Sapporo, JAPAN, [6]Tokyo Medical and Dental University, Tokyo, JAPAN, [7]Toranomon Hospital, Tokyo, JAPAN, [8]Japan Radioisotope Association, Tokyo, JAPAN.

Aim/Introduction: Lecanemab, a new medicine for Alzheimer's disease, developed and is beginning to be used around the world [1]. Amyloid PET imaging is required for selecting patients for this new medicine. Therefore, quality assurance is necessary for each hospital to perform precision amyloid PET imaging. The Japanese Society of Nuclear Medicine is in charge of Quality Assurance of amyloid PET at hospitals all over Japan. Physical and visual evaluation for checking for the presence of Gibbs artifacts and other abnormalities of a large amount of phantom imaging data sent from all over Japan. Visual evaluation is effort-intensive because it is necessary to observe all slices of phantom data to check for the presence of artifacts. In addition, a small number of people are currently qualified to analyze submission data from hospitals all over Japan, and each investigator is in charge of a large number of hospitals. This trend may occur outside of Japan as well. Therefore, visual evaluation was automated by developing and applying a deep-learning model for anomaly detection. ***Materials and Methods:*** We employed 434 normal and 129 abnormal images. Anomaly detection was achieved using Autoencoder, a model that extracts features, and reconstructs the original input data based on the extracted data. By training Autoencoder with only phantom imaging data with no artifacts, it can reproduce the input image as an artifact-free image regardless of the presence or absence of artifacts in the input image. In other words, the output images are subtracted from the input images, and the sum of the values can be defined as the abnormal. Based on this abnormal score, a threshold value was set and the true positive rate and false positive rate associated with the threshold change were calculated. ***Results:*** As a result of receiver operating characteristic analysis, an area under curve value of 0.902 was achieved. It was possible to determine abnormalities including Gibbs artifacts with 90.1% accuracy. The normal and abnormal score were obtained, and it was found that a difference existed between the scores. ***Conclusion:*** We developed a system to automate quality assurance before amyloid PET is performed. This study may provide a milestone in the implementation of quality assurance for the introduction of quality assurance for amyloid PET in the world in the future. ***References:*** [1]Pemberton HG, et al. Quantification of amyloid PET for future clinical use: a state-of-the-art review. Eur J Nucl Med Mol Imaging. 2022, 49(10):3508-3528.

Prediction of 123I-FP-CIT SPECT results from the first acquired projection using a convolutional neural network

W. Othmani, *D. Morland;*
Institut Godinot, Reims, FRANCE.

Aim/Introduction: Dopaminergic imaging with 123I-FP-CIT is commonly used for the diagnosis of parkinsonian syndromes in clinically challenging cases. At least 30 minutes of immobility are required for SPECT acquisition, which can be difficult to achieve in this particular patient population. This study aimed to develop a convolutional neural network (CNN) model able to predict the examination result with a high sensibility from the first acquired projection alone, i.e. detect normal patients with high reliability. ***Materials and Methods:*** All 123I-FP-CIT SPECT performed in our center were retrospectively included from June 2017 to February 2024 and divided into a training (70%) and a validation (30%) set. A total of 100 additional SPECT were used as an independent testing set. All images were labelled by two independent physicians. A VGG16-like CNN model was trained on the first acquired projection (anterior and posterior view at 0°). A threshold to maximize sensitivity while maintaining good accuracy was then determined. The model was validated in the independent testing set. Saliency maps were generated to visualize the most impactful areas in the classification. ***Results:*** A total of 982 123I-FP-CIT SPECT were retrieved and labelled (training set: 618 ; validation set: 264; independent testing set: 100). The trained model achieved a sensibility of 98.0 %, with 1 false negative prediction, resulting in a negative predictive value of 96.3% while maintaining an accuracy of 78.0 %. The saliency maps confirmed that the areas with the greatest impact on the final classification corresponded to the basal ganglia and the background noise. ***Conclusion:*** Our results suggest that this trained CNN could be used to exclude presynaptic dopaminergic loss with high reliability, using only the first acquired 123I-FP-CIT SPECT projection. It could be particularly useful when dealing with compliance issues. Confirmation with images from other centers will be necessary.

EP-0859

Fully automatic lesions segmentation on whole-body [18F]FDG PET/CT using maximum intensity projections images and deep-learning: a novel approach

C. Constantino[1,2], *F. P. M. Oliveira[1], S. Vinga[2], D. C. Costa[1];*
[1]Champalimaud Clinical Centre, Champalimaud Foundation, Lisbon, Portugal, Lisbon, PORTUGAL, [2]INESC-ID, Instituto Superior Tecnico, Universidade de Lisboa, Lisbon, PORTUGAL.

Aim/Introduction: Maximum intensity projections (MIP) images of whole-body [18F]FDG PET investigations are commonly used for first-instance visual interpretation, enabling fast hotspot detection. Our aim is to evaluate the feasibility of using 2D MIP images with deep-learning to obtain automatically segmented whole-body/total-body [18F]FDG PET images. ***Materials and Methods:*** A dataset of 489 staging whole-body/total-body [18F]FDG PET/CT scans with corresponding manually segmented lesions from patients with melanoma (n=177), lung cancer (n=168), and lymphoma (n=144), published by autoPET MICCAI challenge [1,2], were included. Approximately 80% of the patients of each primary cancer were randomly chosen to train (N=391), and the remaining to test. A 2D U-Net was trained based on MIP images of different view angles (coronal, sagittal, and obliques). Twenty (20) out of 391 patients from the training set were left aside from network training and later used to optimize a post-processing methodology to convert

2D into 3D segmentation. For benchmarking, the same training dataset was used to train a 3D U-Net. To train both networks, the state-of-the-art nnU-Net framework was used [3]. To evaluate the segmentation in the test set, voxelwise Dice coefficient (DC), sensitivity, and predictive positive value (PPV); and lesion detection sensitivity score (LDSS) and lesion detection error score (LDES) were computed against the ground truth (manual segmentation). LDSS represents the proportion of the lesions on the ground truth that were segmented/detected by the network. LDES represents the proportion of regions segmented by the network that were not in the ground truth. ***Results:*** MIP-based segmentation achieved a voxelwise median DC, sensitivity, and PPV of 0.70 (interquartile range [IQR]:0.59-0.82), 0.65 (IQR]:0.50-0.87), and 0.88 (IQR:0.71-0.95), respectively. The median LDSS and LDES were 0.73 (IQR:0.55-1) and 0.04 (IQR:0-0.34), respectively. The benchmark 3D segmentation achieved a median DC, sensitivity, PPV, LDSS, and LDES of 0.80 (IQR:0.70-0.88), 0.78 (IQR:0.63-0.89), 0.88 (IQR:0.77-0.95), 0.80 (IQR:0.60-1), and 0.11 (IQR:0-0.33), respectively. The metrics' differences between MIP and 3D-based segmentations were statistically significant for the DC and sensitivity ($p<0.05$). ***Conclusion:*** This novel experimental approach using 2D MIP images achieved excellent results in the segmentation of whole-body/total-body [18F]FDG PET/CT images, with potential for further improvement. At the moment, the current implementation had slightly inferior results compared to the state-of-the-art 3D U-Net. This MIP-based approach may be useful when no special GPU capabilities are available, since 2D networks run faster on the CPU than 3D. ***References:*** Clark et al., https://doi.org/10.1007/s10278-013-9622-7; Gatidis et al., https://doi.org/10.1038/s41597-022-01718-3;Isensee et al., https://doi.org/10.1038/s41592-020-01008-z.

ML-models built using clinical parameters and radiomic features extracted from ^{18}F-choline PET/CT for the prediction of biochemical recurrence after metastasis-directed therapy in patients with oligometastatic prostate cancer

L. Urso[1], *L. Manco[2], N. Ortolan[1], F. Borgia[1], A. Malorgio[3], G. Scribano[4], C. Cittanti[1], L. Uccelli[1], G. Di Domenico[4], A. Stefanelli[3], A. Turra[2], M. Bartolomei[5];*
[1]Department of Translational Medicine, University of Ferrara, Ferrara, ITALY, [2]Medical Physics Unit, University Hospital of Ferrara, Ferrara, ITALY, [3]U.O.C. Radiotherapy, University Hospital of Ferrara, Ferrara, ITALY, [4]Department of Physics and Earth Science, University of Ferrara, Ferrara, ITALY, [5]Nuclear Medicine Unit, Onco-Hematology Department, University Hospital of Ferrara, Ferrara, ITALY.

Aim/Introduction: [18F]F-Fluorocholine (18F-choline) PET/CT is mainly used in biochemical recurrence (BCR) of PCa. Oligometastatic patients at 18F-choline PET/CT may be treated with metastasis-directed therapy (MDT). Aim of this retrospective study was to combine conventional and radiomic parameters extracted from 18F-choline PET/CT and clinical data to build machine learning (ML) models able to predict MDT efficacy. ***Materials and Methods:*** oligorecurrent patients (up to 5 lesions) at 18F-choline PET/CT and treated with MDT were retrospectively retrieved. A per-patient and per-lesion analysis was performed, using BCR after MDT as standard of reference. Clinical parameters (i.e. PSA value and ISUP grade) and conventional PET parameters (i.e. SUVmax and SUVmean and volumetric parameters) were collected. The sites of recurrence were manually segmented on 18F-choline PET/CT images and 854 radiomic features (RFts), including original, first order, texture and wavelet based were extracted using an open-source software on both PET and CT datasets, according to IBSI. The most robust and non-redundant RFts correlated with the outcome of MDT were selected using Wilcoxon-Mann-Whitney U test ($p<0.05$). Five different ML models were trained and tested for both CT and PET RFts using Orange data-mining. Ten-fold cross validation was performed on the training dataset (70% of the whole dataset) and the performance metrics were calculated (i.e. area under the curve - AUC; classification accuracy - CA). Validation was performed on the remaining 30% dataset to evaluate the model's performance to predict MDT efficacy. ***Results:*** Overall, 46 pathological uptakes at 18F-choline PET/CT were selected and segmented in 29 patients. After a median follow-up of 3.5 (1-6.5) years, BCR after MDT occurred in 19 (65.5%) patients corresponding to a total of 35 (76%) lesions. Clinical and conventional PET parameters failed to accurately predict the outcomes of MDT. Seventy-three and 33 robust RFTs, were selected from CT and PET dataset, respectively. PET models showed better performance than CT model to discriminate BR after MDT. Random forest (RF) was the most accurate CT-based ML model (AUC=0.92; CA=0.85). The best PET model was stochastic gradient descendent (SGD) (AUC=0.95; CA=0.90). ***Conclusion:*** ML-models built using clinical parameters and CT and PET RFts extracted by 18F-choline PET/CT can accurately predict BR after MDT in oligorecurrent PCa patients. The best performances were obtained using SGD model trained with PET RFts. If validated externally, our results could contribute to improve the selection of oligorecurrent PCa patients to be referred to MDT or to systemic therapies.

EP-0861

Artificial Intelligence to evaluate metabolic tumor burden in primary staging of rectal cancer with ^{18}F-FDG PET/CT

E. Etchebehere[1,2], *V. Heringer[1], J. Fonseca[1], M. C. Mendes[1], B. Amorim[1], A. Santos[1,2], M. Silveira[1], M. Lima[1], M. Lima[1,2], L. Cunha[1], C. A. Martinez[1], C. Coy[1], J. Barreto[1];*
[1]UNICAMP, Campinas, BRAZIL, [2]MND group, Campinas, BRAZIL.

Aim/Introduction: To evaluate the performance of Artificial Intelligence (AI) software to determine metabolic tumor burden in the primary staging of rectal cancer. ***Materials and Methods:*** A cross-sectional retrospective analysis was conducted on 51 histology-proven rectal cancer patients (35% females; mean age = 61 years) who underwent a staging ^{18}F-FDG PET/CT. Whole-body metabolic tumor burden parameters (wbMTV and wbTLG) were quantified semi-automatically and through AI algorithm. The AI software's ability to correctly identify and classify the primary lesion, regional lymph nodes, and distant metastases was evaluated. In addition, the intraclass correlation coefficient (ICC) was applied to evaluate concordance between the AI-based software and the semiautomatic software in determining wbMTV and wbTLG. Values above 0.7 were considered to indicate substantial agreement. ***Results:*** The AI and semiautomatic tumor burden metrics correlated strongly for both wbMTV (ICC=1.00; 95% CI=0.94 - 0.99; P <0.0000) and wbTLG (ICC=1.00; 95% CI=0.80 - 0.90; P<0.0000). Additionally, the AI software's ability to correctly identify lesions compared to the documented staging was better for the identification of distant metastasis (78,57% of patients), mildly adequate to identify regional lymph nodes (50,00%) and had poor performance for identification of the primary lesion (5,76%). On the other hand, the time spent calculating these metrics was less by AI than by the semiautomatic method,

especially in patients with advanced disease. ***Conclusion:*** The determination of whole-body metabolic tumor burden on ^{18}F-FDG PET/CT with AI software is challenging because of the physiologic bowel activity. However, deep learning may have the ability to overcome these challenges and may, therefore, improve the primary staging of rectal cancer. ***References:*** 1.Fonseca J, Etchebehere E. et al. Automatic Lesion Detection On Whole Body ^{18}F-FDG PET-CT Using A Cluster-Corrected Statistical Method

A. Macula[1], *S. Colombo Serra[2], G. Valbusa[2], A. Bifone[1], P. Gandolfo[3];*
[1]Università di Torino, Torino, ITALY, [2]Bracco Imaging S.p.a., Torino, ITALY, [3]Centro Diagnostico Italiano, Milano, ITALY.

Aim/Introduction: Automated lesion segmentation in [18F] FDG-PET/CT images poses a significant challenge, currently tackled by various AI-based strategies. The aim of this study is to accurately delineate lesions within individual organs through a statistical analysis of the Standard Uptake Value (SUV) signal corrected by a clustering algorithm to reduce the incidence of false positives. This abstract describes the first application of this technique, with a specific focus on liver tissue. ***Materials and Methods:*** The dataset used in this study originates from the AutoPET Challenge 2022 [1], comprising 1014 [18]-FDG PET-CT acquisitions, each annotated with lesions. Half of the dataset represents negative controls, while the other half includes cases of lymphoma, melanoma, and lung tumors. The first step involved employing the TotalSegmentator tool [2] to segment organs from CT images. Subsequently, an organ-wise analysis of SUV distribution was conducted on healthy subjects to verify the physiological tracer uptake in each organ and extract the mean and standard deviation of the distribution. The investigation initially focused on the liver. 74 subjects with liver lesions were selected from the dataset. PET images underwent preprocessing involving a smoothing filter. A distribution probability map was then generated for each patient, where individual pixels denote the likelihood that the corresponding pixel in the PET image belongs to the normal SUV distribution. Pixels with low probability values may indicate potential lesions. A clustering algorithm was applied to exclude isolated pixels and identify "uniform" regions, thereby reducing false positive findings. The performance of the detection method was evaluated using metrics derived from the free receiver operating characteristic (FROC) curve to determine the optimal combination of free parameters (smoothing factor and clustering threshold) considering the mean results on all the 74 patients. ***Results:*** The FROC curve attested that the best combination of free parameters across all patients was smoothing factor equal to 1 and clustering threshold 0.98 (Sensitivity of 0.8, False Positive Per Image=4.5). ***Conclusion:*** Preliminary assessment of the performance of our method in a lesion detection task in the liver appears very encouraging. However, further analysis is required, which should include applying the technique across diverse organs and corroborating its effectiveness using a separate, external dataset. ***References:*** [1] Gatidis S, Kuestner T. EP-0863

Evaluation of combined or separate automatic segmentation models for ^{68}Ga-PSMA PET/CT and ^{177}Lu-PSMA SPECT/CT.

P. Decazes, *S. Perret, L. Albe, D. Tonnelet, Z. Mesbah, R. Modzelewski, P. Bohn, P. Vera, A. Edet-Sanson, A. Dieudonné; Henri Becquerel Cancer Center, Rouen, FRANCE.*

Aim/Introduction: Manual segmentation of metastatic prostate lesions on radiolabeled PSMA PET and SPECT images can be time-consuming and tedious. The goal of this work is to determine whether, for automatic segmentation, a nnU-net model trained on these two modalities jointly is at least as effective than two models trained on these modalities separately. ***Materials and Methods:*** The database consisted of 29 patients. For each patient, baseline 98Ga-PSMA PET/CT images and after first cure 177Lu-PSMA SPECT/CT were available. All images were segmented by a nuclear medicine physician as reference. We divided our database into two parts. The first part consists of 23 patients used for training, while the other 6 were used to evaluate the model. We trained 3 nnUNet models. The first model (MPET) with only PET/CT images, the second model (MSPECT) with SPECT/CT images, and the last model (MPET_SPECT) with both PET/CT and SPECT/CT images. For each model, we used the same patients for both training and validation. Automatic and manually segmented volumes were evaluated and compared by using Dice coefficient. ***Results:*** Average manually segmented volume of the lesions per patient was 610cm3 (+/-684cm3) [min 13cm3-max 2568cm3] for PET/CT and 1147cm3 (+/-1139cm3) [3cm3-4140cm3] for SPECT/CT. Automatic segmented volumes of the lesions per patient were 578cm3 (+/- 804cm3) [27cm3-2325cm3] , 663cm3 (+/-942cm3) [8cm3-2687cm3] , 579cm3 (+/- 803cm3) [25cm3-2323cm3] for PET/CT and 2010cm3 (+/-1530cm3) [598cm3-5090cm3] , 1442cm3 (+/-1711cm3) [157cm3, 4951cm3] , 1459cm3 (+/-1678cm3) [178cm3, 4914cm3] for SPECT/CT for MPET, MSPECT and MPET_SPECT, respectively. Mean absolute pourcentage difference between automatic and manually segmented volumes of the lesions per patient were 8.9% (+/-9.2%) [1.1%-27.9%] , 31.5% (+/-20.8%) [5.3%-61.5%] , 8.1% (+/-5.5%) [1.2%-18.8%] for PET/CT and 152.2% (+/-168.1%) [26.8%-495.9%] , 20.1% (+/-15.3%) [1.2%-48.6%] , 16.1% (+/-11.2%) [1.0%-34.6%] for SPECT/CT for MPET, MSPECT and MPET_SPECT, respectively. Concerning Dice coefficients, they were 0.93 (+/-0.03) [0.87-0.96] , 0.75 (+/-0.15) [0.53-0.92] , 0.93 (+/-0.03) [0.87-0.69] for PET/CT and 0.63 (+/-0.21) [0.24-0.87] , 0.84 (+/-0.08) [0.67-0.91] , 0.86 (+/-0.05) [0.76-0.90] for SPECT/CT for MPET, MSPECT and MPET_SPECT, respectively. ***Conclusion:*** The volume of lesions segmented on PET and SPECT images are different, probably linked to the partial volume effect on SPECT, limiting segmentation accuracy. Despite these differences, an nnU-net model trained on both PET and SPECT modalities achieves results comparable to those trained on both modalities separately.

EP-0864

Predictive Power of Radiomics Analysis of Pretreatment Ga-68 PSMA PET/CT in Patients with Metastatic Castration-Resistant Prostate Cancer Treated With Lu-177 PSMA for Treatment Response and Prognosis

E. Temizer, *Ü. Abdülrezzak, D. Göksülük, D. Algur, A. Tutuş; Erciyes University, Kayseri, TÜRKIYE.*

Aim/Introduction: To determine the predictive power of machine learning (ML) methods using radiomics features and clinicopathological parameters obtained from Ga-68 PSMA PET/CT imaging performed before Lu-177 PSMA radioligand theraphy (RLT) in patients metastatic castration resistant prostate cancer (MCRPC) and to investigate factors associated with overall survival (OS). ***Materials and Methods:*** The study included 63 patients with MCRPC who received at least two sessions of Lu-177 PSMA treatment and underwent Ga-68 PSMA PET/CT examination before treatment. Volumetric regions of interest were determined from three different metastatic bone lesions (189 lesions in total) and 129 radiomics features were obtained from each region of interest. The predictive power of three different ML methods, including mean radiomics features and clinicopathological data, was evaluated with reference to the change in prostate-specific antigen (PSA) levels before and after treatment. Kaplan-Meier analysis and log-rank test were used to determine whether there was a statistically significant difference in OS between the RLT-responsive and non-responsive groups. Cox regression analyses were used to determine the factors associated with OS. ***Results:*** The mean age of the patients was 67.27±7.47 years (47-85). Of the 63 patients with MCRPC, 32 were in the treatment-responsive group (%50.8) and 31 (%49.2) were in the non-responsive group. ML models included 9 radiomics features and 6 clinicopathological variables in the prediction of treatment response. In treatment response prediction, the highest correct classification rates of %86.7 were obtained with the naive bayes (NB) model when recursive feature elimination was used as feature selection and with random forest and NB models when select by filter was used. For the whole patient group, the median OS was 17±1.59 (%95 CI: 13.86-20.13) months by Kaplan-Meier analysis, while the median OS was 21±3.27 (95% CI: 14.58-27.41) months in the RLT-responsive group and 14±3.07 (%95 CI: 7.97-20.02) months in the non-responsive group. Cox regression analyses revealed that haemoglobin level measured before treatment was inversely associated with mortality. ***Conclusion:*** ML methods based on radiomix analysis features and clinicopathological data obtained from Ga-68 PSMA PET/CT imaging performed before Lu-177 PSMA treatment in patients with MCRPC have been shown to predict treatment response. This study shows that evaluating patients with prostate cancer who are planned to undergo RLT with ML models predicting treatment response before treatment and enrolling them in the treatment programme can be more cost-effective, as well as contributing to not involving patients in a tiring and time-consuming treatment process.

EP-0865

Is it feasible for a nuclear medicine physician to develop artificial intelligence model permitting to distinguish the whole-body scintigraphy images obtained with two different radiopharmaceuticals?

B. Duchaj[1], *L. Noskovičová[2], S. Balogová[2,3]; [1]Department of Nuclear Medicine St. Elisabeth Oncology Insitute, Bratislava, SLOVAKIA, [2]Department of Nuclear Medicine, Comenius University Bratislava, St. Elisabeth Oncology Insitute and Bory Hospital, Bratislava, SLOVAKIA, [3]Department of Nuclear Medicine, Hôpital Tenon GH AP.SU, Paris, FRANCE.*

Aim/Introduction: To analyze the feasibility of development of artificial intelligence (AI) model by nuclear medicine physician (NMP) without relying on third-party/developer, using a simple, free-web-based application by creating a prototype AI model permitting to distinguish the normal and abnormal whole-body scintigraphy images obtained with two different radiopharmaceuticals ***Materials and Methods:*** Two free-available, well documented frameworks (TensorFlow and Keras), with clear written tutorials were chosen. A series of 287 and 256 whole-body anterior/posterior (AP/PA) scintigraphies with 99mTc-MDP (bone-scintigraphy, BoS) and 99mTc-besilesomab (besilesomab-scintigraphy, BeS) were chosen for their "visual similarity". Images were cropped, all metadata removed. Two classification goals were set: 1. BoS/BeS binary classification, 2. BoS(132/442) and BeS(323/189) negative/positive multiclass classification, with pretrained Xception network. The negative/positive finding was defined by three experienced NMPs. Train to validation split was 70%/30% for both goals. Learning was performed on Google Colab (TPU), with data augmentation to enhance the datasets. TensorBoard was visually analyzed, the epoch with the best validation/training loss to validation/training accuracy was chosen. The simple prototype application was built with PHP, Python and React languages, taking photo with mobile phone and subsequent image analysis. ***Results:*** Models were evaluated against 20(10/10AP/PA) scintigrams not used for the training in BoS/BeS(Goal1) and in Bos/BeS positive/negative(Goal2) group, respectively. For Goal1: The model accuracy (after 52 epochs) was 98,75%. 10/10 AP/PA BoS and 12/12 AP/PA BeS (both visually checked by NMP) with average accuracy 99,50% for BoS and 94,68% for BeS. For Goal2: The model accuracy (after 84 epochs) was 63%, all BoS and BeS were correctly classified, the model correctly identified 95% and 35% positive and negative BoS, and 30% and 90% positive and negative BeS. The estimated time spent on the project was overall 100hours (with 1.76h-average time-per-day). ***Conclusion:*** The results permit to conclude that it is feasible for a NMP to learn and understand the basic principles of deep learning, to create a dataset, to train simple, pretrained neural network model and to use it in a reasonable time, that can be even shorter with appropriate education in the field (e.g. provided as a dedicated course). The limitation of the study is the small size of dataset for the multi-class classification, especially for BeS, no DICOM analysis, no feature extraction, which can explain the false-negative classification rate in BeS-positive group. The complex multiclass classifications, 3D-studies/segmentations will require a bigger dataset, feature extraction and well-educated and trained multidisciplinary team including NMPs.

EP-0866

Predictive Value of Radiomics Analysis of Flor-18 Flurodeoxyglucose Positron Emission Tomography/Computed Tomography In Response to Neoadjuvant Chemotherapy In Breast Cancer Patients

D. Algur, *Ü. Abdülrezzak, E. Temizer, D. Göksülük, A. Tutuş; Erciyes University Faculty of Medicine, Kayseri, TÜRKIYE.*

Aim/Introduction: To determine the role of machine learning methods using radiomics features and clinicopathologic parameters obtained from PET/CT images in predicting pathologic complete response (PCR) in breast cancer (BC) patients undergoing initial staging with F^{18} FDG PET/CT. ***Materials and Methods:*** A total of 132 BC patients who underwent pre-treatment F^{18} FDG PET/CT imaging and neoadjuvant chemotherapy (NAC) between

January 2017 and December 2021 were included in the study. In the LIFEx v7.4.0 application used for radiomics analysis, the primary malignant lesion in the breast was identified on the images of each patient and volume of interest were created by semi-automatic segmentation method. A total of 129 radiomics features were obtained from each segmented region of interest through the software program and feature selection was performed. The selected features were statistically evaluated together with the patient's clinicopathologic data to create combined models. The dataset was randomly divided into training and test groups in a 7:3 ratio. The predictive power of three different machine learning methods, namely "Naive bayes" (NB), "support vector machines" (SVM) and "random forest" (RF), was evaluated for PCR after NAC. Kaplan-Meier analysis and log-rank test were used to determine whether there was a statistically significant difference between the groups in terms of overall survival. Cox regression analyzes were used to evaluate the effects of variables on overall survival. ***Results:*** PCR was observed in 32 of 132 patients with BC. 18 radiomics features and 5 clinicopathological variables were involved in machine learning models in PCR prediction. Among clinicopathological variables, immunohistochemical subtype and Ki-67 value were common features selected by all three machine learning algorithms. When "recursive feature elimination" and "select by filter" were used as radiomics feature selection methods, the highest correct classification rate of 87.2% was achieved with the RF model. When the molecular subtypes were divided into luminal group and nonluminal group, it was found that the risk of mortality was 3.77 times higher in the nonluminal group. The PCR rate of the nonluminal subgroup was significantly higher than the luminal group. ***Conclusion:*** When radiomics features obtained from F^{18} FDG PET/CT imaging performed before NAC in BC patients were combined with clinicopathological data, machine learning methods were able to predict PCR with high accuracy. Thus, by detecting insufficiently effective NAC early, toxicity can be avoided, cost burden can be prevented and other treatment options can be taken into consideration.

EP-0867

High-Accuracy Prostate Cancer Staging Prediction Using K nearest Neighbour (KNN) Classifier: A Machine Learning Approach

J. Chaudhary[1], *A. Phulia[2], A. K. Pandey[1], P. D. Sharma[3], S. Kumar[1];*
[1]All India Institute of Medical Sciences, New Delhi, INDIA, [2]Maulana Azad Medical College, New Delhi, INDIA, [3]SGTB Khalsa College, University of Delhi, New Delhi, INDIA.

Aim/Introduction: This study was conducted to see whether a KNN classifier-based machine learning model can prognosticate patients of prostate cancer, when given input about primary and metastasis detected on Ga-68 PSMA PET/CT scan, Tc-99m MDP bone scan and multiparametric MRI (mpMRI) scan. ***Materials and Methods:*** The retrospective data of histopathologically confirmed prostate cancer patients who underwent Ga-68 PSMA PET scan between October 2022 and January 2024 were analysed. The presence of primary and metastasis detected through PET/CT scan, Tc-99m MDP bone scan and mpMRI scan were recorded. Following European Association of Nuclear Medicine (1), based on Gleason score (histopathology report) and PSA levels, Patients dataset was categorized into intermediate (N=30) and high-risk groups (N= 65). This imbalance dataset was balanced using oversampling method resulting in 65 patients in each group. Then the following procedure: "random partition of dataset into training and test dataset in the ratio of 80:20, 10-fold cross validation techniques during training, KNN (K nearest neighbour) algorithm as classifier, creating a confusion metrics by taking High risk group as POSITIVE for testing the performance of the trained model on test dataset" was repeated fifty times, creating fifty different machine learning model. The model with the best performance was selected. All experiments were performed on a personal computer (Intel(R) Core (TM) i3-10105 CPU @ 3.70GHz, and 8.00 GB RAM) in R statistical program using the "ROSE" and "CARET" package. ***Results:*** There were ninety-nine patients (30 patients in intermediate risk and 65 patients in high-risk) having age: 67.6 ± 8.07 years. The machine learning model was capable of prognosticating patients of prostate cancer based on their imaging results of PET/CT scan, Tc-99m MDP bone scan and mpMRI scan with high accuracy (80%), sensitivity (77%) and specificity (100%). The execution time for training KNN classifier-based machine learning model was 0.170986 ± 0.021754 seconds. On training dataset, the best performing model was found to have 76% accuracy, 65% sensitivity and 96% specificity. ***Conclusion:*** A KNN classifier-based machine learning model when supplied inputs about primary and metastasis detected on Ga-68 PSMA PET/CT scan, Tc-99m MDP bone scan and mpMRI scan, can prognosticate patients of prostate cancer with high accuracy, sensitivity and specificity. ***References:*** 1. EP-0868

Artificial Intelligence Based CT-free Attenuation Correction in Adolescent and Young Adult Mandibular Condylar Hyperplasia Patients

S. Barna[1,2], *M. Szoliková[3], C. Csikos[2], J. Török[4], B. Husztik[3], J. Varga[2], Á. Kovács[3], I. Garai[1,2];*
[1]Scanomed, Debrecen, HUNGARY, [2]Department of Nuclear Medicine and Translational Imaging, Institute of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY, [3]Mediso, Budapest, HUNGARY, [4]Department of Dentistry, Health Care Service Units, Clinics, University of Debrecen Clinical Centre, University of Debrecen, Debrecen, HUNGARY.

Aim/Introduction: Mandibular condylar hyperplasia is a condition in which one of the mandibular condyles is growing faster than the one on the other side resulting in facial asymmetry. It might be accompanied by chewing dysfunction or dental malocclusion. The cornerstone of diagnosis is 99mTc-MDP bone scan and SPECT/CT. Quantitative analysis of the uptake values can further improve diagnostic accuracy, however, standardized uptake values (SUV) can only be generated with CT-based attenuation correction (AC) which gives unnecessary radiation exposure to patients. AI-based AC could help us eliminate unnecessary radiation while providing sufficient data for quantification. Our aim was to compare the SUV values of patients with condylar hyperplasia using CT-based attenuation correction (CT-AC) and an AI-based synthetic CT attenuation correction (SynCT-AC). ***Materials and Methods:*** SUVmax and SUVmean values of 13 patients (12 female, 1 male + mean age 24) were measured using both CT-based and AI-based attenuation correction. 600MBq 99mTc-MDP iv. administered and 120view, 128matrix size SPECT and Low-Dose CT were done. The reconstruction method was OSEM-3D-RR with attenuation and scatter correcton based on original CT and SynCT. Reference SUV values (clivus, calvaria, vertebra) were also measured. SUV values were measured using 2 cm diameter volume of interests (VOIs). Correlation between CT-AC and Sy-CT-AC was measured in all

reference areas and in the mandibles as well. Significance of the differences between CT-AC and Sy-CT-AC based uptake values were analyzed using paired t-test (in case of Gaussian distribution) and Wilcoxon signed rank test. To visualized the difference in the parameters of Sy-CT-AC and CT-based AC, Bland-Altman plots and box-and-whiskers plots were created. ***Results:*** The CT-AC and SyCT-AC based uptake values correlated well (r2 is above 0.93) in all cases. Mandibular and vertebral SUVs turned out to be biased since both SUVmax and SUVmean values were higher with AI-based AC. SUVmax values of the mandibles and vertebrae had a proportional error with AI, meaning the difference in SUVs from CT-based AC is greater at higher SUV values. The relative mandibular uptakes were not biased. Ratios of SUVmax values resulted in less deviation from the CT-based values. ***Conclusion:*** AI-based attenuation correction can be a promising tool in patient evaluation for mandibular condylar hyperplasia, since it provides appropriate quantitative analysis while avoiding unnecessary CT dose We detected high correlation between CT-based and AI-based SUV values. Further studies need to be conducted to elucidate the difference at higher SUV values.

EP-0869

Delayed PET Generation of ^{64}Cu-DOTA-rituximab PET for Internal Dosimetry by Deep Learning-based Generative Model

***S. Woo*[1],** *K. Kim[1], J. Yang[1], C. Kang[1], I. Lim[2], K. Lee[1];*
[1]Division of Applied RI, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF, [2]Department of Nuclear Medicine, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Internal dosimetry of the radiopharmaceuticals requires obtaining their multi-time biodistributions to estimate the cumulative activity. They are non-invasively acquired as the functional imaging, including positron emission tomography(PET). However, obtaining functional imaging several times causes inconvenience. In this context, we propose the dosimetry method that generates the PET images at delayed time point from PET image scanned earlier using deep learning. ***Materials and Methods:*** We obtained PET image of the six cancer patients by administering 8 mCi of 64Cu-DOTA-rituximab and scanned them at 1, 24, and 48h post-injection. The study was approved by the Institutional Review Board of KIRAMS, and all patients provided written informed consent. The intensity normalized constant was adjusted by the amount of the exponential decay of the radioisotope at scanning time. The paired generative model was based on generative adversarial network. The generator was aimed to generate 64Cu-DOTA-rituximab PET image from one scanned earlier. In training, we used sum of two loss functions, least square GAN and L1-loss between generated PET image and its ground-truth. 64Cu-DOTA-rituximab PET image at 24 and 48h post-injection was generated from 1h post-injected one by the generative model. The 2D axial slices was used in training and whole number of slice was 1,794. Images of five patients were used as tranining set and rest was used as test set. ***Results:*** The generated images were evaluated with respect to the image similarity and dosimetry. As similarity metrics, we used structural similarity index(SSIM) and Fréchet inception distance(FID). At 24 and 48h post-injection, SSIM of test set was 0.80 and 0.77. Moreover, FID was estimated as 62.9 and 74.4, respectively. On the other hand, we compared the organ-wise dosimetry results generated by generative model and the ground-truth. The time-integrated activity coefficient(TIAC) of heart, lung, liver, and kidneys was 0.582, 0.238, 0.506, and 0.107 MBq·h/MBq for acquired PET and 0.519, 0.251, 0.465, 0.0766 MBq·h/MBq for the generated PET. The relative errors were 0.108, 0.0546, 0.0810, and 0.284, respectively. ***Conclusion:*** In this study, we suggested dosimetry method that generates 64Cu-DOTA-rituximab PET images at delayed time points from early-scanned PET images using deep learning. It was found that the model effectively predict the TIAC of the heart, lung, and liver but relative less accurate to predict TIAC of kidney. It is expected that the generative model can alleviate the inconvenience of internal dosimetry, by enabling to conduct internal dosimetry by scanning the subject only once.

EP-0870

CT-guided Deep Learning Denoising of Low-Dose Micro-PET for Intraoperative Breast Cancer Specimen Imaging

***E. Balot*[1],** *L. Maris[1,2], F. M. Muller[1], V. Keereman[1,2], S. Vandenberghe[1], C. Vanhove[1];*
[1]Medical Image and Signal Processing, Department of Electronics and Information Systems, Faculty of Engineering and Architecture, Ghent University, Ghent, BELGIUM, [2]XEOS Medical, Ghent, BELGIUM.

Aim/Introduction: Recently, micro-PET/CT imaging emerged as a promising technique for intraoperative margin assessment in curative breast cancer surgery. During oncological surgery, a direct assessment of resected specimens ensures complete tumour removal and absence of residual cancerous tissue. Intraoperative application requires preoperative radiotracer administration to the patient. To limit exposure to patient and surgical staff, the injected dose should be minimal. However, noise is inherent to low-dose scans, consequently degrading the image quality. We investigated whether deep learning (DL) techniques can be used to improve image quality and whether anatomical guidance, leveraged from CT images, boosts the PET image denoising performance. ***Materials and Methods:*** We acquired micro-PET/CT images of resected breast cancer specimens from 27 patients, who were preoperatively injected with 4 MBq/kg of 18F-FDG 142±52 minutes before acquisition. To simulate low-dose PET acquisitions, 2-min time frames were extracted from the obtained 10-min list-mode scan, resulting in five statistically independent replicates. The data was randomly split into a 17/5/5 ratio for training, validation, and testing. Three different 2D U-Net based DL models were trained to predict the 10-min micro-PET image from different inputs: (1) a PET-only model, taking only the low-dose micro-PET as input, (2) a 2-Channel CT-guided model, taking the low-dose micro-PET, concatenated with the micro-CT, as two-channel input, (3) a 2-Branch CT-guided model, taking the low-dose micro-PET and micro-CT as separate inputs to two encoder branches. To quantify model performance, we defined regions of interest in both tumour and benign tissue to calculate the average and standard deviation of SUVmean across five replicates, as well as the contrast-to-noise ratio (CNR) between the tumour and benign regions. ***Results:*** The SUVmean stayed consistent between the 10-min image (10.6), the low-dose images (10.7±0.4) and the images obtained by the PET-only (10.2±0.3), the 2-Channel CT-guided (10.6±0.3) and the 2-Branch CT-guided DL models (10.8±0.3). The CNR improved for the PET-only (2.9±0.1), 2-Channel CT-guided (2.9±0.1) and 2-Branch CT-guided models (3.2±0.1) compared to the low-dose PET images (1.4±0.1) and the 10-min image (2.1). We plan to evaluate the clinical performance of our models by comparing the PET-signals with the true histopathological tumour segmentation. ***Conclusion:*** Our results show that DL denoising of low-dose micro-PET/CT images of breast specimens is possible with or without CT-guidance and leads to comparable

image quality. The proposed methods enable to reduce the injected dose by a factor of five, optimising the implementation of intraoperative PET/CT in the clinic.

EP-0871

Explainable AI and Alzheimer's: A Comparative Study of Regional vs. Global Uptake Values for Diagnostic and Prognostic applications

J. Thorpe[1], *H. Morgan[1], E. Irish[1], S. Michopoulou[2];*
[1]University of Southampton, Southampton, UNITED KINGDOM, [2]University Hospital Southampton, Southampton, UNITED KINGDOM.

Aim/Introduction: Dementia impacts 55 million people across the globe, Alzheimer's Disease being the most common. Generally, patients with Alzheimer's exhibit biomarkers such as Amyloid-beta plaques deposited within the brain. AI techniques have proven successful in predicting Alzheimer's diagnoses using Standard Uptake Value ratios (SUVrs) through PET imaging of Amyloid-beta plaques. Previous research has used SUVrs averaged across larger regions of the brain. Clinicians are hesitant to implement these techniques due to lack of model transparency. In this study we compare the use of individual region and global SUVrs to determine if they provide improvements in diagnostic/prognostic accuracies as well as better model understanding. ***Materials and Methods:*** 748 [18F] Florabetapir PET scans obtained from the Alzheimer's Diseases Neuroimaging Initiative (ADNI) were normalised to Montreal Neurological Institute (MNI) space using Statistical Parametric Mapping 12 (SPM12). We follow a technique of robust PET-Only-Processing (rPOP) as MRI template scans are often unavailable clinically. Segmentation using the Automated Anatomical Labelling Atlas 3 (AAL3) allows for the quantification of these plaques across 166 individual brain regions. A minimum Redundancy Maximum Relevance (mRMR) feature selection algorithm is used to select the most important regions and patients were classified using a random forest classifier. Explanations of the model predictions are provided by Local Interpretable Model-agnostic Explanations (LIME). ***Results:*** We find using uptake values from individual regions show slight diagnostic improvement and significant prognostic improvement in comparison to global uptake values. Comparing Alzheimer's, Mild Cognitive Impairment and CN patients we find 61.8% and 52.7% prognostic accuracy for individual and global SUVrs respectively. These results are attributed to the individual region's better separation for subjects with MCI to healthy individuals (62.2% and 31.1% MCI sensitivity for individual and global regions respectively). Additionally, LIME explanations produce clearer understanding for individual SUVrs due to the precise region locations and weights provided. ***Conclusion:*** Individual regions show promise in addressing the lack of trust between clinicians and diagnostic AI tools for Alzheimer's Disease. The increased accuracy in detecting early stages of Alzheimer's, as well as prognosis, are well aligned with the current prospects for AI in this field. The classification techniques used are relatively basic and comparison with the use of more sophisticated models is required to better understand the applications of this method. Although this model is not a finished product, individual region SUVrs have shown to address many of the hurdles limiting the implementation of AI in a clinical setting.

EP-0872

Assessment of machine learning models as predictors of radioiodine thyroid ablation outcomes

L. Vávrová[1,2,3], *J. Tapprogge[1], D. Rushforth[1], G. Flux[1], I. Murray[1];*
[1]The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, London, UNITED KINGDOM, [2]St George's University Hospitals NHS Foundation Trust, London, UNITED KINGDOM, [3]King's College London, London, UNITED KINGDOM.

Aim/Introduction: The aim of this study was to explore the potential of machine learning to identify factors predictive of successful radioiodine ablation and to develop a model based on multi-centre clinical data. The resulting model could be utilised for early identification of patients at risk of ablation failure. ***Materials and Methods:*** Data from 106 patients from 4 clinical centres recruited to the MEDIRAD project [1] were included. Out of the 106 patients, 84 achieved complete, 14 indeterminate, and 5 incomplete responses at follow-up, 3 patients were lost to follow-up. Successful outcome was defined as thyroglobulin < 2.0 ng.ml-1 at 9 to 12 months after treatment as per the ATA 2015 guidelines. The data comprised of demographic and physical data, diagnosis, biochemistry results before and after TSH stimulation, haematology data, administered activity, thyroid remnant dosimetry, and treatment outcome. In preparation for statistical analysis (univariate and multivariate logistic regression) and machine learning modelling, the missing values were imputed and initial feature selection performed based on feature correlations. The following basic machine learning models were applied: logistic regression, k-nearest neighbours, decision tree, random forest, gradient boosting, Naïve Bayes, support vector machine. The most important predictive factors were selected using global forward inclusion approach and 4-fold cross-validation. Each algorithm was optimised using Bayesian optimisation. Logistic regression models created in SPSS were evaluated for comparison. All models were validated internally and externally using the weighted F1-score (F1w) as the primary evaluation metric. ***Results:*** During the feature selection process, stimulated thyroglobulin was identified as the strongest predictive factor, followed by stimulated FT3 and thyroid remnant absorbed dose. Most models achieved the highest performance with the first two factors. However, both feature selection and hyperparameter tuning were affected by high uncertainties of the evaluation metrics due to the small imbalanced dataset, which was insufficient to optimise most of the models. The tentative best-performing model was the decision tree with F1w of 0.81. The model outperformed standard statistical models, although its predictive capacity remains limited. ***Conclusion:*** Despite the size of the dataset, machine learning modelling achieved better performance compared to standard logistic regression. However, more data are needed to develop and validate a reliable model with sufficient performance and good generalisability. ***References:*** [1] Taprogge J et al. Eur J Nucl Med Mol Imaging. 2023 Jun 10;1-10.

ML-models trained on clinical data and ^{18}F-FDG PET/CT radiomic features to predict pathological complete response after neoadjuvant chemotherapy in breast cancer patients

L. Urso[1,2], *L. Manco[3], S. Adamantiadis[1,2], N. Ortolan[1], F. Borgia[1,2], N. Mindicini[4], F. Lancia[4], A. Schirone[4], C. Cittanti[1,2], L. Uccelli[1,2], K. Szilagyi[3], G. Scribano[5], A. Turra[3], M. Bartolomei[2];*
[1]Department of Translational Medicine, University of Ferrara, Ferrara, ITALY, [2]Nuclear Medicine Unit, Onco-Hematology Department, University Hospital of Ferrara, Ferrara, ITALY, [3]Medical Physics Unit, University Hospital of Ferrara, Ferrara, ITALY, [4]Oncology Unit, University Hospital of Ferrara, Ferrara, ITALY, [5]Department of Physics and Earth Science, University of Ferrara, Ferrara, ITALY.

Aim/Introduction: [18F]FDG PET/CT is an emerging tool in the baseline assessment of BC patients before neoadjuvant chemotherapy (NAC). In these patients, pathological complete response (pCR) after NAC is a strong prognostic factor. Aim of this work is to combine clinical data and conventional and radiomic parameters extracted from ^{18}F-FDG PET/CT to build machine learning models (ML_models) able to predict pCR after NAC. ***Materials and Methods:*** [18F]FDG PET/CT performed in newly diagnosed BC patients prior to the start of NAC were retrospectively collected. Primary tumor (T) and the most significant lymph node metastasis (N) were manually segmented. Data related to clinical parameters (grade, subtype), NAC and conventional PET parameters (SUVmax, SUVmean and volumetric parameters) were collected. The standard of reference considered was surgical pCR after NAC (ypT0;ypN0). 854 radiomic features (RFts), including original, first order, texture and wavelet based were extracted using 3D-Slicer on both PET and CT datasets, according to IBSI. Synthetic Minority Over-Sampling Technique (SMOTE) was used to balance data. The robust features (RFts) were identified using Mann-Witney U-test (p-value<0.05) and Spearman's coefficient (|Rs|>0.8). The cohort was split in training (70%) and validation (30%) sets. Two independent ML_models (PET and CT) using three different algorithms (Random Forest (RF), Neural Network and Stochastic Gradient Descendent) were trained and tested using clinical data and conventional and radiomic PET/CT features in Orange data-mining. 10-Fold-Cross-Validation was used on training set after Bootstrap. Validation set was used to evaluate performances to predict pCR after NAC (area under the curve - AUC; classification accuracy - CA; True Positive - TP; True Negative - TN). ***Results:*** 72 pathological uptakes at [18F]FDG PET/CT were selected and segmented in 52 patients (52 T; 20 N). After NAC, pCR occurred in 23 (44.2%) patients corresponding to a total of 33 (45.8%) lesions. Patients achieving pCR after NAC showed lower median SUVmax (16.16±13.58 vs 10.51±6.90; p=0.023;|Rs|=0.98) and SUVmean (9.94±8.27 vs 6.30±4.27; p=0.024;|Rs|=0.86). Fifty-seven and 141 RFts were selected from CT and PET dataset, respectively. Overall, PET_ML_models showed better performance than CT_ML_models. The best performances were obtained by RF algorithm (PET_model: AUC=0.83; CA=0.74; TP=78%; TN=72%. CT_model: AUC=0.60; CA=0.61; TP=60%; TN=62%). ***Conclusion:*** SUVmax, SUVmean and PET_ML_models built using clinical parameters and RFts extracted by [18F]FDG PET/CT can accurately predict pCR after NAC. The suboptimal accuracy of the CT_ML_ models might be related to the restricted number of RFts in our population. PET_RF_model could improve BC management if validated in larger cohorts. ***References:*** PMID:36497351.

EP-0874

Fast Brain SPECT Imaging: Leveraging Cross-Tracer Transfer Learning for deep learning Denoising of ^{99m}Tc-ECD Images

Y. Salimi, *Z. Mansouri, A. Sanaat, H. Zaidi;*
Division of Nuclear Medicine and Molecular Imaging, Geneva University Hospital, Geneva, SWITZERLAND.

Aim/Introduction: SPECT brain imaging using various radiopharmaceuticals plays an important role in the diagnosis and monitoring of multiple pathologies. Reducing acquisition time can be beneficial, especially for paediatrics and patients with lower body control, such as epileptic patients referred for 99mTc-ECD scan at ictal phase. However, faster imaging translates to noisier images and lower image quality and diagnostic confidence. Deep learning has shown promising results recovering image quality from faster and low injected activity scans. However, its performance is affected by the availability of large and diverse training data. In this study, we explored the possibility of using cross-tracer transfer learning to train deep neural networks for denoising brain 99mTc-ECD images. ***Materials and Methods:*** This study included 80 123I- ioflupane and 16 99mTc-ECD SPECT images acquired in list mode format on a CZT-based multi-pinhole SPECT camera. Using lister option, the images were reconstructed once using 4 minutes of fast time (Fast) and once with 15 minutes full time (FT). A SwinUnetR transformer network was used for all training scenarios to generate the FT images from Fast images using ADAM optimizer, 1000 epochs,128×128×64 patches and 2.4 mm voxel size. In the 1st scenario, 99mTc-ECD brain SPECT images were used to train models in a three-fold data split strategy. In the second scenario, previously trained models on 123I- ioflupane images were used as initial weights to train models in the same data split through transfer learning. The network output were compared with FT images in terms of voxel-wise and region-wise errors. ***Results:*** The average voxel-wise PSNR, SSIM, relative error(%), and absolute relative error (%) for scenario #1 were 36.45±2.39, 99.26±0.25, 3.71±6.15, and 13.07±3.08, respectively. These metrics improved to 38.15±3.30, 99.40±0.26, 1.23±4.94, and 9.96±1.97, respectively, when transfer learning was used in scenario #2. The region-wise absolute relative error (%) in CSF, grey matter, and white matter was 12.39±2.21, 12.41±2.07, and 13.01±3.27 in scenario #1. These reduced to 7.41±2.05, 7.78±2.00, and 8.41±3.18, respectively, when using transfer learning. ***Conclusion:*** The lack of diverse and big data limits the application of deep learning in medical imaging tasks. We demonstrated the potential advantage of using transfer learning from different radionuclides/ligands in SPECT brain imaging. Despite the different uptake patterns between 99mTc-ECD and 123I- ioflupane, the transformer network initialized by the pretrained weights outperformed the model trainrf from scratch. Faster 99mTc-ECD imaging with comparable image quality may help to diminish patient motion and improve patient comfort.

EP-0875

Construction of a Deep Learning Model for Thyroid Scan Classification

A. Kondakov[1,2], *V. Volkov[2], I. Znamenskiy[3,2];*
[1]Petrovsky National Research Centre of Surgery, Moscow, RUSSIAN FEDERATION, [2]N. I. Pirogov Russian National Research Medical University, Moscow, RUSSIAN FEDERATION, [3]Federal Center of Brain Research and Neurotechnologies of the FMBA of Russia, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Thyroid scintigraphy offers a visual representation of thyroid tissue functional activity that is proportional to the selective absorption of radionuclides like iodine or 99mTc-pertechnetate. However, this method's interpretation remains complicated and depending on radiologist's experience. This study aims to construct a deep learning model to classify thyroid scintigraphy data and categorize patients based on suspected diagnoses, thereby augmenting diagnostic processes. ***Materials and Methods:*** Retrospective analysis of 703 thyroid scintigrams (TS) was performed for the time period 2014 — 2023. Experimental group consisted of 576 (82%) women and 127 (18%) men. Median age was 48 years [IQR 37, 61]. TS was performed in accordance with EANM Guidelines for thyroid uptake measurements [1]. Protocol consisted of intravenous injection of approx. 200 MBq of 99mTc-pertechnetate followed by a static acquisition of a scintigram 20 min p.i. TS were categorized into

eight subgroups based on the following factors: shape alterations, pyramidal lobe presence, nodal characteristics, and uptake level. Subsequently, datasets were formulated for training several neural networks.Convolutional neural networks (CNNs) were employed to build models using the Python programming language. The initial model comprised two convolutional and pooling layers each, employing the ReLu activation function. The second model was an adaptation of the ResNet50 CNN architecture. ***Results:*** The diagnostic accuracy of the CNNs ranged from 85% to 96% when utilizing the ResNet50 architecture. Obtained weighted accuracies (WA) and sensitivities (WS) are presented in the Table 1. Unfortunately, the smaller CNN did not yield significant results.Hence, the ResNet architecture emerges as the most promising for TS evaluation, based on our findings. The achieved accuracy of 85-96% aligns with similar studies [2,3]. ***Conclusion:*** We developed a model that offer decision support to clinicians by providing a presumptive diagnosis utilizing data from TS. Future enhancements may involve integrating additional parameters (hormones and history) a pursuit to be explored in subsequent research endeavors on this subject. ***References:*** 1. EP-0876

Generalizing Deep Learning Denoising for Novel PET Radiotracers to improve image quality

M. Larmuseau[1], *S. DeKeyser[1], T. Brants[1], E. van Genugten[2], S. Ustmert[3], A. Maes[3], E. Aarntzen[1], R. Hustinx[4], S. Vandenberghe[5]; [1]Nuclivision, Ghent, BELGIUM, [2]Radboud UMC, Nijmegen, NETHERLANDS, [3]AZ Groeninge, Kortrijk, BELGIUM, [4]CHU Liège, Liège, BELGIUM, [5]Ghent University, Ghent, BELGIUM.*

Aim/Introduction: While [18F]FDG has long been the reliable workhorse of nuclear imaging, there is an increasing need for more sensitive and specific radiotracers to improve diagnosis and treatment planning. An interesting avenue is the use of Zr-89 labelled monoclonal antibodies, as the longer half-time of Zr-89 matches the slow pharmacokinetics of these antibodies. However, such less established tracers typically suffer from high costs and varying image quality, impeding broader adaptation. The use of deep-learning based denoising algorithms could help remediate these challenges, but generally require many scans for training, which are not commonly available for new tracers. This study aimed to evaluate the generalizability of deep learning-based denoising algorithms, trained on conventional, short-lived radiotracers, to less common tracer types and radioisotopes that were not encountered during model training. ***Materials and Methods:*** First, a deep-learning model with a Unet architecture was trained on matching low-count and standard-count PET scans from two Belgian hospitals (AZ Groeninge and CHU Liège). During training, only matching pairs of two commonly available tracers were seen by the model, [68Ga]Ga-PSMA-11 and [18F]FDG . The model was then validated on 89Zr-labelled durvalumab PET scans from Radboud UMC and a phantom filled with 89Zr that was acquired at different acquisition times, ranging from 60s to 1200s, by downsampling the list-mode data. Image quality was assessed using the coefficient of variation in relevant regions and through visual inspection comparing the original scans with their enhanced counterparts. ***Results:*** The deep learning model could significantly improve image quality of the [89Zr]Zr-DFO-durvalumab scans, strongly reducing the variation in SUV for several organs across different patients. The algorithm also removed some unrealistically high SUVmax that were observed in certain tissues and overall resulted in a visually more appealing scan. Additional validation on the IEC NEMA phantom, confirmed that the matching enhanced images had a lower variance in SUV, both in the spheres and in the background. At the same time, the recovery coefficient for the SUVmean and SUVmax improved in all spheres, for the 10 and 20 minute scans. ***Conclusion:*** In silico denoising by our deep-learning-based model seems to at least partially generalize to 89Zr-labelled radiotracers as shown by this study on [89Zr]Zr-DFO-durvalumab. Strategies for post-hoc enhancement of PET-scans may help to harmonize scan quality, which facilitates pooled analyses of multi-center studies using less commonly used radiotracers.

EP-0877

New standard of Bone Scan study report- appropriate for AI training

K. Filipczak, *P. Gadzicki, P. Cichocki, A. Plachcinska, Z. Adamczewski;*
Medical University of Lodz, Lodz, POLAND.

Aim/Introduction: Artificial Intelligence (AI) algorithms could be trained to analyze medical images, but first a large number of images with their medical interpretation must be used for training. Medical reports with medical images description are created by qualified physicians in the form of sentences readable to other physicians, but not suitable for AI algorithms training. Therefore, it is necessary to convert medical reports (readable for humans) to a set of digital parameters (suitable for AI learning). Considering the constantly increasing usefulness of AI methods, it seems reasonable to develop a method of creating standardized medical reports that are coded in the form of digital parameters simultaneously. ***Materials and Methods:*** 40 consecutive medical images of Bone Scan studies were examined independently by two experienced physicians, one of them was using a newly developed method and the other one was creating report in standard way. The new method uses a specially designed interface which requires buttons and image surface clicking as an interaction and generates reports in the form of sentences and digital code at the same time, allowing the addition of manually written notes if necessary. ***Results:*** When using dedicated method and interface, parametrized report suitable for AI analysis was successfully created in all 40 examined cases. The process of creating Bone Scan study reports using the new method was not significantly longer than using traditional methods. Moreover, the method produces very standardized reports that are much more structured. ***Conclusion:*** Developed method of creating structured study reports allows the creation of coded reports suitable for machine learning, without disrupting or slowing down the routine work of qualified physicians.

EP-0878

Impact of Data Diversity Across TOF and Non-TOF PET Scans on UNET Performance for Attenuation and Scatter Corrections

A. Elkayee Dehno[1,2], *P. Ghafarian[3,4], M. Ay[1,2];*
[1]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging (RCMCI), Advanced Medical Technologies and

Equipment Institute (AMTEI), Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Chronic Respiratory Diseases Research Center, National Research Institute of Tuberculosis and Lung Diseases (NRITLD), Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Precise analysis of Positron Emission Tomography (PET) requires post-acquisition corrections, including attenuation and scatter corrections (ASC). Common ASC involve using Computed Tomography (CT) attenuation maps and model-based scatter corrections. However, CT increases radiation exposure and can introduce artifacts and PET/CT mis-registration. Deep learning (DL) applications lead to using these algorithms for simultaneous translating non-attenuation scatter corrected (NASC) images to measured attenuation scatter corrected (MASC) images. Specifically, our study focused on training a model using PET scans with and without Time-of-Flight (TOF). This allowed us to compare the performance of models trained with diverse and homogeneous data. By integrating data diversity, we aimed to enhance the model's ability to address the complexities inherent in PET imaging and improve accuracy in ASC processes. ***Materials and Methods:*** The UNET algorithm was employed to convert NASC brain ^{18}F-FDG PET images to MASC images. Transfer learning was implemented to exploit pre-trained vgg16 (ImageNet) weights. Training was conducted using three datasets: first comprising data from 40 patients with TOF (Train-TOF), second from 40 patients without TOF (Train-NON-TOF), and third a combination of both (20 TOF and 20 non-TOF images (Train-MIX)). Finally, all three models' performances were evaluated on 3 TOF and 3 non-TOF patients scans, using following quantitative metrics: Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index (SSIM), and Mean Square Error (MSE). ***Results:*** The results indicate that diversifying the composition of a training dataset, while maintaining a constant total number of data enhances model performance. Upon evaluation, the model trained with Train-MIX dataset demonstrated marked improvements in various metrics compared to models trained exclusively on either Train-TOF or Train-NON-TOF datasets: PSNR (Train-TOF=35.24, Train-NON-TOF=33.68, and Train-MIX=37.7), SSIM (Train-TOF=0.86, Train-NON-TOF=0.86, and Train-MIX=0.96), and MSE (TOF=0.0004, Train-NON-TOF=0.0005, and Train-MIX=0.0001). Furthermore, when the Train-MIX model was tested separately on TOF images and NON-TOF images on test dataset, it outperformed models trained on their respective homogeneous datasets—by 1.3 and 4.2 in PSNR, by 0.09 and 0.11 in SSIM, and by -0.0002 and -0.0001 in MSE, respectively. ***Conclusion:*** Incorporating data diversity in DL model training for medical imaging tasks is crucial. By including a more diverse dataset of TOF and NON-TOF PET scans in the training dataset, the study reveals a considerable enhancement in model robustness and generalization capabilities. This comprehensive training approach empowers the model to effectively handle varying image characteristics encountered in clinical settings, thereby yielding superior performance across a range of image quality metrics.

EP-0879

Can a ChatBot Write a Systematic Review? Large Language Models versus Humans

G. Ninatti*[1,2]*, *C. Pini[1,2], F. Gelardi[3,1], M. Kirienko[4], M. Bauckneht[5,6], M. Sollini[1,3], A. Chiti[1,3];*
[1]IRCCS San Raffaele Hospital, Milan, ITALY, [2]University of Milano-Bicocca, Monza, ITALY, [3]Vita-Salute San Raffaele University, Milan, ITALY, [4]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, ITALY, [5]IRCCS Ospedale Policlinico San Martino, Genova, ITALY, [6]University of Genova, Genova, ITALY.

Aim/Introduction: Large Language Models (LLMs) promise to impact human activities, particularly in tasks related to text generation. These tools are increasingly utilised worldwide, not only to handle textual content, but also to assist data analysis and creative processes. As a result, publishers of scientific journals started to ask to declare their use. However, the capability of LLMs to generate a scientific article has not been proven yet. This study aimed to assess the ability of LLMs to generate a systematic literature review. ***Materials and Methods:*** We conducted a comparative analysis of systematic literature reviews produced by LLMs (OpenAI ChatGPT 4.0, Google Gemini, and Microsoft Bing Copilot). The reference standard approach consisted of two human scientists unassisted by such tools. The process involved different tasks of this workflow: (1) literature search and article extraction from databases, (2) article selection based on predefined inclusion and exclusion criteria, and (3) production of the final article. The focus was on experimental studies on the isotope terbium-161, with the search query "terbium-161" OR "161-tb", excluding articles outside the research scope, and those not in English. We minimised human intervention in the LLM workflow, providing the same initial inputs to each model, while allowing for variances in subsequent interactions due to their distinct architectures and outputs. Descriptive statistics and qualitative assessments were used to evaluate LLMs' performance. ***Results:*** The human query yielded 81 papers, while ChatGPT 4.0, Gemini, and Bing retrieved 28 (35%), 21 (26%), and 13 (16%) articles, respectively. Gemini and Bing also fabricated non-existent references in the known phenomenon of "AI hallucination". As for the task of article selection, human experts included 24 papers, while all LLMs yielded no autonomous result explicitly requiring assistance. The final article texts produced by all LLMs were brief (all under 700 words), not compliant to systematic reviews standards, uninformative and uninspiring. ***Conclusion:*** While LLMs represent a revolutionary tool for writing, their role in the field of medical research remains supplementary, reliant on the direction and supervision of human expertise. LLMs can provide timesaving and enriching assistance, but cannot replace the nuanced and critical role of human researchers in the production of systematic reviews. Our results highlight the current limitations of LLMs, particularly in tasks requiring abstract reasoning or deep domain expertise. The aspiration of generating a scientific article from scratch with the bare minimal human supervision remains too optimistic - at least, for the time being.

EP-0880

The use of Machine Learning to predict 68Ga-PSMA-11 PET/CT result in different clinical settings of biochemical relapse after radical treatment for prostate cancer: comparison with a published nomogram.

F. Serani*[1]*, *S. Cecconi[2], F. Ceci[3], L. Bianchi[4], M. Borghesi[5], G. Polverari[6], A. Briganti[7], R. Schiavina[4], E. Brunocilla[4], P. Castellucci[8], S. Fanti[9], A. Farolfi[8];*
[1]"Spirito Santo" Hospital, Nuclear Medicine, Pescara, ITALY, [2]Independent Researcher, Forlì, ITALY, [3]Division of Nuclear Medicine, IEO European Institute of Oncology IRCCS, Milan, ITALY, [4]Division of Urology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, ITALY, [5]Department of Urology, IRCCS

Policlinico San Martino; Department of Surgical and Diagnostic Integrated Sciences (DISC), University of Genova, Genova, ITALY, [6]PET Center, Affidea IRMET, Torino, ITALY, [7]Unit of Urology/Division of Oncology, Urological Research Institute, IRCCS San Raffaele Hospital, Milan, ITALY, [8]Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [9]Nuclear Medicine, Alma Mater Studiorum - University of Bologna, Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: Gallium-68 prostate-specific membrane antigen positron emission tomography (PSMA PET) is valuable for detecting prostate cancer. Its cost-effectiveness and long-term treatment outcomes based on PSMA PET results are uncertain. Correct patient selection for this imaging technique, especially in biochemical recurrence (BCR), is crucial for resource allocation and therapy planning. Machine learning (ML) algorithms show promise results in predicting outcomes, surpassing traditional nomograms.This study compares a published nomogram and a ML model for PSMA PET prediction in various BCR clinical settings. This comparison is essential to offer clinicians a comprehensive, practical, and highly accurate tool in the field of explainable Artificial Intelligence (exAI) for predicting PSMA PET result. ***Materials and Methods:*** The dataset included 703 prostate cancer patients with confirmed BCR post-radical therapy. Various ML algorithms were evaluated based on receiver-operating characteristic (ROC) curve AUC and accuracy. We also explored whether ML, with a Logistic Regression with penalty equal to L1 (LR-L1) analysis can identify different variables, than the current ones used for the nomogram, to develop an alternative ML predictive model. ***Results:*** Logistic Regression emerged as the top-performing model (78.87% accuracy) compared to the nomogram (76.00%). LR-L1 analysis highlighted influential features, including PSA doubling time, PSA value at PSMA PET, clinical stage, and ISUP group, and the subsequent ML model developed showed an accuracy of 80.28%. The DeLong test did not show a statistical significance of the differences of AUC between the two ML models compared with the nomogram. ***Conclusion:*** Although Logistic Regression didn't significantly outperform the nomogram in PSMA positivity prediction, ML methods hold promise as complementary tools for medical applications, particularly in developing exAI for routine clinical use.

Siamese based CNN Bone Lesion Tracking in PSMA-PET/CT Scans

S. P. Hein[1,2], *M. Schultheiss[2], A. Gafita[3], R. Zaum[1], F. Yagubbayli[2], R. Tauber[4], I. Rauscher[1], M. Eiber[1], F. Pfeiffer[2,5], W. A. Weber[1];*
[1]Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY, [2]Chair of Biomedical Physics, Department of Physics, TUM School of Natural Sciences, Technical University of Munich, Garching, GERMANY, [3]Division of Nuclear Medicine and Molecular Imaging, The Russell H. Morgan Department of Radiology and Radiological Science, Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA, [4]Department of Urology, Technical University of Munich, Munich, GERMANY, [5]Munich Institute of Biomedical Engineering, Technical University of Munich, Garching, GERMANY.

Aim/Introduction: One of the main applications of PET/CT is the assessment of tumor response to systemic therapies. Routinely, only a small subset of index lesions out of multiple lesions is analyzed.1 The operator dependent selection may bias the results due to possible significant inter-metastatic heterogeneity of response to therapy. Automated, AI based approaches for lesion tracking may enable the analysis of many more lesions providing a better assessment of tumor response. This work introduces a CNN approach for lesion tracking between PET/CT scans. ***Materials and Methods:*** Our approach is applied on the laborious task of tracking a high number of bone lesions in full-body baseline and follow-up [68Ga]Ga-PSMA-11- or $^{[18F]}$F-rhPSMA-7-PET/CT scans after two cycles of [177Lu]Lu-PSMA-I&T therapy of metastatic castration resistant prostate cancer patients. Data preparation includes lesion segmentation and affine registration of baseline and follow-up scans. Ground truth lesion pairs were manually assigned by an experienced nuclear medicine physician. Based on the PET data, our algorithm extracts suitable lesion patches around the lesion and neighboring anatomical structures for each possible lesion pair. It forwards them into a Siamese CNN trained to classify the lesion patch pairs as corresponding or non-corresponding lesions. The dataset consisted of 36 patients with 2111 baseline and 2658 follow-up lesions. ***Results:*** Experiments have been performed with a 2D and 3D Siamese CNN network and corresponding patch dimensions. Training and testing were performed with four different patch types with either CT one-channel input or two-channel inputs of CT combined with information from PET, binary lesion segmentation, or masked CT. As a reference, a non-trainable model classifying lesion assignments merely by the mean subtracted CT pixel intensities was used, which has been outperformed by all network and patch variations. The CNN model successfully learned to classify lesion assignments. In its best configuration of a 2D Siamese network trained with CT patches, it reaches a lesion tracking accuracy of 83% with an AUC=0.91. For remaining lesions, the pipeline accomplished a re-identification rate of 89%. ***Conclusion:*** We proved that a CNN may facilitate the tracking of multiple lesions in PSMA-PET/CT scans. It could also be applied on other types of PET/CT scans. Future clinical studies are necessary if this improves the prediction of the outcome of therapies. ***References:*** 1. Wahl et al. From RECIST to PERCIST: Evolving Considerations for PET response criteria in solid tumors. JNuclMed 2009; 50Suppl1: 122S-50S. https://doi.org/10.2967/jnumed.108.057307.

EP-0882

AI-Assisted Simplification of PET/CT Reports: Enhancing Medical Communication and Accuracy

R. Durmo, *E. Pedersini, A. Arnone, A. Farina, C. Coruzzi, F. Fioroni, M. Iori, A. Versari, A. Filice;*
AUSL-IRCCS of Reggio Emilia, Reggio Emilia, ITALY.

Aim/Introduction: Patients often receive their PET/CT reports and, instead of waiting for their oncologist appointment, turn to their general practitioners (GPs) for clarification. However, GPs might not possess the specialized knowledge needed to interpret these reports accurately, which can elevate patient anxiety. As AI technology advances, patients and GPs could potentially use AI tools for help in interpreting reports. This study evaluates the effectiveness of AI to simplify PET/CT reports while ensuring the information remains accurate. ***Materials and Methods:*** In this initial investigation, we randomly selected 10 anonymized PET/CT reports. Utilizing ChatGPT version 3.5, we simplified these reports with the prompt: "Compose a version of the following PET/CT report suitable for non-oncologist physicians." Subsequently, two nuclear medicine physicians evaluated the accuracy of the simplified reports using a Likert scale (ranging from 'strongly accurate' to 'not accurate at all'). Additionally, a GP physician assessed the comprehensiveness of the simplified reports. ***Results:*** Ten anonymized PET/CT reports from our institutional

database were rewritten by ChatGPT. Among these reports, seven were FDG PET/CT, two were Ga68-DOTATOC PET/CT, and one was an ^{18}F-PSMA PET/CT report. Nine out of ten reports were rated as strongly accurate or accurate based on the four-point Likert scale, with only one report rated as not accurate at all. The agreement between the two nuclear physicians was high, with a kappa value of 0.90. The GP found nine out of ten reports written with ChatGPT to be simplified and easier to understand. Notably, the report identified as non-simplified by the GP was the same one flagged as inaccurate by the nuclear physician specialists. ***Conclusion:*** AI has the potential to facilitate the comprehension of complex PET/CT reports, thereby improving communication between patients and healthcare providers. However, it's crucial for patients and healthcare provides to recognize the potential for inaccuracies in information provided by AI systems.

EP-0883

Enhancing image quality of preclinical PET scanners through gap correction using Deep Learning method.

Z. Karimi[1], *P. Sh.Zadeh[2], M. Ay[2];*
[1]University of Isfahan, Isfahan, IRAN, ISLAMIC REPUBLIC OF, [2]Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: One of the important challenging problems in PET imaging is the gap between adjacent detector blocks, which introduces partial projection data loss. The missed data can lead to errors in quantitative data analysis. In this research, we use Pix2Pix conditional generative adversarial network (Pix2Pix cGAN) to retrieve and fill missing data in preclinical PET sinograms. ***Materials and Methods:*** The Pix2Pix conditional generative adversarial network (cGAN) was trained on a total of 4000 raw (uncorrected) mice sinograms. The 15 mice (28±10 g) with an average activity of 280±60 µCi of 18F-FDG were scanned using the small animal Xtrim PET. The gap of sinograms were filled with interpolation method and modified as the target. Artificial gaps similar to the original gaps were added at different places except the interpolated areas and modified as the input of network. To test the proposed network, the set of 200 original sinograms was used. The ordered subset expectation maximization (OSEM) algorithm was used to reconstruct the predicted gap-filled sinograms. The reconstructed images were compared quantitatively by computing the contrast-to-noise ratio (CNR) and signal-to-noise (SNR). ***Results:*** Filling the gap in the sinogram domain is possible through this approach. The predicted images of the proposed network (pix2pix) were reconstructed via OSEM method (4 iteration, 6 subsets) and compared to the original images. The star-shape artifact that was created by gaps between inter-block detector was depicted in the original images, but it was not identified in the predicted images. For one of the predicted image's axial slices, the SNR and CNR values were calculated 17.31 and 24.65 respectively. These parameters were also calculated 13.35 and 19.71 for the same original image respectively. These values showed an increase in the quality and quantity of predicted images with less noise, which indicated the proper performance of the proposed network. ***Conclusion:*** This proposed approach can retrieve missing data in sinograms before reconstruction, improve image quality and quantity, and eliminate significant artifacts caused by gaps between adjacent detectors. ***References:***

Exploring Generalizability of a fine-tuned Large Language Model for Impression Generation in PET Reports

F. Yousefirizi[1], *L. Wang[1], C. Gowdy[2], A. Shariftabrizi[3], S. Harsini[4], S. Ahamed[5], M. Sabouri[5], E. Mollaheydar[5], A. Rahmim[5];*
[1]BC Cancer Research Institute, Vancouver, BC, CANADA, [2]BC Children's Hospital, Vancouver, BC, CANADA, [3]University of Iowa Carver College of Medicine, Iowa City, IA, UNITED STATES OF AMERICA, [4]BC Cancer, Vancouver, BC, CANADA, [5]University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: In a previous study, the feasibility of using large language models (LLMs) to generate clinically relevant impressions for PET reporting was considered (Tie et. al. JIIM 2024). This study sought to explore the generalizability of the fine-tuned model on an external PET clinical report dataset in accurately summarizing PET findings and generating clinically valuable impressions. We applied the PEGASUS model that was fine-tuned on PET reports (PEGASUS-PT), to primary mediastinal large B-cell lymphoma (PMBCL) PET reports as an external test dataset. ***Materials and Methods:*** We collected 202 PET reports retrospectively, dictated by 14 physicians, from our institution between September 2005 and January 2020. Performance of PEGASUS PT was assessed by the reference-dependent metrics: Bleu Score (the precision between generated and reference texts with a brevity penalty) and ROUGE-N that assesses the similarity between generated and reference texts by measuring overlapping textual units, where N represents the length of the units. ROUGE-L evaluates the overlap of the longest common subsequence. We also assessed the model's performance in predicting the Deauville score (DS) by measuring 5-class accuracy on cases where both the clinician's and the generated impression contained DS. We randomly chose 13 reports for expert assessment. These reports included the original findings, clinician's impression, and model-generated impression. Three nuclear medicine physicians (NMP), excluding those who authored the original impressions, and three trainees independently evaluated the LLM model. To assess the usability of the generated impressions, a 5-point Likert scale is used (5: Clinically acceptable impressions, 4: Nearly acceptable impressions, 3: Moderately acceptable impressions, 2: Unacceptable impressions, 1: Unusable impressions). ***Results:*** The performance of PEGASUS-PT model on our external test set are: Bleu Score of 6.97 [0.5, 21.21], ROUGE-1 of 38.41 [14.47, 57.52], ROUGE-2 of 16.02 [3.53, 34.19], and ROUGE-L of 24.61 [7.05, 44.08]. Evaluation conducted by NMP and trainees revealed that 71.8% of the impressions produced by the PEGASUS-PT were considered clinically acceptable, achieving an average usability score of 3.41 and 3.03 out of 5. PEGASUS PT performance on DS prediction, measured by 5-Class Accuracy, is 48.0% [26.1%, 69.6%], with a Weighted Cohen's κ of 0.5467 [0.3394, 0.7376]. ***Conclusion:*** For generalizability evaluation, we applied PEGASUS PT to reports with different patient characteristics and diseases, report styles, and report templates. Model performance dropped in terms of reference-dependent metrics, DS prediction, and usability metrics evaluated by NMP and trainees.

EP-0885

Novel Methods for SPECT Scatter Estimation Using Gaussian Blurring and Deep Image Prior

S. Ahamed[1,2], *L. Polson[1,2], A. Rahmim[1,2];*

[1]University of British Columbia, Vancouver, BC, CANADA, [2]BC Cancer Research Institute, Vancouver, BC, CANADA.

Aim/Introduction: Detection of scattered photons degrades quantitative accuracy in SPECT imaging. The SPECT scatter is usually estimated via the triple energy window (TEW) method using the noisy(real) projection data. This method works well for higher counts (or higher projection time, dT) but suffers from a systematic bias for lower dT. In this work, we propose two methods for estimating noiseless scatter, which outperforms traditional methods especially for smaller dT. The first method Gaussian blurs the noisy scatter prior to scatter-correction, while the second method exploits a deep-learning framework called the DeepImagePrior (DIP) for personalized network training on a single data. ***Materials and Methods:*** In this work, we used SPECT projection data simulated via SIMIND. The ground truth (noiseless) and noisy (a single Poisson noise realization) scatter was generated using TEW method for various dT=[1,2,5,15] s. First, 1D Gaussian filters with carefully chosen variances and kernel sizes for each dT were applied in r, theta and z directions to the photopeak and noisy scatter to obtain blurred photopeak and blurred noisy scatter. Furthermore, we trained a UNet under the DIP framework to predict noisy scatter using the blurred photopeak as input. The (i) noiseless, (ii) noisy, (iii) DIP-predicted, and (iv) blurred scatters were used during OSEM (4 iterations,8 subsets) reconstruction. All reconstructions were performed in PyTomography[1]. The counts/dT was computed within the liver, lungs, kidneys, salivary glands and bladder for methods (i)-(iv) for all dT and the %error was evaluated for (ii)-(iv) with respect to (i). ***Results:*** Both DIP-predicted and blurred scatter estimation methods arrived at counts/dT within organs closer to the one obtained from noiseless scatter as compared to noisy scatter, especially for lower dT. In particular, for dT=1s, %error for noisy, DIP and blurred scatter estimation methods were (10.1%,1.7%,1.2%), (30.7%,0.2%,0.8%), (3.7%,1.7%,2.4%), (9.2%,2.6%,3.1%), and (4.5%,1.5%,1.6%) for liver, lungs, kidneys, salivary glands, and bladder respectively. A similar trend was observed for dT=2s and 5s, while the %errors were similar for the three methods for dT=15s. ***Conclusion:*** Preprocessing scatter via Gaussian blurring and DIP might be promising routes for scatter estimation during image reconstruction, thereby enhancing the utility of SPECT images. Having better scatter estimates at smaller dT can also potentially help reduce the scan time for patients. ***References:*** [1] Polson, L., et al, PyTomography: A Python Library for Medical Image Reconstruction, arXiv:2309.01977v3.

Machine Learning Using Baseline Clinical Biomarkers for the Prognostic Stratification of Patients with Neuroendocrine Tumours Teceiving ^{177}Lu oxodotreotide Therapy

R. Meades[1], *S. Navalkissoor[1], G. Gnanasegaran[1], M. Caplin[2], D. McCool[1];*
[1]Department of Nuclear Medicine, Royal Free London NHS Foundation Trust, London, UNITED KINGDOM, [2]Neuroendocrine Tumour Unit, ENETS Centre of Excellence, Royal Free London NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: Prognostic stratification of patients with advanced neuroendocrine tumours receiving 177Lu oxodotreotide therapy enables the identification of those most likely to benefit from treatment, improving cost effectiveness. Previous work at our centre[1] using statistical methods, identified baseline circulating biomarkers associated with 1-year treatment failure and developed a predictive scoring mechanism. However, numerous machine learning (ML) algorithms exist providing the opportunity to explore these biomarkers' predictive nature further. This work is an initial investigation into the predictive potential of a range of ML algorithms applied to this data. ***Materials and Methods:*** 188 patients each with Progression Free Survival (PFS), Time to Treatment Failure (TTF) and 20 baseline circulating biomarker and demographic data were analysed. PFS and TTF data were each converted to binary classes using equal frequency binning to avoid class imbalance. Classification modelling was performed for both PFS and TTF independently using 20 different ML algorithms. Model training was performed on all features and separately on selected feature sets using the "Minimum Redundancy Maximum Relevance" (MRMR) algorithm with "Searching for Uncorrelated List of Variables" method (SULOV) and recursive extreme gradient boosting. Accuracy, sensitivity, specificity, positive predictive value, negative predictive value and F1-score performance metrics were obtained using leave-one-out cross validation. ***Results:*** Using all features, a random forest classifier performed best at predicting PFS (accuracy=0.628, sensitivity= 0.622, specificity=0.632) and an extreme gradient boosting classifier at predicting TTF (accuracy=0.633, sensitivity=0.613, specificity=0.653). For PFS, feature selection identified 10 features (alkaline phosphatase, platelets, lymphocyte, neutrophils, erythrocyte sedimentation rate, monocytes, creatinine, chromogranin A, alanine aminotransferase and haemoglobin) with an extra trees classifier performing best (accuracy=0.702, sensitivity=0.678, specificity= 0.724). For TTF, feature selection identified 9 of the 10 features selected for PFS, excluding chromogranin A, with a decision tree classifier performing best (accuracy=0.676, sensitivity=0.699, specificity=0.653). ***Conclusion:*** These initial results demonstrate certain ML algorithms have the potential to contribute to prognostic stratification of patients with advanced neuroendocrine tumours receiving 177Lu oxodotreotide therapy. Improved model performance arising from biomarker selection highlights the importance of this and our results support the identification of these predictive circulating biomarkers. Further gains in accuracy could be achieved through hyperparameter tuning of the identified models and training on larger datasets. Additionally, separate validation datasets would allow for assessment of generalisability. ***References:*** [1] Chen L, Gnanasegaran G, Mandair D, Toumpanakis C, Caplin M, Navalkissoor S. Prognostic stratification for patients with neuroendocrine tumours receiving 177Lu-Dotatate. Endocr Relat Cancer. 2022 Jan 20;29(2):111-120. doi:10.1530/ERC-21-0248. PMID:34932018

Deep Learning on Enhancing Quality Recovery for Low-dose PET Imaging with Auxiliary Multiple Lower-dose Repetitions

Y. Chen[1], *R. Guo[2,3], S. Xue[1], X. Zhang[2,3], H. Sari[1,4], M. Viscone[1], A. Rominger[1], B. Li[2,3], K. Shi[1];*
[1]Department of Nuclear Medicine, Inselspital, University of Bern, Bern, SWITZERLAND, [2]Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [3]Shanxi Medical University-Collaborative Innovation Center for Molecular Imaging of Precision Medicine, Taiyuan, CHINA, [4]Siemens Healthineers International AG, Zurich, SWITZERLAND.

Aim/Introduction: Despite the advancements in deep learning-based methods for quality recovery in low-dose PET imaging, it remains challenging to further improve the quality of synthetic full-dose PET and reduce the impact of noise on it. This study

aims to enhance generated PET image quality by exploiting the incoherent nature of noise, maximizing the input information of PET, and proposing a strategy of estimating full-dose PET from low-dose PET and its sampled multiple independent lower-dose repetitions. ***Materials and Methods:*** For proof of concept, this new strategy was trained with 3D U-Net from scratch using low-dose total-body [18F]FDG PET subjects (n=30) paired with their full-dose counterparts from uExplorer, and then preliminary tested on data from two different scanners of uExplorer (n=7) and Biograph Vision Quadra (n=1). The input data consists of one low-dose PET and four auxiliary lower-dose PET images. Each low-dose PET with a dose reduction factor (DRF) of 9 was reconstructed through ordered subset expectation maximization algorithm by resampling a 40-second time window during the 6-minute full-dose acquisition. For each low-dose PET, four auxiliary lower-dose PET images with a DRF of 36 were produced by dividing the 40-second sample evenly into four repeated segments. A comparative analysis was conducted to measure the quality enhancement of synthetic full-dose PET, compared with the method only using 40-second low-dose PET. Normalized root mean squared error (NRMSE), peak signal-to-noise ratio (PSNR), and structure similarity (SSIM) are selected as evaluation metrics. ***Results:*** The full-dose PET generated from multiple low-dose PET shows a significantly lower mean NRMSE (0.134%±0.048%, P=0.006), a higher mean PSNR (58.17±4.13, P=0.018), and a higher mean SSIM (0.99963±0.00028, P=0.035), compared with those from single low-dose PET. The mean NRMSE and PSNR improvements are enhanced from 22.14% to 24.98% and from 4.83% to 5.36%, respectively, by adding four lower-dose repetitions as input. Visual assessment by two nuclear radiologists showed no significant differences in image quality between real and synthetic test samples, and neither false positive nor false negative was generated by this method. ***Conclusion:*** The proposed strategy of using low-dose PET with its multiple lower-dose repetitions to estimate full-dose PET through deep learning can significantly enhance the quality of synthetic full-dose PET. Further transfer learning on 1500 patients from ultra-low dose PET Challenge, and systematic optimization and clinical evaluation on more than 200 patients imaged from 4 different scanners with 5 different tracers are ongoing.

Validation of an AI-Based Noise Reduction Filter on Bone Scan Images

C. Csikos[1], *S. Barna[1,2], Á. Kovács[3], Á. Budai[2], M. Szoliková[3], I. Nagy[1], B. Husztik[3], G. Kiszler[3], I. Garai[1,2];*
[1]Department of Nuclear Medicine and Translational Imaging, Institute of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY, [2]Scanomed Ltd., Debrecen, HUNGARY, [3]Mediso Ltd., Budapest, HUNGARY.

Aim/Introduction: Artificial intelligence (AI) is a promising tool in helping physician workflow and raise the effectiveness of their reads. Our work focuses on the validation of an AI based tool developed by Kovacs et al., 2022. In our validation, we aimed to evaluate the performance of an AI-based noise reduction filter. ***Materials and Methods:*** The AI bone scan filter (BS-AI) was validated retrospectively on 99mTc-MDP whole body images. The examinations were performed according to the institutional routine protocol. Validation was done using 47 planar bone scans of different patients which form a representative group of the training set. 3 nuclear medicine experts scored AI-filtered and original images for image quality and contrast. The performance of the BS-AI filter was tested on artificially degraded noisy images - 75-50-25% of total counts - which were generated by binominal sampling. For quantitative analysis, we used an automatic lesion detector (BS-annotator). The total number of lesions detected by the BS-annotator in the BS-AI filtered low-count images were compared to the original filtered images. The total number of pixels in the filtered low-count images relative to the number of pixels in the original filtered images were compared with one-way ANOVA. ***Results:*** Based on visual assessment, observers agreed that image contrast and quality were better in the BS-AI filtered images, increasing their diagnostic confidence. In addition, no new or disappearing lesions were detected in the filtered total-count and in the images degraded to counts of 75% and 50%. However, new and disappearing lesions were detected in images degraded to a count of 25%. The similarities of lesions detected by BS-annotator compared to filtered total-count images were 89%, 83%, 75% for images degraded to counts of 75%, 50% and 25%. There was no significant difference in the number of annotated pixels between filtered images with different counts. ***Conclusion:*** Our results showed that this BS-AI noise reduction filter is able to improve image quality and contrast not only on images with conventional protocol but also on low-count images. The use of this filter may provide an opportunity to reduce acquisition time or decrease the injected dose. ***References:*** Kovacs A, Bukki T, Legradi G, et al. Evaluation of a deep learning based partial volume correction on a simulated patient-based ^{177}Lu SPECT/CT dataset

J. Leube[1], *J. Gustafsson[2], M. Lassmann[1], M. Salas Ramirez[1], J. Tran-Gia[1];*
[1]Department of Nuclear Medicine University Hospital Würzburg, Würzburg, GERMANY, [2]Medical Radiation Physics Lund Lund University, Lund, SWEDEN.

Aim/Introduction: Partial volume errors (PVE) pose a significant limitation to SPECT/CT imaging, and current partial volume corrections (PVCs) are insufficient. Recently, a new methodology for deep learning-based PVC of 177Lu SPECT/CT imaging, called DL-PVC, was presented [1]. The aim of this study was to test DL-PVC on a generic patient-based data set and compare it with iterative Yang PVC (IY-PVC). ***Materials and Methods:*** Two datasets were utilized in this study: dataset (i) consisted of 10,000 pairs of random activity distributions placed inside artificially generated XCAT body phantoms and corresponding SPECT images, created using the Monte Carlo program SIMIND [2]. Compared to the previously used dataset [1], SPECT projections of smaller pixel size (2.4 mm) and thus larger matrix size (256x256) were simulated. SPECT reconstructions were performed using PyTomography ([3], OSEM, 6i6s, AC, SC, with resolution modelling). Dataset (i) was divided in 9000/500/500 for training/validation/testing, respectively, and DL-PVC(i), a u-shaped CNN (u-net), was trained (40 epochs, L1 loss function, input: SPECT images, target: activity distributions). A generic patient-based dataset (ii) was created by generating activity distributions for 717 peri-therapeutic 177Lu SPECT/CT images (429 [177Lu]Lu-PSMA-I&T, 288 [177Lu] Lu-DOTATATE, 202 patients) using a threshold-based approach to avert PVE. SPECT simulations and reconstructions were carried out as for dataset (i) and divided in 617/50/50 for training/validation/testing. Based on dataset (ii), two different u-nets were trained: DL-PVC(ii) trained with random weight initialization; and DL-PVC

(i⟶ii) for which transfer learning based on DL-PVC(i) was performed prior to training. Performance of all u-nets was assessed based on SSIM, NRMSE and voxel activity accuracy (VAA, [1]) against the ground-truth activity distributions. ***Results:*** For SSIM and NRMSE, DL-PVC(i) yielded comparable results to IY-PVC without the need for manual segmentation, and better results for VAA (DL-PVC(i): 0.88/9.6%/52.8%; IY-PVC:0.90/8.5%/12.0% for SSIM/NRMSE/VAA). Both PVC methods provided better results than applying no PVC (0.79/11.7%/10.6%). The same observations were made for dataset (ii) with DL-PVC(ii): 0.90/3.9%/18.0%; DL-PVC(i⟶ii): 0.91/3.6%/19.7%; IY-PVC: 0.94/2.9%/9.2%; no PVC: 0.85/4.5%/4.7%. Notably, transfer learning leads to a significant improvement in performance (paired Wilcoxon test, $p<0.01$). ***Conclusion:*** This study demonstrates the functionality of DL-PVC for patient-based SPECT/CT data. While the image quality (SSIM, NRMSE) was comparable to IY-PVC, the new method clearly outperformed IY-PVC at voxel level; without the need for manual segmentation. ***References:*** [1] Leube J et al. J Nucl Med 2024. Online ahead of print. [2] Ljungberg M, Strand SE. ComputMethProgBio 29(4);1989:257-272 [3] Polson et al., arXiv:2309.01977.

Deep Learning for CT-Free Attenuation and Scatter Correction in Ga-PSMA PET Imaging: A Comparative Study

Z. Adeli[1], *S. Hosseini[1], P. Sheikhzadeh[2], A. Akhavanallaf[3], Y. Salimi[4], H. Zaidi[4];*
[1]Group of Medical Radiation Engineering, Department of Energy Engineering, Sharif University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Nuclear Medicine, Imam Khomeini Hospital Complex, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Radiology, University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA, [4]Division of Nuclear Medicine and Molecular Imaging, Geneva University Hospital, Geneva, SWITZERLAND.

Aim/Introduction: Accurate quantification in positron emission tomography (PET) imaging is essential, which can be determined after attenuation and scatter correction. To achieve this, a computed tomography (CT) scan is used. Redundant radiation dose, especially in repeated PET/CT scans and child cases, CT-related artifacts such as halo artifact which is common in Ga68 imaging, and imaging with stand-alone PET can be the challenges of CT-based attenuation and scatter correction. Implementing a direct deep learning-based attenuation and scatter correction method in image space could be beneficial to eliminate additional CT radiation exposure and probable artifacts. This study aims to investigate the ability of deep learning in performing joint attenuation and scatter correction on Ga68-PSMA images. ***Materials and Methods:*** In this study, 51 whole-body Ga-PSMA PET/CT studies (mean body mass index 26.41 kg/m^2 ± 3.43) were selected to train the SwinUNETR model implemented in the monai platform. heavey bueden metastatic cases were excluded from the training dataset but included in the test samples to assess the model's performance with metastatic samples. Test samples were divided into two groups: 18 cases with zero or low metastatic tumor volume, and 15 individuals with widespread metastases. Prior to training, voxel values were converted to standardized uptake values (SUV). The training was continued for 500 epochs using L1Loss and initial learning rate of 1e-3 reduced piecewise and ADAM optimizer. For assessing the results, the evaluation metrics such as mean absolute error (MAE), relative error (RE), relative absolute error(RAE), peak signal-to-noise ratio (PSNR), and structural similarity index (SSIM) were measured. ***Results:*** Considering the small number of images in the training dataset, this method showed comparable results to the reference PET-CTAC images. In the non-metastatic group, MAE(SUV), RE(%), RAE(%), PSNR, and SSIM of whole body images are 0.02±0.005(SUV), 5.42%±3.96%, 7.95%±3.82%, 52.43±2.60, and 0.99±0.004, respectively. In the metastatic group, they are 0.02±0.006(SUV), 5.66%±4.79%, 8.48% ±4.82%, 50.70±3.52, and 0.98±0.008, respectively. p-values resulting from Mann-Whitney U test of these metrics of two groups are 0.27, 0.67, 0.98, 0.16, and 0.14, respectively. ***Conclusion:*** The proposed deep learning-based CT-free approach could yield reasonable results with minor errors, we compared our model in two groups of external datasets with and without widespread metastasis and it showed robust and comparable performance in both groups with no statistical difference in measured metrics. The proposed methodology may be used to tackle CT related artifacts in Ga-PSMA imaging or remove the unnecessary CT radiation dose and risk.

EP-0891

To evaluate the performance and accuracy of AI-based automated lesion segmentation tool using fully automated deep learning model for [68Ga] PSMA whole body PET/CT scans.

S. Singh[1], *D. Kumar[2], s. nigam[1], P. Wadhwa[3];*
[1]Globe Healthcare, Lucknow, INDIA, [2]United Imaging, New Delhi, INDIA, [3]United imaging, New Delhi, INDIA.

Aim/Introduction: To evaluate the performance and accuracy of AI-based automated lesion segmentation tool using fully automated deep learning model for [68Ga] PSMA whole body PET/CT scans. ***Materials and Methods:*** This is a single center study conducted to test the AI-based lesion segmentation software. This study included 30 patients with newly diagnosed adenocarcinoma prostate. All patients underwent staging workup by 68Ga-PSMA PET/CT performed on digital PET-CT scanner uMI550 (United Imaging). The DICOM data of whole-body PET/CT scans were uploaded onto the AI-based lesion segmentation platform (developed by UIH and available for research use only) using orthanc. The lesions that were then automatically segmented by the software. The lesion segmentation threshold was based on AI algorithm and SUVmax of liver, parotid and blood-pool. The results were reduced to binary scores and were compared with the manual segmentation (conducted by experienced board-certified nuclear medicine physicians). The false positives and false negatives are reported if any. The two methods were compared using dice coefficients. ***Results:*** We segmented the whole-body PET/CT scans in different organs and regions including head & neck region, lung, liver, lymph nodes, bones and so forth. It was observed that AI segmentation tool accurately segmented the primary prostate lesion in 70% of the scans and the rest of the scans reported false negatives. AI-based lesion segmentation tool performed well for bone metastases, where the tool automatically segmented lesions in 93% scans. This tool only demonstrated false negatives in 7% of the scans demonstrating a high accuracy in segmenting PSMA-avid bone metastases. Further, the tool demonstrated its capability in detecting lymph node metastases in 90% of the scans, with false negatives in 6.7% of cases and false positives in 3.3% of cases. The detection accuracy for lesions in other organs including lung and liver was 90% and with 97% in head & neck region. The dice coefficient for lung, liver and bone was 0.92, head& neck region was 0.96, lymph nodes was 0.88 and for pelvis was 0.63. ***Conclusion:*** The AI-based lesion segmentation tool has demonstrated high accuracy in automatically segmenting PSMA-

avid lesions although the detection of primary prostate lesions needs further improvement and training of deep neural network.

DEBI-NN Architecture Evaluation: Implications of Dataset Imbalance and Spatial Dropout on Performance

A. Boukhari[1], *B. Ecsedi[2,3], D. Haberl[2], C. Spielvogel[2], M. Hatt[1], L. Papp[2];*
[1]University of Western Brittany, Brest, FRANCE, [2]Medical University of Vienna, Vienna, AUSTRIA, [3]Georgia Institute of Technology, Atlanta, GA, UNITED STATES OF AMERICA.

Aim/Introduction: This study focuses on the optimization and parameterization of a new neural network (NN) architecture called DEBI-NN [1] that achieves similar accuracy as conventional NN while requiring significantly fewer trainable parameters. DEBI-NNs assign 3D coordinates to neurons, where neuron distances determine weights. DEBI-NNs also employ distance-based spatial dropout (SD) regularization. We aimed to evaluate the impact of data imbalance in small real and synthetic datasets with/without SD on DEBI-NN performance. ***Materials and Methods:*** Our study contained 4 dataset configurations for training. The first was the HECKTOR [2] challenge dataset (patients with H&N cancer and PET/CT images). The second used 500 synthetic samples of HPV-positive (HPV+) and HPV-negative (HPV-) cases, generated with a Conditional Tabular GAN (CTGAN) [3] trained on HECKTOR. The third and fourth datasets introduced an 80% class imbalance to the second dataset, to favor the HPV+ class and the HPV- class, respectively. These 4 datasets were employed twice with and without SD, resulting in 8 experiments. Spatial dropout removed the farthest 50% of neurons in each connecting DEBI-NN layer during training to confer task-specific network abilities. Assessment of balanced accuracy (BACC) utilizing a test set of the HECKTOR dataset was done 10-times in each execution to manifest an independent test-retest scheme. ***Results:*** In both with/without SD experiments, consistent performance was obtained across all configurations (~80% BACC). The use of a balanced dataset contributed to a slight improvement in learning stability and the highest BACC (85.5±2.3 vs 82.3±3.89 for balanced and unbalanced respectively). The implementation of spatial dropout led to slightly lower performance with the synthetic data (84.9±2.0 vs 86.2±2.5 with and without dropout respectively), unlike with the original HECKTOR data. ***Conclusion:*** The effectiveness of SD appears dependent on the properties of the dataset. The synthetic dataset's lack of response to SD suggests potential complexities: either the dataset may have been insufficiently challenging for the network to necessitate SD, or conversely, overly complex, demanding additional neurons to compensate for those omitted. Further investigation is required to understand SD's role in shaping task-specific network structures and its interplay with addressing class imbalance through different methods such as SMOTE-EEN.

Radiation Safety Considerations for Introducing a High-Resolution Mobile PET/CT Camera into Operating Rooms

B. Lambert, *V. Vergucht, N. Dhont, S. Dekeyser, K. Decaestecker, A. De Craene, F. Ameye, B. Van Den Bossche, D. Berwouts, J. Mertens, H. Vanoverschelde, Y. D'Asseler, C. Van Haverbeke, M. Coppens, T. Van Oostveldt;*
AZ Maria Middelares, Gent, BELGIUM.

Aim/Introduction: We tested a mobile high resolution PET/CT-camera for imaging surgical specimens in the operating room. It provides submillimeter resolution images of tissue specimens of patients injected with FDG. Upon implementation of this device at the surgical department of our hospital, we monitored the dose rates in close proximity to the patients. ***Materials and Methods:*** For new indications 4 MBq/kg FDG was injected iv 1h prior to removal of the tumor (thyroid, bladder, renal and skin cancer). For breast cancer 0.8 MBq/kg was prescribed. We conducted dose rate measurements with a Geiger-Mueller from injection till transfer to the recovery ward. Fixed geometries were used: at the level of the trunk and feet at the bedside as well as at 1m distance from trunk and feet. Surgeons, nurses and anaesthesiologists were monitored by an electronic dosimeter during the entire procedure. A 10 min acquisition of the tissue was performed on the PET/CT-camera in the operating room. The results were confronted with the final reports of the pathologists concerning the resection margins. ***Results:*** The median duration of surgery was 75 (range 32-256) min. For 11 procedures performed with 4 MBq/kg we obtained the following measurements:Median (min-max) doserates at bedside trunk level were at 10, 30 60 and 90 minutes respectively 98 (68-111), 85 (40-129), 49 (24-79) and 53 (20-83) µSv/h, Upon arrival at the recovery ward this was 19 µSv/h (4-73).Dose rates dropped by a factor >5 when measured at a the side of the feet instead of trunk. Absorbed dose estimates for the surgeon, assisting surgeon, scrub nurse and anaestesiology team were respectively 57 (10-171), 75 (72-143), 39 (2-144) and 8 (0-17) µSv. Image reconstructions simulating lower injected activities, suggest that -depending on the clinical indication- injected activities can be reduced by a factor 2 to 4. ***Conclusion:*** We successfully introduced the use of a mobile high resolution specimen PET/CT camera in the surgical ward of a general hospital, a process that required significant efforts to inform and train the involved nurses and physicians regarding radiation safety. The use of the standard diagnostic activity (4 MBq/kg) of FDG resulted in absorbed doses for the surgeons ranging from 10 -171 µSv/procedure. Simulating lower injected activities (1-2 MBq/kg FDG) resulted in acceptable image quality of the resected specimens during retrospective analysis. This finding suggests a considerable potential for further reducing doses for both patients and staff.

EP-0894

Impact of patient and staff shielding on staff's radiation dose for frequently used isotopes in nuclear medicine: A GEANT4 Monte Carlo simulation

M. Qutbi[1], *P. Rafiepour[2];*
[1]Shahid Beheshti University of Medical Sciences,

Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Shiraz University, Shiraz, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: To evaluate the deposited dose to the staff in nuclear medicine services for different diagnostic and therapeutic radioisotopes from a patient as an external source of gamma radiation comparatively in different shielding options (, staff-only, patient-only, both, and none shielded). ***Materials and Methods:*** Female MIRD anthropomorphic phantoms are utilized for staff and patient positioned 1.5 m apart. A lead 5-mm-thick semi-cylindrical-shaped shell is used as a protective shield that covers the entire of trunk. Tc99m and F^{18} (positron-emitting Fluoride) as diagnostic and I131 and Lu177 as therapeutic isotopes are determined as the sources. For each source, 4 simulation experiments (each simulation with 50 million particles) are conducted according to shielding of the staff and patient (none, staff-only, patient-only, and lastly, patient-and-staff). Total energy deposited in the trunk and organs is calculated. Deposited dose (in Gray) is computed by dividing by the corresponding mass, and root mean squared error is then determined. The GEANT4 Monte Carlo software is used to run simulations. Afterward, data of deposited dose and amount of dose reduction are comparatively analyzed and plotted using MATLAB software. ***Results:*** The highest dose deposited in the trunk is for F^{18} and followed by for I131 sources. Liver, small and large intestines received the highest dose compared to other organs. The dose deposited is dramatically decreased from no shielding to staff-only and patient-only shielding. The values of dose are almost similar in staff-only and patient-only shielding and then decline more slowly to the situation of both staff and patient shielded. The slope is higher for high-energy gamma sources (isotope of F^{18}). The amount of reduction in trunk dose is greater than 99% for Tc-99m and Lu177 in staff-only, patient-only as well as in both patient and staff shielding. The values of dose reduction for I131 are 81.2%, 81.3%, and 93.9% in staff-only, patient-only as well as in both patient and staff shielding respectively, while the values for F^{18} are 66.7%, 66.8%, and 86.4%. ***Conclusion:*** The benefits of shielding are different for low and high-energy gamma photons. In low-energy radioactive sources, like Tc99m and Lu177, shielding of either staff or patient is sufficient and shielding of both adds little benefit to dose reduction. Conversely, in high-energy gamma sources, F18 and I131, the benefits of concomitant shielding of staff and patient are not negligible, more notably with F18 or other positron-emitting sources, and thus, add a greater reduction in dose.

EP-0895

Calibration in terms of activity per unit volume of the stack monitor at a PET cyclotron centre using Monte Carlo technique

M. Marengo[1], *A. Zorz[2], L. Colombo Gomez[2], F. De Monte[2], M. Marcolin[1], M. Paiusco[2];*
[1]Veneto Oncology Institute, Castelfranco Veneto, ITALY, [2]Veneto Oncology Institute, Padova, ITALY.

Aim/Introduction: In PET centres with cyclotrons, it is common practice to install a radiation detector on the expelled air stack, to measure the possible presence of radioactivity prior to release into the atmosphere. However, given the intended purpose and location, it is complicated to calibrate such systems in terms of activity per unit volume of air released. The aim of this work is to illustrate the method used to calibrate a simple and relatively inexpensive system installed at our centre. ***Materials and Methods:*** FLUKA is a well-known general purpose code for modelling particle transport and interaction with matter, covering a wide range of applications. We used FLUKA.CERN 4-2.2 and its graphical interface Flair. The model includes the main expelled air duct, a cylindrical PVC pipe with a diameter of 40 cm. The inserted probe, also in PVC, houses an energy compensated Centronics ZP1202 type GM tube. The geometric model we created describes in detail the dimensions and materials of the components. For validation, irradiation of the detector probe model with a point source of 137Cs was simulated, reproducing the situation for which the manufacturer expresses the detector specifications. To simulate the operational situation, the filling of the expulsion duct with air uniformly contaminated with 18F was reproduced, for overall lengths of 100, 200 and 300 cm of duct. The cut-offs for electron and photon transport were set at 30 and 15 keV respectively and several high-statistics simulations were repeated and the results scored using the USRBIN and DETECT cards of FLUKA. ***Results:*** In the model validation simulations, the estimated environmental dose rate was 0.99 µSv/h with an uncertainty of 1.5%, to be compared with the expected value based on the gamma emission constant of 0.97 µSv/h. The simulated counting rate was 1.88 cps +/- 4%, against the expected value of 1.97 cps. The model was therefore able to reproduce within error the expected performance of the detector. Tests simulating the contaminated duct showed that the essential part of the response was provided by the first 100 cm of contaminated air around the detector. The average calibration factor was 1.12 +/- 0.09 cps per 1 Bq/cm3 . ***Conclusion:*** A simple and relatively inexpensive stack monitor may be sufficient in many cyclotron PET centres. Monte Carlo simulation techniques allow the detectors to be calibrated with satisfactory accuracy, even under "bad geometry" conditions. ***References:*** Infantino A et al. doi: 10.1093/rpd/ncw302.

EP-0896

Evaluation of shielding provided by hot cells used for theranostics in a clinical setting using Mote Carlo method

M. Marengo[1], *S. Rubow[2];*
[1]University of Bologna, Bologna, ITALY, [2]Stellenbosch University, Stellenbosch, SOUTH AFRICA.

Aim/Introduction: Hot cells to house 68Ge/68Ga generators, for the synthesis of products or the labelling of kits and subsequent dispensing are widely used. The increasing availability of Lutetium-177 has allowed a theranostic approach to be implemented. This work aims to guide the selection of the most appropriate shielding for the hot cells intended for this type of work. ***Materials and Methods:*** Monte Carlo simulation using FLUKA.CERN 4.2 and its graphical interface, Flair, were used. We modelled a hot cell with lead thickness from 30 mm to 50 mm or more in 10 mm layers. Sources were modelled as a small water cylinder, or a volumetric source of 30x40x30 cm, representing e.g. synthesis modules or dispensing systems. The simulations were performed with the source without shielding, and with different thicknesses of lead shielding. 1 GBq sources were considered centered in the hot cell or at 10 cm behind the front wall. ***Results:*** Our FLUKA model was cross-validated by estimating the specific gamma ray emission constants of 68Ga and 177Lu. Gallium-68: In a 30 mm hot cell, an unshielded central point source still causes a dose-rate of 5.5 µSv/h at 10 cm from the outer surface of the hot cell, which is reduced to 3.4 µSv/h with an added 10 mm vial shield. For a volumetric source, the dose-rate at 10 cm from the cell surface is 4.5 µSv/h and 1.3 µSv/h at 50 cm. These values are reduced to 0.8 and 0.26 µSv/h respectively in a 50 mm hot cell. Lutetium-177: The shielding of 177Lu is not a problem in a

30 mm hot cell, even with 0.1% 177mLu impurity. ***Conclusion:*** Our simulations are conservative, providing dose rate values for 1 GBq 68Ga in a single moment, which does not represent the actual situation during radiosynthesis, kit labelling or dispensing. From a radiation safety perspective, in a busy department with a high activity 68Ge/68Ga generator, a 50 mm Pb hot cell would be optimal, 30 mm Pb would require some additional shielding of the source. Working with 177Lu in a hot cell set up for PET work is safe, but aspects of Good Radiopharmacy Practice should also be taken into account if a single hot cell is used for preparing and dispensing both radiopharmaceuticals of a theranostic pair. A simple Monte Carlo model of a hot cell allows accurate estimates of the dose present in working environments.

EP-0897

Effective dose measurements of workers in the Radiopharmaceutical Production Unit at the University of Costa Rica

E. Mora Ramirez;
Cyclotron PET/CT Laboratory, University of Costa Rica, San Pedro, San Jose, COSTA RICA.

Aim/Introduction: According to Costa Rican national authorities effective dose measurement must be provided for each worker when ionizing radiation is present. Since May 2022 workers at the cyclotron unit at the University of Costa Rica are producing ^{18}F-FDG, initially because it was necessary to perform different test to all equipment present in the facility. Since May 2023 first oncologic patients were received to perform ^{18}F-FDG studies. In December 2023 ^{18}F-FDG radiopharmaceutical was exported to Guatemala. Then, different amounts of activity were prepared according to our needs. ***Materials and Methods:*** Cyclotron and modules are used to produce ^{18}F-FDG. Hot cells are used for synthesis and dispensing the final product. At all times, five people are in place when radiopharmaceutical is produced, as follows, one at the cyclotron operator room, one at the hot cells, one at the QC Laboratory, one for cross-check/validation of the radiopharmaceutical product and one radiation protection officer. The ^{18}F activity produced can vary from 3Ci to 8Ci. Workers used TLD detectors for whole body (Hp(10), Hp(3), Hp(0.07)), eyes (Hp(3)) and extremity (writs (Hp(0.07), ring (Hp(0.07)) measurements. One a month TLD detectors are returned to the CICANUM TLD Laboratory for its lectures. ***Results:*** Twenty lectures have been received from the CICANUM TLD laboratory. For all data average, minimum and maximum results in mSv are reported. For Whole body Hp(10) = 0.166, 0.01, 2.97. Hp(0.07) 0.182, 0.015, 2.98. Hp(3) 0.174, 0.015, 2.98. For eyes Hp(3) 0.361, 0.01, 1.66. For extremity (writs) Hp(0.07) 1.254, 0.01, 21.28. For extremity (fingers) Hp(0.07) 5.09, 0.04, 65.31. The effective dose limit for extremities is 41.67 mSv per month. In four occasions workers have lectures above the limit for extremities. For all four cases, an investigation occurred to understand why the limit was exceeded. For these four cases an improvement of the manipulation protocols was implemented, then, for those workers no more lectures above the limit occurred. ***Conclusion:*** For more than 20 months workers at the cyclotron unit at the University of Costa Rica has been received radiation protection surveillance. On few occasions effective dose limits were exceed, however, an investigation occurs to understand how this occurred. After implementation of corrective actions, no more lectures above the limit occurred. ***References:*** Mora, P. Acuña, M. Assessment of medical occupational radiation doses in Costa Rica. DOI:10.1093/rpd/ncr341

EP-0898

Determination of the deposited activity of 99mTc in ventilation and perfusion lung scintigraphy

J. Vogt[1,2], *W. K. Vogt[3,4], O. H. Winz[2], A. Heinzel[5,6], F. M. Mottaghy[2,7]; [1]University Medical Center Hamburg-Eppendorf, Security and Compliance Business Divison, Hamburg, GERMANY, [2]University Hospital RWTH Aachen, Department of Nuclear Medicine, Aachen, GERMANY, [3]University of Applied Sciences, Faculty of Electrical Engineering & Information Technology, Düsseldorf, GERMANY, [4]Max Planck Institute for Sustainable Materials, Düsseldorf, GERMANY, [5]The University Hospital Halle (Saale), Department of Nuclear Medicine, Halle (Saale), GERMANY, [6]Forschungszentrum Jülich, Institute of Neuroscience and Medicine (INM-4), Jülich, GERMANY, [7]Maastricht University Medical Center (MUMC+), Department of Radiology and Nuclear Medicine, Maastricht, NETHERLANDS.*

Aim/Introduction: Diagnostic reference values are used to ensure and control radiation protection during nuclear medicine examinations. Especially, for lung scintigraphy ventilation scans with 99mTc-Technegas, the diagnostic reference values today refer to the prepared amount of ventilation and perfusion activity. Currently, the eluted and injected activity is estimated on the base of biokinetic models according to ICRP80. The aim of this study is to determine the amount of inhaled and injected activity deposited in the lung in order to establish reliable diagnostic reference values. With more precise knowledge of the deposited activity, the scintigraphic examination might be optimised and at the same time an improved estimation of the radiation exposure for the patient can be achieved. ***Materials and Methods:*** A SPECT phantom was homogeneously filled with 99mTc-MAA to calibrate both applied SPECT/CT devices. To determine a device-specific calibration factor (MBq/counts) for each operating mode, half-life corrections were performed and acquisition parameters and sensitivities of both SPECT/CTs were considered. The phantom measurement was analysed using the 3D lung lobe quantification software QLUNG (Q. Lung: Xeleris 4.0, GE Healthcare), considering the different operating modes. A study cohort of 146 patients (59 male, 87 female, age 65.3±15.5 years) underwent ventilation/perfusion single photon emission computed tomography (V/Q-SPECT/CT) to exclude acute PE on two SPECT/CT devices (n=74 on OPTIMA NM/CT 640, GE Healthcare and n=72 on Symbia T16, Siemens Healthineers). A 3D lung segmentation was performed with QLUNG for each patient. The measured counts of all lung lobes for ventilation and perfusion were normalised individually with the corresponding calibration factor to determine the deposited activity in MBq. ***Results:*** For ventilation, 3.6 % ± 1.6 % of the eluted and offered radioactivity was inhaled by all patients and 59.5 % ± 14.2% of the injected perfusion activity remained in the pulmonary circulation. This resulted in the following deposited activities: For ventilation, the deposited activity was (13.7±6.0) MBq and for perfusion the deposited activity was (105.2±27.4) MBq. Prior to the start of the measurement, 389.1 MBq±62.7 MBq Technegas was provided and 176.7 MBq±16.9 MBq 99mTc-MAA was injected to each patient. ***Conclusion:*** Based on the results of this study, the biokinetic models for dose estimation can be verified and refined. This allows an improved estimation of the patient's radiation exposure for lung scintigraphy.

EP-0899

Annual radiation exposure dose of surgeons involved in radio-guided sentinel lymph node biopsy in endometrial cancer

A. Jankulovska, *I. Sazdova Danova, N. Manevska, T. Makazlieva,*

N. Bozinovska, B. Stoilovska Rizova, S. Stojanoski;
Institute of pathophysiology and nuclear medicine "Acad. Isak Tadzer", Faculty of Medicine, Skopje, NORTH MACEDONIA.

Aim/Introduction: Sentinel lymph node biopsy (SLNB) utilizing radiocolloids is associated with radiation exposure of the involved medical workers. This study aimed to investigate the radiation exposure doses of surgeons during radio-guided SLNB procedures in endometrial cancer patients. ***Materials and Methods:*** A prospective study was undertaken to measure the annual radiation exposure of two surgeons during 20 SLNB procedures conducted from September 2022 to August 2023. All patients received a cervical injection of 4mCi Tc99m albumin nanocolloid on the day of the surgery. Radiation exposure was monitored using thermoluminescent dosimeters in the form of badges and bracelets, both during local radiocolloid application and throughout the surgical procedure. ***Results:*** The surgeon and the surgeon's assistant received an annual whole-body dose of 0.52 mSv and 0.57 mSv, respectively. The annual extremity doses were 0.40 mSv and 0.44 mSv, respectively. The average dose per intervention to the whole body was 0.03 mSv, while for extremities, it was 0.02 mSv. ***Conclusion:*** The radiation exposure to the surgeons involved in radio-guided SLNB in endometrial cancer was found to be low and safely below the permissible limits, according to the ICRP (International Commission for Radiological Protection). Based on the above results, approximately 700 SLNB per year would be required for the surgeon to reach the whole-body exposure limit for a radiation worker. Therefore, routine radiation monitoring may not be deemed mandatory.

EP-0900

Radiation Safety in Selective Intravascular Radiotherapy

J. Liukkonen, *A. Lajunen, V. Ruonala;*
Radiation and Nuclear Safety Authority (STUK), Vantaa, FINLAND.

Aim/Introduction: The purpose of the study was to investigate practices related to the selective intravascular radiotherapy (SIRT). This covers the lifespan of the isotope entering the hospital all the way to the waste processing. The aim of the project was to improve the radiation safety of workers and patients. In particular, the aim was to develop a documented method for ensuring radiation-safe operation suitable for regulative inspections and self-assessments. ***Materials and Methods:*** The study material consists of instructions from the hospitals, post operation surveys and on-site inspection reports. Operational instructions were collected from all Finnish hospitals holding license for SIRT. Observational studies were performed in hospitals during SIRT procedures. Surveys (N=27) were conducted immediately after operations covering multidisciplinary personnel related to SIRTs. ***Results:*** The level of radiation safety in SIRT activities was good. Based on the study multi-professional collaboration is a critical factor in radiation safety during SIRT. A documented inspection method for ensuring radiation safety during in SIRT was introduced. The development of more detailed and possibly national guidelines gained impetus. ***Conclusion:*** Regulatory body for radiation safety can and should inspect SIRTs. Self-assessment is also warranted. The documented method will be suggested for international use. In addition, it is applicable for self-assessments in interventional radiology and nuclear medicine units. In complex processes multi-professional collaboration is paramount. ***References:*** Weber, M et al. Diagnostic reference levels for ^{18}F-FDG whole body PET/CT procedures in Costa Rica

E. Mora Ramirez, *J. Mendoza Madrigal;*
University of Costa Rica, San Pedro, San Jose, COSTA RICA.

Aim/Introduction: Diagnostic reference levels are well-established for radiopharmaceuticals in general nuclear medicine. In Central America data for positron emission tomography/computed tomography (PET/CT) results are limited due to the limited amount of equipment available in the region. The aim of this study is to report initial data for ^{18}F-FDG whole body PET/CT procedures performed in the first digital PET/CT Unit available in Central America. ***Materials and Methods:*** In our clinical protocol patients who underwent in ^{18}F-FDG whole body also has a CT image from the thorax. Data was analyzed by checking on DICOM files. Parameters considered were body weight, height, CT dose index volume (CTDIvol), dose-length product (DLP) and administrated activity. ***Results:*** In this study data from 67 patients, 51 male and 16 female were considered with an age range between 25 and 82 years old. The height varies from 1.54 to 1.85 m and the weight from 80.4 to 156 Kg. Administrated activity varies from 353.35 to 714 MBq (7.32 - 19.3 mCi) and the 75th percentile is 480.63 MBq. CTDIvol for thorax CT images varies from 4.45 to 30.87 mGy and the 75th percentile is 14.6 mGy. DLP varies from 148.10 to 1115.80 mGy*cm and the 75th percentile is 526.55. CTDIvol for whole body CT images varies from 7.26 to 46.11 mGy and the 75th percentile is 20 mGy. DLP varies from 546.8 to 5991.60 mGy*cm with a 75th percentile of 2289.8 mGy*cm. ***Conclusion:*** Initial results show the large variation in CT dose values highlights the need for optimization in our studies, then, DRLs are justify in hybrid imaging clinical studies. Further data will be included considering children. ***References:*** Sagara, H., Inoue, K., Yaku, H. et al. EP-0902

Tin Filter Allows Large CT Dose Reduction for SPECT Attenuation Correction with Negligible Impact on SPECTQuantification at Soft Tissue and Trabecular Bone Equivalent Densities

N. Bebbington[1], *J. Frederiksen[2], R. Skall[2], H. M. Nielsen[2], S. Ravn[2];*
[1]Siemens Healthcare A/S, Ballerup, DENMARK, [2]Nuclear Medicine Department, Aalborg University Hospital, Aalborg, DENMARK.

Aim/Introduction: The CT tin filter has demonstrated large CT dose reductions for attenuation correction (AC) in PET-CT with negligible influence on PET quantification. The tin filter was recently introduced to SPECT-CT systems, but available tube voltage settings differ, as do linear attenuation coefficients for PET and SPECT radionuclides. The aim was therefore to determine by how much dose can be reduced with tin filter CT for SPECT AC, without significantly impacting SPECT quantification. ***Materials and Methods:*** The NEMA image quality phantom underwent SPECT-CT under two conditions: firstly water-filled, mixed with Tc-99m-pertechnetate; and secondly with the cylindrical insert containing a homogenous mix of water, sand and flour with Tc-99m-pertechnetate (W-S-F, approximately 300HU), with water

background. The former represented soft tissue density, and the latter trabecular bone density. Each underwent 1 SPECT and 12 CT acquisitions. CT acquisitions used tube current modulation at: 130kV/50mAs (reference standard); 110kV (mAs range 13-50); Sn130kV (13-50mAs) and Sn100kV (13-300mAs), and 24cm CT scan range. SPECT data were reconstructed with AC using attenuation maps generated from each CT dataset. Reconstructions used ordered subset expectation maximisation with resolution recovery (30 updates, 9mm Gaussian post-filter). Volumes-of-interest were assigned to the volumes containing Tc-99m, and total counts measured. Differences in reconstructed SPECT counts were determined relative to the 120kV/50mAs reference, and relative differences in CT dose length product (DLP) compared. ***Results:*** For the water phantom, there was no measurable difference in reconstructed SPECT counts between use of reference CT settings for attenuation map creation, and other CT settings without tin filter. When scanned with tin filter, the greatest relative difference in reconstructed SPECT counts was 0.4% compared with the reference. For the W-S-F phantom scanned without tin filter, the greatest relative difference in SPECT counts was 1.3%, and 1.0% when scanned with tin filter. For both phantoms, for the lowest available tin filter exposure setting of Sn110kV/13mAs (water phantom DLP 4.2mGy.cm), DLP was reduced by 94% compared with the reference , and by 80% compared with use of 110kV/13mAs without tin filter. ***Conclusion:*** The tin filter provides ultra-low CT doses for AC with negligible impact on SPECT quantification at soft tissue and trabecular bone equivalent densities. This will allow dose reduction in SPECT examinations where CT is already performed for AC, or allow the addition of CT for AC for optimised reading of SPECT images in current SPECT-only examinations where the CT dose had previously not been justified.

EP-0903

Feasible correction of personal dosimeters for their response to internally deposited radionuclides or their surface contamination in nuclear medicine

J. Sabol[1], *J. Hudzietzova[2], M. Fülöp[3];*
[1]Department of Crisis Management PACR, Prague, CZECH REPUBLIC, [2]Fuculty of Biomedical Engeneering, Kladno, CZECH REPUBLIC, [3]ABRS, Samorin, SLOVAKIA.

Aim/Introduction: Using personal dosimeters for radiation workers presumes that their response will primarily express the contribution to the total personal dose equivalents due to external radiation. In some cases where unsealed radioactive sources are used, workers may be contaminated due to the inhalation, which may also contaminate the body surface or cloth worn by the personnel. Then, personal dosimeters also react to radiation emitted from the body and radiation from the contaminated body's surface or cloth. Since the personal dosimeters are calibrated for external exposure, the contribution from other radiation is detected, but the response does not correspond to the quantity measured since the dosimeter has not been calibrated for such geometry. Therefore, the dosimeter reading will correspond to two different geometries: response to radiation striking the body from outside and response to radiation from other directions. ***Materials and Methods:*** An attempt was made to assess the sensitivity of the personal dosimeter to other than external radiation to find out to which extent contribution from inside the body and from its surface may affect the reading of the dosimeter calibrated under different geometry. The contribution from the internal radiation may be compensated using another dosimeter equipped with some shielding against external radiation. The dosimeter will mainly be sensitive to radiation emitted by the deposited radionuclide. Its response to external radiation will be significantly suppressed. ***Results:*** The situation reflects the complexities involved in measuring radiation exposure for workers who may be exposed to both external and internal radiation. The use of personal dosimeters is a standard practice in nuclear medicine, where workers are potentially exposed to radiation. Still, their effectiveness can be compromised when these dosimeters are exposed to internal radiation. The total reading of personal dosimeters could sometimes be affected by their exposure to radiation from other directions. Normally, the contribution to the response of a personal dosimeter is almost negligible, but in the case of internal contamination of the worker (corresponding to about 10 microSv/h on the surface), the contribution to its response cannot be neglected). ***Conclusion:*** It has been proven that personal dosimeters, primarily calibrated for external radiation exposure, may not accurately measure radiation emitted from the body or its contaminated surfaces. This limitation can lead to inaccurate readings, as the dosimeter's response may not correspond to the actual radiation dose received by the worker. This study was partially supported by EU Horizon programme No. 101121342.

EP-0904

Suggested recommendations for bystanders after lutetium therapy

J. Hudzietzova[1], *M. Fülöp[2], A. Vondrák[3], P. Nemček[3], I. Gomola[4], J. Sabol[5], M. Mráz[1], L. Foltínová[6];*
[1]Czech Technical University in Prague, Kladno, CZECH REPUBLIC, [2]ABRS, s.r.o., Šamorín, SLOVAKIA, [3]Izotopcentrum, s.r.o., Nitra, SLOVAKIA, [4]Slovak Medical University, Bratislava, SLOVAKIA, [5]Faculty of Security Management, PACR in Prague, Prague, CZECH REPUBLIC, [6]Faculty of Business Management, University of Economics in Bratislava, Bratislava, SLOVAKIA.

Aim/Introduction: During lutetium therapy, workers caring for the administered patient in the medical facility and other hospitalized patients in the same room or persons accompanying the discharged patient home or sharing a household with him are exposed to a certain external radiation. ***Materials and Methods:*** Between April and September 2023, 13 measurements were taken of persons who came into contact with the applied patients (for some people, the measurements were conducted repeatedly). Monitoring persons such as drivers transporting the applied patient and family members living with the applied patient was carried out using coats on which pairs of TLDs were placed in 29 positions (20 positions on the chest, abdomen and small pelvis, four positions on each upper limb and one position on the back between the shoulder blades). In addition, an electronic dosimeter was placed at the reference point (upper left side of the chest). TLDs were calibrated to show reading in terms of Hp(10). ***Results:*** Approximately 20 % of the maximum exposure was measured in a location where personal whole-body dosimeters are routinely worn. The maximum exposure in approximately 45 % of cases was in the abdominal region, where the dosimeter placement would have an average correction factor value of approximately 1.5 relative to the reference site. If we were to consider other areas (back of the neck, upper chest, sleeve) where the maximum exposure was measured relative to the reference site, the correction factors ranged from 1.1 to 6.8. In one case, casing contamination was detected. This local exposure from the contamination was estimated to be approximately 30 times higher than the exposure at a distance of roughly 25 cm from the contamination site. ***Conclusion:*** It is advisable to pay attention to

the spatial distribution of radiation for people in close proximity to the patient after lutetium therapy, which can be administered repeatedly (several times a year). Based on the knowledge of the direction of the dominant radiation, it is possible to recommend a suitable geometry of the treating person towards the patient (sufficient distance from the abdominal area, where, in most cases, the highest radiation level was found) or to suggest the use of a suitable correction factor in the event that the person is monitored with a personal dosimeter on the reference place. This paper was partially supported by the project SGS24/072/OHK4/1T/17.

Aim/Introduction: The main purpose was to measure the lens dose of in-duty workers in three nuclear medicine sites. ***Materials and Methods:*** A total of 23 workers in nuclear medicine departments joined this work. 6 out of 23 were SPECT/ CT technologists, 6 PET/CT technologists, 3 PET/MRI technologists, 5 radiopharmacists, 2 physicists, and 1 physician. EXTDOSE Hp(3) OSL dosimeter with tissue equivalent beryllium-oxide crystal was used for lens dose measurement. All participants were asked to wear the lens dosimeter for 2 months as near to the eye level as possible. ***Results:*** the dose measures yielded an average lens dose of 1.48 ± 0.77 mSv for the radiopharmacy team, 1.44 ± 0.26 for PET/ CT technologists, 0.86 ± 0.45 mSv for SPECT/ CT technologists, 0.38 mSv for the sole physician administered 177Lu, and 0.45 ± 0.02 mSv for the physicists conducting 131I therapy. Moreover, normalizing the lens dose to the labeled activity led to a lens dose of 2.2 ± 1.4 µSv/GBq for the radiopharmacy team. Likewise, per administered activity: 23.8 ± 7.3 µSv/GBq for PET/CT and PET/MRI technologists, 12.2 ± 10.5 µSv/GBq 99mTc for SPECT/CT technologists, 6.0 ± 0.81 µSv/GBq 131I for physicists, and 3.0 µSv/GBq 177Lu for the physician. ***Conclusion:*** It was concluded that the annual occupational lens dose of the nuclear medicine workers varied from 2.3 to 11.5 mSv/year; however, one radiopharmacist showed 17.9 mSv/y annual lens dose close to the lens equivalent dose limit (20 mSv/year).

EP-0906

Evaluation of the wipe test effectiveness of $^{223}RaCl_2$ and $^{99m}TcO_4$ contaminations with ethylenediaminetetraacetic acid (EDTA), 2-propanol and H_2O

B. Bockisch, *B. Leonhäuser, R. A. Werner, C. Happel; Goethe University Frankfurt; University Hospital; Department of Nuclear Medicine; Clinic for Radiology and Nuclear Medicine, Frankfurt, GERMANY.*

Aim/Introduction: 223RaCl2 therapy of osseous metastatic prostate cancer has increasingly become the focus of clinical routine in recent years. The 223RaCl2 transport shielding (TS) must be free of contamination before being returned to the manufacturer. Due to the geometry of the surfaces of the TS, wiping tests are required. Wipe-test effectiveness (WE) also depends on the properties of the liquid being wiped with. Aim of this study was to evaluate the WE of EDTA solution for 223RaCl2 and 99mTcO4 contaminations in comparison to 2-propanol and H2O. ***Materials and Methods:*** 90 TS were contaminated with 2.1 or 7.6 kBq 223RaCl2 or with 8.7 kBq 99mTcO4- on an area of 17 cm2. After 4 hours of exposure, the wipe samples were carried out on 30 TS each using a standardized procedure with EDTA, 2-propanol and H2O. The activity of the wipe samples taken was determined using a calibrated well counter with a connected multi-channel analyzer. The decay-corrected WE for 223RaCl2 and 99mTcO4- were evaluated from the measured activities. ***Results:*** For both radionuclides, the highest WE were found for water (83 ± 3.5% for 99mTcO4-; 66 ± 15% for 223RaCl2). The lowest WE were found in both cases with 2-propanol (61 ± 12.3% for 99mTcO4-; 59 ± 33% for 223RaCl2). In addition, the highest fluctuation range of the measured WE were found when taking 2-propanol. For EDTA, the WE were 74 ± 9.9% for 99mTcO4 and 63 ± 17% for 223RaCl2. ***Conclusion:*** There was no significant difference in the WE of 223RaCl2 between pure water and a liquid solution of the chelator EDTA. Due to the lowest WE and the highest fluctuation range, 2-propanol is the least suitable for taking wiping samples. The polarity of the liquid used appears to be crucial for reliable WE. It can therefore be recommended to carry out the wiping samples with the polar solvent water.

EP-0907

Measuring $^{223}RaCl_2$ contaminations: Comparison of well-counter, contamination monitor and NaI(Tl) sample changer

B. Bockisch, *B. Leonhäuser, R. A. Werner, C. Happel; Goethe University Frankfurt; University Hospital; Department of Nuclear Medicine; Clinic for Radiology and Nuclear Medicine, Frankfurt, GERMANY.*

Aim/Introduction: The approval of 223RaCl2 has brought radiation protection into the focus of nuclear medicine interest when dealing with radiation. Aim of this work was to combine wipe sample measurement as a measurement methodology for absolute quantification of contaminated transport shieldings (TS) with surface measurement using a portable contamination monitor (CM). ***Materials and Methods:*** Contaminations of known 223RaCl2 activity were created to calibrate various devices, evaluate different measurement methods and design a measurement methodology. A well counter (WC) (Dr. Westmeier GmbH), a sample changer (SC) (WIZARD, Wallac-1470) and a CM (Berthold LB124-scint) were examined. Wipe-samples were taken with cotton swabs moistened with EDTA. Effectiveness of the devices, extraction factors (EF) and practical use of the devices were compared. ***Results:*** Efficiencies were 66 cpm/Bq (WC), 58 cpm/Bq (SC), 1.6 cpm/Bq (bottom of the TS) (CM) and 14 cpm/Bq (top of the TS) (CM). Detection limits (DL) were 0.53 Bq (WC), 0.091 Bq (SC), 5.1 Bq (bottom of the TS) (CM) and 0.58 Bq (top of the TS) (CM). EF for the different extraction times were 68 ± 10 % (bottom of the TS) and 81 ± 6 % (top of the TS). There was no significant influence of the exposure time on the EF. Practical feasibility was evaluated by quantifying 1,200 wipe-samples. ***Conclusion:*** All devices examined are suitable for reliably determining 223RaCl2 contamination of 1 Bq due to their DL (3σ). The effectiveness of the WC and the SC were consistently in a comparable range. Due to the relatively large detector-source distance, the CM does not directly measure the α-particles ot the 223Ra but rather the volatile decay product 219Rn. There was a strong dependence on the exposure time of the contamination. When the contamination

is dried, less 219Rn emerges, so the effectiveness of the CM decreases with increasing exposure time.

EP-0908

Occupational radiation dose management in a single cyclotron facility

M. Paphiti;
PHARMAZAC SA, Athens, GREECE.

Aim/Introduction: In the Industrial Zone of Lamia, located in the province of Phthiotis in Central Greece, there is a medical cyclotron that produces 500 GBq of ^{18}F radiopharmaceuticals every day. This radiopharmaceutical is used in the production of various medical products. However, there are high radiation risks during different stages of production due to the cyclotron's 16.5 MeV (PETtrace800, GE) and heavy workload (3-4 times per day). This work describes the precautions and practices implemented to limit radiation exposure to very low levels. ***Materials and Methods:*** To ensure safety and reduce risks associated with radioactive materials, the cyclotron was constructed with a 270 cm thick concrete shield that protects the surrounding area. The hot cells were further shielded with 75 mm of lead, while the hot lab's cabinet was shielded with 50 mm of lead. All vehicles transporting radioactive packages over long distances were equipped with special lead shielding consisting of 3.0 mm behind the driver's seat and another lead shield of 3.0 mm at a distance of 70 cm to reduce radiation exposure to drivers. To ensure the safety of workers, each worker has been categorized based on their respective activities, which include cyclotron operators, chemists, technicians, and radioactivity transport drivers. Electronic pocket dosimeters and Thermoluminescent Dosimeters have been provided to each worker to monitor their daily radiation dose. Moreover, wall detectors for live measurements and contamination monitors have been installed in each lab. The entrance at each separate lab is strictly controlled and permitted only by authorized workers. These measures ensure a safe working environment for all the workers. ***Results:*** The average whole-body dose to cyclotron operators and chemists was less than 0.65 mSv/y, and their finger dose was less than 3.75 mSv/y. The average whole body dose for technicians was 0.1 mSv/y and for drivers 0.0 mSv/y. ***Conclusion:*** To ensure the safety of workers when dealing with radiation, it is essential to implement strict safety protocols, which include using adequate radiation shielding, conducting regular quality assurance of equipment, and managing human resources effectively. These measures are crucial in ensuring that the radiation doses to workers remain below the International Commission on Radiological Protection (ICRP) limit, which is a fundamental goal in all practices involving radiation.

EP-0909

The crucial role of the different ^{18}F tracers biodistributions: the optimization of the radioprotection of caregivers in nuclear medicine (NM)

A. De Maggi[1], F. Bergesio[1], E. Murru[1], L. Coraglia[2], E. Bergalla[2], E. Roberto[1], ***S. Chauvie[1];***
[1]Medical Physics Divisions of Santa Croce e Carle Hospital (Cuneo), Cuneo, ITALY, [2]University of Turin, Cuneo, ITALY.

Aim/Introduction: A correct evaluation of the dose rate of patients injected with different ^{18}F-fluorine radiopharmaceuticals is essential to optimize the radioprotection of caregivers. The aim of this work was to analyze how using measured dose rate of patients not considering the biodistribution to evaluate radiation exposure of caregivers can lead to an underestimated dose to third party. ***Materials and Methods:*** Dose rate of 90 patients injected with FDG,PSMA1007,Choline were measured with an ionization chamber. Dose rates were measured in patients immediately before the acquisition at 30cm and 1m from patient's thorax with the patient upstanding, Average dose rates were reported. All PET images were analyzed and percentage of activity in four macro-areas, head-neck, thorax, abdomen, and pelvis, were evaluated to assess the different bio-distribution. The measurements performed were compared with the calculated values obtained starting from specific gamma considering the retention functions obtained from the IRCP53, considering a self-absorption factor of 0.65 with and without taking into account biodistributions.Then total dose to public after 2 hours from the injection was calculated following Broggio's model using measurements at 30cm and 1 m. ***Results:*** The percentage of counts in the four districts were 29%, 23%, 24%, and 20% for FDG, 10%,22%,55%, and 12%for PSMA and 11%, 22%, 49%, and 16%for choline. A maximum differences of 25% between calculated and measured dose rates were found for PSMA and Choline and at 1m for FDG. In FDG an underestimation of 54% of the dose rate@30cm compared with the calculated one is reduced to 35% taking into account biodistribution. Effective dose to partner, pregnant woman and work colleagues for FDG were 0.34mSv and 0.02mSv and 0.03mSv using 30cm measured dose rate and 0.8mSv, and 0,05 mSv and 0,07 using 1m measured dose rate dose rate respectively. ***Conclusion:*** Biodistribution analysis shows relevant differences between the several ^{18}F tracers.Good agreement between calculated without biodistribution percentage correction and measured dose rates were found for PSMA,Choline and 1m for FDG.The characteristic biodistribution of FDG injected patient means that the dose to third party starting from 30cm measured dose rate of an can lead to underestimate dose up to 55%. ***References:*** Broggio, D., Célier, D., Michel, C., & Isambert, A. (2023). Contact restriction time after common nuclear medicine therapies: spreadsheet implementation based on conservative retention function and individual measurements. EP-0910

Establishing a methodology for evaluation of 68Ga Intakes in a Radiopharmaceutical Production Facility

E. Mora Ramirez[1], *A. Bonilla Araya[1], N. Puerta Yepes[2];*
[1]University of Costa Rica, San Pedro, San Jose, COSTA RICA, [2]RX Asesores, Buenos Aires, ARGENTINA.

Aim/Introduction: Radionuclides intakes are one of the associated risks in their production practice, also handling of radiopharmaceuticals may have a risk. 68Ga it is proposed as an isotope to be used for diagnostic of neuroendocrine and prostate tumors, linked to different radiopharmaceuticals. The aim of this work is to develop a methodology to evaluated intakes when 68Ga is produced when a cyclotron is used. ***Materials and Methods:*** In a previous work a methodology was developed to determine the monitoring type that best describes the needs of the radiopharmaceutical production facility at the University of Costa Rica when ^{18}F is produced. In that work calibration and quality control procedures were created when an uptake probe is used. Due to the knowledge acquired from the facility, equipment and radioactive sources available a methodology is proposed when 68Ga is produced. Also, procedures for estimating the effective dose for the occupational workers exposed are defined considering different international references. ***Results:*** Confirmatory monitoring programme is selected for the synthesis

area, the QC and dispatching areas. Measurement geometries and calibration procedures were created. In addition, the procedure for estimating the committed effective dose was described. ***Conclusion:*** With the methodology established assessment of effective dose for occupational exposed workers can be achieved in accordance with guidelines and recommendations when 68Ga from a cyclotron in a radiopharmaceutical production facility. ***References:*** Bonilla-Araya A.A., Salas-Ramirez M., Astúa-Rodriguez K., Mora-Ramirez E. EP-0911

Occupational exposure in a Nuclear medicine department: six years follow-up and analysis

A. Zagorska, *I. Ilieva-Todorova, S. Stefanov, B. Nikolova, M. Metodieva, A. Kiradjieva, T. Atanasova, K. Ivanova;*
Acibadem City Clinic University Hospital Tokuda, Sofia, BULGARIA.

Aim/Introduction: Nuclear medicine (NM) staff is among the most exposed to ionising radiation. The aim of this study is to provide an overview of the radiation exposure of NM personnel to commonly used tracers, such as technetium-99m, fluorine-18 and iodine-123, 68-gallium and 177Lu, to identify the most exposed staff members and, based on an analysis of specific work habits, to propose improvements in radiation protection practices. ***Materials and Methods:*** Routine occupational monitoring results provided by an accredited dosimetry service with passive thermoluminescent dosimeters were retrospectively collected for six years period and analysed. The whole-body dosimeter is placed at chest level. In addition, radiochemists and nurses were equipped with a ring dosimeters and radiochemists: with eye lens dosemeters. The ring dosimeter is positioned at the base of the index finger with detector facing the palm side of the dominant hand. The occupational doses were normalized to the activities used. Data for the staff working habits and use of protective means were also analyzed. ***Results:*** The average annual occupational exposure in terms of effective dose by type of profession, is: physicians: < 0.1mSv (<0.10-0.30), radiochemists 1.53 mSv (0.43-3.18), medical physicist: 0.15 mSv (<0.10-0.58), nurses: 2.5 mSv (1.09-3.99), NM technicians: 0.31 mSv (<0.1-0.92). The average skin dose, min and max is presented in parenthesis, is: radiochemist 25.0 mSv (9.25-40.93), nurses: 22.30 mSv (2.85-41.88) and the average eye-lens dose (radiochemists) is 0.86 mSv (<0.10-1.3). ***Conclusion:*** The annual occupational exposure dose values are below the annual limits, according to the Bulgarian legislation. The most exposed staff members are the radiochemists, followed by nurses. The reason is in the type of work, involving generator elution, quality control of the labeled radiopharmaceuticals, activity dispensing and injection. When protective aprons are not regularly used, the effective dose is twice higher compared to protected staff in the same position. Although the individual exposure is below the recommended annual dose limits, additional efforts to optimize the practice in the NM department should be focused on discussions to improve the radiation protection practices by periodic radiation protection trainings, following the ALARA principle.

EP-0912

Insights fromn the AMS SPRB Collaboration: Recent Advances in Space Radiobiology

A. Bartoloni[1], *L. Strigari[2];*
[1]Italian Institute of Nuclear Phisycs (INFN), Roma, ITALY, [2]IRCCS AOUBo, Bologna, ITALY.

Aim/Introduction: This presentation introduces the latest discoveries resulting from the collaboration between the Alpha Magnetic Spectrometer Roma Sapienza group and the IRCCS S.Orsola Bologna medical physics division with a primary focus on key aspects of space radiobiology. The collaboration aims to leverage the extensive clinical expertise of the IRCCS S'Orsola and the specialized knowledge of ionizing radiation components expected in space. These investigations hold significant importance in light of the planned resumption of human space exploration by national space agencies in Beyond Low Earth Orbit space areas, such as the Moon and Mars.[2]. ***Materials and Methods:*** It begins by examining advanced dose effects models and assessing the current state of knowledge[3]. This evaluation aims to identify areas requiring further investigation, both to enhance the accuracy of existing models and to pinpoint effects that are most relevant for crew health and mission success. For instance, a dose effects model has been explored to determine tumor prevalence concerning expected exposure to protons in deep space. ***Results:*** The analysis underscores the increasing importance of further investigation, particularly in the realms of cardiovascular disease, the central nervous system, and potentially carcinogenic effects. Furthermore, it demonstrates how models can benefit from the values of space radiation measured by astroparticle experiments like the Alpha Magnetic Spectrometer.[4]. ***Conclusion:*** Through these advancements, the AMS SPRB Collaboration enhances the precision of depth dose estimations by integrating Alpha Magnetic Spectrometer (AMS) data. This refines our understanding of space proton behavior and strengthens the reliability of modeling techniques in radiation dosimetry. Ultimately, these efforts position the collaboration at the forefront of deciphering the radiobiological complexities of space, advancing knowledge to facilitate safer and more informed space exploration. ***References:*** [1] M. Aguilar et al., The Alpha Magnetic Spectrometer (AMS) on the international space station: Part II — Results from the first seven years, Phys.Rept. 894 (2021), 1-116, DOI: 10.1016/j.physrep.2020.09.003[2] A. Bartoloni and, L. Strigari, Can high energy particle detectors be used for improving risk models in space radiobiology? Biodistribution of Actinium-225 (Ac-225) and Bismuth-213 (Bi-213) in the kidney and liver in Ac-225 labeled PSMA and octreotate (DOTA TATE) treatment and the effect of 2,3-Dimercapto-1-propanesulfonic acid (DMPS) on biodistribution.

***E. Karayel*[1]**, *H. Pehlivanoğlu[1], A. Kibar[1], N. Yeyin[1], A. M. Önenerk[1], I. B. Kalaycılar[1], T. Toklu[2], E. M. Ocak[2], E. Demirci[2], N. Alan Selçuk[2], L. Kabasakal[1];*
[1]Istanbul University Cerrahpasa, Istanbul, TÜRKIYE,
[2]Yeditepe University, Istanbul, TÜRKIYE.

Aim/Introduction: Ac-225 undergoes decay, producing three daughter radionuclides (Fr-221, At-217, Bi-213), which are then separated from the radiopharmaceutical. The separated Bi-213 tends to be retained in the kidneys and could potentially elevate renal dosages. This study aims to ascertain whether the daughter radionuclides (Fr-221 and Bi-213) resulting from Ac-225 decay expose the kidneys to additional radiation during Ac-225-PSMA and Ac-225-TATE treatments. It also aims to investigate whether DMPS prevents accumulation in case daughter nuclides build up in the kidneys. ***Materials and Methods:*** Our study consists of 2 steps. In the first step, the biodistribution of Ac-225-PSMA and Ac-225-TATE in the kidney and liver and the presence of free Bi-213 in the kidney were examined. In the second step, if there was free Bi-213 in the kidney it was planned to determine whether DMPS prevents this accumulation. Sixteen female Wistar albino rats were divided into two groups. The animals were euthanized 2 and 4 hours after receiving the radiopharmaceutical injection. Kidney and liver tissues were promptly excised following euthanasia. The tissues underwent immediate analysis and were re-evaluated after 24 hours by being exposed to autoradiography film for 1 hour. As Bi-213 was not detected in the kidneys, step 2 was not executed. ***Results:*** There was no uptake in the livers for all animals. The amount of activity in the cortex and medulla was shown in Table-2 ***Conclusion:*** It was determined that there was no difference in renal uptake of Ac-225 radiopharmaceuticals at the 1st and 24th hours ($p<0.05$). Since the cortex/medulla ratio in the kidneys was very similar in the autoradiography performed at the 1st and 24th hours in the sacrificed animals in both groups, it was concluded that the uptake in the kidneys was entirely caused by Ac-225.This research was supported by Tübitak with number 222S291.

EP-0914

Investigation of the long-term micro-distribution, cellular dosimetry, and radiobiological effect of ^{177}Lu-PSMA in LNCaP cells

***P. Hawarihewa*[1]**, *M. Rumiantcev[1], R. Oos[1], H. Scherthan[2], F. Lindheimer[1], S. Ziegler[1], M. Brendel[1,3,4], A. Delker[1];*
[1]LMU Hospital, Department of Nuclear Medicine, Munich, GERMANY, [2]Bundeswehr Institute of Radiobiology affiliated to the Univ. of Ulm, Munich, GERMANY, [3]German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, GERMANY, [4]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY.

Aim/Introduction: Clinical dosimetry considers the activity uptake at a scale of several millimetres, which is accessible via imaging devices such as SPECT or PET. However, understanding the heterogeneous uptake distribution at the cellular and subcellular level and the associated effect on dosimetry can be an essential tool for understanding response to radionuclide therapy. This study aimed to investigate the prolonged uptake kinetics of 177Lu-PSMA-I&T in LNCaP cells to determine cellular absorbed doses and to correlate them with treatment effects. ***Materials and Methods:*** For the uptake assay, 50,000 LNCaP cells were seeded in 6-well plates and incubated at 37°C / 5% CO2 for 48 h. Cells were treated with 300 kBq/mL of 177Lu-PSMA-I&T solution for 3, 6, 18 and 24 h. The membrane-bound and internalized activities were measured in a calibrated gamma counter. Cell counting was conducted using flow cytometry on untreated PI-stained cells. Time-activity-curves were derived from the prolonged uptake measurement and cellular S values were calculated using MIRDcell using the measured fractions of internalized and membrane-bound activity. For the clonogenic assay 50,000 cells were treated for 3 h and 24 h with varying activity concentrations of 177Lu-PSMA-I&T, ranging from 0 to 1.0 MBq/mL. The cell suspension was diluted, and 1000 cells were seeded into 6-well plates and incubated for 14 days. Imaging was performed after cell staining with crystal violet. Immunofluorescence staining was performed after treatment over 3 h with different activity concentrations to determine the number of DSB foci, marked by colocalization of the two repair 53BP1 and γH2AX. ***Results:*** Changes in cellular uptake were observed over 24 h, with peak internalized uptake at 18 h (3.9±1.6 %AA/100.000 cells) and significant differences between 3 h and 24 h. The absorbed dose in the cell determined to be 10.0 Gy with an added activity of 0.3 MBq, using the average time-integrated-activity for all uptake measurements. The clonogenic assay demonstrated a dose-dependent linear decrease in clonogenic survival, with an α value of 0.3 after 24 h of incubation treatment. DNA damage induction increased linearly with the absorbed dose in the nucleus. ***Conclusion:*** The prolonged uptake measurements indicated different kinetics of the membrane-bound and internalized 177Lu-PSMA-I&T component over 24 h. Clonogenic survival and DNA damage were found to be dose-dependent following treatment with 177Lu-PSMA-I&T in vitro. These findings establish a correlation between therapy response and dosimetry on the cellular level, which may assist in understanding treatment effects in vivo.

Radiation Dosimetry analysis of ^{99m} Tc-Hynic-PSMA-11 in prostate cancer patients for diagnostic scintigraphy

***J. Kumar*[1]**, *V. Shukla[2], M. chauhan[1], M. M V[1], S. Gupta[1];*
[1]Mahamana Pandit Madanmohan Malviya Cancer Centre(A unit of Tata Memorial Centre), Varanasi, INDIA, [2]Homi Bhabha Cancer Hospital & Research Centre (A unit of Tata Memorial Centre), New Chandigarh, INDIA.

Aim/Introduction: The aim of this study was to estimate the dosimetry of organs such as Kidneys, Liver, Spleen, Salivary

gland and Urinary Bladder from diagnostic images of 99mTc-Hynic-PSMA-11 in prostate cancer patients. ***Materials and Methods:*** Dosimetry of 99mTc-Hynic-PSMA-11 was investigated in 5 prostate cancer patients. Whole-body planar imaging with scattered window was acquired in GE Discovery SPECT-CT system at 1, 2, 3, 4 and 6 h after tracer injection. One series of SPECT/CT was also acquired at 3 h after tracer injection. GE dosimetry toolkit was used to process the data and contours of organs were drawn on all acquisitions to determine organ activity at each time point. Residence time was calculated using GE provided Dosimetry Toolkit. Absorbed dose was calculated with the help of OLINDA/EXM software (version 2.0) using the time residence. ***Results:*** The mean injected activity of 99mTc-PSMA-11 was 605 MBq (range 555 MBq-666 MBq). No adverse events related to the injection of 99mTc-Hynic-PSMA-11 were reported. Physiological uptake of 99mTc-Hynic-PSMA-11 was seen in Kidneys, Liver, Spleen, Salivary gland and Urinary Bladder in all patients recruited in this study. Radiation absorbed doses were calculated: 2.12E-02 ± 2.8E-03 mSv/MBq for kidneys, 5.21E-03 ± 3.5E-04 mSv/MBq for liver, 6.34E-03 ± 2.8E-03 mSv/MBq for Spleen,1.32E-02 ± 2.05E-03 mSv/MBq for Salivary Gland and 3.55E-02 ± 5.86 E-03 mSv/MBq for Urinary Bladder. ***Conclusion:*** Radiation doses of 99mTc-Hynic-PSMA-11 were comparable to those known for most of the 99mTc tracers and were lower than for the 68Ga-labeled and 18F-labeled agents. The absorbed doses of 99mTc-Hynic-PSMA-11 in all organs showed that it could be used safely in human body ***References:*** Stabin MG, Sparks RB, Crowe E. Determination of optimal imaging dose of [^{89}Zr]Zr-DFO-Miltuximab and maximum tolerated therapeutic of [^{177}Lu]Lu-DOTA-Miltuximab

***D. Campbell*[1],** *B. J. Walsh[1], Y. Lu[1], D. L. Bailey[2], B. Q. Lee[3], E. Zan[4], A. G. Harris[5], C. R. Hayward[1];*
[1]GlyTherix Ltd, Sydney, AUSTRALIA, [2]University of Sydney, Sydney, AUSTRALIA, [3]Epic Theranostics Ltd, Perth, AUSTRALIA, [4]Weill Cornell, New York, NY, UNITED STATES OF AMERICA, [5]New York University, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: To determine the optimal imaging dose for [89Zr]Zr-DFO-Miltuximab and the predicted maximum tolerated dose for [177Lu]Lu-DOTA-Miltuximab based on biodistribution data from the first in human trial of [67Ga]Ga-DOTA-Miltuximab. ***Materials and Methods:*** Imaging of patients receiving [67Ga]Ga-DOTA-Miltuximab was performed as described previously (1). Organ and whole body absorbed doses were calculated using the OLINDA program. Raw decay corrected data was fitted to mono or bi-exponetial functions to estimate biological half lines. The physical half life of [89Zr]Zr or [177Lu]Lu was incorporated to generate time integrated activity co-efficients (TIACs) for [89Zr]Zr-DFO-Miltuximab and [177Lu]Lu-DOTA-Miltuximab. Absorbed organ and whole body doses were calculated using OLINDA/EXM1.1. ***Results:*** Whole body effective doses were 0.46 mSv/MBq for [89Zr]Zr-DFO-Miltuximab and 0.27 mSv/MBq for [177Lu]Lu-DOTA-Miltuximab. Based on generally accepted normal tissue toxicity for external beam radiation therapy, the dose limiting organ for [177Lu]Lu-DOTA-Miltuximab is bone marrow, with a dose of 6GBq of [177Lu]Lu-DOTA-Miltuximab resulting in 1.9Gy exposure to bone marrow. When used as a theranostic pair, a dose of 50-75MBq for [89Zr]Zr-DFO-Miltuximab and up to 6GBq of [177Lu]Lu-DOTA-Miltuximab is predicted to be within acceptable exposure limits. ***Conclusion:*** Biodistribution data from the first in human trial of [67Ga]Ga-DOTA-Miltuximab was used to determine an optimal imaging dose of 50-75MBq for [89Zr]Zr-DFO-Miltuximab and 6GBq as the predicted maximum tolerated dose of [177Lu]Lu-DOTA-Miltuximab. ***References:*** 1. EP-0917

Semi-automatic segmentation of all lesions on SPECT/CT images for personalized dosimetry of ^{177}Lu-PSMA treatments

***A. Pignard*[1],** *S. Lamart[1], N. Anizan[2], D. Broggio[1], D. Franck[3], S. Leygnac[4], C. Garcia[5];*
[1]French Institute for Radiological Protection and Nuclear Safety (IRSN), PSE-SANTE/SDOS/LEDI, Fontenay-aux-Roses, FRANCE, [2]Institut Bergonié, Service de Physique Médicale, Bordeaux, FRANCE, [3]French Institute for Radiological Protection and Nuclear Safety (IRSN), PSE-SANTE/SDOS, Fontenay-aux-Roses, FRANCE, [4]Gustave Roussy, Service de Physique médicale, Villejuif, FRANCE, [5]Gustave Roussy, Service de Médecine Nucléaire, Villejuif, FRANCE.

Aim/Introduction: Personalized dosimetry for metastatic prostate cancer patients treated with 177Lu-PSMA requires segmentation of lesions, including small volumes. However, this step is time-consuming and is particularly problematic for bone metastases which are often difficult to identify on CT scan. The aim is therefore to semi-automatically segment all lesions on SPECT/CT images for dosimetry purposes, and especially bone lesions. ***Materials and Methods:*** An adaptative threshold algorithm was developed using SPECT/CT images of a NEMA phantom. A calibration Threshold-Volume Curve (TVC) was derived from the unique threshold, based on the local maximum, enabling obtention of the actual volume for every sphere filled with 177Lu. Lesions of 177Lu-PSMA patients were segmented on the post-treatment SPECT images using an initialization volume delimited manually and surrounding roughly each lesion uptake, the calibration curve and the lesion-specific TVC. The resulting segmentations, denoted as global, were then smoothed and upsampled at CT voxel size. Assuming that bone lesions were mainly located inside bones, the volume that intersected with bone contours defined on CT was considered as a refined segmentation. To evaluate this approach, the impact of the choice between global or intersection volumes on dosimetric results was assessed. Moreover, SPECT/CT-based segmentations were compared with those performed on 68Ga-PSMA PET/CT images acquired before and after treatment. Finally, semi-automatic segmentation of non-osseous lesions was validated by comparison to manual segmentation. ***Results:*** Forty-seven bone metastases from two patients were segmented by this adaptative thresholding with intersection volumes ranging from 0.22 to 201 mL (median: 4.75 mL). Although global volumes could be largely (up to 72%) located outside bones, the median of lesion doses for each patient was not significantly affected by constraining lesion volume in bones or not ($p = 0.752$ and $p = 1.000$ respectively). Also, segmentations from diagnostic PET/CT resulted in volumes essentially included within bones and similar to the intersection volumes defined on SPECT/CT. For a third patient with 17 small lesions (< 1 mL) in lungs, comparison between automatic and manual segmentations led to Dice index mostly ranging from 0.9 to 1. ***Conclusion:*** An adaptative threshold algorithm was developed to semi-automatically segment lesions, especially bone lesions, treated by 177Lu-PSMA. It was calibrated for the gamma-camera used to image the patients. It allowed a

consistent segmentation of large and small lesions on SPECT in comparison with a segmentation performed on PET. In addition, it was validated on small non-osseous lesions by comparison to manual segmentation.

EP-0918

Personalized dosimetric workflow for ^{177}Lu-PSMA treatments considering the cross-irradiation from bone metastases to red bone marrow

A. Pignard[1], *S. Lamart[1], C. Garcia[2], D. Broggio[1], D. Franck[3], S. Leygnac[4], N. Anizan[5];*
[1]French Institute for Radiological Protection and Nuclear Safety (IRSN), PSE-SANTE/SDOS/LEDI, Fontenay-aux-Roses, FRANCE, [2]Gustave Roussy, Service de Médecine Nucléaire, Villejuif, FRANCE, [3]French Institute for Radiological Protection and Nuclear Safety (IRSN), PSE-SANTE/SDOS, Fontenay-aux-Roses, FRANCE, [4]Gustave Roussy, Service de Physique médicale, Villejuif, FRANCE, [5]Institut Bergonié, Service de Physique Médicale, Bordeaux, FRANCE.

Aim/Introduction: This work aimed at developing an innovative workflow for 177Lu-PSMA personalized dosimetry to lesions and organs at risk (OAR) simultaneously, considering the cross-irradiation from bone metastases to red bone marrow. ***Materials and Methods:*** Patients were treated for a metastatic castration-resistant prostate cancer with approximately 7.4 GBq of 177Lu-PSMA. Biokinetics in lesions and OAR was assessed using 3 quantitative SPECT/CT images acquired at about 4 h, 24 h and 6 days post-injection. Segmentation of OAR was performed with an open-source code that uses artificial intelligence on CT (TotalSegmentator [1]) and cortical bone was defined using a 1-voxel margin surrounding bones, whereas lesions were delineated using an in-house adaptative threshold algorithm on SPECT/CT images. Then, cumulated activity was computed by fitting a biexponential time-activity curve for lesions and a triexponential curve for OAR [2]. Absorbed dose was estimated by Monte Carlo simulation with Gate 9.0 in a realistic model of the patient based on segmentations previously described. Cross-fire radiation from bone lesions to red bone marrow was evaluated by computing dose with and without cumulated activity in lesions. ***Results:*** First results were obtained for 47 bone lesions after the the first cycle of 177Lu-PSMA of 2 patients, with volumes ranging from 0.2 to 200 mL. Absorbed doses to lesions ranged from 2 Gy to 172 Gy (median: 21 Gy), while dose to kidneys ranged from 5.1 to 6.4 Gy (mean: 5.5 Gy) and from 5.6 to 9.9 Gy (mean: 7.8 Gy) to parotid glands. These results were in accordance with the literature. In addition, absorbed doses to red bone marrow were estimated for the two patients at 1.72 Gy and 1.80 Gy. In particular, bone metastases cross-irradiation contributed respectively to 5.4% and 3.9% of these dose values. ***Conclusion:*** These results indicate the possibility to carry out a comprehensive and personalized computation of absorbed dose to lesions and OAR. Furthermore, this workflow allows consideration of bone lesion contribution to the red bone marrow dose. This contribution might be non-negligible, especially in presence of a high number of lesions located inside bones as often observed for patients who underwent a treatment for a metastatic prostate cancer.

Yttrium-90 post-radiomebolization dosimetry: comparison between SPECT/CT and LAFOV PET/CT

K. Zeimpekis[1], *L. Mercolli[1], H. Sari[2], A. Rominger[1], R. Seifert[1];*
[1]Inselspital, Bern University Hospital, Bern, SWITZERLAND, [2]Siemens Healthcare AG, Lausanne, SWITZERLAND.

Aim/Introduction: To compare the tumor and whole-liver dosimetry post 90Y-radiomebolization between SPECT/CT and a long axial field-of-view (LAFOV) PET/CT. ***Materials and Methods:*** In this retrospective study, 30 patients with either hepatocellular- or cholangio-carcinoma (median age: 71.5 years, 23 males/7 females) treated with 90-yttrium (90Y) microsphere (TheraSphere®: Boston Scientific, Marlborough, MA, USA) radioembolization, received post-treatment a SPECT/CT and a LAFOV PET/CT (each 20 minutes). Pre-treatment dosimetry was based on 99mTc-MAA SPECT/CT. Using Simplicit90Y™ (Mirada Medical Ltd, Oxford, UK), a commercial dosimetry software, the pre- and post-treatment dosimetry plans were defined. The tumor absorbed dose, and the whole-liver normal tissue absorbed dose as well as the lung dose were measured and compared between the post- SPECT and post-PET images. The median injected activity was 2311 MBq (IQR: 1216-3487 MBq) and the median planned tumor absorbed dose was 300 Gy (IQR: 234-350 Gy). Average predicted lung dose was 4.9 ± 7.4 Gy (median: 2.3 Gy, IQR: 0.9-3.7Gy). The lung dose with post-PET was calculated using HERMIA (Hermes Medical, Stockholm). Wilcoxon signed rank test was used to test statistical significance (p-value<0.05). ***Results:*** The median tumor absorbed dose, based on SPECT, over all 30 patients was measured 237.5 Gy (IQR: 181.8-336.2 Gy). The average was 245.5 ± 109 Gy. Similarly for PET, the median and average tumor absorbed dose was: 267 Gy (IQR: 186.3-367.1 Gy), and 276 ± 120 Gy. For the whole-liver normal tissue, there is a dose limit up to 70 Gy, and the measured average absorbed dose for SPECT / PET was 38.1 ± 20 Gy and 36.7 ± 26.3 Gy, whereas the median was 39 Gy (IQR: 22-51) / 35.4 Gy (IQR: 17-48). In addition, the median lung dose for PET was 1.2 Gy (IQR: 0.9-2.6), while the mean was 2.3 ± 2.9, respectively. There was a difference of statistical significance between the post-SPECT and PET tumor and whole-liver absorbed dose. The PET dosimetry was found closer to the planned dose, and higher than the post-SPECT values for the absorbed tumor dose while the dosimetry for the whole liver did not show any difference. ***Conclusion:*** The study investigated 90Y post-radioembolization dosimetry verification based on SPECT/CT and a LAFOV PET/CT. The PET/CT-based dosimetry showed values closer to the planned dose compared to the SPECT, justifying its use over SPECT for reliable 90Y dosimetry validation. LAFOV PET enabled the quantification of the post-therapy lung dose, which might facilitate therapy monitoring.

Patient-specific compartmental models for [^{177}Lu]Lu-PSMA-617 therapy

W. Li[1], *D. Kupitz[2], V. Spielmann[1], A. Kamp[1], L. Katzdobler[1], A. Giussani[1], M. Kreißl[2,3], O. Großer[2,3];*
[1]Bundesamt für Strahlenschutz, Oberschleißheim, GERMANY, [2]Department of Radiology and Nuclear Medicine, University Hospital Magdeburg and Medical Faculty of Otto-von-Guericke University, Magdeburg, GERMANY, [3]Research Campus STIMULATE, Otto-von-Guericke University, Magdeburg, GERMANY.

Aim/Introduction: In radiopharmaceutical therapy, individualized pharmacokinetics in tumours and in organ-at-risk are needed to assess patient-specific dosimetry and the therapeutic index. In this study, a comprehensive data set consisting of planar images

at multiple time points and one-time point SPECT image were acquired according to an established protocol in 27 patients during the first cycle of a treatment with [177Lu]Lu-PSMA-617. From these data time-activity curves (TACs) were derived in tumours and different organs, such as liver, kidneys, spleen, lungs, salivary glands, bone. In addition, blood samples were collected at multiple time points and generally one urine sample. Patient-specific compartmental models were built up using these retrospective clinical data, and the time-integrated activity curves (TIACs) among the individual patient were calculated. Furthermore, a population model will be setup based on these established patient-specific compartmental models for estimation of patient dosimetry by adopting the specific pharmacokinetics. ***Materials and Methods:*** Based on the activity data derived for each patient from the acquired images in organs and tumours, blood samples at various time points and the urine excretion sample, five individual compartmental model structures were built up for each group of patients who share the same sets of imaged organs and tumours. Urine was assumed to be excreted through kidneys and the urinary path. Identifiability of each compartmental model structure was tested against the available data. For comparison and quality assurance purpose, the TACs in organs, tumours and in blood were obtained by fitting the activities at multiple time points using exponential functions. The resulting TIACs were compared to those obtained using compartmental modelling. ***Results:*** The calculated TACs and TIACs using the established patient-specific compartmental models demonstrated a great variability among the patients. Preliminary results show large individual variations for the calculated TIACs not only in the tumours but also in total bone and rest of the body, ranging from a 3- up to 14-fold difference. In contrast, smaller variations, around 30% or less, were observed for TIACs in blood and in kidneys. Setting up a population compartmental model using these patient data is planned. ***Conclusion:*** A comprehensive set of pharmacokinetic data from patients treated with [177Lu]Lu-PSMA-617 was retrospectively analysed in this study. The TIACs of some organs showed a large variability. A population analysis approach will be applied to derive a population compartmental model for [177Lu]Lu-PSMA-617 therapy which can identify population-specific and individual specific features.

Variability of Quantitative Values by Organ/Lesion Location in Quantitative ^{177}Lu Imaging

M. Shiga[1], *H. Daisaki[1], M. Ogawa[2], S. Isogai[1], M. Sato[1], C. Kubota[3], T. Sakashita[4];*
[1]Gunma Prefectural College of Health Sciences, Maebashi, JAPAN, [2]Yokohama City University Hospital, Yokohama, JAPAN, [3]Fukaya Red Cross Hospital, Saitama, JAPAN, [4]National Institutes for Quantum Science and Technology, Gunma, JAPAN.

Aim/Introduction: Dosimetry using high-precision quantitative 177Lu imaging is important for achieving excellent outcomes with radionuclide therapy. The standard imaging methods required for quantitative 177Lu imaging are described in MIRD pamphlet No. 23 [1] and No. 26 [2]. Dickson et al. suggest that the recovery coefficient of the quantitative value depends on the configuration of hot spheres [3]. The purpose of our study is to quantitatively evaluate the variability of quantitative values in 177Lu imaging due to different sphere configurations. ***Materials and Methods:*** The background (BG) region of the NEMA body phantom was filled with 57.9 kBq/mL and the hot spheres (13, 17, 22, 28, 37, 60 mm) with 588.8 kBq/mL of 177Lu solution. Acquisitions of 4 rotations of 360 degrees, 90 views, and 420 s/ 90 views was performed in dynamic SPECT scan mode with detector auto-contouring using a Symbia T16 (Siemens). The main energy window was set at 208 keV ±10%, with a 20% scattering energy window at the bottom. SPECT scan was followed by CT scan (130 kV, 100 mA, 0.5 s/rot). The upper lid was rotated to change the configuration of the hot sphere in six different patterns, and the previously described dynamic SPECT and CT scans were repeated in each configuration. Image reconstruction (Iteration 7, subset 10, Gaussian filter 4.8 mm) was performed using the OSEM method with CTAC, scatter correction, and resolution correction. SPECT images were converted to Bq/mL scale by Bq Calibration Factor using RAVAT (Nihon Medi-Physics Co.,Ltd.). VOIs were set for each hot sphere and BG region (n=12) on the SPECT images, and the variability of the quantitative values due to hot sphere configuration was evaluated by the coefficient of variation (CV). ***Results:*** In SPECT images with a 28-min scan duration, the CVs of the quantitative value of hot spheres were, 9.7%, 19.5%, 7.3%, 6.8%, 4.2% and 1.1% for 13, 17, 22, 28, 37, and 60 mm, respectively. Quantitative values of BG region did not differ significantly by hot sphere configuration. ***Conclusion:*** Quantitative values varied with the configuration of the hot spheres, with smaller hot spheres showing greater variation. For organs/lesions larger than 37 mm, the variation in quantitative values by location would be approximately less than 5%. ***References:*** [1] Dewaraja YK, et al. J Nucl Med. 2012 Aug;53(8):1310-25. [2] Ljungberg M, et al. J Nucl Med. 2016 Jan;57(1):151-62. [3] Dickson JC, et al. Eur J Nucl Med Mol Imaging. 2023 Mar;50(4):980-995.

EP-0922

Investigating Lucy-Richardson deconvolution for partial volume correction for image-based dosimetry after ^{177}Lu radionuclide therapy

Z. Ells[1,2], *G. Liubchenko[2], M. Rumiantcev[2], D. Sennung[1], J. Czernin[1], J. Calais[1], M. Dahlbom[1], S. Resch[2], S. Ziegler[2], M. Brendel[2,3,4], L. Unterrainer[1,2,5], G. Boening[2], A. Delker[2];*
[1]Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, University of California Los Angeles UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [2]Department of Nuclear Medicine, LMU University Hospital, Munich, GERMANY, [3]German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, GERMANY, [4]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY, [5]BZKF, Munich, GERMANY.

Aim/Introduction: While quantitative SPECT/CT allows for patient specific dosimetry of 177Lu, its limited spatial resolution can underestimate the absorbed dose. Lucy-Richardson deconvolution (LRD) has already been applied for partial volume correction in PET. The aim of this study was to investigate the potential of LRD as a means of a partial volume correction in 177Lu SPECT imaging and dosimetry. ***Materials and Methods:*** The NEMA IEC Body Phantom (foreground-to-background ratio 8:1, 237:30kBq/mL) was measured according to the local imaging and reconstruction protocol. Sigma for LRD was determined by fitting the guassian filtered density map to the original image (OI). Phantom recoveries in the spheres were compared between the OI, and OI with applied LRD as a postprocessing to determine the optimal number of iterations. Furthermore, LRD was applied to the reconstructed SPECT series (24, 48, 72 h p.i.) of five patients receiving 177Lu-DOTATATE treatment to compare its effect on the dose estimates. Absorbed dose to the lesions in the OI and LRD was estimated using MIM software. Lesion segmentation (PETedge+ tool on the OI) and curve fitting was identical in the

absorbed dose calculation in both OI and LRD. The absorbed doses from the two methods were then compared. ***Results:*** Based on the phantom measurement, using the optimal number of iterations (4) and a sigma of 1.25mm, there was on average 16% (3-26%) improvement in the recovery coefficients between the OI and LRD. For patients, as expected the total body absorbed dose was within 1% when the OI was used in comparison to the addition of LRD. The liver lesion (N=22) volume was on average 4.4 mL (1.5 - 17.7 mL). Average dose was 5.29±3.00Gy (OI) vs. 6.98±4.44Gy (LRD). When comparing the OI to LRD there was an average increase in absorbed doses of 25±8% (12 - 43%). Mean improvement per patient was 27±6%(N=5), 22±6%(N=3), 14±4%(N=2), 25±10%(N=5), and 28±9%(N=7) respectively. ***Conclusion:*** LDR consistently led to increasing absorbed doses in all lesions for 177Lu-DOTATATE treatment while maintaining the same total body dose. Future work includes adding more patients having received 177Lu-DOTATATE but also patients suffering from prostate cancer who have received 177Lu-PSMA, in which the tumor to background ratio is different. Additionally, the variation of acquisition and reconstruction parameters is advisable for testing the robustness of the LRD approach. This preliminary study suggests that LRD may be a promising option for partial volume correction in 177Lu-SPECT imaging and dosimetry.

EP-0923

An Analytical Uncertainty Estimator for Monoexponential TAC Tail Fits

D. Balfour, *J. M. Y. Willaime, D. Boukerroui;*
Mirada Medical Ltd., Oxford, UNITED KINGDOM.

Aim/Introduction: Uncertainty in absorbed dose estimates in molecular radiotherapy depends directly upon time-integrated activity (TIA) uncertainty. This is sensitive to the modelling of the time-activity curve (TAC) tail [1]. Therefore, good choice of tail extrapolator is critical when using non-parametric TAC integration methods. This work aimed to design an estimator of the TIA uncertainty due to random noise in activity measurements in monoexponential tail modelling. ***Materials and Methods:*** Variance estimators for the tail TIA were derived using Taylor series expansions (TSEs) based on monoexponential fitting of the tail and assuming normally-distributed measurement noise. The estimators were empirically validated up to third order using Monte Carlo sampling. We used a previously published TAC model derived from population measurements of kidneys during [Lu-177]-PSMA-617 treatment [2]. The second-to-last timepoint was fixed at 48h, while the last timepoint varied between 60h and 192h. Empirical estimates were calculated with 10,000 samples, with 5 noise levels (NLs) at 0.1%, 1%, 10%, 20% and 40% of the ground truth TAC value at each timepoint.The method was also applied to a clinical example from the SNMMI 2021 dosimetry challenge [Lu-177]-DOTATATE dataset. Activities were measured using a 1 cm^3 spherical ROI in the left kidney at the 100h and 200h timepoints. Empirical uncertainty estimates were obtained using 5 different ROIs. ***Results:*** Theoretical estimates were in good agreement with empirical values within approximately 2% error. For example, at 10% NL the 2nd order estimate at 140h was 1.63 %iA*h, compared to the empirical value 1.66 %iA*h. Results showed higher order estimators were more accurate. Decrease in estimator accuracy was observed in scenarios when simulated measurements were not decreasing with time; this was more likely the case at higher NLs and at shorter time intervals (i.e., between the consecutive measurements). Empirical uncertainty for the 5 ROIs in the SNMMI case (NLs 4.4-10.3%) was 1.20 MBq*h (12.8% of the mean) whereas predicted uncertainty values using TSEs were between [0.94, 1.38] MBq*h. ***Conclusion:*** Analytical tail TIA uncertainty estimators were derived. Monte Carlo empirical validation indicated relative error below 2% at clinically relevant noise levels, particularly for late final timepoints. The underlying modelling assumptions (noise normality and activity measurements decreasing with time) for the analytical derivation may limit its applicability and are open to further investigation. In particular, the derived estimators are not valid when activity measurements used for the tail modelling are less likely to be decreasing. ***References:*** [1] https://doi.org/10.1007/s00259-022-05727-7 [2] https://doi.org/10.2967/jnumed.123.266268.

EP-0924

Qualitative and quantitative SPECT/CT imaging of actinium-225 for targeted therapy of gliomas - phantom studies.

M. Tulik[1], *R. Kuliński[1], Z. Tabor[2], B. Brzozowska[3], P. Łaba[3], F. Bruchertseifer[4], A. Morgenstern[4], L. Królicki[1], J. Kunikowska[1];*
[1]Department of Nuclear Medicine, Medical University of Warsaw, Warsaw, POLAND, [2]Faculty of Electrical Engineering, Automatics, Computer Science, and Biomedical Engineering, AGH University of Science and Technology, Krakow, POLAND, [3]Biomedical Physics Division, Faculty of Physics, University of Warsaw, Warsaw, POLAND, [4]European Commission, Joint Research Centre, Karlsruhe, GERMANY.

Aim/Introduction: The use of the Ac-225 in radionuclide therapy has recently become popular. Therapeutic use should involve an attempt to estimate the absorbed dose, which in the case of Ac-225 is not an obvious task. It is related to the decay chain involving many isotopes with different physicochemical properties. However, the first step to calculate the absorbed dose is proper quantitative imaging. The study aimed to confirm the feasibility of SPECT/CT imaging of Ac-225. In particular, to present qualitative and qualitative assessment of the received images. Additionally, to present the SPECT image quantitative calibration method, as well as validation measurements and their accuracy. ***Materials and Methods:*** A collarless Jaszczak phantom with cylindrical sources of various sizes was filled with Ac-225 solution. The initial activity concentration was 235 kBq/ml. SPECT/CT imaging was performed after filling the phantom, using a Siemens Symbia T6 with HE collimators. Three energy windows were considered: I. 440 keV (width 10%, Bi-211), II. 218 keV (width 10%, Fr-221), III. 78 keV (width 20%, Ac-225 with bremsstrahlung X-rays).Five combinations were used: only I, only II, only III, sum I+II, sum I+II+III. DEW or TEW method was used for SC. AC based on CT images was performed. Other imaging parameters were as follows: 64 images per detector, time per image of 30 s, OSEM Flash 3D using 8 subsets, 10 iterations, Gaussian filter (FWHM 4 mm). Additionally, the 3D printed model of the glioblastoma tumour was developed and imaged to evaluate the accuracy of the chosen protocol. ***Results:*** The contrast, signal-to-noise ratio and coefficient of variance in the images will be presented, as well as for quantification - calibration factor CF and recovery coefficients RC. The maximum value of CF was calculated for setting I+II+III (21 cps/MBq). Using the calibration factor and recovery coefficients obtained, the activity in a 3D-printed model of a glioblastoma tumour with uncertainty of no more than 10% and satisfying accuracy for (I+II+III) energy window setting was quantified. ***Conclusion:*** Our results showed the possibility of Ac-225 SPECT/CT imaging with good quality in all combinations of energy windows. Moreover, quantification of Ac-225 SPECT/CT image could be performed with satisfactory accuracy and uncertainty for

multiple energy window settings. There are still many challenges that need to be considered in further research on alpha emitter imaging (including high noise in the image, and other than standard SC scattering correction methods).

EP-0925

A retrospective study investigating dose-response in ^{90}Y SIRT, using PET/CT voxel dosimetry and RECIST 1.1 response criteria to identify overall tumor dose-response, and variations due to patient gender and tumor characteristics such as KRAS mutation status, primary tumor location and tumour size.

D. Morgan[1], *D. R. McGowan[1], A. Hallam[1], J. Tipping[2]; [1]Oxford University Hospitals NHS Trust, Oxford, UNITED KINGDOM, [2]The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM.*

Aim/Introduction: This study was a retrospective analysis of tumour dose delivered from selective internal radiation therapy (SIRT), with the aim to identify a dose-response relationship and factors that affect this, including KRAS mutation, patient sex, tumour size and primary location. ***Materials and Methods:*** This study included 38 patients with a total of 86 well-defined tumours. Administered activity was based on a modified body surface area (mBSA) model, with the dose calculated from post-therapy PET/CT scans taken ~18 hours after administration. The voxel dose-map allowed the mean tumour dose and dose to 70% (D70) to be calculated. The response was determined from CT images using RECIST 1.1 (Eisenhauer et al., 2009). ***Results:*** The results showed the median average tumour dose was 81Gy (Range: 21Gy to 245Gy), with a D70 median dose of 57Gy (range 7.4 Gy to 209 Gy). Overall and KRAS status dose-response differences were not statistically significant. A statistically significant difference was observed between male and female patients. Patients with stable disease or partial response were mostly male (74%), with females much less likely to be in these groups (46%). A Chi squared independence test confirmed this ($X2= 7.449$, $df = 2$, $p = 0.024$). Potential causes of these difference were investigated and tumor volume, tumor burden, age, or presence of lung metastasis were not found to have any difference between the sexes. A difference in the location of the primary CRC tumour was observed, but no difference in dose-response between these tumor locations was seen. The characteristics discussed above were also tested independently with no statistically significant differences in dose-response identified. ***Conclusion:*** The mBSA model was not capable of delivering sufficient tumor dose to match recommendations from EANM guidelines (Weber et al. 2022). The switch to using the partition model of dosimetry is therefore required to deliver higher doses.The statically significant differences in dose-response between male and female patients deserves additional study as it was not explained by differences in other characteristics in this work. ***References:*** Eisenhauer, E. A., et al. (2009). 'New response evaluation criteria in solid tumours: Revised recist guideline (version 1.1)' Eur J Cancer, 45 (2), pp. 228-47. DOI: 10.1016/j.ejca.2008.10.026Weber, M., et al. (2022). 'Eanm procedure guideline for the treatment of liver cancer and liver metastases with intra-arterial radioactive compounds' Eur J Nucl Med Mol Imaging, 49 (5), pp. 1682-1699. EP-0926

The effect of thionamides on radioiodine-131 bio-kinetics in patients suffering from Graves' disease.

C. Happel, *B. Leonhäuser, B. Bockisch, R. A. Werner, D. Groener; Goethe University Frankfurt; University Hospital; Department of Nuclear Medicine; Clinic for Radiology and Nuclear Medicine, Frankfurt, GERMANY.*

Aim/Introduction: Thionamides are required in patients suffering from Graves' disease but should be discontinued at least 3 days prior to radioiodine-131 therapy (RIT) to avoid an influence on intra-thyroidal bio-kinetics of iodine. However, the required therapeutic radioiodine-131 activity has to be calculated individually in a radioiodine-131 uptake test (RIUT) one week prior to RIT and may therefore still be performed under thionamides. Therefore, the aim of this retrospective analysis was to evaluate the influence of thionamides on intra-therapeutic uptake. ***Materials and Methods:*** In a retrospective monocentric study, 829 patients suffering from Graves' disease undergoing RIUT and RIT were evaluated. Patients were subdivided into three groups depending on their intake of thionamides (Group A: patients with carbimazole medication (n=312), group B: patients with methimazole medication (n=252) and group C: patients without thionamides (n=265)). The groups A and B were further subdivided depending on the dosage reduction of thionamides. The influence of thionamides was statistically evaluated by calculating the variance of the determined individual intra-thyroidal uptake (EMU) between RIUT and RIT within the single groups and within the subgroups. ***Results:*** No significant differences could be detected when comparing EMU in RIT to EMU in RIUT ($p>0.05$) when administering an equal dose of thionamides or no thionamides in RIUT and RIT. In the subgroups with reduced dosage of thionamides prior to RIT EMU was significantly increased in RIT compared to RIUT (21 % - 80 %) ($p<0.05$) depending on the administered dosage. ***Conclusion:*** Due to the significant dose-dependent increase of EMU in RIT compared to EMU in RIUT, thionamides should be discontinued for at least two days prior to RIUT to achieve the designated target dose more precisely and to minimize radiation exposure of organs at risk.

EP-0927

Correlation Between Longitudinal Dosimetry and PET Follow-Up as Indicator for Salivary Gland Toxicity After Lu-177-PSMA Therapy

A. Noto[1], *X. Shen[1], A. Harbach[1], M. Zacherl[1], S. Resch[1], M. Rumiantcev[1], G. Liubchenko[1], M. Brendel[1,2,3], G. Böning[1], L. Unterrainer[1,4], A. Delker[1], G. Sheikh[1]; [1]Department of Nuclear Medicine, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [2]German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, GERMANY, [3]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY, [4]Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, University of California Los Angeles UCLA, Los Angeles, CA, UNITED STATES OF AMERICA.*

Aim/Introduction: Lu-177 PSMA therapy has been shown to prolong survival in patients with metastatic prostate cancer. However, salivary gland uptake can lead to xerostomia, severly limiting patients' quality of life. Xerostomia is also more likely to develop in consecutive treatment cycles due to the cumulation of absorbed dose. PSMA PET follow-up may be a useful indicator of salivary gland absorbed dose in consecutive treatment cycles, enabling protective means to be taken. Knowing whether major changes in salivary gland absorbed dose are to be expected can also be used to schedule patients for more extensive imaging and dosimetry protocols. The aim of this study is to evaluate the longitudinal salivary gland absorbed dose compared to salivary gland uptake in the initial and follow-up PET exams. ***Materials***

and Methods: Our study included eight patients diagnosed with metastasized castration-resistant prostate cancer, who underwent six cycles of Lu-177-PSMA-I&T therapy (mean injected activity: 7.46 GBq per cycle). After each cycle whole-body SPECT/CT imaging was performed at 24, 48, and 72 hours post administration. F^{18}-PSMA-1007 PET/CT images (mean injected activity: 0.23 GBq) were acquired prior to the first cycle and preceding the third and fifth cycle. Parotid and submandibular glands were segmented in PET and SPECT (24 h) data using PETedge+ in MIM. Dosimetry was performed using MIM SurePlan MRT and a mono-exponential fit model. ***Results:*** The average absorbed doses from cycle one to six were as follows: submandibular glands: 0.29±0.13 Gy/GBq, 0.29±0.18 Gy/GBq, 0.31±0.10 Gy/GBq, 0.28±0.12 Gy/GBq, 0.28±0.09 Gy/GBq, and 0.21±0.09 Gy/GBq; parotid glands: 0.45±0.14 Gy/GBq, 0.46±0.20 Gy/GBq, 0.40±0.17 Gy/GBq, 0.34±0.14 Gy/GBq, 0.33±0.14 Gy/GBq, 0.25±0.15 Gy/GBq. No recovery correction was applied to the data. A strong correlation was observed between the activity uptake of the salivary glands in the first PET and the salivary gland absorbed dose of the first cycle (submandibular glands: r=0.73, p-value=0.003; parotid glands: r=0.71, p-value=0.005). 6/8 patients showed a consistent trend for the uptake in the PET follow-up and the longitudinal dosimetry for the submandibular and the parotid glands (5/6 patients showed constant PET uptake and absorbed dose). ***Conclusion:*** This preliminary analysis suggests that PET may serve as an indicator for the absorbed dose in the salivary glands. This information may also be useful to schedule patients for either single- or multi-time-point imaging. Further evaluation with a larger patient cohort is planned to validate these observations.

EP-0928

Dosimetry from the first-in-human study on [^{68}Ga]Ga-NOTA-PEG$_2$-RM26 - A GRPR antagonist

A. Bjäreback[1], *A. Tzortzakakis[2], U. Estenberg[3], R. Axelsson[1], O. Jonmarker[2], R. Altena[4], C. Li[5], M. Moein[6], A. Orlova[7], T. A. Tran[4], C. Hindorf[1];*
[1]Department of molecular medicine and surgery, Karolinska Institutet, Stockholm, SWEDEN, [2]Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, SWEDEN, [3]Department of nuclear medicine. Karolinska university hospital, Stockholm, SWEDEN, [4]Department of Oncology-Pathology, Karolinska Institutet, Stockholm, SWEDEN, [5]Department of Oncology, Södersjukhuset, Stockholm, SWEDEN, [6]Department of Radiopharmacy, Karolinska University Hospital, Stockholm, SWEDEN, [7]Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Gastrin releasing peptide receptor (GRPR) is overexpressed in several types of malignant tumors making it an attractive target for nuclear medicine diagnostics and therapy. In our study, a new GRPR seeking radiopharmaceutical, [68Ga]Ga-NOTA-PEG2-RM26 has been injected for the first time in humans. The aim of this study is to perform dosimetry of this new radiopharmaceutical. ***Materials and Methods:*** A total of 6 prostate cancer patients and 6 breast cancer patients were injected intravenously with 2 MBq/kg of [68Ga]Ga-NOTA-PEG2-RM26. PET-CT scanning was performed at 5 min, 20 min, 40 min, 1h, 2h and 3h post injection. The voided urine was collected, weighed, and measured in a gamma counter. Organs with significant radiopharmaceutical accumulation were considered source organs (pancreas, spleen, liver, renal cortex, and urinary bladder contents). Segmentation of the PET image determined the total activity of the source organ at each time point. Different segmentation methods were used depending on the characteristics of the uptake. The dosimetry calculation was performed using standardized dosimetry software according to MIRD formalism. A dynamic bladder model was used to determine the time-integrated activity for the bladder content using 1h voiding interval. ***Results:*** An injection of [68Ga]Ga-NOTA-PEG2-RM26 resulted in a sex-averaged effective dose of 14 µSv/MBq (preliminary data on 6 of 12 patients). The uptake of the radiopharmaceutical in pancreas reached a maximum value of 5.0% of injected activity (median, range 2.6-7.3%) at 5 min post injection followed by a fast clearance. The corresponding values for the liver and the kidney cortex were 6.5% (median, range 4.3-12.2%) and 2.9% (median, range 1.6-4.2%) respectively. The pancreas received the highest equivalent dose in both groups, 155 µSv/MBq (range 132-177 µSv/MBq) in the breast cancer group and 128 µSv/MBq (range 87-178 µSv/MBq)) in the prostate cancer group, followed by the urinary bladder wall and the kidneys. ***Conclusion:*** A PET examination of a normal-weighted person with [68Ga]Ga-NOTA-PEG2-RM26, a gastrin releasing peptide antagonist, gives an effective dose of 2 mSv (140 MBq, 2 MBq/kg for a 70 kg patient) and is in the same range as other 68Ga-labelled GRPR targeting radiopharmaceuticals.

EP-0929

Image guided evaluation of ^{212}Pb-VMT-α-NET in metastatic Neuroendocrine tumors: Bio distribution and Dosimetry

D. Malik[1], *P. Thakral[1], N. Rana[1], N. Singh[1], M. Koley[1], J. Gupta[1], D. Thakrani[1], S. Kapoor[2], S. S. Das[1], M. Schultz[2], I. Sen[1];*
[1]Fortis Memorial Research Institute (FMRI), Gurugram, INDIA, [2]Perspective Therapeutics, Iowa, IA, UNITED STATES OF AMERICA.

Aim/Introduction: 212Pb-VMT-α-NET peptide is a somatostatin receptor targeted ligand for targeted alpha therapy in patients with Neuroendocrine tumors (NETs). The aim of this study was to assess the biodistribution and image-guided dosimetric estimates of 212Pb-VMT-α-NET peptide used for targeted alpha therapy. ***Materials and Methods:*** Five patients with confirmed somatostatin-expressing neuroendocrine tumors on 203Pb-VMT-α-NET peptide / 68Ga-DOTANOC imaging were administered with 212Pb-VMT-α-NET peptide (130-135MBq). For dosimetric analyses, SPECT/CT images were acquired for the patients on Siemens Intevo 6 with high-energy collimators using dual windows (40% at 79 keV and 20% at 239 keV) and dual scatter windows of 20% for the 79 keV peak centred on 55 keV and 103 keV and 5% for the 239 keV peak centred on 209 keV and 268 keV at 2,10 and 20hrs post administration. A camera-specific calibration factor derived from phantom measurements was used for quantification. Reconstructed images were generated and uploaded into Hybrid Dosimetry Module™. A dosimetric analysis was done for kidneys, spleen, liver, bone marrow and tumor lesions for the single cycle. Since, therapeutic nuclide 212Pb decays further to 212Bi, 212Po and 208Tl, all time activity curves derived from the 212Pb data were recalculated using the replacement nuclide function for Bi-212 and Tl-208, however, Po-212 was disregarded due to its ultra-short half-life (3µs). ***Results:*** Maximum physiological radiotracer uptake was observed in the kidneys as the radiotracer was observed to be predominantly excreted through the renal route in all patients. Liver, spleen, bone marrow were the other organs showing diffuse physiological uptake of the radiopeptide along with the pathological uptake in tumor lesions. The average equivalent doses from a therapeutic activity of 130-135MBq of 212Pb-VMT-α-peptide, when summed for all the daughter radionuclides were 1.5 Sv to the kidneys, 1.0 Sv to the spleen, 1.7 Sv to the liver, 0.38 Sv to the red marrow, and the tumor doses were in the range of 3-8Sv. ***Conclusion:*** The SPECT/CT imaging

with 212Pb-VMT-α-NET showed prompt tumor accumulation, high tumor retention, and rapid renal excretion. Image guided dosimetry of 212Pb-peptide for targeted alpha therapy seems to be an accurate and a straight forward option for dose calculation, however, the dosimetry estimate for clinical translation requires a larger study.

EP-0930

Impact of cross-irradiation on single time-point dosimetry in ^{177}Lu-PSMA therapy

***L. Vergnaud*[1],** *J. Badel*[2], *A. Giraudet*[2], *D. Sarrut*[1];
[1]*CREATIS laboratory, Villeurbanne, FRANCE,*
[2]*Centre Léon Bérard, Lyon, FRANCE.*

Aim/Introduction: The Single Time-Point (STP) methods enable dosimetry in 177Lu therapy without requiring extensive image acquisition time. They assume that the total absorbed dose by the volume comes solely from self-irradiation. However, some organs may be affected by cross-irradiation, due to their proximity to high uptake tissues. In this study, we adapted three STP methods to include cross-dose and assess its impact on the total absorbed dose. ***Materials and Methods:*** Twenty-one patients with metastatic castration-resistant prostate cancer received treatment with 177Lu-PSMA. A total of 52 cycles were completed, each involving a single whole-body SPECT/CT acquisition at 24 hours post-injection. For each cycle, absorbed doses to the left (LK) and right (RK) kidneys, liver (L), and spleen (S) were estimated using three different single time-point (STP) dosimetry methods named STP1, STP2 and STP3 [1-3], respectively. For sixteen patients, three SPECT acquisitions are available after the first cycle, providing reference doses (MTP) [4]. These simplified methods were further modified to account for cross-dose by computing dose rate maps with low-statistics Monte Carlo simulations. The obtained absorbed doses were then compared to those estimated using the original methods and those using the reference MTP method. ***Results:*** The means and standard deviations of the percentage dose differences for LK, RK, L, and S between the original (reference) and adapted STP1 and STP3 methods are: -31.7±1.0, -31.6±1.0, -27.1±2.4, -26.7±3.6 and 1.6±1.4, 1.8±1.4, 12.2±3.9, 11.3±5.6. For the sixteen cycles for which reference doses are available,the percentage dose differences between the original STP1, and STP3 methods and the MTP method are: 48.4±23.9, 47.4±27.0, 44.8±39.5, and 30.0±41.6, and 4.8±16.9, 2.1±17.8, -5.9±27.2, and -14.7±28.4 while they are 1.5±15.8, 0.8±17.9, 5.4±27.2, and -4.2±28.4 for adapted STP1 and 6.5±16.4, 3.8±17.5, 4.8±27.7, and -4.8±29.4 for adapted STP3. ***Conclusion:*** Cross-irradiation has minimal impact on the STP3 method, whereas for the STP1 method, the MC based methods yields values much closer to those of the MTP method than the original STP1 method. ***References:*** [1] Hänscheid et al., NuklearMedizin, 2017 [2] Hänscheid et al., JNM, 2018 [3] Madsen et al., Medical Physics, 2018 [4] Vergnaud et al., EJNMMI Physics, 2022.

EP-0931

Is pre-therapeutic dosimetry on dynamic ^{68}Ga-PSMA-11 PET/CT imaging a good estimate of post-^{177}Lu-PSMA-617 therapy absorbed dose in metastatic, castration-resistant prostate cancer?

***N. Payan*[1],** *C. Drouet*[1], *A. Jougla*[1], *A. Cochet*[1,2], *J. M. Vrigneaud*[1,2];
[1]*Centre George François Leclerc, Dijon,*
FRANCE, [2]*ICMUB laboratory, UMR CNRS 6302,*
University of Burgundy, Dijon, FRANCE.

Aim/Introduction: In 177Lu-PSMA-617 targeted radionuclide therapy, predicting the absorbed dose based on pre-treatment scans could be a step forward in personalised medicine, by improving patient selection and adjusting the therapeutic dose. The aim of this study was to assess the agreement between mean absorbed dose coefficients extracted from diagnostic dynamic 68Ga-PSMA-11 PET/CT and after the first cycle of 177Lu-PSMA-617 therapy in healthy organs in patients with metastatic, castration-resistant prostate cancer (mCRPC). ***Materials and Methods:*** Seven patients (mean age of 72y) with mCRPC who underwent diagnostic 68Ga-PSMA-11 PET/CT scans followed by a 7.4 (±10%) GBq 177Lu-PSMA-617 therapy were included. Pre-therapeutic mean absorbed dose coefficients in healthy organs (kidneys, liver, spleen, salivary glands and red bone marrow extracted from L2 to L4) were obtained from six passes of 68Ga-PSMA-11 whole-body PET/CT scans performed in continuous bed motion, for approximately one hour. Post-therapeutic mean absorbed dose coefficients of the same organs were extracted from SPECT/CT scans acquired 5h, 24h, 4 days and 8 days after the first injection of 177Lu-PSMA-617 therapy. Healthy organs were manually delineated on the CT images using MIM® software (v.7.3 MIM Inc., Cleveland, OH, USA) and the corresponding organ-specific time-activity curves were generated. Cumulated activities were fitted using a trapezoidal method and considering only physical decay after the last imaging time point. S-value based dosimetry was performed in IDAC-Dose v2.1 using organ time integrated activity coefficients and adjusted masses. Spearman correlation coefficients were calculated between pre- and post-therapeutic mean absorbed dose coefficients. ***Results:*** Two patients had diffuse metastatic bone disease for which red bone marrow analysis could not be performed. The mean (±SD) absorbed doses before and after treatment were 0.35(±0.17), 0.07(±0.05), 0.02(±0.002), 0.11(±0.04) and 0.11(±0.03) mGy/MBq and 0.54(±0.21), 0.17(±0.18), 0.04(±0.05), 0.34(±0.20) and 0.09(±0.05) mGy/MBq for kidney, liver, red bone marrow, salivary glands and spleen respectively. Strong significant correlations were observed between the mean absorbed dose coefficients before and after treatment for kidney (ρ=0.93, p-value=0.007), liver (ρ=0.82, p-value=0.034), salivary glands (ρ=0.93, p-value=0.007) and spleen (ρ=0.86, p-value=0.024). ***Conclusion:*** Strong correlations between pre- and post-therapeutic mean absorbed dose coefficients were observed for kidneys, liver, salivary glands and spleen. These results highlight the potential of a predictive pre-therapeutic dosimetry based on diagnostic imaging. Only red active bone marrow showed no significant agreement between pre- and post-treatment dosimetry. To confirm these results, further investigations are underway by recruiting additional patients, and an extended analysis of tumours dosimetry will be carried out.

EP-0932

Comparison of Organ Dosimetry in ^{177}Lu Theranostics: StarGuide™ vs. Conventional SPECT/CT Camera

R. Danieli, *W. Delbart, C. Marin, B. Vanderlinden, S. Vercauteren, Z. Wimana, P. Flamen, I. Karfis, E. Woff, H. Levillain;*
Institut Jules Bordet, Bruxelles, BELGIUM.

Aim/Introduction: The advent of StarGuide™, a ring-shaped CZT-based SPECT/CT camera, offers promising prospects for optimizing theranostics, particularly for 177Lu-based therapies. Due to its novelty, there is a need to validate its quantitative performance compared to a conventional camera. ***Materials and Methods:*** 177Lu-DOTATATE (7317 MBq) was administered on an off-label compassionate use basis in a patient with advanced multiple myeloma, resistant to all standard therapy lines, and

with intense somatostatin receptor positivity on 68Ga-DOTATATE PET/CT. Subsequently, the patient underwent multiple SPECT/CT scans and blood samples for dosimetry purposes. Four scans were acquired post-injection (at days 0, 1, 3 and 6) on both a StarGuide™ and a Discovery 870 DR. Acquisition durations varied between the systems: 20 min/bed (days 0 and 1) and 40 min/bed (days 3 and 6) on the Discovery, and a fixed 5 min/bed on StarGuide™. Two blood samples were collected within the first hour after the injection, and four additional samples were collected together with the SPECT/CT scans. SPECT data from the 208 keV photopeak were reconstructed using the protocol suggested by the manufacturer for each camera and converted into Bq/ml by applying a previously calculated calibration factor (1). Activity concentration in blood, assumed to be equal to that of red marrow, was measured in a NaI(Tl) well counter. Dosimetry of the liver, spleen, kidneys and red marrow was performed according to the MIRD formalism as described in a previous publication (2). Percentage differences between absorbed doses (ADs) obtained with SPECT/CT data acquired on the Discovery and on the StarGuide™ was computed as Δ(%)=(ADStarGuide-ADDiscovery)/ADmean, with ADmean the mean AD. Treatment and imaging procedures were performed after submission to the local ethics committee and patient informed consent. ***Results:*** ADmean to liver, spleen, kidneys and red marrow were 1.72, 14.0, 6.67, 0.198 Gy, respectively. Corresponding Δ(%) were equal to 7%, -2%, -4% and 1%. ***Conclusion:*** StarGuide™ demonstrated comparable organ dosimetry to the conventional system but with shorter acquisition times. This suggests its potential to streamline therapeutic procedures without compromising dosimetric accuracy. However, it is essential to consolidate these results through a larger sample size and include lesion dosimetry. ***References:*** (1) Danieli et al. Quantitative 177Lu SPECT/CT imaging for personalized dosimetry using a ring-shaped CZT-based camera. EJNMMI Phys 10, 64 (2023). https://doi.org/10.1186/s40658-023-00586-z (2) Marin et al. A dosimetry procedure for organs-at-risk in 177Lu peptide receptor radionuclide therapy of patients with neuroendocrine tumours. Phys Med. 2018;56:41-49. doi:10.1016/j.ejmp.2018.11.001.

Dosimetry comparison of a high affinity FAP imaging agent [Cu-64]LNTH-1363S with other PET diagnostic imaging agents

J. Hesterman[1], *S. DiMagno[1], S. Hillier[1], A. Amor[1], M. Friebe[1], A. Purohit[1], K. Orcutt[1], S. Kouri[1], A. Novicki[1], E. Fenn[1], N. Monks[1], K. Tully[1], S. Kazerounian[1], L. Fanchon[2], D. Russell[2], J. Hoppin[1], J. Babich[1];*
[1]Ratio Therapeutics, Boston, MA, UNITED STATES OF AMERICA,
[2]Invicro, Needham, MA, UNITED STATES OF AMERICA.

Aim/Introduction: Fibroblast activation protein-α (FAP) is emerging as a pivotal target in molecular imaging of cancer as well as inflammatory and fibrotic diseases. FAP-targeted PET ligands have demonstrated improved tumor specificity and sensitivity compared to conventional [18F]FDG across various cancers. Here we report biodistribution and dosimetry estimates from a Phase 1 first-in-human (FIH) imaging study of [Cu-64]LNTH-1363S, a small molecule with an affinity of 21 pM for FAP, including comparisons to other PET diagnostic imaging agents. ***Materials and Methods:*** [Cu-64]LNTH-1363S was prepared in good radiochemical yield (95.8 +/- 1.4%) and radiochemical purity (~100%) for administration to six healthy participants (3M, 3F, age range 24 - 54). Doses ranged from 204 - 222 MBq with administered mass dose ranging from 80 - 97 ug. Whole-body PET/CT (skull vertex to thigh) data were performed at 0.25, 1, 4, and 24 hours post-administration. Whole-blood samples and urine were collected.Time-activity curves for predefined regions of interest (ROIs) were analyzed using exponential models to compute time-integrated activity coefficients (TIACs). A blood-based red marrow TIAC was computed. The voiding bladder model was used for bladder TIAC. Absorbed dose was calculated with OLINDA 2.2.3. The study was conducted in compliance with applicable clinical regulations and ethical standardsPublished data were used to compile dosimetry estimates for [F18]FDG, [Ga-68]FAPI-46, [F-18]DCFPyl, and [Cu-64]DOTATATE. ***Results:*** The effective half-life of [Cu-64]LNTH-1363S was 4.86 ± 0.57 hours with a whole-body effective dose of 0.010 +/- 0.004 mSv/MBq. The organ receiving the highest absorbed dose was the urinary bladder (median 0.068 mGy/MBq, range 0.054 - 0.242 mGy/MBq). All other target organs absorbed doses below 0.025 mGy/MBq, including kidneys at 0.022 +/- 0.007 mGy/MBq.As shown in Table 1, comparative analysis to other PET agents, including [F-18]FDG, [Ga-68]FAPI-46, [Cu-64]DOTATATE, and [F-18]DCFPyl, demonstrated that [Cu-64]LNTH-1363S provides competitive or lower tissue absorbed doses and whole-body effective doses, indicating favorable dosimetry. ***Conclusion:*** The administration of [Cu-64]LNTH-1363S is safe and demonstrates minimal off-target uptake, with primary clearance through the kidneys and bladder. Normal organ absorbed dose and whole-body effective dose were comparable or lower than for several other diagnostic PET imaging agents. The high affinity, low background, and favorable dosimetry of [Cu-64]LNTH-1363S support its further development as a FAP-targeted diagnostic imaging agent. ***References:*** 1. Detectnet [FDA package insert].2. Pylarify [FDA package insert].3. FDG [FDA package insert].4. J Nucl Med 2005; 46:608-6135. FDG [EMA package leaflet].

EP-0934

Optimization in combined radionuclide and external beam radiation therapy using biologically equivalent dose

F. Kähler[1], *J. Ödén[1], A. Leimgruber[2], O. Matzinger[2], A. Angerud[1];*
[1]RaySearch Laboratories AB, Stockholm, SWEDEN,
[2]Swiss Medical Network, Genolier, SWITZERLAND.

Aim/Introduction: Combined planning of radionuclide therapy (RNT) and external beam radiation therapy (EBRT) is currently not done in clinical practice. For the patient regarded in this study, organ at risk (OAR) absorbed dose prognosis showed that the patient may benefit from a combined treatment with EBRT to achieve higher and more homogeneous total doses to the lesions before reaching OAR dose limits, especially kidneys with an assumed dose limit of 23Gy [1]. We aim to investigate EBRT planning based on equivalent dose in 2Gy fractions (EQD2) voxelwise, accounting for delivered RNT-doses in a treatment planning system (TPS). ***Materials and Methods:*** Dosimetry for one 9GBq fraction of 177Lu-PSMA-617 was performed based on 177Lu-SPECT/CT images for one patient with metastatic castration-resistant prostate cancer. Activities were time-integrated using population-averaged effective half-lives. Dose computations were performed using a newly developed GPU based MC which was previously verified against gold-standard Monte Carlo code in phantom geometry [2]. A photon volumetric modulated arc therapy (VMAT) plan and a proton plan with two beams, each 15 fractions, were created to treat lesions located in the spine. Physical RNT-dose was automatically converted voxelwise into EQD2 within the plan optimization and used as background

EQD2 in the optimization. The plans were optimized to achieve an EQD2 for the combined treatment of 60Gy to 99% of the lesion volume (EQD299≥60Gy) while limiting OAR EQD2 using DVH and maximum EQD2 objectives. ***Results:*** The mean absorbed doses were 4.9±0.8Gy (kidneys), 0.18±0.03Gy (bone marrow) and 15.9±4.2Gy with homogeneity index (HI) D5/D95=4.22 (lesions) for the RNT fraction. For combined treatment, mean lesion EQD2 were 60.19±3.69Gy (RNT+VMAT) and 60.21±3.69Gy (RNT+Proton) with HI of 1.14 and 1.10. Mean kidney EQD2 were 6.53±0.54Gy (RNT+VMAT) and 3.53±0.54Gy (RNT+Proton). Spinal cord doses D10=42.27±0.43Gy (RNT+VMAT) and D10=40.57±0.46Gy (RNT+proton) were lower than the dose limit D10=43.68Gy. ***Conclusion:*** The result shows voxelwise MC RNT doses can be combined with EBRT with improved HI and lower OARs doses compared with multiple RNT fractions. To our knowledge, this was the first time that protons were combined with RNT in a retrospective study and that EBRT doses were optimized based on EQD2 without the needed for prior EQD2 conversion within a research version of a commercial TPS. ***References:*** [1]Herrmann K, et al J Nucl Med 2024; 65:71-78, DOI: 10.2967/jnumed.123.265448; [2]Chauvin M, et al J Nucl Med 2020; 61:1514-1519, DOI: 10.2967/jnumed.119.240366.

Comparison of dosimetry results obtained with different software tools in first in-human use of 177Lutetium-labelled HER2 affibody in a patient with breast and lung cancer

R. Moretti[1], *E. Perrone[2], A. Eismant[3], K. Ghai[3], L. Greifenstein[3], D. Benz-Zils[3], A. Capotosti[1], R. P. Baum[3];*
[1]Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY, [2]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Rome, ITALY, [3]CURANOSTICUM Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.

Aim/Introduction: Accurate dosimetry is crucial for optimizing therapeutic efficacy while minimizing toxicities in surrounding healthy tissues, especially in the clinical application of a novel radiopharmaceutical. Different dosimetry calculation methods are now commonly available. This study aimed to evaluate dosimetric results obtained using three distinct software tools with their own dosimetry model - Monte Carlo (MC), Semi-Monte Carlo (SMC) and Voxel S-values (VSV) - in a first in-human use of 177Lutetium-labelled HER2 affibody and to assess how different computational algorithms impact dose calculations for both tumours and Organs at Risk (OARs). ***Materials and Methods:*** An activity of 1.4 GBq of 177Lu-HER2 Affilin was injected in a female patient with metastatic concurrent breast and lung HER2-positive cancers. A SPET/CT tomograph equipped with medium energy collimators was used to perform acquisitions. Dual energy window was used. Three bed positions of 60 frames each, lasting 6.981 seconds, were acquired. A total of 6 SPET/CT acquisitions was performed 28min (t1), 4h, 18h, 42h, 66h and 90h post injection. SPET/CT images were then reconstructed with a dedicated vendor-neutral tool of one of the softwares in order to obtain quantified images (Bq/ml) using the proper tomograph Calibration Factor. Registrations between t1 and subsequent acquisitions were performed and saved as aligned series. Contouring of t1 CT scan was conducted with a physician's assistance. An AI tool was used for OARs contouring (kidneys, liver, spleen and lungs), while primary tumours and metastases were manually contoured in breast, lung and bone. Dosimetry was then performed using the three aforementioned software tools, using MC results as reference. ***Results:*** The difference between mean dose in Gy from SMC and MC was: -0.2 (two lung metastases), 0.1 (lung primary), 0.1 (bone metastasis), 0.0 (breast central and apical); 0.1 (liver), 0.2 (kidneys), -0.5 (lungs), -0.1 (spleen). The difference between mean dose in Gy from VSV and MC was: -0.4 and 0.0 (two lung metastases, respectively), 0.1 (lung primary), -0.1 (bone metastasis), -0.1 and 0.0 (breast central and apical); 0.3 (liver), -0.4 (kidneys), 0.0 (lungs), -0.1 (spleen). ***Conclusion:*** The differences in mean doses calculated by the three software tools were small, with discrepancies mostly ranging from -0.53 Gy to 0.28 Gy across tumours and OARs. This indicates a relatively consistent performance among the used software tools in terms of dosimetric precision. Further studies should be conducted to assess the findings of this study.

EP-0936

How Accurate Should be Dosimetry for Radiopharmaceutical Therapy from a Clinical Perspective?

J. Hu[1], *R. Seifert[2], S. Xue[2], C. Ferreira[2], A. Afshar-Ormieh[2], A. Rominger[2], K. Shi[2];*
[1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Swi, Bern, SWITZERLAND, [2]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Despite the revealed potential of dosimetry in the optimization of radiopharmaceutical therapy (RPT), restriction of clinical implementations leads to the compromised development of simplified protocols to enhance the adoption in clinical routine, which introduces more errors in dosimetry. However, it is still unclear if these errors would influence the impact of dosimetry in clinical practice. ***Materials and Methods:*** In this retrospective study, we analyzed data from 20 patients diagnosed with metastatic castration-resistant prostate cancer (mCRPC) who underwent multiple cycles of 177Lu-PSMA-617 treatment. Cumulative dosimetry of all the treatment cycles were calculated using both the standard multi-time point dosimetry (MTPD) method and the single time point dosimetry (Hänscheid) method. Their correlation with treatment outcome (PSA decline rate and overall survival, OS) and complication risk (anaemia grade) was investigated. The Fisher's Z-Transformed test was performed to statistically evaluate the difference between the correlations. ***Results:*** Compared to MTPD, STPD has introduced a deviation in whole-body tumor dose of a mean percentage error (MPE) of 26.50%, range of (-30.83%, 43.86%). Both STPD and MTPD of whole-body tumor demonstrated non-significant difference in the correlations with PSA decline rate (MTPD: $r = -0.34$, $p<0.001$; STPD: $r= -0.48$, $p<0.001$; $Z= 0.26$, $p=0.80$), and both shown significant impact on OS (MTPD: Hazard Ratio = 1.01, $p<0.01$; STPD: Hazard Ratio = 1.02, $p<0.05$). Additionally, both STPD and MTPD of non-tumor bone shown non-significant difference in correlation with anaemia grade (MTPD: $r = 0.35$, $p<0.001$; STPD: $r= 0.40$, $p<0.001$; $Z= -0.39$, $p=0.70$). ***Conclusion:*** Our preliminary results indicate that, despite an error of up to 43.86% in the simplified dosimetry approach, it still provides a comparable correlation in predicting treatment outcomes and toxicity risks in mCRPC patients undergoing 177Lu-PSMA-617 therapy. Further systematic investigation is needed to determine the acceptable level of accuracy for dosimetry from a clinical perspective.

EP-0937

Determination of a reliable parameter with Monte Carlo Simulation for dosimetry in ^{177}Lu-DOTATATE PRRT

S. Kimura, *N. Miyaji, K. Miwa, T. Yamao, N. Akiya, K. Wachi;*

Fukushima Medical University, Fukushima, JAPAN.

Aim/Introduction: Monte Carlo Simulation (MC) based on 3D patient images has emerged as a next generation dosimetry tool as it can calculate the absorbed dose distribution from quantitative images using repeated random particle history simulations. The MC enables more accurate predictions depending on the number of histories, but it is problematic for computational processing time. Therefore, we aimed to determine an appropriate and reliable number of histories for the MC in patients after 177Lu-DOTATATE PRRT using two types of MC software. ***Materials and Methods:*** We acquired SPECT/CT images at four time points (4h, 28h, 103h, 124h) from a male patient in 177Lu SNMMI Dosimetry Challenge. Absorbed doses were calculated for the left (LK) and right (RK) kidneys, the liver (L), spleen (S) and two lesions (T1, T2) using RT-PHITS (Japan Atomic Energy Agency) and Voxel Dosimetry (Hermes Medical Solutions). The 3D dose-rate distribution at each imaging point calculated by EGS5 simulation code in RT-PHITS was analyzed using 3D Slicer. For Voxel Dosimetry, the 3D dose-rate distribution was determined based on interactions of electrons and photons using PENELOPE. History numbers from 104 to 109 were repeated three times. The calculated dose rates were integrated over time using an exponential model. We evaluated variations in absorbed dose and statistical error derived by RT-PHITS and Voxel Dosimetry. ***Results:*** Variability improved with increasing numbers of histories for both types of software, and the coefficient of variance (CV) for each lesion and organ excluding T2 was < 1% at 107 for RT-PHITS. The CV in T2 was 9.09% at 107 and 1.49% at 108, respectively. These statistical errors with respect to the history were ~ 95% for 106, ~ 50% for 107 and ~ 5% for 5 ×108 histories. The statistical error was larger for the early time points of 4h. Thus, the derived absorbed dose was stable within 5% for 106 histories and within 1% for 107 histories. The absorbed dose derived by Voxel Dosimetry was constant > 105, and the T2 at 104 was reduced by 75% compared to 108. ***Conclusion:*** Setting > 106 histories for RT-PHITS were stable at ≤ 5%, and the optimal history was 107 in terms of calculation time and accuracy. Voxel Dosimetry affected absorbed doses < 104, and we determined the optimal number was 106. However, statistical errors increased during the early phase and the number of histories must be set considering imaging time.

EP-0938

Use of Voxel Based Dosimetric Parameters for Predicting Early Treatment Response to Y-90 TARE

C. KÜÇÜKER, *B. VOLKAN SALANCI, M. F. BOZKURT; Hacettepe University, Ankara, TÜRKIYE.*

Aim/Introduction: The purpose of this study was to determine voxel-based dosimetric parameters in correlation with favorable response based on magnetic resonance (MR) or computer tomography (CT) after Yttrium-90 (Y-90) transarterial radioembolization (TARE) for hepatocellular carcinoma (HCC) to predict early treatment response. ***Materials and Methods:*** 25 patients (21 males, 4 females, mean age 69,5 ± SD 10,4 years) with 25 HCC lesions who underwent radiation segmentectomy (RS) with Y-90-microspheres were retrospectively included between January 2020 and March 2024 at our institution. Multi-compartment dosimetric analysis was performed on post-treatment Y-90 PET-CT images to calculate the average absorbed doses (TAD) and volumes of targeted lesion (TV) and liver parenchyma. The early response of lesions was recorded with initial assessment (1-3 months) after treatment on contrast-enhanced MR or CT reports according to modified Response and Evaluation Criteria in Solid Tumors (mRECIST). Lesions with complete response (CR) and partial response (PR) were deemed dose-tumor responsive group (RG), while lesions that remained stable disease (SD) and progressive disease (PD) were deemed non-responsive group (NRG). The relationship between calculated dosimetric parameters and the response to treatment was statistically evaluated using Mann-Whitney U and ROC analysis. ***Results:*** The average follow-up time was 14,3± SD 9,8 mo and 8 (32%) patients died during this period. In early treatment evaluation, 12 target lesion (48%) were interpreted as PR, 9 (36%) were SD, and 4 (16%) were PD. Average TAD for PR, SD, PD groups was 253,5 ± 117,1 Gy, 239,5 ± 69,1 Gy, 266,5 ± 150,8 Gy respectively. The average TV value was calculated for PR, SD, PD groups (148 ± 192,8 cc, 847,2 ± 836,1 cc, 128,3 ± 82 cc respectively). There was no significant difference in TAD of targeted lesions between RG versus NRG (median, 229 Gy [IQR: 167-300 Gy] vs 219 Gy [IQR: 180-341 Gy], respectively; p=0.936). However, NRG had significantly higher average TV value than RG (respectively median, 408 cc [IQR: 110-863 cc] vs 98 cc [IQR: 22-175 cc]; p=0.026). Optimal cut-off TV value for dose-tumor control success were less than 185 cc (sensitivity 69%, specificity 83%, AUC 0.76). ***Conclusion:*** Although a dose-response relationship in TARE is known for tumoral lesions of liver, definition of standardized dose thresholds between RG or NRG groups could not be demonstrated in our HCC lesions to which RS was performed. However, the average TV value seems to be a more effective parameter for predicting early treatment response.

EP-0939

[^{99m}Tc]Tc-MAA based Predosimetry versus ^{90}Y based Postdosimetry for Resin Microsphere Radioembolization

Z. Balaban Genc[1], *Ö. Erez[1], S. Beykan Schürrle[2], N. Schürrle[2], E. Soydemir[3], K. Niftaliyeva[1], T. Kıssa[1], T. Erdil[1], T. Ones[1]; [1]Marmara University Pendik Training and Research Hospital, Nuclear Medicine Department, ISTANBUL, TÜRKIYE, [2]Curie Science Center, DURRWANGEN, GERMANY, [3]Marmara University Pendik Training and Research Hospital, Radiology Department, ISTANBUL, TÜRKIYE.*

Aim/Introduction: The main goal is to find out the relative difference between the calculated patient-specific absorbed doses (ADs) via [99mTc]Tc-MAA SPECT/CT based predosimetry (before treatment) and to find the difference in ADs calculated via 90Y SPECT/CT and PET/CT based postdosimetry. In addition, between 90Y SPECT/CT and PET/CT based postdosimetry were investigated. ***Materials and Methods:*** 35 patients received radioembolization treatment with resin microspheres based on personalised-BSA method. For all patients, prior to the radioembolization treatment, [^{18F}]F-FDG PET/CT scan, MRI scan, [99mTc]Tc-MAA SPECT/CT were acquired. After radioembolization, post-treatment 90Y SPECT/CT scan for all patients and post-treatment 90Y PET/CT scan for 10/35 patients was acquired. For all dosimetry evaluations, patient-specific lung, healthy liver, perfused liver and tumor analyses were performed by using NUKDOS software. Volume and activity quantifications were performed by using CT-or-MRI and SPECT-or-PET guided drawn segments, separately. For 35 patients, pre- and postdosimetry based ADs of lung, healthy liver, perfused area and tumor were compared. For the same regions , 90Y SPECT/CT and 90Y PET/CT based ADs were compared for 10/35 patients. ***Results:*** Calculated mean ADs of healthy liver, lung and tumor based on predosimetry was 69.5 ± 66.7, 9.9 ± 7.5, 345.2 ± 308.6, respectively, whereas ADs of healthy liver, lung and tumor based on postdosimetry (90Y SPECT/CT

imaging) was 26 ± 25, 7 ± 5, 478 ± 439, respectively. Compared to postdosimetry, [99mTc]Tc-MAA SPECT/CT predosimetry based ADs were always higher as a factor of 1.5 ± 0.6 for lung, 7.2 ± 6.6 for healthy liver, 2.6 ± 2.3 for tumor. Concerning postdosimetry based on 90Y PET/CT and 90Y SPECT/CT scans, calculated ADs of healthy liver and tumor significantly varies between patients, especially when the tumor overload is high. In case less tumor overload, the relative difference between SPECT and PET based post dosimetry was 10-15%, however, for the patients with less tumor load, high differences was observed up to factor of 3. ***Conclusion:*** Compared to postdosimetry results, it's observed that predosimetry overestimated the healthy organs ADs; however, still If the treatment was performed based on [99mTc] Tc-MAA SPECT/CT based predosimetry instead of BSA, as a factor of 2.6 ± 2.3 higher treatment activity can be safely administered which directly increase tumor ADs. As a result higher treatment outcome can be achieved. With dosimetry, maximum tumor ADs with safe ADs in healthy liver can be achieved, which decrease the risk of hepatotoxicity and provides longer-term survival.

EP-0940

Comparison Between Different Methods of Red Marrow Absorbed Dose Calculation in Treatments with [^{177}Lu] Lu-DOTATATE. Correlation with Whole Body Absorbed Dose

T. Monserrat Fuertes[1], *L. Daçi[1], A. Álvarez Amigo[1], A. Hierro Rivero[1], Á. García Balsa[1], N. Montenegro Iglesias[1], J. Blanco Rubio[1], A. Díaz García[1], C. Menéndez García[1], M. A. Peinado Montes[1], P. Mínguez Gabiña[2];*
[1]Hospital Universitario Central de Asturias, Oviedo, SPAIN,
[2]Hospital Universitario Cruces-Gurutzeta, Bilbao, SPAIN.

Aim/Introduction: This work pursues two objectives: -To compare the results of red bone marrow (RM) absorbed doses obtained by blood samples method and by SPECT images method -Check if the whole body (WB) absorbed dose can de used as surrogate for RM dose in treatments with [177Lu]Lu-DOTATATE. ***Materials and Methods:*** RM activity was quantified in 47 treatment cycles of 27 patients treated with [177Lu]Lu-DOTATATE, in two different ways: (1) blood method: taking eight blood samples and measuring the activity concentration in a well counter and (2) images method: delineating the interior of the vertebrae on 3 SPECT/CT images during the first week post-administration. In both cases, the total RM dose was obtained in two ways: (a) complete method: taking into account the contribution of RM, kidneys, liver, spleen and rest of the body (RoB); and (b) simplified method: taking into account only RM and RoB contribution. Finally, WB dose was calculated from WB activity measurements with an ionization chamber. S factors were obtained from OLINDA. Correlations between RM and WB absorbed doses were analyzed. ***Results:*** Median (first quartile, third quartile) doses obtained are 29(22, 48) mGy/GBq for WB, 15(13, 23) mGy/GBq for RM with simplified blood method, 13(11, 18) for RM with complete blood method, 30(21, 35) mGy/GBq for RM with simplified images method and 25(18, 33) mGy/GBq for RM with complete images method. The RM absorbed dose obtained with blood and images methods show a weak correlation (Spearman's coefficient 0.30). The RM absorbed dose obtained with blood method shows a strong correlation with the WB dose (Spearman's coefficient 0.74). The relationship between the RM absorbed dose obtained from images and the WB dose depends on the hepatic uptake. In patients with low hepatic uptake, both variables show a moderate correlation (Spearman's coefficient 0.49) and do not show significant differences. In patients with high hepatic uptake the correlation worsens (Spearman's coefficient 0.38). ***Conclusion:*** The blood and the images methods yield significantly different values of RM dose. The RM absorbed dose from blood shows a strong correlation with the WB dose, so one could be obtained from the other. In patients with low hepatic uptake, RM dose from images and WB dose do not show significant differences, so the WB dose could be used as a surrogate for the RM dose.In both methods, quantifying only the RM and RoB compartments overestimates the RM dose.

Dosimetry Methodology of Targeted Radiopharmaceutical Therapy with n.c.a. [^{177}Lu]Lu-edotreotide in GEP-NET patients: the COMPETE trial

L. Santoro[1], *A. Flaus[2], A. Garcia-Burillo[3], J. B. Cwikla[4], R. Baum[5], G. El-Haddad[6], T. Meyer[7], A. Kluge[7], P. Harris[8], K. Zhernosekov[8];*
[1]Nuclear Medicine Department, Montpellier Cancer Institute (ICM), University of Montpellier, Montpellier, FRANCE, [2]Nuclear Medicine Department, Hospices Civils de Lyon, Faculté Lyon-Est, UCBL1, Lyon, FRANCE, [3]Department of Nuclear Medicine, University Hospital Vall d'Hebron, Barcelona, SPAIN, [4]Diagnostic and Therapy Center, Nuclear Medicine, Warsaw, POLAND, [5]Curanosticum Wiesbaden-Frankfurt, Centre for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY, [6]Department of Diagnostic Imaging and Interventional Radiology, Moffitt Cancer Center, Tampa, FL, UNITED STATES OF AMERICA, [7]ABX-CRO advanced pharmaceutical services Forschungsgesellschaft mbH, Dresden, GERMANY, [8]ITM Oncologics GmbH, Garching/Munich, GERMANY.

Aim/Introduction: Presenting the dosimetry methodology used for assessing the safety and efficacy of radiopharmaceutical therapy (RPT) with non-carrier-added (n.c.a.) [177Lu]Lu-edotreotide (DOTATOC) in treating unresectable or metastatic, progressive, somatostatin receptor (SSTR)-positive, grade 1-2 (Ki-67 ≤20%) gastroenteropancreatic neuroendocrine tumours (GEP-NETs). ***Materials and Methods:*** In the phase 3 COMPETE trial—a global, prospective, randomised, controlled, open-label study comparing the efficacy and safety of [177Lu]Lu-edotreotide with everolimus, 324 participants were enrolled in a 2:1 respective ratio. Although the trial is still ongoing, recruitment and dosimetry evaluations have been completed. The 222 participants allocated to RPT received up to four treatment-cycles (D1 to D4) of [177Lu] Lu-edotreotide (7.5 GBq/cycle) every three months unless a progression was observed. Three additional sub-study groups of approximately 20 participants each were included for: a) initial and repeated assessments at D1-D4, b) full SPECT/CT dosimetry, and c) blood-based bone marrow evaluations. Imaging and calibration protocols were standardised across sites utilising NEMA phantoms. Identical OSEM SPECT reconstruction with scatter and CT based attenuation corrections were performed for all patients' scans. Dosimetry was performed by using QDOSE software. For the dosimetry of tumours and healthy organs, sequential whole-body planar scans acquired nominally at 0.5, 6, 24, 72/96 h post-injection in combination of one SPECT/CT (at 24 h post-injection) was analysed. Organ/tumour segmentations were performed by a medical imaging specialist and confirmed by a board-certified physician. Activity and volume quantifications were carried out separately based on planar/SPECT guided and CT guided segments, respectively. The SPECT guided segments were drawn larger than actual CT-based organ/tumour volumes, to account the spill-out effect. For activity quantification on planar scans, background subtraction correction method was applied. After segmentation, time-activity curves were created, and monoexponential fitting was performed to calculate the resulting time-integrated activity coefficients (TIACs). For absorbed dose calculations, the IDAC-

Dose 2.1 program implemented in QDOSE software was used with organ mass correction based on patient-specific CT volumes. ***Results:*** The comprehensive dosimetry results from the COMPETE trial, which are forthcoming could potentially provide insights into absorbed dose-effect relationship for [177Lu]Lu-edotreotide, potentially contributing to the broader scientific discussion on targeted RPT dosimetry. ***Conclusion:*** The understanding gained from the COMPETE trial's dosimetry sub-studies is thought to enhance [177Lu]Lu-edotreotide treatment optimisation, through standardised absorbed dose determination using simplified protocols, thereby supporting the application of personalised dosimetry in clinical practice.

EP-0942

Streamlining Quantitative SPECT/CT Imaging Protocols for Optimized Lutetium-177 Dosimetry of Radiopharmaceutical Therapies

J. Brosch-Lenz[1], *F. Farhadi[1], M. Katouzian[1], A. Viscomi[2], C. Huffman[2], B. Saboury[1], M. Morris[2];*
[1]Institute of Nuclear Medicine Inc., Bethesda, MD, UNITED STATES OF AMERICA, [2]Advanced Molecular Imaging and Therapy, Glen Burnie, MD, UNITED STATES OF AMERICA.

Aim/Introduction: With rapidly growing numbers of Lutetium-177 radiopharmaceutical therapies, new challenges for safety and efficacy of the treatments arise. Post-therapeutic dosimetry verification is often hampered by the requirement for long and multiple time points (TPs) quantitative SPECT imaging leading to additional burden for patients and limiting capacity to perform dosimetry per patient due to scanner availability. Aim of this work was to investigate quantification accuracy of an ultra-short Lutetium-177 SPECT protocol compared to a standard SPECT imaging protocol to enable routine dosimetry. ***Materials and Methods:*** Four patients underwent quantitative Lutetium-177-PSMA SPECT/CT imaging at three TPs between 24h and 144h post-injection using the standard SPECT imaging protocol (60 steps, 15s/step; total 15min per bed) and a shortened image acquisition protocol (60 steps, 5s/step; total 5 min per bed), and a single CT scan. SPECT scans were quantitatively reconstructed with attenuation and scatter correction. Volumes of interest (VOIs) for kidneys, liver, and spleen were segmented on the CT images using an automatic segmentation algorithm. VOI statistics were extracted, time-activity-curves were generated and fitted mono-exponentially for both protocols. Organ absorbed doses (ADs) were calculated using IDAC-Dose2.1. Percentage differences (PD) in activities between protocols per TP, and in AD were compared. ***Results:*** The median PD in activity between protocols was -3.0% (min: -8.5%, max: 9.3%) for kidneys, -2.6% (min: -11.0%; max: 5.2%) for liver, and -3.8% (min: -11.9%, max: -0.1%) for spleen for the 24h TP. For 48h TP, median PD of -8.5% (min: -15.7; max:2.1%) for kidneys, -3.4% (min:-8.6%; max: .3%) for liver, and -3.7% (min:-27.7; max:-3.5) for spleen were found. For the TP at 72h or 144h, median PD of -2.4% (min: -15.3%; max: 33.4%) for kidneys, -5.7% (min: -16.7%; max: 0.0%) for liver, and -10.9% (min: -19.2%; max: 0.4%) for spleen were found. The median PD in ADs was -6.6% (min: -20.2%; max: 17.2%) across organs and patients. ***Conclusion:*** The ultra-short Lutetium-177 SPECT protocol showed activity quantification in good agreement with the standard protocol for all patients and TPs. The PD increased towards later imaging TPs, where smaller activity concentrations are present. Small median differences in AD below -7% across organs were found. In general, the reduced overall imaging time by two thirds makes the streamlined protocol a valuable alternative for routine clinical dosimetry. Future analysis will expand on a larger patient cohort and include lesions.

EP-0943

Comparative Analysis of PET-MR and PET-CT Imaging for Post-Therapy Assessment of ^{90}Y-Microsphere SIRT in Hepatocellular Carcinoma

D. Hulse[1], *D. Gillett[2], S. Heard[2], V. Warnes[2], S. Ballout[2], V. Lupson[3], N. Shaida[4], T. See[4], N. Hilliard[4], I. Harper[2], L. Aloj[1,2];*
[1]Department of Radiology, University of Cambridge, Cambridge, UNITED KINGDOM, [2]Department of Nuclear Medicine, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UNITED KINGDOM, [3]Wolfson Brain Imaging Centre, University of Cambridge, Cambridge, UNITED KINGDOM, [4]Department of Radiology, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UNITED KINGDOM.

Aim/Introduction: Selective Internal Radiation Therapy (SIRT) with Yttrium-90 Microspheres has become an important intervention in the management of hepatocellular carcinoma and liver metastases. Following therapy, accurate imaging is required to evaluate whether treatment has been successful and to perform dosimetry. PET is the preferred option for post-treatment imaging and at our centre both PET-CT and PET-MR are available. Each imaging modality has advantages over the other, with PET-CT derived attenuation correction considered the gold standard for quantitative accuracy, and PET-MR facilitating superior soft tissue resolution and lesion delineation. This study aimed to assess and compare the performance of these modalities in imaging following SIRT with 90Y-Microspheres. ***Materials and Methods:*** Six patients with hepatocellular carcinoma underwent 90Y-SIRT, followed by both PET-CT and PET-MRI. PET data was reconstructed using a Bayesian Penalized-Likelihood algorithm (Q-clear). A comprehensive analysis was conducted on 227,804 voxel data points retrieved from the PET images. To ensure spatial congruence, CT images were aligned with MR images via automated rigid registration. PET images from PET/CT were transformed to align with MR space, facilitating direct comparison. Conversion from Bq/ml to Gy was performed to permit dose comparison. A difference image was created by subtracting PET-CT from PET-MR, with doses above 20 Gy segmented in both modalities. ***Results:*** The correlation coefficient between PET-MR and PET-CT was found to be 0.88, indicative of a strong positive relationship. Median difference in dose was observed to be -1.03 Gy, with interquartile range (Q1-Q3) spanning from -8.70 Gy to 5.98 Gy. Bland-Altman analysis revealed a mean difference of -1.16 Gy, with upper and lower limits of agreement (±1.96 SD) at +34.05 Gy and -36.36 Gy, respectively ***Conclusion:*** Our study indicates that PET-MR and PET-CT are comparable for post-therapy 90Y-Microspheres imaging, with the voxel level data demonstrating strong correlation and a small bias. Although not considered the gold standard for quantification, the MR attenuation correction works satisfactorily for the purposes of post-SIRT imaging.

EP-0944

Dose distribution parameters for the prescription in ICC (intrahepatic cholangiocarcinoma) patients undergoing Transarterial Radioembolization with 90Y

J. Tarrats-Rosell[1], *A. Cobo-Rodríguez[2], A. Niñerola-Baizán[2,3], S. Casanueva-Elicery[2], I. Romero-Zayas[2], K. Quintero[2], D. Fuster-Pelfort[2];*
[1]Radiotherapy Oncology Department, Hospital Clinic de Barcelona, Barcelona, SPAIN, [2]Nuclear Medicine Department, Hospital Clinic de Barcelona, Barcelona, SPAIN, [3]CIBER de Bioingeniería, Biomateriales y Nanomedicina, Instituto de Salud Carlos III, Barcelona, SPAIN.

Aim/Introduction: Personalized dosimetry is known to be associated with improved response rate in the treatment of liver tumours through transarterial radioembolization (TARE). In daily practice, tumour response can vary considerably. The reported dose-response relationships are based in mean absorbed dose to tumour remaining unclear the significance of other dosimetric parameters as predictive factors of tumour control. In this study we aimed to determine dosimetric parameters associated with radiological response and evaluate the predictive potential of tumour covering in intrahepatic cholangiocarcinoma (ICC) patients undergoing TARE. ***Materials and Methods:*** We conducted a retrospective screening of patients diagnosed with ICC who underwent TARE using Y-90-loaded glass microspheres in our centre between December 2021 and July 2023. The dosimetric analysis was performed with commercial voxel-based software on PET/CT images performed within 24 hours after treatment. Dose-volume histograms of the tumour volume, segmented manually, were obtained. We calculated the average absorbed tumour dose (Dmean), the percentage of the target volume receiving the prescribed dose threshold recommended by the EANM guidelines1 (D260Gy) and the minimum absorbed dose that covers 90% and 95% of the tumour volume (D95%, D90%). Tumour control was assessed 3 months after treatment by CT or MRI using response assessment criteria in solid tumours (mRECIST). ***Results:*** Eight patients (age, median 68 (IQR 63-70) years) were included in the study. Objective radiological tumour control (TC) was observed in 37.5% of the patients (n=3). The responsive lesions showed a higher average tumour dose and percentage of targeted volume covered. The dosimetric parameters that demonstrated the most prominent differences between responsive and non-responsive lesions were D90% and D95%. For the evaluated parameters, the median (interquartile range) were: D95% 14Gy (7-18Gy) TC and 0Gy (0-0Gy) progressive disease (PD); D90% 34Gy (27-41Gy) TC and 2Gy (0-25Gy) PD; V260Gy 49% (47-56%) TC and 30% (14-51%) PD; Dmean 595Gy (461-615Gy) TC and 307Gy (168-321Gy) PD. ***Conclusion:*** Our findings suggest that tumour covering, defined with D90% or D95%, is also a good predictive factor of tumour control and not only average tumour dose, which does not consider the heterogeneity of dose deposition. These findings, if confirmed by more patients and prospective studies, may contribute to the development of more efficient treatment approaches using glass-based Y-90 microspheres. ***References:*** 1. Aim/Introduction: To demonstrate that the first treatment with 131I of metastatic differentiated thyroid cancer (MDTC), optimized with dosimetric treatment planning with 124I, provides an objective response rate on soft tissue metastases at 6 months higher than the fixed activity administrations. ***Materials and Methods:*** 124I is produced in Negrar while therapy is delivered in INT. 124I PET is acquired in both centres. Patients are prepared with hormone withdrawal both for dosimetry and therapy. Oral administration of liquid 124I (100 MBq) is followed by blood sampling and whole body counting at 2, 6, 24, 96 h. PET scans are taken at 24 and 96 h. Lesion post-therapy dosimetry is performed on SPECT/CT taken at 48 and 96 h. Response is assessed by comparison with basal 18F FDG PET, contrast-enhanced CT or MRI, 124I PET and thyroglobulin level, 6 months after one or two optimized treatments. ***Results:*** We studied 20 patients with 124I, sent us by 8 different centres. Ten (50%) were dropped out. Nine to remnant ablation since metastases were 124I negative and one to more urgent radiotherapy. Two will be treated in May 2024 with 12 GBq. Eight received 10 optimised treatments (3, 4a, 4b, 7a, 7b, 8, 10, 11, 12, 13). In treatments 3 and 4a we were forced to reduce the usual activity for MDTC (8-9 GBq) to 6 and 4 GBq, to deliver less than 2 Gy to blood. In treatments 4b and 8, seen the presence of bone metastases, we admistered almost the maximum tolerable activity (20 GBq and 16 GBq, respectively). No patient suffered from moderate/severe haematological toxicity nor from sialoadenitis/xerostomia. Abrorbed dose values were in general lower than predicted both lesions and blood. However, patient 7, with diffuse miliariform lesions in lungs, showed a post-therapy lung absorbed dose 3 times higher than predicted, with suspect cough at 3 months, but without breathing capability reduction at spirometry. Patients 3 & 4, with masses of 106 and 33 cm3 at sacrum and skull respectively, previously unsuccessfully treated with external beam, showed complete response at 124I and are still showing Tg complete response after 28 and 12 months. ***Conclusion:*** 124I PET showed higher diagnostic sensitivity than post-therapy 131I SPECT/CT. Predictive lesion dosimetry was less important than blood dosimetry, since heterogeneity of predicted absorbed dose seldom allowed a true optimisation, leading rather to maximization, especially with bone metastases. The study is funded by the AIRC Foundation.

EP-0946

Estimating lung lesion mass for dosimetry purposes using an oversized VOI in CT images

L. Mikalsen, *M. Stavrinou, T. Husevåg, C. Stokke; Oslo University Hospital, Division of Radiology and Nuclear Medicine, Oslo, NORWAY.*

Aim/Introduction: Mass estimates are important to compute absorbed doses in therapeutic nuclear medicine. Here, we show that an oversized VOI can be used in CT images to measure the lesion volume without delineating its perimeter by inverting the partial volume effect. This "partial volume"-based method is evaluated for CT lung lesions in an anthropomorphic phantom, using a hybrid SPECT/CT and a diagnostic CT. ***Materials and Methods:*** The Kyoto Lungman phantom was used with six different spherical lung lesions of different diameters (5-12 mm) and densities (-800, -630 and +100 HU), placed at diverse locations relative to the bronchial structures of the phantom. Nine datasets were produced from hybrid CT scans for selected combinations of exposure (130 kVp, 18 mAs, 110 kVp 27 mAs; or 80 kVp, 65 mAs), slice thicknesses (1, 3 or 5 mm), and kernels (AC, soft tissue, or lung).

Diagnostic CT scans used the clinical standard (100 kVp, 2.2 mAs, deep learning reconstruction) or low dose protocols (80 kVp, 1.2 mAs, iterative reconstruction), reconstructed with 2.5 mm slices, and using 0.625 mm slices with and without edge enhancement; 6 datasets in total. The proposed volume method uses intensity measurements from an oversized volume of interest (VOI), which contains the whole lesion and a margin of background voxels. The VOI, lesion (L) and background (BG) intensities (I) and volumes (V) are then related by VVOI×IVOI=VL×IL+VBG×IBG, and VVOI=VL+VI, giving: VL=((IVOI-IBG)/(IL-IBG))×VVOI. The lesion intensity (IL) was measured using an internal VOI. The background (IBG) was derived from the difference of two spherical VOIs both containing the full lesion. In addition, three alternative measurements were performed for comparison: Volume estimated by three diameter measurements and the ellipsoid equation; a spherical VOI; and using segmentation tools for solid and sub-solid lesions (-800 HU sphere not supported), respectively. All measurements were performed on the hospital's clinical reading system. Relative errors vs nominal sphere volume is reported (arithmetic mean ± standard deviation). ***Results:*** On the hybrid system the observed deviation a was −5±13%. The reference measurements were 8±28%, −3±19% and 18±16% (one outlier removed). On the diagnostic CT the proposed method achieved 4±9%, while the reference results were −3 ± 15 %, 13 ± 15 % and 18 ± 9 %. ***Conclusion:*** The partial volume estimate using an oversized VOI outperformed the diameter-, sphere- and segmentation based approaches. Future work should include, larger lesions, non-spherical lesions, and hand drawn reference volumes.

EP-0947

Comparison of dosimetry techniques for post-therapy 90Y Radioembolization image-based in LYSO and BGO scintillator PET scanners.

M. Cruz-Gonzalez[1], *N. Perez-Gomez[2], G. Reynes-Llompart[1], R. Martin-Vaello[1], J. Martin-Marcuartu[3], F. Camba[1], M. Crespí Busquets[3], M. Cortes Romera[3], C. Picón[1];*
[1]Physics Department Institut Catala d'Oncologia, Barcelona, SPAIN, [2]Physics Department Elche General University Hospital, Alicante, SPAIN, [3]Bellvitge University Hospital, Barcelona, SPAIN.

Aim/Introduction: Personalized dosimetry has shown its potential in improving treatment response rates and overall survival. Radioembolization post-treatment dosimetry can be computed by the direct conversion of the PET scanner activity concentration or by introducing the known injected activity in a calibration volume. No recommendations exist of which method it's more reliable, however, there is some evidence that a BGO PET calibration factor could be misleading for 90Y. This study aims to compare both dosimetric methods and evaluate the impact of detector technology. ***Materials and Methods:*** A 90Y-resin microspheres NEMA phantom underwent PET scanning to calculate activity concentration relative error. Image acquisition utilized a BGO PET-CT and a Time of Flight (TOF) LYSO PET-CT reconstructed using Q.Clear with a 2500 penalty factor. Results were validated in 21 90Y-resin microsphere patients (19 in the BGO PET and 6 in the LYSO PET). Post-TARE 90Y-resin microspheres dosimetry was performed using the Local Deposition Method with and without known activity. In the latter approach, administered activity was measured and corrected by the ratio of post and pre-treatment dose rate measurements of the vials and catheters utilizing an area detector at fixed position and reconstructed using the phantom experiment parameters. NEMA phantom activity concentration and the patients tumor dose differences by each method were studied via a Bland-Altman analysis. Additionally, the Wilcoxon signed-rank test was conducted comparing both methods. Separate analyses were performed for the LYSO and BGO PET-CT scans. ***Results:*** In the Bland-Altman analysis, all values fell within the confidence interval, with no dependencies observed with the mean tumor dose calculation. For BGO and LYSO PET-CT scans, the mean relative errors were 19% (95% CI: 1%-72%, p=0.03) and 30% (95% CI: 2%-55%, p=0.006), respectively. On the phantom side, the mean relative error difference between LYSO and BGO PET in the 90Y NEMA phantom was 44% (95% CI: 35%-64%). ***Conclusion:*** The method without administered activity consistently resulted in higher mean dose values in the tumor. The disparity between dosimetric methods was more pronounced in LYSO PET acquisitions than in BGO PET acquisitions, contrary to the expected results. More work should be done 90Y-resin microspheres PET calibration and standard measurements of post-treatment administered activity in order to standardize post-treatment dosimetry.

EP-0948

Quantifying the impact of residual activity on therapeutic index: an updated dosimetric comparison between [^{177}Lu]Lu-PSMA-10.1 and [^{177}Lu]Lu-PSMA I&T

A. Rinscheid[1], *A. Dierks[2], M. Kircher[2], C. Pfob[2], R. A. Bundschuh[2], C. Lapa[2];*
[1]Medical Physics and Radiation Protection, University Hospital Augsburg, Augsburg, GERMANY, [2]Nuclear Medicine, Faculty of Medicine, University of Augburg, Augsburg, GERMANY.

Aim/Introduction: Radiohybrid ligands to the prostate-specific membrane antigen (PSMA) are a new group of theranostic agents with favourable pharmacokinetic properties compared to the conventional vectors used in radioligand therapy (RLT). We previously compared one of these radioligands, [177Lu]Lu-rhPSMA-10.1 (rh10), with [177Lu]Lu-PSMA I&T (I&T) in patients with metastatic castration-resistant prostate cancer (mCRPC) [1]. However, residual activities within the organs and tumours from the initial administration were not factored into the second set of dosimetry measurements. This can have a notable effect when radioligands with long tumour retention times such as rh10 are used. Here we investigate the influence of these residual activities on the therapeutic index TI (ratio of mean tumour absorbed dose to renal absorbed dose). ***Materials and Methods:*** Comparative dosimetry was performed for four patients (P1-P4) with advanced, histologically proven mCRPC. Each patient received ~1 GBq of rh10.1 and ~1GBq of I&T separated by a period of 7 days. For P1, P3, P4 the first radioligand administered was rh10, P2 started with I&T. Renal and tumour absorbed doses were determined using four SPECT/CT scans up to one week post injection. For the second radioligand, the absorbed doses were corrected for residual activities by taking into account the extrapolated portion of the area under the time-activity curve of the first radioligand. The TI of both radioligands were compared with and without the correction for residual activities. ***Results:*** The TI for I&T decreased in P1, P3, P4 by 66%, 34% and 23%, respectively, when considering residual activities from previous administration of rh10. This is mainly due to an almost unchanged corrected renal dose (maximal reduction of −3%), but a median decrease in tumour absorbed doses of 33% (minimal and maximal decrease: 22%, 100%). Thus, the ratio of the TI for rh10 to I&T increased from 1.3 to 3.8 in P1, from 1.8 to 2.7 in P3 and from 1.1 to 1.4 in P4. For P2 (I&T first), corrections of tumour and renal absorbed doses for rh10 were negligible (less than 0.5% and 2% reduction respectively). ***Conclusion:*** When comparing two radioligands using dosimetry, residual activities from first dosimetry should be taken into account for second dosimetry if

radioligands with long retention times are used. This additional analysis demonstrates an even greater improvement in TI for rh10 compared to I&T, than previously published values. ***References:*** [1] Rinscheid et al., J Nucl Med, 2023, 1;64(12):1918-1924.

Pharmacokinetic time-dependence and dose-rate effect in molecular radiotherapy - comparing therapeutic potential of different radionuclides?

V. Reijonen[1], *V. Ahtiainen[1], K. Kiviluoto[2], M. Tenhunen[1];*
[1]Helsinki University Hospital Cancer Center, Helsinki, FINLAND,
[2]Helsinki University Hospital Pharmacy, Helsinki, FINLAND.

Aim/Introduction: In molecular radiotherapy (MRT), absorbed doses D(Gy) to tissues are calculated by integrating time-activity curves (TACs). Today, this can be done in a voxel-wise manner and utilizing efficient dose calculation algorithms. As we readily determine TACs in MRT, radiobiological effect of dose-rate could be used in calculation of biologically effective dose (BED). Furthermore, this can be studied to hypothesize, which radionuclide has the best therapeutic potential depending on the radiobiological (RB) parameters of critical organs and tumors. ***Materials and Methods:*** We performed calculations for altogether ten β- decaying radionuclides. We assumed traditional bi-exponential PK functions of a pharmaceutical leading to TACs of the form $A(t)=C(e^{-at}-e^{-bt})e^{-\lambda t}$ in 1) a critical organ K (dose-limiting organ, e.g. kidney) and 2) a tumor lesion T. Biologically effective dose to tumor was then calculated as $BEDmax(\tau)=D(\tau)+G(\tau)D2(\tau)/\alpha/\beta-k\tau$, where $dBEDT(t)/dt=0$ at $t=\tau$. We defined therapeutic ratios RD=DT/DK ("apparent") and RBED=BEDT/BEDK ("effective"). Moreover, we analyzed behavior of a restricted relative ratio defined as RRR(%)=BEDT,2/BEDT,1, when BEDK,2=BEDK,1 ("critical organ dose limit per cycle"; also, see [1]), to sketch the potential difference in therapeutic efficacy of different radionuclides. ***Results:*** RRR was 69% for Y-90 (C=25 MBq, τ=8 d), 108% for I-131 (86 MBq, 15 d), 132% for Pr-143 (48 MBq, 20 d), 61% for Sm-153 (101 MBq, 6 d), 102% for Tb-161 (84 MBq, 14 d), 51% for Ho-166 (55 MBq, 4 d), 115% for Er-169 (155 MBq, 17 d), 199% for W-185 (121 MBq, 32 d), and 229% for H-3 [sic] (2320 MBq, 38 d) when compared to Lu-177 (BEDT=8.8 Gy; 116 MBq, 14 d), with the following parameters: BEDK=5.0 Gy; the biological clearance parameter aK=0.015 h-1, the biological uptake parameter bK=0.2 h-1, the alpha-beta ratio α/βK=3 Gy, the repair half-life tμ,K= 2 h, and the repopulation factor kK=0 for the critical organ; respectively, aT=0.002 h-1, bT=0.1 h-1, α/βT=10 Gy, tμ,T=1 h and kT=0.3 Gy/day for the tumor; we set CK=CT and mass mK=mT=0.1 kg. Local energy deposition of beta radiation was assumed. Subsequently, we studied the behavior of RD, RBED and RRR as a function of varying tissue PK and RB parameters. ***Conclusion:*** We used the Lea-Catcheside factor based radiobiological modeling of dose-rate effect in MRT, and calculated BEDs with exemplary PK and RB parameters. Several β- decaying radionuclides were compared to observe the effect of different beta energies and physical half-lives. ***References:*** 1. Abou-Jaoudé W, Dale R. Cancer Biother Radiopharm. 2004 Jun;19(3):308-21.

EP-0950

A Novel Approach to Biologically Effective Dose Calculation for Various Dose Rate Scenarios

M. Macsuka[1], *R. W. Howell[2], K. A. Vallis[1], D. R. McGowan[1,3];*
[1]Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM, [2]Department of Radiology, New Jersey Medical School, Newark, NJ, UNITED STATES OF AMERICA, [3]Department of Medical Physics and Clinical Engineering, Oxford University Hospitals NHS Foundation Trust, Oxford, UNITED KINGDOM.

Aim/Introduction: Organ dose limits and tumour dose-response correlations in radiopharmaceutical therapy (RPT) are often sought by considering the biologically effective dose (BED) and the equieffective dose in 2 Gy fractions (EQD2). These metrics depend on models that include not only the physical dose, but also various radiobiological parameters characterising the radiosensitivity and damage repair capacity of tissues of interest. Such mechanistic radiobiological models necessitate the BED and EQD2 to depend explicitly on the dose rate and the rate of sublethal DNA damage repair. These dependencies are usually assumed to take the form of a monoexponential, whereas two or more phases are often more appropriate to describe especially the dose rate function. ***Materials and Methods:*** Assuming simple exponential decay for DNA damage repair and a biexponential function for dose rate decay, we rederived the solution for the BED in a closed analytical form. We also arrived at a novel solution for the case of piecewise-defined dose-rate functions, which relies on both numerical and analytical ideas. These two approaches are widely used to model [177Lu]Lu-DOTATATE clearance if comprehensive dosimetry is available. Both expressions were validated using simulated measurements by comparison with a fully numerical method. We further investigated the reliability of the fully numerical, fully analytical, and hybrid methods when attempting to simplify a comprehensive dosimetry protocol. Using publicly available clinical data of two patients undergoing [177Lu]Lu-DOTATATE therapy, we defined the ground truth dose rate as the best biexponential fit to four post-injection SPECT measurements on the organ level and explored the differences in BED and EQD2 values when omitting the last measurement. ***Results:*** It was found that our approaches are accurate and the numerical method converges to our analytical solutions with increasing extrapolation time after injection. A 0.1 Gy difference between methods may necessitate running the numerical method for up to 1300 hours, at which point it may fail due to overflow errors. On the clinical dataset we found that the numerical, hybrid, and analytical approaches underestimated the ground truth to tumours by 15.6 +/- 9.4 %, 5.0 +/- 4.2 %, and 1.5 +/- 2.9 %, respectively, in EQD2 and BED. ***Conclusion:*** As it is often desirable to perform comprehensive dosimetric studies in RPT using more accurate measurements, it is equally important for radiobiological models to match their accuracy, at least theoretically. Our results show that the proposed methods are accurate, scalable, and suitable for radiobiologically motivated RPT dosimetry.

EP-0951

Modelling of the DNA Damage Response in Blood Cells of Patients during Treatment with ^{177}Lu-PSMA

S. Schumann[1], *M. Lassmann[1], H. Scherthan[2], U. Eberlein[1];*
[1]University Hospital Würzburg, Würzburg, GERMANY,
[2]Bundeswehr Institute of Radiobiology affiliated to the University of Ulm, Munich, GERMANY.

Aim/Introduction: The aim of the study was to apply a previously developed compartment model [1] to describe patient-specifically

the absorbed-dose-dependent DNA damage response in peripheral blood mononuclear cells (PBMCs) during treatment with 177Lu-PSMA. For this purpose, we used an already published data set [2]. ***Materials and Methods:*** Blood samples collected at up to 96h after therapy start were analysed for radiation-induced gamma-H2AX+53BP1 foci (RIF) as markers of DNA double-strand breaks (DSBs) in PBMCs, including blood-based dosimetry [3]. To describe the time course of the number of RIF, a linear compartment model was applied assuming that the change in RIF is proportional to the dose rate. The induction is described by a proportionality constant c and the repair by fast (k1) and slow (k2) repair rates [1]. Fits were performed for all patients separately taking into account patient-specific blood dosimetry data. ***Results:*** 16 patients were eligible for this study. Five patients had to be excluded (four due to missing late time points, one because of an uncertainty of the fit variables larger than the variables themselves). In all other patients, the RIF data were described well by the model (r2>0.78 except P15 with r2=0.64). Fit parameters differed substantially between patients. The median value of c is 0.021mGy-1 (min: 0.008mGy-1; max: 0.065mGy-1). Only a single slow repair component k2 could be deduced for 4 patients (median 0.054h-1, min: 0.047h-1, max: 0.075h-1). For seven patients, in average 83% of the damage is repaired with k1 varying between 0.17h1 and 1.75h-1, while k2 ranged from 0.002h-1 to 0.075h-1. Our analysis revealed that patients can be allocated to three groups based on their k1/k2-values: Patients with faster repair rates (n=3, k1>1.1h-1) and slower repair rates (n=4, 0.2<k1<0.7h-1), and four patients with a very slow repair rate (k2 only, <0.075h-1). ***Conclusion:*** The results of our model describe patient-specific DNA damage response well and are for seven patients in good agreement with our previous data on patients after radioiodine treatment [1]. Repair rates also vary strongly between individual patients. The reason why four patients failed to show the fast repair rate k1 needs to be investigated in further studies with a larger patient cohort. ***References:*** [1] Schumann et al., EJNMMI 2023 suppl., p.S362 [2] Schumann et al., EJNMMI 2019, p.1723 [3] Eberlein et al., EJNMMI 2015, p.1739.

EP-0952

Assessment of DNA Double-Strand Breaks in Lymphocytes after Ex Vivo Internal Irradiation: A Monte Carlo Simulation Approach Using Thirty-one Experimentally Unexplored Radionuclides

M. Salas Ramirez, *M. Lassmann, U. Eberlein;*
Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY.

Aim/Introduction: The aim of this study is to apply a Monte Carlo simulation model [1], validated by experiments with the DNA damage assay [4,5] to assess the radiation-induced double-strand breaks (DSBs) in lymphocytes nuclei after internal ex vivo irradiation of whole blood at low absorbed doses (≤100 mGy) using experimentally unexplored radionuclides. ***Materials and Methods:*** The Monte Carlo simulation model integrates GATE [2] at the macroscopic level and Geant4-DNA [3] at the cellular level. The simulations reproduce ex vivo internal irradiation experiments of whole blood [4, 5] using an 8 ml vial filled with water and containing a concentration of 125 spheres/ml (3.75 µm radius) mimicking the lymphocytes. 31 radionuclides were simulated (e.g., 47Sc, 60Co, 137Cs, 211At, 212Pb, and 228Th). For alpha emitting radionuclides, the entire decay chain was simulated except when involving a daughter with a long half-live (>15 days). For these, the decay chain was truncated at the long-lived daughter (e.g., 222Rn decay chain truncated at 210Pb). Several parameters were calculated inside the lymphocyte nucleus (water sphere of 3.1 µm radius) from the simulations, including the S-value, DSBs·cell-1·mGy-1, αtracks·cell1·mGy1, and DSBs·µm-1 (for alpha emitters only). ***Results:*** For beta- and gamma-emitting radionuclides, the S-values vary between 0.2E-4±0.1E-4 mGy·MBq1·s1 (57Co) and 0.020±0.001 mGy·MBq1·s1 (110mAg). For alpha-emitting radionuclides, S-values vary proportionally with the length of the decay chain (0.10±0.01 mGy·MBq1·s1 for 210Po and 0.62±0.04 mGy·MBq1·s1 for 227Th]. The mean number of DSBs induced by beta- and gamma-emitting radionuclides was 0.012±0.002 DSBs·cell-1·mGy-1. The mean number of α-tracks by alpha-emitting radionuclides was 0.0016±0.0001 α-tracks·cell1·mGy1. Furthermore the number of DSBs·µm-1 produced by α-particles showed a dependence on the average deposited energy per α-particle (MeV/α-particle): 15.7±0.1 DSBs·µm-1 for 210Po (0.52 MeV/α-particle) and 9.1±0.1 DSBs·µm-1 for 213Bi (0.39 MeV/α-particle). ***Conclusion:*** This study provides new insights into DNA damage induction in lymphocytes after internal ex vivo irradiation for radionuclides not accessible for experimental validation. For all radionuclides studied, the number of radiation-induced DSBs and α-tracks per mGy show little variability; thus further encouraging the use of the DNA damage assay for biodosimetry. ***References:*** [1] Salas-Ramirez, M. et al. ZMedPhys. 2023 [2] Jan S. et al. Phys Med Biol, 2004.

EP-0953

Biological radiation effect of 662 keV photon radiation and ^{186}Re β-radiation on the human B-cell line BV-173

C. Happel, *J. Staudt, B. Bockisch, W. T. Kranert, R. A. Werner;*
Goethe University Frankfurt; University Hospital; Department of Nuclear Medicine; Clinic for Radiology and Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: To evaluate and compare the radiation effects of 186Re as a β^--emitter and 662 keV photon radiation on prae-B-lymphocytes regarding biological impact of high and low dose rate irradiation. ***Materials and Methods:*** Prae-B-lymphocytes of the human leukemia Cell line BV-173 were exposed with photon radiation (662 keV) or the β^--emitter 186Re. Viability and number of cells were evaluated daily within an incubation oeriod of one week. Survival curves were constructed and analysed. The MIRD 3.1 based equivalent dose for 186Re incubation was calculated on the basis of considering dose decline in border- and ground area of culture bottles filled with liquid solutions. ***Results:*** Survival curves in both of the investigated types of radiation showed a biexponential progress (72 h after start for 186Re and 24 h for photon radiation). For photon radiation, this can be explained by the existence of a radiosensitive lymphocyte subpopulation, for which there is a D0 of 3.3 Gy, for the other portion the D0 is 10 Gy. For the 186Re incubation there is a D0 of 10 Gy at low doses caused by the repair of sublethal damage, which weakens the biological effect. From an accumulated dose of 3.1 Gy within one cell cycle, a significantly steeper curve with a D0 of 5 Gy emerges for 186Re, which reflects a biological effect that is twice as strong as photon radiation in this range (D0 5 Gy for 186Re or 10 Gy for photons). ***Conclusion:*** Radiation at low dose rates weakens the biological effect in areas of low dose rates. There is a limit value for the accumulated dose within a cell cycle, beyond which the biological effect of β--radiation even exceeds that of photon radiation.

Radiolabeling of RGDFK with 113mIn and preliminary biological evaluation in mice bearing U87MG tumors

B. Alirezapour, *F. Badipa, F. Bolorinovin, F. Motamedi Sedeh; Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Phenomenon of angiogenesis as a very effective factor on the growth and spread of cancer cells is the molecular interactions between the components of the extracellular matrix and vascular cells. Integrin αvβ3 is a critical receptor that affects tumor growth and invasion, metastasis, and angiogenesis. Aims of this study are optimization of the peptides radiolabeling by Indium-113m radionuclide and production of suitable radiopharmaceuticals for imaging studies of the αvβ3 Integrin expressing cancers. ***Materials and Methods:*** For the 113mIn labeling Briefly, 20 nmol of DOTA-RGDFK peptide was dissolved in 20 µL of ultrapure water and incubated with 4 mCi (148 MBq) of 113mIn for 15 min at 95°C, pH=3.5. After 15 min the reaction was stopped with 8 ml of WFI water and for more purification the product passed through C18 cartridge. 113mIn -DOTA-RGDFK product was then evaluated by analytical RTLC, the radioactive peak containing desired product was collected. Stability test was checked in the human serum and in PBS buffer, radiolabeling yield, radiochemical purity, cell studies on U-87 MG cell lines, biodistribution study in tumor bearing mice (n=3) at 15, 30, 60 and 120min (expressed as %ID/g) and imaging study were examined. ***Results:*** The percentage of radiochemical purity was 100%. 78% radiolabeling yield. In the stability studies section, which were performed in PBS buffer and human blood serum in 0, 60, 90 and 120 minutes. In general obtained result showed that, the stability of the labeled peptide in PBS buffer is higher than human serum in all times of the study, but overall, in both compounds, the stability has been decreased over time, the result indicated radiochemical purity of 96% in PBS buffer and 94% in human serum after 120 min. Constant values of Kd = 17.8 ± 2.9 nM was obtained indicating the high affinity of In113m -DOTA-RGDFK towards U-87 MG cell line overexpressed αvβ3 receptors. Biodistribution study was performed in mice bearing U87MG tumors at time intervals (15, 30, 60, and 120) minutes after the injection, expressed as percentage of injected dose per gram of tissue (%ID/g), biodistribution study and imaging study of free 113mIn and 113mIn -DOTA-RGDFK showed similar accumulation pattern to the other radiolabeled RGDFK compounds. ***Conclusion:*** 113mIn -DOTA-RGDFK is a potential compound for SPECT imaging of the cancer cells expressing αvβ3 integrin. ***References:*** 1. Radiopharmaceutical properties of hydroxyapatite smaller than 50 nm produced from eggshell and labeled with Tc-99m and its biodistribution in rabbits

A. Gültekin[1], *A. Uğur[2], M. Sulak[3], S. Demirezen[1], D. Yüksel[1];*

[1]Pamukkale University Medical Faculty Department of Nuclear Medicine, Denizli, TÜRKIYE, [2]Pamukkale University Education and Research Hospital Department of Nuclear Medicine, Denizli, TÜRKIYE, [3]Pamukkale University Faculty of Education Department of Mathematics and Science Education, Denizli, TÜRKIYE.

Aim/Introduction: Radiolabeling of nanoparticles has potential benefits for personalized treatments and theranostic applications, which have been on the agenda in recent years. Hydroxyapatite nanoparticles (HANPs), which have a great similarity to bone tissue, stand out as a biocompatible nanoparticle. The different biodistribution properties of hydroxyapatite molecules in different nanosizes may create new opportunities for their use, especially in bone imaging and in the treatment of bone tumors. This study aims to investigate the labeling of hydroxyapatite molecules smaller than 50 nanometers obtained from eggshells with technetium 99m (99mTc) and the in vivo distribution of this molecule in rabbits. ***Materials and Methods:*** Characterization of nanohydroxyapatite particles obtained from eggshells was performed using SEM, EDX, and XRD. Radiolabeling of HANPs smaller than 50 nm with 99mTc radionuclide, stability of the labeled product, and biodistribution profile in rabbits were investigated. ***Results:*** The radiochemical purity of the 99mTc-HANPs was obtained as 96%. The in vitro stability of 99mTc labeled HANPs was examined for up to 12 hours and showed excellent in vitro stability for the first 4 hours in saline. 99mTc-HANPs remained stable in vivo during the 6-hour imaging period. In quantitative analysis, 99mTc-HANPs showed accumulation in bone tissue in the second hour. ***Conclusion:*** 99mTc-HANP nanoradiopharmaceuticals with sizes less than 50 nanometers (20-31 nm) showed high uptake in bone tissue in rabbits. Therefore, HANPs can be developed as imaging radiopharmaceuticals in bone tissue and bone cancers. ***References:*** 1. Kalash RS, Lakshmanan VK, Cho CS, Park IK. Theranostics. In: M. EP-0956

Preclinical evaluation of a nanobody-based SPECT radiotracer ^{99m}Tc-AFN with clinical potential for noninvasive monitoring of fibroblast activation after myocardial infarction

X. Zhang; *Beijing Chao-Yang Hospital, Beijing, CHINA.*

Aim/Introduction: Combining nanomolar affinities and fast blood clearance, nanobodies represent potential radiotracers for cardiovascular molecular imaging1. In this study, we developed a 99mTc-labeled nanobody (99mTc-AFN) with high affinity to fibroblast activation protein (FAP) and explored the feasibility of using 99mTc-AFN for noninvasive monitoring of fibroblast

activation after myocardial infarction (MI). ***Materials and Methods:*** 99mTc-AFN was prepared by site-specific labeling. Ischemia/reperfusion (I/R) mice were constructed for SPECT/CT imaging and biodistribution studies. A series of dynamic imaging from 0.5 to 4 h after injection of 99mTc-AFN was performed in the I/R mice on day 7. Furthermore, I/R mice were subjected to 99mTc-AFN SPECT/CT imaging on postoperative days 3, 7, 14, and 28 at 1 h post injection (p.i). Ex vivo imaging, blocking imaging, and biodistribution studies were performed on day 7, and compared with a 99mTc-labeled FAPI-04-derived radiotracer, HYNIC-FAPi-04 (HFAPi) 99mTc-HFAPi. H&E staining, Masson's staining, and immunohistochemistry were performed to verify the cardiac remodeling after I/R. Pre-clinical evaluation of 99mTc-AFN in a swine model of MI was performed to further explore the feasibility of monitoring activated fibroblasts after MI on day 7. ***Results:*** Dynamic imaging showed that accumulation at infarcted region was most clearly visible at 1 h p.i. 99mTc-AFN uptake in the infarcted myocardium was visible from day 3 and peaked on day 7 after I/R. At 1 h p.i. Both the 99mTc-AFN uptake ratios of the infarcted/noninfarcted region and the infarcted region/blood at 1 h p.i. were higher than that of 99mTc-HFAPi (2.23 ± 0.82 vs. 1.34 ± 0.21; 1.08 ± 0.49 vs. 0.89 ± 0.42). H&E staining, Masson's staining, and immunohistochemical examinations confirmed that myocardium fibrosis and FAP expression reached peak on day 7 after I/R. 99mTc-AFN uptake in the infarcted myocardium was also clearly visualized on day 7 after MI in the swine model. ***Conclusion:*** This study demonstrated the potential of 99mTc-AFN for noninvasive monitoring of fibroblast activation after MI. Moreover, 99mTc-AFN holds the advantages of faster blood clearance and better target-to-background ratio than 99mTc-HFAPi, which provides a new option for clinical imaging. ***References:*** 1. Synthesis and evaluation of a novel PSMA-targeted EuK-based radiotracer (^{99m}Tc-IDA-EuKfG) from in silico to in vivo study

B. Lee[1,2], *J. Choi[1], S. Lee[3,4], W. Lee[1], G. Mangiatordi[5], D. Yoon[1,2], W. Lee[1], H. Im[2,4], H. Youn[3,4];*
[1]Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, KOREA, REPUBLIC OF, [2]Graduate School of Convergence Science and Technology, Seoul National University, Seoul, KOREA, REPUBLIC OF, [3]Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [4]Cancer Research Institute, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [5]Institute of Crystallography, National Research Council of Italy, Bari, ITALY.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is a well-known biomarker for nuclear diagnostics and radionuclide therapy (theranostiscs) in prostate cancer (PC). In this study, we intended to discovery the promising EuK derivatives with aromatic amino acids including comparison with L-/D-isomers for PSMA-targeting. Among them, EuKf-based derivative was utilized to develop the new PSMA-targeted theranostics by incorporating a 99mTc or 188Re-tricarbonyl complex. ***Materials and Methods:*** EuK-based derivatives including L-/D-aromatic amino acids (n = 8) were evaluated by molecular docking simulations with the crystal structure of PSMA, and followed by in vitro competitive binding assay with 125I-MIP-1095. The authentic compound and radiotracer were prepared by 185/187Re-/99mTc-(CO)3 incorporation to the precursor (IDA-EuKfG), respectively. Specific cellular uptake and efflux assay of 99mTc-IDA-EuKfG were carried out with PC cells. In vivo biokinetics and tumor imaging properties of 99mTc-IDA-EuKfG was evaluated in orthotopic PC and LNCaP-bearing animal models comparing with 68Ga-PSMA-11. ***Results:*** EuKf derivative was shown the highest binding affinity (IC50 = 2.3 nM) and thermodynamically binding free energy (– 68 kcal/mol). Likewise, Re-IDA-EuKfG showed high binding affinity (IC50 = 3.0 nM) to PSMA. 99mTc-IDA-EuKfG was prepared in high radiochemical yield (>80%) and molar activity (>3.7 TBq/mmol). Comparing to 68Ga-PSMA-11, 99mTc-IDA-EuKfG showed higher accumulation (42%) and internalization (12%) prolonged retention within PC cells after 1 h incubation. The tumor uptake of 99mTc-IDA-EuKfG was comparable to that of 68Ga-PSMA-11. Notably, negligible salivary gland uptake of 99mTc-IDA-EuKfG was observed. ***Conclusion:*** We identified the chirality of amino acid in EuK-based radiotracer as a crucial factor in determining PSMA binding properties. Our new PSMA-targeted radiotracer, 99mTc-IDA-EuKfG, exhibited desirable PSMA binding potency, effective cell internalization in PC cells, and significant tumor accumulation in the PC model. These findings highlight the potential of the novel PSMA ligand IDA-EuKfG as a promising theranostic agent for developing PSMA-targeted theranostics.

New radio-labelling approaches in OMV biodistribution

K. Szigeti[1], *Z. Varga[2], D. Szöllősi[1], P. Padmanabhan[3], B. Gulyás[3], R. Bergmann[4], D. Mathe[5];*
[1]Semmelweis University, Budapest, HUNGARY, [2]HUN-REN Research Centre for Natural Sciences, Budapest, HUNGARY, [3]Nanyang Technological University, Singapore, SINGAPORE, [4]Helmholtz-Zentrum Dresden-Rossendorf, Budapest, HUNGARY, [5]Hungarian Centre of Excellence for Molecular Medicine, Szeged, HUNGARY.

Aim/Introduction: Radio-labeling techniques have become an important area of molecular imaging in the study of biological vesicles, extracellular vesicles (EV), outer membrane vesicles (OMV) and platelets. This research focuses on the development of new isotope-based labelling methods for quantitative in vivo imaging, which improve the determination of the biodistribution and understanding the function of these vesicles. ***Materials and Methods:*** Three radiolabeling approaches were used in our work. Eukaryotic EVs were labeled with 99mTc-tricarbonyl. OMVs isolated from a novel E. coli strain were labeled with two different approaches: i) 64Cu labeling was carried out using SpyTag-NODAGA conjugates and outer membrane-anchored SpyCatcher; while ii) HYNIC-duramycin was used for 99mTc labeling. High-resolution biodistribution data in mouse models were obtained using several imaging techniques: SPECT and PET/MRI. ***Results:*** 99mTc-labeled EVs predominantly accumulated in liver and spleen, demonstrating the method's in vivo efficacy. OMVs labeled either with 64Cu or 99mTc-duramycin exhibited stable and specific biodistribution patterns, aligning with previous findings. Together, these in vivo imaging studies demonstrate the importance of radio-labelling in understanding the function of biological vesicles. They provide novel insights into vesicle biodistribution and open new way for diagnostic and therapeutic applications. ***Conclusion:*** Our aim is to demonstrate that these methods hold significant potential for molecular imaging and the development of targeted therapeutic strategies.

^{68}Ga-radiolabeled triphenylphosphonium PET tracers for rhabdomyosarcoma tumor targeting

C. Yang[1,2], *A. Loh[3,2], W. Lam[1,2], D. Ng[1,2], Y. Khor[1,2];*
[1]Singapore General Hospital, Singapore, SINGAPORE, [2]Duke-NUS Medical School, Singapore, SINGAPORE, [3]KK Women's and Children's Hospital, Singapore, SINGAPORE.

Aim/Introduction: The lipophilic organic cation triphenylphosphonium (TPP) is a molecular probe targeting mitochondria. A series of TPP derivatives have been successfully labeled with the 64Cu radioisotope to image glioma tumors rich in mitochondria in mice, yielding promising outcomes. Our goal is to develop 68Ga-radiolabeled TPP tracers for rhabdomyosarcoma tumors and to investigate the impact of the targeting moiety and bifunctional chelator on the tracers' biodistribution. ***Materials and Methods:*** Radiolabeling of 68Ga to four TPP ligands (DO3A-xy-TPEP, DO3A-xy-TPP, NOTA-xy-TPEP, NOTA-xy-TPP) was achieved by reacting a 68Ga solution (2.0-3.0 mCi) in 0.05 N HCl from a 68Ga generator with the ligands in 0.1 M NaOAc buffer (pH 5.0 - 5.5) at 100 °C for 30 min. After cooling the mixture to room temperature and purifying it using a C-18 cartridge, a sample of the resulting solution was analyzed by radio-TLC. The 68Ga radiotracers (~2 MBq) were administered to rhabdomyosarcoma tumor-bearing mice (RHB14-0120) via the tail vein. Three mice were sacrificed at each time point: 15, 30, 60, and 90 min post-injection (p.i). Organ uptake was calculated as a percentage of the injected dose per gram of organ tissue (%ID/g). ***Results:*** Radio-TLCs indicated that the radiolabeling yields for all four TPP ligands with 68Ga are approximately 70 ± 5%. After purification by a C-18 Sep-Pak column, the radiochemical yields exceeded 95%. 68Ga-DO3A-xy-TPEP exhibited the highest tumor-to-muscle ratio of 2.9 at 90 min post-injection and the highest renal uptake (19.5%ID/g at 15 min post-injection). The highest liver uptake was observed with 68Ga-NOTA-xy-TPP (8.4%ID/g at 90 min post-injection). ***Conclusion:*** The radiolabeling of four TPP ligands with 68Ga was accomplished with high efficiency, resulting in isolation of the compounds with a purity higher than 95%. Altering the TPP ligands and chelators lead to change the biodistribution and targeting capabilities of the 68Ga-radiolabeled tracers. The 68Ga-DO3A-xy-TPEP exhibited the most promising with the highest tumor-to-muscle ratio in a rhabdomyosarcoma mouse model. Further modification of TPP ligands is needed to improve targeting ability for further preclinical and possible clinical applications.

EP-0960

Basic evaluation of the heart-derived fatty acid-binding protein ligand $^{[18F]}$HY11-8

J. Toyohara[1], *T. Komoda[2], T. Tago[1], M. Ito[2], H. Yoshino[2];*
[1]Tokyo Metropolitan Institute for Geriatrics and Gerontology, Itabashi-ku, Tokyo, JAPAN, [2]Shiratori Pharmaceuticals, Narashino, Chiba, JAPAN.

Aim/Introduction: The heart-derived fatty acid-binding protein (FABP3) is involved in the intracellular transport of fatty acids and is known to be abundantly expressed in cardiac and skeletal muscles. We previously discovered the compound HY11-8, which has high affinity for FABP3 [1]. In the present study, we attempted to radiolabel HY11-8 with fluorine-18 and evaluate its pharmacokinetics and potential as a novel myocardial imaging agent. ***Materials and Methods:*** Radiosynthesis of $^{[18F]}$HY11-8 was performed by 18F-fluorination of the corresponding pinacol boronic acid ester precursor and subsequent deprotection of the ethyl ester protecting group. A mouse biodistribution study was conducted to analyse radioactive metabolites in plasma and myocardial tissue. In addition, dynamic changes of radioactivity in the myocardium were measured using small-animal PET/CT. ***Results:*** The decay-corrected radiochemical yield of $^{[18F]}$HY11-8 was 17.9±3.5% (n = 5; range, 14.5-23.6%), and the radiochemical purity was 99.8±0.1% (n = 5; range, 99.7-99.9%). The molar activity was 256.8±162.8 MBq/nmol (n = 5, range, 109.4-488.2 MBq/nmol). A biodistribution study showed rapid clearance of radioactivity from the blood, high accumulation of radioactivity in the heart, and low accumulation of radioactivity in background tissues such as lung and liver. Furthermore, the accumulation of radioactivity in bone, which is an indicator of defluorination in vivo, was low and the stability of the 18F label in vivo was considered high. Metabolic analysis revealed that $^{[18F]}$HY11-8 was stable in the mouse body and was present mostly in the unchanged form in the plasma and myocardium. In PET measurements of small animals, the heart was clearly visualised and showed an accumulation pattern over time. ***Conclusion:*** The present results suggest the potential use of $^{[18F]}$HY11-8, a ligand that binds to FABP3, as a novel myocardial imaging agent. ***References:*** [1] Guo et al., Redox Biol. (2023) 59:102547.

EP-0962

GMP validation (CMC) and Radiation dosimetry for clinical application of a novel α7-nAChR radioligand: [^{11}C]Kln83

K. Jia[1], *S. Nag[2], P. Datta[1], A. Morén[1], M. Bolin[1], H. Asem[1], H. Ågren[3], B. Långström[3], C. Halldin[2], A. Nordberg[1];*
[1]Karolinska Institutet, Solna, SWEDEN, [2]Karolinska Institutet, Stockholm, SWEDEN, [3]Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Nicotinic acetylcholine receptor (α7-nAChR), is closely associated with cognitive functions, memory formation, and attention processes. Utilizing PET imaging to map the α7-nAChR has gained significant attention for understanding the mechanisms and progression of central nervous system disorders like Alzheimer's disease (AD), Parkinson's disease (PD)1. In our earlier work, we described the development of a new α7-nAChR radioligand, [^{11}C]Kln83, and assessed its biological properties2. The aims of this current PET study were (i) to offer dosimetry assessments for [^{11}C]Kln83 utilizing NHP whole-body PET data and (ii) to verify the GMP-compliant production of [^{11}C]Kln83 (CMC) for potential clinical use. ***Materials and Methods:*** Two female cynomolgus monkeys were utilized for whole-body PET scans. Regions of interest (ROIs) were drawn for anatomical structures including the brain, heart, liver, lung, kidney, gall bladder, bone, urinary bladder, stomach, small intestine, spleen, and pancreas based on CT images. Using the OLINDA/EXM 1.1 software and the adult reference model (70 kg), absorbed radiation dose estimates for humans were subsequently calculated. The production of [^{11}C]Kln83 underwent validation procedures in accordance with current Good Manufacturing Practices (cGMP). The radiolabeling and delivery of the product [^{11}C]Kln83 were carried out using an automated synthesis module within a tightly controlled GMP setting. Quality control tests and product specifications adhered to the guidelines outlined in the European Pharmacopoeia.

Results: The radioactivity injected was 150 MBq for one NHP and 155 MBq for the other. The estimated radiation dose was 0.0047 mSv/MBq. In humans, up to 400 MBq can be injected, resulting in a total radiation exposure of <2 mSv. This level of exposure is comparable to that of other 11C-labeled radioligands. During the process validation, three consecutive batches of [^{11}C]Kln83 solution for injection were manufactured successfully. Throughout the validation process, thorough quality control measures are implemented. Radiopharmaceutical batch release criteria are established, including testing for physical appearance, filter integrity, pH, radiochemical purity, molar activity, radiochemical identity, chemical impurity, structural identity, stability, residual solvent, sterility, and endotoxin levels. ***Conclusion:*** The [^{11}C]Kln83 synthesis procedure (CMC) has been validated with successful production. Quality control tests on the final product passed all acceptance criteria. The dosimetry study showed an estimated radiation burden of 0.0047 mSv/MBq, indicating the potential for repeated scans in the same human subject due to its distribution characteristics. ***References:*** (1) Fontana, I. et al.; Acs Chem Neurosci 2024, 15, 328. (2) Nag, S.; et al. ; Acs Chem Neurosci 2022, 13, 352.

EP-0963

Synthesis and Application of meta-TDBFB for F^{18} Indirect Labeling via Suzuki Coupling

M. Ando[1], *Y. Yagi[1,2], M. Omokawa[3], H. Kimura[4], T. Higuchi[2];*
[1]Kyoto College of Medical Science, Nantan, JAPAN, [2]University Hospital Würzburg, Würzburg, GERMANY, [3]Okayama University, Okayama, JAPAN, [4]Kanazawa University, Kanazawa, JAPAN.

Aim/Introduction: Positron emission tomography (PET) uses bioactive compounds labeled with F^{18} radioisotopes as probes. The introduction of F^{18} into electron-rich aromatic rings through nucleophilic substitution reactions with the [^{18}F] fluoride ion remains challenging. We previously reported a new F^{18} labeling method using the Suzuki coupling reaction with an indirect labeling reagent, the boronic acid derivative 4-(4,4,5,5-Tetramethyl-1,3,2-dioxaborolan-2-yl)-[^{18}F]fluorobenzene (para-[^{18}F]TDBFB). In this study, we investigated the synthesis of meta [^{18}F]TDBFB and its application to PET probes. We attempted to synthesize 3-[^{18}F]fluorobiphenyl and [^{18}F]Fluprofen for the COX-2 imaging tracer. ***Materials and Methods:*** First, we investigated the conditions for the synthesis of 4- [^{18}F]TDBFB, including various F18 sources, solvents, reaction temperatures, and additives. The labeling rate of F18 fluorination was evaluated using Radio-Thin Layer Chromatography (Radio-TLC) and Radio-HPLC. Then, meta-[^{18}F]TDBFB was synthesized under optimal conditions and, [^{18}F]fluorobiphenyl and the NSAIDs derivative [^{18}F]fluprofen were synthesized with meta-[^{18}F]TDBFB as applications. ***Results:*** The [^{18}F]fluoride ion was eluted from the cation exchange resin using DMAP/OTf, and then heated at 120ºC for 20 min in dimethylacetamide, in the presence of TDBFB precursor and CuOTfPy4. This led to the confirmation of the target product on Radio-TLC. This reaction condition resulted in a 4-fold increase in yield compared to previously reported condition [1]. The reaction progress was also evaluated using meta-[^{18}F]TDBFB, yielding similar results and giving the product by Radio-HPLC purification. To synthesize 3-[^{18}F]fluorobiphenyl and [^{18}F]Fluprofen, we employed meta-[^{18}F]TDBFB with the iodo precursor for [^{18}F]fluorobiphenyl, and a triflate precursor for fluprofen, and the desired compound was obtained. ***Conclusion:*** This study supports the notion that meta-[^{18}F]TDBFB could serve as a more versatile indirect labeling reagent. ***References:*** [1]Tetrahedron Letters, 107, 154010 (2022).

EP-0964

Development of automatic synthesis system and basic evaluation of [^{18}F]FBPA synthesis from[^{18}F]HF ([^{18}F$^-$]).

Y. Kanai[1], *T. Watanabe[2], Y. Hattori[3], Y. Ohta[3], S. Naka[4], T. Sakai[5], K. Ono[1], M. Kirihata[3];*
[1]Kansai BNCT Medical Center/BNCT Joint Clinical Institute, Osaka Medical and Pharmaceutical University, Takatsuki, Osaka, JAPAN, [2]Sumitomo Heavy Industries, LTD, Tokyo, JAPAN, [3]BNCT Research center, Osaka Metroplitan University, Sakai, Osaka, JAPAN, [4]Osaka University Graduate school of Medicine, Suita, Osaka, JAPAN, [5]Hanwa Intelligent Medical Center, Sakai, Osaka, JAPAN.

Aim/Introduction: 2-[^{18}F]Fluoro-4-borono-phenylalanine (FBPA) is an important PET tracer for the determination of Boron Neutron Capture Therapy (BNCT) applicability. Now BNCT has possibility to expanding all over the world, because cyclotron based BNCT system was developed. As BNCT expands, we need more [^{18}F] FBPA radioactivity in one synthesis. Since nuclear reaction yield is larger in 18O(p, n)18F nuclear reaction than 20Ne (d, α)18F. We previously reported a novel [^{18}F]FBPA synthesis from [^{18}F]F- which is produced by 18O(p, n)18F nuclear reaction. In this study, we tried to adopt this method for automatic synthesizer. In addition, we investigated that in vivo bio-distribution of both [^{18}F]FBPA which produced by our method and traditional method. ***Materials and Methods:*** We used a modified type of MPS-200 Aβ (Sumitomo Heavy Industry, LTD, Tokyo) as the automatic synthesizer. Our method is consisted of 3 main steps. That is 18F-fluorination in the first reaction vessel (RV) 1 (80-degree and 20 min), borylation step in RV2 (110-degree and 20 min) and deprotection step in RV3 (100 degree and 5 min). A crude mixture was purified by HPLC. Finally, [^{18}F]FBPA fraction was collected after HPLC purification of the crude mixture. Radiochemical purity (RCP) and molar activity (MA) were determined by HPLC. The concentrations of n-BuOH, DMA and DMF were measured with gas chromatography. In animal experiment, about 0.5 MBq of [^{18}F]FBPA which was synthesized our method and traditional method was administrated to each tumor bearing mouse. 60 minutes after injection, mice were sacrificed and issues are removed, weighed and counted. ***Results:*** The radiochemical yield of [^{18}F]FBPA from [^{18}F]HF was more than 10% (non-decay collected). Total synthesis time from the end of bombardment was about 110 min. RCP and MA of [^{18}F]FBPA were more than 90% and 1,000 GBq/μmol, respectively. Each concentration of n-BuOH, DMA and DMF was less than 100 ppm. About 9 GBq of [^{18}F]FBPA was produced by our method with 60 min and 50 μA irradiation using 12 MeV cyclotron. In vivo study, the accumulation of FBPA prepared by both synthesis methods has no differences. It was about 12 %ID/g in tumors. ***Conclusion:*** We succeeded in synthesizing [^{18}F]FBPA from [^{18}F]HF using an automatic synthesizer. We confirmed that the FBPA synthesized by our method has enough quality for clinical use. It has bioequivalent to FBPA produced by traditional methods.

EP-0965

An improved procedure for the GMP production and formulation of the sigma-1 receptor ligand [^{18}F]FTC146 from a precursor with a chlorine leaving group

A. Marešová[1], *P. Cihlářová[1], L. Procházka[2], O. Lebeda[2], A. Popkov[3,4], C. Paul[5,6], P. Drašar[1], M. Jurášek[1];*
[1]University of Chemistry and Technology, Prague, CZECH REPUBLIC, [2]Czech Academy of Sciences, Husinec - Rez, CZECH REPUBLIC, [3]Samo Biomedical Center, Pardubice, CZECH REPUBLIC, [4]Johannes Kepler University, Linz, AUSTRIA, [5]University Hospital Bern, Bern, SWITZERLAND, [6]Queensland University of Technology, Brisbane, AUSTRALIA.

Aim/Introduction: The σ-1 receptor is a transmembrane protein implicated in various human pathologies including neurodegenerative diseases, inflammation, and cancer [1]. The previously published ligand [18F]FTC-146 is among the most promising tools for molecular imaging of σ-1 receptors in vivo using positron emission tomography (PET), with potential for clinical diagnostic and research applications [2]. However, the published six-step synthesis of the tosyl ester precursor for its radiosynthesis is complicated and time-consuming. Therefore, we designed and tested a simple procedure that facilitates the preparation of [18F]FTC-146. Instead of a tosylate-based precursor, we developed a novel one-step synthesis of the AM-16 precursor containing chlorine as a leaving group for the SN2 reaction with [18F]fluoride [3]. For further development and in consideration of possible GMP production for human PET studies, we aimed to optimize the preparative chromatographic conditions for the purification of the radiotracer and to replace the previously mobile phase additive triethylamine (TEA) [2,3] with non-toxic dimethylaminoethanol (DMAE). DMAE is a choline precursor, and unlike TEA, does not require analysis after the tracer formulation for human application. Here we present the results of optimizing preparative chromatographic purification of [18F]FTC-146. The next development step shall be to optimize the radiosynthesis to increase the radiochemical yield. ***Materials and Methods:*** To the dried [18F]fluoride was added AM-16 (4.46 µmol) in DMSO (0.6 mL). The mixture was heated to 155 °C for 5 min, quenched with mobile phase, and directly applied onto preparative HPLC (Kinetex EVO C18 Axia column, 21.2 × 100 mm; 5 mM-DMAE in H2O/EtOH, flow = 4 ml/min, step gradient of H2O/EtOH 0-5 min 60/40, 5-30 min 30/70). ***Results:*** The replacement of TEA with DMAE in the preparative chromatography was successful, giving much better separation of the tracer from its precursor compared to previously published results [3]. The radiochemical yield of the [18F]fluorination step has been significantly improved to over 20%, encouraging us to seek further optimisation. ***Conclusion:*** We successfully replaced the chromatographic additive TEA with DMAE, which should enable a simpler quality control routine for human application of the tracer. The substitution gave distinctly improved chromatographic separation of the precursor and the radiotracer, along with a significant improvement in radiochemical yield of the tracer. ***References:*** (1) Walker, J. EP-0966

Preclinical study of dual-targeted SSTR2 and FAP molecular probe ^{68}Ga-TATE-46

H. Liu, *X. Zhang, J. Zhang;*
Department of Nuclear Medicine, The First Medical Center of Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: At present, 68Ga-labeled somatostatin analogue (SSA) is the most commonly used imaging agent for neuroendocrine tumors (NETs). Among them, 68Ga-DOTA-TATE has strong selectivity for somatostatin receptor type 2 (SSTR-2) frequently expressed by NETs, but its uptake value in NETs is not ideal. To enhance the uptake of tracers in NETs, a combination of SSTR2 and Fibroblast Activation Protein was designed. FAP's dual-targeted radiotracer 68Ga-TATE-46 was evaluated and compared with 68Ga-DOTA-TATE and 68Ga-FAPI-46 to screen novel neuroendocrine tumor therapeutics suitable for 177Lu labeling. ***Materials and Methods:*** The precursor DOTA-TATE-46 was designed and synthesized from somatostatin analogue TATE and quinoline compound FAPI-46. After confirmed by mass spectrometry, 68Ga was used to label it as 68Ga-TATE-46. Its radiochemical purity and stability were verified by HPLC, and its binding affinity was evaluated at the cellular level. Preclinical studies, including micro-PET imaging and biodistribution evaluation, were performed on NCI-H727 tumor xenografts and compared with conventional 68Ga-DOTA-TATE and 68Ga-FAPI-46. ***Results:*** 68Ga-TATE-46 was easily labeled and the radiochemical purity was greater than 95%. Let it sit at room temperature for 2 hours. 68Ga-TATE-46 has high affinity for both FAP and SSTR2. The uptake and retention of 68Ga-TATE-46 were significantly higher than those of 68Ga-DOTA-TATE and 68Ga-FAPI-46 in NCI-H727-bearing mice. ***Conclusion:*** The results of this study validate the clinical potential of the dual-targeted molecular probe 68Ga-TATE-46 for PET imaging and further targeted therapy of neuroendocrine tumors, but further structural modification of 68Ga-TATE-46 is needed to accelerate the clearance rate of normal tissues.

Imaging Synaptic Vesicle Protein SV2C with 18F-UCB-F: An In Vitro Autoradiography and In Vivo NHP PET Study

S. Nag[1], *A. Forsberg Moren[1], V. Sousa[1], P. Datta[1], Y. Khani Meynaq[1], A. Valade[2], C. Vermeiren[2], P. Motte[2], J. Mercier[3], H. Ågren[4], C. Halldin[1], A. Varrone[1];*
[1]Karolinska Institutet, Stockholm, SWEDEN, [2]UCB Biopharma, Braine l'Alleud, BELGIUM, [3]Biogen MA Inc, Braine l'Alleud, BELGIUM, [4]Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: The synaptic vesicle protein SV2C protein, mainly found in the basal ganglia, is linked to Parkinson's disease through genetic studies. It plays a role in regulating dopamine release and has been disrupted in PD animal models and brain tissue from PD patients. In studying PD-related synaptopathy, SV2C could be a potential imaging target for tracking changes with disease progression and treatment. This study aims to assess [18F]UCB-F, a PET tracer for imaging SV2C in PD, previously tested in small animals. [18F]UCB-F was evaluated in-vitro using autoradiography (ARG) on rat and non-human primate (NHP) brain tissue and in vivo using NHP PET. ***Materials and Methods:*** The mesylate-precursor and UCB-F reference standard were synthesized at Eurofins Advinus, India. Radiolabeling was accomplished through fluorine-18 nucleophilic substitution reaction. The [18F]UCB-F binding distribution across regions was evaluated using autoradiography (ARG) on brain sections from rats and NHP. A blocking experiment was conducted using cold UCB-F (10 µM). The brain distribution of [18F]UCB-F binding was examined with PET in NHPs. Two PET measurements were conducted in two different cynomolgus monkeys (NHP1 and NHP2), using a high-resolution PET/CT system (LFER, Mediso). Radiometabolites were analyzed in plasma samples using gradient radio HPLC. ***Results:*** [18F]UCB-F was synthesized effectively from the corresponding precursor, yielding over 50% incorporation. At the time of administration, the molar activity was 16 and 25 GBq/µmol. The radioligand exhibited stability, maintaining a radiochemical purity of over 99% even after 2 hours of formulation in a sterile phosphate-buffered solution. ARG on brain slices from rats and NHPs showed specific binding of [18F]UCB-F in pallidum, striatum, substantia nigra and brainstem, consistent with the expression of SV2C in the brain. In NHPs, [18F]UCB-F rapidly entered the brain with a whole brain peak uptake SUV of 3.3 for NHP1 and 3.0 for NHP2 at 3 minutes. The wash-out from the brain was rapid with no

clear evidence of regional distribution. Radiometabolite studies showed the formation of only more polar radiometabolites, with approximately 15% of unchanged radioligand remaining in plasma at 15 minutes post-injection. ***Conclusion:*** [18F]UCB-F was successfully radiolabelled. In vitro, it showed specific binding on tissue slices from rodent and NHP brains. However, in-vivo, [18F]UCB-F displayed too rapid washout from the brain, lack of regional brain distribution and rapid metabolism . Overall, these findings indicate that [18F]UCB-F is not a suitable PET radioligand for imaging SV2C and additional work is needed to identify a potential candidate.

EP-0969

ImmunoPET imaging of ^{89}Zr-labeled antiTrop2 monoclonal antibody in lung cancer models

Z. Lu, *M. Shi, S. Li, Y. Liang, Z. Zou, Y. Zhou, X. Li;*
NHC Key Laboratory of Nuclear Technology Medical Transformation, Mianyang Central Hospital, School of Medicine, University of Electronic Science and Technology of China, Mianyang, CHINA.

Aim/Introduction: Lung cancer, a prominent contributor to cancer-related mortality, is frequently identified in its advanced stages as a result of insufficient early detection techniques. Recently, immuno-positron emission tomography (immunoPET) has emerged as a valuable tool for the early diagnosis of tumors. Trophoblast cell-surface antigen 2 (Trop2), a transmembrane glycoprotein, is frequently overexpressed in lung tumors and is a potential diagnostic target for early-stage lung cancer. Our study aimed to develop 89Zr-labeled anti-Trop2 monoclonal antibody (aTMAB) for immunoPET imaging and evaluate the diagnostic abilities in preclinical stage for lung cancer models. ***Materials and Methods:*** Based on the 89Y(p,n)89Zr nuclear reaction principle, 89Zr was produced using a cyclotron solid target system (11 MeV, 15 µA, 1h) and an automated separation device. The expression of Trop2 in lung cancer was determined by immunohistochemistry on tissue microarray. Flow cytometry was used to screen the Trop2 expression of lung cancer cell lines. Anti-Trop2 monoclonal antibodies were conjugated with p-SCN-Bn-DFO (DFO) for zirconium-89 (89Zr, T1/2=78.4 h) radiolabeling to construct immunoPET probe. The diagnostic accuracy of the probe was evaluated in subcutaneous lung cancer models by ImmunoPET imaging. ***Results:*** A total of approximately 14 millicuries (mCi) of 89Zr was successfully obtained, with a measured radioactive isotope purity of up to 99%. Analysis of immunohistochemical staining on tissue microarrays derived from lung cancer samples revealed a notably elevated expression of Trop2 in both lung adenocarcinoma and squamous carcinoma. Flow cytometry analysis indicated that the HCC-827 cell line exhibited the most pronounced Trop2 expression. Furthermore, the radiochemical purity of 89Zr-DFO-aTMAB surpassed 95%. ImmunoPET imaging demonstrated a substantial and specific accumulation of radioactivity from 89Zr-DFO-aTMAB in the tumor region. The uptake of the tumor exhibited a gradual increase from 1.59 ± 0.11 at 3 hours to 4.77 ± 0.48 at 144 hours, with the maximum tumor uptake value recorded at 9.58 ± 1.23 (n=3) at 144 hours post-injection. Additionally, there was a gradual decrease in radioactive uptake in the blood and liver, leading to elevated tumor-to-background ratios. ***Conclusion:*** This study successfully developed a Trop2-targeted immunoPET probe, facilitating precise visualization of Trop2 and aiding in the diagnosis of lung cancer. The findings suggest strong potential for clinical translation and offer a promising diagnostic approach for Trop2-overexpressing tumors, including lung cancer.

EP-0970

Optimization of [18F]F-FAPI-74 in-house production: technical and economical analysis

A. Morisco, *C. Maisto, R. de Marino, E. Squame, L. D'Ambrosio, M. Talamo, M. Aurilio, V. Porfidia, M. Buonanno Recchimuzzo, A. Esposito, F. Manna, S. Lastoria;*
Istituto Nazionale Tumori-IRCCS-Fondazione G. Pascale, Napoli, ITALY.

Aim/Introduction: Radiolabeled FAP Inhibitors (FAPI) rapidly gained a clinical interest as successful pantumoral PET agents, being characterized by either elevated FAP expression in tumor microenvironment and high tumor-to-background ratios. Several FAPI molecules have been tested for PET/CT imaging; among these, one of the most appealing is FAPI-74. In this study, we evaluated the optimization of in-house synthesis of [18F]F-FAPI-74 in relation with an expected elevated clinical demand. ***Materials and Methods:*** FAPI-74 (SOFIE, USA) radiolabeled with [18F]fluoride was produced using a fully automated radiosynthesizer (TRASIS, Belgium) following the manufacturer's procedures [1]. [18F]fluoride was produced by a 18/9 MeV cyclotron (IBA, Belgium) irradiating a standard volume of 2.6 mL of [18O]H2O, using a fixed target current of 60 µA, but different times of beam (10', 20'and 40'). Three starting activities of [18F]fluoride (A= 20 GBq, B= 55 GBq and C= 100 GBq) were used for labeling FAPI-74 (at fixed mass of 72 µg) were used to define the best option to achieve the highest Radiochemical Yield (RCY)/final amount of [18F]F-FAPI-74 along with the analysis of costs related to the different activities. ***Results:*** The RCY values at the end of synthesis, not corrected for decay, were respectively 51% for starting activity A (10,2 GBq vs initial 20 GBq), 54% for B (30 GBq vs initial 55 GBq), and 40% for C (40 GBq vs initial 100 GBq). The cost for the production of [18F]F-FAPI-74 was estimated in 1.037€ (considering the amount of FAPI-74, disposable/reagents, personnel, technologies and maintenance, radioactive waste dismission disposables) and it was unchanged for the different activities. The Radiochemical Purity (RCP) evaluated after each production by radio-HPLC and Thin-Layer Chromatography (iTLC) were >99% for the three activity ranges. ***Conclusion:*** According to our results, the most convenient condition in the preparation of large amounts of [18F]F-FAPI-74, is represented by the starting activity B (achieved with the shorter beam time) which allows to perform up to 25 PET/CT exams. These evaluations may represent an useful body of knowledge to evaluate the costs effectiveness of new radioligands introduced in clinical practice. ***References:***

EP-0971

BY-271-[18F]F-TEG a new Amyloid β PET radiotracer with improved pharmacokinetics

S. Bagheri[1], *B. Uzuegbunam[2], W. Weber[2], C. D`Alessandria[2], M. Luster[1], D. Librizzi[1], B. H. Yousefi[1];*
[1]Philipps University of Marburg, Marburg, GERMANY,
[2]Technical University Munich, Munich, GERMANY.

Aim/Introduction: Amyloid β (Aβ) plaques and neurofibrillary tangles (NFT) are a hallmark features of Alzheimer's disease (AD). Aβ positron emission tomography (PET) is an established research tool for non-invasive early diagnosis for AD patients. Our goal is to evaluate an improved 18F-labeled analog of FIBT (DOI: 10.1038/s41380-018-0203-5), BY-271-[18F]F-TEG, utilized as Aβ tracer with high affinity, excellent selectivity and favorable pharmacokinetics with excellent brain uptake kinetics and low nonspecific binding.

Materials and Methods: BY-271-[18F]F-TEG was chosen due to its exceptional selective Aβ plaque binding out of over 500 compounds. It was then radiolabeled, purified using HPLC, and utilized directly in a 60-minute dynamic PET/MR and PET/CT scans using single and double-transgenic mice model of AD (Arctic APP and Arte-10 APP/PS1 transgenic mice, n≥3) versus age-matched control mice (n≥3). The brain regions were segmented using the Ma-Benveniste-Mirrione mouse template to evaluate uptake values, time activity curves, and parametric mapping analysis. The frontal cortex and cerebellum were considered regions of interest and reference, then the left ventricle was performed as an arterial input function through the parametric mapping analysis. Additionally, plasma stability, biodistribution, in vivo metabolite analyses, and postmortem autoradiography have been studied. ***Results:*** BY-271-[18F]F-TEG shows high binding affinity (Ki 0.7nM), excellent selectivity toward Aβ plaques over NFT (>1000 fold), logD= 1.9±0.13, plasma protein binding 0.47± 0.12 and favorable pharmacokinetics (radiolabel chemical yield 11±1% and purity ≥99.5%). Autoradiography results also confirm an excellent binding to tg mice and cortical regions of postmortem AD versus no binding to healthy control brains confirmed by Immunohistochemistry (IHC). Besides, it shows brain uptake >7 %ID/g (5 min p.i.) and exceptional stability in brain (t1/2 > 8h). It shows excellent PET imaging results in tg vs ctrl with initial uptake >10%ID/g and fast washout down to 1%ID/g (60 min). The parametric mapping analysis represented significantly higher DVR (up to 2.8 ml/cm3), on the frontal cortex and cerebellum of tg brain versus no specific signal (down to 1.07 ml/cm3, 45-60 min) in ctrl mice brain. ***Conclusion:*** The combined preclinical results of BY-271-[18F]F-TEG encourage us to further study it in our translational research towards first in human study.

EP-0972

Development of two pyrrolo-pyridine and -pyrimidine LRRK2 selective PET radioligands

V. Stepanov[1], *S. Nag[1], A. Takano[1], R. Arakawa[1], M. Swedberg[1], N. Amini[1], G. P. Smith[2], G. Mikkelsen[2], T. Jensen[2], M. Hentzer[2], K. V. Christensen[2], B. Bang-Andersen[2], C. Halldin[1];*
[1]Karolinska Institutet, Stockholm, SWEDEN, [2]H. Lundbeck A/S, Copenhagen-Valby, DENMARK.

Aim/Introduction: Leucine-rich repeat kinase 2 plays a key role in human biology. Elevated LRRK2 levels in cytoplasm and mitochondrial membranes are associated with increased intracellular tau levels and accumulation of oligomeric tau, often alongside β-amyloid plaques. Recent studies highlight a connection between LRRK2 and Parkinson's disease (PD), suggesting monitoring LRRK2 expression in brain regions could aid in understanding neurodegenerative progression. Using a LRRK2-specific radioligand PET imaging would allow for quantification of LRRK2 levels in brain. The objectives of this study were i) Fluorine-18 label of two pyrrolo-pyridine and -pyrimidine ligands (1 and 2 respectively) from the chemical series previously published (Williamson et al. J. Med. Chem. 2021, 64, 10312-10332) ii) evaluate their binding properties through in vitro autoradiography (ARG) and in vivo PET. ***Materials and Methods:*** Lundbeck provided precursors and standards for radiolabeling [18F]1 and [18F]2 in a single-step fluorine-18 substitution. Radiochemical yields and purity were assessed via HPLC analysis. Binding properties were evaluated using ARG in postmortem brain slices. ARG blocking experiments were performed using cold 1 and a LRRK2-specific ligand PFE-360 (US patent US20140005183). PET measurements in NHP brain were performed using HRRT PET scanner. Radiometabolites were measured in plasma using gradient HPLC. ***Results:*** The radiolabeling of [18F]1 and [18F]2 was successful, yielding over 2 GBq of product. Radiochemical purity exceeded 99% at EOS, with MA >120 GBq/µmol. ARG demonstrated significant binding of [18F]1 and [18F]2 in rodent, NHP, and human brain slices under baseline conditions. [18F]1 binding was blocked by 10 µM cold 1 but not by 0.1 µM PFE-360. [18F]2 binding in human striatum, hippocampus, and cerebellum was blocked by 10 µM of PFE-360, implying potential specific binding to LRRK2 in vitro. PET scans in cynomolgus monkeys revealed high brain uptake of both [18F]1 and [18F]2. [18F]1 showed highest uptake in the thalamus, followed by the putamen, caudate, hippocampus, frontal cortex, and lowest in the cerebellum. In contrast, brain uptake of [18F]2 was consistent across all regions of interest. No significant blocking effect of [18F]1 was observed in PET imaging experiments after pretreatment with PFE-360 (0.5 mg/kg, iv). Radiometabolite analysis indicated rapid metabolism with less than 10% of parent compounds remaining at 120 minutes post-injection. ***Conclusion:*** The radiolabeling of [18F]1 and [18F]2 was successful. However, subsequent PET imaging, including displacement experiments, revealed low specific binding in the cynomolgus brain. Consequently, these radioligands are unlikely to be suitable for LRRK2 imaging in vivo using PET.

EP-0973

PARP10 targeting by a [18F]fluorinated PET imaging agent

J. Martinelli[1,2], *M. Riondato[1,2], G. Destro[3], F. Vitale[2], M. Bauckneht[1,2], C. Marini[2,4], E. Terreno[3], G. Sambuceti[1,2];*
[1]University of Genova, Genova, ITALY, [2]IRCCS Ospedale Policlinico San Martino, Genova, ITALY, [3]University of Torino, Torino, ITALY, [4]CNR Institute of Bioimages and Molecular Physiology, Milano, ITALY.

Aim/Introduction: Human poly-ADP-ribose polymerases (PARPs) are a group of enzymes that promote the covalent attachment of poly- or mono- ADP-ribose units post-translationally on a variety of amino acids of target proteins. While the search for new PARP1/2 inhibitors is widely pursued because of their use as anticancer agents, the development of inhibitors for mono-ADP-ribose transferases is still at the early stages. In this context, the role of PARP10 has not been completely elucidated yet, although its overexpression in various cancer cells leads to hypothesise its involvement in cancer proliferation. It has been recently reported that PARP10 suppression by selective inhibitors has a huge impact in tumour progression, thus making it a promising target. On the basis of a previous work about PARP10 inhibitors (PARP10i),[1] we aimed at developing a new positron emission tomography (PET) agent to study the role of this enzyme in different cancer models. ***Materials and Methods:*** A flexible radiolabelling protocol was developed on a state-of-the-art synthesizer platform by Cu-mediated [18F]-fluorodeboronation starting from different boronic pinacol esters, including deprotection and semi-preparative purification before reformulation. The optimized protocol resulted in the reaction of a SEM-protected precursor (SEM = 2-((Trimethylsilyl)ethoxy)methyl) in 1,3-dimethyl-2-imidazolidinone (DMI), followed by cleavage with HCl. In vitro assays with the [18F]PARP10i tracer were carried out and analysed on different cell lines expressing PARP10 (e.g. MCF7, A549) by using a gamma-counter to assess the activity and a real-time monitoring equipment to investigate the uptake kinetics. ***Results:*** The optimised automated radiosynthesis allowed to reliably produce [18F]PARP10i as the first promising PET imaging candidate in good yield and high radiochemical purity, suitable for in vitro and in vivo experiments, in ~90 minutes including HPLC purification

and final reformulation. From 1.75 to 4.42 GBq were produced, with an activity yield of 10-24% (n.d.c.) and a molar activity in the range 75-223 GBq/μmol. [18F]PARP10i was finally tested on different tumour cell lines expressing PARP10 (according to Western Blot assessments), showing a fast and stable uptake. Competition experiments were also carried out using the corresponding [19F]-analogous compound as "cold" competitor. ***Conclusion:*** The preliminary results show the potential of [18F]PARP10i as new PET tracer for PARP10 imaging in cancer. Further experiments are in progress to improve the chemical yield, as well as to confirm the potential of this new PET diagnostic agent on tumour cell lines with and without PARP10 expression. ***References:*** [1] Nizi M.G. et al. Journal of Medicinal Chemistry, 2022, 65(11), 7532-7560.

EP-0974

Synthesis and evaluation of radiofluorinated GSK321 analogues as candidate radiotracers for imaging mutant IDH1 expression in gliomas

S. Kaur[1,2], *S. Dukic-Stefanovic[1], W. Deuther-Conrad[1], M. Touissant[1], B. Wenzel[1], K. Kopka[1,2], R. Moldovan[1];*
[1]Helmhotz-Zentrum Dresden-Rossendorf (HZDR), Institute of Radiopharmaceutical Cancer Research, Department of Neuroradiopharmaceuticals, Leipzig, GERMANY, [2]Faculty of Chemistry and Food Chemistry, School of Science, TU Dresden, Dresden, GERMANY.

Aim/Introduction: Mutant isocitrate dehydrogenase (mIDH) has become an important biomarker for effective diagnosis, prognosis, treatment planning and patient stratification in patients with mIDH. Currently, mIDH status is determined by an invasive immunohistochemical method. A non-invasive PET imaging method for the detection of isocitrate dehydrogenase mutations represents a potentially better alternative. To date, there is no clinically available PET radiotracer targeting mIDH. In this study, we have developed [18F]SK60 and [18F]SK87 and are currently investigating their ability to visualise mIDH1.1 ***Materials and Methods:*** A SAR study was carried out starting from the structure of the mIDH inhibitor GSK321.2 Our medicinal chemistry program led to the development of dimethylated GSK321 analogues, SK60 and SK87 which were radiofluorinated in view of their high potency and selectivity towards the mIDH1R13H. To develop [18F]SK60 and [18F]SK87, copper-mediated radiofluorination was performed with optimized reaction conditions. For [18F]SK60, the ex vivo metabolic stability was investigated in female CD-1 mice at 30 min post-injection (p.i) and the biodistribution was evaluated ex vivo at 5, 15, 30 and 60 min as well as by dynamic PET scan studies (60 min) in healthy female CD-1 mice. ***Results:*** The structural optimization and medicinal chemistry on GSK321 resulted in SK60 (IC50 mIDH1R132H = 14.5 nM and IC50 wtIDH1 = 374 nM) and SK87 (IC50 mIDH1R132H = 25.9 nM and IC50 wtIDH1 >10,000 nM). Compounds [18F]SK60 and [18F]SK87 were successfully synthesized by copper-mediated radiofluorination from the respective Bpin and BEpin precursors, respectively. In vivo studies conducted in healthy female CD-1 mice, exhibited the excellent metabolic stability of [18F]SK60, with parent fractions of 80% and 100% in plasma and brain at 30 min p.i., respectively. The ex vivo biodistribution studies and dynamic PET scan showed a low brain uptake (0.6 % ID/g 15 min p.i.) and hepatobiliary excretion of [18F]SK60 in healthy mice. ***Conclusion:*** This study resulted in the development of a novel series of fluorinated mIDHR132H inhibitors. Consequently, [18F]SK60 and [18F]SK87 were successfully radiofluorinated. Our preclinical evaluation of [18F]SK60 demonstrated high metabolic stability, limited brain uptake and hepatobiliary excretion in vivo in healthy mice. In general, further structural modifications in [18F]SK60 are required to enhance the brain uptake. Currently, we are conducting the biological evaluation of [18F]SK87, the analogue with reduced lipophilicity. ***References:*** 1. Patent application number: DE 10 2024 110 434.1 (15 April 2024) 2. Okoye-Okafor, U. C.; et al. Nat. Chem. Bio. 2015, 11 (11), 878-886.

EP-0975

PET imaging of CXCR4 expression with [18F]AlF-NOTA-QHY-04 in multiple tumors

S. Xu, *T. Liu, S. Wang, J. Yu, J. Liu;*
Department of Radiation Oncology and Shandong Provincial Key Laboratory of Radiation Oncology, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, CHINA.

Aim/Introduction: C-X-C motif chemokine receptor 4 (CXCR4) is a promising target for the diagnosis and treatment of cancers. Here, we aimed to develop a new CXCR4-targeted PET tracer, and to investigate the translational potential for noninvasive imaging of CXCR4 expression in various cancer entities through both preclinical and pilot clinical studies. ***Materials and Methods:*** [18F]AlF-NOTA-QHY-04 was synthesized based on a potent CXCR4 peptide antagonist, and evaluated by cellular uptake, blocking and biolayer interferometry studies in vitro. The pharmacokinetics, biodistribution, and tumor imaging specificity of [18F]AlF-NOTA-QHY-04 were researched in tumor-bearing mice. [18F]AlF-NOTA-QHY-04 PET/CT imaging was performed on 55 patients with 8 different types of cancer. Correlations between ex vivo CXCR4 expression and PET parameters, and CXCR4 expression characteristics in different tumors were analyzed by histopathological staining in patients. ***Results:*** [18F]AlF-NOTA-QHY-04 was prepared with a high radiolabeling yield and radiochemical purity. [18F]AlF-NOTA-QHY-04 exhibited good stability, high binding affinity and specificity for CXCR4 both in vitro and in vivo. NCI-H69 (small cell lung cancer, SCLC) tumor-bearing mice showed the highest tumor uptake of [18F]AlF-NOTA-QHY-04 on PET imaging except for Daudi lymphoma xenograft model, which was consistent with the results of cellular and histological analyses. Similar results were observed in PET imaging of cancer patients (SUVmax for diffuse large B-cell lymphoma and SCLC, 11.10 ± 4.79 vs. 7.51 ± 3.01, $P = 0.004$), which were both significantly higher than other solid tumors ($P < 0.05$). Significant higher T/N of [18F]AlF-NOTA-QHY-04 than [18F]FDG (62.55 ± 38.67 vs. 1.69 ± 0.22, $P = 0.027$) was found in primary brain tumors. Positive correlations between ex vivo CXCR4 expression and [18F]AlF-NOTA-QHY-04 uptake (all $P < 0.01$) were recorded. Multicolor immunofluorescence staining indicated the high tracer uptake in certain patients was mainly due to the high expression of CXCR4 in tumor cells, followed by macrophages and neutrophils. ***Conclusion:*** The CXCR4-targeted radiotracer [18F]AlF-NOTA-QHY-04 was successfully prepared with favorable yield, high specificity and binding affinity to CXCR4. Preclinical and pilot clinical studies demonstrated its feasibility and potential application in precise diagnosis and CXCR4-targeted therapies for not only lymphoma but also SCLC and glioma. [18F]AlF-NOTA-QHY-04 PET/CT can also provide a complementary mapping for brain tumors to [18F]FDG PET/CT.

EP-0976

Biodistribution of Zirconium-89 Conjugated Escherichia Coli for Positron Emission Tomography imaging of Tumor Targeting

D. Jeong[1,2], *G. Kim[1], S. Park[2], H. Lee[1], S. Kim[2];*

[1]Dongnam Institute of Radiological and Medical Sciences (DIRAMS), Busan, KOREA, REPUBLIC OF, [2]DonggukUniversity, Gyeongju, KOREA, REPUBLIC OF.

Aim/Introduction: The conventional drug delivery systems often exhibit low intravenous delivery efficiency and restricted transport within tumor tissues. To overcome these limitations, this study chemically modified the surface of Escherichia coli (E. coli), known for its inherent motility and accumulation in tumor tissues, to stably introduce the diagnostic radioisotope zirconium-89. The possibility of these modified bacteria as a radiopharmaceutical for positron emission tomography (PET) was assessed through in vivo PET studies. ***Materials and Methods:*** For quantitative analysis, the primary amines on the surface of E. coli were reacted with fluorescein isothiocyanate (FITC) in phosphate-buffered saline (PBS). At pH 8.83, deferoxamine (DFO), which contains a terminal isothiocyanate (-NCS) group, was chemically conjugated to the primary amine groups on the surface of E. coli. Subsequently, a stable isotope of zirconium was chelated to the DFO-modified bacterial surface using 0.1M HEPES buffer at pH 7.4, preparing the bacteria for PET imaging. CT-26 cells were dispersed in saline and subcutaneously injected into the thighs of Balb/c mice. After the tumors grew to a length of 120 mm, each mouse was intravenously injected with the radiolabeled bacteria (3.7 MBq/100 µL per mouse). The mice were anesthetized with isoflurane and whole-animal imaging was conducted using PET for one day. ***Results:*** As a result of of measuring E. coli combined with FITC using a microplate reader, it was found that the amount of FITC was 0.06 µmol per 2 x 108 cells of E. coli. The binding of the stable isotope zirconium was confirmed through inductive coupled plasma mass spectrometry (ICP-MS). PET was utilized to evaluate the drug delivery efficacy of 89Zr-labeled E. coli within the body. After intravenous tail injection of 89Zr-labeled E. coli, PET imaging conducted one day post-injection revealed that the E. coli initially accumulated in the tumor tissue, and this accumulation was maintained for one day. ***Conclusion:*** In this study, the diagnostic radioisotope zirconium-89 was successfully labeled on the surface of E. coli, and the in vivo targeting capabilities of these modified bacteria were confirmed through PET imaging studies. Through the targeted delivery capabilities of modified E. coli, it is expected that future research focusing on various modifications to the surface of E. coli will contribute to tumor targeting studies by enabling evasion of the reticuloendothelial system (RES).

EP-0977

Development of Antimicrobial Peptide-based Radiopharmaceuticals in Radiotheranostics of S. aureus Infection

S. Jiang, *S. Zhang, R. Wang, K. Hu;*
Institute of Materia Medica, Chinese Academy of Medical Science, Beijing, CHINA.

Aim/Introduction: Infections are the second leading cause of death worldwide(1). Biopsy or CT/MRI are commonly used for infection diagnosis, but they mostly only reveal tissue changes caused by advanced infections. Besides, Biopsies also have the disadvantage of not being able to be tested multiple times. The diagnostic modalities such as PET/SPECT to detect infections has yielded promising results, such as $^{[18F]}$FDG(2), however it is unable to distinguish between infection and inflammation. Radiopharmaceuticals are the best option to circumvent such problems due to their affinity is so higher that they can diagnose earlier, more frequent and more accurate than other detectors. In this research, antimicrobial peptide-based radiopharmaceuticals accurately targeting to S. aureus, a pathogen causing metastatic or complicated infections, was developed. The diagnosis specificity was investigated to demonstrate the potential for clinical use. ***Materials and Methods:*** The model in imaging experiment are New Zealand White rabbits (male, 2-3 months), which are divided into infected group (in situ injected with S. aureus in right knee joint, 108cfu) and control group. After injecting for 3 days, [68Ga] KJT3 was injected to rabbits (i.v., 1mCi/rabbit) for PET imaging. The SD rats (male, 4-6 weeks) were injected S. aureus into the right knee joint (106cfu). The diagnosis specificity was compared using [68Ga]KJT3 and $^{[18F]}$FDG (i.v., 0.2 mCi/rat). ***Results:*** PET imaging demonstrated that the uptake of [68Ga]KJT3 was higher in the right knee joint of infected rabbit compared to their right counterpart, as well as rabbit without S. aureus infection. HE and Gram staining indicate significant joint cavity injury and S. aureus infiltration in cartilaginous tissue. The study demonstrated that the targeting specificity of [68Ga]KJT3 was 12.17, which is 4.5 times higher than $^{[18F]}$FDG according to the ratio of ROI in lesion to ROI in muscle. ***Conclusion:*** Highly specific antimicrobial peptide-based radiopharmaceuticals were used in the diagnose of S. aureus infection, presaging the potential acquisition of ever more powerful and meaningful results of such studies going forward. ***References:*** 1.Global burden of 369 diseases and injuries in 204 countries and territories, 1990-2019: a systematic analysis for the Global Burden of Disease Study 2019. EP-0978

Production development and evaluation of Ga-68 labelled Affibody molecule based radiopharmaceutical targeting platelet derived growth factor receptor beta for phase 0 clinical trial in patients with heart injury

I. Velikyan[1], *O. Eriksson[2];*
[1]PET Centre, Uppsala University Hospital, Uppsala, SWEDEN, [2]Department of medicinal chemistry, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Activation of platelet derived growth factor receptor beta (PDGFRβ) drives proliferation, migration, and production of extracellular matrix involved in fibrogenic activity. In vivo quantitative imaging of PDGFRβ may significantly improve management of patients, with heart diseases undergoing invasive procedures, in terms of the risk of the formation of fibrotic tissue. The visualization of PDGFRβ using a 18F-labelled Affibody molecule has been preclinically proven by us earlier [1]. This study is devoted to the development of the production of 68Ga-labelled analogue for phase 0 clinical trial and preclinical characterization of the resulting radiopharmaceutical. ***Materials and Methods:*** Affibody molecule Z09591 was generated by chemical synthesis and conjugated with a DOTA chelator moiety at the C-terminal cysteine. The fully automated production of [68Ga]Ga-Z09591 was developed using pharmaceutical grade 68Ge/68Ga-generator, disposable and sterile cassettes developed earlier [2] for Modular-Lab PharmTrace synthesis platform (Eckert & Ziegler). The heating temperature and duration, radical scavenger, product purification and formulation steps, and pH were optimized. The identity and purity of the product were determined using UV-Radio-HPLC. Affinity and specific binding of [68Ga]Ga-Z09591 was investigated in vitro by LigandTracer technology using U87 cells, and autoradiography using U87 xenograft and MC38 tumor sections, respectively. The presence of PDGFRβ was verified by immunohistochemistry (IHC). ***Results:*** Fully automated, reproducible (100% success rate), and GMP

compliant production of [68Ga]Ga-Z09591 was developed. The slight radiolysis was suppressed by ethanol, and heat sensitivity of the precursor required lower temperature. The radiochemical purity of the product was over 95% with total peptide content of 120 ± 15 µg. Radionuclidic purity, sterility, endotoxin content, residual solvent content, and sterile filter integrity were controlled and met acceptance criteria. The product was stable at ambient temperature for at least 2 h. The interaction of [68Ga]Ga-Z09591 towards PDGFRβ on U87 cells had a dissociation constant of Kd=65±35 pM. The biological activity of the product was confirmed using frozen sections of tumor tissues, wherein binding was seen in both U87 xenografts expressing human PDGFRβ receptor as well as in tumor stroma of murine MC38 tumors, and correlated well to PDGFRβ expression as assessed by IHC. ***Conclusion:*** Automated production of [68Ga]Ga-Z09591 was established and validated for the use in phase 0 clinical trial. In addition, the biological activity was evaluated in vitro, and the radiopharmaceutical demonstrated full viability. ***References:*** [1] Wegrzyniak et al., EJNMMI Radiopharmacy and Chemistry, 2023, 8(1):23; [2] Velikyan et al., AJNMMI, 2019, 12-23.

EP-0979

A bifunctional CyHOPO derivative for labeling antibodies with ^{89}Zr and ^{177}Lu for theranostic use

M. Cheveau[1,2], *T. Bailly[1], P. Adumeau[1], Y. Moutaa[1,2], R. Vizier[1], M. Moreau[1], F. Boschetti[2], V. Goncalves[1], I. E. Valverde[1], F. Denat[1];*
[1]ICMUB - Institut de Chimie Moléculaire de l'Université de Bourgogne, Dijon, FRANCE, [2]Chematech, Dijon, FRANCE.

Aim/Introduction: With the immunoPET development, 89Zr has become a radioisotope of choice because of its prolonged half-life (t1/2 = 78.4 h) matching monoclonal antibodies (mAb) pharmacokinetic. For 89Zr chelation, most mAb conjugates use natural desferrioxamine B (DFO). Yet, preclinical studies demonstrated [89Zr]Zr-DFO complexes are not perfectly stable in vivo. Accumulation of released 89Zr is observed in bones, which can be perceived as a major drawback for the clinical translation of 89Zr-radiopharmaceuticals1. The main reason of this release is the uncomplete coordination sphere of 89Zr with DFO. To reach more stable radio-immunoconjugates, several groups worked on alternative chelating agents containing hydroxamate/hydroxypyridinone functions, such as 1,2-hydroxypyridinone (1,2-HOPO) group, demonstrating excellent chelation properties1. However, very few chelators based on cyclic scaffolds containing 1,2-HOPO groups have been tested. Recently, a 1,2-HOPO based chelator named Lumi804 exhibited high affinity for 89Zr, but also for 177Lu, a β- emitter used in targeted radionuclide therapy (TRT), enabling a theranostic application2. Herein, we report the development of a new bifunctional tetra-1,2-HOPO chelator, based on the cyclen scaffold, and adapted from an already published model used for lanthanide luminescence studies3. We present its conjugation to trastuzumab and radiolabeling with 89Zr and 177Lu. ***Materials and Methods:*** A bifunctional tetra-1,2-HOPO chelating agent (N3AMCyHOPO) was synthetized based on the aminomethyl-cyclen (AMC) scaffold. N3AMCyHOPO was then bioconjugated site-specifically to trastuzumab via enzymatic and click reactions. The resulting immunoconjugates were radiolabeled with 89Zr. Radioconjugates stability were assessed in presence of competitor (DFO) and compared to a DFO immunoconjugate analog. We also determined the immunoconjugate radiolabeling potential with 177Lu and compared to DOTA analog, to explore a possible theranostic application. ***Results:*** N3AMCyHOPO was synthesized in 5 steps from AMC and site-specifically conjugated to trastuzumab with a degree of labeling (DOL) = 1.8. Regarding 89Zr complexation, N3AMCyHOPO exhibited excellent properties with high radiochemical yield (>95%) and substantially higher radioconjugate stability compared to DFO model. For 177Lu, radiochemical yields were around 94%, outperforming DOTA conjugates, the gold standard for this radioisotope. Unfortunately, substantial release was observed in stability tests for our conjugates, highlighting a poor stability of the 177Lu-complex. ***Conclusion:*** N3AMCyHOPO demonstrated effective conjugation to mAb and its potential for 89Zr coordination should overcome DFO limitations. However, our experiments with 177Lu resulted in more contrasted results. ***References:*** 1) Heskamp, S. et al. Bioconjugate Chem. 2017, 28 (9), 2211-2223. 2) Foster, A. et al. eBioMedicine 2021, 71. 3) Dai, L. et al. Chem. Sci. 2019, 10 (17), 4550-4559.

EP-0980

Estrogen-positive metastatic breast cancer examined with [^{68}Ga]Ga-NOTA-PEG$_2$-RM26 PET/CT - First in Human experience

A. Tzortzakakis[1], *A. Bjäreback[1], C. Hindorf[1], S. A. Buren[1], E. Jussing[1], V. Tolmachev[2], Z. Varasteh[3], M. Moein[1], T. Tran[1], R. Axelsson[1], A. Orlova[2], R. Altena[1];*
[1]Karolinska Institutet, Stockholm, SWEDEN, [2]Akademiska University Hospital, Uppsala, SWEDEN, [3]Klinikum rechts der Isar der Technischen Universität, München, GERMANY.

Aim/Introduction: This study aims to introduce a new diagnostic radiotracer specific for gastrin-releasing peptide receptors (GRPR)-producing tumours. GRPR is part of the bombesin peptide family and is overexpressed in various tumours. GRPR overexpression in breast cancer has been extensively demonstrated, particularly in estrogen receptor (ER) expressing tumours [1]. This First-in-Human study aimed to visualise GRPR overexpression in ER-positive (ER+) metastatic breast cancer (mBC) using [68Ga]Ga-NOTA-PEG2-RM26 Positron Emission Tomography/Computed Tomography (RM26 PET/CT). ***Materials and Methods:*** Six female patients diagnosed with ER+ mBC were enrolled in this study from October 2022 to February 2024. The intravenous administration of [68Ga]Ga-NOTA-PEG2-RM26 was dosed at 2 MBq per kilogram of body weight. PET scans were conducted at 5-minute intervals post-injection, including time points at 20, 40, 60, 120, and 180 minutes. Bed position durations were adjusted, starting from 30 seconds per bed for the initial four scans and increased to 2.5 minutes per bed for the final two scans. Reconstruction of PET images utilised ordered subset expectation maximisation (3 iterations, 16 subsets) with a 5.5 cm Gaussian postprocessing filter. Corrections for attenuation, scatter, randoms, normalisation, and dead time were applied, incorporating time-of-flight and point spread function in the reconstructions. The imaging procedures were conducted using a GE Discovery MI4 PET/CT system from GE Healthcare (Milwaukee, WI, USA). ***Results:*** Four study participants had biopsy-proven ER+ mBC, which showed RM26 uptake. One patient with a biopsy-proven ER-negative lymph node showed no RM26 uptake. The remaining patient had no increased RM26 uptake in a biopsied ER+ skeletal metastasis. At the writing moment, no results of immunohistochemical correlation of the GRPR expression exist that would serve as proof of concept for the actual performance of RM26 tracer using PET/CT. The RM26 uptake on ER+ metastatic lesions was evident from the early PET scans in skeletal and soft tissue metastases of various sizes. ***Conclusion:*** PET/CT imaging with GRPR targeting radiopharmaceuticals like [68Ga]Ga-NOTA-PEG2-RM26 represents an attractive future development and clinical implementation in the era of precision medicine. It

holds potential as an attractive target for the development of therapeutic radiopharmaceuticals. ***References:*** [1] Baratto L, Duan H, Mäcke H, et al. Imaging the distribution of gastrin-releasing peptide receptors in cancer. J Nucl Med. 2020;61:792-798.

Via Piero Maroncelli, 40 - 47014 Meldola (FC), Italy, Meldola, ITALY, [10]Department of Medicine and Surgery, University of Milan Bicocca and ASST-Ospedale Papa Giovanni XXIII Bergamo, Bergamo, ITALY.

Aim/Introduction: Fibroblast Activation Protein (FAP) is an emerging pan-tumoural target for the delivery of diagnostic and therapeutic radio-conjugates. OncoFAP is a high-affinity FAP ligand1,2 which is currently studied in a prospective Phase I clinical trial as a diagnostic radiotracer (NCT05784597). ***Materials and Methods:*** The dosimetry of 68Ga-OncoFAP will be evaluated among patients enrolled in cohort A of the ongoing clinical trial PH-FAPGA-01/22. Patients with a confirmed diagnosis of breast, oesophageal, pancreatic, or colorectal cancer are eligible for inclusion. All patients will receive a single administration of 250 (225-275) MBq 68Ga-OncoFAP followed by a series of PET scans starting at 0 min, 10 min, 20 min, 60 min and 120 min after administration. Low-dose CT images will be acquired at 0 min, 60 min and 120 min post-injection. Volumes of interest (VOIs) will be semiautomatically drawn around the organs, and verified by an experienced physician for proper organ delineation and corrected, if necessary, using PLANET Dose internal dosimetry software (DOSIsoft SA). Tumour VOIs will be drawn using patient-specific SUV thresholding (2.5-3.5) using DOSIsoft SA. In organs with tumours, lesion activity will be subtracted from normal-organ source volumes and incorporated in the body remainder term. Residence time in the whole body, in each single organ, and in tumours will be calculated based on the time-integrated activity coefficient by applying a three-exponential fit to the five data points and correcting the data for decay. Radiation absorbed doses and effective doses will be calculated based on the RADAR method3 by entering the time-integrated activity coefficient of each source organ into OLINDA/EXM 1.14, using the reference adult male and female models, and using the MIRD algorithm with S-factors corrected for actual mass of the patients. ***Results:*** At the cutoff date of the 15th April, 3 male and 3 female patients have been enrolled. Data analysis is ongoing. Preliminary dosimetry on the first two patients analysed is in line with those reported for other FAP tracers and 68Ga-labelled PET radiotracers such as PSMA-11 and DOTATOC. ***Conclusion:*** 68Ga-OncoFAP is a promising diagnostic radiotracer for the detection of various solid tumours. ***References:*** 1) Millul et al, PNAS, 2021 2) Backhaus et al, EJNMMI, 2022 3) Stabin MG, Siegel JA. Development of a click radio-iodination labeling method using the[^{125}I]Iodo-azide/ADIBO pair

T. Choi, *B. Kim; KIRAMS, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: N-3-azidopropyl-3-[125I]Iodo-benzamide ([125I]Iodo-azide) is a residualizing linker that can be click radio-iodinated with ADIBO pair. The [125I]Iodo-azide/ADIBO pair allows for the production of radio-conjugates in high yields across a wide range of materials and biological environments, from small molecules to large molecular weight proteins. In this study, we evaluated the click radio-iodination labeling efficiency of ADIBO-conjugated rituximab with [125I]Iodo-azide. ***Materials and Methods:*** Radioiodinated Iodo-azide was prepared by iododestannylation using Na[125I]I and H2O2 as an oxidizing agent. The [125I]Iodo-azide was then purified using radio-HPLC equipped with a C18 RP column. The antibody, rituximab, and ADIBO-NHS ester were dissolved in pH 7.2 phosphate buffer at a molar ratio of Ab:ADIBO-NHS= 1:12. The mixture was then reacted at 37 degrees for 2 hours. After the reaction was complete, the buffer was exchanged with PBS pH 7.4 using a desalting column. To determine the ADIBO to antibody ratio, the antibody was deglycosylated with PNGase F and analyzed by LC/TOF after undergoing PNGase F digestion. The click radio-iodination labeling efficiency of [125I]Iodo-azide and ADIBO-rituximab was observed at 37 degrees for 4 hours. ***Results:*** Radio-HPLC was used to analyse [125I]Iodo-azide, with a labeling efficiency of 97%. The retention time (RT) of [125I]Iodo-azide was 11.7 minutes, while the precursor Bu3Sn-azide had an RT of 18.9 minutes. The deconvoluted results of LC/TOF showed that the number of ADIBO bindings per antibody ranged from 0 to 6, with the most common distribution being 2 and 3 bindings per antibody. The efficiency of click radio-iodination labelling was evaluated and found to be 32.3±0.57%, 54.0±3.60%, 92.3±0.57%, and 96.6±2.51% at 30, 60, 120, and 240 minutes, respectively. ***Conclusion:*** High labeling rates were achieved through successful click radio-iodination of ADIBO-rituximab antibody using the newly developed [125I]Iodo-azide. ***References:*** Improved In Vivo Stability of Radioiodinated Rituximab Using an Iodination Linker for Radioimmunotherapy E. EP-0983

Liposomes as Promising Radiotheranostics Platforms Capable of Carrying Diverse Radionuclides within the Same Framework

H. Fujii[1,2], *A. Inaki[1], I. O. Umeda[3,1];*
[1]National Cancer Center, Kashiwa, JAPAN, [2]Japan Radioisotope Association, Tokyo, JAPAN, [3]Kyoto College

of Medical Science, Nantan, Kyoto, JAPAN.

Aim/Introduction: Radionuclide therapy has emerged as a promising treatment for systemic cancer, and the combination of radionuclide therapy and diagnostic radionuclide imaging, known as radiotheranostics, is expected to facilitate precision medicine. However, there are still few radio-theranostic pharmaceuticals that have actually been introduced into clinical practice. Liposomes have the potential to encapsulate various radionuclides and regulate their in vivo dynamics, making them a promising platform for radiotheranostics. In this study, we investigated efficient encapsulation conditions for diagnostic radionuclides such as 111In, 67/68Ga, and 99mTc, as well as therapeutic radionuclides like 64/67Cu, 90Y, and 186/188Re within liposomes. Subsequently, we attempted to construct a system that allows the encapsulation of various diagnostic and therapeutic radionuclides for a single liposomal framework, and explored the radiotheranostic potential of their diverse combination. ***Materials and Methods:*** Liposomes were preloaded various hydrophilic chelating ligands, and the remote loading methods used complex exchange reactions for the encapsulation of various radionuclides. Radionuclide-ligand complex formation was evaluated by paper chromatography and HPLC. The tissue distribution of these radionuclides-carrying liposomes and their therapeutic effects were studied using colon 26-bearing BALB/c mice. ***Results:*** Having already established optimal conditions for 111In encapsulation within liposomes, we proceeded to investigate the optimal encapsulation conditions for various radionuclides in comparison to 111In. As lipophilic ligands, 8-hydroxyquinoline, acetylacetone, and tropolone were examined, while as hydrophilic ligands inside the liposomes, DOTA, DTPA, NTA, EC were tested. 64Cu readily formed complexes with lipophilic ligands, and loading into liposomes was completed in a shorter time at lower temperatures than 111In. 88/90Y required more severe conditions to form stable complexes and load into liposomes. 67/68Ga reactivity was similar to 111In. Optimizing types of ligands and reaction conditions for each radionuclide enabled efficient encapsulation into liposomes (>85%). We were able to efficiently encapsulate 111In, 67/68Ga, 64Cu, and 88/90Y in liposomes of the same composition preloaded with DOTA, suggesting that the liposomes were promising as radiotheranostics platforms. When administered to tumor-bearing mice, these radionuclide-carrying liposomes showed nearly equivalent and good tumor accumulation (8-10% administered dose/g). The tumor was clearly depicted in SPECT/CT imaging of tumor-bearing mice administered with 111In-carrying-liposomes. Administration of 90Y-carrying-liposomes to tumor-bearing mice led to significant tumor growth inhibition. ***Conclusion:*** We have established efficient methods for encapsulating various radionuclides in liposomes. By utilizing liposomes as platforms for encapsulating imaging radionuclides and therapeutic radionuclides with different energies, expanding the potential of radiotheranostics is expected.

EP-0984

^{211}At-labeled alpha-melanocyte stimulating hormone peptide analogs for the treatment of malignant melanoma

H. Suzuki[1], *S. Yamashita[1], S. Tanaka[1], K. Kannaka[1], Y. Ohshima[2], I. Sasaki[2], S. Watanabe[2], K. Ooe[3], T. Watabe[4], N. S. Ishioka[2], H. Tanaka[5], T. Uehara[1];*
[1]Chiba University, Chiba, JAPAN, [2]National Institutes for Quantum Science and Technology, Takasaki, JAPAN, [3]Osaka University, Toyonaka, JAPAN, [4]Osaka University, Suita, JAPAN, [5]Tokyo Institute of Technology, Meguro-ku, Tokyo, JAPAN.

Aim/Introduction: Malignant melanoma is the most aggressive type of skin cancer, and metastatic melanoma is associated with high mortality. Recent advances in the treatment of melanoma have improved clinical outcomes. However, the survival of patients with late-stage melanoma still needs to be improved, and new treatment for malignant melanoma is desired. Although malignant melanoma is traditionally considered radioresistant cancer, targeted alpha therapy (TAT) could provide an effective treatment of malignant melanoma due to the high LET of alpha-particles. Alpha-melanocyte stimulating hormone (α-MSH) peptide analogs show high affinities to melanocortin-1 receptors that are overexpressed in over 80% of human malignant melanoma. Astatine-211 (211At) is an alpha emitter appropriate for TAT, and its relatively short half-life (7.2 h) is suitable for rapid pharmacokinetics of radiolabeled peptides. In this study, we prepared 211At-labeled α-MSH analogs by using a neopentyl glycol scaffold that we recently developed [1], and the usefulness was evaluated. ***Materials and Methods:*** Prior to the study using 211At, we prepared four 125I-labeled α-MSH analogs ([125I]1b-[125I]4b). Binding affinities of each non-radioactive iodinated analogs (1a-4a) against B16F10 melanoma cells were determined by competitive binding assays. Four 125I-labeled α-MSH analogs were subjected to biodistribution study in B16F10 tumor-bearing mice. Then, we prepared two 211At-labeled α-MSH analogs, [211At]3c and [211At]4c, which consist of an 211At-labeled neopentyl glycol scaffold, a hydrophilic dipeptide linker (D-Glu-D-Glu (ee) for [211At]3c or D-Glu-D-Arg (er) for [211At]4c), and an α-MSH analog. Two 211At-labeled analogs were subjected to biodistribution study in B16F10 tumor-bearing mice. ***Results:*** The Ki values of α-MSH analogs including ee (3a) and er (4a) linkers were 1.37 nM and 14.9 nM, respectively. In the biodistribution study, 125I-labeled α-MSH analogs without a linker ([125I]1b) and a D-Glu linker ([125I]2b) showed high accumulation in the intestine. Meanwhile, insertion of a dipeptide linker (ee for [125I]3b or er for [125I]4b) dramatically reduced radioactivity levels in the intestine. Both two 211At-labeled α-MSH analogs exhibited biodistribution similar to those of their corresponding 125I-labeled analogs. Correlated with the Ki values, [211At]4c showed higher tumor accumulation than [211At]3c. ***Conclusion:*** Because high tumor accumulation was observed, [211At]4c is a promising TAT agent for the treatment of metastatic melanoma. ***References:*** [1] Suzuki H. et al. J. Med. Chem. 64, 15846-15857 (2021).

EP-0985

Radiolabelling DOTA-HYNIC-panPSMA with actinium-225 for in vivo studies

J. Roetman[1], *K. Attia[1], M. W. Hallund[2], K. R. Jorgensen[2];*
[1]Telix Pharmaceuticals, Melbourne, AUSTRALIA,
[2]Minerva Imaging, Ølstykke, DENMARK.

Aim/Introduction: Prostate specific membrane antigen (PSMA) has emerged as a valuable theranostic target in nuclear medicine, with >95% of prostate cancer cells expressing PSMA. DOTA-HYNIC-panPSMA (formerly DOTA-HYNIC-iPSMA) is a compound with high affinity for PSMA that has been used in studies radiolabelled with lutecium-177 (177Lu). Actinium-225 (225Ac) is a promising alpha-emitting radioactive isotope that can be complimentary to beta-emitting 177Lu at different stages of disease by delivering high energy at short lengths to cancer cells while decreasing the risk of damage to surrounding healthy tissue. Here, we established a radiolabelling and quality control (QC) protocol of DOTA-HYNIC-panPSMA with 225Ac for future in vivo studies. ***Materials and Methods:*** DOTA-HYNIC-panPSMA was labelled with 1.5 MBq of 225Ac at a specific activity of 100 kBq/nmol for 15 minutes at

95°C by stirring and incorporation was determined by radio-thin layer chromatography (TLC). The compound was purified on a C18 SepPak purification column, washed with sodium citrate, and eluted in absolute ethanol. The compound was then formulated to an activity concentration of 370 kBq/mL in formulation buffer (sodium ascorbate and pentetic acid) and the radiochemical purity (RCP) of the purified and formulated product was determined by radio-TLC and radio high performance liquid chromatography (HPLC). The compound was re-analysed by radio-HPLC 4 hours after the end of synthesis to assess stability. ***Results:*** DOTA-HYNIC-panPSMA was radiolabelled with 225Ac an showed incorporation of 89.5% in the crude reaction mixture by radio-TLC. The RCP was 98.6% by radio-TLC and 99.0% in the final product determined by radio-HPLC. No major signs of instability were observed when the compound was re-analysed 4 hours after synthesis, resulting in an RCP of 97.9%. Based upon the radiolabelling data, the QC release criteria of ≥95.0% purity and ≤5.0% of free 225Ac by radio-TLC was established. ***Conclusion:*** A radiolabelling procedure and the QC release criteria for in vivo study of 225Ac-labelled DOTA-HYNIC-panPSMA was established. Future studies of 225Ac-DOTA-HYNIC-panPSMA will determine whether targeted alpha therapy is a promising option in the treatment of prostate cancer.

$^{18}F/^{131}I$-labeledMS438, a small molecularagonist of thyroid-stimulating hormone receptor for theranostic in radioiodine refractory differentiated thyroid cancer

S. Huang, *R. Huang;*
1.Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, Sichuan, CHINA.

Aim/Introduction: Differentiated Thyroid cancer (DTC) with a great prognosis was the most common cancer of thyroid[1]. However, two-thirds metastatic patients would lose the ability of iodine uptake and develop into be radioiodine refractory DTC (RAIR-DTC)[2]. Therefore, new target for radiotherapy needs to be explored. Thyroid-stimulating hormone receptor (TSHR) retained expression in RAIR-DTC. MS438 is a small molecular agonist of TSHR with nanomolar level of affinity[3]. Therefore, we thought MS438 targeting TSHR is a potential drug to be labeled for theranostic in RAIR-DTC. ***Materials and Methods:*** The 18F/131I-MS438 was labeled based on the substitution of trimethyltin. Purified 131I-MS438 mixed with phosphate buffer saline and saline were incubated in room temperature to explore the stability of 131I-MS438. The cell uptake of 131I-MS438 was examined by TPC-1 cell. 18F-MS438 was evaluated by micro-PET/CT in TPC-1 tumor xenograft. ***Results:*** The radiochemical purity of 18F/131I-MS438 > 95.0%. Besides, 131I-MS438 was stable in phosphate buffer saline and saline at 2 h and 4 h with radiochemical purity > 95.0%. In vitro, the rate TPC-1 cell uptake of 131I-MS438 continuously increased at 30 min, 60 min, 1 h, 2 h, 4 h and 24 h. The rate of TPC-1 cell uptake at 24h in 131I-MS438 group was higher than blocked group (18.96 % ± 0.50% vs. 11.13 % ± 0.55 %, $P < 0.001$). CCK-8 assays and plate clone formation assays demonstrated 131I-MS438 can effectively inhibit the growth and proliferation of TPC-1 cell. In vivo, preclinical 18F-MS438 PET/CT in a mouse bearing TPC-1 tumor xenograft showed fast hepatobiliary excretion and elevated tumor uptake. The uptake of tumor at 30 min, 60 min and 120 min were 3.38 %ID/g, 3.10 %ID/g and 2.95 %ID/g, respectively. ***Conclusion:*** In preclinical studies, 18F/131I-MS438 is a promising radiotracer for imaging and therapy for RAIR-DTC, however, it further needs to be explored in animal and human. ***References:*** 1. EP-0987

Therapeutic application of ^{177}Lu-labeled anti-claudin-18.2 humanized VHH-based recombinant antibody in gastric cancer mouse xenograft model

Z. Wei, *B. Li, C. Li, X. Chen, J. Zhang;*
National University of Singapore, Singapore, SINGAPORE.

Aim/Introduction: Gastric cancer (GC) is a leading cause of cancer death globally, often diagnosed late with few treatment options. CLDN18.2, a protein overexpressed in GC, is a prime target for therapy and a vital biomaker. Zolbetuximab, an antibody targeting CLDN18.2, is a promising treatment, acting as more than a radionuclide carrier-it is a key part of the immune system. Full-size Zolbetuximab radioimmunoconjugates can accumulate in the non-target tissues, affecting the T/B ratio. Using smaller antibody fragments can improve tumor targeting and radiotracer clearance. This study explores the therapeutic efficacy of 177Lu-labeled Zolbetuximab and its scFv-Fc fragment (hTCE009) in GC mouse models. ***Materials and Methods:*** Flow cytometry was conducted using the CLDN18.2 humanized VHH-based recombinant antibody hTCE009 or Zolbetuximab. Zolbetuximab, or hTCE009, was conjugated with ρ-SCN-Bn-DOTA (DOTA) for 177Lu radiolabeling separately, followed by 177Lu labeling, purification, and evaluation. Cell uptake experiments were carried out with radiolabeled products, and activity measurement was performed using a gamma counter after incubation for different periods of time. SPECT imaging was conducted on the NUGCCLDN18.2 tumor model at multiple time points after administration of 177Lu-labeled antibodies. Biodistribution analysis was performed at the end of the imaging timepoint (168 h). ***Results:*** The NUGC4CLDN18.2 cell line showed the strongest expression of CLDN18.2 and the specific binding ability of hTCE009 or Zolbetuximab according to the results of flow cytometry and cell immunofluorescence. The radiochemical purity of 177Lu-DOTA-hTCE009 or 177Lu-DOTA-Zolbetuximab exceeded 95%. Cell uptake experiments showed a gradual increase in radioactive uptake values over time for both 177Lu-Zolbetuximab and 177Lu-hTCE009 in NUGCCLDN18.2 cell, about 3.03± 0.18 % and 5.45 ± 0.14 % at 4 h, respectively. While the 177Lu -Zolbetuximab blocking group exhibited lower radioactive uptake at all time points, about 0.86 ± 0.06 % at 24 h. And the 177Lu-hTCE009 blocking group exhibited lower radioactive uptake at all time points, about 0.33 ± 0.16 % at 4 h. In vivo SPECT imaging of 177Lu-Zolbetuximab and 177Lu-hTCE009 revealed an increasing tumor-specific uptake over time, and obvious tumor uptake could be observed at 16 h and 18h post-injection, respectively. Radioactive uptake values in the heart, liver, and kidneys rapidly increased initially and gradually decreased. ***Conclusion:*** In preclinical studies, 177Lu-hTCE009 demonstrated significant detecting efficiency of CLDN18.2-overexpressing tumor. It exhibits strong potential for clinical translation, providing a new promising treatment option for CLDN18.2-overexpressing tumors, including GC.

Cost Utility Analysis of ^{177}Lu-PSMA-617 Radioligand Therapy for Metastatic Castration-Resistant Prostate Cancer (mCRPC) in Germany

***T. Stargardt*[1],** *C. Brinkmann[1], R. P. Baum[2,3];*
[1]Universität Hamburg, Hamburg Center for Health Economics, Hamburg, GERMANY, [2]International Centers for Precision Oncology (ICPO), Wiesbaden, GERMANY, [3]CURANOSTICUM, Wiesbaden, GERMANY.

Aim/Introduction: The approval of 177Lu-PSMA-617 radioligand therapy (PRLT) offers targeted treatment for metastatic castration-resistant prostate cancer (mCRPC). Our aim is to determine the cost-effectiveness in Germany of (a) PRLT in addition to standard of care (SoC) compared to SoC alone as third-line treatment for mCRPC and of (b) PRLT compared to second-line Cabazitaxel chemotherapy, thus reflecting earlier use of PRLT in the treatment sequence. ***Materials and Methods:*** Two cohort state transition models were developed with (a) three health states (treatment/stable after treatment, progression, death) and (b) four health states (treatment/stable after treatment, 2nd treatment after first progression/stable after 2nd treatment, 2nd progression, death). Tunnel states were implemented to reflect different cost and quality of life values over time. Dynamic transition probabilities were obtained by fitting hazard models to published data from the VISION trial and the TheraP trial. Quality of life data was derived from the VISION trial and the CARD trial. We used claims data on cost of mCRPC patients between 2019 and 2022 from German SHI funds provided by GWQ ServicePlus AG. The models simulated a time span of 5 years with a cycle length of one month each. Half-cycle correction using the life table method and a 3% discount rate was applied. Deterministic and probabilistic sensitivity analyses were conducted to consider uncertainty. ***Results:*** For model (a), the incremental costs incurred by PRLT and SoC compared to SoC as third-line treatment for mCRPC patients amounted to €27,199.62 per patient, while 0.39 quality-adjusted life years (QALYs) were gained per patient. The Incremental Cost-Effectiveness Ratio (ICER) was €69,417.68 per QALY gained. For model (b), PRLT plus SoC compared to Cabazitaxel as second-line treatment for mCRPC followed by SoC or PRLT plus SoC after progression resulted in incremental savings of €1,460.43 per patient and a gain in QALYs of 0.11 per patient and was thus the dominant option. ***Conclusion:*** While there is no explicit willingness to pay threshold for Germany to interpret the ICER of model (a), our ICER is in the range of the ICER of other reimbursed cancer therapies. This indicates that PRLT may be cost-effective as second-line or third-line treatment for mCRPC. However, it should be noted that our cost data originate between 2019 and 2022, when hospitals mainly used self-produced 177Lu-PSMA-617, which is less costly than the one now commercially available, which limits the generalizability of our findings.

Biodistribution of ^{177}Lu- and ^{90}Y-labeled nanoparticles in tumor-bearing mice

A. Vukadinovic, *D. Stankovic, D. Jankovic, M. Radovic, M. Mirkovic, M. Peric, Z. Milanovic, S. Vranjes-Djuric;*
"VINCA" Institute of Nuclear Sciences - National Institute of the Republic of Serbia, University of Belgrade, Belgrade, SERBIA.

Aim/Introduction: Radioisotopes that emit beta particles are widely recognized for their effectiveness in tumor therapy. Additionally, using nanoparticles to deliver various therapeutics has emerged as a significant area of research recently. This study investigates the biodistribution of two nanoparticle formulations designed to carry the therapeutic radioisotopes 177Lu and 90Y. The first formulation studied is superparamagnetic iron-oxide nanoparticles coated with citrate and labeled with 90Y (90Y-CA-SPION), while the second formulation involves superparamagnetic iron-oxide nanoparticles coated with DMSA and labeled with 177Lu (177Lu-DMSA-SPION). The goal was to examine the biodistribution of radioactive nanoparticles which could potentially be used for tumor therapy. ***Materials and Methods:*** The bare superparamagnetic iron-oxide nanoparticles (SPIONs) were synthesized using Massart's method1, which involves the alkaline co-precipitation of iron salts in aqueous solutions. These SPIONs were then functionalized with either citric acid (CA) or dimercaptosuccinic acid (DMSA) and radiolabeled with either Yttrium (90Y) or Lutetium (177Lu). For the experiments, female BALB/c mice aged 8-10 weeks were used. These mice were implanted with murine CT-26 colon cancer cells to establish tumor xenograft models for the study. Biodistribution was investigated after i.v. applications of nanoparticles as well as after direct i.t. injections. After the application of nanoparticles, the experimental animals were sacrificed after 24 hours and after 4 days, and their organs were measured for radioactivity. In addition, In vivo imaging of the mice was performed using a direct radioisotopic imaging (DRI) instrument. ***Results:*** Radiolabelling yield was higher than 98% and remained high and practically unchanged at 72h post-labelling showing the great stability of both 90Y-CA-SPIONs and 177Lu-DMSA-SPIONs. Biodistribution results revealed that after the i.v. injection, both formulations of nanoparticles were taken up mainly by the liver and spleen (>90% ID). None of the formulations had a tumor uptake of more than 1% ID. In contrast, after the direct intratumoral injection, both formulations were shown to be stable, and radioactivity remained only in tumors during the four days of follow-up with high tumor retention (>95% ID). ***Conclusion:*** This study confirms the delivery of nanoparticles to solid tumors after i.v. injection is a challenge due to the low uptake by tumor tissue. Nevertheless, we believe that intratumorally injected radiolabeled SPIONs can be considered as a potential therapeutic agent for localized cancer therapy using direct intratumoral application. ***References:*** 1. Development and characterization of small molecules targeting tachykinin receptor 1 (TACR1) as potential theranostic agents

***S. Chopra*[1],** *H. Yushchyshyna[1], O. Vorontsova[1], H. Westin[2], P. Jha[1,3], U. Rosenström[4], U. Yngve[4,5], M. Nestor[1];*
[1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [2]Ridgeview Instruments AB, Uppsala, SWEDEN, [3]Department of Radiology, University of Texas Southwestern Medical Center, Dallas, TX, UNITED STATES OF AMERICA, [4]Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, [5]Science for Life Laboratory (SciLifeLab), Drug Discovery and Development platform, Uppsala, SWEDEN.

Aim/Introduction: The tachykinin receptor 1 (TACR1) has emerged as a promising target for theranostic applications due to its heightened expression in various cancers, including glioblastoma, neuroblastoma, childhood leukemia, and osteosarcoma. This upregulation of TACR1 influences critical processes like apoptosis, angiogenesis, and migration, making

it pivotal in carcinogenesis. Targeted radionuclide imaging and therapy offer potential for personalized diagnosis and treatment of patients with TACR1-positive tumors. ***Materials and Methods:*** Over fifty de novo stable iodine-containing TACR1-specific small molecules were designed, and synthesized. In vitro assessments were conducted to evaluate essential drug candidate properties, including solubility, metabolic stability, and plasma protein binding. Real-time binding studies using LigandTracer Green on TACR1-positive cells assessed the interaction of FAM-SP (FAM labelled Substance P) with TACR1, followed by competition assays of investigated compounds to FAM-SP to determine the binding affinity of the molecules. A manual inhibition assay using [125I]-substance P validated the replacement capacity of the molecules. Selected compounds were radiolabeled with 125I, followed by HPLC purification and assessment of stability, binding specificity and affinity on cells. ***Results:*** Following purification, the molecules demonstrated a purity of ≥ 98% and the radiolabeled compounds were stable for at least 20 days. Evaluation of FAM-SP binding kinetics on live cells revealed an affinity of 27±10 nM to TACR1. Compounds were ranked based on their efficacy in replacing FAM-SP, with top binders selected for subsequent iodination. The inhibition percentage of [125I]-substance P correlated with FAM-SP replacement efficacy. Radio-iodinated molecules displayed varying binding affinity and kinetics towards TACR1, with some compounds exhibiting affinities in the picomolar range. Specificity assays revealed significant blocking of the compounds by both validated TACR1-binders SP and aprepitant as well as with the cold investigated compound. ***Conclusion:*** Several TACR1-binding compounds have been successfully synthesized and characterized, displaying promising potential for theranostic applications. LigandTracer and specificity assays demonstrated specific binding and high affinity of selected compounds. Further in vitro and in vivo investigations are warranted to validate and expand upon these findings.

EP-0991

Biodistribution and in vivo efficacy of ^{161}Tb-labeled AKIR001, a novel anti-CD44v6 antibody

A. Mortensen[1,2,3], *A. Gustafsson[4,3], R. Selvaraju[4,5], F. Y. Frejd[4,3], M. Nestor[4,3];*
[1]Karolinska Institutet, Stockholm, SWEDEN, [2]Department of Molecular Medicine and Surgery, Stockholm, SWEDEN, [3]Department of Immunology, Genetics & Pathology, Science for Life Laboratory (SciLifeLab), Uppsala, SWEDEN, [4]Uppsala University, Uppsala, SWEDEN, [5]Department of Medicinal Chemistry, Uppsala, SWEDEN.

Aim/Introduction: Terbium-161 ([161Tb]Tb3+) has been suggested as a possible substitute for Lutetium-177 ([177Lu]Lu3+) in molecular radiotherapy. Both 177Lu- and 161Tb have favorable emissions and half-lives that align well with the pharmacokinetic properties of monoclonal antibodies. We have developed a full-size human IgG1 antibody toward the cell-surface antigen, CD44v6, AKIR001. In previous studies, AKIR001 was conjugated with DOTA and subsequently labeled with [177Lu]Lu3+ for biodistribution, dosimetry and efficacy studies in tumor-bearing mice. In the current study, we present a substantial exploration of [161Tb]Tb-DOTA-AKIR001 from in vitro to in vivo, in terms of stability, affinity, biodistribution and efficacy using the high CD44v6- expressing squamous cell carcinoma (SCC) xenograft model. ***Materials and Methods:*** AKIR001 was labeled with [161Tb]Tb3+ and evaluated for serum stability and EDTA-challenge, using a 500-fold molar excess of EDTA. Affinity of the radioconjugate was evaluated on cancer cell lines with varying degree of CD44v6 expression using LigandTracer technology and in vitro assays determined the specificity of the radioconjugate. Further, biodistribution studies in the SCC xenograft model evaluated the peak uptake and tumor-to-organ ratios of [161Tb]Tb-DOTA-AKIR001. Finally, efficacy of 161Tb-labeled AKIR001 was evaluated using the SCC xenograft model, and small-animal SPECT evaluated and verified tumor-specific uptake. Hematopoietic toxicity was measured by blood sampling throughout the efficacy study. ***Results:*** The radioconjugate was stable in both serum and in the presence of EDTA (> 98% at 48 h) with double-digit picomolar affinities to the target as expressed on cancer cell lines. Biodistribution revealed high peak uptake at 96 h p.i. and favorable tumor-to-organ ratios, while uptake was successfully and significantly impaired in the presence of a 30-fold molar excess of non-radiolabeled AKIR001 in vivo. Further, the radioconjugate demonstrated excellent efficacy in an activity-dose-dependent manner and SPECT-imaging verified tumor-specific at all dose levels. ***Conclusion:*** The 161Tb-labeled AKIR001 demonstrated excellent properties and could potentially be a highly relevant substitution for [177Lu]Lu3+ for future studies both at the preclinical and clinical level.

EP-0992

Fractionation of [^{177}Lu]Lu-DOTA-AKIR001 results in increased curative rates and favorable hematopoietic toxicities compared to single high dose

A. Mortensen[1,2,3], *A. Gustafsson[4,3], H. Berglund[4,3], T. Mohajer Shojai[4,3], R. Selvaraju[4,5], F. Y. Frejd[4,3], M. Nestor[4,3];*
[1]Karolinska Institutet, Stockholm, SWEDEN, [2]Department of Molecular Medicine and Surgery, Stockholm, SWEDEN, [3]Department of Immunology, Genetics & Pathology, Science for Life Laboratory (SciLifeLab), Uppsala, SWEDEN, [4]Uppsala University, Uppsala, SWEDEN, [5]Department of Medicinal Chemistry, Uppsala, SWEDEN.

Aim/Introduction: One of the main dose-limiting organs in molecular radiotherapy is the radiosensitive bone-marrow. It has been demonstrated that a fractionated dose in a "two-punch" setting can circumvent the toxicity compared to a single, high dose of the same compound. The current study evaluated the efficacy and hematopoietic toxicity a fractionated dose of [177Lu]Lu-DOTA-AKIR001, a full-size anti-CD44v6 antibody in tumor-bearing mice. ***Materials and Methods:*** AKIR001 was labeled with [177Lu]Lu3+ according to standard methods and stability was evaluated in the presence of both mouse- and human serum. The radioconjugate was evaluated for biodistribution and subsequent dosimetric calculations were extrapolated to human equivalent doses. The efficacy of three different dose levels (5 MBq, 7.5 MBq and 15 MBq) was evaluated in SCC xenografts with high CD44v6-expression levels and hematopoietic toxicity was evaluated through hematopoietic analyses. The 7.5 MBq dose was repeated at 14 days post injection (p.i.). Small animal SPECT was used to evaluate and verify tumor-specific uptake of [177Lu]Lu-DOTA-AKIR001. ***Results:*** Labeling yields were > 99% and remained stable in the presence of both mouse- and human serum (> 98% at 48 h). Biodistribution in SCC xenografts revealed peak tumor uptake of [177Lu]Lu-DOTA-AKIR001 at 96 h p.i. (65%ID/g), while tumor uptake was significantly decreased in vivo at 96 h p.i. in the presence of a 30-fold molar excess of non-radiolabeled AKIR001. Efficacy studies in the SCC xenograft model demonstrated an activity-dose-dependent correlation in tumor response, resulting in high curative rates in the fractionated group (100%) and the high dose group (75%) at day 60 p.i. Median survival for the PBS control group was 7 days, while median survival for the 5 MBq [177Lu]Lu-DOTA-AKIR001 group was 31 days, a >four-fold

increase in survival. SPECT imaging at 6 days p.i. verified specific tumor uptake in all treatment groups. Hematopoietic parameters revealed that white blood cells and platelets were greatly affected by the treatment, albeit in a dose-dependent manner. A rapid and considerable decrease in white blood cells, red blood cells and platelets was observed for the single dose, while a moderate decrease was observed for the fractionated dose. ***Conclusion:*** 177Lu-labeled AKIR001 has an activity dose-dependent effect on tumor growth and subsequent survival of tumor-bearing mice. The study verified that a fractionated dose yields better tolerability compared to a single, high dose, while retaining the desired efficacy, indicating that the upcoming clinical assessment of AKIR001 would benefit from a fractionated dose-setting.

EP-0993

Evaluation and Design of New Chelators using Density Functional Theory Modeling : Implications for Improved Performance of ^{203}Pb/^{212}Pb-based Theranostic for Cancers

***D. Lee*[1]**, *J. Kim*[2], *G. Kang*[3], *K. Shin*[4], *W. Lee*[2], *M. K. Schultz*[5];
[1]*Department of Physics and Chemistry, Korea Military Academy, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Chemical and Biological Engineering, Seoul National University, Seoul, KOREA, REPUBLIC OF,* [3]*Chemical, Biological, Radiological Defense Research Institute, Seoul, KOREA, REPUBLIC OF,* [4]*Department of Materials Science and Engineering, Hanbat National University, Daejeon, KOREA, REPUBLIC OF,* [5]*Perspective Therapeutics Inc., Coralville, IA, UNITED STATES OF AMERICA.*

Aim/Introduction: 203Pb/212Pb-based alpha-particle theranostics holds significant potential for targeted imaging and therapy for cancers. One of the key factors leading to the success of the targeted theranostics is the sophisticated matching of the chelator to the specific radionuclide, ensuring stability and targeted delivery. In this study, we evaluated multiple chelators for imaging and therapeutic radionuclides, and newly designed chelator compositions to potentially optimize for the Pb isotopes. ***Materials and Methods:*** Density Functional Theory (DFT) modeling techniques were utilized to analyze the interaction energies between radionuclides and chelators and to determine the chelation configuration of the complexes. Multiple chelators extensively used in targeted theranostics (i.e., DOTA, NOTA, and TETA), were investigated with imaging (e.g., 68Ga, 64Cu, 111In) and therapeutic radionuclides (e.g., 177Lu, 90Y). Based on the findings of the initial studies, new chelator compositions were designed and being evaluated for 203Pb/212Pb to identify an optimized form the theranostic pair. ***Results:*** The computational analyses elucidated that the physicochemical properties, particularly size and charge compatibility between chelators and radionuclides, influence the stability of the complexes. NOTA-Ga, DOTA-Y, and TETA-Cu complexes showed the highest levels of stability as suggested previously. The configuration analysis suggested that the coordination number varied depending on the ionic radius. Small ions (e.g., Ga3+, Cu2+) tend to prefer 6-coordinated complex (octahedron), whereas large ions (lanthanide ions) are mostly found in 8-coordinated complexes (square antiprism). Bader charge analysis indicated that the stability of the chelator-radionuclide complex increased when minimal alterations occurred in the total charge before and after chelation. In addition, we observed that a new chelator composition form, Pb specific chelator (PSC), exhibited lower chelation energy, indicating better chelation performance, and preferred configuration compared to the DOTA counterpart. Further analyses with new designs are being performed to identify better chelator candidates. ***Conclusion:*** This study elucidates how each chelator react with imaging and therapeutic radionuclides, optimizing chelating form for the respect radionuclide. The results confirmed the superior performance of the modified chelators when compared to conventional forms and thus validated our computational strategy to be an effective tool for customizing chelators for targeted theranostics. Ongoing studies are expected to suggest novel chelator compositions designed for improved stability and specificity for 203Pb/212Pb theranostic radionuclides.

Radiolabelling, In Vitro Receptor Binding, and In Vivo Distribution of Anti-VEGFR2 Monoclonal Antibody Ramucirumab Radiolabelled with Terbium-161

***F. Trejtnar*[1]**, *P. Barta*[1], *Z. Novy*[2], *J. Maixnerova*[1], *M. Vlk*[3], *P. Pavek*[1], *J. Kozempel*[3];
[1]*Charles University, Faculty of Pharmacy in Hradec Kralove, Hradec Kralove, CZECH REPUBLIC,* [2]*Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University Olomouc, Czech Republic, Olomouc, CZECH REPUBLIC,* [3]*Faculty of Nuclear Sciences and Physical Engineering, Czech Technical University in Prague, Czech Republic, Prague, CZECH REPUBLIC.*

Aim/Introduction: Anti-VEGFR2 agents such as monoclonal antibody ramucirumab (RAM) can inhibit the VEGFR2 receptor and suppress undesired angiogenesis in tumours. The fully humanized RAM targets the extracellular receptor binding site and hence prevents interactions with natural VEGF ligands. Besides FDA and EMA approved therapeutic application non-labelled RAM, the antibody can be potentially applied for radio imaging or radiotherapeutic treatment of VEGFR2-positive tumours using appropriate radiolabel. The aim of the study was to prepare an applicable preparation of 161Tb-radiolabelled RAM and evaluate 161TbRAM biological characteristics in vitro and in vivo, including binding to the target and accumulation in a model tumour. ***Materials and Methods:*** Ramucirumab was conjugated with pSCNBnDOTA using a standard method. The purified immunoconjugate DOTA-RAM was further radiolabelled with terbium-161, a β- and γ emitter. The binding ability of the prepared radioimmunoconjugate to the target receptor was tested in vitro using real-time analysis to determine equilibrium dissociation constant (KD) in VEGFR2-bearing human prostate adenocarcinoma (PC-3) and ovary adenocarcinoma (SKOV3) cell lines. [161Tb]Tb-DOTA-RAM organ distribution ex vivo was analysed in BALB/c mice. SCID PC-3 mouse xenografts were used to obtain SPECT/CT imaging in selected timepoints. ***Results:*** The prepared [161Tb]Tb-DOTA-RAM radioimmunoconjugate exhibited a high radiochemical purity (>95 %) and metabolic stability. In vitro experiments found a high binding affinity of [161Tb]Tb-DOTA-RAM to the target receptors in PC3 and SKOV3 cells, respectively. The obtained biodistribution data of [161Tb]TbDOTARAM in noncancerous mice demonstrated dominant accumulation of [161Tb]Tb-DOTA-RAM in lung, liver and spleen (7.0, 5.3 and 3.6 % /g) at 72 h p.i. Similar biodistribution patterns were found in xenografted mice but relatively high radioactivity was found to be continuously accumulated in the model tumour in dependence on time following administration. ***Conclusion:*** The prepared 161Tb-labelled RAM showed adequate radiopharmaceutical parameters to be applicable for biological experiments. The used method for radiolabelling with terbium-161 enabled to preserve high binding ability to the target receptors. In addition, the observed gradual accumulation in the tumour tissue could be a base for potential therapeutic application of the tested

radioimmunoconjugate. ***References:*** Acknowledgements:The authors would like to thank for the financial support to Ministry of Health of the Czech Republic (grant NU23-08-00214), and to Charles University, program Cooperatio Pharmaceutical Sciences.

Comparative study: Exploring the Advantages of Tb-161 over Lu-177 in Targeted Radionuclide Therapy and the impact of Antagonist vs Agonist

C. Ntihabose[1], *M. Handula[1], S. Beekman[1], A. Piet[1], L. van Dalen[1], J. Zink[1], D. Stuurman[1], C. de Ridder[1], G. Tamborino[1], M. Konijnenberg[1], T. Brabander[1], J. Nonnekens[1], Y. Seimbille[1,2], E. de Blois[1];*
[1]Erasmus MC, Rotterdam, NETHERLANDS,
[2]TRIUMF, Vancouver, BC, CANADA.

Aim/Introduction: In the field of targeted radionuclide therapy (TRT), [177Lu]Lu-DOTA-TATE is one of the pioneers in the treatment of neuroendocrine tumors (NETs) by targeting the SSTR2 receptor. Over the years, new approaches such as the labeling of antagonists (e.g., DOTA-JR11) have been introduced. Regardless, these studies have shown that SSTR2 antagonists have a lower binding affinity to the receptor in comparison to SSTR2 agonists (e.g., DOTA-TATE), but still results in higher cell-uptake. With the rationale that antagonist are not internalized but remain at the membrane, TRT could potentially be improved by combining an antagonist with an Auger/conversion emitting nuclide, since the cell membrane has been identified as an optimal target for these types of electrons [1]. Similar to Lu-177, Tb-161 is a β--emitter, but additionally emits Auger/conversion electrons. Therefore, Tb-161 could be an interesting isotope for the treatment of NETs. In this study, antagonist/agonist were compared using both Lu-177 and Tb-161 ***Materials and Methods:*** DOTA-TATE and DOTA-JR11 were labeled with either Lu-177 or Tb-161 under identical labeling conditions. The radiochemical yield (RCY) and radiochemical purity (RCP) were determined by iTLC and radio-HPLC, respectively. The stability of the four radiopharmaceuticals were determined in labeling formulation, PBS and mouse serum (MS) at 2, 4 and 24h. Cell-binding assays on U2OS-SSTR2+ cells were performed to evaluate the differences between Lu-177 and Tb-161 labeled compounds at 1h, 2h and 3h. Mouse bio-distributions were performed at 4, 24, 48 and 72h (5MBq/0.5nmol) post injection for all 4 labelled compounds. ***Results:*** Radiolabeling results of Tb-161 were similar to Lu-177. All 4 compounds showed stability >90% RCP in formulation solution, PBS and MS after 24 hours. Cell binding experiments showed a similar pattern in total binding at all-time points for [177Lu]Lu-DOTA-TATE (61.14% at 3h n=3) and [161Tb]Tb-DOTA-TATE (53.07% at 3h n=3) as for [161Tb]Tb-DOTA-JR11 (69.31% at 3h n=3) and [177Lu]Lu-DOTA-JR11 (72.68% at 3h n=3). Preliminary bio-distribution studies showed a tumor-kidney ratio for [177Lu]Lu-DOTA-TATE (0.61% at 4h n=4) , [161Tb]Tb-DOTA-TATE (0.58% at 4h n=4) and [161Tb]Tb-DOTA-JR11 (0.43% at 4h n=4), [177Lu]Lu-DOTA-JR11 (0.7% at 4h n=4). ***Conclusion:*** The labeling conditions and stability were similar for all the 4 radiopharmaceuticals. Cell-binding experiments showed no significant difference between either [177Lu]Lu-DOTA-TATE and [161Tb]Tb-DOTA-TATE or [161Tb]Tb-DOTA-JR11 and [177Lu]Lu-DOTA-JR11. Bio-distribution showed no significant difference in uptake ex vivo. These outcomes underlines the similarity of Lu-177/Tb-161 labelled compound, and will be used to for future therapeutic comparison. ***References:*** 1. Muller, et al, EJNMMI (2023).

EP-0996

Preclinical efficacy of CAIX-targeting [^{177}Lu]Lu-WT-735-0626 for aggressive renal cell carcinomas

H. Comas Rojas[1], *N. Clemons[1], H. Chen[2], B. Dyck[2], J. R. Young[2], R. Hernandez[1];*
[1]Department of Medical Physics, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA, [2]WARF Therapeutics, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Clear cell renal carcinoma (ccRCC), which accounts for 80-90% of all kidney cancers, is one of the most aggressive subtypes with a high incidence of metastases and low survival. Carbonic anhydrase IX (CAIX), a cell membrane protein overexpressed in >90% of cell ccRCC patients, is an attractive tumor-specific target for radiopharmaceutical therapy (RPT). We aim to develop a novel series of high affinity, selective radioligands targeting CAIX as next-generation RPT agents for ccRCC. ***Materials and Methods:*** Radioligands were synthesized featuring our potent CAIX binders and DO3A as chelating moiety. Lead candidates, WT-735-0626 (626; Ki=2.8 nM) and WT-735-0729 (729; Ki=0.17 nM) were radiolabeled with 111In or 177Lu, for Single-Photon Emission Computerized Tomography (SPECT) and therapeutic studies, at an apparent molar activity of 7.4 or 1.8 GBq/μmol. [111In]In-626/729 (8.4 MBq) was intravenously injected in female nude mice bearing subcutaneous SK-RC-52 ccRCC xenografts and SPECT/CT acquired in an MI Labs U-SPECT scanner at 1, 4, 24, 48, 120 and 168 h post-injection (p.i.). Ex vivo biodistribution followed the last imaging time point. Region of interest analyses of the SPECT/CT images using Imalytics 3.0 software determined tumor and normal tissue uptake, reported as injected activity per gram of tissue (%IA/g; mean ± SD) and absorbed dose per activity (Gy/MBq) for each agent. In therapeutic studies, groups of mice (N=5-10) received IV [177Lu]Lu-626 or [177Lu]Lu-729 (18.5, 37 or 111 MBq), [177Lu]Lu-girentuximab, or vehicle control. Tumor growth, overall survival, and animal health were recorded three times weekly. ***Results:*** Radiolabeling of 626 and 729 with 111In/177Lu proceeded quantitatively with high radiochemical purity and stability (>95%). SPECT/CT images revealed high uptake and prolonged retention in SK-RC-52 tumors, peaking at 45.3 ± 1.8 %IA/g and 51.7 ± 12.1 %IA/g for [111In]In-626 and [111In]In-729, at 24 h p.i. Dosimetry estimates for 177Lu-labeled analogs showed unprecedented tumor adsorbed dose rates north of 3.0 Gy/MBq. Consequently, [177Lu]Lu-626/729 treatment led to significant tumor regression and extended animal survival for over 60 days in all treatment arms compared to the control. Repeat efficacy studies escalating [177Lu]Lu-626 IA confirmed the efficacy and tolerability of the treatment. ***Conclusion:*** We have developed novel CAIX radioligands with exquisite potency, selectivity, in vivo tumor targeting, and normal tissue distribution. Our therapeutic efficacy data evidenced best-in-class potential of [177Lu]Lu-626/729, supporting our current efforts toward the clinical translation of these promising RPT agents in ccRCC and other CAIX-expressing cancers.

Targeting Esophageal Cancerfor Imaging and Therapy Using Claudin 6 Radioligands

H. Du, *X. Hao;*
University of Electronic Science and technology, Chengdu, CHINA.

Aim/Introduction: Advanced or metastatic esophageal cancer(EC) is associated with poor prognosis; new and effective treatment methods are needed. The purpose of this study was to assess whether Claudin 6 (CLDN6) is a useful target for imaging and radioligand therapy of EC, using a novel pair of radioactive nuclides, 89Zr and 177Lu. ***Materials and Methods:*** CLDN6 expression was evaluated in two BC datasets (n = 436 biopsies). We performed a retrospective analysis of 109 patients with EC to evaluate CLDN6 expression. we use the anti-CLDN6 mAb labelled with 89Zr and 177Lu for PET imaging and therapy, respectively. We performed imaging and biodistribution analyses on a xenograft model characterized by high levels of CLDN6 expression. Furthermore,we have evaluated the therapeutic potential of 177Lu-IMAB027 within this model. ***Results:*** CLDN6 is not expressed in normal esophagus, but its expression rate in esophageal cancer tissue is 79.8%. 89Zr-IMAB027 has shown good stability in vitro and can effectively image EC xenografts with high expression of CLDN6. 177Lu-IMAB027 has demonstrated favorable tumor targeting in vivo, with higher tumor uptake compared to other tissues. Therapy studies with a single dose of 177Lu-IMAB027 in the TE-1-CLDN6 model exhibited better tumor regression and survival outcomes compared with the monoclonal antibody and control groups ($p < 0.05$). ***Conclusion:*** CLDN6 has a high expression rate in esophageal cancer and is a promising target for imaging and radioligand therapy. 89Zr-IMAB027 showed high contrast to visualize CLDN6 expressing xenografts for PET imaging, and 177Lu-IMAB027 induced rapid tumor regression in a preclinical model of EC.

EP-0999

Development of Follicle Stimulating Hormone Receptor Ligands for Ovarian Cancer Theranostics

L. Bohrmann[1], *R. Coelho[2], R. Mansi[1], F. Jacob[2], M. Fani[1];*
[1]University Hospital Basel, Division of Radiopharmaceutical Chemistry, Basel, SWITZERLAND, [2]University of Basel, Department of Biomedicine, Ovarian Cancer Research, Basel, SWITZERLAND.

Aim/Introduction: The Follicle Stimulating Hormone Receptor (FSHR) is physiologically expressed only in the reproductive system, while being overexpressed in many primary and metastatic tumors[1], and notably within the majority of gynecological cancers, like ovarian cancer[2]. We aim to develop first-in-class radioligands targeting FSHR as theranostics for ovarian cancer, based on binding domains of the α- and β-subunit of Follicle Stimulating Hormone (FSH). In parallel, we aim to develop and validate a panel of FSHR-expressing cell lines and tumor models for the preclinical assessment. ***Materials and Methods:*** A series of six rationally designed linear and cyclic peptidomimetics were synthesized by solid phase peptide synthesis; FNM-101, FNM-102 and FNM-103 were based on domains of the FSHβ, and FNM-1, FNM-2 and FNM-4 combined binding domains of FSHα- and FSHβ subunit. All ligands were conjugated to DOTA, characterized by RP-HPLC and ESI-MS and labeled with [177Lu]LuCl3. Their distribution coefficients (log D) were determined in octanol/PBS7.4. A panel of 6 cell lines (HT1080, OVCAR-8, SKOV-3, HEK-293, SKRC-52 and A431) were subjected to lentiviral transduction with pUltra plasmid encoding human FSHR, enabling bicistronic expression of FSHR and EGFP fluorescent reporter (FSHR+), or empty pUltra plasmid to produce FSHR-negative control cell lines (FSHR-). Transduced cells were sorted by FACS and further validated by flow cytometry. ***Results:*** Six new FSH-based ligands were designed and synthesized with >95% purity. They were labeled with Lu-177 with radiochemical purity of >95%, at an apparent molar activity of 50 MBq/nmol. All radioligands demonstrated high hydrophilicity, with log D values ranging from -4.42 ± 0.37 to -3.08 ± 0.33, suggesting favorable biodistribution. Flow cytometry on live FSHR+ cells with Alexafluor647-conjugated FSHR and isotype control antibody demonstrated high and specific expression of FSHR on the cell surface. Mean fluorescence intensity values of FSHR+ cells ranged from 34 to 66-fold increased fluorescence over background. ***Conclusion:*** A first series of 177Lu-labeled peptidomimetics of FSH was synthesized. The successful generation of FSHR-expressing cell lines enables their in vitro evaluation and ensures the generation of a FSHR-expressing tumor model(s) for in vivo assessment. The in vitro and in vivo characterization of the radioligands is currently ongoing and will be presented. ***References:*** [1] A. Radu et al., NEJM 363, 1621-1630 (2010). [2] A. Perales-Puchalt et al., Clin Cancer Res 23, 441-453 (2017).

Fibroblast-activating protein (FAP) expression in high-grade meningioma: a potential target for theranostic treatments

M. Mair[1,2], *S. Hartenbach[3], E. Tomasich[1], S. L. N. Maas[4,5], S. A. Bosch[1], G. Widhalm[6], F. Eckert[7], F. Sahm[8], J. A. Hainfellner[9], M. Hartenbach[3], A. S. Berghoff[1], M. Preusser[1], N. L. Albert[2];*
[1]Division of Oncology, Department of Medicine I, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Nuclear Medicine, Ludwig Maximilians University Munich, Munich, GERMANY, [3]MINUTEmedical GmbH, Vienna, AUSTRIA, [4]Department of Pathology, Leiden University Medical Center, Leiden, NETHERLANDS, [5]Department of Pathology, Erasmus MC Cancer Institute, University Medical Center Rotterdam, Rotterdam, NETHERLANDS, [6]Department of Neurosurgery, Medical University of Vienna, Vienna, AUSTRIA, [7]Department of Radiation Oncology, Medical University of Vienna, Vienna, AUSTRIA, [8]Department of Neuropathology, Institute of Pathology, Ruprecht-Karls University Heidelberg, and Clinical Cooperation Unit Neuropathology, German Consortium for Translational Cancer Research (DKTK), German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [9]Division of Neuropathology and Neurochemistry, Department of Neurology, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Fibroblast activating protein (FAP) is a promising target of diagnostic and therapeutic nuclear medicine approaches in a variety of solid tumors. Higher-grade meningiomas represent an unmet clinical need in neuro-oncology, as they are associated with high recurrence rates, limited treatment options and shorter survival times. ***Materials and Methods:*** Overall, 58 samples of high-grade meningioma were retrieved from the institutional Neuro-Biobank. Immunohistochemical stainings of FAP and somatostatin receptor subtype 2a (SSTR2a) have been performed using monoclonal rabbit anti-FAP (clone JA56-11, Thermo Fisher Scientific) and anti-SSTR2a (clone EP149, Cell Marque) antibodies. DNA methylation analysis was performed using Illumina EPIC 850k chips, and panel sequencing for NF2, TRAF7, KLF4, SMO, AKT1, TERT promotor, ARID, SUFU and PIK3CA was done using Illumina NextSeq. ***Results:*** Median age of included patients was 60 years (range: 19-83), and 35/58 (60.3%) of patients were female. Most meningiomas were atypical according to initial diagnosis (30/58, 51.7%), followed by anaplastic (18/58, 31.0%), chordoid (9/58, 15.5%), and rhabdoid histologies (1/58,

1.7%). WHO grades as to the current 2021 classification were CNS WHO grade 1 in 1/58 (1.7%), CNS WHO grade 2 in 39/58 (67.2%), and CNS WHO grade 3 in 18/58 (31.0%) of samples. Most tumors were located at the falx and the cerebral convexity (36/58, 62.1%). FAP expression was seen in 15/58 (25.9%) included samples with marked spatial heterogeneity as positive areas were most frequently located in the stroma or at tumor edges. Overall, 12/18 (66.7%) tumors of CNS WHO grade 3 tumors were positive for FAP as opposed to 3/39 (7.7%) of CNS WHO grade 2 meningiomas ($p < 0.001$). In line, DNA methylation subtyping showed numerically more frequent FAP+ staining in tumors of malignant methylation class (4/8, 50.0%) compared to benign (4/23, 17.4%) or intermediate (7/27, 25.9%, $p = 0.069$). In addition, 4/5 (80.0%) samples with homozygous deletion in CDKN2A/B showed FAP staining. FAP expression was more frequently observed in patients with NF2 mutations (10/25, 40.0%) than in those without (5/33, 15.2%, $p = 0.032$). Of FAP+ samples, 12/15 (80.0%) were also positive for SSTR2a on tumor cell membranes. ***Conclusion:*** FAP is expressed in a subset of high-grade meningioma samples. Further investigation of FAPi-based radioligands is warranted, and given the complimentary expression pattern with SSTR2a, combination treatments with DOTATATE-based treatments could represent a promising strategy.

Development of a Preclinical Physiologically-Based Pharmacokinetic Model for ^{161}Tb-DOTATATE

J. Henriot[1,2], *L. Struelens[1], M. Andersson[1,3], K. Spoormans[1,2], M. Koole[2], C. Saldarriaga Vargas[1];*
[1]Research in Dosimetry Applications, Belgian Nuclear Research Centre (SCK CEN), Mol, BELGIUM, [2]Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, Katholieke Universiteit Leuven (KUL), Leuven, BELGIUM, [3]Faculté de Médecine, Université Libre de Bruxelles (ULB), Brussels, BELGIUM.

Aim/Introduction: 161Tb-DOTA-TATE is an emerging β- and Auger electron emitter with a high potential for radioligand therapy (RLT) against neuroendocrine tumours overexpressing the somatostatin receptor type 2 (SSTR2). RLT is often associated with both an interindividual variability and a heterogenous distribution of the radiopharmaceutical between and within tissues, due to patient- and tissue-specific SSTR2 expressions and tumour burden. Therefore, there is a need to consider the influence of tumour SSTR2 expression levels on radiopharmaceutical uptake by both the tumour and the organs-at-risk. In this respect, this study aimed to investigate and describe the pharmacokinetic behaviour of 161Tb-DOTA-TATE firstly in healthy mice using physiologically-based pharmacokinetic (PBPK) modelling. ***Materials and Methods:*** A murine whole-body PBPK model was implemented for 161Tb-DOTA-TATE using MATLAB Simbiology®. The model structure and model parameters were based on a published 212Pb-DOTAM-TATE tumour mice PBPK model [1]. The model was adapted to 161Tb-DOTA-TATE physicochemical properties and novel in vitro binding data for the CA20948 cell line and healthy mice characteristics. The kinetic parameters and SSTR2 densities of the different compartments were investigated by fitting the model to preclinical biokinetic data of 161Tb-DOTA-TATE in blood, kidneys, pancreas, liver, spleen and lungs obtained from healthy C57BL/6 mice at 6 time points. Model performance was evaluated by comparing the simulated time-integrated activity (TIA) with the observed data. Additionally, parameter sensitivity analyses were conducted. ***Results:*** A good fit of the model to the biodistribution data was observed with relative errors for the TIA ranging from -24% for pancreas, to 38% for spleen. Compared to the values used in [1], substantial organ-specific increases of SSTR2 densities were needed to match the observed data. This increase was up to +120% for lungs, spleen, and pancreas, while much higher adjustments were required for liver (+1700%) and kidneys (+4400%). Thus, the contribution of renal specific binding was substantially increased, while the nonspecific endocytosis rate associated to tubular reabsorption was lowered, compared to [1]. ***Conclusion:*** The developed PBPK model successfully described the pharmacokinetic behaviour of 161Tb-DOTA-TATE in mice. The high influence of SSTR2 expression on the radiopharmaceutical kinetics emphasized the need for an accurate description and quantification of SSTR2 expression in tissues at the organ and sub-organ levels, which will be our next research goal. These results in a preclinical setting constitute a first step towards the application of PBPK modelling to support dosimetry-based RLT personalization with radiolabelled somatostatin analogues. ***References:*** [1] Zaid et al., Pharmaceutics. 2021;10;13(12):2132. https://doi.org/10.1089/cbr.2020.4112.

EP-1002

^{11}C-labeling in two different positions of the prodrug of a potential novel antidepressant.

V. Stepanov[1], *A. Forsberg[1], Y. K. Meynaq[1], R. Mohammadi[1], A. Varrone[1], P. Kilburn[2], T. Frihed[2], T. Andersen[2], C. Jones[2], B. Bang-Andersen[2], C. Halldin[1];*
[1]Karolinska Institutet, Stockholm, SWEDEN, [2]H. Lundbeck A/S, Copenhagen-Valby, DENMARK.

Aim/Introduction: An amino acid-based methyl ester prodrug of a potent and selective glycine binding site partial agonist of the N-methyl-D-aspartate (NMDA) receptor was investigated for blood-brain barrier (BBB) penetration. The aim of the study was to label the prodrug with carbon-11 in two different positions to investigate the BBB penetration of the prodrug in a NHP model. ***Materials and Methods:*** The two versions of the prodrug labeled in different positions, but structurally identical, were synthesized from the corresponding precursors using TracerMaker (Scansys, Denmark) module. First, [^{11}C]methyl ester labeled prodrug (1) was synthesized using amino Boc-protected acid precursor, with the carbon-11 introduced using [^{11}C]MeOTf in acetone (with NaHCO3 as base), followed by deprotection with 6M HCl and purification on Shodex Asahipak ODP-50 6E column with MeCN/aq. K-phosphate buffer pH 5.8 (0.05M) as mobile phase. After SPE isolation, the product was formulated in saline/EtOH mixture (<10% EtOH w/v). Secondly, a [^{11}C]methyl group was introduced in the substituted aromatic ring of the prodrug (2) from amino Boc-protected stannyl precursor using a previously published approach (Pretze et al. Molecules 2011, 16, 1129), followed by deprotection. Purification and formulation were conducted similarly to [^{11}C]methyl ester labeled analog. NHP PET imaging was conducted in cynomolgus monkeys on Siemens HRRT system (imaging time of 120 minutes, average injection of 110±40 MBq). ***Results:*** Labeling of 1 and 2 was successfully accomplished, with possibility of producing up to 1 GBq of the [^{11}C]methyl ester labeled prodrug 1 per synthesis. Yield of prodrug 2 were much lower due to labelling complexity.

Labeling of the prodrug, independent of label position, was complicated due to sensitivity of the compound to radiolysis on silica-based stationary phases. This necessitated use of polymer-based SPE cartridges (Oasis HLB) and Asahipak ODP-50 6E semi-prep column. Both compounds were produced in RCP >95% and were stable in formulation for at least 40 min, MA was 173±90 GBq/μmol at TOI, average carrier mass injected was <0.25 μg. Brain uptake of 1 ranged from 0.9 to 1.8 in SUV and between 1.2 to 2.4% injected dose %ID. Peak brain uptake of 2 ranged from 0.7 to 0.9 in SUV and between 0.7 to 0.9 %ID. ***Conclusion:*** A methyl ester prodrug was labelled in two different positions and BBB penetration was clearly seen for both versions in a NHP model. Findings support further evaluation of brain uptake in human subjects using these carbon-11 labelled prodrugs to verify brain penetrance.

EP-1003

Model-Informed Drug Development Framework for the Development and Dose Optimization of Targeted Radiation Therapies

H. Stephens, *B. Koirala, K. Watson, M. Trame, A. Manon, J. Apgar; Certara, Radnor, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: While targeted radiation therapies (TRTs) are raising more and more interest in the oncology space, the regulatory landscape continues to evolve leaving development teams without clear guidance. Model-Informed Drug Development (MIDD) can provide key insights into optimizing doses to achieve maximum efficacy within safety bounds, as well as the design of novel therapeutics with enhanced therapeutic index. The theranostic nature of TRTs allows for precise modelling and prediction of drug kinetics and absorbed doses which will allow for better decision-making in the development process. In this abstract, we present an end-to-end framework for using MIDD with TRTs, specifically with PSMA targeting radio-ligands. ***Materials and Methods:*** Taking both plasma activity and combining with nuclear imaging, the drug kinetics was modelled in both the blood and organs of interest. The semi-mechanistic compartmental models incorporated any saturable uptake of the radio-ligand into peripheral organs of interest as a function of tissue volume and target expression. Parameterizing the models in terms of drug radioactivity allowed for the calculation and prediction of absorbed doses into specific organs of interest. These models were used to optimize drug properties such as binding affinity, and plasma half-life to improve therapeutic index and support candidate selection. Subsequently, at later stages, with the ability to predict organ absorbed dose, the dosing regimen can be optimized by minimizing the simulated adverse event profile linked to specific organs while maximizing tumour exposure. ***Results:*** The MIDD framework was validated using published clinical data with published Pluvicto (lutetium Lu 177 vipivotide tetraxetan). The framework made accurate predictions of across a range of doses, PSMA densities, and tumor volumes accounting for distribution and competitive binding of labeled and un-labeled drug in tumor and non-tumor tissues. In addition, the framework allowed to characterize the specific radioactive dose absorbed into blood and various organs such as liver, kidney, spleen, salivary gland and tumor. The absorbed dose predictions were in good alignment with the patient specific dosimetry results. Subsequently, the model predicted exposures were linked to safety and efficacy endpoints which allowed extrapolation from the dosimetry to clinical endpoints. ***Conclusion:*** The MIDD framework can be utilized to translate drug design features such as receptor binding affinity on the disposition in various organs of the radio-labeled drug to inform clinical candidate selection to help maximize the therapeutic index. Subsequently, the framework can be utilized to establish first-in-human dosing regimens and to optimize recommended Phase 2 doses.

EP-1004

PET/CT monitoring of lung-targeted extracellular vesicles delivery of siRNA for the treatment of lung metastatic tumors

R. Guo, *X. Lan, R. An, D. Jiang;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College,Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Extracellular vesicles (EVs) possess natural material transport properties and excellent biocompatibility, making them uniquely advantageous as gene delivery carriers[1]. However, the tendency of nanomaterials to accumulate in the liver and spleen poses a significant barrier to their clinical translation[2]. Currently, there is a lack of rational design strategies for efficient EVs delivery to target cells in tissues other than the liver. Here, auxiliary molecules are added to the EVs membrane surface to enable targeted delivery of siPD-L1 to the lungs for tumor treatment via endogenous targeting. PET/CT and fluorescence imaging monitor its metabolic distribution in the body. ***Materials and Methods:*** B16-F10 tumor cell-derived microvesicles (TMVs) were extracted using differential centrifugation. The cationic lipid DOTAP was engineered for lung targeting, and the surface of TMVs was modified with the NOTA group for 68Ga labeling. Mice received injections of either 68Ga-TMVs-DOTAP or 68Ga-TMVs via the tail vein. PET/CT imaging was conducted for each group. DiR was used to label TMVs-DOTAP and TMVs, and fluorescence images were collected after intravenous injection into mice. B16-F10 cells were incubated with TMVs-DOTAP/siPD-L1, confirming its ability to silence the PD-L1 gene in vitro. A mouse model of melanoma lung metastasis was established. Subsequently, TMVs-DOTAP/siPD-L1, TMVs-DOTAP/siNC, TMVs-DOTAP, TMVs, and PBS were injected via the tail vein to assess their in vivo anti-tumor effects. ***Results:*** TMVs are extracted from the cell supernatant through multi-step centrifugation. The protein content is 0.4-0.6 mg/mL. The particle sizes of TMVS, NOTA-TMVS, and NOTA-TMVs-DOTAP measured by nanoflow cytometry are 150.2±18.7, 153.2±18.3, and 195.8±14.7 nm. PET/CT imaging revealed that TMVs-DOTAP selectively accumulated in the lungs. In contrast, unmodified TMVs predominantly accumulated in the liver. Fluorescence imaging showed that TMVs-DOTAP persisted in the lungs 72 h post-injection. Western blotting and flow cytometry confirmed that TMVs-DOTAP/siPD-L1 effectively reduced PD-L1 protein expression levels to exert anti-tumor effects. ***Conclusion:*** This study focuses on developing new technologies for functionalized EVs strategies. We introduced the cationic lipid DOTAP to the EVs membrane surface for targeted delivery of siPD-L1 to the lungs through endogenous targeting. This advancement enhances the applicability of EVs in both preclinical and clinical settings. ***References:*** [1] WITWER K W, WOLFRAM J. EP-1005

Preclinical PET kinetic modeling studies with IP injection in mice

A. Miranda, *S. Shidar, S. Staelens, F. Elvas;*

Molecular Imaging and Radiology, Antwerp, BELGIUM.

Aim/Introduction: Preclinical positron emission tomography (PET) kinetic modeling is typically performed by injection of the radiotracer via intravenous (IV) tail vein bolus injection. In mice, this route of administration can be challenging due to the small vein size, and in awake animals, it can be painful and stressful. To circumvent these issues, in this study we investigate the feasibility of an alternative method which consists in the intraperitoneal (IP) injection of the radiotracer to perform brain kinetic modeling studies in mice. The dopamine D2/3 receptor antagonist [18F] Fallypride was used for the investigation. ***Materials and Methods:*** Animals (C57BL/6J mice; N = 8 per group) were anesthetized with isoflurane (3% for induction, 1.5% for maintenance) followed by [18F]Fallypride administration via the tail vein (IV), or by inserting a catheter in the animal peritoneum (IP). Two-hour-dynamic PET/CT scans were performed immediately after tracer injection. PET images were reconstructed and processed for analysis. Additionally, to reduce spill-over of skull uptake to the brain, non-negative matrix factorization (NMF) was performed to extract and subtract the skull uptake signal from the rest of the brain. The striatum and cerebellum time activity curves were extracted, and the mean striatum non-displaceable binding potential (BPND) was calculated using the simplified reference tissue model (SRTM), and the BPND standard error (SE) was evaluated in both routes of administration. The coefficient of variation of BPND is reported as well. ***Results:*** Skull uptake signal subtraction with NMF reduced the bone spill-over activity to the brain by 44% and 17% in IP and IV mice respectively. Overall radiotracer brain uptake was half in IP injected mice compared with IV (0.27 vs 0.56 standard uptake value). SRTM kinetic modeling fit was visually adequate in IP injected mice, with similar BPND SE in IP (3.4 ± 1.3%) vs IV (2.7 ± 0.55%). BPND was 4 times lower in IP (5.63 ± 2.1) vs IV (20.1 ± 6.4), and BPND coefficient of variation was similar between IP (37.1%) and IV (31.8 %) injected mice. ***Conclusion:*** We have successfully demonstrated the feasibility of using the IP route of administration to perform PET kinetic modeling studies. Despite lower brain tracer uptake in IP administered mice compared with IV, SRTM kinetic modeling produced accurate model curve fits, and BPND standard error and variability similar to values obtained in IV administered mice.

EP-1006

[11C]Metoclopramide-PET shows that P-glycoprotein function cannot be induced at the human blood-brain barrier via pregnane X receptor activation

M. Jackwerth;
Medical University of Vienna, Department for Clinical Pharmacology, Vienna, AUSTRIA.

Aim/Introduction: Amyloid-β (Aβ) plays a critical role in Alzheimer's disease (AD). The FDA-approved disease-modifying monoclonal anti-Aβ antibody lecanemab leads in AD patients to a significant reduction in Aβ burden with a moderate delay in disease progression. However, there are safety concerns related to the use of anti-Aβ antibodies due to the occurrence of serious adverse effects. There is thus a need for alternative, safer therapies that target distinct pathways. Preclinical studies showed that the efflux transporter P-glycoprotein (P-gp) mediates at the blood-brain barrier (BBB) the clearance of Aβ peptides from brain into blood and that pharmacological induction of P-gp function via activation of the pregnane X receptor (PXR) decreases brain Aβ load. PET with the radiolabelled P-gp substrate [11C]metoclopramide can measure pharmacological or disease-associated P-gp induction at the mouse or human BBB, respectively. The aim of this study was to assess with [11C]metoclopramide-PET whether treatment with St. John's wort extract (SJW) with a high content of hyperforin, a potent activator of human PXR, leads to induction of cerebral P-gp function in healthy volunteers. ***Materials and Methods:*** Healthy volunteers (n=10) underwent brain PET imaging with [11C] metoclopramide on a fully-integrated PET/MRI system and arterial blood sampling before and after oral treatment with SJW (3-6% hyperforin content) for 12-19 days (1800 mg/day). Concomitant with PET imaging, a low dose of the P-gp probe substrate fexofenadine was orally administered to assess peripheral P-gp function. Using a metabolite-corrected arterial plasma input function, the brain kinetics of [11C]metoclopramide were analysed with a 1-tissue-2-rate constant compartmental model to estimate the rate constants for radiotracer transfer from plasma into brain (K1), from brain into plasma (k2), and the total volume of distribution (VT = K1/k2). ***Results:*** Treatment with SJW increased P-gp function in the intestine as reflected by a significant decrease (-45%) in the area under the blood concentration-time curve of fexofenadine. Despite peripheral P-gp induction, no significant differences in K1, k2 and VT of [11C]metoclopramide were detected in whole brain grey matter between scans before and after treatment with SJW. ***Conclusion:*** Our data show that P-gp function cannot be induced at the human BBB via PXR activation with SJW. This may be related to low expression levels of PXR in human brain capillary endothelial cells and/or insufficient intracellular concentration levels of hyperforin. The targeting of alternative regulatory pathways may be required to achieve P-gp induction at the human BBB.

EP-1007

Recombinant human TSH administration versus thyroid hormone withdrawal prior radioiodine therapy: results evaluation from treated patients

M. Vivar Pérez, *M. Villar Pulido, R. Alessandra, M. Valiente Alarcón, P. Mondéjar Hernández, C. Salomón, A. Guerra Velastegui, F. Vega Martínez;*
Hospital Universitari Son Espases, Palma de Mallorca, SPAIN.

Aim/Introduction: Patients with differentiated thyroid cancer (DTC) who undergo partial or total thyroidectomy require an elevation in thyrotropin (thyroid-stimulation hormone, TSH) levels prior to thyroid remnant ablation to enhace radioiodine (RAI) uptake. Stimulation of TSH levels can be achieved exogenously by administering recombinant human TSH (rhTSH) or endogenously, through thyroid hormone withdrawal (THW). Although, our centre's guidelines contemplate both methods, using rhTSH, despite its higher cost, may be justified by the temporary hypothyroidism associated with THW, which can affect patients´ quality of life. Recent literature reviews, highlight the lack of consensus over these stimulations methods. This review aims to demonstrate the impact of the chosen stimulation method on TSH levels as well as on the dose rate at hospital discharge. ***Materials and Methods:*** A retrospective study was conducted on 129 patients with DTC diagnosis and treated with RAI at our hospital. The patients were categorized into two groups, depending on the type of TSH stimulation method used: endogenous or exogenous. Medical reports were reviewed to collect data on TSH levels on the day of hospital admission, the administered dose of iodine-131(MBq) and the dose rate(μSv/h) at the time of hospital discharge. ***Results:*** In the rhTSH-group (n:64), 73% of the cases showed TSH levels exceeding 80 μUI/mL, significantly higher than the 31% observed in the THW group (n:65). Regarding

dose rate, all values were less than 40µSv/h at 1 meter distance (according to the 2010 guidelines of the Heads of the European Radiological Protection Competent Authorities (HERCA)). Median and interquartile range (RIC) of those values are exposed below, classified by iodine-131 dose: - 1110MBq: THW-group(29 patients), median 16.8µSv/h (RIC:9.7) vs rhTSH-group(27 patients), median 9.0µSv/h (RIC:11.7)- 3700MBq: THW-group(21 patients), median 15.4µSv/h (RIC:10.0) vs rhTSH-group(16 patients), median 7.0µSv/h (RIC:8.0) - 5550MBq: THW-group(15 patients), median 10.6µSv/h (RIC:9.9) vs rhTSH-group(21 patients), median 13.8µSv/h (RIC:10.8). ***Conclusion:*** Exogenous stimulation presents higher values of TSH, which increase radioiodine uptake. However, despite the same administered doses, the dose rate at hospital discharge, was lower with exogenous stimulation, except in treatments with 5550MBq, likely due to the advanced metastatic nature of the disease, promoting increased extra-thyroidal uptake. Using rhTSH not only improves ablation success rates but also optimizes radioiodine organification and enhances patient quality of life, making rhTSH an effective and practical choice for TSH stimulation. ***References:*** -Clinical Nuclear Medicine, 2024, 49: e96-e104.-EJNMMI, 2023, 50: 3324-3348. -EJE, 2023, 188: R23-R35.-JNM, 2022, 63(6): 15N-35N.-EJNMMI, 2019, 46: 2514-2525.

EP-1008

Kinetic modelling and test-retest reproducibility of the selective PET radiotracer [18F]2FNQ1P for serotonin 5-HT$_e$receptor imaging in pigs

A. Deschavannes[1,2], *P. Courault[1,2], I. Mérida[2], J. Langlois[2], N. Costes[2], J. Redouté[2], L. Zimmer[1,2,3], S. Lancelot[1,2,3];*
[1]Hospices Civils de Lyon, Lyon, FRANCE, [2]CERMEP - Imagerie du Vivant, Lyon, FRANCE, [3]Université Claude Bernard Lyon 1, Lyon, FRANCE.

Aim/Introduction: [18F]2FNQ1P is a new PET radiotracer with highly specific and selective binding to 5-HT6 receptors (1,2). Preclinical studies in non-human primates suggest that [18F]2FNQ1P is a reliable PET radiotracer for visualization and quantification of 5-HT6 receptors in the brain (3). The objectives of this study were to perform a full PET kinetic modeling of [18F]2FNQ1P using arterial input function (AIF) in pigs, to identify a reference region suitable for a simplified modeling method, and to assess reproducibility with test-retest scans. ***Materials and Methods:*** Twelve healthy male or female pigs (33.6±2.0 kg) underwent MRI scans and two 90-min [18F]2FNQ1P PET/CT scans in a test-retest protocol, with arterial input function (AIF) in the second session. Regional time-activity curves (TAC) were obtained by co-registering the MRI and PET images to Saikali's pig atlas (3). Kinetic models were compared (one-tissue compartment, two-tissue compartment, and Logan) and two reference region models were evaluated (simplified reference tissue model, SRTM, and the Logan reference model, LREF). ***Results:*** The mean plasma-to-whole blood ratio was 0.98±0.11, suggesting an equal distribution between plasma and blood. The free plasma fraction remained stable over time with a mean value of 17.4±1.6%. The radiotracer was metabolized and progressively decreased from 59.9±23.4% (1-min post-injection) to 25.9±17.4% of the parent fraction (90-min post-injection) (Figure 1). TAC showed facilitated intracerebral crossing (Figure 2). Interestingly, cerebellum, vermis and insula showed rapid and high uptake followed by a notable fast washout phase. At the end of acquisition (90-min), striatum, amygdala and frontal cortex presented the highest steady-state value while cerebellum and vermis showed the lowest. The cerebellum appears as a possible reference region for simplified kinetic modeling. Figure 3 shows a PET overlay on MRI, demonstrating sufficient signal intensity and contrast for voxel-wise parametric imaging. Interestingly, an important signal was detected in a region identified as the pituitary gland (not included in the atlas). Furthermore, the voxels clusters with highest uptake were located in the caudate nucleus, putamen, prefrontal cortex, and frontal cortex. ***Conclusion:*** So far, [18F]2FNQ1P emerges as a reliable radiotracer to explore 5-HT6 receptors in brain. The favorable brain labeling and pharmacokinetic profile open new perspectives for the study of 5-HT6 receptors. Further analyses are in progress to perform brain quantification of kinetic parameters using AIF models or reference region models and to assess test-retest reproducibility. ***References:*** 1. EP-1009

Comparative evaluation of albumin binding domain-fused DARPin-drug conjugates targeting EpCAM for ovarian cancer treatment using radiolabeling

M. Din[1], *T. Xu[1], A. Schulga[2], J. Garousi[3], E. Konovalova[2], D. Niculae[1], Y. Liu[1], A. Orlova[1], T. Gräslund[4], S. Deyev[2], V. Tolmachev[1], A. Vorobyeva[1];*
[1]Uppsala University, Uppsala, SWEDEN, [2]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Moscow, RUSSIAN FEDERATION, [3]Karolinska University Hospital, Stockholm, SWEDEN, [4]Royal Institute of Technology (KTH), Sweden, Stockholm, SWEDEN.

Aim/Introduction: Epithelial Cell Adhesion Molecule (EpCAM) shows overexpression in ca. 70% of epithelial ovarian cancers and is a promising target for drug delivery. Designed Ankyrin Repeat Protein (DARPin) Ec1 has picomolar affinity to EpCAM. Loading Ec1 with a cytotoxic drug DM1 might enable specific eradication of cancer cells. To extend half-life in blood and minimize damage to healthy tissues, Ec1 was fused with an albumin binding domain (ABD) at C- or N-terminus and site-specifically conjugated to DM1, providing Ec1-ABD-DM1 and ABD-Ec1-DM1. The aim of the study was to investigate the impact of molecular design on the functional properties of two Ec1-ABD conjugates in vitro and their biodistribution and tumor targeting in vivo. ***Materials and Methods:*** Ec1-ABD-DM1 and ABD-Ec1-DM1 were radiolabelled with [99mTc]Tc(CO)3 via N-terminal (HE)3 tag for quantitative analysis. Their binding and internalization were evaluated using EpCAM-expressing SKOV3 and OVCAR3 ovarian cancer cell lines. Cytotoxicity in SKOV3 and OVCAR3 cells was determined in the presence and absence of human serum albumin (HSA). Biodistribution of [99mTc]Tc(CO)3-labeled drug conjugates was measured in Balb/c nu/nu mice bearing SKOV3 xenografts at 4, 24, and 48 hours post-injection (p.i.) to assess distribution kinetics. Mice bearing EpCAM-negative Ramos xenografts were used as a negative control. Ec1 (not fused to ABD) was used as a control for evaluation of half-life extension. ***Results:*** The conjugates were radiolabeled and purified with radiochemical purities over 95%. The radiolabel was stable under histidine challenge. The specific binding of both compounds to EpCAM was confirmed. [99mTc]Tc(CO)3-Ec1-ABD-DM1 exhibited stronger binding affinity (0.14±0.1 nM) compared to [99mTc]Tc(CO)3-ABD-Ec1-DM1 (1.24±0.11 nM). Internalized fractions of 25-30% in OVCAR3 cells and 35% in SKOV3 cells within 24 hours suggest efficient drug delivery for both constructs. IC50 values were in the nanomolar range for both conjugates in both cell lines, and were lower for ABD-Ec1-DM1. Biodistribution of [99mTc]Tc(CO)3-labeled conjugates was characterized by predominantly renal clearance. Fusion of Ec1 with ABD extended residence in blood and improved tumour uptake. Tumor targeting specificity was confirmed for both conjugates. Biodistribution showed no major

differences in the uptake of drug conjugates in tumours and normal organs, except 20-30% lower uptake in lungs for [99mTc]Tc(CO)3-Ec1-ABD-DM1. ***Conclusion:*** Radiolabeling of DARPin-drug conjugates using residualizing technetium-99m tricarbonyl label enabled their quantitative characterization and comparison. No major influence of molecular design on tumour targeting and biodistribution was observed. The combination of more potent cytotoxicity and favorable biodistribution profile suggests ABD-Ec1-DM1 as a preferable candidate for therapy.

EP-1010

Development of [18F]-labelled lactate for oxidative cancer imaging

M. da Silva Morais[1], *V. F. Hee[1], T. Sepehrizadeh[2], M. O'Hara[2], M. Wheatcroft[2], P. Sonveaux[1,3];*
[1]Pole of Pharmacology, Institut de Recherche Expérimentale et Clinique (IREC), Université catholique de Louvain (UCLouvain), 1200 Brussels, BELGIUM, [2]Telix Pharmaceuticals LTD, North Melbourne, VIC 3051, AUSTRALIA, [3]WEL Research Institute Research Institute, Walloon Excellence in Life Sciences and Biotechnology (WELBIO) department, Wavre, BELGIUM.

Aim/Introduction: Glucose analogue PET tracer 2-deoxy-2-[18F]-fluoro-D-glucose (18FDG) is routinely used to detect and monitor malignant tumours in the clinics. Contrast is provided by 6-phospho-18FDG accumulation in cancer cells that have high-rate metabolic activities and take up glucose abundantly. However, slowly growing tumours/metastases with low metabolic activities are often missed, and 18FDG does not inform on oxidative versus glycolytic metabolisms, thus limiting personalized medicine applications. Based on the observation that most clinical tumours use lactate as an oxidative fuel, we aimed to solve these issues by producing [18F]-3-fluoro-2-hydroxypropionate ([18F]-FLac) as a new tracer for imaging oxidative tumours. ***Materials and Methods:*** [18F]-fluoride was produced on a medical-isotope cyclotron (IBA Cyclone 18/9). [18F]-FLac was synthesized in minimally basic conditions on a remote-controlled clinical radiosynthesis module, purified using semi-reparative HPLC, and authenticated using H NMR and mass spectrometry. Metabolic stability was assessed in murine and human serum. For in vitro and in vivo evaluation, cervix, head-and-neck, breast, colon and prostate human cancer cells were screened for monocarboxylate transporter 1 (MCT1) and lactate dehydrogenase B (LDHB) expression using RT-qPCR and western blotting, and for exogenous lactate uptake on an ISCUSflex enzymatic analyser. Whole body mouse PET imaging was performed using a Mosaic PET scan on NMRI tumour-bearing nude mice treated or nor with MCT1 inhibitors AR-C155858 and AZD3965. ***Results:*** To produce [18F]-FLac, we synthesized epoxybenzylacrylate as a precursor by reacting benzylacrylate with meta-chloroperoxybenzoic acid (yield = 53%). Epoxybenzylacrylate was then reacted with [18F]-fluoride in tert-amyl alcohol to yield [18F]-3-fluoro-2-hydroxybenzylacrylate as a preferred regio-isomer, followed by semi-preparative HPLC isolation. The fluorination yield was 15-20%. [18F]-3-fluoro-2-hydroxybenzylacrylate hydrolysis in 0.5 N NaOH yielded [18F]-FLac after 5 minutes, which was confirmed by analytical HPLC and mass spectrometry. The compound was stable in serum. Among all tested human cell lines, SiHa cervix, SQD9 head-and-neck and PC3 prostate cancer cells had elevated MCT1 and LDHB expression, with lactate uptake being sensitive to MCT1 inhibition. In vivo, [18F]-FLac successfully imaged SiHa and SQD9 tumours, with little background from non-cancer tissues (including intestines) to the exception of kidneys and the bladder that cleared the tracer. ***Conclusion:*** [18F]-FLac is a promising PET radiotracer to detect oxidative tumours including those silent to 18FDG. This possibility is currently tested with slowly growing PC3 tumours and metastases in mice. [18F]-FLac could further be used alone or sequentially with 18FDG as a companion diagnostic for personalized treatments selectively targeting oxidative or glycolytic cancer cells.

EP-1011

Comparison Of Mathematical Methods For The Calculation Of Renal Glomerular Filtration Rate With [99mTc]Tc-DTPA in Living Renal Donors

L. Cebollada-Cameo, *R. Maestre-Cutillas, L. Baz-Sanz, G. Rubio-Fernández, C. Piedelobo-Vaquero, V. Lopes-Martin, S. Horcas-Villaverde, M. Vaquero-Palomo, A. Gomez-Lorenzo, J. Pérez-Iruela; Hospital Universitario Ramón y Cajal, Madrid, SPAIN.*

Aim/Introduction: The objective is to test whether or not there is equivalence between the different methods for calculating glomerular filtration rate (GFR) in potential renal donors and to determine which is the most appropriate. ***Materials and Methods:*** GFR was calculated using the Bröchner-Mortensen (BM) method, described in different guidelines, with [99mTc]Tc-DTPA, in 53 healthy renal donor candidates, from three blood samples taken at different times (t=120, 180, 240 min). Alternative methods were used for comparison: modified BM, Constable and Christensen-Groth. The latter two methods use a single blood sample, at 180 and 240 min, respectively. The modified BM method involves first normalising by body surface area before applying the mathematical model, the opposite order to the original method. A comparison of means was performed using the Student's t-test, considering a 95% confidence interval (CI) and the significance value (p) was obtained. ***Results:*** Expressed as mean ± standard deviation, the results were: — BM method: 83.91 ± 15.89 mL/min/1.73m2 — Modified BM method: 82.89 ± 16.52 mL/min/1,73m2 — Constable method: 90.63 ± 23.31 mL/min/1,73m2 — Christensen-Groth method: 90.36 ± 17.94 mL/min/1,73m2 Comparing the BM method with the Constable and Christensen-Groth methods, p=0.000 (p<0.05) was obtained. Between the BM method and the modified BM, p=0.275 was obtained; and between the Constable and Christensen-Groth methods, p=0.765. ***Conclusion:*** The modification of the BM method does not significantly change the GFR calculation (p=0.275), so it could be used as an equivalent. The single sample methods have shown equality between them (p=0.765), but differences with respect to the original BM method (p=0.000). The BM method will continue to be used for the calculation of GFR, as we consider it the most complete method as it includes three blood samples and is the most widely used in the literature.

EP-1012

In Silico Microscopic Dosimetry Modeling using Spatial Transcriptomics for Various targets of Radiopharmaceutical Therapy to Compare Effects and Feasibility of Combination

J. Hong[1], *S. Bae[2], L. Cavinato[3], M. Ryhiner[1], A. Rominger[1], H. Choi[4], K. Shi[1];*
[1]University of Bern/Inselspital, Bern, SWITZERLAND, [2]Institute of Radiation Medicine, Medical Research Center, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [3]Department of Mathematics, Politecnico de Milano, Milan, ITALY, [4]Institute of Radiation Medicine, Medical Research Center, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: With the growing momentum of

radiopharmaceutical therapy (RPT) in prostate cancer, it is essential to investigate the dosimetry and biological effects of RPT in cellular level, given the complexities of the tumor microenvironment (TME). Here, we combined spatial transcriptomics (ST) and conventional pharmacokinetic modelling to compare the effect of RPT targeting prostate-specific membrane antigen (PSMA), fibroblast activation protein (FAP), and gastrin-releasing peptide receptor (GRPR) and to investigate feasibility of combinations of RPT for different targets. ***Materials and Methods:*** We utilized three publicly available Visium ST datasets from primary tissue samples of two prostate cancer patients. From these, we extracted various gene expressions, including FOLH1, GRPR, FAP, and Hypoxia signature, and estimated the proportions of cell types—epithelial, endothelial, and prostate cancer (PC) cells—in the corresponding ST spots. The spatiotemporal distribution of each radiopharmaceutical therapy was computed by solving the partial differential equation (PDE) using a convection-reaction-diffusion model. A well-established physiologically based pharmacokinetic (PBPK) model was used for input function, which was carefully determined to depost 10 Gy in prostate tumor in 20 days. Kinetic parameters sourced from literature were assumed uniform across RPTs. Dosimetry was then estimated following the Medical Internal Radiation Dose (MIRD) formalism, using dose point kernels (DVK) method. The survival probability was estimated using the linear quadratic model. ***Results:*** The study indicated higher FAP expression in regions with fewer tumor cells, while GRPR expression was more aligned with the presence of tumor cells. Cell survival was moderately higher in these regions for both 177Lu- and 225Ac-labeled therapies, but 225Ac generally led to lower survival rates. PSMA-targeted RPTs resulted in lower cell survival compared to FAP and GRPR, with some regions of malignant cells responding better to FAP or GRPR, advocating for potential combination therapies. The findings emphasize tailoring RPT based on the tumor's unique profile. ***Conclusion:*** Our in silico approach offers a detailed microscopic dosimetry-based evaluation of RPT effects according to targets, supporting the design of new radioligands and their combination for optimizing therapeutic strategies for cancer treatment.

Preparation of Ga/Ni Solid Target for Cyclotron-produced ^{68}Ge by Electrodeposition

Y. Shen;
China Institute of Atomic Energy, Beijing, CHINA.

Aim/Introduction: The main applications of 68Ge are its use as a long-lived positron source for attenuation corrections and calibration of Positron Emission Computed Tomography, and its role as mother radionuclide for the preparation of 68Ge/68Ga radionuclide generators. The 68Ge/68Ga radionuclide generator systems attracted interest in nuclear medicine because of its significant potential for PET/CT imaging using 68Ga labelled radiopharmaceuticals. The low melting point of the target material in the production reaction 69Ga (p, 2n) 68Ge has limited the availability of 68Ge. In order to use the existing industrial cyclotron hardware to produce 68Ge, a method of electrodepositing gallium-nickel alloy was set up in this study. ***Materials and Methods:*** The Ga/Ni solid target was prepared by electric deposition method for cyclotron producing 68Ge. Acidic requirements were met through the preparation of the gallium-nickel alloy targets and by optimizing the plating bath composition and electrodepositing conditions, the influences of current density, temperature, pH value, Ga/Ni concentration on the target quality were investigated. ***Results:*** The gallium-nickel solid targets with a gallium content of 75% was prepared by electric deposition method. After three irradiation tests, the process was certified to produce targets of Germanium 68. ***Conclusion:*** This process is user-friendly, the preparation of the targets is of stable quality, and it can be applied to the cyclotron production of Germanium 68.

EP-1014

Long-term evaluation of a PARS-GalluGEN 70 (^{68}Ge/^{68}Ga) generator and its performance in the clinical production of ^{68}Ga-PSMA-11

M. Gholamhosseini-Nazari, *M. Hahsemizadeh, M. Gilani, R. Sardari, A. Gravand;*
PARS ISOTOPE, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The 68Ge/68Ga generator has emerged as a convenient source to provide 68Ga in a hospital radiopharmacy for synthesizing 68Ga-labeled radiopharmaceuticals. In the 2021 EANM, we reported a new 4.45 GBq (120 mCi) TiO2-SnO2 -based 68Ge/68Ga generator of PARS Isotope as named PARS-GalluGEN 70 [1]. The focus of this study was to provide performance evaluation and Long-Term behavior of the PARS-GalluGEN 70. The generator was evaluated in terms of 68Ga yield, elution profile, 68Ge breakthrough, chemical and radiochemical purity of the 68Ga solution for 9 month in conjunction with the production of 68Ga labeled PSMA-HBED-CC intended for clinical use. ***Materials and Methods:*** All other reagents and solvents were purchased from commercial vendors and used directly unless otherwise noted. ***Results:*** PARS-GalluGEN 70 generator eluted more than 700 times in 9 month with 3 mL of 0.1 M HCl. Elution profile of the generator show more than 90% of activity in the first 2 mL. The first eluted activity of this generator was about 75 mCi and elution yield was > 65%. The radionuclide purity of 68Ga was ≥99.999% and the radiochemical purity of 68Ga3+ was 99.9. Although 68Ge breakthrough slightly increased over time, but always remained <0.0001%. Iron and zinc were detected as metal impurities in the eluent but both were ≤0.1 µg/GBq. The endotoxin concentration of the generator eluted was ≤25 EU/mL, and the eluent passed the sterility test. These results show that the generator can stably provide 68Ga solution over a 9 month period and used for routine production of 68Ga-PSMA-11 for clinical imaging. The average radiochemical yield for 200 68Ga-PSMA-11 clinical preparations using this generator was 92 ± 3%. ***Conclusion:*** The new, higher-activity 4.45 GBq (120 mCi) generator (PARS-GalluGEN 70) provides users with more flexibility by increasing the number of daily elutions and the activity in each elution, ultimately increasing the number of patients that can be served. The obtained results indicate that this generator has all the specifications of the European Pharmacopoeia for use. The better performance characteristics such as chemical, radiochemical, radionuclide purity, and acceptable elution yield introduce a new effective 68Ge/68Ga generator for clinical use. ***References:*** 1-Gholamhosseini-Nazari, M., and A. Construction of an automatic device for Cu-64 purification

K. Kim[1], *N. Lee[2], K. Lee[1], Y. Hong[2], B. Lee[1];*
[1]Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF, [2]Research & Development Team, NEW KOREA Industrial Co., LTD., Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Imaging technique using positron emission tomography (PET) is useful for diagnosing various diseases and assessing treatment outcomes. A positron emitter Cu-64 is highly regarded for PET tracers due to its proper physical properties (12.7 hour half-life, 17.9% beta+ and 37.1% beta- radiations) and mild labeling condition for radiopharmaceutical productions. Cu-64 radioisotope is produced by cyclotron using Ni-64 target through the (p, n) nuclear reaction. In this study, we established an automatic processing system to purify produced Cu-64 from target. ***Materials and Methods:*** The irradiated Ni-64 solid target was transferred to a reaction vial in a heating bath, and 6 M HCl (10 mL) was added into the reaction vial. The solution was heated to 100 °C for 30 min, and then cooled to room temperature. The cooled solution was loaded onto a pre-conditioned ion exchange resin (SAX, AG1X8). After the column was washed with 6 M HCl solution (10 mL), Cu-64 was recovered using water (10 mL). Fluid delivery was achieved by a syringe pump, directing the flow through isolation valves. All process was controlled by a user-friendly interface (UFI) based program. The device was qualified by test productions of Cu-64 produced from a cyclotron. ***Results:*** The automatic device for Cu-64 purification process had consisted of chemical resistant valves and tubing, it was designed to be driven by sequential operation control. The dissolution by heating and purification using two columns processes were executed in succession. Components and tubing were easily changeable to minimize contamination. The User Interface was configured to produce Cu-64 according to desired process conditions, all process was allowed to continue without the manual intervention of operators. The system was designed to utilize its built-in power source to continue the process in event of a power outage. ***Conclusion:*** We developed a new device for Cu-64 purification process. Using the automatic system, Cu-64 was successfully obtained with minimizing radiation exposure to operators. The device was designed to easily modify the reaction processes, thus we expected that it would be feasible to automate the productions of radiolabeled pharmaceuticals using not only Cu-64 but also any other radioactive isotopes.

EP-1016

Feasability of ^{64}Cu production in a low-power Nuclear Reactor.

L. Canziani[1], *A. Gandini[1], G. Pepe[2], A. Salvini[1];*
[1]Laboratorio Energia Nucleare Applicata - Università di Pavia, Pavia, ITALY, [2]Fondazione IRCCS Policlinico San Matteo, Pavia, ITALY.

Aim/Introduction: In the field of nuclear medicine, among the metal-based radionuclides for positron emission tomography (PET) and therapeutic applications, 64Cu has garnered escalating attention. This radioisotope exhibits advantageous characteristics due to its relatively long half-life (12.7 hours) and decay modes: low-energy positron emission (17.5%), beta emission (38.5%), and electron capture (44.0%). While typically produced in cyclotrons, alternative methods, like reactor systems, emerges as an useful opportunity to support research, despite an inferior radioactivity yield. We here present a comprehensive investigation, delineating the production and refinement processes of 64Cu, within the confines of a TRIGA Mark II reactor. Demostrating how even a low-power reactor not intended for isotopes production can be an useful tools for research. ***Materials and Methods:*** Eight samples of 20 µg, four of Copper Oxide and four of Metallic Copper, underwent irradiation for 6 hours within a TRIGA Mark II nuclear reactor, at 250 kWatt. Then, they were dissolved in aqua regia and stripped in concentrated HCl. Six samples of 20 µg of Zinc Oxide each, were irradiated for 6 hours in the same TRIGA Mark II nuclear reactor at 250 kWatt. They were dissolved in 8M HCl and separated using an anionic resin. One sample was separated using TK200 resin cartridges (Triskem International) in 1M HCl, while the other was separated using Dowex1X8 chloride form resin (Sigma Aldrich), eluted with 4M and 2M HCl solutions. Radiochemical purity and specific radioactivity were subsequently analyzed. ***Results:*** Copper Oxide and Metallic Copper samples exhibited similar production yields of 64Cu, amounting to 12.67 (± 2.35) MBq with a specific activity of 633.5 MBq/g. However, issues arose with Aqua Regia dissolution, leading to insoluble copper precipitates. Irradiated samples of Zinc Oxide yielded 83.2 KBq (± 0.7) of 65Zn and 11.6 (± 1.21) KBq of 64Cu. The separation demonstrated a radiochemical purity >99.8% of 64Cu. The remaining three samples were dissolved in 4 M HCl, diluted to 1M, and separated using TK200. The separation exhibited a radiochemical purity >98% of 64Cu. ***Conclusion:*** This study demonstrates the feasibility and cost-effectiveness of 64Cu production in the TRIGA Mark II reactor for radiopharmaceutical labeling. Direct production from natural copper yields higher radioactivity but lacks carrier-free purity, while zinc-based production offers carrier-free isolation despite lower yields. Low-power reactors even not intended for isotopes production hold promise for scientific research, with future investigations focusing on enhancing yields through larger mass samples and enriched targets.

EP-1017

^{99m}Tc radionuclide generators based on Low Specific Activity ^{99}Mo: Future Technical Developments to Meet the increasing Medical Demands

M. Nawar, *A. Eldaoushy, A. Türler;*
University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Diagnostic interventions in nuclear medicine strongly rely on 99mTc-radiopharmaceuticals. 99mTc is commercially available from low-pressure column chromatographic 99Mo/99mTc generators that use acidic alumina as a sorbent matrix. However, the limited sorption capability of alumina asks for high specific activity 99Mo, which poses serious production challenges and raises proliferation concerns. Therefore, many ideas aimed to use low specific activity (LSA) 99Mo. Nonetheless, the main roadblock is the low sorption capacity of the used alumina. This work demonstrates the feasibility of using different nano-sorbents developed in our laboratory as potential column material for developing 99Mo/99mTc generators by using low specific activity 99Mo. ***Materials and Methods:*** First, several nano-sorbents were synthesized using a simple preparation method. Then, their structural characterization was performed using different techniques. Additionally, we evaluated the distribution ratios (Kd) of 99Mo and 99mTc, the 99Mo breakthrough profile, and the sorption capacity of the synthesized

sorbents for carrier-added 99Mo. Eventually, we prepared a 99mTc generator, and its elution performance was repeatedly evaluated. ***Results:*** Our findings indicate that the materials synthesized are mesoporous and possess a large surface area. Furthermore, The Kd values prove that the parent, 99Mo, is selectively retained on the prepared sorbents, and its daughter, 99mTc, can be readily collected by using 0.9% NaCl solution. Moreover, the eluted daughter exhibits high chemical, radiochemical, and radionuclidic purity suitable for clinical applications. ***Conclusion:*** The use of nanomaterial-based sorbents offers new advantages that could not be achieved with classical materials due to their high sorption capacity, which arises from a higher surface area along with their high radiation resistance and chemical stability. The payoff for the successful investment of the proposed approach will open up a new possibility to supply onsite, clinical-grade 99mTc for millions of cancer patients worldwide independently of the fission-produced 99Mo. ***References:*** Nawar M.F., and Türler A. (2022). New Strategies for a Sustainable 99mTc Supply to Meet Increasing Medical Demands: Promising Solutions for Current Problems. Front Chem; Volume 10. https://doi.org/10.3389/fchem.2022.926258.

EP-1018

Production of ^{67}Cu via neutron induced reaction: A potential radionuclide in Nuclear Medicine

Z. Karimi;
Parsisotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The 67Cu therapeutic radionuclide (T1/2=61.83 h, β− =100%, < Eβ- > =145 keV) is a β− emitter that has potential for therapy and can be utilized in SPECT/CT (Eγ=91.3 and 93.3 keV (21.1%) and Eγ=185 keV (44.2%)). This study seeks to develop the production yield of 67Cu from natZnO and natZnONPs targets through both experiment and theory in Tehran Research Reactor (TRR). ***Materials and Methods:*** The targets were irradiated in TRR for 0.5 hours within a fast neutron flux of 1.4×1013 n.cm-2.s-1. The neutron distribution function and average cross section of 67Zn(n,p)67Cu reaction were achieved through the use of nuclear codes of MCNPX and TALYS-1.8. The theoretical activity was also calculated for 300 mg of 67Zn (95% enriched target) with irradiation time of 185 hours. The enrichment of the 67Zn target material is crucial to produce the 67Cu in a n.c.a form suitable for medical application. Scanning Electronic Microscopy (SEM) analysis of zinc oxide nanoparticles were done before and after irradiation process. ***Results:*** The activity of 67Cu at the end of bombardment with nanoscale target was achieved 0.0326 MBq and for its bulk form 0.0168 MBq which indicate the increment activity of nanoscale with relative difference of 48.46 %. The average size of 10-30 nm for zinc oxide nanoparticles were achieved with SEM analysis with no definite changes in before and after irradiation process. The average cross section from TALYS code was achieved 0.8 mb. The theoretical activity was achieved 0.0218 MBq from MCNPX with relative difference of 23.63% in comparison to experimental value (bulk target). The theoretical activity for enriched target was also calculated about 25.066 MBq. This method could be used to estimate the production yield of other radionuclides in the reactor. This reaction has low cross section, which high flux of fast neutrons for high production yield were needed. ***Conclusion:*** The activity of 67Cu from nanoscale target was increased in comparison of bulk state target due to their greater reactivity. Using MCNPX, a proper method for estimating the theoretical radionuclide production yield in the TRR. ***References:*** 1. Preclinical validation of a new PET CBF tracer [^{11}C]MMP on the premise of clinical use

J. Toyohara, *T. Tago, M. Sakata;*
Tokyo Metropolitan Institute for Geriatrics and Gerontology, Itabashi-ku, Tokyo, JAPAN.

Aim/Introduction: As [^{18F}]FDG is an analogue of glucose, the accumulation of tracer in the brain is affected by blood glucose levels. In contrast, the cerebral blood flow (CBF) tracer is theoretically not affected by blood glucose levels and is therefore expected to be a useful alternative method for dementia diagnosis in patients complicated by diabetes. However, the techniques currently used for CBF imaging using SPECT and 15O-gas PET are limited as they do not have sufficient resolution or sensitivity for regional brain imaging, especially when accompanied by brain atrophy. To overcome these problems, we developed N-isopropyl-4-[^{11}C] methylamphetamine ([^{11}C]MMP) as a possible CBF tracer with high resolution and sensitivity. PET measurements in conscious nonhuman primates have revealed that [^{11}C]MMP exhibited performance comparable to [15O]H2O, the gold standard for measuring cerebral blood flow [1]. Here, we present the results of preclinical studies based on the clinical application of [^{11}C]MMP to first-in-human studies. ***Materials and Methods:*** The previously used synthesis method using tributyltin as a precursor had a low yield of approximately 11% (decay-corrected) [1]. To obtain a higher yield, pinacol boronic acid ester (Bpin) was used as the precursor. A three-process validation (3 PV) test was conducted using this Bpin precursor. In preclinical safety tests, we performed a single intraperitoneal dose toxicity test for MMP, a single intravenous dose toxicity test for decay-outdated [^{11}C]MMP, and an Ames test for MMP. The radiation exposure dose in humans was estimated from mouse biodistribution data. The affinity of the MMP for various neuroreceptors was measured. ***Results:*** Using Bpin as the precursor, the yield improved significantly to 34%-47%. The results of the 3 PV test met the quality control (QC) standards. No signs of toxicity were observed in a single administration toxicity test of MMP and [^{11}C]MMP. The effective dose calculated according to the MIRD method was 5.4 μSv/MBq, and the maximum absorbed dose to the bladder wall was 57.6 μGy/MBq. MMP, a derivative of phenylalkylamine, showed binding to the Sigma receptor, but had approximately 1/100 of the affinity of existing Sigma receptor imaging agents. The affinity for other brain neuroreceptors was low. ***Conclusion:*** The 3 PV tests met the QC standard criteria for clinical use, and the preclinical toxicological and dosimetry studies indicated that [^{11}C]MMP showed acceptable pharmacological safety at the dose required for adequate PET imaging. ***References:*** [1]Toyohara et al., EJNMMI Res (2020) 10:115.

Evaluations for quality management of metal impurities in [^{64}Cu]Cu-diacetyl-bis(N^4-methylthiosemicarbazone) ([^{64}Cu]Cu-ATSM) as a radiopharmaceutical

M. Shinada[1,2,3], *H. Suzuki[2], M. Hanyu[2], C. Igarashi[2,3], H. Matsumoto[2,3], M. Takahashi[1,2], F. Hihara[2], T. Tachibana[1,2], C.*

Sogawa[2], M. Zhang[2], T. Higashi[2], H. Sato[3], H. Kurihara[3], Y. Yoshii[2,3], Y. Doi[1];
[1]Faculty of Science, Toho University, Funabashi, JAPAN, [2]Institute for Quantum Medical Science, National Institutes for Quantum Science and Technology, Chiba, JAPAN, [3]Kanagawa Cancer Center, Kanagawa, JAPAN.

Aim/Introduction: [64Cu]Cu-diacetyl-bis (N4-methylthiosemicarbazone) ([64Cu]Cu-ATSM) is a promising radioactive hypoxia-targeting therapeutic agent and the Phase 1 clinical trials of this agent are currently conducted for patients with recurrent malignant brain tumors. For the quality management of [64Cu]Cu-ATSM as a radiopharmaceutical, understanding the effect of trace metal impurities during the preparation of the chelate between the ATSM ligand and 64Cu is important. To address this, we conducted some coordination chemical studies on metal-ATSM complexes. ***Materials and Methods:*** First, the effects of nonradioactive metal ions on the formation of [64Cu]Cu-ATSM were evaluated. Copper(II), nickel(II), zinc(II), and iron(II) ions were chosen for this experiment since these metals were possibly contaminated by the target system of cyclotron or manufacturing lines. Second, these metals were reacted with ATSM, and chelate formation rates were measured using ultraviolet-visible (UV-Vis) absorption spectra. Finally, since ATSM was found to react quickly with only Cu2+ but not in the other three species, we additionally investigated whether the other three species could react with ATSM when the reaction temperature was increased to 40°C from room temperature. ***Results:*** When the amount of Cu2+ or Ni2+ added was 1.2 or 288 equivalent to ATSM, the labeling yield of [64Cu]Cu-ATSM decreased below 90%. The addition of excess amounts of Fe2+ or Zn2+ to ATSM had little effect. UV-Vis spectra showed a rapid formation of Cu-ATSM complex upon mixing. The reaction rate of chelate formation by Ni2+ and ATSM was lower than that by Cu2+ and ATSM. Fe2+ and Zn2+ showed much slower reactions with the ATSM than Ni2+. The complexation rates of Ni2+ and Fe2+ with ATSM became faster with increased reaction temperature, while that of Zn2+ with ATSM was almost the same. ***Conclusion:*** This study showed that trace amounts of Ni2+, Fe2+, and Zn2+ had little effect on the quality of [64Cu]Cu-ATSM. However, it was concluded that the concentration of Cu2+ should be controlled. These results would provide useful information for the quality management of [64Cu]Cu-ATSM.

EP-1021

Towards a GMP comliant automated radiosynthesis of [18F]FLUDA

T. Kniess[1], *S. Hübner[1], T. Lai[2], J. Zessin[1], M. Kreller[1];*
[1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY, [2]ROTOP Pharmaka GmbH, Dresden, GERMANY.

Aim/Introduction: [18F]FLUDA is a selective radiotracer for the in vivo imaging of A2A receptors by positron emission tomography (PET). Recent imaging studies in rodents and piglets have demonstrated the potential of [18F]FLUDA as probe for imaging A2A receptors.[1] The automated radiosynthesis of [18F]FLUDA by an one-pot two-step radiolabeling procedure was published recently.[2] This work describes further optimization of the radiosynthesis and its translation to a GMP-compliant procedure providing an injectable solution for clinical studies in humans. ***Materials and Methods:*** For two-step radiofluorination and purification, an automated TRACERlab FX2 N radiosynthesizer was used. In first experiments, the reported procedure was adapted and tested with low starting activities (0.5 - 2 GBq). The amount of used precursors (d4-fluoroethyltosylate and phenol) and solvent volumes (0.5 ml to 1 ml acetonitrile and 0.5 ml TBAOHaq/acetonitrile to 1 ml DMSO), as well as the temperature for the labeling steps were varied and optimized. Moreover, the C18 light purification cartridge was replaced by a tC18 cartridge. The formulation of the purified product solution was adjusted to requirements for injection in humans by replacing the DMSO solution by saline containing ethanol and subsequently final sterile filtration with Millex GV filter. Finally, the optimized method was evaluated with starting [18F]fluoride activities in the range of 10 - 50 GBq, produced by a TR-Flex cyclotron. ***Results:*** By adding the phenol precursor and the TBAOHaq solution (40 wt.% in water) separately instead of premixed,[1] the labeling yield was significantly improved. In summary, the radiochemical yield of [18F]FLUDA could be increased from 9±1% (EOB)[2] to 30±4% (EOB) in a total radiosynthesis time of 65 min. Starting from ca. 50 GBq [18F]fluoride, 10 GBq [18F]FLUDA were obtained in isotonic saline with 6% ethanol with a radiochemical purity of ≥ 95%. The molar activity after sterile filtration was 90 - 188 GBq/µmol (n=3). Stability studies from the final solution (isotonic saline with 6% ethanol) over 6 h confirmed the stability. ***Conclusion:*** In summary an optimized and fully automated GMP-compliant radiosynthesis was established, supplying [18F]FLUDA in high radiochemical yield, purity and adequate pharmaceutical quality to further explore this promising radiotracer in prospective clinical trials. ***References:*** [1] T.H. Lai et al., Eur J Nucl Med Mol Imaging, 2021, 48(9), 2727-2736 [2] T.H. Lai et al., J Label Compd Radiopharm, 2022, 1-5.

EP-1022

177Lu-DOTATOC : Development of a Fully Automatized In-Hospital Production

K. Casagrande[1], *J. Costes[1], A. Pierrot[1], J. Delage[1], N. Schaefer[2], J. Prior[2], F. Sadeghipour[3,4,5];*
[1]Radiopharmacy Unit, Department of Pharmacy, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND, [2]Department of Nuclear Medicine and Molecular Imaging, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND, [3]Department of Pharmacy, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND, [4]Center for Research and Innovation in Clinical Pharmaceutical Sciences, Lausanne University Hospital and University of Lausanne, Lausanne, SWITZERLAND, [5]Institute of Pharmaceutical Sciences of Western Switzerland, University of Geneva, University of Lausanne, Lausanne, SWITZERLAND.

Aim/Introduction: 177Lu-DOTA-peptides are beta-particle-emitting radioactive therapeutic agents indicated for the treatment of neuroendocrine tumors. To date, two radiopharmaceuticals sharing similar profiles are mainly used, 177Lu-DOTATATE which is commercially supplied and 177Lu-DOTATOC with no market authorization holder. The aim of our work is to develop an automated synthesis of 177Lu-DOTATOC to reduce the cost of this treatment and extend its accessibility. ***Materials and Methods:*** Using a MiniAiO® (Trasis) synthesizer, the complexation reaction is performed in acetate buffer at pH 4-5 and with thermal heating (100°C for 28,5min) of 115µg (one dose) to 465µg (4 doses) of DOTATOC and 8,0 to 32,0GBq of 177Lu. At the end of the incubation, the drug substance is eluted through a sterile filter into the product vial. Then, saline is added to dilute the solution.Regarding the quality control, the radiochemical purity (RCP) of 177Lu-DOTATOC was determined by radio-HPLC using the formula : RCP (%) = 100 - (177LuCl3 (%) + other impurities (%)). The radiochemical stability was demonstrated by measuring RCP until 24h post-production. UV-HPLC was used to quantify the amount of DOTATOC per dose and confirm the

identity of 177Lu-DOTATOC using a non-radioactive standard. The concentration of ascorbate in the drug product, which should be ≥ 7mg/mL was measured with a semi-quantitative method. Due to the long half-life of 177Lu, sterility tests were achieved with simulated labelling. Sterility and endotoxin tests were performed in accordance to Ph. Eur. An automated filter integrity test was performed on the final sterilizing filter. ***Results:*** Five validation batches of 177Lu-DOTATOC were performed, 3 with an activity of 8,53±0,42GBq, one with 25,42GBq and one with 32,45GBq. The application volume was from 18mL to 20mL. The RCP at end of synthesis was 97,8±0,6%. Based on the stability data, a shelf-life of 24h was defined for syntheses using 8GBq of starting activity with a RCP of 96,2±0,3% at 24h. The concentration of ascorbate met the specification. The retention time comparison between the standard and 177Lu-DOTATOC was inferior to 6s. The total amount of DOTATOC was inferior to 250µg per dose. Bubble point tests were superior to 3bars for each batch. The drug products were sterile and endotoxin free. ***Conclusion:*** 177Lu-DOTATOC is prepared in sterile conditions by using MiniAiO® synthesizer with high final radiochemical purity. The validation with starting activity ranging between 8 to 32GBq will allow us to perform one production for one to four patient standard doses of 7,4GBq.

EP-1023

Process validation of [^{211}At]PSMA-5 solution using an automated synthesizer for investigator-initiated clinical trial

S. Naka[1], *Y. Shirakami[1], K. Ooe[1], K. Kurimoto[1], T. Sakai[1], Y. Kon[1], X. Yin[2], H. Haba[2], A. Toyoshima[1], T. Watabe[1], N. Tomiyama[1];*
[1]Osaka University, Suita, Osaka, JAPAN,
[2]RIKEN, Wako, Saitama, JAPAN.

Aim/Introduction: [211At]PSMA-5, an alpha-therapy drug developed at Osaka University that targets PSMA, has shown excellent tumor growth inhibition in a mouse model of prostate cancer with minimal side effects in normal organs, and is expected to be a new targeted alpha therapy, especially metastatic castration-resistant prostate cancer (1). We have already optimized the synthesis procedure and performed scale-up production with automated synthesizer of [211At]PSMA-5. In this study, process validation was conducted under the conditions optimized in the scale-up production for investigator-initiated clinical trial. ***Materials and Methods:*** 211At was produced with the nuclear reaction of 209Bi(4He, 2n) using AVF Cyclotron at RIKEN or Research Center for Nuclear Physics, Osaka University. 211At in irradiated Bi target was purified by an automated dry distillation apparatus installed at the GMP manufacturing facility of Osaka University Hospital. Six lots of [211At]PSMA-5 were synthesized (three times by each target) using automated synthesizer. [211At]PSMA-5 was produced by reacting 211At recovered with 7% sodium bicarbonate injection (700 µL), 1 mg/mL precursor solution (10 µL) and 0.1 M potassium iodide (290 µL) at 95°C for 45 min, followed by purification with solid phase extraction (HLB) column. The solutions after filter filtration sterilization were checked for compliance with the specification criteria. ***Results:*** In the six-lot tests, [211At]PSMA-5 was obtained in a synthesis time of approximately 130 minutes with a radiochemical yield of 29±3% (after decay collection). Radiochemical purity was 96±1% at the end of synthesis, and it was remained above 90% after 6 hours of synthesis. The concentration of related substances, including precursor (PSMA-5), was less than 1.0 µg/mL, and the concentration of ethanol used as a solvent to recover [211At]PSMA-5 from the HLB column was 2.8 v/v % on average. Furthermore, the amount of iodine in the potassium iodide used in the synthesis reagent and the amount of bismuth in the target substance were measured and confirmed to be less than 1 ppm. All other quality test items were also confirmed to meet the specification criteria of [211At]PSMA-5 solution. ***Conclusion:*** In this study, [211At]PSMA-5 was obtained stably in a six-lot tests, meeting all quality specification criteria and conforming to process validation. ***References:*** Watabe et al. Eur J Nucl Med Mol Imaging. 2023doi: 10.2967/jnumed.120.245084.

EP-1024

Automated production of [^{68}Ga]Ga-FAPI-46 via routinely used synthesis module and optimised HPLC analysis for safe clinical application

B. Klasen[1], *M. K. Sarvestani[2], D. Kerner[1], S. Bühler[3], U. Hennrich[4], T. Lindner[5], U. Haberkorn[5], M. Röhrich[1], M. Schreckenberger[1];*
[1]Universitätsmedizin Mainz, Mainz, GERMANY,
[2]Universitätsklinikum Frankfurt, Frankfurt, GERMANY,
[3]Helios Kliniken Schwerin, Schwerin, GERMANY, [4]Deutsches Krebsforschungszentrum Heidelberg, Heidelberg, GERMANY,
[5]Universitätsklinikum Heidelberg, Heidelberg, GERMANY.

Aim/Introduction: Cancer-associated fibroblasts (CAFs) in the tumor microenvironment play a key role in proliferation and metastatic spreading of cancer cells. The fibroblast activation protein (FAP) is highly expressed on the surface of CAFs thus representing a promising target for pantumoral PET imaging [1]. The 68Ga-labelled inhibitor FAPI-46 has proven to be a successful tracer candidate for this purpose [2]. The aim of this study was the automated production of [68Ga]Ga-FAPI-46 via a routinely applied synthesis module using standard disposable materials as well as optimisation of the quality control for safe clinical application. ***Materials and Methods:*** For the production via a fully automated synthesis module, commercially available disposable cassettes and reagents, which are applied as standard materials for established 68Ga tracers on this system, were used. The sequence included elution of the 68Ge/68Ga generator, purification of the eluate by cation exchange, labelling in ammonium acetate buffer at 95 °C and purification and formulation of the product. Furthermore, the influence of ascorbic acid in the reaction mixture on the purity of the final product was investigated. The process was optimised in terms of yield and duration by varying the amount of precursor and reaction time. As release criteria, γ-energy, half-life, pH value, radiochemical purity and identity as well as solvent and endotoxin content were determined. ***Results:*** Within 52 steps and 24-26 min, [68Ga]Ga-FAPI-46 was reproducibly obtained with a radiochemical yield of 72-85%, an apparent molar activity of 7.7-22.3 GBq/µmol and a radiochemical purity of > 97%. Unexpected problems in the HPLC-analysis, probably caused by a certain interaction of the radiotracer in the HPLC system, could be systematically solved by spiking the HPLC-sample with a defined excess of cold natGa-reference compound. The addition of ascorbic acid to the reaction mixture successfully prevented the formation of radiolysis side-products. All quality parameters complied with the defined acceptance criteria based on pharmacopoeia specifications for comparable radiopharmaceuticals. ***Conclusion:*** The automated production of [68Ga]Ga-FAPI-46 using a routine synthesis module and standard disposable materials was successfully optimised and performed reproducibly. The quality of the multi-dose formulation met all the criteria for a safe clinical PET-application. ***References:*** [1] L. Gilardi, et al. Radiolabelling of different quantities of PSMA-617 with ^{225}Ac: the more the better?

A. Esposito, *M. J. Buonanno, M. Aurilio, E. Squame, A. Morisco, C. Maisto, V. Porfidia, R. de Marino, S. Lastoria;*
IRCCS Fondazione G. Pascale, Napoli, ITALY.

Aim/Introduction: Recently, Target Alpha Therapy (TAT) has attracted a great interest in nuclear medicine, particularly in tumor patients who develop resistance to β- therapy. Typically, TAT for solid tumors involves attaching an α-particle-emitter to a tumor targeting carrier, usually a small peptide. Peptide chemical mass may play a crucial role in competitive binding when it competitively binds a target with a saturable receptor density. Therefore, the specific activity (MBq/µg) of a radiopharmaceutical can significantly influence the efficacy of TAT. The impact of the specific activity has been investigated for several targets, and it was reported to be highly pronounced for PSMA radioligands. The aim of this work was to determine the optimal quantity of PSMA-617 required in a standardized method for producing [225Ac]Ac-PSMA-617, keeping the minimum peptide mass that ensures a radiochemical purity (RCP) according to the Pharmacopeia acceptance criteria. ***Materials and Methods:*** It was investigated three different starting amounts of PSMA-617: 100 (A), 50 (B) or 25 (C) µg dissolved in water. The peptide was added to 350 µL of gentisic buffer (gentisic acid 0,25M and sodium acetate 0,35M) pH 5.5. This solution was added to 100 µL of 225AcCl3 (~8 MBq) and heated at 97±2°C for 30 minutes. [225Ac]Ac-PSMA-617 was monitored via iTLC analysis, performed using silica gel as stationary phase and, sodium citrate 0,1M pH 5 (1) and acetonitrile/water 1:1 (2) as mobile phases. The iTLC strips were acquired post-synthesis (t0) and reacquired at 3 hours (t0+R3h), when 221Fr and 213Bi were in Secular Equilibrium with 225Ac, to establish with accuracy the RCP of radiopharmaceutical. ***Results:*** Among three amounts of PSMA-617 used, RCP (t0) of [225Ac]Ac-PSMA-617 was more high for A condition (96,50±0,10 in 1, 95,50±1,10 in 2). However, reacquiring the iTLC strips (t0+R3h), the RCP values for B condition, were closer to A results: 97,77±0,25% vs 87,80±0,95 in 1 and 96,07±1,12 vs 94,80±0,30% in 2. Under 50 µg of PSMA-617, the results were not considered because the RCP was <70%. ***Conclusion:*** The radioligand mass plays a crucial role in optimizing tumor targeting while minimizing accumulation and retention in normal organs. Utilizing low quantities of ligand enhances the specific activity, leading to fewer receptors being occupied by in vivo unlabelled PSMA. However, it is important to acknowledge the possibility of radiolysis phenomena. Additionally, given the recoil effect of 225Ac, it would be prudent to employ the highest tested amount.

EP-1026

Optimizing routine production of $^{[18F]}$BCPP-EF by CFN-MPS-200 multipurpose synthesizer

Y. Shimizu[1], *N. Uemura[2], Y. Fushimi[2], Y. Nakamoto[2];*
[1]Kyoto University Hospital, Kyoto, JAPAN, [2]Graduate School of Medicine, Kyoto University, Kyoto, JAPAN.

Aim/Introduction: Multiple System Atrophy (MSA) is a disorder that presents with parkinsonism, cerebellar ataxia, and autonomic ataxia. Recently, it has been reported that mitochondrial dysfunction is involved in the pathogenesis of MSA. Therefore, to elucidate the pathogenesis of MSA, we have planned to perform a clinical trial of PET imaging with $^{[18F]}$BCPP-EF, which binds specifically to Mitochondrial Complex-I and makes it possible to monitor mitochondrial activity. In this study, we optimized an automated synthesis method of $^{[18F]}$BCPP-EF with a multipurpose synthesizer, "CFN-MPS-200", aiming at its stable supply for clinical use. ***Materials and Methods:*** $^{[18F]}$Fluoride was produced by the 18O(p, n)18F nuclear reaction using a cyclotron with 16.5 MeV energy (PETtrace860, GE Healthcare). The synthesis of $^{[18F]}$BCPP-EF was performed using a CFN-MPS-200 multipurpose synthesizer (Sumitomo Heavy Industry, Ltd) with the following method. $^{[18F]}$Fluoride was loaded onto a QMA carbonate column and then eluted by Kryptofix 222 (10 mg/1 mL 94% acetonitrile, 33 mM K2CO3) into a reaction vial. After the evaporation, Tosyl-BCPP-EF dissolved in DMSO was added to the vial and then reacted at 80 °C for 10 min. The reaction solution was then diluted by 1 mL 50% acetonitrile and then was purified by HPLC equipped with Waters XBridge 5C18 Column, 10ID x 250 mm, or Phenomenex Luna PFP(2) column. The purified $^{[18F]}$BCPP-EF was then evaporated, redissolved in 0.01% tween80, and then transferred to a product vial through the sterile 0.22-µm filter. The quality control tests (radiochemical and chemical purity, radionuclidic identity, half-life, pH, endotoxin, residual solvent, and sterility test) were performed. ***Results:*** The synthesis of $^{[18F]}$BCPP-EF by CFN-MPS-200 automated synthesis module was completed up to 51 min. $^{[18F]}$BCPP-EF was obtained with a radioactivity of 2730 ± 674 MBq, and a radiochemical yield of 9.5 ± 2.4% (decay correlated) (n=3). The solution of $^{[18F]}$BCPP-EF purified by Phenomenex Luna PFP(2) column contained Kryptofix 222 over 40 ppm, while that purified by Waters XBridge 5C18 Column contained less than 40 ppm of Kryptofix 222, and passed all other quality control tests (acceptance criteria: radiochemical purity: >95%, specific activity: >3.7 MBq/µg, pH: 4-8, endotoxin: <15 EU/mL, sterility: negative). ***Conclusion:*** Our results suggest that the optimized production method with CFN-MPS-200 can provide enough radioactivity and quality of $^{[18F]}$BCPP-EF for clinical use.

EP-1027

Radiochemical purity determination of ^{99m}Tc-(EDDA)$_2$/HYNIC-TOC. Is the manufacturer method thorough enough?

Á. Alonso García, *E. Miñana Olmo, T. Chivato Martín-Falquina;*
Unidad de Radiofarmacia. Hospital General Universitario Santa Lucía, Cartagena, SPAIN.

Aim/Introduction: 99mTc-(EDDA)2/HYNIC-TOC is a radiopharmaceutical with high affinity to somatostatin receptor. The radiolabelling is carried out in two steps: first 99mTc-(tricine)2/HYNIC-TOC is formed, which after heating is exchanged to 99mTc-(EDDA)2/HYNIC-TOC. Radiochemical Purity (RCP) is performed according to the manufacturer's method by Instant Thin Layer Chromatography (ITLC) with a double Silica Gel (SG) strip using Methylethylketone (MEK) to determine free 99mTcO4- (Rf=1) and acetonitrile:water 1:1 (ACNW) or water/acetonitrile/pure acetic acid 1:1:2 (WAE) for the 99mTc-colloid fraction (Rf=0). However, literature describes the formation of another impurity, 99mTc-coligands (99mTc-tricine and 99mTc-EDDA), during labelling[1]. The aim of our study is to find out whether the manufacturer's method adequately detects all the impurities generated. ***Materials and Methods:*** n=17 cold kits were radiolabelled with 1600MBq of sodium pertechnetate (99mTc) solution following the manufacturer's instructions. RCP was determined by ITLC-SG using MEK and ACNW (reference method), and adding a third strip developed with sodium chloride 0,9% for the non-peptide bound 99mTc-coligand (Rf=1) (alternative method). RCP was performed once the incubation was finished and on n=5 kits it was also done immediately prior to heating at 100°C. RCP was calculated for both
