Aim/Introduction: Within the diagnostic molecular imaging setting, PET/CT is widely considered to be the leading imaging modality. Not only because of its superior sensitivity and resolution, but also because of the availability of dedicated radiopharmaceuticals. When PET/CT roadmaps are used to identify patients with local disease that will benefit from surgery, ideally such surgery targets the exact same lesion. Despite the many ongoing efforts with regards to low-energy (<150keV) γ-emission or fluorescence guided surgery, detecting the beta-emitting radiopharmaceutical directly seemingly provided the most direct readout method. In this contribution we present the first in-vivo use of robotic 68Ga-PSMA surgical guidance using a DROP-IN beta probe with dedicated signal interpretation algorithm. ***Materials and Methods:*** A sterilizable DROP-IN beta probe has been developed, compatible with the daVinci robotic platform.The core of the β detector consists of a cylindrical mono-crystalline para-terphenyl. Scintillation light conversion was performed by a 3x3 mm2 silicon photomultiplier (SiPM Hamamatsu S13360-3050PE) powered and read-out by a custom microcontroller, connected to the device with a biocompatible and sterilizable latex-free cable. The prototype was evaluated during robotic resections in 8 primary prostate cancer patients that had at least 1 lymph node metastases visible on their PSMA-PET roadmap. At the beginning of surgery, patients were injected with 1.1 MBq/kg of [^{68}Ga]Ga-PSMA. The DROP-IN β probe was used

to trace PSMA-expressing lymph nodes in vivo during the pelvic lymph node dissection. To support the surgeon in discriminating between probe signals coming from tumor and healthy tissue, a statistical software algorithm was developed and optimized on this dataset, and will be presented in this contribution ***Results:*** During robotic surgery, the DROP-IN β probe helped provide the surgeon with an efficient means to detect PSMA-avid lesions. A total of 76 samples (i.e., lymph nodes specimens) were analyzed in vivo, of which 37 (49%) were found to be malignant (21 being PET positive). Using our dedicated detection algorithm, we found a probe detection rate of 80% of the PSMA-PET-positive samples (n = 17/21), yielding a sensitivity of 80% and specificity of 85%, as compared to pathologic evaluation ***Conclusion:*** This study is the first-in-human validation of a DROP-IN β probe, supporting β radio guidance during robotic surgery.Opening the way for the widespread surgical use of beta-emitting radiopharmaceuticals. The obtained sensitivity and specificity values for nodal metastases were found to be competitive to values obtained for other RGS strategies.

Investigation of a Nuclear Medicine Compton Camera for low dose imaging using Timepix3 technology

S. Cournane[1,2], *B. Kamtchou[3], R. McNulty[4], L. Leon Vintro[4];*
[1]St Vincent's University Hospital, Dublin 4, IRELAND, [2]UCD Centre for Physics in Health and Medicine, Dublin, IRELAND, [3]UCD Centre for Physics in Health and Medicine, Dublin 4, IRELAND, [4]UCD School of Physics, Dublin 4, IRELAND.

Aim/Introduction: Current nuclear medicine gamma camera technology relies on the use of collimators to determine the positional information of gamma ray photons emitted from radiopharmaceuticals. However, collimators typically attenuate >95% of incident photons. A Compton camera is an imaging device that can determine the direction of photons based on the kinematics of Compton scattering. The development of a Compton camera would negate the need for collimators and, thus, lead to a significant reduction in the required radioactivity administered to patients, or reduce the scanning time needed. The purpose of this study was to investigate the use of Timepix3 technology as a Compton camera for Nuclear Medicine imaging. ***Materials and Methods:*** A high spatial, high contrast resolution Timepix3 (55 µm pixel pitch, 1.56 ns timing resolution, energy resolution of 9% at 140 keV) device with a Cadmium Telluride (CdTe, 1mm thick) sensor layer was used to acquire 2D image datasets for 99mTc,131I and 137Cs test objects. Analysis pipelines for identifying appropriate interaction events and clusters were established. Compton cone data were subsequently reconstructed onto single and multiple planes using maximum likelihood expectation maximization (MLEM) techniques. Monte Carlo (MC) simulations of the Timepix3 detector Compton camera were developed using EGSnrc MC software and reconstructed similarly. Images of anthropomorphic thyroid phantoms acquired on conventional gamma cameras and the Timepix3 were compared in terms of sensitivity and spatial resolution. ***Results:*** The MC model of the Timepix3 Compton camera was validated using the experimentally acquired data, accounting for Doppler broadening, energy and spatial resolution effects. The spatial resolution, as measured by the full width half maximum (FWHM) of 99mTc and 137Cs point sources was found to be 7.3 and 5 mm, respectively, which is of the order of conventional gamma cameras. The Compton camera sensitivity was approximately 15-20 times that of conventional gamma cameras, demonstrating potential to significantly reduce the required nuclear medicine patient radiation dose or reduce the required scanning time. Further work is needed to optimise the detection and reconstruction techniques for improved spatial resolution in the case of anthropomorphic phantoms. ***Conclusion:*** Timepix3 technology has been investigated for use as a nuclear medicine Compton camera, with experimental and simulated data demonstrating its potential for Compton imaging applications. Future work will look to optimise the use of the Timepix3 detector for more complex nuclear medicine imaging applications, to investigate the technology's potential to significantly reduce administered patient activities or increase throughput.

Preclinical and First-in-Human Evaluation of a Novel Brain-Dedicated PET System

H. Barthel[1], *M. Rullmann[1], K. Steinhoff[1], I. Sacco[2], A. Buck[2], M. Hüllner[3], M. Jehl[2], F. von Kistowski[2], G. Kopylov[2], E. Mikhaylova[2], M. Palka[2], J. Streb[2], V. Treyer[3], P. Kaufmann[3], M. Ahnen[2], J. Fischer[2], B. Sattler[1], O. Sabri[1];*
[1]University of Leipzig, Department of Nuclear Medicine, Leipzig, GERMANY, [2]Positrigo, Zürich, SWITZERLAND, [3]University Hospital Zürich, Department of Nuclear Medicine, Zürich, SWITZERLAND.

Aim/Introduction: With the recent introduction of concepts defining neurodegenerative disorders on biological grounds, and with the advent of disease-modifying drugs in Alzheimer's disease, there is growing interest in brain-dedicated PET systems. The NeuroLF system (Positrigo, Zurich, Switzerland) consisting of a LYSO-SiPM detector ring placed around the head of a patient sitting on an armchair was developed as a compact, versatile and cost-effective option. The aim of this study is to evaluate the performance of this system according to NEMA specifications and in a first-in-human scenario. ***Materials and Methods:*** The spatial resolution and sensitivity of the system was determined according to the NEMA (NU2-2018) standard using FBP and OSEM reconstructions. Hoffman brain phantom images were acquired on the NeuroLF system and compared with those obtained on Siemens Quadra and GE Discovery MI systems. In addition, by now, eight patients (5 female, age 61±10yrs) were enrolled into a first-in-human study. After undergoing exams on a standard of truth (SoT) PET system (Biograph Vision Quadra, Siemens) with $^{[18F]}$FDG (n=3; ~300MBq; for whole-body staging to exclude malignancy), $^{[18F]}$florbetaben beta-amyloid (n=3; ~300MBq; suspected Alzheimer's disease) or $^{[18F]}$PI-2620 tau (n=2; ~200MBq; suspected progressive supranuclear palsy), patients underwent 15 min brain PET imaging on the NeuroLF system at 114±8min p.i., 145±13min p.i., or 62±26min p.i., respectively. To investigate the non-inferiority hypothesis of the NeuroLF system, the PET scans acquired with NeuroLF are compared to those obtained with the SoT clinical PET system. All brain scans are analysed using tracer-specific standardized visual and semi-quantitative approaches. Additionally, the level of comfort for both patients and technologists when using the new system is scored. ***Results:*** FWHM resolution was determined as 2.2mm (radial), 3.5mm (tangential), and 2.5mm (axial) using FBP reconstruction at 10mm offset from the scanner axis. The sensitivity of the system was measured at 4.8cps/kBq. The Hoffman brain phantom images demonstrated similar quality compared to those acquired with the reference systems. The first human PET images were deemed to be of good quality, suitable for deriving a clinical diagnosis. This far, the PET findings obtained with NeuroLF have not differed from those acquired with the SoT system in any patient. ***Conclusion:*** The data analysis of the first-in-human study is currently ongoing. More patients, including patients scanned with other brain

PET tracers, will be enrolled. However, the NEMA results and preliminary clinical data indicate the suitability of the novel brain-dedicated PET system for providing valuable clinical information.

Development of a Fluidics Phantom for Dynamic PET Imaging

***J. Fowler*[1,2],** *J. Atwal*[2], *I. Grewal*[2], *A. Peters*[2], *N. Waldal*[2], *R. Zibyan*[2], *R. Fedrigo*[1,2], *C. F. Uribe*[1,2], *A. Rahmim*[1,2];

[2]*University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: Positron emission tomography (PET) imaging is used in oncology for diagnosis and staging of cancer. Standardized uptake values (SUV) and other quantifiable PET imaging metrics facilitate the comparison of various disease presentations, enhancing treatment planning. Phantoms are the gold-standard for validating these quantities, as they provide a controlled environment that mimics the properties of a human subject with a well-defined ground truth. However, few anthropomorphic phantoms exist which capture the time-dependent radiopharmaceutical distribution observed in dynamic PET imaging. In this work, we aimed to develop a novel fluidics phantom to accurately mimic the pharmacokinetics of prostate-specific membrane antigen (PSMA) radiotracers, enabling the precise measurement of dynamic ground truth. ***Materials and Methods:*** The devised dynamic PET phantom consists of resin 3D printed fluidics chambers. Spherical lesion chambers (17mm, 22mm, and 28mm) and anthropomorphic kidney chambers (~115mL) were created due to the high kidney uptake of PSMA tracers. Fluidic port locations were optimized through computational fluid dynamics to prevent stagnation. These chambers are supplied with a mixture of water and 18F-fluorodeoxyglucose (18FDG) as an analog to 18F-DCFPyL. The variable mixing of water and 18FDG using diaphragm pumps allows the system to dynamically follow a moving set point along an input time activity curve (TAC). NaCl is added to the 18FDG solution to allow for indirect activity concentration measurements with a conductivity sensor. The flow rates of the diaphragm pumps are regulated by a proportional-integral-derivative (PID) controller responding to conductivity sensor feedback. Three spherical chambers are connected in series in one fluidics loop, while the kidneys are connected in series in another loop. All the chambers are mounted in an anthropomorphic Probe-IQ phantom with other static organ chambers. ***Results:*** Non-radioactive tests have shown that the system is capable of following simulated activity curves with a maximum of 9.2% transient state error and negligible steady-state error. A settling time of less than 4 seconds was achieved for TACs. Further dynamic activity validation with PET imaging is planned. ***Conclusion:*** In this work, we developed a novel fluidic system to model time-dependent radiopharmaceutical distributions characterized by dynamic PET imaging. The system has a settling time of less than 4 seconds, allowing it to replicate in vivo tracer dynamics with rapid transit times. Integrated with additional organ chambers, this technology has the capability to be used as a validation tool for new image acquisition methods and dosimetry workflows.

Walk-Through Flat-Panel Total Body PET: system design simulations, deep learning, and prototype measurements.

***S. Vandenberghe*[1],** *J. Maebe*[1], *M. Dadgar*[1], *M. Abi Akl*[1], *F. Muller*[1], *N. Withofs*[2], *B. Vervenne*[1], *R. Aziz*[1], *C. Vanhove*[3], *J. Karp*[4];
[1]*Universiteit Gent, Gent, BELGIUM,* [2]*CHU liege, Liege, BELGIUM,* [3]*Christian Vanhove, Gent, BELGIUM,* [4]*University of Pennsylvania, Philadelphie, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: Long axial field-of-view (LAFOV) PET offers heightened sensitivity compared to standard AFOV PET, enabling quicker and/or lower-dose imaging. However, patient positioning on the bed constrains effective patient throughput for LAFOV, and high system costs make it hard to justify for routine imaging. We propose a novel approach: a dual flat-panel Walk-Through (WT) PET designed for scanning patients in standing position, eliminating time for positioning on the bed[1]. Our solution entails a patient-centric design based on high resolution monolithic detectors with depth-of-interaction (DOI). An optional sequential rectangular shaped spectral multi-source standing CT aims for high quality anatomical images. ***Materials and Methods:*** The system design dimensions are based on patient size measurements. Two large flat panels (with a 50 cm gap) 70 cm wide and 106 cm high accommodate whole-body (pelvic to head) PET. Further cost reduction is obtained by axial gaps between each row. Deep learning is implemented to compensate for the reduced count statistics from sparse WT-PET. The system spatial resolution is estimated from Monte Carlo simulations and a measured detector model. The full system has been modeled in Gate, XCAT simulations have been reconstructed and compared to a model of the Siemens Vision Quadra system. A mockup has been constructed to evaluate patient experience and first prototype measurements are being acquired. Energy based scatter correction and deep learning derived attenuation maps from emission data enable quantitative standalone PET. ***Results:*** The large opening angle, TOF and DOI reduces the expected limited angle artefacts (only visible close to the detectors). Despite a much less detectors (2-4 x), the proximity leads to comparable sensitivity as LAFOV systems. Excellent system spatial resolution (< 2mm throughout the FOV) is obtained due to DOI-capable monolithic detectors. Good image quality is obtained at standard dose (3MBq/kg) for XCAT simulations of 30 sec, further enhanced by deep learning noise reduction. Infrared based motion tracking show that rigid head and body motion in 30 sec was limited (<2mm) for free-breathing and breath-hold conditions to be reduced by motion compensation methods. ***Conclusion:*** The WT-PET reduces cost (2-3 x) approaching that of a SAFOV system, while maintaining LAFOV coverage. and image quality. Higher throughput is achieved by simplifying patient positioning, with the aim to significantly accelerate routine PET torso scans. ***References:*** [1] Vandenberghe, S.,et al (2023). Walk-through flat panel TB pet: a patient-centered design for high throughput imaging at lower cost using doi-capable high-resolution monolithic detectors. EJNMMI 50(12), 3558-3571.

First in vivo positronium lifetime measurement with a commercial long axial field-of-view PET/CT

***L. Mercolli*[1],** *W. Steinberger*[2], *A. Afshar-Oromieh*[1], *F. Caobelli*[1], *M. Conti*[2], *A. R. Felgosa Cardoso*[1], *C. Mingels*[1], *P. Moskal*[3], *T. Pyka*[1], *H. Sari*[4], *R. Schepers*[1], *R. Seifert*[1], *K. Shi*[1], *E. L. Stepien*[3], *M. Viscione*[1], *A. Rominger*[1];
[1]*Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND,* [2]*Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA,* [3]*Faculty of Physics, Astronomy and Applied Computer Science, Jagiellonian University, Krakow, POLAND,* [4]*Siemens Healthineers International AG, Zürich, SWITZERLAND.*

Aim/Introduction: While the lifetime of the triplet state of positronium (oPs) in vacuum is about 142 ns, it shortens significantly and becomes dependent on the surrounding material with which the oPs can interact. Measuring oPs lifetimes in patients therefore carries the potential for obtaining additional information about the molecular structure of the surrounding tissue [1]. First promising ex-vivo [2] and in-vivo [3] positronium images were recently reported with the modular J-PET system prototype. We report the first in vivo positronium lifetime measurements with a commercial long axial field-of-view (LAFOV) PET/CT scanner. ***Materials and Methods:*** Three subjects (m 58y, f 39y, m 39y) received a standard dose of [68Ga]Ga-PSMA-11, [68Ga]Ga-DOTATOC and [82Rb]Cl and were scanned for 40, 20 and 10 minutes using a special acquisition mode which saves the single-crystal interactions on a commercial LAFOV PET/CT system in addition to the standard PET scan. Triple events were selected from the listmode data based on energy, time and spatial selection criteria. We performed a Bayesian fit to the measured time difference distributions (TDD) with an appropriate prior for the branching fractions of the direct, singlet and triplet annihilation in order to determine the oPs lifetime at the organ level. ***Results:*** We describe histoimages of triple events for the three patients and the resulting oPs lifetime spectra for several organs. The left and right heart chambers, i.e. collecting triple events from the atria and ventricles, of the subject receiving [82Rb]Cl show a distinct oPs lifetime: the 68% credible intervals of the oPs lifetime's posterior distribution are [1.25, 1.48] ns (left) and [1.51, 1.79] ns (right) with mean values 1.38 and 1.66 ns, respectively. This might signal the different oxygenation levels of the blood in the two heart chambers. Challenges for oPs lifetime measurements remain. Several examples of these challenges include the statistics of triple events (e.g. a peak-to-background ratio of ~1.25 in the TDD from 68Ga in the kidneys, liver and pancreas), correction for random triple events and the energy selection for the prompt photon of 68Ga and 82Rb. ***Conclusion:*** In vivo oPs lifetime measurements in patients on a commercial LAFOV PET/CT system are feasible and have the potential to provide additional physiological information presently unavailable in coincidence PET/CT imaging.

Novel hybrid ultrasound/gamma probe: First clinical experience

M. Biermann[1], *J. Sjåvik[1], K. Brauckhoff[2], N. Brekke[1];*
[1]Nuclear Medicine/PET-senter, Bergen, NORWAY,
[2]Endocrine Surgery, Bergen, NORWAY.

Aim/Introduction: Hybrid nuclear medicine modalities such as SPECT/CT, PET/CT and PET/MR have revolutionized functional imaging, but practical solutions for integrating radionuclide imaging with high-resolution ultrasound are lacking. ***Materials and Methods:*** We constructed a novel hybrid ultrasound/gamma probe by 3D printing a snap-on adapter to attach standard gamma probe for sentinel lymph node surgery to a high-resolution "hockey" probe connected to our clinical ultrasound system. To test clinical feasibility, we performed high-resolution ultrasound in 10 consecutive patients (60 % female, age 55 ± 19 years, mean standard ± deviation) undergoing posttherapeutic imaging incl. SPECT/CT following thyroid ablation for differentiated thyroid cancer (DTC) 72 hours after oral application of 1.1 and 3 GBq [131I]NaI (n = 5 each), respectively. ***Results:*** SPECT/CT revealed an iodine avid pyramidal lobe in 8 out of 10 patients. Only in 1 out of 8 patients, a pyramidal lobe measuring 8 x 6 x 11 mm (260 mm3) could be localized using standard ultrasound probes in the knowledge of the SPECT/CT findings. In the remaining 7 patients, the iodine-avid pyramidal lobe could not be visualized using conventional ultrasound by the same experienced observer, but only using the novel hybrid probe. The lesions had a maximum diameter of 7 ± 2 mm and a volume of 54 ± 24 mm3 ($p < 0.001$) at a maximum count rate of 1500 ± 800 s-1. ***Conclusion:*** Our novel hybrid ultrasound/gamma probe allows the identifcation of small radiotracer-avid lesions with superior sensitivity and precision, thus aiding surgical managment of thyroid cancer and other conditions such hyperparathyroidism.

Assess the Added Value of Al^{18}F-NOTA-LM3 Compared to^{68}Ga-DOTATATE and^{68}Ga-NODAGA-LM3 in Patients with Well-differentiated Neuroendocrine Tumors

M. Liu, *Y. Zhang, H. Zhang, C. Ren, Z. Huang, Y. Cheng, Q. Xu, W. Zhu, L. Huo;*
Peking Union Medical College Hospital, Beijing, CHINA.

Aim/Introduction: 18F-labelled somatostatin receptor (SSTR) analogs present multiple advantages over 68Ga, including improved yield, cost-effectiveness, enhanced spatial resolution, and a higher detection rate. This study aims to evaluate the diagnostic efficacy and the impact on clinical management of Al18F-NOTA-LM3 in comparison with 68Ga-DOTATATE and 68Ga-NODAGA-LM3 in patients with well-differentiated neuroendocrine tumors (NETs). ***Materials and Methods:*** Patients with histologically confirmed well-differentiated NETs (G1 and G2) were prospectively recruited and randomized into two arms: Arm A, where patients underwent Al18F-NOTA-LM3 and 68Ga-DOTATATE PET/CT within a week, and Arm B, where patients underwent Al18F-NOTA-LM3 and 68Ga-NODAGA-LM3 PET/CT within a week. In both arms, the interval between the two scans was set to be at least 24h to avoid interference. Lesion numbers, lesion uptake, and tumor-to-background ratio (TBR) were compared. The impact on clinical management was evaluated. ***Results:*** A total of 50 patients were enrolled in this study, 30 in arm A, and 20 in arm B. On a per-patient basis, Al18F-NOTA-LM3 had a higher detection rate for liver and lymph node lesions than either 68Ga-DOTATATE or 68Ga-NODAGA-LM3. On a per-lesion basis, Al18F-NOTA-LM3 detected significantly more liver metastases (503 vs. 331, P=0.003) and lymph node metastases (33 vs. 24, P=0.007) than 68Ga-DOTATATE. Al18F-NOTA-LM3 identified significantly more liver metastases (375 vs. 261, P=0.008) than 68Ga-NODAGA-LM3. Compared to 68Ga-DOTATATE, Al18F-NOTA-LM3 showed comparable lesion uptake but significantly higher TBR of primary lesions, liver lesions, and bone lesions. Compared to 68Ga-NODAGA-LM3, Al18F-NOTA-LM3 showed lower uptake but higher TBR of liver lesions. Al18F-NOTA-LM3 led to a change in clinical management in 16.7%

(5/30) of the cases in arm A, and 10% (2/20) of the cases in arm B, primarily due to the identification of new, unexpected findings. ***Conclusion:*** AI18F-NOTA-LM3 demonstrated superior diagnostic efficacy compared to 68Ga-DOTATATE and 68Ga-NODAGA-LM3 in patients with well-differentiated NETs, thus providing additional value and impacting clinical management decisions.

OP-609

Assessment of inter- and intraobserver agreement in [^{68}Ga]Ga-DOTA-SSA PET/CT and [^{18F}]AlF-NOTA-octreotide PET/CT imaging

H. Leupe[1], *N. Ahmadi Bidakhvidi[1], K. Goffin[1], B. Van den Broeck[2], S. Jentjens[1], A. Laenen[3], E. Pauwels[1], W. Lybaert[4], E. Van Cutsem[1], G. Bormans[3], T. Vandamme[5], F. Cleeren[3], J. Dekervel[1], K. Geboes[2], S. Stroobants[5], C. Verslype[1], C. M. Deroose[1];*
[1]UZ Leuven, Leuven, BELGIUM, [2]Ghent University Hospital, Ghent, BELGIUM, [3]KU Leuven, Leuven, BELGIUM, [4]NETwerk Antwerpen-Waasland CoE, Edegem, BELGIUM, [5]Antwerp University Hospital, Antwerp, BELGIUM.

Aim/Introduction: [18F]AlF-NOTA-octreotide ([18F]AlF-OC) is an alternative for [68Ga]Ga-DOTA-somatostatin analogues (SSAs) in PET imaging of the somatostatin receptor (SSTR) in neuroendocrine tumor (NET) patients. Our aim is to compare inter- and intraobserver agreement in [68Ga]Ga-DOTA-SSA PET/CT and [18F]AlF-OC PET/CT imaging. ***Materials and Methods:*** This is a secondary endpoint analysis of the data from our previously published multicenter trial (1). In this cohort, 75 patients with a histologically confirmed NET received both a [68Ga]Ga-DOTATATE (n=56) or [68Ga]Ga-DOTA-NOC (n=19) PET and a [18F]AlF-OC PET. A randomized read-out of the masked images from both tracers was performed by 5 readers. Concordance of lesion detection per organ was measured between [68Ga]Ga-DOTA-SSA and [18F]AlF-OC images. Lesions were characterized per organ as either benign or malignant, while lesion conspicuity per organ was assessed using a 5-point Likert scale. Six bins were used to categorize the number of malignant lesions (0, 1, 2-5, 6-10, 11-20 and >20) per organ. All PET/CT images underwent scoring for both a global Krenning score and overall image quality (5-point Likert scale) as well. Intraobserver agreement was determined by two readers who reassessed PET images from both tracers for 20 patients. The GWET AC statistic was determined as a measure of agreement on ordinal and categorical scores. ***Results:*** We observed almost perfect interobserver agreement for lesion characterization with [18F]AlF-OC and [68Ga]Ga-DOTA-SSAs, both across all organs as evidenced by a GWET agreement coefficient of 0.921 vs. 0.934, respectively, and at the organ level. Comparable agreement was found in terms of the number of lesions over all organs (GWET agreement 0.736 for [18F]AlF-OC and 0.749 for [68Ga]Ga-DOTA-SSAs). Organ-specific analysis revealed similar agreement for bone (0.819 vs. 0.823) and liver (0.788 vs. 0.786) lesions between [18F]AlF-OC and [68Ga]Ga-DOTA-SSAs, respectively. However, for lymph node assessment, slightly lower agreement was found for [18F]AlF-OC in terms of the number of lesions (0.490 vs. 0.618), although characterization agreement was higher (0.757 vs. 0.616). Both tracers demonstrated almost perfect agreement in determining Krenning scores (0.925 for [18F]AlF-OC and 0.927 for [68Ga]Ga-DOTA-SSAs). Mean lesion conspicuity was similar across all organs for both tracers, while [18F]AlF-OC exhibited a higher mean global image quality score compared to [68Ga]Ga-DOTA-SSAs (4.22 vs. 3.86; p<0.0001). Intra-observer agreement was comparable between the two tracers for lesion characterization and number of lesions. ***Conclusion:*** [18F]AlF-OC and [68Ga]Ga-DOTA-SSAs demonstrate comparable inter- and intraobserver agreement, further validating their potential interchangeability in clinical practice. ***References:*** Pauwels E et al. J Nucl Med. 2023;64:632-638

OP-610

Development of PET Response Criteria In Neuroendocrine tumors (PERCIN)

A. Chaban[1], *V. Dinkel[1], M. Eiber[1], Y. Song[1], J. Brosch-Lenz[1], S. Krebs[2], L. Bodei[2], W. Weber[1];*
[1]Klinik und Poliklinik für Nuklearmedizin, Klinikum rechts der Isar, Technische Universität München, München, GERMANY, [2]Memorial Sloan Kettering Center, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: It is now well established that PET/CT imaging with radiolabeled somatostatin receptor ligands (SSTR-PET/CT) has a higher diagnostic accuracy for staging of neuroendocrine tumors (NETS) than anatomic imaging with CT or MRI. This suggests that SSTR-PET/CT may also be superior for assessing tumor response to therapy in NETs. However, this application of SSTR-PET/CT has been much less studied and validated criteria for assessing response are still lacking. ***Materials and Methods:*** In this international, dual center study we evaluated response by measuring changes in tumor volumes on SSTR-PET/CT before and after SSTR-targeted radionuclide therapy (typically 4 treatment cycles). Tissue specific threshold values were used to automatically delineate tumor volume on the pre- and post-therapeutic SSTR-PET/CT scans: for liver metastases voxels with a SUVbw more than 2.2 g/ml higher than the maximum liver SUVbw were included in the total tumor volume, for lung and bone metastases voxels with a SUVbw of more than 2.0 g/ml, and for all other metastases voxels with a SUVbw higher than the maximum liver SUVbw. These thresholds were derived from an analysis of a subset of patients with well defined tumor borders on CT. Changes in tumor volumes from the pre- to the post-therapeutic scan were correlated with progression-free survival (PFS). For comparison, tumor response was also assessed with CT and classified according to RECIST. ***Results:*** A total of 90 patients with well-differentiated GEP-NETs treated by SSTR-targeted radionuclide therapy at two centers were retrospectively analyzed. The highest concordance with progression-free survival was achieved by defining response as a 40% decrease of the tumor volume and progression as a 20% increase in tumor volume (p=0.008, c-index=0.62). The prognostic value was improved by defining progression also by the appearance of new metastatic lesions, irrespective of volume changes (p<0.0001, c-index=0.668). Response assessment by RECIST had a lower prognostic value (p=0.0002, c-index=0.590), this was mostly due to the lower sensitivity of CT to detect new lesions. Changes in tumor SUVbw were not significantly correlated with PFS (p=0.47) for various thresholds tested. ***Conclusion:*** Metastatic NETs can be automatically segmented by tissue specific thresholds using routinely available software. Changes of these tumor volumes are correlated with PFS, and their prognostic value is promising when compared to RECIST. Prospective validation of the response criteria derived from this retrospective analysis (PERCIN) is ongoing.

Biochemical subtyping of pheochromocytoma and paraganglioma with quantitative parameters in ^{18}F-DOPA PET/CT

P. Dahlmann;
Ludwig-Maximilians-Universität, Munich, GERMANY.

Aim/Introduction: 18F-DOPA PET/CT is currently the most

sensitive functional imaging modality for the diagnosis of cluster 1B and cluster 2 pheochromocytoma/paraganglioma (PPGLs). The assessment of the biochemical secretion type is crucial for patient management, being linked to varying aggressiveness and metastatic risk. Therefore, the aim of this study was to compare the biochemical phenotype as well as single catecholamine metabolite levels measured in plasma and urine samples with uptake intensity and tumor volume on 18F-DOPA PET/CT imaging. ***Materials and Methods:*** All patients with histologically verified PPGLs who underwent 18F-DOPA PET/CT between 03/2012 and 11/2023 as well as hormonal laboratory analysis within up to 3 months after the PET/CT at LMU Klinikum were included. Patients with head and neck paragangliomas were excluded. The metabolic tumour volume (MTV) was quantified based on a threshold value of an SUVmax ≥ 4. Metabolic parameters on 18F-DOPA PET/CT (SUVmax, SUVmean) and total lesion uptake (TLU = MTV x SUVmean) were compared with catecholamine metabolite levels in plasma and 24-hour urine samples using Pearson's or Spearman's correlation analysis after testing for normal distribution with Kolmogorov-Smirnov test. Additionally, the diagnostic discriminative power of SUVmax in distinguishing between different biochemical phenotypes (noradrenergic/adrenergic phenotype) was evaluated using an ROC analysis. ***Results:*** 74/77 patients presented with DOPA-positive PPGLs, 3/77 patients showed DOPA-negative tumors. SUVmax showed moderate correlations with normetanephrines and noradrenaline in plasma (r=0.34, r=0.37, p=0.006-0.007) and urinary samples (r=0.36, r=0.41, p=0.008-0.018). TLU showed strong correlations with plasma normetanephrine (r=0.72, p<0.01), plasma metanephrine (r= 0.67, p<0.01), plasma noradrenaline (r=0.56, p<0.01), chromogranin A (r=0.61, p=0.003), urinary noradrenaline (r=0.60,p<0.01) and urinary metanephrines (r=0.69, p<0.01). Based on the ROC-analysis, a cut-off value of SUVmax 13.6 was determined for the detection of the non-adrenergic subgroup, giving a sensitivity of 78% and a specificity of 74%. ***Conclusion:*** The SUVmax of pheochromocytoma and paraganglioma on 18F-DOPA PET/CT indicates the biochemical phenotype. Furthermore, the total lesion uptake of PPGLs on 18F-DOPA PET/CT is predictive for the level of catecholamine metabolites in plasma samples and 24-hour urine samples potentially facilitating the metabolic profiling of patients with episodic hormonal secretion or suspected impaired laboratory results (e.g. with comorbidities like sleep apnoe or intake of certain medications).

Pharmacokinetic analysis of 177Lu-DOTATATE using Mixed model across treatment cycles

A. Akhavanallaf[1], *A. Golzaryan[2], M. Clark[1], H. Siebinga[3], J. Hendrikx[3], B. Viglianti[1], K. Wong[4], Y. Dewaraja[1];*
[1]University of Michigan, Ann arbor, MI, UNITED STATES OF AMERICA, [2]K. N. Toosi University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]The Netherlands Cancer Institute, Amsterdam, NETHERLANDS, [4]University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: Recent studies have presented evidence regarding the impact of decreased tumor uptake in subsequent cycles of peptide receptor radionuclide therapy (PRRT). However, this evidence remains limited, prompting a crucial exploration of potential cycle effects. Hence, our primary aim was to quantify these effects in tumors and normal organs with physiological uptake. ***Materials and Methods:*** : A pharmacokinetic model was developed using post-therapy SPECT images from 12 patients who received four cycles of 177Lu-DOTATATE. Our data acquired at the University of Michigan includes serial post-therapy SPECT/CT imaging at ~ 4, 24, 96, and 168 hours after each PRRT cycle. A 25 min single-bed SPECT/CT acquisition is performed on a Siemens Intevo using manufacturer-recommended protocol and quantitatively reconstructed with Siemens xSPECT. Up to five index lesions were manually segmented by a radiologist while the normal organs were segmented using a deep learning model on the CT portion of SPECT/CT images. The compartments' activities were obtained as the total activity in the volume of interest (MBq) and were normalized to the injected activity and decay-corrected to the administration time using the physical half-lives of 177Lu. We implemented a six-compartment model including a central, kidney, spleen, target tumor volume and rest compartment. The radiotracer transport between the central and other compartments was described by two rate constant parameters, while the elimination was defined by a bi-phasic rate constant from the central compartment. The cycle effect was evaluated in terms of changes in kinetic rates using mixed effect model. All model processing was performed using SimBiology (MATLAB version 2024a). ***Results:*** The biological half-life for kidneys (84.8±22.4), spleen (146.4±40.4) and tumor tissues (264.5±196.2) were calculated from non-compartmental analysis. From the multi-compartmental mixed model, the absorption and elimination rate for each compartment was calculated as follows: spleen (kin= 0.01; kout= 0.20), kidney (kin= 0.05; kout= 0.92), tumor (kin=0.02; kout=0.15). We observed a trend in which the population-based tumor absorption rate decreased to 81%, 66%, and 53% in the subsequent cycles compared to cycle one, indicating an impact of the treatment cycle on tumor physiology. ***Conclusion:*** Using population PK modeling, we investigated the cycle effect on tumor uptake in subsequent PRRT cycles highlighting a negative trend in tumor uptake that aligns with other studies, warranting further investigation for PRRT outcome enhancement. ***References:*** Siebinga, H., et al, (2024). "The cycle effect quantified: reduced tumour uptake in subsequent cycles of [(177)Lu]Lu-HA-DOTATATE during peptide receptor radionuclide therapy." EJNMMI 51(3): 820-827.

OP-613

Image quality for two administration regimens for [^{68}Ga]Ga-DOTA-TOC PET/CT-imaging - how low can we go?

A. Stenvall[1], *C. Hindorf[2,3], B. Olsson[1], L. Jönsson[4], U. Bitzén[5], F. Hedeer[5];*
[1]Radiation Physics, Department of Haematology, Oncology, and Radiation Physics, Skåne University Hospital, Lund, SWEDEN, [2]Nuclear Medicine and Medical Physics, Karolinska University Hospital, Stockholm, SWEDEN, [3]Molecular medicine and Surgery, Karolinska Institutet, Stockholm, SWEDEN, [4]Department of Medical Radiation Physics, Lund University, Lund, SWEDEN, [5]Department of Clinical Physiology and Nuclear Medicine, Lund University, Skåne University Hospital, Lund, SWEDEN.

Aim/Introduction: For positron emission tomography (PET) with [68Ga]Ga-DOTA-TOC, guidelines recommend an administered activity to adults of 148 MBq (Food and Drug Administration) and 100-200 MBq (European Medicines Agency), respectively [1]. While administration of a fixed activity might have logistical advantages, a disadvantage might be an inconsistent image quality for differently sized patients, possibly affecting diagnostic confidence. The aim of this study was to evaluate how fixed dosing regimens is related to image quality and diagnostic confidence compared to weight-adjusted dosing, and to evaluate the minimum administered activity where diagnostic image quality is preserved. ***Materials***

and Methods: Fifty patients referred for [68Ga]Ga-DOTA-TOC-PET/CT (average: 83kg, 27.3kg/m2, 19 females) were included. Each patient received 2 MBq/kg [68Ga]Ga-DOTA-TOC and after on average 61.5 minutes, images were acquired in listmode for 3 minutes/bed position on a PET/CT system (20 cm axial field-of-view). Images were resampled to mimic administrations with fixed activities (200, 150, 100, 80 and 60 MBq) or weight-adjusted activity (2.0, 1.6, 1.2, 0.8, 0.6 and 0.4 MBq/kg). Images were reconstructed with a block-sequential regularization-expectation-maximization reconstruction-algorithm (beta-value 900). Image quality according to a four-grade scale (1-unacceptable, 2-poor, 3-moderate, 4-good) were assessed by two expert readers. The level of confidence regarding presence of pathology was evaluated on a binary scale ("confident"/"not confident"). From volumes-of-interest drawn in liver and muscle, mean activity concentration and standard deviation (std) were noted, and signal-to-noise ratios (SNR=mean/std) were calculated. ***Results:*** Assessed image quality agreed with average SNR in liver. A weight-adjusted activity regimen gave more consistent assessed image quality. For weight-adjusted activities of 2.0, 1.6, 1.2 and 0.8 MBq/kg the average image quality score was 3.7, 3.2, 2.9, 2.1. and average SNR in liver 16.2, 15.0, 13.7 and 11.4. The percentage of images scored as 4-good or 3-moderate was 100%, 100%, 85%, 5% with diagnostic confidence of 92%, 88%, 77% and 48%. For fixed activities of 200, 150, 100 and 60 MBq average image quality score was 3.4, 3.2, 2.9, 2.2, average SNR in liver 16.2, 14.6, 13.6 and 11.3, the percentage of images scored as 4-good or 3-moderate was 100%, 95%, 68%, 21% with diagnostic confidence of 92%, 89%,71% and 39%. ***Conclusion:*** For a consistent good-to-moderate image quality an activity of at least 1.6 MBq/kg or 150 MBq for 3-min/bed is needed, hence guidelines suggesting fixed dosing of 100 MBq may compromise diagnostic image quality. ***References:*** SNMMI Procedure Standard/EANM Practice Guideline for SSTR Receptor PET: Imaging Neuroendocrine Tumors (2023)

OP-614

Cholecystokinin-2 Receptor PET/CT Imaging using the ^{68}Ga-Labelled Minigastrin Analogue DOTA-MGS5 in Patients with advanced Neuroendocrine Tumours: a Prospective Phase I/IIA Study

E. von Guggenberg, *C. Uprimny, S. Bayerschmidt, A. Sviridenko, G. Santo, B. Warwitz, C. Rangger, C. Decristoforo, G. di Santo, I. J. Virgolini;*
Department of Nuclear Medicine, Medical University of Innsbruck, Innsbruck, AUSTRIA.

Aim/Introduction: Cholecystokinin-2 receptor (CCK2R) PET/CT can improve the diagnostic work-up in patients with neuroendocrine tumours (NET) and could serve as baseline imaging for potential peptide receptor radionuclide therapy (PRRT) targeting CCK2R. This receptor is expressed at high incidence >90% in medullary thyroid carcinoma (MTC) and by other NET. Within a prospective phase I/IIA pilot study PET/CT imaging with the 68Ga-labelled minigastrin analogue DOTA-MGS5 (68Ga-DOTA-MGS5) was performed in twelve patients at our center. ***Materials and Methods:*** In this prospective, monocentric, open-label, single-dose, diagnostic trial (ClinicalTrials.gov: NCT06155994) six patients with advanced MTC and six patients with other NET were included. The primary objective of the study was the evaluation of safety and tolerability, as well as whole body distribution and dosimetry. Local or distant metastases in the patients were confirmed by previous PET/CT imaging with 18F-DOPA or 68Ga-DOTA-TOC. Preliminary targeting properties of 68Ga-DOTA-MGS5 were investigated in comparison with standard imaging modalities. Intensity of tracer accumulation was measured using SUVmax/SUVmean and tumour-to-background ratios (TBR) were calculated. ***Results:*** In all patients the administered single dose of 180 MBq 68Ga-DOTA-MGS5 (range 111-222 MBq; maximum injected peptide amount of 50 µg) was well tolerated with minor side effects occurring only in three patients. The uptake of 68Ga-DOTA-MGS5 was highest in renal pelvis and urinary bladder as well as CCK2R-expressing stomach. About 50% of the activity was excreted within the first three hours after administration resulting in an acceptable effective whole body dose <5 mSv. On visual assessment, imaging at 2 h allowed for improved contrast in comparison with the time point of 1 h after injection. In four of six patients (67%) with advanced MTC (Calcitonin: 422-23,403 ng/L; CEA: 18-13,156 µg/L) CCK2R-positive lesions were detected and ~90% of the metastatic lesions known from previous 18F-DOPA or 68Ga-DOTA-TOC PET/CT were confirmed. In the six patients with other NET (CgA: <19-33,849 µg/L; NSE: 14-80 µg/L), 68Ga-DOTA-MGS5 PET/CT was rated positive in two patients with lung NET and one patient with ileal NET (50% of the patients) confirming ~70% of the lesions. ***Conclusion:*** The results from the prospective phase I/IIA study show that the intravenous administration of 68Ga-DOTA-MGS5 is well tolerated. The new PET-tracer allows for high-contrast PET/CT imaging of CCK2R-positive lesions. A good tumour detection was found in MTC patients indicating the potential applicability of DOTA-MGS5 labelled with therapeutic radiometals in PRRT. The additional value in patients with other NET was moderate.

Diagnostic performance of [^{99m}Tc]Tc-N4-LM-3 (TECANT-1), a novel somatostatin receptor antagonist for imaging of neuroendocrine neoplasms - results of a first-in-human multicentre ERA-PerMed TECANT study

L. Lezaic[1], *C. Decristoforo[2], C. Rangger[2], G. di Santo[2], I. Virgolini[3], P. Kolenc[1], K. Zaletel[1], P. Garnuszek[4], R. Mikolajczak[4], A. Studen[5], U. Simoncic[5], M. Opalinska[6], K. Skorkiewicz[6], B. Glowa[6], M. Fani[7], M. Trofimiuk-Muldner[8], A. Hubalewska-Dydejczyk[8];*
[1]University Medical Centre Ljubljana, Department for Nuclear Medicine, Ljubljana, SLOVENIA, [2]Department of Nuclear Medicine, Medical University Innsbruck, Innsbruck, AUSTRIA, [3]Department of Nuclear Medicine, Medical University Innsbruck, Innsbruck, SLOVENIA, [4]Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, Otwock, POLAND, [5]Faculty of Mathematics and Physics, University of Ljubljana, Ljubljana, SLOVENIA, [6]Nuclear Medicine Unit, Endocrinology, Oncologic Endocrinology and Nuclear Medicine Department, University Hospital, Krakow, Krakow, POLAND, [7]Division of Radiopharmaceutical Chemistry, University Hospital Basel, Universitätsspital Basel, Basel, SWITZERLAND, [8]Department of Endocrinology, Jagiellonian University Medical College, Krakow, Krakow, POLAND.

Aim/Introduction: Somatostatin receptor (SSTR) expression is one of the defining features of neuroendocrine neoplasms (NEN), which allows them to be targeted by a molecular imaging approach. The paradigm of using SSTR agonists for theranostics of NEN is increasingly being challenged, with SSTR antagonists typically exhibiting higher and more sustained target binding in addition to lower background retention. As the availability of SPECT and SPECT/CT equipment is still higher than the PET/CT alternative, a single-photon emitting somatostatin receptor antagonist imaged with a robust, reproducible quantitative approach would represent a significant step forward towards patient-tailored management of NEN. The study aimed to develop and evaluate the performance of a novel single-photon emitting

radiopharmaceutical, SSTR antagonist [99mTc]Tc-N4-LM-3 (TECANT-1) for imaging of NEN. ***Materials and Methods:*** Patients with G1/G2 advanced NEN with metastatic disease proven on PET SSTR imaging ([68Ga]Ga-DOTATATE) were enrolled. Imaging consisted of a serial total-body (5 min, 30 min, 4h, 24h pi.) planar images and dual-bed SPECT/CT acquisition 4h pi. Patients were monitored for vital signs and potential adverse events. Dosimetry was performed in five patients using MIRD formalism and hybrid 2D/3D approach (planar and AC/SC SPECT/CT images). Target-to background (T/B) ratios (liver, bone and blood-pool background regions, as appropriate) were calculated for five lesions with the highest uptake in each patient; comparison with T/B ratios on PET imaging was performed in three patients. ***Results:*** Ten patients were enrolled (phase 0/I clinical trial). A significant adverse event unrelated to the radiopharmaceutical administration with no permanent effect on health status was noted in one patient. The kidneys received the highest absorbed dose (18,5±7,7 mSv), absorbed doses for the bone marrow and the bladder wall were 2,3±0,5 mSv and 5,5±2,1 mSv; total-body effective dose was estimated at 3,6±0,9 mSv. T/B ratio for the lesion with the highest uptake averaged at 18,2 (range 5,2-52,6) and at 11,4 (range 1,6-52,6) for all lesions; T/B ratios for SPECT/CT imaging were higher than for PET/CT imaging with average SPECT/PET ratio of 2,2 (range 1,4-2,8) for the lesion with the highest uptake and 1,6 (range 1,1-1,9) for all lesions (with several lesions not detected on PET imaging). ***Conclusion:*** SSTR antagonist [99mTc]Tc-N4-LM-3 (TECANT-1) is a safe, highly effective radiopharmaceutical with superior imaging characteristics to SSTR PET agonist imaging and comparable dosimetry profile to single photon agonist alternatives, warranting further validation and translation into clinical routine.

[18F]F-AI-NOTA-Octreotide versus [111In]In-DTPA-Octreotide: Update on Fluorine-Octreo-PET Clinical Study

B. Lima[1,2], *P. B. Pujatti[1], R. M. Felix[1], P. G. L. Lacerda[1], D. A. Bulzico[1], M. P. Carneiro[1], M. A. S. Cardoso[1], M. L. Gomes[1], T. T. Guimarães[1], J. W. E. Silva[1], E. R. Oliveira[1], C. M. T. P. Menezes[1], C. F. Costa[1], M. V. Vanzeler[1], L. F. Fontes[1], A. C. Bispo[3], C. C. F. Gomes[3], D. Zouain[3];*
[1]Brazilian National Cancer Institute, Rio de Janeiro, BRAZIL, [2]Real Hospital Português de Beneficência em Pernambuco, Recife, BRAZIL, [3]R2 Radiopharmaceuticals, Rio de Janeiro, BRAZIL.

Aim/Introduction: SPECT with [111In]In-DTPA-octreotide remains the option available in some countries for neuroendocrine tumor (NET) imaging, despite its limitations. An recently option is PET/CT with [18F]F-AIF-NOTA-Octreotide, with superior spatial resolution and improved anatomical localization, technical implementation and cost-effectiveness, making it the preferred choice for facilities unable to prepare [68Ga]Ga-radiopharmaceuticals. This study was a prospective, non-randomized clinical trial, aimed at comparing, for the first time, the efficacy of PET/CT with [18F]F-AIF-NOTA-Octreotide to SPECT/CT with [111In]In-DTPA-octreotide. ***Materials and Methods:*** Patients referred to the nuclear medicine department for SPECT with [111In]In-DTPA-octreotide were also invited to undergo PET/CT with [18F]F-AIF-NOTA-Octreotide within three weeks after SPECT. Lesions identified per organ in both exams were categorized as 1, 2-5, or > 5; nominal variables were analysed using Fisher's exact test. Differences with $p < 0.05$ were considered significant. ***Results:*** 32 patients were included, 19 female; mean age 53.3 ± 13.9 years; most of them grade I (n = 15) or grade II (n = 13) gastrointestinal (n = 15), pancreatic (n = 5) or lung (n = 4) NET. [111In]In-DTPA-octreotide identified hepatic disease in 15 patients - one patient with one, two with 2-5 and 12 with >5 lesions (Kreening 3-4) - and [18F]F-AIF-NOTA-Octreotide in 17 patients ($p < 0.001$) - four with 2-5 and 12 patients with >5 lesions (SUVmax 22.73 ± 11.4 versus SUVmax background 4.13 ± 1.3). Positive lymphonodes were found in six patients with [111In]In-DTPA-octreotide - one in four patients and 2-5 in two patients (Kreening 1-4) - and 16 in PET/CT with [18F]F-AIF-NOTA-Octreotide - one in six patients; 2-5 in six and >5 in four patients (SUVmax 17.9 ± 18.6 versus SUVmax background 1.00 ± 0.7) in PET/CT ($p = 0.034$). Differences were also found in bone lesions detection, with positive bone scan in four patients with [111In]In-DTPA-octreotide (Kreening 1-3) and in six patients with [18F]F-AIF-NOTA-Octreotide ($p < 0.001$) (SUVmax 7.75 ± 5.4 versus SUVmax background 0.95 ± 0.5). Additionally, [18F]F-AIF-NOTA-Octreotide imaged lesions in colon and rectum and heart, which were not identified by [111In]In-DTPA-octreotide. ***Conclusion:*** PET/CT with [18F]F-AIF-NOTA-Octreotide detected a greater number of lesions (upstaging) than SPECT/CT with [111In]In-DTPA-octreotide in liver, lymphonodes and bone and also imaged extra-hepatic disease not identified in SPECT/CT with [111In]In-DTPA-octreotide. We expect completing patient enrollment and assessing the clinical impact of the results on patient management by December 2024.

Longitudinal monitoring of tau aggregation in 4-repeat tauopathies [18F]PI-2620 PET imaging

J. Kusche-Palenga[1], *J. Gnörich[1], C. Palleis[2,3,4], A. Kling[1], A. Jäck[3], A. Bernhardt[3], S. Katzdobler[2,3,4], M. Zaganjori[1], M. Scheifele[1], F. Hopfner[3], A. Zwergal[3,5], R. Pernecky[6], S. Stöcklein[7], J. Levin[3,2,4], N. Franzmeier[4,8], G. Höglinger[3,2,4], M. Brendel[1,2,4];*
[1]Department of Nuclear Medicine, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [2]German Center for Neurodegenerative Diseases (DZNE) Munich, Munich, GERMANY, [3]Department of Neurology, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [4]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY, [5]German Center for Vertigo and Balance Disorders, DSGZ, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [6]Department of Psychiatry and Psychotherapy, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [7]Department of Radiology, LMU Hospital, Ludwig-Maximilians-University of Munich, Munich, GERMANY, [8]Institute for Stroke and Dementia Research, LMU Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: Progressive supranuclear palsy (PSP) and corticobasal degeneration (CBD), two primary 4-repeat (4RT) tauopathies, can be detected with tau-PET imaging using the second generation radiotracer [18F]PI-2620. However, unlike for Alzheimer's disease (AD), the value of sequential [18F]PI-2620 imaging for disease progression tracking has not yet

been investigated. ***Materials and Methods:*** We conducted a longitudinal [18F]PI-2620 study in individuals with probable or possible PSP and CBD (n=17), diagnosed according to the Movement Disorder Society PSP criteria. All patients received two (FUP 22.5±3.7 months) dynamic [18F]PI-2620-PET scans from 0 to 60 minutes post-injection. Serial imaging data, including atrophy correction, were compared to a cross-sectional cohort of healthy individuals (n=18) and disease controls (AD n=7). Distribution volume ratios (DVR, temporal reference region) of [18F]PI-2620-PET were measured in the globus pallidus internus and externus, putamen, subthalamic nucleus, substantia nigra, dorsal midbrain, dentate nucleus and dorsolateral prefrontal cortex and correlated with changes in disease severity. ***Results:*** DVR z-scores increased longitudinally among individuals with 4R-Tauopathies, particularly pronounced in the Globus pallidus (+46%, p=0.0038). Intriguingly, the most substantial increase in DVR occurred in individuals with a low initial tau burden at baseline, whereas those starting with a high DVR did not exhibit a similarly significant escalation (R= -0.7891, p=0.0002). According to disease specific measures of severity including PSPRS (+44%, p=0.0002), UPDRS (+43%, p<0.0001) and Schwab and England ADL scale (-22%, p<0.0001) patients deteriorated but there was no association between changes in tau PET and individual clinical deterioration. All effects were robust with and without voxel-based partial volume effect correction of [18F]PI-2620 PET signals. ***Conclusion:*** In summary, our longitudinal evaluation utilizing [18F]PI-2620 highlights its potential for diagnosing and tracking disease progression in individuals with 4R-tauopathies. Our data suggest a ceiling effect of tau pathology in 4R-Tauopathies once a specific threshold of tau load is attained.

OP-619

Cortical Tau Aggregation Patterns are associated with Apraxia in Alzheimer's Disease

G. Bischof;
Department of Nuclear Medicine, University Hospital Cologne, Cologne, GERMANY.

Aim/Introduction: Apraxia is a characteristic feature of Alzheimer's disease symptomatology, but the underlying mechanisms of this behavioural trait are poorly understood. In this study, we embarked on a systematic investigation of apraxia profiles in a carefully defined cohort of AD patients, complemented by PET imaging using the second-generation tau PET tracer [18F]PI-2620. ***Materials and Methods:*** Our hypothesis was that different patterns of tau pathology might underlie apraxic deficits. We assembled a group of 32 patients with a confirmed diagnosis of AD, additionally a sample of cognitively unimpaired controls (CU1; N=41). Both cohorts underwent comprehensive neuropsychological assessment for apraxia using the Dementia Apraxia Screening Test (DATE) and the Cologne Apraxia Screening (KAS). In addition, PET imaging with [18F]PI-2620 was used to assess tau pathology specifically in the AD patients. To investigate the relationship between apraxia and regional tau pathology, we compared PET data from the AD group with an independent set of amyloid-negative cognitively unimpaired participants (CU2; N=54) and computed z-score deviation maps, which were submitted to a voxel-based multiple regression analysis. ***Results:*** We observed significant clusters of tau aggregation within apraxia-associated regions, such as the angular gyrus and various temporal, parietal and lateral occipital cortical areas, all of which showed correlations with apraxia. Importantly, these regions were consistent across both apraxia assessment tools. Conversely, no correlations were found between tau tracer uptake in primary motor cortical or subcortical brain regions and apraxia. ***Conclusion:*** Our results suggest that tau deposition in specific cortical regions may trigger local neuronal dysfunction, ultimately leading to a dose-dependent deterioration in praxis performance. Our results provide an important step towards unravelling the complex interplay between tau pathology and the manifestation of apraxia in AD.

OP-620

Extent of Tauopathy and neural dysfunction and loss: how does it match? Insights from a cross-sectional study comparing [18F]MK-6240 to [18F]FDG PET.

T. Gérard, *L. Colman, Y. Salman, L. Quenon, L. Huyghe, B. Hanseeuw, R. Lhommel;*
Université Catholique de Louvain, Brussels, BELGIUM.

Aim/Introduction: In this study, we aimed to investigate whether the Extent Of Tauopathy (EOT index) extracted from [18F]MK-6240 Tau PET correlates with the degree of neurodegeneration (synaptic dysfunction, neuronal loss...) depicted by [18F]FDG PET/CT. ***Materials and Methods:*** Sixty-seven subjects underwent both [18F]MK-6240 tau PET and [18F]FDG PET within a one-year timeframe. The cohort was divided into 3 amyloid-negative(AMY-)/cognitively normal(CN) individuals, 16 AMY-/cognitively impaired subjects and 48 amyloid-positive(AMY+) subjects covering the full spectrum of Alzheimer's disease (AD) (5 cognitively unimpaired, 28 presenting mild cognitive impairment (MCI) and 15 demented subjects). [18F]MK-6240 tau PET were quantified using previously published method[1] resulting in a global (Braak≤6) EOT percentage. [18F]FDG PET were quantified using the PALZ 4.3 workflow (AD-score)[2]. Simple linear regressions were computed between EOT and AD-scores for the whole population initially and later focused on the AMY+ population.Categorial analyses Tau (T+/-) vs Neurodegeneration (ND+/-) were then performed using previously established cutoffs (T+ >12.1% EOT [1]; ND+ >1.0 AD-score). ***Results:*** The first simple linear regression revealed a decent correlation between the EOT and the AD-score, with a R2 of 0.39 (p<0.0001). After excluding the 16 AMY- subjects, the correlation improved significantly (R2: 0.57; p<0.0001). None of the AMY- (but one with frontotemporal lobar degeneration) presented a significative EOT, while some of them presented light to severe signs of neurodegeneration (max 3.04 AD-score). Accordingly, the simple linear regression in the AMY- population was not significant (R2= 0.06; p=0.32).Regarding the categorial analysis focused on AMY+(N=48) and 3 CN subjects (n=51), complete results were: T-/ND-: 7 (14%) ; T-/ND+: 4 (8%), T+/ND- 15 (29%) ;T+/ND+: 25 (49%).While only 4 (8%) subjects were T-/ND+ (slightly ND+, with AD-scores range [1.04-1.26]), 15 (29%) were T+/ND- (EOT range [12.6%-55.6%]). This potentially illustrates the hypothesis of a front of tauopathy preceding the neuronal dysfunction/loss - and subsequent neurodegeneration revealed by [18F]FDG PET. ND- and ND+ groups were also significantly different in terms of EOT, with respective mean EOT of 21.5% [range:0.7%-55.6%] versus 51.5% [range:3.5%-87.5%] (p<0.0001). ***Conclusion:*** In a cross-sectional timeframe, [18F]MK-6240 tauopathy strongly correlated with markers of neurodegeneration in the AD spectrum population. The categorical T/ND mismatch between AD-Score and EOT mainly concerned mild-to-moderate tauopathies without concurrent neurodegeneration. Ongoing and future longitudinal studies will enlighten the chronological relationship between the outbreak of tauopathy and the subsequent neuronal dysfunction and death depicted by [18F]FDG PET. ***References:*** [1]:https://doi.org/10.1007/s00259-024-06603-2 [2]:https://doi.org/10.1006/nimg.2002.1208

Aim/Introduction: Efforts to standardize tau-PET scans for 4R-tauopathies through automated quantification methods highlight the need for clinically practical approaches. This study aims to investigate the effectiveness of visual evaluation of [18F] PI-2620 images for diagnosing 4R-tauopathies and to develop a straight-forward reading algorithm to improve objectivity and data reproducibility. ***Materials and Methods:*** A total of 83 individuals with [18F]PI-2620 PET scans were included. A priori clinical evaluations categorized participants into probable 4R-tauopathies, Alzheimer's disease (AD), α-synucleinopathies, and healthy controls. Visual assessment of tau-PET scans was conducted using either 20-40- or 40-60-minute intervals, with unprocessed (conventional) and cerebellum grey matter scaled standardized reading settings (prescaled). Two primary readers evaluated scans independently, with a third reader providing consensus in case of discrepancies. A subregion analysis was performed using frontal cortex, basal ganglia, midbrain, and dentate nucleus. Sensitivity, specificity, and interrater agreement were calculated for all modalities and compared against the visual reads of parametric images (0-60 min, distribution volume ratios, DVR). ***Results:*** Visual assessment of 4R-tauopathies resulted in greater sensitivity with 79% at the highest for the 20-40 minute time window compared to the 40-60 interval with 55% at the lowest, albeit concomitant with slightly reduced specificity. The prescaled reading setting demonstrated higher specificity, particularly notable in the earlier time frame compared to the conventional setting. In addition the prescaled mode showed almost perfect interrater agreement (κ=0.87). Combined assessment of multiple brain regions did not significantly improve diagnostic accuracy compared to assessing the basal ganglia alone. Dynamic scans had higher sensitivity of 86% compared to static scans with a maximum of 79% at similar specificity. ***Conclusion:*** Visual tau-PET reading of [18F]PI-2620 tau-PET scans demonstrated reliable detection of 4R-tauopathies, particularly when standardized processing methods and early imaging windows were employed, improving diagnostic accuracy.

OP-622

Tau PET deposition measured by [18F]PI-2620 increases along the Alzheimer's disease continuum in Down Syndrome

***V. Camacho[1],** L. Vaqué[2], P. Stefaneli[1], M. Calls[1], A. Fernandez[1], J. Duch[1], I. Barroeta[2,3], M. Carmona[2,3], M. Velasco[1], C. Soldevila[1], G. Guzmán[1], S. Castejón[1], A. Bejanin[2,4], A. Lleó[2,4,3], J. Fortea[2,4,3], A. Flotats[1];*
[1]Nuclear Medicine Department. Hospital Sant Pau, Barcelona, SPAIN, [2]Sant Pau Memory Unit, Department of Neurology, Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [3]Barcelona Down Medical Center, Fundació Catalana de Síndrome de Down, Barcelona, SPAIN, [4]CIBERNED, Madrid, SPAIN.

Aim/Introduction: Down syndrome (DS) arises from chromosome 21 trisomy, leading to extra APP gene copies and triggering early-onset Alzheimer's disease (AD) pathology. DS-related AD shares neuropathological similarities with autosomal dominant AD (ADAD). Despite ADAD's tau burden dynamics are well-characterized, tau-PET imaging patterns in DS remains largely unexplored. This study aims to assess neurofibrillary tau burden in DS adults using [18F]PI-2620, aiming to evaluate the visual rate, correlate with clinical status, delineate tau deposition patterns, and investigate links with amyloid PET. ***Materials and Methods:*** Seventy-six subjects (20 euploid healthy controls [HC], 31 asymptomatic DS [aDS], 8 prodromal DS [pDS] and 17 demented DS [dDS]) underwent [18F]PI-2620 PET/CT and T1w-MRI, and 62 of them also [18F]Flutemetamol PET/CT. PET images were co-registered to the corresponding T1w-MRI and intensity normalized to inferior cerebelar cortex for [18F]PI-2620) and cerebellum for [18F]Flutemetamol. We computed the Centiloids for amyloid-PET and [18F]PI-2620 tracer retention was quantified as individual Standardized Uptake Value ratio (SUVr) in the anatomical definitions of Braak stages I-II, III-IV and V-VI. To assess the spatial pattern of tau deposition and the relationship with amyloid deposition, vertex-wise analysis (FWE-corrected $p<0.05$) were performed using PETSurf toolbox (Freesurfer). ***Results:*** We observed an increase of tau and amyloid deposition increase along the AD continuum: all the HC as well as the 83,9% of aDS (26/31) presented normal distribution of [18F]PI-2620, while 75% (6/8) of pDS and 82.2% (15/17) of dDS participants presented cortical [18F]PI-2620 deposition in AD areas (posterior-lateral temporal, occipital, parietal/precuneus, posterior cingulate or frontal cortex. These results aligned with the expected outcomes derived from the ROC analyses for visual inspection vs SUVr (AUC Braak I-II = 0.974; AUC Braak III-IV = 0.9874; AUC Braak V-VI = 0.9694). Differences in [18F]-PI2620 uptake were statistically significant in the three Braak staging for pDS and dDS when compared to HC and aDS ($p<0.05$), but no differences were found between the symptomatic subgroups (pDS vs dDS). Vertex-wise maps in symptomatic DS revealed tau deposition typical AD areas, regions where also there was identified a strong correlation between tau burden and global amyloid deposition ***Conclusion:*** [18F]PI-2620 PET presented high affinity to tau aggregates in symptomatic DS subjects, and allowed discrimination between asymptomatic subjects (euploid and aDS subjects) from symptomatic DS subjects. Tau PET deposition measured by [18F]PI-2620 increases along the AD continuum in DS and it was present in subjects with high amyloid burden.

Aim/Introduction: The second-generation tau PET ligand [18F] Florzolotau shows distinct binding patterns in patients with 3R/4R- (i.e., Alzheimer's disease, [AD]) and 4R-tauopathies (i.e., progressive supranuclear palsy [PSP] and β-amyloid-negative corticobasal syndrome [CBS]).1 However, quantification of tau PET data across different disease identities is hampered by the lack of a suitable reference region devoid of possibly specific binding. The aim of this study was to evaluate the feasibility of reference-region-independent analysis of [18F]Florzolotau PET with covariance patterns in patients with tauopathie. ***Materials and Methods:*** [18F]Florzolotau PET data were acquired at four different centres. A dataset of 30 healthy controls (HC, β-amyloid-negative) and 30 patients each with AD (β-amyloid-positive) and PSP with Richardson's syndrome (PSP-RS) served to establish disease-related covariance patterns by using scaled sub-profile modelling principal components analysis.2 We then calculated the AD- and PSP-RS-related pattern expression scores in an independent cohort of 44, 51, 6, 15 and 17 patients with AD, PSP/CBS, multiple system atrophy (MSA), Lewy body diseases, and frontotemporal dementia (FTD), respectively. ***Results:*** The AD-related pattern showed strong positive voxel weights in temporoparietal, precuneus/posterior cingulate, and frontal cortices and negative weights in cerebellum, brainstem, and sensorimotor cortex. The PSP-RS-related pattern had strong positive weights in brainstem, midbrain, thalamus, globus pallidus, striatum, sensorimotor cortex, and mild positive weights in dentate nucleus, occipital cortex, and parts of white matter. In the derivation cohort, both the AD- and PSP-RS-expression scores were strongly increased compared to HC (both p<0.001, AUC-ROC=0.99 and 0.90). In the validation cohort, patients with AD showed a clear increase of AD-scores compared to all other patients (p<0.001, AUC-ROC=0.95). PSP-RS-scores were higher in patients with PSP/CBS compared to all other (p<0.001, AUC-ROC=0.73). A mildly increased PSP-RS score was observed in FTD and MSA, though lower than in PSP/CBS (each groups vs. PSP/CBS, p<0.05). ***Conclusion:*** Definition of disease-specific covariance patterns with principal components analysis allows for reference-region-independent quantification of [18F]Florzolotau PET data. AD- and PSP-RS-related patterns showed high discriminatory power in both the derivation and the clinically heterogeneous validation cohorts. Increased PSP-RS-related pattern expression in patients with FTD and MSA may be related to 4R-pathology and known off-target binding in the putamen, respectively. ***References:*** 1. Drzezga[2];*
[1]Research Center Juelich, Juelich, GERMANY, [2]University Hospital Cologne, Cologne, GERMANY.

Aim/Introduction: Recent evidence suggests that disturbances of sleep architecture are linked to Alzheimer's disease (AD) pathology. Here, we assessed the association between sleep architecture and regional amyloid and tau pathology employing a sleep-monitoring device in addition to PET imaging. ***Materials and Methods:*** 14 healthy controls (HC; M(Age) = 63.57 (7.23), Sex (M/F) =4/10) and 14 patients with mild cognitive impairment (MCI) or early AD (M(Age) = 64.79 (7.42), Sex (M/F) =7/7) were included from the "Tau Propagation Over Time" (T-POT) study. All subjects underwent amyloid ([11C]-PiB) and tau ([18F]-AV1451) PET imaging. PET images were normalized and intensity standardized to the whole cerebellum ([11C]-PiB) or the inferior cerebellum ([18F]-AV1451). All subjects were provided with a portable sleep-monitoring EEG-headband by Beacon Biosignal (former Dreem), which has been shown to reliably detect the different sleep phases similar to polysomnography. Participants were asked to wear the device for at least three consecutive nights within six months of the PET acquisition. Total duration of sleep phases per minutes (i.e. REM, N1, N2, N3) were extracted for the respective recordings. Nightly measurements were then averaged across the three nights after confirmation of their stability. Next, whole-brain voxel-wise correlation analyses were performed between the sleep measures (i.e. mean duration in respective sleep phase) and amyloid and tau load as assessed by PET imaging, respectively. Analyses were corrected for age and the significance threshold of the voxel-wise analyses was set at a p-value of p<.001 (uncorrected). ***Results:*** The MCI/AD group presented significantly reduced N3 duration (p=.011) and increased N1 duration (p=.039) in comparison to the HC group. The whole-brain voxel-wise analyses yielded that decreased N3 duration was linked to greater amyloid burden in the insula, prefrontal cortex and precuneus. In terms of tau pathology, a decrease in N3 duration was associated with greater medio-temporal, superior parietal and precentral gyrus tau pathology. N1 duration was not linked to regional neuropathological burden. ***Conclusion:*** Local changes in sleep architecture may arise from regionally-specific accumulation patterns of AD pathology. Yet, it remains unknown whether disruptions in sleep architecture are the cause or the consequence of pathology build-up.

OP-625

Amyloid and tau dynamics in preclinical autosomal dominant Alzheimer's disease mutation carriers: a dual-tracer PET/MRI study

L. Fu[1], *Z. Zhou[2], J. Gao[1], L. Liu[3], Q. Wang[4], Q. Wang[4], Y. Wei[1], S. Xu[4], F. Li[4], S. Cao[4];*
[1]Department of Nuclear Medicine, China-Japanese Friendship Hospital, Beijing, CHINA, [2]Department of Neurology, China-Japanese Friendship Hospital, Beijing, CHINA, [3]Theranostics and Translational Research Center, Institute of Clinical Medicine, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, CHINA, [4]Innovation Center for Neurological Disorders and Department of Neurology, Xuanwu Hospital, Capital Medical University, National Clinical Research Center for Geriatric Diseases, Beijing, CHINA.

Aim/Introduction: Neuroimaging studies of autosomal dominant Alzheimer's disease (ADAD) enable characterization of the trajectories of cerebral amyloid-β (Aβ) and tau accumulation in the decades prior to clinical symptom onset. This study aims to assess the spread dynamics of 11C-PIB and 18F-MK6240 PET, and evaluate its relationship with the neuropsychological scores in asymptomatic ADAD mutation carriers. ***Materials and Methods:*** The study cohort consisted of 11 non-demented ADAD carriers and 11 age-matched healthy controls (HC). We acquired 20 mins PIB-PET with uptake time from 40 to 60 min, and 20 mins of MK6240-PET with uptake time from 70 to 90 min. The cortical-to-cerebellum standardized uptake value ratio (SUVR) was calculated. The ROI-based t-test analysis was employed to assess the SUVR

difference between groups, and spearman correlation analysis was used to evaluate the correlations between the SUVR of each tracer and neuropsychological scores. ***Results:*** Compared to HC, mutation carriers exhibited higher amyloid burden in whole cortex and striatum area, but no significant difference in tau PET binding. The mutation carriers were further divided into tau PET positive (tau+) and tau PET negative (tau-) groups according to the qualitative visual analysis. The tau+ group demonstrated higher MK6240-PET uptake in medial temporal lobe (MTL) and frontal cortex (FC) compared to the tau- group, and higher MK6240-PET binding in MTL, FC and parietal cortex compared to HC. Compared to HC, the tau+ group exhibited increased 11C-PIB retention in the neocortex, but much greater in the striatum. While the tau- group presented negative PIB retention or only slightly increased amyloid binding in the partial cortical regions. In mutation carriers, higher PIB-PET binging in the striatum area was correlated with worse global cognitive function (MMSE, r=-0.716, P=0.013), and the higher Tau PET binding in striatum was correlated with less estimated years to/from symptom onset (r=0.755, P=0.007). ***Conclusion:*** Our study suggests that amyloid initially accumulated in the cortex, followed by striatum in the preclinical stage of ADAD. In contrast, tau pathology firstly accumulated in MTL, suggesting that the pathological changes in ADAD is similar to sporadic AD and highlighting the common spatiotemporal dynamics. ***References:*** 1. OP-626

Sex-specific differences in patients with differentiated thyroid carcinoma and their possible impact on survival

E. Blickle[1], *M. Heinrich[1], A. Kerscher[2], H. Hänscheid[1], F. Verburg[3], A. K. Buck[1], K. Michalski[1];*
[1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Comprehensive Cancer Center Mainfranken, University Hospital Würzburg, Würzburg, GERMANY, [3]Radiology and Nuclear Medicine, Erasmus Medical Center, University Rotterdam, Rotterdam, NETHERLANDS.

Aim/Introduction: The incidence of thyroid cancer is increasing in Germany. Women are more frequently affected by differentiated thyroid carcinoma (DTC) than men, although women are more likely to develop a less aggressive subtype. The aim of this study is to investigate whether these differences are also reflected in the survival probabilities of men and women with DTC. ***Materials and Methods:*** This study is a retrospective analysis of a monocentric cancer registry from 01/1965 to 09/2023 and included adult patients with DTC and all tumor stages. For each case, an age- and sex-matched control (Monte Carlo simulation) was simulated, relying on data derived from official mortality tables from the federal statistical office of Germany. Overall survival (OS) in the complete cohort was analyzed using a proportional hazards model with multivariable cox regression and a two-way interactions model. ***Results:*** This analysis includes 3186 patients with DTC as well as their respective matched-pair (complete cohort: n = 6372). Most DTC patients were affected by UICC stage I (n = 2405, 76%; stage II: n = 355, 11%; stage III: n = 32, 1%; stage IVa: n = 10, 0,3%; stage IVb: n = 164, 5%; unknown: n = 220, 7%). Women (n = 2251, 71%) suffered more frequently from DTC than men (n = 935, 29%). Follicular thyroid carcinoma was relatively more common in men (n = 245, 27%) than in women (n = 449, 20%). Female sex and presence of DTC in the medical history were both associated with a significantly longer OS (hazard ratio (HR) = 0.74; 95% CI 0.68 - 0.79; $p < 0.0001$ and HR = 0.71, 95% CI 0.60 - 0.83; $p < 0.0001$, respectively). However, the interaction model showed no sex-specific impact on survival in DTC patients (HR = 1.03: 95% CI 0.85 - 1.25; p = 0.79). ***Conclusion:*** This analysis of a large German cancer registry shows sex-specific differences in incidence of DTC subtypes. Life expectancy in the general population is higher for women than for men. Interestingly, patients with DTC including all tumor stages show a longer OS, which is presumably due to a greater health awareness and regular preventive visits, but also reflects the highly effective therapeutic regimen. However, there is no sex-specific impact on survival in patients with DTC.

OP-627

Obesity and differentiated thyroid cancer aggressiveness: more is better?

A. Campenni; *R. Ruggeri, M. Siracusa, A. Alibrandi, A. Nicocia, A. Rappazzo, P. Ovcaricek, S. Baldari, L. Giovanella;*
Ospedale Gaetano Martino, Messina, ITALY.

Aim/Introduction: Some authors postulated the possible relationship between obesity and different cancers. Recently, the association between obesity and differentiated thyroid cancer (DTC) aggressiveness has also been postulated but available data are sparse. We aimed to evaluate the prevalence of obesity in a large series of DTC patients and the impact of obesity on the response to initial treatments in such patients. ***Materials and Methods:*** 209 consecutive DTC [papillary thyroid carcinoma (PTC)=192 (91.9%), follicular thyroid carcinoma (FTC)= 12 (5.7%), Hurthle-cells carcinoma (HC)= 5 (2.4%)] patients (F=156, M=53, F/M ratio=2.94:1, mean age 49.75±14.70, median= 50 yr) were retrospectively reviewed. They were enrolled for iodine-131 therapy (RIT) with ablative (1.1-2.2 MBq) or adjuvant (2.2-5.5 MBq) purpose within three months after thyroidectomy. A post-therapy whole body scintigraphy coupled with SPECT/CT imaging (i.e. pT-imaging) was obtained 2-5 days after RIT. The response assessment was performed 6-12 months after RIT according to 2015 ATA guidelines thus using laboratory test (i.e. basal and stimulated thyroglobulin), neck-ultrasound and, in selected patients, 123/131I diagnostic whole body scintigraphy coupled with SPECT/CT imaging as well. ***Results:*** Among all patients, one hundred and sixty-five (78.9%) and forty-four (21.1%) were not obese (i.e. BMI <30) and obese (i.e. BMI ≥30), respectively. No significant difference in terms of age, gender and ATA score distribution were noted (p= 0.191, p= 0.440, p= 0.267). Among low-risk (n=28) and intermediate-risk DTC (n=16) patients 16, 10, 2 and 11, 2 and, 3 carried a grade I, II and, III obesity, respectively. We did not observe a significant difference in the prevalence of obese

patients between low and intermediate risk-DTC ones (p= 0.425) regardless of age (p= 0.526), gender (p= 0.798), obesity grading (p= 0.179), BMI (p= 0.750) and, absolute weight (p= 0.471). Persistent disease occurred in 14.9% of intermediate risk and 4.9% of low-risk DTC (4.9%) patients (p= 0.013). Moreover, persistent disease occurred in 16.9% and 5.3% of non-obese patients having intermediate rather than low-risk DTC, respectively (p=0.015). Conversely, we did not observe any significant difference among obese patients having intermediate (6.2%) or low-risk (3.6%) DTC (p=0.682). Finally, obesity was not an additional risk factor for having both a more aggressive DTC (Odds ratio 0.75, p= 0.433) and a less than ER to initial treatments (Odds ratio 0.38, p= 0.222) regardless of gender and age. ***Conclusion:*** In our patients series obesity was not associated with a more aggressive DTC and/or a worse response to initial therapies.

Thyroglobulin Measurement is the Most Powerful Outcome Predictor in Differentiated Thyroid Cancer: A Decision Tree Analysis in a European Multicenter Series

***M. Tuncel*[1],** *L. Milan*[2], *W. Roll*[3], *M. Weber*[4], *S. Schenke*[5], *M. Kreissl*[5], *A. Vrachimis*[6], *K. Pabst*[4], *P. Petranović Ovčariček*[7], *A. Campenni*[8], *R. Görges*[4], *L. Ceriani*[2], *L. Giovanella*[9];
[1]*Nuclear Medicine, Hacettepe University, Ankara, TÜRKIYE,* [2]*Nuclear Medicine, Ente Ospedaliero Cantonale, Bellinzona, SWITZERLAND,* [3]*Nuclear Medicine, University Hospital Münster, Münster, GERMANY,* [4]*Nuclear Medicine, University Hospital Essen, Essen, GERMANY,* [5]*Nuclear Medicine, University Hospital Magdeburg, Magdeburg, GERMANY,* [6]*Nuclear Medicine, German Oncology Center, Limassol, CYPRUS,* [7]*Oncology and Nuclear Medicine, University Hospital Center "Sestre milosrdnice", Zagreb, CROATIA,* [8]*Nuclear Medicine, University Hospital Messina, Messina, ITALY,* [9]*Nuclear Medicine, Gruppo Ospedaliero Moncucco, Lugano, SWITZERLAND.*

Aim/Introduction: An accurate prognostic assessment is pivotal to adequately inform and individualize follow-up and management of patients with differentiated thyroid cancer (DTC). We aimed to develop a predictive model for recurrent disease in DTC patients treated by surgery and 131I by adopting a decision tree model. ***Materials and Methods:*** Age, sex, histology, T stage, N stage, risk classes, remnant estimation, TSH, Tg, administered 131I activities and post-therapy whole body scintigraphy (PT-WBS) were identified as potential predictors and put into regression algorithm (conditional inference tree, c-tree) to develop a risk stratification model for predicting persistent/recurrent disease over time. ***Results:*** The PT-WBS pattern identified a partition of the population into two subgroups (PT-WBS positive or negative for distant metastases). Patients with distant metastases exhibited lower disease-free survival (either structural, DFS-SD, and biochemical, DFS-BD, disease) compared to those without metastases (MTS). Meanwhile, the latter were further stratified into three risk subgroups based on their Tg values. Notably, Tg values >63.1 ng/mL predicted a shorter survival time, with increased DFS-SD for Tg values <63.1 and <8.9 ng/mL, respectively. A comparable model was generated for biochemical disease (BD), albeit different DFS were predicted by slightly different Tg cutoff values (41.2 and 8.8 ng/mL) compared to DFS-SD (Table 1). ***Conclusion:*** We developed a simple, accurate and reproducible decision tree model able to provide reliable information on the probability of structurally and/or biochemically persistent/relapsed DTC after a TTA. In turn, the provided information is highly relevant to refine the initial risk stratification, identify patients at higher risk of reduced structural and biochemical DFS, and modulate additional therapies and the relative follow-up.

OP-629

The Role of ^{18}F-Tetrafluoroborate Imaging in the Follow-up of Patients with Differentiated Thyroid Cancer

K. Saglam, *O. E. Sahin, M. T. Bodur, E. Karayel, H. Pehlivanoğlu, A. Aygün, R. L. Uslu Beşli, K. Sönmezoğlu;
Cerrahpasa Medical Faculty, Istanbul, TÜRKIYE.*

Aim/Introduction: Different anions including tetrofluoroborate are transported into thyrocytes by Sodium-iodine symporter (NIS) receptors similar to radioiodines i.e. I-123, I-131 and I-124. Therefore, F^{18} labeled tetrofluoroborate (TFB) could be expected as a suitable radiopharmaceutical to evaluate the function of the NIS carrying system in tissues and a few studies have supported this hypothesis suggesting that it would be an alternative PET imaging agent in the follow-up of well-differentiated thyroid cancer (DTC) to come over disadvantages of radioiodines. In this prospective study, we aimed to evaluate the role of TFB in patients with DTC. ***Materials and Methods:*** 52 patients who are seemed as candidates for radioiodine therapy (RAIT) following total thyroidectomy were included in this prospective study. PET imaging is performed at 60 min after injection of 3-6 mCi TBF. All patients have stimulated TSH levels being at least 30 mIU/L. PET findings compared with either post-treatment high dose I-131 (post-RAIT) SPECT images or diagnostic whole-body scans with 5 mCi I-131 (Dx) SPECT images. TFB scans were divided into 4 groups according to performing timeline: a) before RAIT (n=19), b) after RAIT (n=11), c) before Dx-SPECT (n=8), and d) after Dx-SPECT (n=14). ***Results:*** A total of 47 different lesions were observed with SPECT and PET in 19 patients in group A. While 45 of them had been detected in TFB, only 31 of them could be seen with post-RAIT SPECT. A total of 8 lesions were observed in group B, and while all of them were shown with SPECT, only 2 of them could be shown with TFB-PET, probably due to the stunning effect created by radioiodine. 1 lesions in group C were monitored with both methods. While all 4 lesions in group D were observed with SPECT, only 2 of them could be observed with TFB-PET (possible stunning). The average SUVmax and SUVmean values were 39.41 and 25.6, respectively, in TFB-positive lesions. Additionally, atypical increased TFB accumulations in pelvis were observed in 18 patients due to Nabothi cysts (averageSUVmax: 19.76). ***Conclusion:*** TFB-PET has a higher sensitivity compared to radioiodine-SPECT in detecting residual/metastatic lesions in patients with DTC (50/60 vs 44/60). However, the sensitivity has been decreased when TFB-PET imaging is performed after RAIT, probably due to the stunning effect. It seems as a better alternative agent to radioiodine scanning if it is performed before RAIT or Dx-SPECT.

68Ga-Pentixafor PET/CT demonstrates the in vivo evidence of CXCR4 expression in radioiodine refractory thyroid cancer patients

B. Singh, *M. Nayeem, A. Watts, S. Bhadada;
Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, INDIA.*

Aim/Introduction: The undifferentiated radioiodine refractory thyroid cancers (RAI-R) pose a therapeutic challenge. Though, this fraction (5.0-15%) of thyroid cancer patients often shows high avidity to ^{18}F-FDG, but there are no radionuclide therapeutic options available currently. In this pilot study, we used 68Ga-Pentixafor PET/CT imaging to document the presence of CXCR4 receptors' expression in a small group of radioiodine refractory (RAI-R) patients. ***Materials and Methods:*** Ten (3-Male: 7-Female, mean age = 48.8 ± 12.9 years) papillary thyroid cancer patients

documented as refractory to radioiodine treatment were recruited in the study. All the patients underwent both ^{18}F-FDG and 68Ga-Pentixafor PET/CT within a gap of 7- days. Whole body acquisitions from skull to mid-thigh (7-9 bed positions) were done at 1-h post injection with mean injected dose of 7.52 ± 0.71 mCi & 2.26 ± 0.55 mCi of ^{18}F-FDG & 68Ga-Pentixafor respectively. The reconstructed images projected in three planes (cross-sectional; coronal and sagittal) were used for visual and quantitative analysis for both the scans. A head-to-head lesion-based comparison was done between both the PET procedures. ***Results:*** All the ten patients showed scan evidence of residual/metastatic disease on ^{18}F-FDG while 9/10 showed 68Ga-Pentixafor scan positivity. A total of 70 lesions were identified which showed increased ^{18}F-FDG avidity as compared to 61 lesions showing increased CXCR4 expression on 68Ga-Pentixafor scan. The mean SUV-max of the lesions on 18F-FDG was found to be significantly higher as compared to 68Ga-Pentixafor (9.3±7.3 vs 2.9±1.6, p=0.003) PET/CT. The regional distribution of lesions were as follows: remnant or recurrent thyroid lesions, loco-regional lymph nodes and distant metastasis. ^{18}F-FDG outscored 68Ga-Pentixafor in picking up local (5/4) and loco regional lymph nodes (45/40) respectively. However, 68Ga-Pentixafor picked more metastatic bone lesions (13 versus 11) as compared to ^{18}F-FDG. ***Conclusion:*** 68Ga-Pentixafor PET/CT imaging demonstrated the in vivo evidence of CXCR4 expression both in the primary recurrent tumors, lymph nodes and distant metastatic sites. In the background of absence of no definitive treatment available in RAI-R thyroid cancers, CXCR4 receptors may be potential disease targets for therapeutic applications in widely disseminated RAI-R thyroid cancer using the CXCR4 based radio-theranostics. However, expanding the study in to larger number of RAI-R variants of thyroid cancer may further explore the potential of CXCR4 based radio-theranostics in such patients.

OP-631

Comparison of Ga-68 DOTATATE PET and Ga-68 PSMA PET in Radioactive Iodine Refractory Thyroid Cancer

A. Kibar, *S. Sager, K. Sahin, S. E. Biyikoglu, M. T. Bodur, K. Saglam, C. Guneren, O. E. Sahin, S. Asa, L. Uslu-Besli, K. Sonmezoglu, H. B. Sayman;*
Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: The prognosis of radioactive iodine refractory thyroid cancer (RAIR-TC) is worse than in other patients, and 10-year survival is predicted to be approximately 10%. RAIR-TC patients are treated with TKIs, but generally the aim is to stabilize the disease or slow the progression. For this reason, new treatment studies are gaining importance. In our study, we compared the patients in whom we performed Ga-68 DOTATATE and Ga-68 PSMA PET in order to evaluate the possibility of Lu-177 DOTATATE and Lu-177 PSMA treatment in this patient group. ***Materials and Methods:*** Patients underwent Ga-68 DOTATATE PET/CT and Ga-68 PSMA PET/CT imaging in accordance with current guidelines. Uptakes higher than background activity were considered positive. SUVmax and SUVmean values of all positive lesions were calculated. Background SUVmean was calculated by drawing a 1 cm3 volumetric region of interest (VOI) from the mediastinal blood pool, liver SUVmean was calculated by drawing VOI in 1 cm3 volume from the liver. ***Results:*** 15 patients were included in the study (6M, 9W). Average age was 60.7 (±11.5) years. Cumulative RAI dosage was 546.7 mCi (±275.4). Tg values of 5 patients were >500 ng/ml, and the average Tg value of the other 10 patients was 30.3 ng/ml. TSH values of 12 patients were <1 mIU/L. While 58 lesions were detected in DOTATATE PET, 52 lesions were detected in PSMA PET. While DOTATATE PET showed more lesions in 6 patients, PSMA PET showed more lesions in 3 patients, and an equal number of lesions were detected in 6 patients. In 2 patients, no lesion was observed on DOTATATE PET, in 1 patient, no lesion was observed on PSMA PET. The mean SUVmax, mean SUVmean, mean SUVmax/blood pool SUVmean values of the lesions detected in DOTATATE PET were 4.64±3.75, 2.50±2.01, 10.1±7.73, respectively. The mean SUVmax, mean SUVmean, mean SUVmax/blood pool SUVmean values of the lesions detected in PSMA PET were 4.59±3.36, 2.54±1.92, 4.65±4.35, respectively. Lesions with SUVmax value greater than the liver SUVmean value were detected in DOTATATE PET in 2 patients and in PSMA PET in 4 patients. In 2 patients, lesions with SUVmax values greater than the liver SUVmean value were detected in both DOTATATE PET and PSMA PET. ***Conclusion:*** With new imaging methods in RAIR-TC, it is possible to better understand the extent of the disease and investigate radionuclide treatment possibilities. More comprehensive studies need to be conducted on this subject.

OP-632

Diagnostic accuracy of [18F]TFB-PET-CT compared with therapeutic activity of [131I]iodine SPECT-CT and [18F] FDG-PET-CT in recurrent differentiated thyroid cancer

D. Ventura[1], *M. Dittmann[2], F. Büther[1], M. Schäfers[1], K. Rahbar[1], P. Schindler[3], B. Riemann[1], R. Seifert[1], W. Roll[1];*
[1]Department of Nuclear Medicine, Münster, GERMANY,
[2]Department of Nuclear Medicine, Lünen, GERMANY,
[3]Department of Radiology, Münster, GERMANY.

Aim/Introduction: [18F]tetrafluoroborate (TFB) is a promising positron emission tomography (PET) tracer for NIS-based imaging in patients with differentiated thyroid cancer (DTC). It has excellent properties for this purpose. The objective of this study was to compare [18F]TFB-PET with high-activity post-therapeutic [131I]iodine whole-body-scintigraphy/single photon emission computed tomography (TxWBS-SPECT-CT) in recurrent DTC and [18F]Fluorodeoxyglucose(FDG)-PET-CT in suspected dedifferentiation. ***Materials and Methods:*** Twenty-six patients were retrospectively included in the study, who had been treated with high-activity radioactive [131I]iodine therapy (RAI) between May 2020 and November 2022, with a range of 5.00 - 10.23 GBq. Prior to treatment, all patients underwent [18F]TFB-PET-CT 40 minutes after receiving a median dose of 321 MBq [18F]TFB. To investigate tracer kinetics in DTC lesions, an additional scan was performed on 23 patients at 90 minutes. [131I]Iodine-TxWBS-SPECT-CT was performed at a median of 3.8 days after treatment. Additionally, [18F]FDG-PET was performed on 25 patients. ***Results:*** A total of 62 suspicious lesions were identified. Of these, 30 were [131I]iodine-positive, 32 were [18F]TFB-positive, and 52 were [18F]FDG-positive. The Tumor-to-Background Ratio (TBR) measurements at the 40 and 90-minute timepoints showed a close correlation (e.g. TBR_muscle: rp = 0.91, p < 0.001, n = 49). A significant negative correlation was found between [18F]TFB and [18F]FDG uptake, which could serve as a potential marker for dedifferentiation (rp = -0.26, p = 0.041, n = 62). ***Conclusion:*** Pre-therapeutic [18F]TFB-PET-CT can predict the positivity of recurrent DTC lesions on [131I]iodine scans, aiding in the selection of patients for [131I]iodine therapy. Future prospective trials are needed for iodine therapy guidance. Lesional [18F]TFB uptake appears to be inversely correlated with [18F]FDG uptake and could potentially serve as a dedifferentiation marker in DTC.

OP-633

Limited diagnostic role of ^{18}F FDG PET/CT in metastatic pediatric thyroid carcinoma : A retrospective analysis.

M. Borsali[1], *C. Garcia[1], A. Bettaieb[1], F. Pani[2], K. Trabelsi[1], S. Moog[2], J. Hadoux[2], E. Baudin[2], L. Lamartina[2], D. Deandreis[1];*
[1]Nuclear Medicine Division , Department of Medical Imaging, Gustave Roussy, Villejuif, FRANCE,
[2]Endocrine Oncology Division, Department of Medical Imaging, Gustave Roussy, Villejuif, FRANCE.

Aim/Introduction: To evaluate the usefulness of ^{18}F FDG PET/CT in differentiated thyroid carcinoma of pediatric and adolescent populations; notably its role in disease detection, in patients with distant metastases and treated with radioactive iodine. ***Materials and Methods:*** A retrospective analysis was conducted on 264 patients (median age 11 years ; range 6-18) who underwent total thyroidectomy for thyroid cancer and received iodine-131 therapy between 1991 and 2019 at Gustave Roussy 1MCi/Kg of Iodine 131 was administered within 3 months after surgery and Whole Body Scan±SPECT/CT was performed 3-5 days after treatment. A total of 17 patients performed ^{18} FDG PET within less than 6 months following the initial course of iodine therapy and were considered for this analysis. ***Results:*** 13/17 patients presented with Papillary thyroid carcinoma and 4/17 with tall cells sub-type The TNM stage was respectively: 35 % T2, 29% T3a , 17% T3b, 11 % T4a and 5% T1b),(82% N1b , 11 % Nx 5% N1a) and all patients presented M1 at diagnosis. Median Tg at the moment of RAI treatment was 414 ng/ml (range: 29-4200 ng/ml) A median number of 3 (range: 2-10) 131I treatment was administered. The initial 131I WBS revealed thyroid remnant in 15 patients, cervical lymphnodes metastases in 9, and distant metastases in 12 patients (lung =11, mediastinal lymph nodes 1). In 16/17 patients 18FDG PET was negative without any significant uptake in the cervical region or a distant level despite elevated Tg levels and 131I WBS uptake. The only case of positive ^{18}FDG PET/CT examination revealed cervical lymph nodes and bilateral pulmonary micro nodular lesions uptake in a female patients of 13 years old .Tg levels at the moment of 131I uptake was 425 ng/ml and WBS was also positive at the same sites. After a median follow up of 90 months 12/17 patient was in remission and 5/17 presented persistent elevated Tg or structural disease. The patient with positive ^{18}FDG PET/CT received a total of 7 131I treatment showing stable disease at the end of follow up. ***Conclusion:*** FDG PET is rarely positive in pediatric metastatic thyroid cancer. This cohort underscores its limited utility in detecting pathological sites and in predicting response to treatment, despite it is porposed in guidelines. Further studies are need to confirm these data and to evaluate its prognostic value.

OP-634

The Role of ^{18}F-FDG PET/CT and 68Ga-DOTATOC PET/CT imaging in evaluating Patients with Differentiated Thyroid Cancer (DTC) with Elevated Serum Thyroglobulin and Negative Whole-Body I-131 Scan (TENIS syndrome)

A. Aghaee, *K. Aryana, M. Esmatinia, Z. Adinehpoor, E. Soltani;*
Nuclear medicine research center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The study aims to critically assess the effectiveness of ^{18}F-FDG PET/CT and 68Ga-DOTATOC PET/CT in detecting recurrent or metastatic differentiated thyroid cancer (DTC) in patients who have raised serum thyroglobulin but negative I-131 whole-body scans. It is crucial for patients with the TENIS syndrome, a condition marked by elevated thyroglobulin levels and metastases that do not absorb iodine, since it has been associated with a reduced 10-year survival rate. ***Materials and Methods:*** This retrospective study examined 20 DTC patients at Mashhad's Ghaem Hospital's nuclear medicine ward thyroid clinic. This study investigated patients with recent negative whole-body scans with I-131 and thyroglobulin (Tg) levels over 10 with TSH stimulation by levothyroxine withdrawal or above 5 with rhTSH Injection After total thyroidectomy, thyroid ablation, or iodine therapy. All patients had an ^{18}F-FDG PET/CT scan initially, then Ga68-DOTATOC PET / CT in a week. ***Results:*** A total of 20 patients with TENIS syndrome were examined.19 individuals had papillary thyroid cancer (PTC) and 1 had follicular thyroid cancer (FTC). Both scans found 23 of 27 lesions positive. 68Ga-DOTATOC and ^{18}F-FDG scans were positive in 65% and 70% of patients, respectively. Most patients were in stage IV according to the seventh AJCC edition, while 10 were stage I according to the eighth AJCC edition. Patients with positive 68Ga-DOTATOC results were 13 candidates for therapy. Six had Lu177-DOTATATE therapy, five had surgery, one had surgery plus radiotherapy, and one received lutetium and radiation. Six of 14 patients with positive ^{18}F-FDG scans had surgery, and one had radiation plus surgery. In both PET tracers, positive and negative results were not statistically related (P=1). 68Ga-DOTATOC and ^{18}F-FDG scan results had no association with patient Tg levels (P=0.67). There was a significant association between Tg levels and ^{18}F-FDG scan results, notably in the non-TSH stimulation condition (P=0.015), but not in the TSH stimulation state (P=0.262). No association was seen between Tg levels and pathogenic subtypes (P=0.602). ***Conclusion:*** 68Ga-DOTATOC PET/CT shows somatostatin receptor expression in patients with negative whole-body iodine scans and elevated Tg levels, suggesting alternative diagnostic modality for restaging and metastasis work up. Positive results from both modalities revealed no significant difference and The study suggests that 68Ga-DOTATOC PET/CT may guide therapy with lu177-Dotatate for patients with positive FDG PET/CT results who need a systemic therapy.

Comparing ^{68}Ga-Pentixafor, ^{18}F-FDG PET/CT and chemokine receptor 4 immunohistochemistry staining in locally advanced breast cancer: a prospective cross sectional study

B. Hadebe-Chonco[1], *L. Harry[1], L. Gabela[1], T. Nxasana[1], N. Ndlovu[1], S. Masikane[1], M. Patel[1], S. Zwane[2], D. Mpanya[1], T. Buthelezi-Zulu[1], T. Lusu[1], I. Buccimaza[1], P. Ramdass[1], M. Msimang[1], C. Aldous[1], M. Sathekge[3], M. Vorster[1];*
[1]University of KwaZulu Natal, Durban, SOUTH AFRICA,
[2]Inkosi Albert Luthuli Central Hospital, Durban, SOUTH AFRICA, [3]University of Pretoria, Pretoria, SOUTH AFRICA.

Aim/Introduction: CXCR4 is a chemokine receptor that is frequently overexpressed in invasive breast cancer and plays a major role in tumour proliferation, aggressiveness and metastasis. The aim of this prospective study was to establish the value

CXCR4-directed PET imaging in patients with breast cancer using 68Ga-Pentixafor by comparing it with 18F-FDG PET/CT and CXCR4 immunohistochemistry staining (IHC) and correlate these with molecular subtypes, HIV status and patient survival. ***Materials and Methods:*** Thirty-three (33) patients with breast cancer aged 33-81, mean±SD 56.5±13.5 with initially diagnosed breast cancer, underwent CXCR4-targeted PET imaging using 68Ga-Pentixafor. Maximum standardised uptake values (SUVmax), total lesion uptake (TLU) and metabolic tumour volume (MTV) of primary tumour were measured and correlated with pathological prognostic factors, molecular subtypes and CXCR4 IHC. The patients were followed up for an average of 10 months (range 4-80 months) and CXCR4 expression was correlated with survival. ***Results:*** 68Ga-Pentixafor-PET/CT, though positive in all cases, demonstrated less uptake compared to 18F-FDG PET. The SUVmax for 68Ga-Pentixafor and 18F-FDG were 6.93(5.31-8.72) and 18.2(14.3-25.7) , and SUVmean 3.94(3.15-4.94) and 10.6±5.56(52.4), TLU 342(121-807) and 626(258-1210) and MTV were 75.6(28.0-180) and 92.0(28.0-205) respectively. The histological subtypes were: (50%) triple negative breast cancer (n=16), 25% (n=8) Luminal B (25%), 12.5% (n=4) had Luminal A and 12.5% (n=4) HER-2 enriched. Twelve (12/33) patients (36%) were HIV positive. There was a statistically significant correlation between grade of primary tumour and 68Ga-Pentixafor SUVmax p0.046. A weak but significant positive correlation was seen between SUVmean for 68Ga-Pentixafor PET and proliferative index (Ki67) r= 0.337 p=0.052. Higher 68Ga-Pentixafor accumulation was seen in triple negative breast cancer (TNBC) compared to other molecular subtypes. The median (Q1-Q3) 68Ga-Pentixafor TLU was significantly higher in HIV positive 376(219-881) compared to HIV negative 174(105-557) breast cancer patient 68Ga-Pentixafor MTV was higher in HIV positive patients compared to HIV negative p=0.049. There was no correlation between 68Ga-Pentixafor PET uptake and CXCR4 IHC or survival. Also, 68Ga-Pentixafor detected more brain lesions than 18F-FDG, which detected more bone marrow lesions. ***Conclusion:*** 68Ga-Pentixafor showed lower tracer accumulation than 18F-FDG PET. Patients with triple negative breast cancer, HIV+, higher tumour grade and Ki-67 had more 68Ga-Pentixafor uptake. This suggests that CXCR4-targeted PET imaging may be more useful in TNBC as well as high grade tumours. Future research on CXCR4 targeted imaging should examine the impact of this technique in the selection of triple negative breast cancer patients who are eligible for CXCR4-targeted therapies.

EPS-191

Pre-treatment [18F]FDG PET biomarkers and clinical outcomes of patients with metastatic triple-negative breast cancer treated with Sacituzumab govitecan

R. Seban[1], *A. De Moura[2], D. Loirat[3], F. Bidard[2], N. Jehanno[4], V. Huchet[4], T. Genevee[5], I. Buvat[6], L. Champion[1];*
[1]Nuclear Medicine, Institut Curie, Saint-Cloud, FRANCE, [2]Medical Oncology, Institut Curie, Saint-Cloud, FRANCE, [3]Medical Oncology, Institut Curie, Paris, FRANCE, [4]Nuclear Medicine, Institut Curie, Paris, FRANCE, [5]Pharmacy, Institut Curie, Saint-Cloud, FRANCE, [6]Laboratory of Translational Imaging in Oncology, Inserm U1288, PSL Research University, Institut Curie, Orsay, FRANCE.

Aim/Introduction: Sacituzumab govitecan (SG), a Trop-2-directed antibody-drug conjugate (ADC), has recently been approved as a monotherapy for metastatic triple-negative breast cancer (mTNBC) patients who have undergone two or more prior systemic therapies. We aimed to evaluate the prognostic significance of [18F]FDG PET/CT biomarkers before SG in mTNBC. ***Materials and Methods:*** This bicentric retrospective study included mTNBC patients who underwent [18F]FDG PET/CT imaging before SG and were treated from August 2020 to October 2023. PET biomarkers studied included total metabolic tumor volume (TMTV), maximum standardized uptake value (SUVmax), and maximum tumor dissemination (Dmax), extracted using LIFEx software. Overall response rate (ORR) corresponded to the proportion of patients who had a partial or complete response. The median (m) was used to dichotomize initially continuous biomarker values. The median follow-up (mFU) was estimated by the reverse Kaplan-Meier (KM) method. Cox proportional hazards models for progression-free survival (PFS) and overall survival (OS) with KM curves were used. Statistical analysis was performed using R studio. ***Results:*** Seventy-one patients were eligible. ORR was 45%. After a mFU of 12.9 (95%CI 9.7-17.5) months, 64 (90%) and 42 (59%) patients experienced progression and death, respectively. The mPFS and mOS were 4.8 (95%CI 4.2-5.5) and 8.9 (95%CI 7.7-10.0) months, respectively. In univariable analyses, high TMTV (>38.5 cm3) and high Dmax (>34cm) were associated with shorter PFS (HR 2.7, 95%CI 1.6-4.5 and HR 2.0, 95%CI 1.2-3.3) and shorter OS (HR 4.3, 95%CI 2.1-8.5 and HR 2.9, 95%CI 1.5-5.6). TMTV and Dmax were combined to stratify the population into three groups: a low-risk group with low TMTV and low Dmax (n=28, 39%), an intermediate-risk group with high TMTV or high Dmax (n=17, 24%) and a high-risk group with high TMTV and high Dmax (n=26, 37%). mPFS was 5.7 (95%CI 4.9-9.5) months for the low-risk group versus 4.2 (95%CI 2.9-9.6) and 2.9 (95%CI 2.0-5.1) months for the intermediate-risk and high-risk groups, respectively. mOS was 25.3 months (95%CI 17.0-not reached/NR) for the low-risk group versus 8.9 (95%CI 6.2-NR) and 7.2 (95%CI 4.3-NR) months for the intermediate-risk and high-risk groups, respectively. ***Conclusion:*** Pre-treatment [18F]FDG PET/CT biomarkers TMTV and Dmax hold promise as prognostic indicators for mTNBC patients prior to SG therapy. The combination of TMTV and Dmax accurately identifies patient groups with markedly different clinical outcomes under SG. These findings warrant further validation in prospective studies to establish their clinical utility.

EPS-192

Myocardial [18F]FDG uptake patterns at staging PET are related to patient outcome in lung cancer patients.

E. Abenavoli[1], *A. Grosso[2], T. Beyer[3], D. Ferrara[3], S. Gruenert[4], M. Hacker[4], S. Hesse[5], A. Frille[5], L. Hofmann[5], S. Holm[6], M. Pepponi[1], O. Sabri[5], L. Shiyam Sundar[3], J. Yu[3], R. Sciagrà[1];*
[1]Nuclear Medicine Unit, Azienda Ospedaliero Universitaria Careggi, Florence, ITALY, [2]Division of Pneumology, Florence, ITALY, [3]QIMP Team, Medical University of Vienna, Vienna, AUSTRIA, [4]Nuclear Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [5]University Hospital of Leipzig, Leipzig, GERMANY, [6]University of Copenhagen, Copenhagen, Copenhagen, DENMARK.

Aim/Introduction: The LuCaPET project (ERAPERMED 2021-324) has been conceived to explore the relationship of multi-organ [18F]-FDG uptake and the onset of cancer-induced cachexia and subsequent overall survival in lung cancer patients. Here, we investigated how both qualitative and quantitative analyses of myocardial uptake correlate with patient outcomes. ***Materials and Methods:*** We evaluated 188 treatment-naïve lung cancer patients. All patientsunderwent a whole-body [18F]-FDG PET/CT study for staging before advancing on the most appropriatefirst-line treatment and finally to clinical follow up. [8F]-FDG PET/CT was evaluated for the visualuptake pattern according to the established classification (A = no uptake, B = diffuse, C = focal and D =focal on diffuse uptake). We employed the automated segmentation

tool MOOSE to define themyocardial volume of interest on the CT images from which we calculated the SUVmean, normalized tothe aorta uptake. ***Results:*** The following tumor stages were found on [18F]-FDG PET/CT: I (53/188 patients), II (36/188), III in (37/188) and IV (62/188). Myocardial uptake pattern was A in 105 patients, B in 24, C in 32 and Din 27 patients. During follow up (17 ± 13 months) 53 tumor-related deaths were registered. There was asignificant difference (p<0.001) in the Kaplan-Meier survival curves of the different tumor stages, withstage IV showing the worst survival. However, a significant difference (p<0.01) was as well observedamong the four myocardial uptake patterns; the two groups with worst prognosis were A and B. It couldmean that the focal patterns (C and D) are potential favorable indicators, whilst uptake absence (A) hasadverse implications. The diffuse intense uptake B could be regarded as a casual interference causedby dietary variables. This was confirmed by the finding that myocardial SUVmean between survivorsand non-survivors is just borderline significant on the whole cohort (p<0.05), whilst it becomes highlysignificant (p<0.005) after exclusion of the B pattern patients. ***Conclusion:*** Data from this small cohort suggest that the myocardial uptake pattern is related to patient outcome. Thus, they confirm that metabolic changes in organs not affected by cancer could play a role in the disease evolution. ***References:*** Shiyam Sundar LK, Yu J et al.Fully Automated, Semantic Segmentation of Whole-Body ^{18}F-FDG PET/CT Images Based on Data-Centric Artificial Intelligence. Development and validation of a PET/CT-based radiomics model for preoperative prediction of spread through air spaces in non-small cell lung cancer

Z. Jiang[1], *D. Haberl[1], C. P Spielvogel[1], J. Yu[1], L. Kenner[2], M. Hacker[1]; [1]Department of Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Division of Experimental and Translational Pathology, Department of Pathology, Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: Spread through air spaces (STAS) is a recently identified invasive pattern in non-small cell lung cancer (NSCLC), associated with increased recurrence risk and poor prognosis1. The objective of this research was to develop and validate a predictive radiomics model using 18F-FDG-PET/CT imaging to assess the preoperative presence of STAS and to identify related genomic markers. ***Materials and Methods:*** This investigation encompassed patients histopathologically verified to have STAS at two medical institutions. The inclusion criteria constituted adults diagnosed with stage I-III NSCLC, excluding those previously treated for lung cancer. Radiomics features were derived from preoperative PET-CT scans. Tumors and an adjacent 8 mm peritumoral region were segmented independently by two radiologists, with resolution of discrepancies achieved through consensus. A comprehensive set of 3,078 radiomics features were organized into seven categories including shape, texture, and intensity. Feature selection was performed utilizing a Random Forest algorithm, and model efficacy and robustness were assessed via k-fold cross-validation. A radiomic risk-score signature was established through a Cox regression model employing LASSO regularization. Furthermore, RNA sequencing data from The Cancer Genome Atlas were examined to discern gene expression linked to radiologically predicted STAS. ***Results:*** The study cohort included 350 patients, distributed across a training set (n=165), an external validation set (n=95), and a set for RNA sequencing analysis (n=90). The integration of radiomic and clinical features (including age, smoking status, and tumor stage) significantly improved STAS prediction over clinical features alone, evidenced by an increase in the area under the receiver operating characteristic curve (AUC) from 0.760 to 0.826 in the training set and from 0.731 to 0.788 in the external validation set (P<0.05). Radiomic signatures were significantly correlated with overall survival (P<0.05). Differentially expressed genes associated with the radiomics profiles were predominantly involved in glucose metabolism pathways. ***Conclusion:*** The PET/CT-based radiomics model, integrating both peritumoral and intratumoral features, effectively predicted STAS and indicated prognostic value for overall survival in patients with NSCLC. The incorporation of radiomic and clinical data provides superior predictive accuracy, offering potential improvements in preoperative decision-making and patient management. ***References:*** 1. Spread Through Air Spaces (STAS) in Lung Cancer: A Multiple-Perspective and Update Review. Cancer Manag Res. 2020;12:2743-2752.2. EPS-194

Heterogeneity of PD-L1 expression: Correlation of immunohistochemical PD-L1 expression and genetic profile with 99mTc-iPD-L1 SPECT/CT in patients with metastatic non-small cell lung cancer

O. Garcia-Perez, *E. Michel Sánchez, L. Cabrera Miranda, G. Ferro Flores, I. Soldevilla Gallardo, S. González Rueda; Instituto Nacional de Cancerologia, Mexico City, MEXICO.*

Aim/Introduction: Lung cancer modulates the immune response through the expression of PDL1 and PDL2, these ligands targets the surface receptor of the programmed cell death protein (PD1), which is expressed on the surface of T cells, B cells and NK cells. There are no immunohistochemical biomarkers with adequate prediction of selection and response because the expression of this receptor is dynamic and highly heterogeneous. Molecular imaging has helped to complement the study and characterization of neoplasms with a cyclic peptide inhibitor of PD-L1 (iPD-L1) radiolabeled. The aim of this pilot study is to analyze the correlation of 99mTc-iPD -L1 SPECT/CT with ^{18}F-PET/CT and the immunohistochemical expression of PD-L1 to demonstrate its high heterogeneity. ***Materials and Methods:*** We evaluated prospectively 10 patients with a diagnosis histologically and immunohistochemistry confirmed non-small cell lung carcinoma, oncogenic driver mutation, ^{18}F-PET/CT and 99mTc-iPD-L1 SPECT/CT. Performing a qualitative and semiquantitative analysis with volumetric parameters with the subsequent correlation between these, the. immunohistochemistry results, and we correlate with the tomography used to take the biopsy to verify that the sampling sites match with the uptake sites. We classify uptake patterns in peripherical, homogeneous and patched. ***Results:*** We included 7 woman and 3 men, mean age of 62 y/o (range 44 to 90). 8 had adenocarcinoma and 2 squamous cell carcinomas. All patients were stage IV, 50% (n=5) had EGFR mutation, 40% (n=4) were wild-type and 10% (n=1) ALK (+). MTV with FDG and iPD-L1 in primary tumor showed a statistically significant correlation (r:0.81, p=0.0038). Immunohistochemistry was performed with Sp263:1 assay: 2 patients had positivity of 20% , 1 of 1% and the remaining patients (n=7) 0%. 9/10 patients had peripherical uptake pattern with iPD-L1 and 6/10 with FDG, 1/10 patients had patched pattern

with iPD-L1 and 0/10 with FDG and none had homogenous uptake pattern with iPD-L1 and 4/10 with FDG. In 5 patients biopsy sites did not correlate with areas of iPD-L1 uptake due to a peripheral uptake pattern, explaining negative immunohistochemistry. There was no correlation between patterns or intensity of PD-L1 imaging with oncogenic driver mutation. ***Conclusion:*** Our results indicate a high intratumoral heterogeneity evaluated with 99mTc-iPD-L1 SPECT/CT that does not fully correlate with FDG, these preliminary findings may help explain discrepancy in biopsy sites; Therefore, this new imaging tool could be a potential diagnostic biomarker for selection and response to immunotherapy, as well as auxiliary in biopsy sampling.

EPS-195

Diagnostic performance of 99mTc-IFAP SPECT/CT in the initial staging of patients with lung cancer: A comparative analysis with ^{18}F-FDG-PET/CT

O. Garcia-Perez, *D. Gutierrez, F. Sinisterra;*
Instituto Nacional de Cancerologia, Mexico City, MEXICO.

Aim/Introduction: Lung cancer is a major problem worldwide, with the highest morbidity and mortality of all cancers. Fluorodeoxyglucose remains the most widely used PET marker for the diagnosis of malignant diseases. However, there are limitations in the availability of PET equipment in many countries. Therefore, a more accessible diagnostic modality at an early stage is crucial and inspired us to evaluate the performance of 99mTc EDDA HYNIC- iFAP SPECT/CT for lung cancer patients with that of 18F-FDG PET/CT as the reference standard. ***Materials and Methods:*** A prospective controlled analysis from September 2023 to February 2024, of 16 individuals with suspected lung cancer who underwent 99mTc-iFAP SPECT and ^{18}F-FDG PET/CT was conducted. Histopathological findings were used for final diagnostic determinations for all primary tumors. The performance of the two imaging modalities was compared based on visual assessment, rates of cancer detection, and semi-quantitative parameters (target-to-background ratio [TBR] for both primary tumors and metastases. ***Results:*** In total, this study enrolled 16 participants (8 female; median age: 57.5 years, range: 35 - 79 years. A total of 253 lesions were analyzed. For the 16 primary tumors 99mTc-iFAP and 18F-FDG had identical detection performance (16/16). 99mTc-iFAP detected 36 of 78 locoregional lymph nodes (46%), and 44 of 159 metastatic lesions on the central nervous system (2/4), pulmonary contralateral lymph nodes (2/5), non locoregional lymph nodes (11/45), adrenal glands (2/3), bone lesions (18/93). Furthermore,99mTc-iFAPSPECT/CT demonstrates good performance on metastases in pleura (6/6), liver (2/2), and omental lesions (1/1). There were no statistically significant differences between TBR values in relation to that of 18F-FDG and 99mTc -iFAP SPECT/CT. (p=0.71) There was no significant difference in detection of primary tumors, lymph nodes, and metastases based on pathological type: adenocarcinoma (n=13), squamous cell carcinoma (n=2), and small cell carcinoma (n=1), between the two examination modalities. We also found the lowest sensitivity of the IFAP in the detection of lymph nodes smaller than 14 mm, and visceral metastases smaller than 20 mm. ***Conclusion:*** 99mTc iFAP SPECT imaging of lung cancer is feasible and provides diagnostic image quality in the assessment of pulmonary masses. In response to the limited availability of infrastructure and resources in developing countries to offer PET/CT studies to their population. Our results demonstrate non-inferiority in primary diagnosis with 99mTc iFAP SPECT in comparison with PET in lung cancer. This could encourage its use and promote the benefit of its clinical utility.

EPS-196

^{18}FDG PET/CT PERCIST outperforms RECIST as predictor of pathological response to preoperative immune checkpoint inhibition in patients with resectable NSCLC: a prospective trial

H. Hautzel[1], *M. Wiesweg[2], T. Plönes[3,4], D. Theegarten[5], C. Aigner[3,6], K. Herrmann[1], M. Schuler[2];*
[1]University Hospital Essen, Department of Nuclear Medicine, West German Cancer Center, University Duisburg - Essen, Essen, GERMANY, [2]University Hospital Essen, Department of Medical Oncology, West German Cancer Center, University Duisburg - Essen, Essen, GERMANY, [3]Department of Thoracic Surgery, West German Cancer Center, University Medical Center Essen-Ruhrlandklinik, University Duisburg - Essen, Essen, GERMANY, [4]University Hospital Carl Gustav Carus, Department of Surgery, Division of Thoracic Surgery, Technical University Dresden, Dresden, GERMANY, [5]University Hospital Essen, Institute for Pathology, West German Cancer Center, University Duisburg - Essen, Essen, GERMANY, [6]General Hospital Vienna, Department of Thoracic Surgery, Medical University Vienna, Vienna, AUSTRIA.

Aim/Introduction: Immune checkpoint inhibition (ICI) with antibodies targeting PD-1/PD-L1 and CTLA-4 prior to surgery is active in patients with curatively resectable non-small-cell-lung-cancer (NSCLC). A prospective, randomized, multicenter study, NEOpredict-Lung, explores short-term preoperative ICI with nivolumab (anti PD-1) with/without relatlimab (anti-LAG-3) in patients with NSCLC stages I B, II or III A (1). Aim of the present analysis was to compare the non-invasive imaging-based response estimation using either 18FDG PET/CT PERCIST or RECIST1.1 criteria for prediction of the pathological response in NEOpredict-Lung participants. ***Materials and Methods:*** NEOpredict-Lung (NCT04205552) requires imaging-based staging at baseline, and immediately prior to surgery. In one center, 18FDG PET/CT was prospectively used for these imaging studies. Imaging-related responses to ICI were estimated by PERCIST and RECIST1.1. Pathological response rates were determined in resected tumors following IASLC criteria. Results were correlated by calculating Spearman's Rho. Correlational results were regarded significant when $p<0.05$. ***Results:*** 30 patients with baseline 18FDG PET/CT staging (mean 22±11 days prior to first ICI therapy; range: 1 to 47 days) were included in this post-hoc analysis. Per protocol curative resections had to be performed within 43 days of initiation of ICI therapy. A second 18FDG PET/CT was performed at a median of 4 days before surgery. A mayor pathological response (MPR, 0-10% viable tumor cells) was achieved in 8 patients, a pathological response (11-50% viable tumor cells) was observed in 12 patients, and no response (≥51% viable tumor cells) was found in 10 patients. PERCIST identified partial metabolic responses in n=12, stable disease in n=13 and progressive disease in n=5 patients. In contrast, RECIST1.1 demonstrated partial responses in n=2, stable disease in n=23, and progressive disease in n=5 patients. A significant correlation between PERCIST response (Spearman's Rho 0.56, p=0.001), but not RECIST 1.1 response (Spearman's Rho 0.26, p=0.17) and pathological responses was observed. ***Conclusion:*** 18FDG PET/CT PERCIST- but not RECIST1.1- holds promise as predictor of pathological response following short-course ICI therapy in patients with resectable NSCLC. Our results demonstrate the high potential of baseline 18FDG PET/CT plus follow-up 18FDG PET/CT instead of sole CT follow-up for non-invasive response assessment to ICI treatment in NSCLC patients. This provides a basis for future studies on metabolic imaging-based personalization of immunotherapy in lung cancer patients. ***References:*** (1) Schuler M et al.: Neoadjuvant nivolumab with or without relatlimab in resectable non-small-cell lung cancer:

a randomized phase 2 trial. Nat Med. 2024. doi: 10.1038/s41591-024-02965-0.

PET-CT guided versus CT guided lung biopsy in suspected lung malignancies: An interim analysis of randomized controlled trial

K. Kiran Kandula, *G. K. Parida, P. R. Mohapatra, K. Agrawal, S. K. Majumdar, T. P. Tripathy, P. Mishra, B. M. Padhy;*
All India Institute Of Medical Sciences, Bhubaneswar, INDIA.

Aim/Introduction: Histopathology is a cornerstone in the evaluation of lung masses. The standard sampling technique for peripheral lung lesions is CT-guided lung biopsy. Still, large lesions may yield inconclusive results (12-16%) due to sampling from adjacent atelectasis or necrosis due to poor differentiation on CT. PET-CT-guided biopsy targets metabolically active areas of mass, minimizing sampling errors. This study aims to compare PET-CT-guided lung biopsy's diagnostic efficacy and safety to CT-guided lung biopsy. ***Materials and Methods:*** This is a prospective, open-label, randomized controlled trial performed at AIIMS Bhubaneswar. Between August 2023 to March 2024, 43 subjects with peripheral lung mass were enrolled in this study, of which 36 patients met the eligible criteria. 36 subjects were randomized in 1:2 ratio using computer generated randomization chart.12 patients were enrolled in the PET-CT guided biopsy arm, and 24 were enrolled in the guided biopsy arm. Lung biopsies were performed under standard aseptic precautions. An interim analysis compared the diagnostic yield and complication rates between 2 arms. ***Results:*** Baseline characteristics like age, coagulation parameters, size of lesion and depth from the surface showed no significant differences between the PET/CT-guided biopsy arm (n=12) and the CT-guided biopsy arm (n=24) ($p > 0.05$). Conclusive results in the PET/CT-guided biopsy arm were obtained in 11/12 cases (91.67%) compared to 20/24 cases (83%) in the CT-guided biopsy arm. The diagnostic yield was higher in the PET/CT-guided biopsy group (91.67%) compared to the CT-guided biopsy group (83%) ($p < 0.05$). No serious periprocedural or post-procedural complications were observed in either group. The most common complications were mild pneumothorax and haemoptysis. In the PET/CT guided biopsy arm, the rate of complications was pneumothorax 1/12 (8.3%) and haemoptysis 1/12 (8.3%). In the CT-guided biopsy arm, pneumothorax was seen in 3/24 (12.5%) and haemoptysis in 2/24 (8.3%) ($P < 0.05$). ***Conclusion:*** PET-CT-guided lung biopsy is a safe and effective alternative to CT-guided lung biopsy with higher diagnostic yield and comparable complication rates.

EPS-198

Predicting lung cancer response to radiotherapy with pre- and early post-treatment $^{[18F]}$FDG PET/CT imaging

C. Constantino[1,2], *F. P. M. Oliveira[1], A. Canudo[1], R. Teixeira[1], C. Matos[1], S. Vieira[1], J. Kociolek[1], N. Pimentel[1], S. Vinga[2], D. C. Costa[1];*
[1]Champalimaud Clinical Centre, Champalimaud Foundation, Lisbon, PORTUGAL, [2]INESC-ID, Instituto Superior Tecnico, Universidade de Lisboa, Lisbon, PORTUGAL.

Aim/Introduction: This study aims to investigate the potential power of metabolic features extracted from pre- and early post-treatment $^{[18F]}$FDG PET/CT images of primary and secondary lung cancer lesions to predict local response to radiotherapy one year after treatment. ***Materials and Methods:*** 156 lung lesions from 95 oncology patients (66±10 y.o., 55 female), treated with radiotherapy alone or chemoradiotherapy, were retrospectively included. All patients underwent pre-treatment (up to 3 months before radiotherapy) and one-year post-treatment $^{[18F]}$FDG PET/CT scans. From these, for a subgroup of 142 lesions, an early post-treatment $^{[18F]}$FDG PET/CT (3 to 6 months post-radiotherapy) was also available. Demographic (age, sex), clinical (primary tumor, staging, treatment combination), and dosimetry-related features (clinical tumor volume, total dose, and percentage of dose cover) were collected. $^{[18F]}$FDG uptake-related features (8 first-order and 4 geometry-based) were extracted from treated lesions. Segmentation was performed semi-automatically with an adaptive Bayesian classifier [1]. Classification into responder/non-responder lesion was based on clinical reports from one-year post-treatment PET/CT. The association between features and response was assessed using univariate and multivariate logistic regression. Multivariate classification performance was assessed with the area under the receiver operating characteristic curve (AUC) and balanced accuracy (BAcc). Leave-one-out cross-validation (LOOCV) was further performed to assess evaluation metrics' reproducibility. ***Results:*** 100 out of 156 lung lesions responded to treatment (92 out of 142 lesions in the subset with early post-treatment PET/CT). In the univariate analysis, no demographic, clinical, or dosimetric features were significantly associated with the response. Association with response was significant ($p<0.05$) for kurtosis, skewness, and coefficient of variation (CoV) from the pre-treatment $^{[18F]}$FDG uptake; and for SUVmax, SUVmean, and SUVpeak from early post-treatment $^{[18F]}$FDG uptake. The multivariate models achieved the following significant AUC and BAcc: 0.70 and 0.55 for the model with demographic, clinical and dosimetry-related features; 0.72 and 0.65 for the model based on pre-treatment $^{[18F]}$FDG uptake; 0.79 and 0.73 for the model based on the early post-treatment $^{[18F]}$FDG uptake, and 0.86 and 0.75 for the model combining features from both pre- and early post-treatment $^{[18F]}$FDG uptake. When applying LOOCV, there was a decrease in BAcc to 0.54, 0.61, 0.66, and 0.66, respectively, for the above-mentioned models. ***Conclusion:*** This preliminary study showed that $^{[18F]}$FDG uptake-based features from lung cancer lesions may have value in predicting local response to radiotherapy/chemoradiotherapy. Further studies, with larger data sampling and stratified tumors, are needed to evaluate the potential added value of these features. ***References:*** [1]Constantino et al, doi:10.1007/s10278-023-00823-y.

EPS-199

Predictive modeling of lymphovascular invasion in NSCLC using PET/CT-derived body composition indicators

Z. Jiang[1], *D. Haberl[1], C. P Spielvogel[1], J. Yu[1], L. Kenner[2], M. Hacker[1];*
[1]Department of Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Division of Experimental and Translational Pathology, Department of Pathology, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Lymphovascular invasion (LVI) in non-small cell lung cancer (NSCLC) significantly influences prognosis and treatment strategies due to its association with higher metastasis and recurrence risks1,2. This study aims to develop and validate a predictive model using body composition metrics from 18F-FDG PET/CT imaging to assess LVI risk non-invasively in early-stage NSCLC patients before surgery. ***Materials and Methods:*** This retrospective cohort study analyzed 262 NSCLC patients—166 from Vienna and 96 from Budapest medical center. All patients underwent preoperative PET/CT scans and surgical resections, with at least 5 years of follow-up. Metabolic parameters of primary

tumors and several body composition parameters, including visceral and subcutaneous adipose tissues, intermuscular adipose tissue, and skeletal muscle from the region confined between the L1-L5 vertebrae were assessed. Employing LASSO logistic regression, we developed a predictive nomogram, validated through calibration curves, ROC analysis, and decision curve analysis. The model's ability to predict lymphovascular invasion (LVI) was evaluated using ROC curves. The prognostic value was assessed by Kaplan-Meier estimates and Cox regression analysis using progression-free survival (PFS) as primary endpoint. ***Results:*** LVI was identified in 116 of 262 patients (44.3%). Key prognostic factors included metabolic tumor volume, SUVmean of intermuscular adipose tissue and visceral adipose tissue, TNM stage, and age, all significantly associated with LVI (HRs: 3.323, 3.031, 2.772, 1.924, 1.035; $p < 0.05$). The nomogram incorporating these factors reached concordance indexes of 0.79 and 0.73 in the training and validation cohorts. ROC curves and decision curve analysis of the nomogram showed better performance compared with the model depending on clinical or imaging features. Multivariate Cox regression showed that LVI predicted by the nomogram was linked to poorer PFS ($p < 0.05$). ***Conclusion:*** This study highlights the value of detailed body composition analysis via PET/CT scans in predicting LVI in early-stage NSCLC. The integration of body composition data with tumor and clinical features provides new insights into NSCLC prognosis, potentially improving management strategies and patient care. ***References:*** 1. EPS-200

The role of [18F]FDG PET/CT in pulmonary microwave ablation

G. Zuccotti[1], *A. Castello[2], P. Mendogni[2], A. Ierardi[2], L. Florimonte[2], S. Franzi[2], A. Palleschi[2], L. Rosso[2], G. Carrafiello[2], D. Tosi[2], M. Castellani[2];*
[1]Università degli Studi di Milano, Milano, ITALY, [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, ITALY.

Aim/Introduction: As the population ages, an increasing number of patients cannot afford surgery because of comorbidities. Consequently, in the last two decades numerous techniques for local treatment have been developed. Microwave ablation (MWA) presents several advantages, such as higher temperatures, larger ablation volumes, shorter ablation times, and less intra-procedural pain. Today, [18F]FDG PET/CT is continually applied in clinical oncology routine for assessing treatment response. The purpose of our study was to retrospectively evaluate whether semi-quantitative and volumetric parameters from [18F]FDG PET/CT could be associated with clinical outcomes in patients with pulmonary lesions treated with MWA. ***Materials and Methods:*** Between January 2013 and December 2023, 40 patients (26 male, 14 female, mean age 76 years) underwent MWA in our hospital. [18F]FDG PET/CT was performed before and after a median of 3 ± 3 months (median ± IQR; range: 1-17 months) from procedure. For each lesion we semi-automatically calculated SUVmax, SUVmean, total lesion glycolysis (TLG), and metabolic tumor volume (MTV), as well as their percentage of change (Δ) using Syngo-via software. Progression-free survival (PFS) and overall survival (OS) were determined and compared using the Kaplan-Meier and the log-rank test. The median follow-up was 76 months. ***Results:*** Overall 50 pulmonary lesions, primary lung cancers (n=41) and metastases (n=9), were treated with MWA. The mean maximal axial diameter of lesions was 16.4 ± 6.97 mm (mean ± SD; range: 5-35 mm). The complication rate was 40%: pneumothorax (n=15), pulmonary hemorrhage (n=2), pneumonia (n=2), and pleural effusion (n=1), while no adverse events occurred in 25 (62.5%) patients. Patients with median SUVmax after MWA lower than 2.53 and those with median ΔSUVmean lower than -4.17% showed longer PFS (p=0.02 and p=0.021, respectively). Likewise, median SUVmax and median SUVmean after MWA, as well as median ΔSUVmean were significantly associated with OS (p=0.038, p=0.037, and p=0.02, rispectively), whereas median SUVmax at baseline showed only a tendency (p=0.06). On the other hand, volumetric parameters, SUVmax at baseline showed only a tendency (p=0.06). On the other hand, volumetric parameters, expressed by TLG and MTV, were not prognostic neither for PFS nor for OS. ***Conclusion:*** Even if these are preliminary data, this is the first study which showed that the metabolic activity, at the first evaluation after MWA, was correlated with PFS and OS. SUVs parameters can be a potentially valuable tools for identifying patients who are likely to benefit from MWA.

EPS-201

Comparison between PET/CT with 68Ga-FAPI46 and FDG for the detection of primary and metastatic lesions in patients with different types of cancer. Initial experience.

L. Yamaga, *G. B. d. Teles, D. B. Santos, O. Smaletz, R. Pestana, P. Blasi, R. Kalics, S. A. Nogueira, J. M. Cabeza, A. C. Camargo, L. M. Quaglio, M. F. Barboza;*
Hospital Israelita Albert Einstein, São Paulo/São Paulo, BRAZIL.

Aim/Introduction: To evaluate the diagnostic efficacy of PET/CT with fibroblast activation protein inhibitor (FAPI) labeled with gallium 68 (68Ga-FAPI46) for detecting primary and metastatic lesions in patients with different types of cancer, compared to PET/CT with FDG. ***Materials and Methods:*** Patients with different types of cancer confirmed by histopathological study were evaluated with PET/CT with 68Ga-FAPI and with FDG for initial staging or to detect tumor recurrence. The results of PET/CTs were compared to the findings of conventional imaging methods, such as computed tomography and magnetic resonance imaging and with anatomopathological studies. ***Results:*** Fifteen patients were evaluated, 7 of whom were male, aged between 20 and 78 years, ten of whom were diagnosed with lung carcinoma, three with soft tissue sarcoma, one with gastric carcinoma and one with breast carcinoma. Three patients with lung cancer underwent paired studies with 68Ga-FAPI46 and FDG for initial staging. The remaining patients underwent paired studies to detect tumor recurrence/restaging. The primary tumor detection rate was the same for both radiopharmaceuticals. However, the degree of investigation into the primary lesion of 68Ga-FAPI46 was higher compared to FDG in most cases. On the other hand, PET/CT with 68Ga-FAPI46 detected a greater number of lung carcinoma metastases compared to PET/CT with FDG, especially in lymph nodes, pleura, skeleton and central nervous system, observing a greater intensity of 68Ga-FAPI46 uptake in most metastatic lesions. In patients with soft tissue sarcoma and breast carcinoma, PET/CT with 68Ga-FAPI46 generally showed a greater number of positive lung metastases and a greater degree of uptake in secondary bone and lymph node lesions. By contrast, there was false-positive 68Ga-FAPI46 uptake in inflammatory process.

Conclusion: PET/CT with 68Ga-FAPI46 is a promising alternative to PET/CT with FDG in the detection of primary and metastatic neoplastic processes and can detect a greater number/extent of secondary lesions, particularly in lymph nodes, pleura, central nervous system and skeleton. ***References:*** Chen, H.; Pang, Y.; Wu, J. et al. Head-to-head intra-individual comparison of biodistribution and tumor uptake of (68)Ga-FAPI and ^{18}F-FDG PET/CT in cancer patients. Eur. J. Nucl. Med. Mol. Imaging 2021, 48, 1-19.

EPS-202

Higher diagnostic accuracy in NSCLC lymph node staging with Total-Body compared to conventional PET/CT - results form a prospective single center head-to-head comparative study

*C. Mingels[1,2], M. H. Madani[1], H. Nalbant[1], J. Riess[3], Y. Abdelhafez[1], A. Ghasemiesfe[1], **F. Sen[1],** M. Guindani[4], R. D. Badawi[1], B. A. Spencer[1], L. Nardo[1];*
[1]Department of Radiology, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [2]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [3]Department of Hematology/Oncology, Division of Internal Medicine, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [4]Department of Biostatistics, University of California, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: To compare Total-Body (TB) and short-axial field-of-view (SAFOV) PET/CT diagnostic performance in mediastinal lymph nodes (N-staging) of non-small cell lung cancer (NSCLC) and assess potential changes in tumor stage. ***Materials and Methods:*** 68 patients were included of which 28 (male: 10, female: 18) were referred for staging/restaging of NSCLC. Patients received both TB (uEXPLORER, United Imaging Healthcare) and SAFOV (Biograph mCT, Siemens Healthineers) PET/CT on the same day in a cross-over prospective single-center head-to-head comparative study design. PET/CT was acquired after 60- or 90-minutes post injection of ~370 MBq [18F]FDG. PET was read by two blinded experts in a randomized order. Follow-up data (histology after biopsy/mediastinoscopy, treatment, imaging, therapy response) after 24 [2-41] months was used for validation of positive and negative lymph nodes and N-stage. Twenty-five different mediastinal lymph node levels (1R/L, 2R/L, 3a/p, 4R/L, 5, 6, 7, 8-14R/L) were evaluated per patient and per scan. Sensitivity, specificity, negative and positive predictive values (NPV/PPV) were analyzed for both PET scans with 95% confidence interval (CI). TNM-staging and tumor stage group according to 8th Edition (AJCC) was recorded for each patient on both PET/CTs. McNemar's test was used to assess statistically significant differences ($p<0.05$). ***Results:*** Overall, 700 mediastinal lymph node levels were evaluated. We detected higher numbers of true positive lymph nodes on TB PET (50 vs. 41), whereas false positive (7 vs. 13) and false negative (6 vs. 15) lymph nodes were lower on TB compared to SAFOV PET. Subsequently, sensitivity (89% CI: 81-97% vs. 73% CI: 62-85%) and PPV (88% CI:79-97% vs. 76% CI: 65-87%) was higher on TB, whereas specificity (99% CI: 98-99% vs. 98% CI: 97-99%) and NPV (99% CI: 98-99% vs. 98% CI: 97-99%) was similar between TB and SAFOV PET. The diagnostic accuracy was significantly higher for TB compared to SAFOV PET/CT ($p=0.005$). In total, N-staging was correct in 22/28 patients (79%) on SAFOV PET and in 27/28 patients (96%) on TB PET. The tumor stage group was incorrect in one SAFOV PET case, where biopsy confirmed correct upstaging in TB PET/CT, which may have impacted the patient's management. ***Conclusion:*** TB PET/CT showed significantly higher sensitivity and PPV in lymph node staging compared to SAFOV PET/CT, which affected N-staging in 18% of patients and might have changed clinical management in one case. TB PET/CT may therefore be of importance to establish the best therapy plan in clinical routine for NSCLC patients.

EPS-203

Role of ^{18}F-FDG PET/CT in the management of secondary Hemophagocytic lymphohistiocytosis

P. Aggarwal, *H. Singh, R. Kumar, V. Gunasekaran, B. R. Mittal, G. Prakash;*
PGIMER CHANDIGARH, Chandigarh, INDIA.

Aim/Introduction: Hemophagocytic lymphohistiocytosis (HLH) is a rare and potentially fatal systemic inflammatory syndrome, developing secondary to varied aetiologies ranging from infection, inflammation to malignancy. This single-centre retrospective study aims to assess the utility of 18F-FDG PET/CT in secondary HLH. ***Materials and Methods:*** A retrospective analysis of patients who underwent 18F-FDG PET/CT from 2010 to 2024 for workup of HLH was done. Whole-body 18F-FDG PET/CT images were analysed to find secondary causes of HLH, and findings were correlated with clinical, biochemical parameters and the final diagnosis. Focal PET uptake was considered positive at sites other than physiological sites. SUVmax was measured in liver, spleen and bone marrow (BM), and spleen-to-liver ratio (SLR) and bone-to-liver ratio (BLR) were calculated. ***Results:*** Data of 23 patients [median age 22 years (IQR 13-35)] and male preponderance (n=17) was analysed. Hepatomegaly was observed in all patients (100%), splenomegaly in 18 (78.3%), splenic FDG uptake > liver in 17 (73.9%), BM uptake > liver in 17 (73.9%), lymphadenopathy in 15 (65.2%), lung involvement in 6 (26.1%) and basal ganglia hypermetabolism in nine (39.1%) patients. There was no significant difference in SUVmax and BLR in patients with and without evidence of HLH on BM sampling, but a significant difference in median marrow SUVmax (4.5 vs 2.1, p=0.002), spleen SUVmax (4.7 vs 2.2, p=0.006) and BLR (1.51 vs 1.0, p=0.016) was observed in patients with hypercellular vs normo/hypocellular marrow. BLR showed a statistically significant moderate positive correlation with total leukocyte count (r 0.557, p =0.013) and absolute neutrophil count (r 0.592, p = 0.006).The most common aetiology of secondary HLH was infection (11/23, 47.8%) with Ebstein barr virus (n=3), parvovirus B19 and hepatitis A virus (PET negative) in one each. One patient with X-linked lymphoproliferative disorder was seropositive for EBV, CMV, HAV and herpes simplex viruses. Two patients (8.7%) had brucellosis, and three (13%) had mycobacterium tuberculosis infection. PET was positive in 10/11 patients with infections (91%). Three (13%) had Still's disease and 1 patient had combination of malignancy (B-NHL) and infection (CMV) (4.3%). Six patients (26.1%) had haematological malignancies - T-cell rich B-cell lymphoma, cutaneous T-cell lymphoma, B-ALL, HL, DLBCL and B-NHL (in one each) with PET-positive findings in all. PET was also positive in two patients with idiopathic HLH (8.6%). ***Conclusion:*** 18F-FDG PET/CT is useful in localising the malignant and infective cause of secondary HLH and uptake correlates with bone marrow and peripheral blood findings.

EPS-204

Prognostic Role of FDG PET/MRI Findings in Patients with R-ISS Stage 2 Multiple Myeloma

E. Erbil Capci, *Y. Unluer Ates, U. Aydos, L. Atay; Gazi University Faculty of Medicine, Ankara, TÜRKIYE., Ankara, TÜRKIYE.*

Aim/Introduction: Revised International Staging System (R-ISS) was develop in 2015 and is used in the risk classification in multiple myeloma (MM). However, the number of patients classified as stage 2 is high and this group includes a heterogeneous patient population in terms of survival. This study aimed to evaluate the prognostic value of FDG PET/MR in further risk stratification in R-ISS stage 2 MM patients. ***Materials and Methods:*** This study analyzed 77 newly diagnosed, R-ISS stage 2 MM patients who underwent FDG PET/MRI for primary staging. FDG PET, T1 and T2-w images, DWI and ADC maps were analyzed to evaluate the presence and number of FDG (+) and DWI (+) focal lesions (FL), diffuse bone marrow (BM) involvement, the presence of extramedullary and paramedullary disease (EMD/PMD). In quantitative evaluation, the highest SUVmax and the lowest ADCmin values were obtained. International Staging System (ISS) and Durie-Salmon stages, BM plasma cell ratios and laboratory parameters were recorded. Cox proportional hazard regression models were performed to determine the prognostic factors for overall survival (OS). Survival curves were estimated by using the Kaplan-Meier method. Statistical analyses were performed on SPSS version 23.0. ***Results:*** The median follow-up duration after the start of therapy was 22 months. During the follow-up period, 29 patients had died. In univariate Cox regression analyses, Durie-Salmon stage (stage 1-2 vs 3), FL number on FDG PET/MRI and DWI (<5 vs ≥5), the presence of EMD/PMD and the highest SUVmax levels were found to be prognostic factors. In multivariate analysis, the presence of EMD/PMD on FDG PET/MRI and FL number on DWI were found as independent prognostic factors for OS (HR: 3.3, 95% CI: 1.4-7.6, p=0.006 and HR: 3.1, 95% CI: 1.4-6.9, p=0.005, respectively). The Kaplan-Meier survival analysis showed that EMD/PMD positive patient group and the patients with higher FL number on DWI (≥5) had significantly lower OS rates (38.5% vs 67.2%, p=0.002; 39.4% vs 79.5%, p=0.002, respectively). ***Conclusion:*** The presence of EMD/PMD on FDG PET/MRI and higher FL number on DWI can be used as prognostic biomarkers to identify higher risk patients within the heterogeneous R-ISS stage 2 MM group. However, prospective larger studies are needed to confirm these findings.

EPS-205

Prospective Comparison of [18F]FDG and [68Ga]Ga-PSMA PET/CT in Staging Multiple Myeloma

M. Di Franco[1], *D. Bezzi[2], M. Talarico[3], E. Zamagni[3], V. Cabitza[4], L. Filippo[4], S. Fanti[1,4], C. Nanni[4]; [1]Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine Unit, AUSL Romagna, Forlì, ITALY, [3]Seràgnoli Institute of Hematology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.*

Aim/Introduction: PSMA is expressed on the endothelium of neoangiogenic blood vessels; therefore, it can be targeted to image a variety of tumors. The aim of this study is to evaluate the diagnostic performance and limits of [68Ga]Ga-PSMA PET/CT(PSMA-PET) in assessing Multiple Myeloma (MM) through the comparison with [18F]FDG-PET/CT (FDG-PET), particularly in the light of possible novel theranostic approaches. ***Materials and Methods:*** We prospectively enrolled 41 consecutive patients(pts) with newly diagnosed symptomatic MM and performed a FDG-PET and a PSMA-PET within 14 days. The two scans were compared in terms of number of bone focal lesions (FL), paramedullary lesions (PM), SUVmax and diffuse bone marrow (BM) uptake. ***Results:*** R-ISS and mean plasma cell bone marrow infiltration were: I(14pts, 58%), II(18pts, 64%), III(4pts, 90%), not-valuable(5pts, 27%). 32/41 patients(78%) had concordant FDG-PET and PSMA-PET scans, while 9/41(22%) had discordant scans in terms of positivity/negativity(p .00015). Among concordant studies, 12/32(37%)pts were negative at both the tracers while 20/32(63%) were positive at both. In 9/20(45%) the two tracers identified the same number and sites of lesions. In the remaining 11/20(55%), FDG and PSMA showed a different number of lesions; in 5/11(45%) FDG-PET detected more lesions, in 5/11 less lesions, while in 1/11(9%) there were both types of discordant lesions. Among discordant studies, 8/9pts had a positive FDG-PET and a negative PSMA-PET, whereas 1/9 had a positive PSMA-PET and a negative FDG-PET. Overall, 298 focal lesions were detected, of which 286 were FL and 12 were PM. FDG-PET detected 276/298(93%) lesions in 26 patients and PSMA 100/298(34%) lesions in 21 patients. All(12/12) PM lesions were FDG positive and 11/12 showed PSMA uptake(p 1.0). BM diffuse uptake was observed in 5 PSMA-PET, all positive in the FDG counterpart, and in 16 FDG-PET (DS4 in 13, DS3 in 3)(p .02). FL-SUVmax had a median of 5,8(3,9-7,4) for FDG and 5,3(3,5-6,2) for PSMA; PM-SUVmax had a median of 5,8(3,9-11,5) for FDG and 4,9(4,3-6,1) for PSMA. However, the higher PSMA-PET SUVmax was superior to physiologic liver uptake (reference for radioligand therapy clinical indication) only in 2/13 PSMA positive scans. ***Conclusion:*** According to these preliminary results, FDG-PET features a higher positivity rate than PSMA-PET in detecting myelomatous lesions. For this reason and for the low PSMA uptake, PSMA does not seem optimal for imaging MM. It is not excluded that PSMA uptake may increase in advanced phases of the disease. Further analysis of larger cohorts is needed.

EPS-206

Imaging features and clinical data-based network analysis of CAR-T treated B-cell lymphoma patients in relation to their TP53 mutation status

A. Estepa-Fernández[1], *B. Ferrer-Lores[2], A. Serrano-Alcalá[2], A. Picó-Peris[1], E. Lucena-Sánchez[1], F. Bellvís-Bataller[1], G. J. Weiss[3], J. P. Fernández[1], A. Jimenez-Pastor[1], A. Sopena-Novales[6], A. Balaguer-Rosello[7], M. Guerreiro[7], J. Sanz[7], L. Martí-Bonmatí[8], M. J. Terol[2], Á. Alberich-Bayarri[1]; [1]Quibim, Quantitative Imaging Biomarkers in Medicine, Valencia, SPAIN, [2]Hematology Department, Hospital Clínico Universitario-INCLIVA, Valencia, SPAIN, [3]Quibim, Quantitative Imaging Biomarkers in Medicine, New York, NY, UNITED STATES OF AMERICA, [4]Department of Pathology, Hospital Clínico Universitario, INCLIVA Biomedical Research Institute, University of Valencia, Valencia, SPAIN, [5]Department of Radiology, Hospital Clínico Universitario, Valencia, SPAIN, [6]Nuclear Medicine Department, Área Clínica de Imagen Médica, La Fe Hospital, Valencia, SPAIN, [7]Hematology Department, Hospital Universitari i Politècnic La Fe, Valencia, SPAIN, [8]Radiology Department, Área Clínica de Imagen Médica, La Fe Hospital, Valencia, Spain, Valencia, SPAIN.*

Aim/Introduction: Despite the promising results of Chimeric antigen receptor T-cell (CAR-T) therapy for relapsed/refractory (R/R) B-cell lymphoma, the heterogeneity of treatment responses requires further understanding of the triggering factors, such

as the TP53-mutation status. This study aims to investigate the network patterns among R/R B-cell lymphoma patients treated with CAR-T therapy based on their TP53-mutation status. ***Materials and Methods:*** Fifty-four R/R B-cell lymphoma patients that underwent TP53 determination, treated with CAR-T therapy at Valencia Clinic and La Fe University Hospitals between 2019 and 2023 were included. Pre-infusion ^{18}F-FDG PET/CT scans, clinical, and genetic data were collected. Imaging features included maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), total lesion glycolysis (TLG), entropy, and kurtosis radiomics, were calculated across all lesions (total). To evaluate the network profile, sparse gaussian graphical models were constructed. Graphical Lasso regularization function and Extended Bayesian Information criterium were used as tuning parameter. Additionally, 200 nonparametric bootstrap samples were generated. Weights between nodes were estimated as partial correlations under a high-dimensional nonparanormal model. Partial correlations were estimated by regularized nodewise regression based on the ranks from the original data. ***Results:*** Mean age of included patients (n=54) was 57.5 [range 21-76] years, with gender balance. Axicabtagene ciloleucel and tisagenlecleucel were administered to 37 (68.5%) and 17 (31.5%) patients, respectively. TP53 mutations were detected in 19 (35.2%) patients. The exploration of network patterns revealed that entropy, an imaging feature that specifies randomness or disorder in the image region of interest, plays a significant role in both networks, occupying a central position. However, node connection between TP53-mutated and non-mutated patients differ. Entropy shows a positive association with LDHratio and SUVmax in TP53-mutated patients as indicated by the estimated edge weights 0.372 and 0.513 respectively, while these associations were lower in non-mutated patients (0.000 and 0.261). Kurtosis, which measures the peakedness of the distribution, also shows a significant relationship with progression-free survival time, overall survival time, and the AUC of the CAR-T follow-up by digital PCR. Both networks exhibited the strongest positive correlation between MTVtotal and TLGtotal, showing edge-weights of 0.789 for TP53-mutated patients and 0.669 for non-mutated. ***Conclusion:*** The complex network pattern in R/R B-cell lymphoma patients undergoing CAR-T therapy, emphasizing the influence of TP53-mutational status shows differential associations, highlighting the importance of personalized treatment strategies. These findings contribute to understanding treatment responses in CAR-T therapy and may guide future therapeutic approaches for improved patient outcomes.

EPS-207

Prognostic Ability Of The Measurement Of Maximum Tumor Dissemination (Dmax) In PET/CT Images Of Patients With Diffuse Large B Cell Lymphoma (DLBCL)

M. Contreras Ameduri[1], *F. López-Bermejo García[1], J. Rodríguez Gómez[1], F. Pena Pardo[1], R. Angulo Amorese[1], M. Amo Salas[2], S. Pozuelo Campos[2], M. Sicilia Pozo[1], A. Padilla Bermejo[1], M. Carrero Lérida[1], G. Molina Mendoza[1], M. Talavera Rubio[1], V. Poblete García[1];*
[1]General University Hospital of Ciudad Real, Ciudad Real, SPAIN, [2]University of Castilla-La Mancha, Faculty of Medicine, Ciudad Real, SPAIN.

Aim/Introduction: To analyse the prognostic performance of the measurement of maximum tumour dissemination (Dmax) in PET/CT images with [^{18F}]FDG of patients affected by diffuse large B cell lymphoma (DLBCL). ***Materials and Methods:*** Retrospective observational study of consecutive patients diagnosed with DLBCL between January/2016-May/2019, with histopathological confirmed diagnosis, and studied by staging PET/CT. The distance in millimetres from centre to centre (Dmax) of the two most distant lesions in the obtained images was measured; that same distance corrected by the patients' body surface area (SDmax) was also measured. Statistical analysis was conducted using SPSS v29. Cox regression analysis between the quantitative variables (Dmax and SDmax) and overall (OS) and disease-free survival (DFS) was performed. ***Results:*** One hundred and forty-three patients (63 women) with a mean age of 64.6 years (19-92) were included, with the following mean distances: Dmax 341.9 mm (17.8-807.7) and SDmax 190.2 mm (9.4-502.3). Forty-three of the patients in our sample (30.1%) presented progression or recurrence of their disease, and forty-six (32.2%) died during clinical follow-up. About the progressions, it is worth noting that only 2 patients with a Dmax less than or equal to 99 mm progressed. Cox regression analysis found a statistically significant correlation between Dmax and SDmax with DFS: p=0.003 and HR=1.002 (95%CI: 1.001-1.003) for Dmax, p=0.004 and HR=1.003 (95%CI: 1.001-1.005) for SDmax; this represents an increase in the risk of progression of 3% for every centimetre that the interlesional distance increases. A statistically significant correlation was also found with OS, with p=0.006 and HR=1.002 (95%CI: 1.000-1.003) and p=0.005 and HR=1.003 (95%CI: 1.001-1.005) for Dmax and SDmax, respectively, both showing a similar trend, with SDmax being slightly better associated with an increased risk of progression or recurrence than Dmax. Overall, the HR shows an increase in risk the greater the interlesional distance. Cox regression analysis also showed that advanced Ann-Arbor stages (III and IV) showed a significant correlation with OS (p=0.005 and p=0.04, respectively). ***Conclusion:*** Dmax and SDmax seem to have a potential role as prognostic estimation measures in patients affected by DLBCL and could be useful tools to implement in daily clinical practice, given their value and simple calculation, but further studies may be warranted.

EPS-208

Prognostic value of maximum height-normalized tumour dissemination (HDmax) from ^{18}F-FDG PET/CT staging studies in follicular lymphoma

R. Angulo Amorese[1], *J. Rodríguez Gómez[1], F. Pena Pardo[1], E. Noriega-Alvaréz[2], M. Amo Salas[3], M. Contreras Ameduri[1], F. López-Bermejo García[1], S. Pozuelo Campos[3], A. Padilla Bermejo[1], N. Disotuar Ruiz[1], B. Gonzalez García[1], M. Talavera Rubio[1], V. Poblete García[1];*
[1]Nuclear Medicine Department, University General Hospital of Ciudad Real, Ciudad Real, SPAIN, [2]Nuclear Medicine Department, University Hospital of Guadalajara, Guadalajara, SPAIN, [3]Mathematics Department, Castilla la Mancha University of Ciudad Real, Ciudad Real, SPAIN.

Aim/Introduction: To analyse the prognostic value of maximum height-normalized tumour dissemination (HDmax) from 18FDG-PET/CT staging scans in patients with a histologically confirmed diagnosis of follicular lymphoma (FL). ***Materials and Methods:*** A retrospective analysis of consecutive patients with FL undergoing 18FDG-PET/CT staging scan between January/2017 and November/2020 was conducted. The Euclidean distance (centre-centre) between the two most distant pathological lesions corrected for height (HDmax) was measured, and its relationship with disease-free survival (DFS) and overall survival (OS) was studied using Cox regression analysis and Pearson's correlation coefficient (ρ). ***Results:*** A total of 107 patients (56 men), mean age 60 years (13-86), with a mean HDmax value of 211.3 mm (112.8-354.6), wereincluded. Thirty-one patients had progression confirmed by clinical and/or imaging evidence and

20 died during a minimum follow-up of 4 years. In the analysis with Pearson's correlation, statistically significant relationships were obtained between HDmax and death (ρ:0.223; p<0.05) and HDmax and age (ρ:0.960; p<0.001). However, no statistically significant correlation was obtained with DFS or OS, although in the Kaplan Meier curves there is a visual increase in risk with higher HDmax. These findings maintained the same trend in Cox regression analysis, with HR of 1.002 for DFS and OS without reaching statistical significance. This means that the risk of death or progression is increased by 2% for every centimetre of distance. Patients with HDmax ≤152.1 mm had no progression at 2 years, nor did they die during follow-up. ***Conclusion:*** HDmax from 18FDG-PET/CT staging scans could play a role as prognostic factor in FL patients, with a cutoff level of ≤152.1 mm potentially representing patients with a better prognosis.

EPS-209

MTV-based risk scores for outcome prediction in large B-cell lymphoma: Data from a multicenter analysis of patients undergoing chimeric antigen receptor T-cell therapy

C. Voltin[1], *S. Flossdorf[2], A. Paccagnella[3], M. Winkelmann[4], L. Beckmann[1], J. Heger[1], B. Casadei[3], K. Herrmann[2], F. J. Dekorsy[4], N. Kutsch[1], P. Borchmann[1], S. Fanti[3], K. Rahbar[5], M. Subklewe[4], P. L. Zinzani[3], A. Drzezga[1], M. Dietlein[1], H. C. Reinhardt[2], W. G. Kunz[4], B. von Tresckow[2], R. Seifert[2,5,6], J. C. Albring[5], V. Blumenberg[4], A. Farolfi[3], P. Gödel[1], C. Hanoun[2];*
[1]University of Cologne, Cologne, GERMANY, [2]University of Duisburg-Essen, Essen, GERMANY, [3]University of Bologna, Bologna, ITALY, [4]Ludwig Maximilian University Munich, Munich, GERMANY, [5]University of Münster, Münster, GERMANY, [6]University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Chimeric antigen receptor (CAR) T-cell therapy has shown remarkable efficacy in relapsed and refractory large B-cell lymphoma. However, it remains unclear how potential non-responders can be identified before infusion and successfully treated. Some international research groups are currently undertaking efforts to integrate metabolic tumour volume (MTV) measured on 2-[18F]fluoro-2-deoxy-D-glucose positron emission tomography (PET) into newly developed stratification tools, particularly for first-line therapy. We therefore investigated the predictive value of proposed risk scores in patients undergoing CAR T-cell treatment. ***Materials and Methods:*** Our analysis set consisted of 88 individuals from four German university hospitals and one Italian centre who underwent PET-based staging before CAR T-cell therapy with tisagenlecleucel or axicabtagene ciloleucel. We examined the risk scores published by Leithner et al.,1 Thieblemont et al.,2 and our group,3 which, in addition to MTV, include lactate dehydrogenase level, Eastern Cooperative Oncology Group status, and extra-nodal involvement, respectively. All study sites provided information about basic patient characteristics, conventional disease parameters, and PET measures. The models' predictive values with regards to six-month progression-free survival (PFS) were determined based on receiver operating characteristic analysis. Additionally, we assessed whether their performance can be improved through use of individual MTV thresholds that have proved optimal for the CAR T-cell products in a previous study.3 ***Results:*** The risk scores considered showed different PFS prediction power in our cohort of patients undergoing CAR T-cell treatment. We found areas under the curve (AUC) of 0.52 (95% confidence interval [CI], [0.40, 0.63]), 0.60 (95% CI, [0.49, 0.71]), and 0.68 (95% CI, [0.57, 0.78]) for the models proposed by Leithner et al., Thieblemont et al., and our group, respectively. In all scores assessed, patients without any risk factors had the lowest PFS event rates after six months. When using construct-specific MTV thresholds for tisagenlecleucel and axicabtagene ciloleucel, AUC of the stratification tool published by Leithner et al. increased to 0.57 (95% CI, [0.46, 0.69]). ***Conclusion:*** Our study suggests that different PET-based models might be useful for risk stratification in the context of CAR T-cell therapy. Their predictive performance can improve by optimization with construct-specific MTV thresholds. We are currently enrolling additional patients to evaluate the risk scores and identify further relevant factors. Results from our extended analysis will be available at the time of presentation. ***References:*** (1) Leithner D, et al. DOI: 10.1186/s13045-024-01540-x. (2) Thieblemont C, et al. OP-635

Paediatric Dose Optimization for Long Axial Field-of-View FDG PET/CT

D. van der Kaap, *M. Deuten, P. J. H. van Snick, W. Noordzij, R. H. J. A. Slart, A. H. Brouwers, A. W. J. M. Glaudemans, K. P. Koopmans, O. V. Ivashchenko;*
UMCG, Groningen, NETHERLANDS.

Aim/Introduction: Paediatric patients are more radiation-sensitive, therefore minimizing exposure during imaging is vital, while tailoring protocols to their varying sizes and ages is complex. The European Association of Nuclear Medicine (EANM) developed the paediatric dose card, a tool helping to determine safe and sufficient tracer activity levels. This dose card relies on data from large retrospective paediatric patient cohorts. Consequently failing to incorporate recent breakthroughs in whole-body and long axial field-of-view (LAFOV) PET/CT imaging, which hold significant promise for reducing radiation exposure in children. This study evaluates the potential dose reduction capabilities of LAFOV-PET/CT for paediatric [18F]FDG imaging. ***Materials and Methods:*** Between October 2021 and April 2024, 39 paediatric patients underwent [18F]FDG LAFOV-PET/CT imaging, aged 0.2 to 17 years (mean 11 ± 5.3). Post-introduction of the LAFOV system, a systematic dose reduction was implemented, resulting in a wide range of doses (0.6 to 4 MBq/kg) and scan durations (mean 9.3 ± 2.1 minutes, range 3 to 15 minutes). To facilitate data comparison, a regression model was employed to derive an average count statistic for the study cohort, so-called reference image quality (RIQ), corresponding to a dose model of 1.87 MBq/kg (1.2 MBq offset) for a 5-minute scan. Subsequent reconstructions were generated at 100%, 75%, 50%, 25%, and 12.5% of the RIQ. Quantitative assessment focused on measuring SUV mean, max, and peak within predefined liver volumes, alongside subjective clinical image quality (IQ) evaluation using a Likert scale by five nuclear medicine physicians. ***Results:*** The RIQ served as an internal reference for further dose-image quality optimization

and already represents a reduction of 67% and 49% in FDG dose compared to the EANM dose cards of 2016 and 2023, respectively. Qualitative clinical IQ analysis demonstrated the possibility of additional dose reductions by 51% (0.78 MBq/kg, 3.5 MBq offset) and 64% (0.55 MBq/kg, 3.12 MBq offset) if the IQ is reduced to 4 and 3.5 Likert score, respectively. Quantitative image analysis revealed no significant reduction in mean SUV with up to a 50% dose reduction. ***Conclusion:*** This study highlights that LAFOV-PET/CT can significantly reduce paediatric doses by a total of 88% and 81%, compared to EANM dose cards from 2016 and 2023, respectively, without compromising acceptable image quality. The dose-reducing potential can be further maximized by leveraging the ultra-high sensitivity mode of LAFOV-PET/CT, technology that has recently become available and was not covered in this work.

OP-636

CT dose reduction possible with tin filter in SPECT-CT

H. Nielsen[1], *N. Bebbington[2], S. Ravn[1];*
[1]Nuclear Medicine Department, Aalborg, DENMARK,
[2]Siemens Healthcare A/S, Ballerup, DENMARK.

Aim/Introduction: Previous work demonstrated that a new generation of SPECT-CT system allows large CT dose reductions based on improved detector design and iterative reconstruction (IR). A tin filter is also available for further CT dose reduction. Aim of this study was to determine by how much CT dose can be reduced with the tin filter in different tissue types, whilst achieving comparable image quality to images acquired with standard aluminium filtration alone. ***Materials and Methods:*** A whole-body phantom was scanned from vertex to proximal femur, with and without tin filter. Non-tin filter scans were made using 130kV and 110kV, at 100, 50, 30, 20, and 13mAs, whilst tin filter scans were made using Sn130kV and Sn110kV, at 400, 300, 200, 100, 50, 20, and 13mAs. Regions-of-interest were placed in the lung, spine, cerebellum, thyroid, heart, liver and spleen. Contrast-to-noise-ratios (CNR) of the tissues of interest were calculated using the heart as a reference. CNR was plotted against dose-length-product (DLP) for tin filter and non-tin filter scans, for each tissue type and tube voltage, and maximum dose-saving with the tin filter calculated for each kV and tissue, where the greatest relative difference in DLP was seen at comparable CNR. ***Results:*** Dose reductions with the tin filter were dependent on tube voltage and absolute CNR, with relative dose reductions often being greater at lower CNR. At 130kV, maximum relative dose reductions with tin filter for comparable image quality to non-tin filter scans were 17%, 17%, 40%, 43%, 32% and 0% for lung, spine, liver, spleen, thyroid bed and cerebellum, whilst at 110kV maximum relative dose reductions were 61%, 31%, 43%, 33%, 11% and 0%, respectively. At 110kV/13mAs, the scan with standard filtration scan delivered a DLP of 87mGy.cm (effective dose 1.13mSv) for the vertex to proximal femur scan range, whilst the tin filter scan with these settings delivered a DLP of 18mGy.cm (effective dose 0.23mSv), representing an 80% dose reduction with tin filter. ***Conclusion:*** Tin filter can provide additional dose reduction to the already-high reductions provided by a new detector and IR on a next generation SPECT-CT system. Furthermore, the tin filter allows these high theoretical dose reductions to be realised in clinical practice by delivering a much lower dose at a given mAs. Such CT dose reductions in SPECT-CT may make transition to cross-sectional rather than planar imaging more feasible, potentially improving diagnostic accuracy for some Nuclear Medicine examinations.

OP-637

Implementing $^{[18F]}$fluorocholine PET/CT leads to a reduced effective patient dose compared to standard [^{99m}Tc]-sestamibi and [^{99m}Tc]-pertechnetate scintigraphy SPECT/CT

M. Rode, *H. Reilev Moeller, L. Lange Oestergaard, P. Holdgaard;*
Lillebaelt Hospital University Hospital of
Southern Denmark, Vejle, DENMARK.

Aim/Introduction: Minimizing radiation dose in nuclear imaging is paramount, as patients receive dose from both the radioactive tracer and CT. Protocol specifications were designed considering image quality and patient dose to comply with the As-Low-As-Reasonable-Achievable (ALARA) principle. To replace the standard [99mTc]-sestamibi and [99mTc]-pertechnetate scintigraphy SPECT/CT (Tc-99m), $^{[18F]}$fluorocholine PET/CT (FCH) was implemented, aiming for a better sensitivity and specificity for parathyroid detection. The literature reports an effective patient dose from 2.6-6 mSv for FCH and 6.3-12 mSv for Tc-99m, respectively. The aim of this study was to assess the radiation burden of FCH compared to Tc-99m at our department. ***Materials and Methods:*** There are currently no standardized imaging acquisition guidelines for PET/CT parathyroid imaging according to EANM Guidelines [1]. Aiming for a diagnostic quality of the CT scan, acquisition parameters were inspired and optimized from other studies in the literature and a collaborating hospital. Two groups, each consisting of 82 patients were included in the study. Scan ranges covered lower neck and upper mediastinum, with a minimum axial field-of-view of 263 mm, limited by the scanner. The total injected dose was 2.5 MBq/kg and 840 MBq for FCH and Tc-99m, respectively. All examinations were performed on a LSO/SiPM-based (249 ps. timing resolution) PET/CT system for FCH and a conventional dual-headed gamma camera for Tc-99m. The effective dose of injected radiotracer, CT dose and the total effective dose was determined for each patient. Results are presented as mean values ± SD (min-max), and the total effective doses were analysed to establish the difference between the two methods. ***Results:*** The effective dose for the administered radiotracer was 3.8 mSv ± 0.8 (2.4-5.9) for FCH and 8 mSv ± 0 (8.0) for Tc-99m. Effective CT dose was 1.4 mSv ± 0.5 (0.6-2.8) for FCH (high-dose) and 1.1 mSv ± 0.3 (0.6-2.1) for Tc-99m (low-dose). The total effective patient dose was 5.2 mSv ± 1.2 (3.3-8.2) for FCH and 9.1 mSv ± 0.3 (8.6-10.1) for Tc-99m, resulting in a significant reduction of 43 % ($p<0.05$). ***Conclusion:*** Implementing and optimizing FCH for localizing potential parathyroid adenomas, results in a significant reduction in total effective patient dose. This reduction is due to the lower effective dose from the administered radiotracer. CT doses were unchanged but image quality was improved from low dose to diagnostic quality. ***References:*** P.P. OP-638

Optimizing lung ventilation protocol on 3D digital SPECT-CT by using measured count rate- comparison of detection efficiency with conventional SPECT-CT

J. Kaunisto, *S. Halttunen, M. Hakulinen, T. Laitinen, H. Gröhn;*
Kuopio University Hospital, Kuopio, FINLAND.

Aim/Introduction: We use measured count rate, during Technegas inhalation, to define sufficient inhaled 99mTc activity in pulmonary ventilation study. Current clinical cut-off value is set to 1.2kcps on PA detector for the conventional SPECT-CT (cSPECT-CT) to indicate adequate inhaled activity. However, our 3D digital SPECT-

CT (3D-CZT) might enable use of lower activity and/or shorter scan time due to increased sensitivity and different acquisition geometry. The aim of the study was to setup lung ventilation protocol on 3D-CZT using count rate to define adequate inhaled activity. And to evaluate the possibility to decrease inhaled activity and/or scan time by comparing measured count rate and image quality with cSPECT-CT. ***Materials and Methods:*** Count rates were measured using typical inhaled activities in syringe and lung phantom. The lung phantom consisted of activity filled, healthy lung mimicking, containers placed inside a chest cavity phantom. Count rates, with 99mTc energy window, were measured using seven different activities (20-85MBq) from the bottom detector and all detectors on 3D-CZT and from PA detector on cSPECT-CT. Count rates from five patients were measured similarly. To evaluate image quality, a lung phantom containing 10 different sizes of defects, was scanned for 10min on 3D-CZT and according to clinical protocol on cSPECT-CT. In addition, five patients were scanned on both scanners. ***Results:*** Count rate increased linearly (R2>0.97) with increasing activity on both scanners, in syringe and phantom measurements. Measured count rates were 1.7 to 3.3 times higher from syringe than phantom for the same activity, which should be noted if deciding cut-off value based on syringe measurements. Count rate from bottom detector was more sensitive to patient positioning, making total count rate from all detectors more reproducible. Total count rates from phantom on 3D-CZT were 1.7 to 2.2 times higher than those measured on cSPECT-CT. Cut-off value of 1.20kcps in current protocol corresponded 2.55kcps in 3D-CZT, with activity of 28MBq. Count rates from phantom were in the same range as count rates from patients. However, in patient studies variation between scanners was greater. ***Conclusion:*** Total count rate measured on 3D-CZT was the most reproducible method to assess if enough activity has been inhaled. Due to different measurement geometry, count rate values between scanners are not directly comparable. However higher achieved count rate values indicate potential to decrease scan time and/or injected activity on 3D-CZT. This will be further evaluated in ongoing data analysis of lung phantom with defects.

OP-639

Large CT dose savings associated with new generation of SPECT-CT system: impact of new state-of-the-art CT detector and iterative reconstruction

R. Skall*[1]*, *J. Frederiksen*[1]*, N. Bebbington*[2]*, S. Ravn*[1]*;*
[1]Nuclear Medicine Department, Aalborg University Hospital, Aalborg, DENMARK, [2]Siemens Healthcare A/S, Ballerup, DENMARK.

Aim/Introduction: A new generation of CT system was recently introduced to SPECT-CT, with advanced CT noise reduction technologies, including a new-state-of-the-art detector(ND) and second generation Iterative Reconstruction (IR). The aim was to determine by how much CT dose could be reduced, whilst providing comparable image quality to an older generation SPECT-CT system, comprising a standard detector and filtered back projection (FBP) reconstruction. ***Materials and Methods:*** A whole-body phantom was CT scanned from vertex to proximal femur on a recently installed system (new) equipped with ND and IR, and a 13 year-old system (old) with standard detector and FBP reconstruction. CT scans were made at 130kV and 110kV, and a range of mAs settings: 13-100mAs (new) and 8-100mAs (old). Images were reconstructed on the new system with IR and FBP, and on the old system with FBP only. On each reconstruction, regions-of-interest (ROIs) were drawn in homogenous areas of the lung, spine, cerebellum, thyroid, heart, liver and spleen. For each tissue and kV, image noise (standard deviation of Hounsfield Units, SD HU) was plotted against dose, for: old (standard detector)+FBP; new+FBP; and new+IR. Logarithmic fits were applied. Dose-length-product (DLP) and HU SD were compared for New+FBP vs Old+FBP, New+IR vs New+FBP and New+IR vs Old+FBP, to determine the relative dose reductions provided by ND, IR and the two technologies combined, respectively. ***Results:*** At 13mAs the new system provided DLPs of 87mGy.cm and 135mGy.cm, with 110kV and 130kV tube voltages respectively, giving whole-body effective doses of 1.1 and 1.8 mSv. When considering noise reduction with the ND only, these doses represented a 40% to >90% dose reduction for comparable image quality to the old system, according to tissue type and tube voltage. When considering noise reduction with IR compared with FBP, there was a 47% to >90% dose reduction for comparable image quality. When considering the combined effect of ND and IR, dose-savings were 68% to >90% for comparable image quality to the old system. ***Conclusion:*** Substantial CT dose reductions can be made on the new generation SPECT-CT system with ND and IR, as compared with an older generation system. In addition to providing lower radiation doses for current patients. The dose reduction may also justify greater use of SPECT-CT over planar imaging in clinical practice for improved diagnostic accuracy, where justification of the CT radiation dose has previously been a barrier.

OP-640

Prospective PET Dose Reduction Study of F^{18}-PSMA: Dose Reduction, Optimization of Acquisition Time and Radioprotection

M. Anelli*[1]*, *M. V. Mattoli*[1]*, A. Zambelli*[2]*, A. D. Di Nicola*[1]*;*
[1]Azienda Sanitaria Locale di Pescara, Pescara, ITALY, [2]Aziendal Ospedale-Università di Padova, Padova, ITALY.

Aim/Introduction: ^{18}F-PSMA is a PET radiopharmaceutical used for the diagnosis and follow-up of prostate cancer. PET-CT with PSMA is an innovative method for the diagnosis of prostate cancer that overcomes the limitations of traditional techniques such as PET-CT with choline Among the main advantages is greater accuracy: in fact, PET-CT with PSMA is much more sensitive and specific in detecting prostate cancer, especially when other tests tend to give non-definitive values, as in the case of:o Low PSA valueso Negative prostate biopsyo Suspicion of biochemical recurrenceo Advanced prostate cancer• Better visualization of metastases: PET-CT with PSMA allows you to identify prostate cancer metastases with greater accuracy, even in locations that are difficult to reach with other tests, such as lymph nodes and viscera. Furthermore, the package leaflet indicates an administration dose of 3-5 MBq/Kg. ***Materials and Methods:*** This prospective study aims to reduce the radiation exposure by reducing the activity of ^{18}F-PSMA administered to patients, optimizing their radiation protection, and aiming to reduce the acquisition time per bed. Methodology:• Phase 1 (March-May 2024): 20 patients will receive 4.5 MBq/Kg of ^{18}F-PSMA and the acquisition time will be of 2.5 minutes per bed.• Phase 2 (June-August 2024): 20 patients will be acquired after 3 MBq/Kg of ^{18}F-PSMA with an acquisition time of 2.5 minutes per table.• Phase 3, Analysis: Liver SUV will be compared between Phase 1 and Phase 2 patients to evaluate the impact of reducing dose and acquisition time on image quality. Additionally, list-mode data from both phases will be used for retrospective image reconstruction simulating a 2-minute acquisition time per bed position. These reconstructed images will be evaluated by the medical team in a double-blinded fashion to assess potential image quality degradation with a shorter acquisition time. ***Results:***

This study is expected to demonstrate the feasibility of reducing the administered dose of ^{18}F-PSMA, optimizing patient radiation, while maintaining image quality for prostate cancer detection. Furthermore, a secondary expected objective is also the reduction of the acquisition time per patient, with the possibility of acquiring a higher number of patients in each single session. ***Conclusion:*** The study will evaluate whether the reduction of ^{18}F-PSMA activity and acquisition time is compatible with satisfactory image quality. If the results are favorable, this strategy could be adopted to improve the radioprotection of patients, optimize the use of the radiopharmaceutical and increase the number of patients subjected to the examination.

OP-641

Determining the Impact of Low Dose Administrations of [^{11}C]UCB-J on $SUV_{R'}$ for PET-MR Brain Datasets

D. Ribeiro[1], *W. Hallett[2], D. Nutt[3], D. Erritzoe[3], C. Agnorelli[3], S. Husbands[1];*
[1]University of Bath, Bath, UNITED KINGDOM, [2]Invicro, A Konica Minolta Company, London, UNITED KINGDOM, [3]Imperial College London, London, UNITED KINGDOM.

Aim/Introduction: Positron Emission Tomography (PET)-Magnetic Resonance (MR) is an imaging technique used to investigate the pathophysiology of neurological conditions, which allows for the simultaneous acquisition of PET and MR images. The [^{11}C]UCB-J radiopharmaceutical has been proposed as a marker of synaptic density for Alzheimer's disease (AD) patients, due to targeting the synaptic vesicle glycoprotein 2A. Patients with AD are likely to undergo longitudinal PET-MR examinations with [^{11}C]UCB-J, for disease monitoring and treatment follow-up. The aim of this project is to investigate the impact of low dose administration of [^{11}C]UCB-J, in PET-MR brain datasets, to optimise clinical protocols and reduce radiation burden. ***Materials and Methods:*** Five in vivo datasets, belonging to five healthy volunteers who received 228.6±58.3 MBq of [^{11}C]UCB-J and were scanned on a General Electric SIGNA PET-MR, were reconstructed once with the full administered dose and 7 times with different simulated low doses. The low dose simulations were obtained by undersampling the time frames and represented 1/2, 1/3, 1/4, 1/5, 1/6, 1/10, 1/15 of the full dose. An OSEM algorithm with time-of-flight was used with 6 iterations, 16 subsets, a 5mm filter (xy-axis). Regions of interest were drawn in the accumbens, substantia nigra, thalamus, striatum, caudate, putamen, hippocampus, insular cortex, temporal lobe, parietal lobe, frontal cortex and cerebellum. The standardised uptake value ratio (SUVR) was determined for each of the brain regions, per reconstruction. Coefficient of variation (CV) and bias were calculated. The two-way ANOVA and Kruskal-Wallis tests were used for group comparisons between the low dose and the full dose datasets. ***Results:*** The caudate (10.21%), cerebellum (11.21%), substantia nigra (10.68%) and temporal lobe (10.25%) presented the highest CV, for the full dose datasets. When investigating the difference between the CV from the full dose with the highest CV from the low dose datasets, no differences exceed 3%. The 1/2 low dose reconstruction consistently produced the lowest bias, when compared to the full dose. The 1/10 and 1/15 low dose datasets produced the highest bias, for all structures. The 1/2 and 1/3 low dose datasets consistently did not show significant differences for the regions under investigation. Apart from the thalamus and cerebellum, the remaining regions also did not present significant differences when the 1/4 low dose was compared to the full dose dataset. ***Conclusion:*** Results indicate that, when investigating the outcome measure SUVR for the [^{11}C]UCB-J datasets, it is possible to reduce the administered to 1/2 or 1/3.

OP-642

Quality assurance of [^{18F}]FDG-PET/CT scans after reduction of the FDG dose

S. Laugesen, *S. S. Lorentzen, K. M. Buch-Olsen, N. M. Jakobsen, S. Nadaraja, S. T. Nygaard, K. Thilsing-Hansen, C. G. Pedersen, M. N. Behzad, O. Gerke, M. G. Hildebrandt;*
Department of Nuclear Medicine, Odense, DENMARK.

Aim/Introduction: When conducting [^{18F}]FDG-PET/CT scans, it is desirable to keep the radiation dose low and at the same time maintain high image quality for accurate diagnosis. In this quality-assurance study, we aimed to show that reducing the FDG dose for [^{18F}]FDG-PET/CT can be done without compromising image quality and diagnostic confidence. ***Materials and Methods:*** At the Department of Nuclear Medicine at Odense University Hospital, Denmark, we reduced the FDG dose from 4 to 3 MBq/kg. We standardized the overlap and scan time on different generations of PET/CT scanners aiming to gain the same sensitivity. We included patients with metastatic breast cancer who had undergone a minimum of four repetitive [^{18F}]FDG-PET/CT scans to evaluate treatment response; two should be conducted before and two after the FDG dose reduction. Four nuclear medicine specialists evaluated the scans independently and blinded to one another and to FDG dose. A five-point scale was used for evaluation of the scans that were graded according to noise, sharpness, and diagnostic confidence. Scans performed with an FDG dose of 4 versus 3 MBq/kg were compared. Differences between the dose levels were assessed with linear regression adjusting for intra-patient correlation. Agreement across raters was evaluated with proportions of agreement. ***Results:*** We included 25 breast cancer patients, resulting in 100 [^{18F}]FDG-PET/CT scans, using either FDG doses of 3 (n=50) or 4 MBq/kg (n=50), respectively. Only top scores of 1 and 2 were given for evaluations of noise and sharpness, and the best score of 1 was given to all scans for diagnostic confidence. No difference was observed for evaluation diagnostic confidence. Regarding noise, scans with FDG doses of 3 and 4 MBq/kg were comparable (mean score: 1.53 vs. 1.5; p=0.56), whereas the mean score in sharpness was slightly worse for low-dose than for high-dose scans (mean score: 1.35 vs. 1.2; p=0.026). Our results showed reasonable agreement between four raters according to their evaluation of the scans with proportion of agreement for noise, sharpness and diagnostic confidence of 0.6, 0.6, and 1, respectively, for low-dose scans and 0.5, 0.7, and 1 for high-dose scans. ***Conclusion:*** While there was a slight decrease in sharpness observed in the low-dose scans, our study found that reducing the FDG dose did not compromise the diagnostic confidence of [^{18F}]FDG-PET/CT. This dose reduction initiative aligns with the ALARA principle and supports our goal of minimizing radiation exposure for patients and the technologists performing the scans.

OP-643

Deep Learning-based Whole-liver Segmentation Using only ^{18}F-FDG PET Images

T. Yamao[1], *Y. Kaneko[2], K. Miwa[1], N. Miyaji[1], R. Nishii[3], K. Yamazaki[4], T. Higashi[4];*
[1]Fukushima Medical University, Fukushima-shi, JAPAN, [2]Fukushima Medical University Hospital, Fukushima-shi, JAPAN, [3]Nagoya University Graduate School of

Medicine, Nagoya-shi, JAPAN, [4]National Institutes for Quantum Science and Technology, Chiba-shi, JAPAN.

Aim/Introduction: 18F-FDG PET imaging uses liver uptake measurements as a key metric, and in this context, deep learning countouring of liver region has been proposed because it has small errors compared to manual contouring. However, although approaches using mask images generated from CT or MRI are widely used for deep learning segmentation of PET images, the quantitative accuracy is variable due to differences in PET resolution and misregistration during image fusion. Consequently, the aim of this study was to develop a deep learning segmentation method of whole-liver regions based on the exclusive use of 18F-FDG PET images. ***Materials and Methods:*** We retrospectively analyzed 18F-FDG PET images of 120 patients (normal: 99, tumor: 11, cyst: 10). Consecutive slices containing the liver regions were extracted from whole-body PET images. The PET image scale was converted to standardized uptake value (SUV) units, and to stabilize the image in the abdomen, the SUV range was subsequently set from 0 to 6. As the deep learning architecture, we used the 3D U-net for semantic segmentation of the nnUNet system. The whole-liver region of the ground truth for supervised learning was created by manual contouring. The 120 PET images were randomly divided into 100 training and 20 test datasets, and segmentation accuracy was evaluated using the images from 20 patients that were not used for training. As evaluation measures, we used intersection over union (IoU) and Dice coefficients. The quantitative accuracy and image quality of volumes of interest (VOI) generated by deep learning were compared with those generated by manual contouring, using SUVmean, SUVmax, and signal-to-noise ratio (SNR). ***Results:*** The deep learning-extracted liver regions from 18F-FDG PET images were comparable to the ground truth regions. In the test dataset, the mean IoU and mean Dice coefficients were 0.890 and 0.941, respectively. Furthermore, the SUVmean values obtained for the deep learning and ground truth VOIs were almost identical, although the SUVmax and SNR tended to be slightly higher for the deep learning VOI. Notably, using deep learning segmentation, whole-liver regions were extracted in approximately 10 s. ***Conclusion:*** We developed a deep learning liver segmentation method based exclusively on the use of 18F-FDG PET images. The PET-only segmentation approach offers considerable potential for rapid and stable image analysis, thereby facilitating the accurate evaluation of whole-liver uptake.

M2M Track - Featured Session: Radiopharmaceutical Sciences + Translational Molecular Imaging & Therapy Committee: Combination Therapies in Oncology

OP-645

Combination of Fibroblast Activation Protein (FAP)-targeted Radioligand Therapy with Anti-PD-L1 immunotherapy and Anti-VEGF Therapy

T. Zhao[1], *L. Zhao[1,2], Y. Pang[1,2], V. Jakobsson[1,3], R. P. Baum[3,4], X. Chen[1], J. Zhang[1,3];*
[1]National University of Singapore, Singapore, SINGAPORE, [2]Xiamen University, Xiamen, CHINA, [3]International Centers for Precision Oncology, Wiesbaden, GERMANY, [4]Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.

Aim/Introduction: Fibroblast activation protein (FAP) has emerged as a promising cancer theranostic target, which is highly expressed in cancer-associated fibroblasts (CAFs) in various solid tumours. While FAP has been extensively utilised in diagnostic imaging, recent efforts have focused on optimising FAP-targeted compounds for therapeutic applications. Our group has previously reported such optimised compounds, including strategies like conjugation of an albumin-binding moiety, multimerisation of FAP inhibitors (FAPIs) and peptide cyclisation. When radiolabelled with therapeutic radioisotopes from bench to bedside, these compounds have shown more favourable pharmacokinetics and a better therapeutic effect. We envision an even stronger, synergistic antitumor effect by combining targeted radioligand therapy (RLT) with chemotherapy and/or immunotherapy. In this study, we used a group of optimised FAP peptides and inhibitors with either anti-VEGF (vascular endothelial cell growth factor) or anti-PD-L1 (programmed death-ligand 1) treatment to evaluate the converging force of the combination therapy preclinically. ***Materials and Methods:*** Three FAP compounds were used in this study, including a cyclic peptide, 3BP-3940, a FAP derivative conjugated with a truncated albumin-binding moiety, Evans-blue (EB)-FAPI (LNC1004), and a homodimer, DOTA-2P[FAPI]2. Tumour models were established by inoculating BALB/c mice with transfected CT26 cell lines, overexpressing murine FAP. The mice were randomly grouped (n = 8/group) to receive control, monotherapy or combinational therapy treated using 18.5 MBq 177Lu-3BP-3940 with anti-VEGF; 177Lu-LNC1004 with anti-PD-L1; 177Lu-DOTA-2P[FAPI]2 with anti-PD-L1 and monitored for body weight and tumour size. ***Results:*** The combination therapies were well-tolerated with a better anti-tumour effect than either monotherapy alone. Intravenous administration of single FAP-targeted RLT for the three compounds demonstrated adequate therapeutic effect, as reported previously - the additional anti-VEGF and anti-PD-L1 treatment greatly enhanced tumour suppression. For 177Lu-3BP-3940 and anti-VEGF, we observed enhanced treatment response and 2/8 complete response (CR). For 177Lu-LNC1004 and 177Lu-DOTA-[FAPI]2 with anti-PD-L1, all mice (8/8) achieved CR by day 28 and day 18 post-treatment, suggesting a tremendous tumour eradication efficacy and a synergistic effect, as all mice receiving a control treatment, anti-PD-L1 only or 177Lu-LNC1004 had succumbed to the disease by day 20, 34 and 42 respectively, while 177Lu-DOTA-[FAPI]2 monotherapy-treated mice succumbed on day 30. Remarkably, the immune response persisted when the mice were rechallenged three months post-therapy. ***Conclusion:*** Combining FAP-targeted RLT with anti-PD-L1 and anti-VEGF therapies demonstrated significant promise in FAP-positive tumour-bearing mouse models. With the development of novel compounds for FAP-targeted theranostics, investigating complementary treatment strategies is poised for a new clinical regimen for cancer management.

OP-646

Combination therapy of ^{211}At-labeled RGD peptide with immune checkpoint blockade to enhance anti-tumor efficacy

H. Echigo[1], *M. Munekane[1], T. Fuchigami[1], K. Washiyama[2], K. Mishiro[1], H. Wakabayashi[1], K. Takahashi[2], S. Kinuya[1], K. Ogawa[1];*
[1]Kanazawa University, Kanazawa, JAPAN, [2]Fukushima Medical University, Fukushima, JAPAN.

Aim/Introduction: Targeted alpha therapy (TAT) has gained much attention because of its high therapeutic effects derived from the high linear energy transfer of α-particles. We recently synthesized and evaluated a compound (Ga-DOTA-K(APBA)-c(RGDfK) (1)) for TAT using RGD peptide with 4-(4-astatophenyl)butyric acid (APBA) as an albumin binding moiety. In U-87 MG human glioma cells inoculated BALB/c nu/nu mice, [211At]1 accumulated highly in the tumor and inhibited tumor growth1. Meanwhile, it was reported that a TAT agent could alter the tumor microenvironment and induce antitumoral immune responses, and the combination of a TAT agent with immune checkpoint blockade (ICB) enhanced anti-tumor efficacy2. Thus, we supposed that [211At]1 also induces antitumoral immune responses. In this study, the antitumoral immune responses induced by [211At]1 treatment were evaluated using Colon-26 murine colon cancer cells inoculated BALB/c mice. ***Materials and Methods:*** The biodistribution experiments of [211At]1 and therapeutic experiments by two doses of [211At]1 (370 or 925 kBq) with or without anti-PD-1 antibody (αPD-1, 10 μg/g) were performed in Colon-26 cells inoculated BALB/c mice. Colon-26 cells were subcutaneously reinoculated into BALB/c mice treated with [211At]1 (925 kBq) without αPD-1 to confirm antitumoral immune responses. As a control group, Colon-26 cells were inoculated subcutaneously into BALB/c mice without prior inoculation of Colon-26 cells and treatment of [211At]1. Therapeutic experiments treated with [211At]1 (925 kBq) in Colon-26 cells inoculated BALB/c nu/nu mice were also conducted and compared to the therapeutic effects in BALB/c mice. ***Results:*** [211At]1 was highly accumulated in the tumor (4 h: 7.12±0.95%ID/g) and inhibited tumor growth dose-dependently in Colon-26 cells inoculated BALB/c mice. Colon-26 tumors were not engrafted (6 out of 8 mice) or were remarkably inhibited tumor growth (2 out of 8 mice) in Colon-26 cells reinoculated BALB/c mice after [211At]1 treatment. The effects of inhibiting tumor growth in BALB/c nu/nu mice model were reduced compared to those in BALB/c model. Also, combining [211At]1 (925 kBq) and αPD-1 drastically enhanced anti-tumor efficacy in 2 out of 4 mice and not very effective in 2 out of 4 mice. ***Conclusion:*** These results suggest that [211At]1 could induce antitumoral immune responses, and combination therapy of [211At]1 and ICB could be effective against cancer. ***References:*** 1. H. Echigo et al. Eur J Nucl Med Mol Imaging. 2024. 2. T. Ertveldt et al. J Nucl Med. 2023.

OP-647

The impact of cytotoxic drug type and drug-to-affibody ratio on biodistribution of HER2-targeting affibody-drug conjugates using radiolabeling

A. Vorobyeva[1], *T. Xu[1], R. Li[2], E. Bezverkhniaia[1], M. Oroujeni[1], E. Papalanis[1], A. Orlova[1], T. Gräslund[2], V. Tolmachev[1];*
[1]Uppsala University, Uppsala, SWEDEN, [2]KTH Royal Institute of Technology, Stockholm, SWEDEN.

Aim/Introduction: Affibody molecules are promising for targeted delivery of cytotoxic drugs to cancer due to selective and high-affinity binding to molecular targets. Their fusion to an albumin-binding domain (ABD) extends the half-life in vivo and reduces renal reabsorption. We previously developed an affibody-ABD-drug conjugate (AffiDC) with the maytansinoid DM1 ZHER2-ABD-DM1 targeting human epidermal growth factor receptor 2 (HER2), which demonstrated potent anti-tumor effect in mice bearing SKOV3 xenografts. Comparing the payload DM1 with a clinically relevant deruxtecan (DXD) is of interest. Increasing the payload number from one to three might further improve the anti-tumor efficacy of AffiDCs. The aim of this study was to investigate the impact of a cytotoxic payload type and number, and compare the AffiDC carrying DM1 with the conjugates carrying DXD in vitro and in vivo. ***Materials and Methods:*** AffiDCs were site-specifically radiolabeled using technetium-99m tricarbonyl via N-terminal (HE)3-tag. Binding specificity, affinity and internalization were studied using HER2-overexpressing SKOV3, BT474 and SKBR3 cells. Cytotoxicity was investigated. Biodistribution of [99mTc]Tc(CO)3-labeled AffiDCs was performed in Balb/c nu/nu mice bearing SKOV3 xenografts at 4, 24 and 48 h post-injection. Specificity of tumor targeting was tested in HER2-negative Ramos xenografts. The therapeutic efficacy of ZHER2-ABD-DM1, ZHER2-ABD-DXD, ZHER2-ABD-(DM1)3 and ZHER2-ABD-(DXD)3 was compared at equimolar doses with vehicle control in SKOV3-xenografted mice. ***Results:*** AffiDCs were radiolabeled with radiochemical yield over 75%, purified with 98% radiochemical purity and high label stability. Binding to HER2-overexpressing cancer cells was specific with sub-to-low nanomolar affinity. Internalization by SKOV3 cells varied between 24 to 42% at 24 h. Biodistribution of [99mTc]Tc(CO)3-labeled AffiDCs was characterized by extended half-life in blood and renal clearance. Area Under the Curve (AUC) for tumor uptake was the largest for ZHER2-ABD-DXD, followed by ZHER2-ABD-DM1, ZHER2-ABD-(DXD)3 and the lowest for ZHER2-ABD-(DM1)3. AUCs for hepatic uptake of ZHER2-ABD-DXD and ZHER2-ABD-DM1 carrying single drug molecules were similar and were ca. 2.2-2.5-fold lower than for the conjugates carrying triple drugs. Estimation of uptake in drug equivalents suggested higher potential liver toxicity for triple conjugates. An ongoing therapy study shows effective suppression of tumor growth for all conjugates, however, a higher general toxicity of ZHER2-ABD-(DM1)3 is seen in comparison to the other groups. ***Conclusion:*** Radiolabeling using a residualizing technetium-99m tricarbonyl radiolabel enabled quantitative characterization of AffiDCs in vitro and measurements of uptake in normal organs and tissues in vivo. This allowed for prediction of toxicity and selection of doses for experimental therapy showing promising preliminary results.

OP-648

Evaluation of a Preclinical Radio-Antibody-Drug-Conjugate-^{131}I-HLX-58-Deruxtecan for the Precision Treatment of Gastric Cancer

Y. Liu, *X. Wang, S. Song;*
Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: CLDN18.2 is exclusively present in gastric mucosa and is retained on malignant transformation. Due to the high malignancy of Gastric cancer (GC), we hypothesis to combine therapeutic radionuclide-131I and cytotoxic drug-Deruxtecan with antibody targeting CLDN18.2 to synthesize Radio-Antibody-Drug-Conjugate (RADC). The combination of accurate internal irradiation therapy achieved by 131I and cytotoxicity of Deruxtecan can achieve a dual strike to GC. ***Materials and Methods:*** The antibody HLX-58 targeting CLDN18.2 was humanized to optimize its physicochemical properties such as affinity, stability, immunogenicity and aggregation behavior. We attached topoisomerase I (TopI) inhibitor Dxd to the functionalized antibody through maleimide-GGFG peptide linker with a drug to antibody ratio (DAR) of 2. Further, by labeling 131I on the tyrosine of the HLX-58, we obtained the CLDN18.2 targeting RADC-131I-HLX-58-Deruxtecan. The binding affinity, tumor killing ability, metabolic characteristics and biodistribution were performed in vitro and in vivo. ***Results:*** 131I-HLX-58-Deruxtecan was stable for more than 14 days. 131I-HLX-58-Deruxtecan showed significantly higher uptake in CLDN18.2 high-expression cells than that in CLDN18.2 low-expression cells ($P<0.05$). The required concentration for

HLX-58 to inhibit 50% binding of 131I-HLX-58-Deruxtecan to intracellular CLDN18.2 is 0.19 nM. Remarkable inhibitory activity to the cell growth was observed for 131I-HLX-58-Deruxtecan against NUGC4-CLDN18.2, with the IC50 value of 11.28 ng/mL (131I: 0.148 MBq). We monitored the biodistribution of 131I-HLX-58-Deruxtecan in vivo by SPECT/CT imaging. SPECT/CT imaging of 131I-HLX-58-Deruxtecan showed an increased tumor-to-muscle ratio (T/NT) with the maximum T/NT of 5.49±1.12 at 72 h post-injection for NUGC4-CLDN18.2 tumors (n = 3). The effective dose of 131I-HLX-58-Deruxtecan against tumor in vivo was 5 mg/kg (131I: 0.74 MBq). The results showed that for the treatment group of 131I-HLX-58-Deruxtecan, significant inhibition of tumor growth was observed. Within 24 d, the standard tumor volume of 131I-HLX-58-Deruxtecan was significantly less than other groups. Therefore, the effectiveness of the treatment was demonstrated in our study. Besides, the body weight of 131I-HLX-58-Deruxtecan did not change significantly, indicating the safety of the RADC in vivo. ***Conclusion:*** 131I-HLX-58-Deruxtecan displayed a significant CLDN18.2 positive tumor affinity and effective tumor therapy without significant toxicity. Therefore, the RADC-131I-HLX-58-Deruxtecan could be further investigated in the theranostic field of gastric cancer.

OP-649

Gastrin-releasing peptide receptor as theranostic target in breast cancer. A preclinical study of the theranostic pair [^{55}Co]Co- and [^{177}Lu]Lu-DOTA-RM26

***C. Baun*[1,2],** *B. B. Olsen[1], M. G. Hildebrandt[1,2,3], C. A. Poulsen[1], L. G. Gé[1,2], V. S. Gammelsrød[1,2], A. Orlova[4], J. H. Dam[5,1], H. Thisgaard[1,2];*
[1]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]Department of Clinical Research, University of Southern Denmark, Odense, DENMARK, [3]Center for Personalized Response Monitoring in Oncology (PREMIO), Odense University Hospital, Odense, DENMARK, [4]Department of Medicinal Chemistry, Faculty of Pharmacy, Uppsala University, Uppsala, SWEDEN, [5]Minerva Imaging, Oelstykke, DENMARK.

Aim/Introduction: Patients with advanced metastatic estrogen receptor-positive breast cancer often develop resistance to standard treatments, leading to uncontrolled progression. Thus, innovative therapies are urgently needed. The gastrin-releasing peptide receptor (GRPR) is overexpressed in various cancers, including breast cancer, making it an interesting target for radionuclide therapy. RM26, a GRPR-targeting antagonist, has demonstrated promising in vivo kinetics in prostate cancer models [1]. This study evaluates the theranostic capabilities of [55Co]Co-/[177Lu]Lu-DOTA-RM26 in vitro in estrogen receptor-positive breast cancer cells and assesses the diagnostic potential of [55Co]Co-DOTA-RM26 in vivo in a breast cancer mouse model. ***Materials and Methods:*** We analyzed the binding specificity of [57Co]Co-/[177Lu]Lu-DOTA-RM26 in T47D breast cancer cells, using [57Co]Co-DOTA-RM26 as a surrogate for [55Co]Co-DOTA-RM26. The therapeutic efficacy of increasing concentrations of [177Lu]Lu-DOTA-RM26 was determined via viability assay in vitro. Ex vivo biodistribution of [57Co]Co-DOTA-RM26 (17.2±2.7 kBq, 33±5.2 pmol/ mouse) was investigated in 12 mice (n= 4/group) with orthotopic breast cancer tumors. The mice were sacrificed at 4 and 24 hours post-injection (pi), including a blocking group (20 nmol of unlabeled [Tyr4]-Bombesin) at 4 hours pi. [55Co]Co-DOTA-RM26 PET/CT imaging of tumor-bearing mice was performed at 4 and 24 hours pi (2.8±0.2 MBq, 167.5±0.5 pmol/mouse), ± GRPR blocking. ***Results:*** In vitro studies revealed high, specific cell-associated binding of [57Co]Co-DOTA-RM26 (43±1% of total added activity per 106 cells) and [177Lu]Lu-DOTA-RM26 (37±4% of total added activity per 106 cells). The activity was predominantly localized at the cell surface; 71±3% and 80±6% for [57Co]Co-DOTA-RM26 and [177Lu]Lu-DOTA-RM26, respectively. [177Lu]Lu-DOTA-RM26 significantly reduced cell viability at all activity concentrations >0.625 MBq/ml ($p<0.0001$), with cell viability below 1% at concentrations ≥5 MBq/mL. Biodistribution data indicated a high, specific tumor uptake of [57Co]Co-DOTA-RM26, surpassing all other tissues significantly at both time points, 3.7±0.6% of the injected activity per gram (IA/g) 4 hours pi and 0.98±0.05% IA/g 24 hours pi. The kidneys showed the second-highest uptake (2.0±0.1% IA/g 4 hours pi), followed by the pancreas (1.4±0.4% IA/g 4 hours pi). PET/CT imaging with [55Co]Co-DOTA-RM26 distinctly visualized the tumor 24 hours pi, while other GRPR-expressing tissues cleared over time. Effective GRPR blocking significantly reduced tumor uptake in the PET images 24 hours pi. ***Conclusion:*** These findings suggest that the theranostic pair [55Co]Co-/[177Lu]Lu-DOTA-RM26 holds significant promise as a theranostic agent for estrogen receptor-positive breast cancer. ***References:*** 1. HER2-radioligand therapy using [^{131}I]I-GMIB-2Rs15d combined with olaparib results in prolonged survival in HER2 low expressing preclinical animal models.

J. Dewulf, *L. Navarro, L. Mahmud, N. Dumauthioz, V. Gaspariunaite, M. Miranda Lucero, J. Eersels, A. Pombo Antunes, M. D'Huyvetter;*
Precirix, Brussels, BELGIUM.

Aim/Introduction: Radioligand therapy (RLT) has recently emerged as a promising tool for treating cancer patients. However, the complete treatment response is limited to only a subset of patients; therefore, attempts have been made to improve RLT through combination strategies. Similarly, [131I]I-GMIB-2Rs15d showed therapeutic efficacy only in xenografts expressing high levels of HER2[1]. This study describes the first proof-of-concept combination therapy with [131I]I-GMIB-2Rs15d and Olaparib in HER2 low tumor xenografts. ***Materials and Methods:*** Radiotracer [131I]I-GMIB-2Rs15d was produced as previously described[1]. Human colon cancer DLD-1 and DLD-1-BRCA(-/-) cells (Horizon Discovery) were plated and incubated with [131I]I-GMIB-2Rs15d (1 or 10MBq/mL, for 1h), Olaparib (1µM, 5 days incubation) or a combination of both sequentially. Cell viability was assessed using an ATP assay (Promega), normalized to non-treated cells. To assess pharmacokinetics, tumor-bearing DLD-1-BRCA(-/-) athymic mice (n=3 per time point) were iv injected with [131I]I-GMIB-2Rs15d (~6.5MBq,~5µg), and sacrificed at different timepoints up to 192h pi, after which animals were dissected for ex vivo analysis and dosimetry calculations. For therapeutic efficacy, DLD-1 BRCA(-/-) tumor-bearing athymic mice (n=8) were subjected to single [131I]I-GMIB-2Rs15d (6x37MBq,~20µg), single olaparib (IP injection 50 mg/kg, 28 consecutive days), 0.9% NaCl, or a combination of [131I]I-GMIB-2Rs15d and olaparib (regimen as described above). Survival curves were analyzed using the Log-Rank(MantelCox) test with Holm-Bonferroni correction. ***Results:*** DLD-1 cells showed ~100% at 1µM Olaparib, ~92% at 1MBq/mL or ~77% cell viability at 10MBq/mL [131I]I-GMIB-2Rs15d. No combinatorial effect was observed in DLD-1 cells. DLD-1-BRCA(-/-) showed higher sensitivity with a cell viability of ~65% for 1µM Olaparib and ~85% for 1MBq/mL and ~37% for 10MBq/mL [131I]I-GMIB-2Rs15d. A combination effect was visible with, cell viability of ~45% for

1MBq/mL and ~25% for 10MBq/mL [131I]I-GMIB-2Rs15d with 1µM Olaparib. Long-term biodistribution of [131I]I-GMIB-2Rs15d in DLD-1 BRCA(-/-) xenografts revealed limited tumor uptake (1.47±0.32%IA/g) 1h pi which decreased to 0.14±0.029%IA/g 24h pi. Kidney uptake was high at early timepoints (50.17±4.22%IA/g, 1h pi) but cleared quickly with only 0.54±0.10%IA/g remaining at 24h pi. The combination of [131I]I-GMIB-2Rs15d and olaparib resulted in prolonged survival compared with single [131I]I-GMIB-2Rs15d (p=0.0107), single olaparib (p=0.0022), and 0.9% NaCl (p=0.0009). Dosimetry calculations for the therapeutic regimen showed 5.35Gy for the tumor and 38Gy for the kidney as a dose-limiting organ, without weight loss. Similar fractionated treatment regimens showed no kidney toxicity[2]. ***Conclusion:*** Prolonged survival was observed when treated with a combination of [131I]I-GMIB-2Rs15d with olaparib compared to mono treatment arms in HER2 low expressing tumor xenografted mice. ***References:*** [1]D'Huyvetter,ClinCancerRes,(2017),23(21). $^{123/125}$Iodine labelled-PARP inhibitor-loaded polymeric micelles for combination radio-chemotherapy against triple-negative breast cancer

L. Schäfer[1], *A. Wang[2], A. Florea[1,3], Z. Lu[1], E. Henrard[1], E. M. Buhl[4], M. Frings[5], C. Bolm[5], T. Lammers[2], F. M. Mottaghy[1], A. Morgenroth[1], Q. Peña[2];*
[1]Department of Nuclear Medicine, University Hospital RWTH Aachen, Aachen, GERMANY, [2]Institute for Experimental Molecular Imaging, RWTH Aachen University Hospital, Aachen, GERMANY, [3]Department of Radiology and Nuclear Medicine, Maastricht University Medical Center, Maastricht, NETHERLANDS, [4]Electron Microscopy Facility, Institute of Pathology, RWTH Aachen University Hospital, Aachen, GERMANY, [5]Institute of Organic Chemistry, RWTH Aachen University, Aachen, GERMANY.

Aim/Introduction: Radio-nanomedicine, the combination of nuclear- and nanomedicine, is an emerging strategy in nuclear imaging and therapy. Nanoformulations offer benefits as protection of radiopharmaceutical agents, reduction of hepatic degradation, prolongation of blood circulation time, which finally increase drug´s therapeutic efficacy. BRCA-mutated (BRCAmut) triple-negative breast cancer (TNBC) is commonly treated with poly (ADP-ribose) polymerase inhibitors (PARPi). We have previously developed a therapeutic radiotracer combining the inhibitory effect of PARPi with the radiotherapeutic properties of 125Iodine (125I). Preclinical evaluation of the 125I-PARPi indicated poor biodistribution and tracer instability in vivo, resulting in suboptimal therapeutic outcomes. To improve tracer stability, biodistribution and tumor accumulation, we developed a combined radio-nanoformulation consisting of polymeric micelles co-loaded with radioactive and non-radioactive I-PARPi. ***Materials and Methods:*** Radiolabeling was performed using a tributyltin-precursor with chloramine-T as catalyst. Radioactive and non-radioactive I-PARPi co-loaded polymeric micelles were prepared via nanoprecipitation method. Formulation properties were analyzed by high-performance liquid chromatography (HPLC), dynamic light scattering (DLS) and transmission electron microscopy (TEM). Investigation of the in vivo biodistribution via SPECT/CT and therapeutic efficacy of the radio-nanoformulation was done using human BRCAmut TNBC xenograft models in mice. ***Results:*** Microscopy (TEM) images of co-loaded micelles showed a homogenous size distribution of spherical particles, with diameters around 70nm and polydispersity indices below 0.1, as confirmed by DLS. Encapsulation efficiency of radioactive and non-radioactive I-PARPi was > 80%. Co-loaded micelles showed a similar release profile for both compounds (i.e., 60% released after 48h). Formulation in micelles improved in vitro tracer stability about 10-fold. In vivo SPECT/CT measurements revealed prolonged circulation, higher tumor accumulation and decelerated deiodination of the tracer encapsulated in micelles as compared to the naked tracer. In vivo one-shot therapy with co-loaded micelles showed a significant reduction in tumor volume (> 50%) after 12 days of treatment compared to both the NaCl control group and the corresponding carrier-free PARPi-group. Ex vivo immunohistochemical analysis of the tumors showed characteristic γ-H2AX nuclear foci signal in the group treated with co-loaded micelles. ***Conclusion:*** This newly developed co-loaded micelle formulation showed improved in vivo tracer stability, prolonged blood circulation and cell uptake, resulting in increased therapeutic efficacy in a BRCAmut TNBC model compared to the "naked" application of compounds. Ongoing work involves dose optimization studies to maximize clinical benefit with optimal tolerability. Overall, this dedicated radio-nanoformulation combination allows for precise monitoring and adjustment of drug levels based on imaging, thereby individualizing and improving treatment outcomes.

Radionuclide Therapy Using ^{177}Lu-HER2-BCH Affibody Molecule in Combination with Trastuzumab or Immunotherapy in HER2 High Expression and Resistant Models

J. Liu, *X. Guo, H. Zhu, Z. Yang;*
Department of Nuclear Medicine, Peking University Cancer Hospital & Institute, Beijing, CHINA.

Aim/Introduction: HER2-BCH is a scaffold-protein-based HER2-targeting affibody molecule. The purpose of this study was to evaluate the efficacy of 177Lu-HER2-BCH in HER2 high-expression tumor models, including trastuzumab-resistant models. And to explore its utility in combination with trastuzumab or immunotherapy. ***Materials and Methods:*** In vitro cellular uptake and cytotoxicity assays were performed in HER2-overexpressing N87 cells, while SPECT/CT imaging, biodistribution, and treatment with single 177Lu-HER2-BCH or trastuzumab and combination of both were performed in the HER2 high-expressing gastric cancer patient-derived xenografts (PDX) model. 177Lu-HER2-BCH treatment and combined anti-CD47 immunotherapy were performed in the N87 trastuzumab-resistant model. Maximum dose toxicity monitoring was performed in KM mice for 28 days. ***Results:*** In vitro cellular assays in HER2 high-expressing cells showed significant specific uptake and cytotoxicity of 177Lu-HER2-BCH. High tumor uptake and favorable retention of this tracer in SPECT/CT imaging and biodistribution assays within the HER2 high-expression PDX model. The uptake of 177Lu-HER2-BCH was not replaced by excess trastuzumab, suggesting a different binding site. Compared to the control, 177Lu-HER2-BCH was effective in reducing tumor growth in a dose-dependent manner, with increased efficacy of treatment in combination with trastuzumab. Tumor growth was also significantly inhibited in the drug-resistant model, and the anti-tumor effect of combined anti-CD47 immunotherapy was superior. ***Conclusion:*** Targeted radionuclide therapy with 177Lu-HER2-BCH or in combination with trastuzumab, or immunotherapy is a potential therapeutic strategy for HER2-overexpressing tumors, including trastuzumab-resistant tumors.

Comparative Evaluation of [161Tb]Tb-NeoB and [177Lu]Lu-NeoB for GRPR-mediated Targeted Radionuclide Therapy

L. Bokhout[1], *C. M. Ntihabose[1,2], E. de Blois[1], S. U. Dalm[1]; [1]Department of Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [2]Department of Hospital Pharmacy, Erasmus MC, Rotterdam, NETHERLANDS.*

Aim/Introduction: Targeted radionuclide therapy (TRT) with lutetium-177 labelled molecules has proven to be effective for the treatment of several malignancies. This includes radiopharmaceuticals targeting the gastrin releasing peptide receptor (GRPR), e.g. [177Lu]Lu-NeoB, which is currently in clinical trials for treatment of GRPR-expressing cancers such as breast cancer (BCa) and prostate cancer (PCa). Due to the growing demand of lutetium-177 for TRT, as well as the aim to further improve the efficacy of the therapy, alternative radionuclides are being explored. A promising radionuclide is terbium-161; this radionuclide emits β- radiation similar to lutetium-177, while also emitting auger electrons. Accordingly, we aimed to compare [161Tb]Tb-NeoB and [177Lu]Lu-NeoB for targeting GRPR-expressing cancers. ***Materials and Methods:*** The binding affinity of both [161Tb]Tb-NeoB or [177Lu]Lu-NeoB was assessed by performing an in vitro autoradiography on frozen GRPR-positive human BCa sections (n=3). Tissue slices were incubated with 1nM [161Tb]Tb-NeoB or [177Lu]Lu-NeoB (+/- 1 µM unlabelled NeoB) for 1 hour, exposed to phosphor screens, and read using a Cyclone phosphor imager. Binding of the radiopharmaceuticals was expressed as percentage added dose/mm2 (%AD/mm2) by normalizing the data to standards. Additionally, the uptake of [161Tb]Tb-NeoB and [177Lu]Lu-NeoB was determined in a human GRPR-expressing PCa cell line PC3-PIP. Cells were incubated with 1nM [161Tb]Tb-NeoB or [177Lu]Lu-NeoB (+/- 1 µM unlabelled NeoB) for 1 hour and cellular uptake was determined using a γ-counter, expressed as percentage added dose/200.000 cells (%AD/200.000 cells). ***Results:*** In vitro autoradiography revealed an overall slightly lower binding affinity of [161Tb]Tb-NeoB compared to [177Lu]Lu-NeoB in the same tissue sections, with respective values ranging from 0.020-0.11 %AD/mm2 vs. 0.013-0.15 %AD/mm2. Similarly, the specific uptake of [161Tb]Tb-NeoB was slightly lower but within the same range as that of [177Lu]Lu-NeoB, i.e. 9.16±0.61 vs. 12.02±0.41 %AD/200.000 cells, respectively. ***Conclusion:*** Our studies demonstrate that the binding affinity and specific cellular uptake of [161Tb]Tb-NeoB is slightly lower but still within the same range as that of [177Lu]Lu-NeoB. We have previously observed similar slightly lower specific uptake of terbium-161 labelled compounds directed to different targets, with a yet unknown underlying cause. Further assessment of the cytotoxic effects of [161Tb]Tb-NeoB in comparison to [177Lu]Lu-NeoB are currently ongoing. So far, our observations support the idea that terbium-161 can be a good alternative to lutetium-177 for GRPR-mediated TRT. Our future studies will reveal whether the auger electrons emitted by terbium-161 will benefit GRPR-mediated TRT.

OP-669

A 47Sc-labeled GRPR Antagonist with Superior SPECT Imaging Characteristics Compared to its 177Lu-labeled Counterpart

T. Läppchen[1], *E. Pilatis[1], E. Menéndez[1], A. Bilinska[1], A. D'Onofrio[1], E. Moon[2], M. Zoltowska[3], D. Pawlak[3], I. Cieszykowska[3], R. Mikolajczak[3], F. Rösch[2], A. Rominger[1], E. Gourni[1]; [1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [2]Department of Chemistry - TRIGA site, Johannes Gutenberg University Mainz, Mainz, GERMANY, [3]Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND.*

Aim/Introduction: In view of the increasing importance of targeted radioligand therapy (RLT), apart from new targets and targeting vectors, also novel radionuclides are finding their way in the clinic. While lutetium-177 is commonly used for RLT and therapy monitoring by SPECT, the decay characteristics (208 keV gamma, 11%) lead to limited spatial resolution and longer imaging times. With a half-life of 3.35 days, the beta emitter scandium-47 has recently garnered interest due to its 159 keV gamma (68%), making it suitable for RLT and SPECT. In this comparative study, we report first preclinical data on a gastrin releasing peptide receptor (GRPR) antagonist labeled with scandium-47, and evaluate the in vitro and in vivo performance and imaging characteristics compared to the 177Lu-labeled counterpart. ***Materials and Methods:*** AZZTA5-Pip-D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH2 (LF1) was radiolabeled with lutetium-177 and scandium-47, which was provided by NCBJ/Polatom within PRISMAP. [177Lu]Lu-LF1 and [47Sc]Sc-LF1 were evaluated in vitro (lipophilicity, protein binding, saturation, internalization) on GRPR+ PC3 cells. In vivo studies (SPECT/CT imaging, metabolic stability, biodistribution) were performed on PC3 xenografts. ***Results:*** [177Lu]Lu-LF1 and [47Sc]Sc-LF1 were obtained in >99% radiochemical purity and molar activities up to 38 GBq/µmol. They were stable for a period of 6 days post labeling exhibiting a hydrophilic profile with a LogDoctanol/PBS value of -2.9 and -2.8, respectively. The activity bound to human serum proteins was ~10% in both cases. Both radiotracers showed high affinity for GRPR, with Kd values between 2 and 5 nM. Internalization studies revealed slow internalization with a maximum of 10% at 6h, while at the same time point the specific cell-surface bound uptake was 15-25%. In the in vivo studies, [177Lu]Lu-LF1 and [47Sc]Sc-LF1 exhibited high, retained and specific tumor uptake, with values of 36.5±4.9 and 7.2±1.9 %IA/g and 40.4±5.2 and 5.6±1.2 %IA/g at 4 and 72 h p.i., respectively. The activity from the pancreas was washed out fast (from ~55 to ~13 %IA/g from 1 to 4h p.i. for both tracers). HPLC analysis of the blood indicated formation of three radioactive metabolites. The ex vivo biodistribution

results are well illustrated by SPECT/CT imaging. Importantly, the superior decay characteristics of scandium-47 compared to lutetium-177, was clearly reflected in the higher resolution of the corresponding SPECT images, which were obtained in much shorter time. ***Conclusion:*** [177Lu]Lu-LF1 and [47Sc]Sc-LF1 showed promising potential for RLT due to their high tumor uptake and low background signal. [47Sc]Sc-LF1 demonstrated superior resolution and shorter imaging time for SPECT.

OP-670

Abscopal effect following targeted radionuclide therapy in metastatic melanoma: preclinical studies in a new double-tumor mouse model

M. Delmas[1,2], *N. Harismendy[1], B. Chaussin[1], C. Montemagno[3], J. Durivault[3], E. Miot-Noirault[1], F. Cachin[1], P. Auzeloux[1], A. Dougé[4], P. Rouzaire[4], S. Besse[1], E. Chautard[1,2], E. Jouberton[1,2], D. Michel[1,5], J. Rouanet[1,5];*
[1]UMR 1240 INSERM, Université Clermont Auvergne, Imagerie Moléculaire et Stratégies Théranostiques, Clermont-Ferrand, FRANCE, [2]Centre Jean Perrin, Clermont-Ferrand, FRANCE, [3]Centre Scientifique de Monaco, Monaco, FRANCE, [4]CHU Gabriel-Montpied, Clermont-Ferrand, FRANCE, [5]Service de Dermatologie et d'Oncodermatologie, CHU Estaing, Clermont-Ferrand, FRANCE.

Aim/Introduction: The radiopharmaceutical 131I-ICF01012, targeting intra- and extracellular melanin, was developed for targeted radionuclide therapy (TRT) of metastatic melanoma. Promising preclinical results in reducing tumour growth and improving survival have led to an ongoing Phase 1 clinical trial (NCT03784625)1. However, one of the limitations of 131I-ICF01012 is its ability to target only pigmented metastases, whereas pigmented and non-pigmented metastases may coexist in the same patient. The abscopal effect is an immunological phenomenon occurring after external radiotherapy and resulting in the metastases regression outside the irradiated target tumour. This effect, although suspected, has never been demonstrated for TRT, but if there is an abscopal effect induced by the use of 131I-ICF01012, it could enable the non-pigmented metastases immunological decrease. In this study, we aim to demonstrate this possible abscopal effect. ***Materials and Methods:*** To study the immunological mechanisms linked to this effect, we developed a new murine C57BL6/J double pigmented (B16-OVA) and non-pigmented tumour (B16-OVAmTYR-/-) model for treatment with 131I-ICF01012. This model made it possible to transpose clinical observations into a preclinical model. Moreover, two single-tumour models, one pigmented (B16-OVA) and one unpigmented (B16-OVAmTYR-/-), were used for control purposes. ***Results:*** After tumour growth and pigmentation characterization, imaging and biodistribution studies confirmed a 131I-ICF01012 accumulation in the pigmented tumour and an absence of binding in the non-pigmented tumour. In this double-tumour mouse model, 131I-ICF01012 significantly decreased the non-pigmented tumour volume 9 days after TRT injection. Immunofluorescence and transcriptomics studies showed a trend towards increased CD8+ T cells markers 6 days after treatment in the non-pigmented tumour of the double tumour model. ***Conclusion:*** Firstly, results showed it is possible to study the abscopal effect by inhibiting a target of interest, and this method can be extrapolated to other studies. Secondly, these results were the first to demonstrate the possibility of an abscopal effect in a pre-clinical model of pigmented and non-pigmented double-tumour melanoma after TRT with 131I-ICF01012. Finally, this project demonstrated the proof-of-concept of a double tumor model, one carrying the target and the other not, for the study of the abscopal effect following TRT. ***References:*** 1 Thivat, E et al. Discovery of [^{177}Lu]Lu-EVS459, a novel low-molecular weight radioligand therapy for the treatment of folate receptor positive cancers

J. Reber, *G. Birindelli, S. Bongarzone, S. Cameron, D. Camporese, R. Chawla, M. Collin-Kroepelin, L. Dharmarajan, R. Ducray, I. Hanna, S. Hindupur, P. Klein, M. Kurz, V. Mainero, Q. Nguyen, M. Reschke, A. Short, Q. Simmons, F. Zecri, P. Holzer;*
Novartis Pharma AG, Basel, SWITZERLAND.

Aim/Introduction: Folate receptor (FR) α is a GPI-anchored protein present at the cell membrane and overexpressed in several types of epithelial cancers including ovarian, endometrial, lung and breast cancers. Due to its highly restricted expression in normal tissues, FRα is an attractive target for anti-cancer therapies, as demonstrated with the antibody-drug conjugate mirvetuximab soravtansine, recently approved by the FDA for the treatment of FRα-positive ovarian cancer. We report herein the discovery and preclinical characterization of [177Lu]Lu-EVS459 (alternative name GIZ943), a novel radioligand therapeutic targeting the FR, as well as [68Ga]Ga-EVS459, an associated PET radioligand for detection of FR-positive solid tumors. ***Materials and Methods:*** The drug precursor EVS459, composed of DOTA conjugated to a folic acid derivative via an optimized spacer, was radiolabeled with either lutetium-177 or gallium-68. Both [177Lu]Lu-EVS459 and [68Ga]Ga-EVS459 were evaluated in vitro in IGROV-1 cells for their binding affinity to FRα and specific cell uptake. The biodistribution, dosimetry, and anti-tumor activity of [177Lu]Lu-EVS459 was tested in two NSCLC PDX mouse models expressing different levels of FRα. SPECT/CT imaging was performed, and anti-tumor activity was measured over a 12-week period. In addition, the biodistribution of [68Ga]Ga-EVS459 was evaluated in tumor-bearing mice using PET imaging. ***Results:*** [177Lu]Lu-EVS459 and [68Ga]Ga-EVS459 demonstrated similar binding affinity and specificity to FRα in vitro. In tumor-bearing mice, [177Lu]Lu-EVS459 showed significant tumor uptake as visualized by SPECT imaging (24 hrs p.i.) and achieved tumor regression at a dose of 37 MBq q6w. The treatment was well tolerated, and all animals were still alive at the end of the 12-week observation period. PET images obtained 2 hrs after injection of [68Ga]Ga-EVS459 showed significant uptake in tumors and kidney, where FRα is expressed in the renal proximal tubules. ***Conclusion:*** We disclose the discovery and identity of lutetium-177 or gallium-68 radiolabeled EVS459, a novel low-molecular weight FR-targeting radiopharmaceutical. Preclinical evaluation of [177Lu]Lu-EVS459 supports its clinical development as a radioligand therapy targeting FR-positive tumors in patients. A phase 1 study is ongoing to evaluate the safety, tolerability, dosimetry, and preliminary anti-tumor activity of [177Lu]Lu-EVS459, as well as the safety and PET imaging properties of [68Ga]Ga-EVS459, see reference. ***References:*** Study Details | A Phase I Study of [177Lu]Lu-EVS459 in Patients With Ovarian and Lung Cancers | ClinicalTrials.gov

Targeted radionuclide therapy of ovarian cancer stem cells with Terbium-161

J. Grünberg[1], *T. Todorov[1], R. Coelho[2], S. Dellea[1], F. Jacob[2], V. Heinzelmann-Schwarz[2,3], P. V. Grundler[1], N. P. van der Meulen[1,4], R. Schibli[1,5], M. Béhé[1], M. Grzmil[1];*
[1]Paul Scherrer Institut, Center for Radiopharmaceutical Sciences

ETH-PSI-USZ, Villigen PSI, SWITZERLAND, [2]Ovarian Cancer Research, Department of Biomedicine, University Hospital Basel, and University of Basel, Basel, SWITZERLAND, [3]Department of Gynecology and Gynecological Oncology, Hospital for Women, University Hospital Basel, Basel, SWITZERLAND, [4]Paul Scherrer Institut, Laboratory of Radiochemistry, Villigen PSI, SWITZERLAND, [5]Department of Chemistry and Applied Biosciences, ETH Zurich, Zurich, SWITZERLAND.

Aim/Introduction: Previously we have shown that the L1 cell adhesion molecule (L1CAM) in combination with CD133 defines a new ovarian cancer stem cell population (OCSC) with high resistance towards ionizing radiation. L1CAM was mainly responsible for the radioresistance of this cell population (1). Based on these results, we asked whether the in vivo efficacy of an anti-L1CAM radioimmunotherapy (RIT) against human OCSC using terbium-161 (161Tb) is sufficient, to eradicate these cells. We compared the 161Tb anti-L1CAM RIT with Lutetium-177 (177Lu) RIT in an OCSC xenograft model. Furthermore, to investigate L1CAM-associated radioresistance we explored L1CAM-regulated signalling pathways in OC cells. ***Materials and Methods:*** Immunofluorescence staining for L1CAM and CD133 was performed to confirm the presence of L1CAM+/CD133+ CSC in HGSOC patient samples. Cell uptake, and radiocytotoxicity of 161Tb- and 177Lu-labelled anti-L1CAM mAb chCE7 were analyse by MTT tests in OC cells. L1CAM+/CD133+ OCSCs were isolated via fluorescence-activated cell sorting (FACS) from OC cell lines and inoculated into CD-1 immunodeficient mice. Radioimmunotherapy with 80% MTD of [161Tb]Tb-DOTA-chCE7 and [177Lu]Lu-DOTA-chCE7 were performed to study the potential of 161Tb to eradicate CSCs compared to 177Lu. Proteomics and phosphoproteomics studies of L1CAM and L1CAM knockout OC cells were conducted to reveal L1CAM-associated signalling pathways, in particularly those involved in the radioresistance mechanisms. ***Results:*** In chemonaïve and relapse OC patient samples we found 0.3%-21% of L1CAM+/CD133+ cells. RICs showed similar uptake of 50%-75% in all tested OC cell lines. The 161Tb-labelled RIC resulted in significantly increased cytotoxicity in vitro with Log IC50 ± SD of -0.52 ± 0.61 (0.3 MBq/mL) for 161Tb, vs. 1.07 ± 0.13 (11.8 MBq/mL) for 177Lu in OVCAR8 and 0.68 ± 0.38 (4.8 MBq/mL) vs. 1.28 ± 0.23 (19.0 MBq/mL) in SKOV3ip cells. [161Tb]Tb-DOTA-chCE7 eradicated all tumour cells in vivo including the L1CAM+/CD133+ ovarian CSCs resulting in no tumour progression. In contrast, 177Lu was not sufficient to eradicate the CSCs. Phosphoproteomics profiling provided evidence, that L1CAM regulates phosphorylation of proteins involved in DNA damage response, and mTORC1-signalling pathways in OC cells. ***Conclusion:*** Anti-L1CAM 161Tb-based RIT represents a novel therapeutic option for CSC-targeted therapies and is a promising treatment strategy for clinical use. The higher radiotoxicity of 161Tb caused by the additional emission of Auger-electrons is sufficient to eradicate single cells. This property of 161Tb is an encouragement for the management of minimal residual disease. Further validation of the data related to L1CAM-mediated radioresistance regulation is underway. ***References:*** (1) Cancers 2020, 12, 217

Preclinical characterization of a phage display derived MT1-MMP-specific bicyclic peptide for radiotheranostic application

A. Eder[1,2], *A. R. Regupathy[3], M. El Fakiri[1,2], L. Domogalla[1,2], N. Steinacker[1,2], L. Uhlmann[1,2], J. Lahdenranta[4], B. Blakeman[3], F. Wood[3], P. T. Meyer[1,2], P. Huxley[3], G. E. Mudd[3], M. Eder[1,2];*

[1]University Medical Center Freiburg, Freiburg, GERMANY, [2]German Cancer Consortium (DKTK), partner site Freiburg, Freiburg, GERMANY, [3]BicycleTx Limited, Cambridge, UNITED KINGDOM, [4]Bicycle Therapeutics, Cambridge, MA, UNITED STATES OF AMERICA.

Aim/Introduction: Tumor-associated membrane type 1 matrix metalloproteinase (MT1-MMP) plays a particular role in extracellular matrix remodeling, resulting in metastatic dissemination. MT1-MMP expression is further associated with poor prognosis in a variety of cancers (e.g. non-small cell lung cancer, gastric and breast cancer). This study identifies and preclinically characterizes a phage display-derived MT1-MMP-targeting bicyclic peptide to investigate the clinical potential as theranostic agent. ***Materials and Methods:*** The MT1-MMP-targeting bicyclic peptide BCY25286 was radiolabeled with Ga-68 or Lu-177, respectively, and preclinically characterized with regard to stability, binding affinity to MT1-MMP and internalization properties. Subsequently, an organ distribution study (up to 24 h post injection (p.i.)) and µPET/MR imaging were performed using MT1-MMP+ HT1080 tumor-bearing nude mice. ***Results:*** Radiolabeling of BCY25286 resulted in radiochemical yields and radiochemical purity >99 % for both radionuclides, Ga-68 and Lu-177. The compound showed proteolytic stability in human and mouse serum up to 72 h. Besides MT1-MMP specific internalization a high binding affinity to MT1-MMP of 7.2 ± 1.6 nM was detected in vitro. Organ distribution studies revealed a significant MT1-MMP-specific tumor uptake of 10.6 ± 1.1 %ID/g at 1 h p.i. which was persistent up to 24 h p.i.. BCY25286 exhibited fast background clearance (< 1 %ID/g for all organs except the kidneys) resulting in high imaging contrast in µPET/MRI as early as 30 minutes p.i.. ***Conclusion:*** Aiming at tailor therapeutic strategies, MT1-MMP targeting bicyclic peptides might be a valuable tool for advanced radiotheranostic applications. Thus, the bicyclic peptide BCY25286 presenting high and specific tumor uptake with fast pharmacokinetic properties encourages further translational research for future clinical PET imaging and therapeutic management of patients.

^{225}Ac-labeled anti-EGFR antibody drug radioconjugate elicits durable anti-tumor responses in mouse models of colorectal cancer

F. Tikum, *N. Henning, A. Doroudi, J. Ketchemen, H. Babeker, F. Njotu, A. Monzer, E. Nwangele, M. Uppalapati, B. Gray, E. Torlakovic, H. Fonge;*
University of Saskatchewan, Saskatoon, SK, CANADA.

Aim/Introduction: Overall survival of colorectal cancer (CRC) is poor because almost half of patients present with metastatic disease (stage III - IV) at initial diagnosis. About 85% of colorectal cancer (CRC) patients overexpress epidermal growth factor receptor (EGFR) with about 40% or 10% having KRAS or BRAF mutation, respectively. Here, we propose a theranostic approach that uses an anti-EGFR antibody-drug conjugate (ADC) radiolabeled with either 225Ac or 89Zr for therapy and imaging of KRAS-mutant/BRAF mutant EGFR-positive CRC mouse models. ***Materials and Methods:*** The ADC was developed by conjugating nimotuzumab to PEG6-DM1. Eighteen-membered macrocyclic bifunctional chelator p-Bz-SCN-macropa or deferoxamine (DFO) were used to conjugate nimotuzumab-PEG6-DM1 or matuzumab for radiolabeling with 225Ac and 89Zr, respectively. The immunoconjugate and radioimmunoconjugates were characterized by flow cytometry, bioanalyzer, radioligand binding assays, HPLC and internalization rate (live-cell imaging). In vivo

efficacy of [225Ac]Ac-Macropa-nimotuzumab-PEG6-DM1 was evaluated in mice bearing KRASG13D mutant DLD-1 or BRAFv600E mutant HT-29 xenografts. Dosimetry of [225Ac]Ac-Macropa-nimotuzumab-PEG6-DM1 was studied in healthy Balb-c mice. Tumor growth was monitored using digital caliper. Mice were treated with three doses of 350 nCi/dose administered 10 days apart. In vivo study endpoint was tumor volume >= 1500 mm3. ***Results:*** [225Ac]Ac-Macropa-nimotuzumab-PEG6-DM1 showed enhanced in vitro cytotoxicity compared with nimotuzumab-PEG6-DM1. [225Ac]Ac-Macropa-nimotuzumab-PEG6-DM1 extended the survival of mice in all tested xenografts compared to the control groups. For HT-29, the median survival was not reached for the 225Ac treated group while it was 24.5 and 39 days for the saline and nimotuzumab-PEG6-DM1 treated groups, respectively. Similar trends were observed for other xenografts. PET imaging before and after treatment of the orthotopic xenograft showed that 1/5 mice from the treatment group had complete remission and the agent prevented metastatic spread in the other mice (4/5), as compared with untreated mice. The results showed [225Ac]Ac-nimotuzumab-PEG6-DM1 was effective against KRASG13D and BRAFV600E mutant CRC models. ***Conclusion:*** [225Ac]Ac-Macropa-nimotuzumab-PEG6-DM1 is very effective against EGFR-positive CRC models and warrants further investigation. ***References:*** 1. Evaluation of Anti-uPAR Antibody as a Radiopharmaceutical for Imaging and Treatment of Solid Tumors

R. Nair, *A. Cittadine, E. Kawamoto, A. Kelly, C. Robinson;*
Monopar Therapeutics, Wilmette, IL, UNITED STATES OF AMERICA.

Aim/Introduction: MNPR-101 is a humanized monoclonal antibody to the urokinase plasminogen activator receptor (uPAR). uPAR is over-expressed in multiple aggressive cancers, while it is rarely expressed in healthy tissue. uPAR has a pivotal role in cancer growth, invasion, and metastasis, rendering it a promising target for cancer diagnosis and therapy. MNPR-101 has high selectivity and affinity for uPAR. We conducted preclinical evaluation of MNPR-101 as a radiopharmaceutical agent for imaging and therapy in solid tumors. A first-in-human Phase 1 PET imaging study in advanced cancer patients was recently initiated. ***Materials and Methods:*** MNPR-101 was conjugated to a bifunctional chelator and labeled with zirconium-89 (89Zr) for PET imaging, and with lutetium-177 (177Lu) or actinium-225 (225Ac) for therapy. For preclinical evaluation, human cell lines of triple-negative breast and pancreatic cancer were cultured and injected subcutaneously in athymic nude mice to grow xenograft tumors. After administration of 89Zr labeled agent (~250 µCi), PET scans were performed at multiple time points. Ex-vivo biodistribution was measured using a gamma counter after the terminal imaging time point. Human absorbed dose estimates were predicted using data from this pre-clinical mouse study. After single dose administration of 177Lu (~100 - 250 µCi) or 225Ac (~100 nCi) labeled MNPR-101, mice were monitored for tumor growth and survival for 90 days. SPECT imaging of mice receiving 177Lu labeled agent was performed at multiple time points after drug administration. ***Results:*** MNPR-101 is highly specific for uPAR. Whole-body PET imaging of mice bearing uPAR expressing tumors showed high and selective uptake of the 89Zr-labeled antibody in the tumors. Ex-vivo distribution analysis confirmed that the tumors exhibited high uptake relative to blood and other organs. The animals did not show any reaction to the antibody or radiation-induced toxicities, and the absorbed dose estimates in humans are well within safety limits. Efficacy data using 177Lu or 225Ac labeled MNPR-101 showed near complete elimination of established tumors after a single injection of the agents. SPECT imaging of 177Lu labeled agent showed high specificity and durable tumor uptake relative to normal tissue. ***Conclusion:*** These preclinical studies support the development of MNPR-101-89Zr as a radio-diagnostic and the recently initiated first-in-human PET imaging study in various cancers. It also serves as a basis for future therapeutic studies using an actinium-225 (225Ac) or lutetium-177 (177Lu) labeled version of MNPR-101. Overall, the data show that MNPR-101 is a promising theranostic anti-cancer candidate for cancer treatment.

Preclinical development of FL-091, a novel NTSR1 targeting radionuclide drug conjugate for the treatment of NTSR1-positive cancers

J. Zhang[1], *J. Yang[1], F. Liu[1], N. C. L. Wong[1], K. T. Thrane[2], M. W. Hallund[2], R. V. Grønlund[2];*
[1]Full-Life Technologies, Shanghai, CHINA, [2]Minerva Imaging ApS, Ølstykke, DENMARK.

Aim/Introduction: Neurotensin receptor 1 (NTSR1) belongs to the family of neurotensin receptors, which is the primary mediator of neurotensin signaling due to its sub-nanomolar affinity to its natural ligand. Overexpression of NTSR1 is associated with disease progression of multiple types of cancers, making it a promising target for diagnostic imaging and radionuclide drug conjugate (RDC) therapy. This study evaluated the preclinical characteristics of a novel NTSR1-targeted RDC, 177Lu-FL-091, which demonstrated favorable biodistribution profiles and encouraging anti-tumor activity in various tumor models. ***Materials and Methods:*** Protein expression of NTSR1 was evaluated by immunohistochemistry in tissue microarrays from tumor biopsies covering a variety of cancer types. Binding affinity against NTSR1 and internalization of 111In-labeled compounds were evaluated in NTSR1-epxressing HCT116 cells. The biodistribution profiles of 177Lu-labeled compounds were characterized by SPECT/CT and ex vivo biodistribution assays in mice bearing AsPC1 pancreatic cancer xenografts. The anti-tumor activities of 177Lu-labeled compounds were assessed in a set of NTSR1 expressing cancer xenograft models. ***Results:*** The NTSR1 positive rate ranged from 10.7% to 54.3% across different indications, with the highest rate in head and neck cancer and highest H-score in colorectal cancer. 111In-FL091 potently bound to NTSR1-expressing HCT116 cells with high internalization rate observed. High and sustained tumor uptake was shown for 177Lu-FL-091 in AsPC1 xenograft model with a fast clearance in normal organs. 177Lu-FL-091 demonstrated an improved biodistribution profile compared with industry reference 177Lu-3BP-227, with a 2-fold higher tumor radiation load and 2 to 4-fold higher tumor to normal organ ratios. Moreover, 177Lu-FL-091 exhibited promising in vivo anti-tumor activity in multiple xenograft models. In the PC-3 model (AR and PSMA expression negative), a single dose of 177Lu-FL-091 at 37 MBq induced >30% tumor shrinkage in all treated mice. In AsPC-1 and HT-29 models, a single dose of 177Lu-FL-091 at 37 MBq resulted in superior anti-tumor activity compared with 177Lu-3BP-227 ($p<0.05$) at the same dose level.

Efficacy in all models was achieved without negatively affecting body weight and the treatment was well tolerated at dose levels up to 148 MBq, suggesting a favorable safety profile of 177Lu-FL-091. ***Conclusion:*** NTSR1 was highly expressed across multiple types of cancers, especially in head and neck and colorectal cancer. These data, along with the encouraging anti-tumor activity observed across in vivo models, suggest that 177Lu-FL-091 is a promising RDC candidate for the treatment of NTSR1-positive cancers. Studies to investigate FL-091 conjugated to the radionuclide Actinium-225 are in progress.

Enhanced Lung Cancer Survival Prediction via Semi-Supervised Learning and Pseudo-Labeling Applied to Diverse PET/CT Data Sources

M. Salmanpour[1,2], *R. Yuan[2,3], A. Rahmim[1,2];*
[1]Department of Integrative Oncology, BC Cancer Research Institute, Vancouver, BC, CANADA, [2]Department of Radiology, University of British Columbia, Vancouver, BC, CANADA, [3]BC Cancer, Vancouver Center, Vancouver, BC, CANADA.

Aim/Introduction: The high mortality and low survival rates associated with lung cancer (LCa) highlight the critical need for precise survival predictions to customize treatment plans. This study explores using diverse datasets from various diseases, like head and neck cancer (HNCa), in a semi-supervised model employing pseudo-labeling to enhance prediction accuracy by addressing dataset size limitations. It contrasts these methods with traditional models that only use LCa data. The study applies machine learning (ML) techniques to both Handcrafted and Deep Radiomic Features (HRF and DRF) from PET and CT images to improve survival predictions for LCa patients. ***Materials and Methods:*** 221 LCa patients with both PET & CT images, obtained from The Cancer Imaging Archive (TCIA) and our local database, alongside 408 HNCa with PET & CT images from TCIA, underwent registration, SUV correction, clipping, and normalization. We enhanced risk modeling with two frameworks implemented within ViSERA software (visera.ca): 215 HRFs from PySERA, and 1024 DRFs from an Autoencoder's bottleneck layer, applied to primary tumors. Supervised and semi-supervised techniques were used to predict overall survival outcomes, categorizing them into two classes: class 1, alive after two years (averaged death time in LCa dataset), and class 2, deceased within two years of diagnosis. The supervised approach employed a Principal Component Analysis (PCA) algorithm combining three classifiers—Multilayer Perceptron (MLP), Support Vector Machines, and K-nearest neighbors (KNN)—on both HRF and DRF sets. Meanwhile, the semi-supervised method expanded the dataset by incorporating 408 pseudo-labeled HNCa cases alongside 221 LCa cases, applying identical ML methods. A Random Forest algorithm was used to label the HNCa cases based on training data, which were then included in the training dataset for further use. Datasets were divided into 80% for five-fold cross-validation (FFCV) and 20% for external nested testing, optimizing algorithms through grid search. ***Results:*** ML systems employed in the semi-supervised approach significantly outperformed the supervised approach (p-value<0.05, paired t-test). In semi-supervised approach, the best averaged FFCV accuracy of 0.85±0.05 with external nested testing of 0.80±0.01 was obtained by DRFs extracted from PET, linked with PCA+MLP. By contrast, in supervised approach, the highest averaged FFCV accuracy of 0.65±0.08 with external nested testing of 0.64±0.06 was obtained by DRFs extracted from CT, linked with PCA+KNN. ***Conclusion:*** We showed that semi-supervised approach integrating HNCa datasets with labeled LCa data, linked with HRFs/DRFs from PET/CT images significantly outperformed traditional supervised learning in predicting LCa patient survival (p-value<0.05, paired t-test)

OP-678

Are early and delta radiomic features more useful to predict prognosis in locally advanced cervical cancer patients than baseline radiomic features?

A. Florit[1], *W. A. Noortman[2], E. Pfaehler[3], R. Boellaard[4], M. G. Ferrandina[5,6], L. F. de Geus-Oei[7], S. Annunziata[1], V. Rufini[1,8], F. H. P. van Velden[7], A. Collarino[1];*
[1]Nuclear Medicine Unit, Department of Radiology, Radiotherapy and Haematology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY, [2]Department of Medical Oncology, Groningen University Medical Center, Groningen, NETHERLANDS, [3]Department of Nuclear Medicine, University Hospital Augsburg, Augsburg, GERMANY, [4]Department of Radiology and Nuclear Medicine, Amsterdam UMC – Location VU University Medical Center, Amsterdam, NETHERLANDS, [5]Department of Woman and Child Health and Public Health, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY, [6]Section of Obstetrics and Gynaecology, Department of Life Science and Public Health, Università Cattolica del Sacro Cuore, Rome, ITALY, [7]Section of Nuclear Medicine, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS, [8]Section of Nuclear Medicine, Department of Radiology, Radiotherapy and Haematology, Università Cattolica del Sacro Cuore, Rome, ITALY.

Aim/Introduction: This study investigated whether radiomic features extracted from $^{[18F]}$FDG PET scans acquired before treatment (baseline) and after 2 weeks of neoadjuvant treatment (early), and the variation between the two timepoints (delta), could predict prognosis in locally advanced cervical cancer (LACC) patients treated with neoadjuvant chemo-radiotherapy (CRT) followed by surgery. ***Materials and Methods:*** We retrospectively reviewed medical records of patients with LACC referred to the Gynaecologic Oncology Unit of Gemelli IRCCS between July 2010 and July 2016. The following patients' characteristics were retrieved: age, FIGO stage, histotype, tumour grade, pathological residual disease after surgery and pelvic nodal involvement. $^{[18F]}$FDG-PET/CT was performed before neoadjuvant CRT (baseline) and 2 weeks after the start of treatment (early). Radiomic features were extracted after semi-automatic delineation of the primary tumour, on baseline and early PET images, with a background-corrected 50% isocontour of the SUVpeak. In addition, delta radiomics were calculated as the relative differences between baseline and early features. Patients were split into a training (n=76, 80%) and test cohort (n=19, 20%). We performed 5-fold cross validation stratified for the outcomes (recurrence and cancer-specific death), integrating dimensionality reduction of the radiomic features using redundancy filtering (threshold: 0.8) and variable hunting with importance within the folds. After supervised feature selection, we built for each timepoint a radiomic model with the best-performing features; clinical models (based on patients' clinical characteristics) and combined

clinico-radiomic models were also built. Model performances are presented as test cohort C-indices, for prediction of recurrence/progression (disease-free survival, DFS) and cancer-specific death (overall survival, OS). ***Results:*** 95 patients were included. With a median follow up of 76.0 months (95% CI: 59.5-82.1), 31.6% of patients had recurrence/progression and 20.0% died of LACC. None of the models could predict DFS (C-indices ≤ 0.70). Model performances for OS yielded slightly better results, with mean C-indices of 0.75 for both the radiomic and combined model based on early features, 0.79 and 0.78 for the radiomic and combined model derived from delta features, and 0.74 for the clinical models. ***Conclusion:*** $^{[18F]}$FDG PET early and delta radiomic features could not predict DFS in patients with LACC treated with neoadjuvant CRT followed by surgery. Although slightly improved performances for the radiomic and combined models were observed in the prediction of OS compared to the clinical model, the added value of these information seems to be limited, compared to the challenging process of feature extraction.

OP-679

A new evaluation of whole-mount Gleason grading in prostate cancer for identifying radical prostatectomy candidates: a multiomics study using machine learning

J. Ning, *C. Spielvogel, D. Haberl, K. Trachtova, S. Stoiber, S. Rasul, V. Bystry, G. Wasinger, E. Gurnhofer, G. Timelthaler, M. Schlederer, L. Papp, B. Grubmüller, S. Shariat, M. Hacker, A. Haug, L. Kenner;*
Christian Doppler Lab for Applied Metabolomics, Vienna, AUSTRIA.

Aim/Introduction: In the clinical setting, the decision on whether prostate cancer (PCa) patients undergo the radical prostatectomy (RP) depends on the whole mount Gleason grading (GG) predicted by biopsy proven Gleason Score (bxGS). However, there is a huge discrepancy between bxGS and whole mount GG after RP. Therefore, a more effective approach for evaluating whole-mount GG is essential to accurately determine candidates for RP. Our study aims to evaluate the accuracy of a multiomics-based machine learning (ML) model in grading GG in PCa and compare its effectiveness against bxGG. ***Materials and Methods:*** In this side study, 146 PCa patients from a prospective clinical trial (NCT02659527) were analyzed. These patients had undergone integrated 68Ga-PSMA-11 positron emission tomography (PET)/magnetic resonance (MR) prior to RP from May 2014 to April 2020. The multiomics ML model was developed using radiomics features from PET/MR images, genomics features from whole exome sequencing, and pathomics features from immunohistochemical staining of 11 biomarkers. Five ML models were then built and tested through 100-fold Monte Carlo cross-validation. ***Results:*** Of the five ML models, the random forest (RF) model achieved the highest area under the curve (AUC). It outperformed the bxGG in AUC (0.87 vs. 0.75), specificity (0.72 vs. 0.61), positive predictive value (0.79 vs. 0.75), and overall accuracy (0.78 vs. 0.77), although it had a slightly lower sensitivity (0.83 vs. 0.89) and negative predictive value (0.80 vs. 0.81). In terms of feature importance, bxGG was the most critical, followed by pathomics, clinical, radiomics, and genomics features. The top individual features were bxGG, PSA staining, and an intensity-related radiomics feature. A surrogate model was developed to create a simplified diagnostic process that mirrors the more complex ML model (Randdom Forest). This streamlined diagnostic approach incorporated three features—GLCM_Joint Energy, PSAmax_IHC, and bxISUP—achieving an area under the curve (AUC) of 0.89 in approximating the output of the intricate ML model. ***Conclusion:*** The multiomics-based ML model proved more effective than traditional bxGG in assessing whole-mount GG in PCa, enhancing the ability to tailor management strategies for low-risk patients to avoid unnecessary treatment. ***References:*** 1. Predicting PD-L1 expression and survival in NSCLC through deep learning incorporating non-invasive measurements and multi-modal PET/CT fusion

R. Da-ano[1], *O. Tankyevych[2], C. Cheze Le Rest[2], D. Visvikis[1];*
[1]INSERM - DR GRAND OUEST/ LaTIM U1101, Brest, FRANCE,
[2]Nuclear Medicine, University Hospital of Poitiers, Poitiers, FRANCE.

Aim/Introduction: The approved diagnostic biomarker for immunotherapy in lung cancer is Programmed Death-Ligand 1 (PD-L1), assessed through immunohistochemical assays. However, challenges arise from the invasive sampling and intertumoral heterogeneity associated with the tumor proportion score (TPS) of PD-L1. There is therefore a significant interest for the non-invasive measurement of PD-L1 expression signature using imaging techniques. We have previously shown that artificial intelligence (AI) models using a combination of computed tomography (CT) and positron emission tomography (PET) images can predict the status of PD-L1. Our hypothesis in this work is that combining deep learning features and hand-crafted radiomics can improve the model's performance. ***Materials and Methods:*** We used the PET and CT scans of 189 non-small cell lung cancer (NSCLC) patients with PD-L1 status and employed three (PET/CT early fusion features, radiomics features and the combination of both) data pipelines as separate inputs in the constructed classifier for the prediction and evaluation tasks. The deep learning multi-modal early fusion features were obtained using a 3D ResNet model. Models were assessed utilizing areas under the receiver operating characteristic curves (AUCs) considering 95% confidence interval (CI). ***Results:*** The combined model demonstrated the best performance with an AUC of 0.89 (95% CI, 0.88-0.94) for PD-L1 prediction in the testing cohort. Moreover, training the combination model on multi-source features yielded superior overall survival evaluation performance (C-index: 0.86) compared to using radiomics (C-index: 0.81) and deep features features (C-index: 0.76). ***Conclusion:*** A non-invasive assessment leveraging deep learning with multi-modal PET/CT fusion combined with the use of hand-crafted radiomics features provides the best performance in non-invasive image based PD-L1 expression prediction in NSCLC. ***References:*** Toshiaki Takahashi, Akiko Tateishi, Andrey Bychkov,and Junya Fukuoka, "Remarkable alteration of PD-L1expression after immune checkpoint therapy in patientswith non-small-cell lung cancer: two autopsy case re-ports," International Journal of Molecular Sciences,vol. 20, no. 10, pp. 2578, 2019.and Junya Fukuoka, "Remarkable alteration of PD-L1expression after immune checkpoint therapy in patientswith non-small-cell lung cancer: two autopsy case re-ports," International Journal of Molecular Sciences,vol. 20, no. 10, pp. 2578, 2019.

Predictive Efficacy of a Radiomics Random Forest Model to Characterize Growth Potential of Neuroendocrine Cancer Lesions on 68Ga-DOTATATE PET

A. Dupuis[1,2,3], *G. Richard[2,4], E. Croteau[2,4], Y. Collin[5], B. Guérin[1,2,4], E. Turcotte[1,2], E. Rousseau[1,2,3];*
[1]Department of Nuclear Medicine and Radiobiology, Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, QC, CANADA, [2]Centre de recherche du CHUS, Sherbrooke, QC, CANADA, [3]Institut de recherche sur le cancer de l'Université de Sherbrooke, Sherbrooke, QC, CANADA, [4]Sherbrooke Molecular Imaging Center (CIMS), Sherbrooke, QC, CANADA, [5]Department of Surgery, Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, QC, CANADA.

Aim/Introduction: Neuroendocrine tumors (NETs) are a rare, but increasingly incident contingent of cancers. Their growth and prognosis vary widely according to their pathological grading obtainable via invasive methods. This study aims at using radiomics on 68Ga-DOTATATE PET scans to build a random forest (RF) machine learning model that predicts NET lesions growth potential. ***Materials and Methods:*** Patients with NETs who have undergone two or more 68Ga-DOTATATE studies within a 2-year interval were retrospectively randomly selected, for a total of 298 individual NET lesions across 53 patients. For each patient, semi-automatic lesion segmentation was performed on the first study using the software MIM Encore, whereas the second study was used to assess individual lesion growth based on a modified RECIST 1.1 scale. 108 radiomic features were extracted from each lesion's volume of interest (VOI) using PyRadiomics. VOIs were then randomly split in training and validation sets (8:2 ratio). Using Python's scikit-learn library, the training data was used to build RF prediction models and perform hyperparameter tuning using 5-fold cross-validation to optimize area under curve (AUC). This step was iterated 1000 times, building different RF models by changing the random seed used to generate the decision trees and to perform the randomized search necessary for hyperparameter optimisation. The model that scored the highest AUC on the validation group was retained and its final performance was also assessed using accuracy, sensitivity, and specificity. ***Results:*** The final RF model had a high AUC of 0.93 coupled with a predictive accuracy of 0.85 on the training group. When tested on the validation group, AUC was 0.77 and accuracy was 0.72, along with a sensitivity of 0.66 and a specificity of 0.74 at predicting progressive NET lesions. Among the most important radiomic features used by the RF's decision trees, we note gray-level co-occurrence correlation, gray-level size zone variance and least axis length, which were all significantly superior in progressive NETs ($p<0.05$). Interestingly, while the shape elongation feature was not a significant predictor when considered individually ($p=0.69$), it had the highest feature importance score when used in conjunction with other features as a part of the RF model. ***Conclusion:*** This study showcases the potential of combining radiomics and machine learning to easily and non-invasively assess for NET lesions growth potential. An optimized RF model trained on extensive data could eventually help physicians plan localized treatment selection for patients suffering from NETs, improving their prognosis.

OP-683

Evaluation of PET-CT scans radiomics features in NSCLC patients with metastatic hilar/mediastinal lymph nodes.

K. Albattat, *C. Marshall, R. Smith;*
Cardiff University, Cardiff, UNITED KINGDOM.

Aim/Introduction: Accurate identification of Lymph Node Metastasis (LNM) is essential for optimal therapy selection and prognosis in Non-Small Cell Lung Cancer (NSCLC) patients. While complete excision and histopathology of lymph nodes (LN) are highly accurate, they increase patient trauma. Thus, developing a non-surgical approach using radiomic biomarkers from PET/CT images could significantly enhance the clinical diagnosis of nodal metastasis in NSCLC (1). This study hypothesizes that radiomics will accurately predict LNM in NSCLC and aims to develop and validate a prognostic radiomics model for this purpose. ***Materials and Methods:*** The study analyzed 383 patients with NSCLC, extracting 158 RFs from each tumor. Variable selection was performed using the Mann-Whitney U test to discern RFs with significant differences between the LNM group and the non-LNM group. Multicollinearity among these RFs was assessed using the variance inflation factor. Thirteen RFs showing significant associations ($p < 0.05$) were incorporated into the final logistic regression model, alongside age, gender, radiological stage, and PET-derived predictors. The model's robustness was quantified through regression coefficients, hazard ratios, and confidence intervals, and validated using 10-fold cross-validation. ***Results:*** In the predictive model, age was identified as a significant risk factor, indicating that younger patients with NSCLC are more prone to LNM. Furthermore, both tumor volume and maximum standardized uptake value (SUVmax) were significantly associated with an increased risk of LNM, with larger tumor volumes and higher SUVmax serving as predictors of LNM. The model also underscored important Gray Level Co-occurrence Matrix features, such as inverse difference and correlation. A reduced inverse difference within the LNM group suggests heightened tumor heterogeneity, whereas an elevated correlation reflects more complex non-linear relationships among the grey-level values of the tumor. Moreover, an increase in zone variance among the LNM group was indicative of more pronounced heterogeneity relative to the non-LNM group, further characterizing the textural differences observed between the two groups. ***Conclusion:*** A predictive model using radiomics was developed to non-invasively assess LN status in NSCLC patients, potentially enhancing precision oncology and influencing treatment decisions. Future work will extend our analysis to include RFs from metastatic LNs and explore their potential as predictors of overall survival and prognosis in primary tumors, enhancing disease understanding and treatment strategies. ***References:*** Liu Y, Kim J, Balagurunathan Y, Hawkins S, Stringfield O, Schabath MB, et al. Prediction of pathological nodal involvement by CT-based Radiomic features of the primary tumor in patients with clinically node-negative peripheral lung adenocarcinomas.

Comparative machine learning approach to evaluate the role of [18F]FDG PET radiomics for preoperative characterization of endometrial cancer

C. Bezzi[1,2], *A. Bergamini[3], G. Candotti[3], C. Sabini[3], F. Fallanca[2], S. Ghezzo[1], A. M. Samanes Gajate[2], L. Monticelli[1], L. Bocciolone[3], G. L. Taccagni[4], G. Mangili[3], M. Candiani[3], A. Chiti[1,2], P. Mapelli[1], M. Picchio[1,2];*

[1]Vita-Salute San Raffaele University, Milan, ITALY, [2]Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [3]Unit of Obstetrics and Gynaecology, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [4]Pathology Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim/Introduction: Comparative analyses of machine learning (ML) models performance is limited in literature. This study aims at investigating the role of radiomics in assisting the presurgical characterization of endometrial cancer (EC), by comparing several ML approaches. ***Materials and Methods:*** Retrospective study including 169 EC patients who underwent [18F]FDG PET for preoperative staging. Post-surgical assessment of lymph nodal (LN) metastases, p53 immunohistochemical analysis, and post-surgical administration of adjuvant therapy (AT) were used as reference standards. Primary EC tumors were manually segmented; images were resampled, normalized and discretized, and radiomic features (RFs) were extracted. RFs were selected for their robustness against inter-observer segmentation variability. The cohort was split into training (70%) and test (30%) in a stratified manner; in the training set, RFs were selected using the minimum redundancy maximum relevance (mRMR) algorithm and used to train different ML models, including linear discriminant analysis (LDA), logistic regression (LR), support vector machine (SVM) and k-nearest neighbour (KNN). In case of imbalanced classes, synthetic data were generated to oversample the minority class in the training set. Area under the curve (AUC), balanced accuracy (bACC), sensitivity (SN), specificity (SP), positive and negative predictive values (PPV, NPV) were collected on the test set for each model and compared using mcNemar test. ***Results:*** LN histological examination was available for 150/169 patients (85% LN-; 15% LN+), p53 data was available for 122/169 patients (37% p53abn; 63% p53 wild-type), and in 84/166 patients adjuvant therapy was administrated. Oversampling of the minority class was performed for LN and p53 predictions. ML models were first trained using the complete radiomic signature, and then features were iteratively removed based on the mRMR ranking, each time repeating model's training. Entropy and Metabolic Tumour Volume (MTV) parameters were overall selected in the radiomic signature of each outcome. Models achieved AUC=79% (bACC=76%, SN=82%, SP=71%, PPV=47%, NPV=92%) for LN, AUC=77% (bACC=78%, SN=92%, SP=64%, PPV=55%, NPV=94%) for p53, and AUC=77% (bACC=74%, SN=76%, SP=72%, PPV=73%%, NPV=75%) for AT; according to mcNemar test, no statistical significance was found among the 4 investigated classifiers for each outcome (p>0.05). ***Conclusion:*** Application of radiomics for presurgical EC characterization appears to provide comparable promising results, regardless of the specific ML model employed.

The role of ^{18}FPSMA-1007 PET/MRI radiomics in the diagnosis of malignant prostate lesion and clinically significant prostate cancer

M. Xu, *Y. Zhang, M. Tu, T. Li, G. Wang, Y. Wu, K. Zhao, X. Su;*
The First Affiliated Hospital Zhejiang University of School of Medicine, Hangzhou, CHINA.

Aim/Introduction: Prostate cancer (PCa) is a malignant tumor with high heterogeneity, which creates a challenge for early diagnosis. Positron emission tomography (PET) imaging with the tracer of prostate specific membrane antigen (PSMA) is used for staging and biochemical recurrent PCa. Radiomics has demonstrated superiority over visual image interpretation for making a precise diagnosis. Herein, the purpose of this study was to evaluate the application value of 18FPSMA-1007 PET/MRI-T2-derived radiomics in distinguishing malignant prostate lesion and clinically significant prostate cancer (cPCa) from benign prostatic disease in newly diagnosed patients. ***Materials and Methods:*** Patients (n= 176) with suspected PCa, who underwent 18FPSMA-1007 PET/MRI and pathological biopsy within 1 month after 18FPSMA-1007 PET/MRI, were retrospectively analyzed. 74 patients were found malignant prostate lesion, and 30 patients were diagnosed as cPCa, cPCa was defined as ISUP GG (the International Society of Urological Pathology grade group) ≥ 3. PET and MRI-T2 radiomic features were extracted by using LIFEx (7.3.0) according to the image biomarker standardization initiative (IBSI) guidelines. Clinical data were collected, including age, tPSA, PSA density (PSAD) and miPSMA expression score. Five different models were developed and calculated their performances, including 1) clinical model, 2) PET radiomic model, 3) MRI-T2 radiomic model, 4) PET+MRI-T2 radiomic model, 5) PET+MRI-T2+clinical model. A cross-validation approach was used to evaluate the internal validity of the models. ***Results:*** The best performed radiomic model was PET+MRI-T2 radiomic model, showing high showing sensitivity, specificity, accuracy, AUC of 0.797, 0.892, 0.852, 0.888 and 0.733, 0.884, 0.858, 0.890 for diagnosing malignant prostate lesion and cPCa respectively. PET+MRI-T2 radiomic model outperformed both the PET radiomic model and MRI-T2 radiomic model (all P< 0.05). PET radiomic model was superior to MRI-T2 radiomic model (P= 0.018), when distinguishing malignant prostate lesion from benign prostatic disease, but not for diagnosing cPCa (P= 0.654). However, an addition of the clinical model to the radiomic model did not improve the diagnostic performance for diagnosing malignant prostate lesion (P= 0.067) and cPCa (P= 0.060). The performances of PET+MRI-T2 radiomic model and PET+MRI-T2+clinical model as per the cross-validation scheme yielded an accuracy of 0.837 (AUC=0.853) and 0.837 (AUC=0.890) for diagnosing malignant prostate lesion, as well as 0.838 (AUC=0.860) and 0.801 (AUC=0.891) for cPCa. ***Conclusion:*** The combination of PET+MRI-T2 radiomic model outperformed single radiomic model of PET and MRI-T2 for diagnosing malignant prostate lesion and cPCa, and there was no significant difference after an addition of clinical data.

Safety and Efficacy of Short Intensive Treatment with Two Cycles of 7.4GBq [^{177}Lu]Lu-PSMA-I&T in Two Weeks for Patients with mCRPC

E. Owers, *D. M. V. de Vries - Huizing, L. W. van Golen, Z. J. Cheung, M. L. Donswijk, S. Heijmink, J. J. M. A. Hendrikx, W. V. Vogel, A. J. A. T. Braat;*
Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS.

Aim/Introduction: Peptide radio ligand therapy (PRLT) is gaining ground in the treatment of metastatic castration resistant prostate cancer (mCRPC). Based on the VISION trial, most centres administer

PRLT cycles six weeks apart (4-6 cycles) with intermittent clinical assessment, biochemical assessment and sometimes imaging. However, the best timing and criteria for on-treatment assessment are yet unclear. Ideally non-responders are identified before they have undergone the standard 4-6 cycles. Another published strategy involves two cycles with a two-week interval. [1] This condensed treatment regimen may deliver more radiation dose in the first and most potent phase of treatment, and it allows standardized response evaluation prior to continued treatment. We therefore opted to administer the first two cycles of 7.4 GBq [177Lu]Lu-PSMA-I&T only two weeks apart. Safety and efficacy are reported. ***Materials and Methods:*** All patients who started this regimen in the first two years at our centre are included in this retrospective analysis. Clinical, biochemical and imaging response are reported, as well as haematological toxicity. ***Results:*** The 112 patients were extensively pre-treated, with median 4 prior lines of therapy for mCRPC. Only one did not receive either androgen receptor-targeted agents (low PSA) or chemotherapy (refused) prior to PRLT. Baseline ECOG score was 0-1 in 65%, score 2 and 3 in 32% and 3%, respectively. CTCAE grade 3 anaemia was seen in four patients and grade 3 thrombocytopenia in three patients. There was no grade 4 haematotoxicity. No grade 3-4 xerostomia was reported. At four weeks post-treatment, a PSA decrease ≥50% was seen in 41%, and ≥90% in 10% of patients. Thirty-six patients (32%) stopped after the first or second cycle due to either biochemical progression (15%), progression on CT only (3%) or because they became clinically/biochemically unfit (14%). Of the 63 patients who had a contrast enhanced CT at baseline and four weeks post-treatment, 33% did not have RECIST 1.1 measurable disease. Of the 42 patients with measurable disease, 26% showed partial remission. Stable disease and progressive disease were seen in 55% and 19% respectively. ***Conclusion:*** Two cycles of 7.4 GBq [177Lu]Lu-PSMA-I&T two weeks apart can be safely administered, with haematological toxicity within an acceptable range. Biochemical response at four weeks after only 2 cycles is promising. ***References:*** [1] Tagawa et al. JCO 35 (2017)

Aim/Introduction: PROGNOSTICS phase Ia study (NCT06343038) aims to determine the absorbed doses in tumors and relevant organs after test injection of [161Tb]Tb-SibuDAB in comparison to [177Lu]Lu-PSMA-I&T in patients with metastatic castration resistant prostate cancer (mCRPC). SibuDAB is a novel peptidomimetic, developed at PSI, derived from a urea-based PSMA-binding entity which is conjugated to (S)-ibuprofen to provide albumin-binding properties with potential for enhanced tumor accumulation. ***Materials and Methods:*** In this prospective randomized, cross-over, single-blind phase Ia study, 10 patients will receive 1 GBq [161Tb]Tb-SibuDAB and 1 GBq [177Lu]Lu-PSMA-I&T over a 3-week interval. Quantitative SPECT/CT imaging will be performed (~3, 24, 48, and 168 h) after infusion of both radiopharmaceuticals to calculate tumor and organ absorbed doses (3D dosimetry using a Monte Carlo-based OSEM algorithm). Additionally, multiple "omics" (clinical-/ biochemical-/ imaging-/ cellular-/ transcriptomes) as well as circulating tumor cells and tumor-cell clusters will be evaluated as potential predictive biomarkers for RLT response and toxicity. ***Results:*** So far, 4 of 10 patients have been enrolled. Of them, 2 patients have received both the [161Tb]Tb-SibuDAB test injection and the [177Lu]Lu-PSMA-I&T comparator. After injection of only 1 GBq [161Tb]Tb-SibuDAB, SPECT/CT revealed excellent image quality with intense tumor uptake. To date, dosimetry results (including all four imaging time points) are available for the first patient. The mean absorbed tumor doses after [161Tb]Tb-SibuDAB and [177Lu]Lu-PSMA-I&T test injections were 8.6 and 4.0 Gy/GBq, respectively. The mean absorbed kidney doses were 2.5 vs 1.4Gy/GBq, respectively. The mean absorbed parotid doses were 0.29 vs 0.16 Gy/GBq, respectively. Blood derived bone marrow dosimetry revealed 0.107 vs 0.021 Gy/GBq, respectively. The tumor-to-kidney and tumor-to-parotid ratios were slightly higher for [161Tb]Tb-SibuDAB: 3.4 vs 2.9, respectively and 30 vs 25, respectively; while the tumor-to-marrow ratio was lower for [161Tb]Tb-SibuDAB, likely reflecting the longer circulation time: 80 vs 188, respectively. The effective tumor half-life was clearly superior for [161Tb]Tb-SibuDAB compared to [177Lu]Lu-PSMA-I&T: 120 vs 64 hours, respectively. No drug induced adverse events (according to CTCAE 5) have been recorded. ***Conclusion:*** Preliminary data of PROGNOSTICS study showed promising results with high tumor dose after [161Tb]Tb-SibuDAB test injection without adverse events. Complete data, including comparative dosimetry of the entire cohort, will be presented.

[13]Cliniques Universitaires Saint Luc, Brussels, BELGIUM, [14]Mayo Clinic, Rochester, MN, UNITED STATES OF AMERICA.

Aim/Introduction: Validated predictive biomarkers of response to radium-223 dichloride (223Ra) therapy would help identify patients with metastatic castration-resistant prostate cancer (mCRPC) most likely to benefit from treatment. In patients treated with 223Ra, ALP levels have been shown to decline throughout treatment. We evaluated whether ALP decline after first 223Ra injection can predict longer OS, using data from the prospective, multicentre, real-world REASSURE study (NCT02141438). ***Materials and Methods:*** This descriptive analysis investigated associations between ALP decline after first 223Ra cycle and OS in patients with mCRPC and bone metastases who received ≥1 223Ra dose. Baseline ALP (normal [≤147 U/L] or high [>147 U/L]) and extent of ALP decline 4 weeks after first 223Ra injection (<10% [no decline] or ≥10% [decline]) were used to divide patients into five subgroups: normal ALP/decline (group 1), normal ALP/no decline (group 2), high ALP/decline (group 3), high ALP/no decline (group 4) and a combined group (5), which included groups 1-3. ***Results:*** 811 patients were analysed; 238 (29%) in group 1, 209 (26%) in group 2, 258 (32%) in group 3, 106 (13%) in group 4 and 705 (87%) in group 5. Median duration of observation was 13.4 months (range 1.1-48.7). Median ALP levels at baseline were 92.5 (group 1), 76.0 (group 2), 298.5 (group 3) and 269.0 (group 4) U/L. More patients in groups 1 and 2 received ≥5 223Ra injections (84% and 77%, respectively) than in groups 3 and 4 (68% and 49%, respectively). Median OS was 21.5 months (95% CI, 18.5-23.6), 19.4 months (16.0-21.0), 12.2 months (10.8-14.1), 9.0 months (7.6-10.7) and 17.0 months (16.0-18.2) in groups 1-5, respectively. ***Conclusion:*** Patients with a decline in ALP following first 223Ra dose showed improvements in OS versus those who did not, with this finding being more pronounced in those with high ALP at baseline than in those with normal ALP. Patients in group 4 had worse OS versus all other groups (1-3 and 5). As in other reports, patients with normal ALP at baseline had a longer OS than those with high ALP, perhaps limiting the benefit of ALP decline for patients with normal ALP at baseline. Longer survival may be due in part to the higher rates of 223Ra completion among patients with normal ALP at baseline or an ALP decline. These results, along with other clinical features, may be of benefit when monitoring patients during therapy.

Results of phase 2 study of [^{177}Lu]Ludotadipep for metastatic castration-resistant prostate cancer

J. O[1], *S. Kwon[1], J. Lee[1], C. Park[2], J. Min[1], S. Ha[1];*
[1]The Catholic University of Korea, Seoul, KOREA, REPUBLIC OF, [2]Development Division, FutureChem Co., Ltd., Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: [177Lu]Ludotadipep is a radiopharmaceutical developed for prostate specific membrane antigen (PSMA) targeting radioligand therapy (RLT) and contains albumin binders to increase the circulation time. The phase 1 clinical trials were completed in South Korea and the United States [1, 2]. The phase 2 trial with up to 6 cycles of [177Lu]Ludotadipep (3.7 GBq each cycle) completed enrollment, and the last subject has received the second dose at the time of writing (clinical trial number NCT05579184). This phase 2 trial is the first multi-cycle RLT performed in metastatic castration-resistant prostate cancer (mCRPC) patients of Korean ethnicity, who as an ethnic group had not been well-represented in previous clinical trials, and aimed to evaluate the efficacy of repeat doses of [177Lu] Ludotadipep. ***Materials and Methods:*** In this open-label, phase 2 trial, participants with mCRPC who had been previously treated with at least one second-generation hormonal agent or standard taxane-based chemotherapy but progressed were enrolled. Both PSMA and FDG PET/CT were obtained, and the metastatic lesions had to be PSMA positive (>liver activity) without any lesion showing higher FDG uptake than PSMA uptake. Scheduled for up to 6 cycles at 8-week intervals with fixed dose of 3.7 GBq of [177Lu]Ludotadipep, the subjects were assessed with PSMA PET/CT and laboratory follow-up after each cycle. ***Results:*** Total 60 patients were screened, and 23 were considered ineligible due to higher FDG uptake than PSMA uptake in metastatic lesion(s). For the 20 enrolled patients, the baseline PSA was 228.7±239.6 ng/dl (mean±standard deviation). After average number of 3 cycles at the time of writing, 12/20 of participants achieved a ≥50% reduction in PSA levels. Three patients so far have attained complete response with undetectable PSA levels (two after 3 cycles, one after 4 cycles). Grade 3 or 4 adverse events were observed in 5 patients: thrombocytopenia (n=2), pathologic fracture, sepsis and weakness in both legs. ***Conclusion:*** Interim results signal that multiple cycles of 3.7 GBq [177Lu] Ludotadipep could be an effective radiopharmaceutical for RLT in mCRPC patients of Korean ethnicity. ***References:*** 1. OP-690

Investigating Combination Therapy: The Impact of [^{177}Lu]Lu PSMA and Androgen Receptor Pathway Inhibitors in Metastatic Castration Resistance Prostate Cancer

G. Beydagi[1], *O. Kinikoglu[2], B. B. Oven[3], S. Celik[3], K. Akcay[1], L. Kabasakal[4], N. Alan-Selcuk[1];*
[1]Yeditepe University, Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Department of Medical Oncology, Kartal Dr. Lütfi Kirdar City Hospital, Health Science University, Istanbul, Turkey, Istanbul, TÜRKIYE, [3]Yeditepe University, Department of Medical Oncology, Istanbul, TÜRKIYE, [4]Istanbul Unıversity-Cerrahpasa, Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: Androgen deprivation therapy (ADT) and androgen receptor pathway inhibitors (ARPis) are among the most important treatment options in metastatic castration-resistant prostate cancer. Despite these therapies, most patients develop resistance to castration. The aim of this study is to investigate the efficacy of [177Lu]Lu PSMA therapy, alone or in combination with androgen inhibitors such as abiraterone and enzalutamide, prostate cancer patients who are resistant to previous systemic therapies. ***Materials and Methods:*** In our study, 104 patients with mCRPC who had received [177Lu]Lu PSMA at Yeditepe University Hospital were retrospectively analyzed. The mean age of the patients was 65.7 ± 12.5 years. In this study, 60% of the patients also received ADT. Thirty-four patients (33%) received ARPi treatment in combination with [177Lu]Lu PSMA therapy. The remaining patients received [177Lu]Lu PSMA therapy after discontinuing ARPIs (74%). The median number of [177Lu]Lu PSMA cycles administered was 4 (range: 1-8). ***Results:*** According to the results of the univariate analysis, progression-free survival (PFS) was significantly prolonged in patients who received ARPI

treatment in combination with [177Lu]Lu PSMA. The median PFS was 11 months (4.9-17) for patients receiving combined therapy, compared to 5.9 months (3.4-8.4, p=0.013) for those receiving [177Lu]Lu PSMA therapy alone. The median PFS for all patients receiving [177Lu]Lu PSMA therapy was 6.8 months. In our evaluation of median overall survival (OS) among patients receiving the combination therapy of [177Lu]Lu PSMA and ARPi, we noted a numerically enhanced OS compared to those administered [177Lu]Lu PSMA as monotherapy. Although the observed difference did not achieve statistical significance (p=0.06, 20.3 vs. 15.9 months; HR: 0.58, 95% CI: 0.33-1.02), multivariate analysis indicated a significant improvement in OS favoring the combination therapy (p=0.01, HR: 0.58, 95% CI: 0.25-0.86). Further scrutiny revealed a strong association between age and superior OS outcomes (p<0.001, 21.2 vs. 12.4 months; HR: 0.50, 95% CI: 0.30-0.83). For patients receiving [177Lu]Lu PSMA therapy as second-line therapy, PFS was 8.6 months compared to 6.7 months for the others, but this did not reach statistical significance (p=0.44; Table 1). Regarding the side effect profile, grade 3 myelotoxicity occurred in 8 patients (9%) and grade 1-2 nephrotoxicity according to CTCAE v 5 occurred in 12 patients (13%). ***Conclusion:*** In conclusion, [177Lu]Lu PSMA therapy in combination with systemic antiandrogen therapy has the potential to prolong PFS time with an acceptable side effect profile. Additional prospective studies are needed to further substantiate these results.

Added Value of Interim FDG PET/CT Imaging for Patients with Metastatic Prostate Cancer Undergoing ^{177}Lu-PSMA Radioligand Therapy

M. Léger, *D. Tahmi, R. Latif Zeiter, Q. Shagera, T. Guiot, M. Manley, P. Flamen, C. Artigas;*
Institut Jules Bordet, Bruxelles, BELGIUM.

Aim/Introduction: Radionuclide therapy with 177Lu-PSMA has revolutionized the treatment of advanced metastatic castration-resistant prostate cancer (mCRPC). Baseline PET imaging with PSMA and FDG is pivotal in confirming patient eligibility and providing prognostic value. The value of interim FDG PET/CT however remains elusive in the literature. We assessed the added value of interim FDG PET/CT imaging in patients undergoing 177Lu-PSMA-RLT. ***Materials and Methods:*** This retrospective monocentric analysis included mCRPC patients who received at least 2 cycles of 177Lu-PSMA-RLT and underwent FDG PET/CT at baseline and after 2 cycles of 177Lu-PSMA-RLT (interim). SUVmax, and tumor SUVmean were calculated contouring total tumor volume using a fixed threshold based on liver SUVmean + 2SD. The delta of PET parameters and PSA values between baseline and interim were calculated. PSA response was defined as a decrease of >50% (PSA50). FDG response was defined using best cut-off based on ROC curve analysis of PSA50. The association between interim parameters and overall survival (OS) was evaluated using univariate and multivariate Cox Proportional Hazards model. Kaplan Meier curves were performed. ***Results:*** Sixty-eight patients were included with 64 having FDG mesurable disease. After a median follow-up of 10.6 months, median PFS and OS were 6.7 and 16.6 months, respectively. 44% of patients presented PSA response. Parameters showing significant association with OS were delta SUVmax (p=0.03), delta SUVmean (p=0.01), and delta PSA (p<0.001). Delta SUVmax -40% cutoff defined FDG-responders and non-responders. FDG-responders presented longer OS than FDG non-responders (11.76 months versus not reached, respectively), HR of 0.390 (95%CI 0.164 - 0.932, p=0.03), as well as PSA50 responders vs non-responders (9.59 months versus not reached, respectively), HR of 0.271 (95%CI 0.121 - 0.608, p=0.002). When combining both PSA and FDG response status, patients with PSA and FDG responses presented better outcome than those with any of both PSA or FDG non-response HR=0.199 (95%CI 0.065 - 0.606, p=0.003). This remained significant in a multivariate analysis (p=0.05). ***Conclusion:*** This analysis demonstrates the value of interim FDG PET/CT imaging to assess response to 177Lu-PSMA-RLT. Assessing FDG response using delta SUVmax is simple and provides key prognostic information, particularly for patients who are classified as responders per PSA criteria. These findings hold potential implications in terms of therapeutic management but should be validated in prospective clinical trials.

OP-692

Volume based parameters of pre-treatment F^{18} FDG PET/CT images in patients with Endometrial carcinoma: Is there any relation with histopathological features of the tumour and survival outcomes?

I. Ak Sivrikoz[1], *D. Arik*[2], *H. Deveci*[1], *E. Tekin*[2];
[1]*ESOGU School of Medicine Department of Nuclear Medicine, Eskisehir, TÜRKIYE,* [2]*ESOGU School of Medicine Department of Pathology, Eskisehir, TÜRKIYE.*

Aim/Introduction: Endometrial cancer (EC) is the most common invasive gynaecological malignancy. This study aimed to evaluate the association of F^{18} FDG PET/CT parameters with postoperative pathology and to determine the relation between survival outcomes in patients with EC. ***Materials and Methods:*** A total of 79 patients with EC, aged between 44 and 87 years (mean 67.86 years) were included in the study. Between 2012 and 2022, patients diagnosed with EC who underwent F^{18} FDG PET/CT for staging were evaluated retrospectively. SUVmax, SUVmean, metabolic tumour volume (MTV), and total lesion glycolysis (TLG) of the lesions were noted. FIGO2023 classifications, histopathology, the depth of myometrial invasion (MI), lymph node metastasis (LNM), cervical stromal invasion (CSI), low uterine segment invasion, extrauterin involvement (EUI), lymphovascular invasion, nuclear grade, p53 mutation and microsatellite instability, tumour sizes and extra uterine involvement were noted. Ethic committee was approved. ***Results:*** Eleven cases were at FIGO2023 stage I, 22 at stage II, 9 at stage III, and 14 stage IV. The surgery was performed in 50 of 79 patients. FDG uptake was avid in all cases, and the median SUVmax, SUVmean, MTV40 and TLG40 were 15.44 (range, 4.51-37.92), 8.96 (range, 2.94-21.10), 156.60 (range, 3.88-4710.0) and 8.2 (range, 0.9-790.3), respectively. SUMmax was significantly associated with both LNM and peritoneal implant (p=0.045). There were significant association between MTV40 and MI (p=0.002), EUI (p=0.016). There was also significant correlation between TLG and MI (p=0.022), EUI (p=0.002). AUC of MTV40 for MI were 0,779 (p=0,0004), TLG for 0,710 (p=0,008). For MTV>7.43 cut-off, sensitivity in detecting MI was 84% and specificity was 64%. TLG>115 cut-off, sensitivity in detecting MI was 67% and specificity was 71%. AUC of MTV40 for EUI were 0,791 (p=0,0001), TLG for 0,850 (p=0,0001). The other 29 patients who did not undergo surgery were diagnosed by biopsy. Overall (OS) and Progression free survey (PFS) were calculated for all 79 patients. Significantly shorter OS was noted in patients with higher MTV (p< 0.001) and TLG (p< 0.001). Significantly shorter PFS was also noted in patients with higher MTV (p= 0.01) and TLG (p = 0.03). In the multivariate analysis, both MTV and TLG were independent predictors of PFS and OS (p = 0.001, p = 0.001). ***Conclusion:*** Both MTV and TLG of primary lesions are related in myometrial invasion and extrauterin involvement of EC, also independent predictors of PFS and OS in patients with EC.

OP-693

Diagnostic accuracy and molecular characterization of endometrial cancer using hybrid [18F]FDG PET/MRI

***C. Bezzi*[1,2]**, *T. Russo*[1,3], *G. Candotti*[4], *A. Bergamini*[4], *G. Ironi*[3], *C. Sabini*[4], *F. Fallanca*[2], *S. Ghezzo*[2], *A. M. Samanes Gajate*[2], *L. Bocciolone*[4], *P. Scifo*[2], *G. L. Taccagni*[5], *G. Mangili*[4], *M. Candiani*[4], *F. De Cobelli*[1,3], *A. Chiti*[1,2], *P. Mapelli*[1,2], *M. Picchio*[1,2];**
[1]Vita-Salute San Raffaele University, Milan, ITALY, [2]Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [3]Radiology Department, IRCCS San Raffele Institute, Milan, ITALY, [4]Unit of Obstetrics and Gynaecology, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [5]Pathology Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim/Introduction: The outcome of patients affected by endometrial cancer (EC) may vary according to several factors, including regional lymph node (LN) involvement. Moreover, recent focus has turned to EC molecular profiling, revealing alterations such as DNA mismatch repair deficiency (MMRd) and p53 mutation (p53abn). This study aims at investigating the utility of hybrid [18F] FDG PET/MRI in EC staging, exploring its diagnostic accuracy and potential of derived parameters in predicting LN, MMRd, and p53abn. ***Materials and Methods:*** Prospective study including 61 patients with biopsy-proven EC who underwent preoperative [18F]FDG PET/MRI for staging . Histological examination following surgical intervention and immunohistochemical analysis served as gold standards. [18F]FDG PET/MRI scans were blindly reviewed by a nuclear medicine physician and a radiologist, evaluating the diagnostic balanced accuracy (bACC), sensitivity (SN), and specificity (SP), and deriving imaging parameters. Mann-Whitney U test, Fisher's exact test, Logistic regression and ROC analysis were used for the statistical analysis. ***Results:*** Median age was 64 years (range:36-87). LN histological examination was available for 53/61 patients (19% LN+; 81% LN-); MMRd immunohistochemical analysis was available in 31/61 patients (61% MMR proficient-MMRp; 39% MMRd), and p53 data was available for all 61/61 subjects (80% p53 wild-type; 20% p53abn). [18F]FDG PET/MRI accurately identified the primary EC in all patients (bACC=100%,SN=100%). bACC of [18F]FDG PET in detecting LN was 92.5% (SN=90%,SP=95%), while MRI's metrics were bACC= 85.50% (SN=80%,SP=91%). Higher values of parameters describing tumor volume on T1 post-contrast, ADC, and T2 sequences (volume index-VI, total tumor volume-TTV, tumor volume ratio-TVR) and PET scans (metabolic tumor volume-MTV, total lesion glycolysis-TLG) were observed in patients with LN ($p<0.05$), as well as a higher frequency of myometrial infiltration ($p=0.031$) and cervical stroma invasion ($p=0.033$) observed on MRI scans. T1-derived TTV provided the highest prediction (AUC=75%, SN=80%, SP=70%, cut-off=13mm). In MMRd patients, SUVmax, SUVmean, and TLG PET parameters, and the frequency of LNs detected on PET and MRI were significantly higher compared to MMRp patients ($p<0.05$); the cut-off of 11.35 of SUVmean showed the highest prediction ability (AUC=73.2%, SN=83%, SP=63%). [18F]FDG LN uptake on PET, and MRI-derived TVR, ADCmean, and ADCmin allowed to discriminate patients presenting p53abn ($p<0.05$), with the best performance provided by ADCmin (AUC=80.78%, SN=83.33%, SP=75.55%, cut-off=618). ***Conclusion:*** [18F]FDG PET/MRI showed good accuracy in the staging of EC patients. Given their promising predictive capabilities, PET and MRI-derived parameters could enhance the characterization of tumor aggressiveness and molecular alterations, including DNA MMRd and p53 hyperexpression.

OP-694

The value of [18F]-FDG PET/CT in the evaluation of early treatment response in cervical cancer patients

M. Gutierrez Guerrero, *T. Navarro Martínez, O. Ajuria Illarramendi, A. Martínez Lorca, P. Azpeitia Hernández, U. Vera Schmülling, I. Hernández Pérez, E. Pérez de los Ríos, M. Ottino Lombardi, D. Tamayo Carabaño, M. Orduña Díez;*
Hospital Universitario Ramón y Cajal, Madrid, SPAIN.

Aim/Introduction: To study the usefulness of [18F]-FDG PET/CT to evaluate the early response to treatment in patients with IB2-IVA stage cervical cancer who received QT/RT+brachytherapy. ***Materials and Methods:*** Retrospective descriptive review of patients with cervical cancer who underwent [18F]-FDG PET/CT scan between January 2020-January 2023 after 3 month of treatment with QT/RT+ brachitheraphy. Age, size, HPV subtype, FIGO, clinical symptoms, physical examination, cytology, [18F]-FDG PET/CT, MRI at 3, 6, 12 months and current global situation (follow-up 12 months-3 years) were collected. The results of [18F]-FDG PET/CT and MRI were studied at 3 months post-treatment, correlating it with clinical/radiological follow-up. [18F]-FDG PET/CT and MRI results were graded as negative, positive, or indeterminate. S, E, PPV and NPV of both techniques were evaluated. For statistical analysis, indeterminate results were assumed positive. ***Results:*** 101 patients(p) were included. 56p (56% 56/101p) were excluded due to: stage IVB (24/56p), lack of follow-up (20/56p), suspicion of recurrence (10/56p) or minimally invasive disease (2/56p). The remaining 45p (44% 45/101p) were treated with QT/RT+brachytherapy. 3-month post-treatment [18F]-FDG PET/CT (3m) showed the following ***results:*** negative 86.6%(39p), positive 8.8%(4p), indeterminate 4.4%(2) while MRI-3m was negative in 42.2%(19), positive in 26.6 %(12) and indeterminate in 31.1%(14). [18F]-FDG PET/CT demonstrate a S 100%, E95%, PPV 71% and NPV 100%. On the other hand, RM obtained a S 100%, E 47.5%, PPV 19%, NPV 100%. Indeterminate MRI results were subanalyzed (14n) comparing them with those obtained with [18F]-FDG PET/CT (10/14 negative, 2/14 positive, 2/14 indeterminate). The success in the right diagnosis of [18F]-FDG PET/CT was confirmed after one year of follow-up. Moreover, the success rate of post-treatment [18F]-FDG PET/CT-3m in patients with indeterminate 3m-MRI, was 85%. In 100% of cases, the [18F]-FDG PET/CT result was confirmed after one year of follow-up. ***Conclusion:*** [18F]-FDG PET/CT is an excellent tool on the assessment of early treatment response in patients with cervical cancer, gaining an especial relevance in those cases with indeterminate MRI and thus offering the possibility to allowing an early evaluation to treatment.

Safety, pharmacokinetics, radiation dosimetry and preliminary diagnostic performance of [^{68}Ga]Ga-deferoxamin in patients with bacterial infections - results from a Phase I/IIa study

C. Decristoforo[1], *M. Mann[1], B. Nilica[1], S. Rauch[1], G. di Santo[1], M. Petrik[2], C. Rangger[1], B. Warwitz[1], M. Hajduch[2], I. Vigolini[1];*
[1]Medical University Innsbruck, Innsbruck, AUSTRIA, [2]IMTM Palacky University, Olomouc, CZECH REPUBLIC.

Aim/Introduction: Molecular imaging has the potential for specific and sensitive detection of bacterial infections, thereby allowing timely and accurate diagnosis. Targeting the siderophore iron acquisition system of bacteria, not existing in mammalian cells, allows to access one of the few microbe specific targets. In recent studies we could show that the siderophore deferoxamine, established for treating iron overload diseases (as Desferal®), can be radiolabelled with 68Ga and used for imaging of bacterial infections by PET [1]. In preclinical studies excellent targeting of various clinically relevant bacteria such as Pseudomonas, Staphylococcus and Streptococcus ssp. resulting in high contrast imaging in Micro-PET/CT studies with high specificity. We here report initial results of a Phase I/IIa study (EudraCT Nr: 2020-002868-31) on safety, tolerability, pharmacokinetics, radiation dosimetry and preliminary diagnostic performance in patients with bacterial infections using [68Ga]Ga-deferoxamine. ***Materials and Methods:*** [68Ga]Ga-deferoxamine was prepared using an automated module and released based on defined quality criteria. In the initial Phase 4 patients with joint implant infections were included. Sequential PET imaging (0-15min dynamic, 30, 60, 120 and 180min whole body) was performed after injection of 3MBq/kgBW of [68Ga]Ga-deferoxamine for assessment of safety, tolerability and to calculate radiation absorbed doses. Pharmacokinetics were assessed by sequential imaging, measuring activity in blood and urine and HPLC-analysis of blood and urine metabolites. In 3 patient comparative FDG imaging was available. ***Results:*** [68Ga]Ga-deferoxamine production resulted in high radiochemical yields and purity. No sign of metabolic degradation was seen in blood samples, with slow rate of blood elimination, in urine variable amounts of metabolites were detected. Effective dose was calculated to be below 0.01mSv/MBq. PET imaging revealed rapid and stable accumulation in the infected area in 3 patients up to 3hr. p.i., one patient showed a mismatch of positivity in FDG and negative [68Ga]Ga-deferoxamine uptake after initiation of antibiotic therapy. ***Conclusion:*** This clinical study provided pharmacokinetics and dosimetry data of [68Ga]Ga-deferoxamine and a first proof of concept for infection imaging with radiolabelled siderophores. High blood pool activity and slow rate of elimination, however, has been identified as a specific limitation of [68Ga]Ga-deferoxamine in humans.

Clinical Significance of the Relationship Between FDG PET/CT, PSMA PET/CT, Salivary Flow Rate and USG Findings in Sjögren's Syndrome

K. Oksuzoglu[1], *T. N. Kissa[1], Z. Balaban Genc[1], A. Avcu[2], K. Y. Abacar[2], G. Mumcu[3], G. Bruyn[4], H. T. Turoglu[1], T. Y. Erdil[1], N. Inanc[2], T. Ones[1];*
[1]Marmara University Pendik Research and Training Hospital, Department of Nuclear Medicine, Istanbul, TÜRKIYE,
[2]Marmara University Pendik Research and Training Hospital, Department of Rheumatology, Istanbul, TÜRKIYE, [3]Marmara University, Faculty of Health Sciences, Department of Health Management, Istanbul, TÜRKIYE, [4]Reumakliniek Lelystad, Lelystad, and Tergooi MC Hospitals, Lelystad, NETHERLANDS.

Aim/Introduction: The diagnosis of Sjögren's Syndrome (SjS) is based on dryness symptoms/autoantibodies, and histopathological examination (2016 ACR/EULAR criteria). USG has a high accuracy in diagnosing SjS. FDG-PET assesses autoimmune inflammation and salivary glands show intense PSMA uptake. This prospective study aims to investigate the relationship between FDGPET/68GaPSMA PET, USG, and salivary flow rate (SFR), and also the clinical significance of this relationship and its possible contribution to treatment management in SjS. ***Materials and Methods:*** FDG-SUVmax, SUVmean, PSMA-SUVmax, SUVmean, PSMAbased Functional Glandular Volume (PSMAGlVol) and PSMAbased Total Glandular Activity (PSMATotGlAct: PSMASUVmean x PSMAGlVol) were calculated for Parotid/Submandibular glands. Homogeneity/hypoechoic areas/hyperechoic bands/glandular boundaries and OMERACT scores for each gland were evaluated on USG. SFR was measured. ***Results:*** OS was 2-3 in 57% of submandibular and in 38% of parotid glands. Hyperechoic appearance indicating fibrotic changes was more prominent in submandibular glands (42%-33%). Statistically significant lower levels of PSMA-SUVmax, SUVmean, PSMATotGlAct in parotid/submandibular and PSMAGlVol in submandibular glands presumed to be more severely affected by SjS with higher OS were observed. Higher OS were associated with statistically higher FDG-SUVmax and SUVmean in parotid glands, whereas no such relationship was observed for submandibular glands. Parotid with higher OS exhibited higher FDG-SUVmax compared to submandibular glands (p=0.004-indicating ongoing inflammation in parotid glands affected at a later stage). A positive correlation was found between SFR and FDG-SUVmax/SUVmean for submandibular glands. FDG-SUVmax/SUVmean in patients with SFR ≥0.1 ml/min were higher than in patients with low SFR for only submandibular glands (in favor of a relative higher SFR in patients with inflammation persisting in submandibular glands while a decrease in comparison to normal). No statistical correlation was found between SFR and OS, or SFR and PSMA parameters. ***Conclusion:*** If FDG uptake indicating autoimmune inflammatory changes persists in submandibular glands and SFR is ≥0.1 ml/min, these patients may benefit from anti-inflammatory treatment. However, the effectiveness of treatment may be limited or absent in patients with a concomitant decrease in FDG and PSMA. To the best of our knowledge, our study is the first to address this issue. PSMA uptake in parotid/submandibular glands more severely affected by Sjs with higher OS decreases. FDG uptake in parotid glands, which are affected in later stages, with high OS suggests that inflammation may still continue at recent stage. A decrease in SFR in patients whose PSMA parameters remain stable may possibly be related to glandular epithelial dysfunction reported in the literature.

Department, Lausanne University Hospital (CHUV), Lausanne, SWITZERLAND, [4]Swiss Vaccine Research Institute, Lausanne University Hospital (CHUV), Lausanne, SWITZERLAND, [5]Institute of Applied Radiation Physics, Lausanne University Hospital (CHUV), Lausanne, SWITZERLAND, [6]Infectious Diseases Department, Lausanne University Hospital (CHUV), Lausanne, SWITZERLAND, [7]The Rockefeller University, New York, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: HIV is known to hide in cells as a provirus integrated into cellular DNA to form the latent HIV-reservoir against which antiviral drugs are ineffective. Our aim was to demonstrate the feasibility of molecular imaging with antibodies in a first-in-human study to image HIV reservoirs and compare uptake before and after HIV antiretroviral therapy (ART). ***Materials and Methods:*** We labelled the broadly neutralizing antibody 3BNC117 with [123I]-iodine and performed quantitative SPECT/CT imaging in 5 patients with chronic HIV-1 infection at diagnosis and 3-6 months after ART initiation. We administered a human IgG preparation to saturate unspecific immunoglobulin targets within two hours prior to the injection of 200MBq of [123I]-I-3BNC117 and potassium iodide was administered to prevent thyroid radioactive exposure. Whole-body scans were performed 30min, 1, 3 , 6 and 23h after injection. SPECT with low-dose CT were performed 6 and 23h after injection. Dosimetry was performed on this first session in 3 patients. A second imaging session, was performed 3-6 months after antiretroviral therapy at undetectable viremia, 23h after [123I]I-3BNC117 injection under the same conditions. ***Results:*** 5 patients underwent the imaging protocol. A dosimetry based on 3 patients gave an effective radiation dose from the [123I]-3BNC117 of 26±6µSv/MBq. Visually, no obvious changes in the biodistribution were observed between both sessions. Individually, some changes were observed in the lymphatic tissue in the oropharyngeal region. Quantitative image analysis shows a significant tracer uptake decreases in the oropharynx (mean±SEM -28%±11%), testes (-9%±5%), posterior cervical lymph nodes (-18%±10%) and a tracer uptake increase in the liver (20%±5%) and muscles (+19%±10%). ***Conclusion:*** In this first-in-human imaging study with broadly neutralizing antibody [123I]I-3BNC117 performed in 5 individuals with chronic HIV infection at diagnosis and after ART initiation, we observe small but significant reductions in uptake in the oropharynx region, cervical lymph nodes, and testes after effective ART, suggesting specific uptake due to HIV in these tissues. Despite the limitations of the current study, molecular imaging with direct labelling of HIV-targeting antibodies is feasible and could contribute to a better understanding of the anatomical compartmentalization of HIV reservoirs.

OP-698

The Role of ^{68}Ga-Pentixafor PET/CT in The Diagnosis of Chronic Bone and Soft Tissue Infections

D. Denizmen[1], *S. Kuyumcu[1], D. Has Simsek[1], M. Karacam[2], O. N. Ergin[2], A. A. Cagatay[3], F. Buyukkaya[1], Y. Sanli[1];*
[1]Istanbul University Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Istanbul University Department of Orthopedics and Traumatology, Istanbul, TÜRKIYE, [3]Istanbul University Department of Infectious Diseases and Clinical Microbiology, Istanbul, TÜRKIYE.

Aim/Introduction: Leukocyte distribution is variable in chronic infections, potentially leading to false negative results on HMPAO white blood cell scintigraphy (WBC scan). 68Ga-Pentixafor PET/CT, targeting CXCR4 receptors predominantly expressed on lymphocytes, may be effective in detecting chronic infections. This study aims to investigate the diagnostic efficacy of 68Ga-Pentixafor PET/CT in suspected chronic bone and soft tissue infections. ***Materials and Methods:*** Patients with suspected chronic bone and soft tissue infections, who underwent three-phase bone scintigraphy with SPECT/CT, WBC (+/- bone marrow) scan, and concurrent 68Ga-Pentixafor PET/CT, were analysed. Asymptomatic orthopaedic material and diabetic foot areas served as the control group. Two nuclear medicine specialists visually and quantitatively evaluated images. Patients' biochemical, clinical, and microbiological results and other imaging findings were documented. The final diagnosis was confirmed by microbiological examination in addition to clinical and radiological findings. ***Results:*** In a cohort of 20 patients, 9 had chronic periprosthetic infections (PPI), 5 had diabetic foot infections (DFI), and 6 were under investigation for other chronic bone and soft tissue infections (Table 1). A total of 25 infection-suspicious foci were assessed, compared with 13 lesions observed in the control group, which comprised 6 asymptomatic prosthesis, 4 orthopaedic materials, and 3 diabetic foot regions. The final diagnosis was confirmed through surgical pathology and tissue culture in 7 patients, bacteriology in 10 patients, and clinical-radiological findings in 3 patients, while in the control group, diagnosis relied solely on clinical-radiological findings. A total of 21 out of 25 focal infection diagnosys were made, with no evidence of infection observed in any of the lesions within the control group. Scintigraphy detected 19/21 infection foci, resulting in 2 false negatives, 3 false positives, and 15 true negatives. 68Ga-Pentixafor PET/CT yielded positive results in all 21 infection foci, with 2 false positives and 16 true negatives. Respective sensitivity, specificity, accuracy, PPV, and NPV were found to be 90%, 83%, 87%, 86%, and 88% for scintigraphy, and 100%, 89%, 95%, 91%, and 100% for 68Ga-Pentixafor PET/CT. In ROC comparison analysis, PET was found to be as good as scintigraphy(p:0.07), also AUC analysis showed that PET provides more reliable results (AUC for PET and WBC scan; 0.94 and 0.86). ***Conclusion:*** 68Ga-Pentixafor PET/CT seems highly sensitive and accurate for diagnosing chronic infections with the added benefits of low radiation dose and shorter acquisition time. Its potential to replace standard imaging modalities deserves further investigation.

OP-699

Deep-learning noise reduction algorithms advantageously replace the spatial filters previously required for bone tomoscintigraphy analysis

A. Bahloul[1], *F. Rajadhas[1], G. Karcher[2], L. Imbert[1], P. Marie[1];*
[1]CHU de Nancy, Vandoeuvre Les Nancy, FRANCE, [2]Nancyclotep, Vandoeuvre Les Nancy, FRANCE.

Aim/Introduction: When added to conventional spatial filters (CSF), deep-learning noise reduction algorithms (DLNR) further decrease the noise level of tomoscintigraphies, enabling reduction of injected activities and recording times. This study aimed to determine whether CSFs are still required when a dedicated DLNR is applied to the bone tomoscintigraphies recorded on a whole-body 360° CZT camera. ***Materials and Methods:*** The CSF recommended for bone tomoscintigrapy with this CZT camera (a median post-filter associated with a 0.2 kernel inter-iterative filter) was used. Quantitative activity parameters (maximum activity concentration recovery coefficient (RCmax) and SUVmax) and a lesion detectability parameter (contrast-to-noise ratio (CNR)), were obtained with DLNR applied on phantom spheres and patient bone lesions. Comparisons were made between parameters obtained using CSF alone, DLNR alone, and using DLNR plus

CSF. The comparisons were performed on (i) bone lesions from whole-body acquisitions recorded in 10 polyarthritis patients (5 men, mean age: 62.7±15.5 years, mean body mass index: 25.4±6.0 kg/m2), 3 to 4 hours after the injection of 544±21.8 MBq [99mTc] Tc-HDP, and (ii) hot spheres from an IEC body phantom filled-in with a 99mTc solution, a 10/1 spheres/background activity ratio, and a global activity equivalent to that recorded during bone tomoscintigraphy. ***Results:*** The CNR, measured in a total of 49 diseased joints in patients, were equivalent between images with only DLNR applied and images with DLNR plus CSF (12.8±9.7 and 12.6±10.8, respectively), and they were both improved when compared with the CNR obtained with CSF alone (11.8±9.3, $p < 0.001$ for both comparisons). However, the addition of DLNR to CSF has the disadvantage of further decreasing the SUVmax from diseased joints (from 9.0±3.7 to 8.2±3.7, $p< 0.001$), whereas this decrease was not observed when using DLNR alone (9.2±4.0). Comparable results were obtained on medium (6 mL) and small (1.3 mL) volume phantom spheres, with the RCmax being better preserved with DLNR alone (46.6% and 78.9%, respectively) than with DLNR plus CSF (33.6% and 69.9%, respectively). However, only the small sphere exhibited a clear CNR improvement when only DLNR was used, rather than DLNR plus CSF. ***Conclusion:*** When assessed by contrast to noise ratios, this DLNR algorithm better preserves the absolute activity values of bone lesions and hot spheres when used alone than when associated with conventional spatial filters, and provides at least equivalent lesion detectability. Therefore, such algorithms could advantageously replace the spatial filters previously required for bone tomoscintigraphy analysis.

Extracerebral [18F]DPA-714 binding in individuals with and without post-COVID syndrome: associations with complaints

D. Visser[1], *X. Palard-Novello[2,3], M. Yaqub[2], E. van de Giessen[2], M. den Hollander[2], A. Verveen[4,5], A. D. Windhorst[2], S. C. J. Verfaillie[4,6], H. Knoop[4,5], B. N. M. van Berckel[2], S. S. V. Golla[2], R. Boellaard[2], N. Tolboom[1];*
[1]Department of Radiology and Nuclear Medicine, Division of Imaging and Oncology, University Medical Center Utrecht, Utrecht, NETHERLANDS, [2]Amsterdam UMC location Vrije Universiteit Amsterdam, Radiology & Nuclear Medicine, Amsterdam, NETHERLANDS, [3]Univ Rennes, CLCC Eugène Marquis, INSERM, LTSI - UMR 1099, Rennes, FRANCE, [4]Amsterdam UMC location University of Amsterdam, Department of Medical Psychology, Amsterdam, NETHERLANDS, [5]Amsterdam Public Health, Amsterdam, NETHERLANDS, [6]GGz inGeest Specialized Mental Health Care, Amsterdam, NETHERLANDS.

Aim/Introduction: While the underlying pathophysiology of post-COVID is still unclear, altered immune-activation is a potential disease mechanism. The PET tracer [18F]DPA-714 binds with high affinity to translocator protein (TSPO) expressed on activated microglia and macrophages, reflecting (neuro)inflammatory activity. The aim of this study is to investigate extracerebral [18F] DPA-714 uptake in individuals with and without post-COVID syndrome using a long axial field of view (LAFOV) PET scanner and to relate binding levels to the degree of complaints. ***Materials and Methods:*** Individuals who were high-affinity binders according to their TSPO genotype were included. Post-COVID related complaints (primarily fatigue and pain related quality of life) were measured with the Checklist-of-Individuals-Strength (CIS; for fatigue), and RAND-36 item Health Survey pain and physical subscales. Each participant received ~250 MBq [18F]DPA-714 directly followed by a 60 minutes acquisition on the Siemens Quadra PET/CT scanner. One volume of interest (VOI) was manually defined in skeletal muscle, lung and myocardium (as these were considered the organs most likely to be linked to fatigue and pain related complaints) for all participants. After assessment of organ-specific time-activity-curves, Patlak linearization was applied to estimate the net influx rate (Ki) in skeletal muscle, and Logan linearization was performed to estimate the distribution volume (VT) in lung and myocardium. Differences between groups were assessed using ANOVA, and associations between organs-specific [18F]DPA-714 binding and questionnaire scores were assessed using regression models, adjusted for age, sex and time since infection. ***Results:*** We included 30 individuals who suffered a SARS-CoV-2 infection, of whom 20 suffered from post-COVID syndrome (age 49±8, 60% female, 27±8 months post-infection), and 10 did not (age 45±10, 20% female, 25±10 months post-infection). In line with group definition, CIS score, Rand36 physical and -pain scores were indicative of more severe complaints in individuals with post-COVID syndrome (103±16, 58±21, 57±25, respectively) compared to individuals without (40±23, 97±6, 96±10, respectively; all $p<0.001$). Although some individuals showed organ-specific high binding, on group level binding in skeletal muscle (Ki 0.037±0.015 vs 0.032±0.014), lung (VT 6.3±3.6 versus 4.9±2.6) and myocardium (VT 27.0±6.4 versus 30.9±10.3) did not differ between individuals with and without post-COVID syndrome. No associations between [18F]DPA-714 binding and questionnaire scores were found. ***Conclusion:*** Using [18F]DPA-714, we found no group-level associations between inflammatory activity in skeletal muscle, lung and myocardium, with (severity of) post-COVID syndrome, although individual cases showed increased organ specific binding. Further research assessing other organs and organ-type specific complaint-questionnaires is warranted.

Initial Results of [68Ga]Ga-DOTA-Siglec-9 PET/CT to Assess Pulmonary Sarcoidosis

P. Dadson[1,2], *H. Ylä-Outinen[3], K. Kalliokoski[1,2], T. Tuokkola[1,2], M. Koivumäki[1,2], O. Moisio[1], N. Rajala[1], T. Tolvanen[2], P. Taimen[4,5], P. Nuutila[1,2,6], S. Jalkanen[6,7], T. Saaresranta[3], A. Roivainen[1,2,6];*
[1]Turku PET Centre, University of Turku, Turku, FINLAND, [2]Turku PET Centre, Turku University Hospital, Turku, FINLAND, [3]Department of Pulmonary Diseases, Turku University Hospital, Turku, FINLAND, [4]Institute of Biomedicine, University of Turku, Turku, FINLAND, [5]Department of Pathology, Turku University Hospital, Turku, FINLAND, [6]InFLAMES Research Flagship Center, University of Turku, Turku, FINLAND, [7]MediCity Research Laboratory, University of Turku, Turku, FINLAND.

Aim/Introduction: Sarcoidosis is a multisystem inflammatory disorder characterized by the formation of non-caseating granulomas. Pulmonary involvement is common, accounting for one of the major causes of death associated with the disease. Positron emission tomography (PET) utilizing Gallium-68-labeled 1,4,7,10-tetraazacyclododecane-N,N',N",N"-tetra-acetic acid conjugated sialic acid-binding immunoglobulin-like lectin 9 motif-containing peptide ([68Ga]Ga-DOTA-Siglec-9) specifically targets vascular adhesion protein-1 (VAP-1), a molecule crucial for Leukocyte recruitment to inflammatory sites. This study aimed to assess the feasibility of using [68Ga]Ga-DOTA-Siglec-9 PET for detecting pulmonary sarcoidosis. ***Materials and Methods:*** We enrolled six patients diagnosed with active pulmonary sarcoidosis (3 females, 3 males; age: 51 ± 13 years), as confirmed by histological examination, diagnostic high-resolution computed tomography (HRCT), and elevated serum angiotensin-converting enzyme

concentration (> 60 U/L; normal range < 40 U/L). Six healthy male volunteers (age: 37 ± 10 years) served as controls. Standardized uptake values (SUV) were determined from the [68Ga]Ga-DOTA-Siglec-9 PET in combination with CT imaging. ***Results:*** The tracer uptake was significantly higher in the lungs of sarcoidosis patients compared to healthy controls (SUVmean 1.82 ± 0.52 vs. 0.61 ± 0.17 g/mL, p = 0.0003). Additionally, uptake in lymph nodes was higher in the patient than in controls (SUVmean 5.3 ± 0.44 vs. 3.76 ± 0.60 g/mL, p = 0.00005). ***Conclusion:*** Our findings demonstrate the potential of [68Ga]Ga-DOTA-Siglec-9 PET imaging for detecting pulmonary inflammation and associated lymphadenopathy in sarcoidosis patients. ***References:*** • Grunewald J et al. Macrophage activation imaging using total-body ^{18}F-DPA714 PET/CT for detecting large vessel vasculitis: a pilot study

M. Zhang[1], *Y. Jia[1], Y. Wang[1], H. Shi[2], B. Li[1];*
[1]Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [2]Department of Rheumatology and Immunology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.

Aim/Introduction: Large vessel vasculitis (LVV) is a serious autoimmune disease that includes giant cell arteritis (GCA) and Takayasu arteritis (TAK). 18F-FDG PET as a tool for imaging inflammation has already proven to be useful for early diagnosis of LVV, but it shows limited value due to an inability to differentiate long lasting vessel wall remodeling with active vasculitis. The radiotracers targeting translocator protein (TSPO) of macrophage have been used in PET imaging for neuroinflammatory and rheumatic inflammatory diseases. This study aims to investigate the feasibility of 18F-DPA714 for LVV imaging on total-body PET/CT in a small cohort of patients with LVV. ***Materials and Methods:*** Six adult patients with LVV before glucocorticoids treatment and four healthy controls (HC) were enrolled in this prospective study. All participants underwent both 90-minutes dynamic total-body 18F-DPA714 PET/CT and 10-minutes static 18F-FDG PET/CT. Dynamic two-compartment model (2TCM), Simplified Reference Tissue Model (SRTM) model, and static standard uptake value (SUV) mapping were applied for quantitatively assessing the inflammation level of arterial walls on 18F-DPA714 PET/CT. PET vascular activity score (PETVAS) was used for quantitative assessment of inflammatory activity of vessel wall on 18F-FDG PET/CT. The uptake intensity of both 18F-DPA714 and 18F-FDG in the involved vessel walls was compared. ***Results:*** A total of 6 patients with LVV (mean age, 51.83 ± 19.49 years; 4 females and 2 males; 3 GCA and 3 TAK) and 4 HCs (mean age, 53.25 ± 9.46 years; 2 females and 2 males) were included. Our pilot study found that 2TCM, and using the cerebellum or muscle as the reference tissue for SRTM, as well as a simplified static 50-70-minute SUV (SUV50-70) mapping, might effectively quantify abnormal uptake of 18F-DPA-714 in the large arterial wall. On the TAC curve, the SUV50-70 of 18F-DPA714 in the arterial walls of the thoracic aorta or subclavian arteries, which are mainly affected large vessels in all 6 patients, were significantly higher than those in HC (1.05 ± 0.29 vs 0.54 ± 0.15, p = 0.006). The SUVmax of involved vessels walls on 18F-FDG PET were higher than those of 18F-DPA714 PET in 5 of 6 patients with PETVAS of grade 2-3, but one patient with PETVAS of grade 1 still showed significantly positive uptake of 18F-DPA714 in the thoracic aorta wall. ***Conclusion:*** 18F-DPA-714 PET might have potential value in supplementing 18F-FDG PET for the detection of LVV.

OP-703

Potential Role of Bone SPECT/CT in Early Diagnosis of Calciphylaxis. Pilot Study in Ukraine

P. Korol[1], *O. Shcherbina[1], M. Tkachenko[2];*
[1]Shupik National University Healthcare of Ukraine, Kyiv, UKRAINE, [2]Bogomolets National Medical University of Ukraine, Kyiv, UKRAINE.

Aim/Introduction: Calciphylaxis is a rarely understood phenomenon disturbance of vascular calcification with subsequent necrosis skin and soft tissue affecting patients with end-stage renal disease. Three-year mortality from sepsis ranges from 55% to 75%. In this regard, early diagnosis and subsequent treatment is necessary. The purpose of this study is to determine sensitivity of bone SPECT/CT as a diagnostic method in patients with skin lesions indicating calciphylaxis ***Materials and Methods:*** Completed descriptive cross-sectional retrospective study performed at the Department of Nuclear Medicine of the Shupik National University Healthcare of Ukraine. A total of 42 consecutive patients with cutaneous lesions suggestive of calciphylaxis treated with 99mTc-MDP bone SPECT/CT from 2015 to 2023 year were included in this is a pilot study. Sensitivity, specificity and accuracy of 99mTc-MDP SPECT/CT bones were identified. The results have been confirmed histological analysis and response to treatment sodium thiosulfate ***Results:*** 42 patients (64.8% women, 35.2% male) were included in this study with a mean of 62.3 ± 10.2 years. 89.7% of patients had end-stage renal disease and were in hemodialysis, 10.3% of them did not have kidney disease. There were defeats localized in the lower extremities in 78.5% of cases (33 of 42). Hybrid imaging was performed an average of 140 days after appearance of rashes (range 18-650 days). Histological analysis was performed in 52.4% of cases (22 out of 42). The sensitivity of the test was 100% with a specificity of 29.55% (PPV: 71%; NPV 100%). The diagnostic accuracy was 74%. Histopathology was positive in 68% of cases (15 of 22) ***Conclusion:*** Bone SPECT/CT is a non-invasive tool with high sensitivity to diagnosis of calciphylaxis. Its indication in the early stages diseases can improve early diagnosis and specific care. This also avoids skin biopsies, which may have serious complications such as septicemia

Design and Development of a Dual Energy Scatter Correction on Animal SPECT List Mode Data
A. Dareyni[1,2], *A. AliKhani[2], M. Farahani[2], B. Teymourian[2], M. Ay[1,2]; [1]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging (RCMCI), Advanced Medical Technologies and Equipment (AMTEI), Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Scattered photons present a significant challenge in SPECT imaging, leading to reduced contrast, resolution, and quantitative accuracy. Scatter correction methods play a crucial role in addressing these issues. One common approach involves using energy window-based methods, such as Dual-Energy Window (DEW) or Triple-Energy Window (TEW) techniques. These methods utilize sub-windows to approximate the scatter distribution in the main photopeak window, allowing for the estimation and correction of scatter events. In this study, we aimed to implement and evaluate the DEW scatter correction method using Animal SPECT list mode data. ***Materials and Methods:*** Raw data is transmitted to the computer using the User Datagram Protocol (UDP). A multi-threaded acquisition pipeline is initialized to process the received data packets and generate calibrated projections, including linearity, uniformity, and energy calibration. Simultaneous acquisition of photopeak and scatter window projections was performed using a 30% energy window centered on the 140 KeV photopeak of Tc99m, along with a 20% scatter window below it. Scatter projections were subtracted from the photopeak using a k-value of approximately 0.57, assuming a similar scatter distribution in both windows. The corrected projections were then reconstructed using the Maximum Likelihood Expectation Maximization (MLEM) algorithm with 20 iterations. To evaluate the effectiveness of the correction method, reconstructed images were compared with non-corrected ones, focusing on data acquired from a NEMA IQ phantom in Animal SPECT studies. ***Results:*** To assess the effectiveness of scatter correction methods, we calculated two key parameters influenced by scatter photons, Contrast-to-Noise Ratio (CNR) and Spill-Over Ratio (SPR), within the cold spheres of the IQ phantom. The SPR was calculated within two cold spheres of a phantom containing air and water. The SPR values were reduced after scatter correction, in the air sphere decreasing from 0.38 to 0.31 and the water sphere decreasing from 0.4 to 0.34. Additionally, CNR was computed for hot rods and cold spheres within the phantom, revealing a notable increase of approximately fivefold in both regions following scatter correction. ***Conclusion:*** scattered photons can harm the quality of medical images and reduce their diagnostic accuracy. Our research demonstrates that by effectively removing scattered photons from the primary image, we can enhance image quality, as evidenced by improvements in Contrast-to-Noise Ratio (CNR) and reduced Spill- Over Ratio (SPR). This indicates that photons that were erroneously detected in false positions can be identified and eliminated, leading to more accurate results.

EPS-212
Design and development of a resolution recovery algorithm on Animal SPECT List mode data
M. Ay[1,2], *A. Dareyni[1,2], M. Farahani[2], B. Teymourian[2], M. Mohebi[2]; [1]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging (RCMCI), Advanced Medical Technologies and Equipment (AMTEI), Tehran University of Medical Sciences (Tums), Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: The demand for dedicated small animal imaging systems is increasing, driven by their extensive use in the molecular imaging field for achieving superior resolution and sensitivity. Recent developments have concentrated on improving both hardware and software components to elevate spatial resolution in small animal SPECT imaging. In this study, our objective was to develop an iterative image reconstruction algorithm incorporating CDRF modeling to restore lost resolution. ***Materials and Methods:*** We developed an iterative reconstruction method using Maximum Likelihood Expectation Maximization (MLEM), which employs a system matrix to represent the imaging system in each iteration. A plastic capillary source containing 1 mCi of Tc99m was positioned parallel to the detector head at distances of 30 mm, 45 mm, 60 mm, 75 mm, and 90 mm. The Collimator-Detector Response Function (CDRF) was measured at each distance during planar image analysis. Subsequently, this data was fitted to a Gaussian function to determine specific mean and standard deviation parameters. These parameters were then utilized in generating the system matrix to model the response of every voxel in the object across each cell of the detector array. Finally, the reconstructed image underwent analysis for resolution recovery ***Results:*** The images were reconstructed using an MLEM algorithm with 20 iterations. Prior to applying resolution recovery, the Full Width at Half Maximum (FWHM) analysis indicated values of 2.11 mm, 3.29 mm, 3.99 mm, 4.3 mm, and 4.9 mm at distances of 30 mm, 45 mm, 60 mm, 75 mm, and 90 mm, respectively. After implementing resolution recovery, the FWHM values improved to 2.078 mm, 2.12 mm, 2.22 mm, 2.25 mm, and 2.31 mm at the corresponding distances. ***Conclusion:*** The finite dispersion of detected photons due to collisions with the collimator results in an increased number of detector cells detecting counts, thereby leading to resolution degradation. Modeling the dispersion related to distance with a Gaussian function enables more precise system modeling, facilitating the recovery of lost resolution.

Exploring the Earliest and Optimal Imaging Time for PET/CT Imaging after [18F]FDG Injection: An Evidence-based Study

Y. He, *H. Gao, H. Yu, R. Yang, Y. Zhang, H. Shi;*
Department of Nuclear Medicine, Zhongshan Hospital, Fudan University, Shanghai, CHINA.

Aim/Introduction: The recommended interval between 2-[18F] fluoro-2-deoxy-D-glucose ([18F]FDG) administration and positron emission tomography (PET) acquisition is 60 min (acceptable range: 55-75 min), according to the procedure guidelines. To accommodate patient waiting times, additional space is required when the number of patients is high. Based on this, the aim of this study was to investigate whether the waiting time after [18F] FDG injection could be shortened while meeting diagnostic needs. ***Materials and Methods:*** In total, 44 oncological patients with pathological results who underwent 60-min total-body dynamic PET imaging with full activity (3.7 MBq/kg) of [18F]FDG were retrospectively included. The raw data was reconstructed into 55 frames: 5 s/frame for the initial 3 min, and 180 s/frame for the last 57 min (55th frame served as reference). Time-to-activity curves (TACs) were obtained by drawing volumes of interest in the background tissues and lesions in all image frames. Lesion-to-background ratios (LBRs), in terms of lesion-to-blood ratio (LBR), lesion-to-liver ratio (LLR), lesion-to-muscle ratio (LMR), and lesion-to-non-tumour ratio (LNR) of different image frames were calculated and compared. The data from 40-50 min and 58-60 min were then reconstructed into six groups of static images (G40-42, G42-44, G44-46, G46-48, G48-50, and G58-60). The differences in image quality (standardized uptake value [SUV], signal-to-noise ratio [SNR], and LBRs) and lesions detectability (lesion-detection rate) between G58-60 and the other groups were further evaluated. ***Results:*** In the TACs analysis, the average LBRs of all lesions gradually increased over time and achieved no significant difference from those of the 55th image frame at 51th image frame (derived from 45-48 min data, all $p \geq 0.34$). There were no significant differences in the SUVmean of all background tissues between G48-50 and G58-60 (all $p \geq 0.09$). As for the background SNRs, the differences between G58-60 and the remaining groups were insignificant (all $p \geq 0.19$). The SUVmax and LBRs of all lesions did not differ significantly between G48-50 and G58-60 (all $p \geq 0.12$). Pathological results served as reference, the lesion-detection rate was 86.0% (49/57) in G40-42 and 87.7% (50/57) in the remaining groups, with no significant difference between groups ($p > 0.99$). ***Conclusion:*** By advancing the imaging time point to 40 min after [18F]FDG injection, PET images still maintain the lesion detectability for diagnostic needs. If relaxed to 48 min, the image quality can be further improved. ***References:*** Boellaard R, Delgado-Bolton R, Oyen WJ, et al. FDG PET/CT: EANM procedure guidelines for tumour imaging: version 2.0. Eur J Nucl Med Mol Imaging. 2015;42(2):328-54.

Acquisition and reconstruction protocol for [89Zr] Z-DFO-girentuzimab studies on BGO based PET/CT system

M. Olivieri[1,2], *L. Antunovic[1], F. Gelardi[1,2], A. Larcher[1], M. Sollini[1,2], A. Salonia[1,2], A. Chiti[1,2], A. Savi[1];*
[1]IRCCS San Raffaele Scientific Institute, Milan, ITALY,
[2]Vita-Salute San Raffaele University, Milan, ITALY.

Aim/Introduction: The monoclonal antibody targeting carbonic anhydrase IX (CA-IX), [89Zr]Zr-DFO-girentuzimab (GTB) demonstrated high accuracy for clear cell renal cell carcinoma (ccRCC). Aim of this study was the optimization of the GTB acquisition and reconstruction parameters with a BGO based PET/CT system, using phantom and patient data. ***Materials and Methods:*** We acquired phantom and patient data on a digital BGO based PET-CT system with 32-cm axial field-of-view, in list mode. Data from the NEMA image quality phantom were acquired using a lesion-to-background ratio of 4.1 in a single bed position for 30 min. Images from 3 patients with renal masses suspicious for ccRCC were acquired 5.2 days after the administration of 37 MBq of GTB. Total body images were acquired from the skull to the feet (5 min x bed plus an additional 15 min bed on the kidneys). The mean counts for the additional bed with high statistics were used to rescale the phantom data in list mode and obtain comparable statistics with patients' data. The images of each patient were reconstructed using the full and shorter acquisition time (3min x bed, 15 min in the upper abdominal region). Phantom and patient data were reconstructed using Bayesian penalized likelihood reconstruction algorithm with different β values (100,1500,2000,2500,3600) and different matrix size (256, 384). Contrast recovery (CR) and background variability (BV) were measured on phantom images obtained with the different β values. In patients, liver signal-to-noise ratio (S/N) was obtained as the pixel mean/SD within the ROI. ***Results:*** Phantom: as β increases CR and BV decrease. The matrix size of 384 performs better than 256 for CR for all β. For the smallest sphere, CR ranged from 31,4 to 14,3 and from 34,6 to 15,9 for matrix size of 256 and 384 respectively. BV showed a similar behavior for the two considered matrix. Patients: Focusing on the target bed with 15 min of acquisition, an acceptable quality corresponding to a liver S/N of 10 was obtained with β values of 1500 and 2000. Acquisition with 3 min/bed and β=3600 showed the better image quality from a clinical point of view. ***Conclusion:*** The 32 cm field of view of the Omni Legend PET system and the implemented reconstruction algorithm allow to obtain high quality GTB clinical images with an acceptable acquisition time.

EPS-216

Comparison of Early Dynamic Patlak-Rutland Influx Rate Constant (K_i) Images from [^{68}Ga]PSMA Compared with Conventional Delayed Static Images

D. L. Bailey, *K. P. Willowson, E. J. Bernard, P. J. Roach;*
Royal North Shore Hospital, Sydney, AUSTRALIA.

Aim/Introduction: To use a long axial field-of-view (LAFOV) PET/CT scanner (Siemens Biograph Vision Quadra) to examine the ability of early (0-10 min after injection) whole body (WB) [68Ga] PSMA parametric images of influx rate constant (Ki) generated by the Patlak-Rutland graphical analysis at the voxel level to detect the full extent of disease compared to conventional static images acquired at 60 mins post-injection. ***Materials and Methods:*** Subjects for routine early dynamic with later delayed static scanning protocol were recruited and administered ~125 MBq of [68Ga]PSMA-11 while in the scanner with imaging for 10 mins commencing upon injection. Images in the dynamic sequence were reconstructed for 20 secs per frame resulting in 30 frames in total and compared to the 5 min static images acquired at 60 mins post-injection. The dynamic sequence generated two WB parametric images: influx rate constant (Ki in units %/min) and volume of distribution (Vd - unitless). The left ventricular contents were used to generate the time-activity curve for the input function. The Ki images and the delayed static images were assessed independently by an experienced nuclear medicine

physician who had full access to the clinical history and all prior and contemporary imaging. ***Results:*** Twenty-one subjects were recruited. The Ki images and the static images were fully concordant in 16 of the 21 subjects. Three of the 21 scans were read as normal on both the delayed images and the Ki images. A further 3 subjects showed a single abnormal focus on the delayed images not seen on the Ki images while two scans showed foci present in the Ki images only and hence must be presumed to be false positive results at this stage. The absence of radioactivity in the bladder was noted on the majority of the Ki images. ***Conclusion:*** The LAFOV PET/CT systems provide whole body coverage providing new approaches to imaging. In this study, a 10 min dynamic from injection was investigated as a potential alternative to the routine 60 min uptake and delayed imaging protocol by using a parametric imaging approach to remove the early blood pool component from the early phase image. In the majority of cases the Ki images could be used as an alternative to conventional delayed imaging. This protocol could reduce the time burden on subjects referred for scans and the need for dedicated uptake rooms.

Aim/Introduction: Neuroendocrine tumors (NETs) are a highly heterogeneous group of malignancies that are biologically characterized by the overexpression of somatostatin receptors [1]. Detection, staging, and therapy monitoring of NETs are often difficult due to their varied localization and cellular heterogeneity. Conventional PET/CT imaging using somatostatin analogues with 68Ga is a current method of choice for evaluating the NETs [2]. During PET examination about 40% of positron annihilations occur through the creation of positronium [3]. Positronium is an exotic atom composed of an electron from tissue and the positron emitted by the radionuclide. Positronium decay in a patient's body is sensitive to the nanostructure and metabolism of human tissues [3]. The first ex-vivo and in-vivo positronium images have shown differences in the positronium mean lifetime in healthy and cancerous tissues, indicating that positronium lifetime may be used as an indicator for in-vivo cancer classification [4,5,6]. ***Materials and Methods:*** The studies (approved by bioethics committees, agreement: 1072.6120.92.2023 (NCT06242119) and. KB16/2022 (NCT06211803)) were conducted at the University Hospital in Cracow and in the Medical University of Warsaw. In total, 13 patients were examined. After administration of [68Ga]-Ga-DOTA-TATE, each patient was first examined with a standard PET/CT system and then with the novel PET prototype constructed at the Jagiellonian University which is the first multi-photon system capable of simultaneous PET and positronium imaging [7,8,9]. The method used for positronium imaging is described in detail in recent works [4,7,8,9]. ***Results:*** We demonstrate the first positronium images of 13 patients with indications for NETs tumors. We determine the lifetime of positronium in different organs including liver, spleen, and pancreas, and correlate it with the result of standard PET/CT diagnosis and clinical assessments. ***Conclusion:*** We demonstrate the feasibility of positronium imaging, a novel type of diagnosis, that is becoming available with the advent of high-sensitivity PET systems [7]. The correlation between the positronium lifetime and the neuroendocrine tumor stage will be presented and discussed. ***References:*** [1] F. Panzuto et al., J Neuroendocrinol. 2023;35(8):e13306. Performance in detecting metabolic pulmonary lesions with PET/CT system using OSEM and Deep Learning reconstruction techniques.

A. Montaño, *E. A. Marino, G. A. Peña;*
Fundación Escuela de Medicina Nuclear, Mendoza, ARGENTINA.

Aim/Introduction: PET/CT systems utilize advanced image reconstruction techniques, such as Ordered Subset Expectation Maximization (OSEM), known for its precision but challenged by noise issues due to multiple iterations. Alternatively, techniques like Hyper Iterative Reconstruction and Deep Progressive Hyper Reconstruction (HYPER DPR), the latter employing artificial intelligence, are being explored. This research focuses on comparing the effectiveness of OSEM versus HYPER Iterative and HYPER DPR in detecting metabolic pulmonary micronodules (μNPs). ***Materials and Methods:*** Acquisitions were performed on 35 patients with oncological lung lesions, following 60 minutes after the administration of fluorodeoxyglucose activity labeled with Fluor-18 (18F-FDG). Ten-minute acquisitions were triggered in the lung, and standard OSEM reconstruction was performed in 2 minutes, while the other Hyper techniques were reconstructed at 2, 4, 6, 8, and 10-minute intervals. Volumes of interest (VOIs) were placed in the lung parenchyma and nodules, measuring maximum SUV, average SUV, and standard deviation (SD). Using these values and the axial anatomical size of the lesions, contrast-to-noise ratio (CNR) values were quantified across different reconstructions and times. ***Results:*** 55 pulmonary nodules (NPs) were obtained with diameters ranging from 3.8 to 11.9 millimeters, and the range of 4 to 7 mm was selected within the μNPs category. In this range, the HYPER DPR technique began with a CNR value of 40.69 at 2 minutes, significantly surpassing OSEM, which achieved values of 27.42 at the same time. Furthermore, the CNR values of HYPER DPR showed steady growth, reaching 68.33 at 10 minutes. On the other hand, HYPER Iterative started with a value of 34.52 at 2 minutes, and although it began lower than HYPER DPR, it demonstrated notable improvement over time, surpassing HYPER DPR in the longer intervals, culminating in maximum CNR values of 76.25 at 10 minutes. ***Conclusion:*** HYPER Iterative stands out as the most effective technique in terms of CNR improvement over time, while HYPER DPR also demonstrates good performance, especially in shorter intervals. OSEM, although limited to a single data point, lags behind in comparative performance in the detectability of μNPs.

EPS-219

Exploration the Feasibility and Additional Value of ^{18}F-FDG/^{68}Ga-FAPI-04 Dual-low-activity-tracer One-stop Total-body PET Imaging after ^{68}Ga-FAPI-04 Injected at 34min

Z. Zheng, *Y. He, R. Yang, H. Gao, P. Hu, H. Shi;*
Zhongshan hospital, fudan university, Shanghai, CHINA.

Aim/Introduction: Currently, a widely used 2-day protocol combined with the use of 18F-FDG and 68Ga-FAPI can be completed on various conventional PET devices, exhibiting excellent general applicability. However, there are drawbacks in this protocol. Our team developed a one-stop FDG-FAPI dual-low-activity-tracer imaging protocol using a total-body PET[1] and confirmed that satisfactory images can be obtained at 34-minute after the injection of 68Ga-FAPI-04 in the 2-day protocol [2]. In this study, we aimed to further validate the feasibility of one-stop FDG-FAPI PET/CT after injection of 68Ga-FAPI-04 at 34min and explore its additional value. ***Materials and Methods:*** Thirty pairs of patients with suspect malignancies who underwent dual-tracer PET were enrolled in this retrospective study. The images were reconstructed at 34-39 and 50-60min after additional injection of 68Ga-FAPI-04 (named PETFDG, PETD34-39, and PETD50-60 in one-stop FDG-FAPI PET, named PETFDG', PETF34-39, and PETF50-60 in the 2-day protocol, respectively). Tumor-to-normal ratios (TNRs) of lesions in PETFDG, PETD34-39, and PETD50-60 and TNRs of lesions in PETF34-39 and PETF50-60 were evaluated separately. To evaluate the potential added value of one-stop FDG-FAPI PET over the 2-day protocol, TNRs of PETFDG, PETD34-39, and PETD50-60 were compared with PETF34-39. The lesion detectability of two imaging protocols was evaluated by chi-square test. ***Results:*** Comparing dual-tracer imaging (PETD34-39 and PETD50-60) and single-tracer imaging (PETFDG) in one-stop FDG-FAPI PET, TNRs of dual-tracer imaging were higher than those of PETFDG. PETD34-39 and PETD50-60 showed similar performance in lesion detectability and TNRs (all $P > 0.05$). In the 2-day protocol, there are no statistically significant differences in TNRs of all lesions at PETF34-39 and PETF50-60. Comparing one-stop FDG-FAPI PET with the 2-day protocol, TNRs of PETF34-39 were significantly higher than those of PETFDG but lower than those of PETD34-39 and PETD50-60. Lesion detectability in the one-stop FDG-FAPI PET was higher than that in the 2-day protocol. The average radiation dose in one-stop FDG-FAPI PET was significantly lower than that in the 2-day protocol ($P<0.001$). ***Conclusion:*** One-stop FDG-FAPI PET at 34 min could provide sufficient information to meet clinical diagnosis and showed better lesion detectability than that in the 2-day protocol. ***References:*** 1. Voxel-Wise Delay Correction in Whole-Body Parametric Perfusion Imaging - Application in Metastatic Prostate Cancer

L. Tolbod[1,2], *N. L. Christensen[1], P. Iversen[1], L. C. Gormsen[1,2], J. Sörensen[2,3], M. R. Jochumsen[1];*
[1]Dept. of Nuclear Medicine & PET, Aarhus University Hospital, Aarhus, DENMARK, [2]Dept. of Clinical Medicine, Aarhus University, Aarhus, DENMARK, [3]Dept. of Surgical Sciences, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Tumour perfusion serves as a versatile biomarker for assessing cancer metabolic activity, regardless of nutrient type. With the advent of long-axial field-of-view (LAFoV) PET scanners, primary tumours and metastases can be visualized and quantified in a single scan. However, the injected tracer arrives at different times in different parts of the body and quantification of fast phenomena, such as perfusion, is sensitive to this time delay. Thus, it is necessary to correct for time delay when calculating parametric images. We propose a method where voxel-wise delay estimation is combined with a basis-function approach to obtain robust and quantitative parametric images of perfusion. ***Materials and Methods:*** Ten metastatic prostate cancer patients underwent dynamic [15O]H2O PET (5 min) followed by [^{18F}]PSMA-1007 PET in the same session on a LAFoV PET/CT scanner (106 cm FoV). Parametric images of perfusion were made automatically with no user interaction: The blood input function (BIF) was automatically extracted from the images by cluster analysis on a reduced FoV corresponding to the heart. The signal delay in each voxel relative to the BIF was estimated using a leading-edge approach (1), creating a map of delays. The dynamic image series was then corrected for the delay and whole-body parametric images were calculated using a basis-function approach (2) and exported as DICOM series. To validate the parametric images, values of perfusion were compared to those obtained by standard 1-tissue compartment modelling with time delay included in the model using volume-of-interest (VOI) averaged time-activity-curves. VOIs were produced by delineating primary tumours and metastases on the [^{18F}]PSMA-1007 PET scan and transferring the VOIs to the [15O]H2O dynamic series and parametric images. ***Results:*** Parametric perfusion images were successfully produced for all patients with visualization of all delineated primary tumours (n=8), lymph node metastases (n=64), and bone metastases (n=85). Median perfusion were 19, 16 and 26 mL/min/100mL, respectively. There was excellent linear correlation between parametric images and VOI-based modelling (r=0.99) with a slope close to unity (0.98). ***Conclusion:*** Quantitative parametric images of whole-body tumour perfusion can be calculated from a single, short [15O]H2O PET scan using voxel-wise delay correction and a basis-function approach. ***References:*** 1) Christensen et al. EPS-221

Diagnostic value of AL^{18}F-NOTA-FAPI PET/CT in patients with colorectal cancer in comparison with enhanced CT

W. Yao, *G. Hou, X. Cheng, H. Chen, X. Wang, R. Zheng;*
National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital,Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, CHINA.

Aim/Introduction: This study aims to compare the diagnostic performance of AL18F-NOTA-FAPI positron emission tomography computed tomography (PET/CT) and enhanced CT in preoperative staging and postoperative local recurrence and distant metastases in patients with colorectal cancer. ***Materials and Methods:*** This prospective study analyzed patients with confirmed colorectal cancer who underwent concurrent AL18F-NOTA-FAPI PET/CT and contrast-enhanced CT between July 2023 and January 2024. PET/CT and enhanced CT findings were confirmed by histopathology or radiographic follow-up.The diagnostic accuracy of PET/CT in preoperative staging and detection of postoperative local recurrence and distant metastases were analyzed. ***Results:*** In this study,a total of 30 patients colorectal cancer (including one case of

ileocecal carcinoma) were enrolled.Pathological findings showed that 29 patients were adenocarcinomas of different differentiation degrees, and one patient was mucinous adenocarcinoma. Among them,27 underwent PET/CT for initial staging and 3 for recurrence detection.Regarding lesion-based diagnostic accuracy, The sensitivity of AL18F-NOTA-FAPI PET/CT and enhanced CT for primary tumor detection was 100% ([28/28];P>0.05). AL18F-NOTA-FAPI PET/CT and enhanced CT showed no signs of tumor recurrence in 3 postoperative patients.AL18F-NOTA-FAPI PET/CT showed higher sensitivity for lymph node metastasis (98.4%[61/62]vs.80.6%[50/62];p<0.05), liver metastasis (94.6%[35/37]vs.67.6%[25/37];p<0.05), peritoneal metastasis (100%[48/48]vs.86.0%[40/48];p<0.05) and bone metastasis (100%[1/1]vs.0%[0/1]; P>0.05).For lung metastasis, the sensitivity of AL18F-NOTA-FAPI PET/CT and enhanced CT was 100% ([66/66]; P>0.05). ***Conclusion:*** Both AL18F-NOTA-FAPI PET/CT and enhanced CT are very accurate for the detection of primary tumors.AL18F-NOTA-FAPI PET/CT is superior to enhanced CT in detecting metastatic lesions,involving lymph nodes,liver, peritoneal and bone,and there is no difference in lung metastasis.Thus AL18F-NOTA-FAPI PET/CT can provided a more accurate TNM staging,prompting the optimisation or adjustment of treatment decisions.

Stępień[1,2], for the J-PET Collaboration;*
[1]Faculty of Physics, Astronomy and Applied Computer Science, Jagiellonian University, S. Łojasiewicza 11, 30-348, Kraków, POLAND, [2]Centre for Theranostics, Jagiellonian University, Kopernika 40, 31-501, Kraków, POLAND, [3]High Energy Department, National Centre for Nuclear Research, 05-400, Otwock-Świerk, POLAND, [4]Chair and Department of Endocrinology, Jagiellonian University Medical College, Kraków, POLAND.

Aim/Introduction: J-PET is the first Positron Emission Tomography, PET, scanner constructed from organic scintillator strips [1]. Currently, clinically available PET tomographs are predominantly based on inorganic crystal scintillators operating on the photoelectric effect principle [2]. However, the principle of operation of a plastic-based scanner is inherently distinct and focuses on the Compton interaction [3]. The axial arrangement of the organic strips compels scintillation light transfer along the scanner, hence, changing the read-out method [4]. Employment of such approaches reduces the costs of a device, opens the prospect of improving accessibility of PET imaging [2] and allows for adaptivity of the tomograph to various conditions and facilitation of handling [5]. In this study, we evaluate first clinical images determined with the modular J-PET prototype in view of normalization and random coincidences corrections. ***Materials and Methods:*** The study was approved by the bioethics committee of the Collegium Medicum of the Jagiellonian University No. 1072.6120.92.2023 (NCT06242119). In the presented trial we performed a single-bed imaging of a patient administered with ^{18F}-Fluorodeoxyglucose. This procedure was preceded by the standard PET/CT imaging session. Normalization corrections were estimated using the component-based approach. There, normalization coefficients can be decomposed and each component can be evaluated separately [6]. Correction for random coincidences was applied based on the delayed time window method [7]. This algorithm requires the preparation of coincidences within a time window shifted with respect to the initial interaction, traditionally forcing a second, parallel data acquisition. However, utilization of the J-PET's singles-mode acquisition (saving each interaction) allows for storage of both information simultaneously. ***Results:*** We developed correction algorithms for normalization and random coincidences. Next, we applied them during the reconstruction of clinical images obtained with the plastic-based PET tomograph and evaluated their impact. ***Conclusion:*** We demonstrated random coincidences and normalization corrections of clinical PET images for patients administered with ^{18F}-Fluorodeoxyglucose performed with the novel J-PET tomograph. J-PET is a cost-effective light and portable scanner based on plastic scintillators. ***References:*** [1] P. Moskal et al., Bio-Algorithms and Med-Systems 7 (2011) 73-78[2] S. EPS-223

Quantitative error analysis of injection time recording in Patlak parametric imaging with population-based input function

W. Liu[1,2], *X. Chen[1], H. Zeng[2], Y. Lu[2], Q. Ye[2];*
[1]Institute of Biomedical Manufacturing and Life Quality Engineering, School of Mechanical Engineering, Shanghai Jiao Tong University, Shanghai, CHINA, [2]United Imaging Healthcare, Shanghai, CHINA.

Aim/Introduction: Parametric imaging using a population-based input function (PBIF) has demonstrated its feasibility in reducing the duration of dynamic acquisition compared to the full dynamic protocol that uses an image-derived input function (IDIF). However, the PBIF method's accuracy is prone to errors related to the recording of tracer injection times, unlike the IDIF method. Specifically, discrepancies between the PBIF template and the actual input function lead to errors in parametric images. In clinical settings, instances of inaccurate recording of injection times are common. This study aims to conduct a quantitative error analysis for both simulated and actual injection time points. ***Materials and Methods:*** Whole-body 60-min dynamic 18F-FDG (2.5-11.4 mCi) scans of 10 participants (6/4 M/F, 26-69 yrs, 49-79 kg) were performed on a long axial field-of-view PET/CT scanner. The image-derived input function (IDIF) was extracted from the descending aorta. Analysis of IDIF allowed us to estimate the recorded injection time errors (ITE), which ranged from -70.2 minutes to 0.9 minute (recorded time minus the correct time). The correct time was estimated from the last time point with zero IDIF value. PBIF templates were created from the corrected IDIFs using the leave-one-out criterion. We simulated ITEs from -10 minutes to +10 minutes using the corrected injection time. Patlak parametric imaging was performed on the final six frames (5 minutes/frame) using PBIF, with IDIF serving as the reference. We calculated the relative error of the input function's area under the curve (AUC), as well as the normalized mean square error (NMSE) and relative error of the Ki image. ***Results:*** The relative error of the input function's area under curve (AUC) exhibited a negative correlation with the simulated ITE, while the relative error of Patlak Ki images showed a positive correlation. For ITE within 30 seconds

(3 minutes), the absolute relative error of input function AUC was less than 1.5% (8.0%), the NMSE was less than 5.0×10-4 (2.0×10-3) and the absolute relative error of Ki images was less than 1.0% (5.0%); Consistent results were observed with real patient data as well. ***Conclusion:*** The relative error of Patlak Ki images exhibited a positive correlation with ITE. Differences in Ki images were negligible when ITE was within 30 seconds. The absolute error of Ki images remained below 5% when ITE was within 3 minutes.

EPS-224

Validation and Clinical Impact of Motion-Free PET Imaging Using Data-Driven Respiratory Gating and Elastic PET-CT Registration

A. H. Dias[1], *J. Schaefferkoetter[2], J. R. Madsen[1], T. Ø. Barkholt[1], A. B. Rodell[3], N. Birge[2], P. Schleyer[2], O. L. Munk[1,4];*
[1]Aarhus University Hospital, Aarhus, DENMARK, [2]Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA, [3]Siemens Healthcare A/S, Aarhus, DENMARK, [4]Department of Clinical Medicine, Aarhus University, Aarhus, DENMARK.

Aim/Introduction: Clinical whole-body (WB) PET images can be compensated for respiratory motion using data-driven gating (DDG) [1]. Still, DDG PET images can have respiratory motion artefacts at the diaphragm, such as the "banana artefact", if the CT is acquired in a different respiration phase than the PET image. In this work, we explore the combined use of DDG PET and a novel deep-learning (DL) model that performs elastic registration of CT to an uncorrected PET image (WarpCT) [2], which enables reconstruction of PET and DDG PET images using WarpCTs for improved attenuation- and scatter correction. ***Materials and Methods:*** Our validation cohort consisted of 20 patients referred for clinical FDG WB examination on a PET/CT scanner (26.3cm FOV, 214ps TOF) that performed two CT scans: a free respiration CT (CTfree) and an additional end-expiration breath-hold CT (CTex). The novel DL model was used for elastic registration of each CT to the uncorrected PET and DDG PET images. Then, PET and DDG PET image sets were reconstructed using both CTs and both WarpCTs. These data were used to verify the robustness of the DL algorithm. Finally, the clinical impact cohort consisted of 10 selected clinical patients with FDG avid malignant foci around the diaphragm and/or large "banana artefacts" was evaluated for improvement in image quality and tumor to background ratios. ***Results:*** We evaluated visually that WarpCTs had a better anatomical match to the PET than the original CTs. When evaluating the difference image of the original CTs (CTfree - CTex), and of both the ungated and gated WarpCTs (WarpCTfree - WarpCTex or DDGWarpCTfree - DDGWarpCTex), we found a WB mean reduction of ~40%, of the error in Hounsfield units per mL ($p<0.001$) for both WarpCT difference images. Thus, the DL model makes similar WarpCTs when registering two different CTs to the same PET. In the 10 selected clinical patients, we observed a clear reduction of "banana artefacts" when combining DDG PET and the new DL model. A cumulative improvement in lesion-to-background ratios around the diaphragm was also observed when applying the DL model together with DDG. ***Conclusion:*** The application of the novel elastic PET/CT registration DL model, combined with DDG PET, results in motion-free PET images, reduced respiratory motion artefacts and enhanced lesion-to-background ratios around the diaphragm. ***References:*** 1. EPS-225

Head-to-head comparison of the detection performance and tumor uptake of ^{68}Ga-FAPI-04 and ^{18}F-FDG PET/CT in liver metastases from cancers of different type

G. Ma, *S. Song;*
Fudan university shanghai cancer center, Shanghai, CHINA.

Aim/Introduction: We sought to compare the detection performance and tumor uptake of 68Ga-FAPI-04 and 18F-FDG in liver metastases from cancers of different type. ***Materials and Methods:*** Total of 76 patients were included between May 2020 and April 2023.The detection performance of 18F-FDG and 68Ga-FAPI-04 PET/CT was determined via visual evaluation. Differences in the maximum standardized uptake value (SUVmax) and tumor-to-background ratio (TBR) were also analyzed between 18F-FDG and 68Ga-FAPI-04 PET/CT. ***Results:*** For detecting liver metastases, the sensitivity (94.80% vs. 69.94%, $p<0.001$) and accuracy (91.53% vs. 70.37%, $p<0.001$) of 68Ga-FAPI-04 PET/CT were significantly greater than that of 18F-FDG PET/CT in total of cancer (with 76 patients), the sensitivity (97.87% vs. 73.05%, $p<0.001$) and accuracy (96.05% vs. 74.34%, $p<0.001$) of 68Ga-FAPI-04 PET/CT were significantly greater than that of 18F-FDG PET/CT in carcinoma (with 65 patients), and the sensitivity (94.96% vs. 69.75%, $p=0.021$) of 68Ga-FAPI-04 PET/CT was significantly greater than that of 18F-FDG PET/CT in sarcoma (with 11 patients). In addition, in the digestive system cancer (54 out of 76 patients), the sensitivity (94.96% vs. 69.75%, $p<0.001$) and accuracy (92.31% vs. 70.00%, $p<0.001$) of 68Ga-FAPI-04 PET/CT were significantly greater than that of 18F-FDG PET/CT. On semiquantitative analysis, the SUVmax of 68Ga-FAPI-04 was significantly greater than that of 18F-FDG for digestive system cancer (mean, 6.45 vs. 5.20; $p=0.002$) and carcinoma (mean, 6.33 vs. 5.39; $p=0.017$). The TBR of 68Ga-FAPI-04 was significantly greater than that of 18F-FDG for total of cancer (median, 4.60 vs. 1.67; $p<0.001$), digestive system cancer (median, 4.80 vs. 1.67; $p<0.001$), carcinoma (median, 4.83 vs. 1.69; $p<0.001$), and sarcoma (median, 3.25 vs. 1.49; $p<0.001$). ***Conclusion:*** 68Ga-FAPI-04 PET/CT has a significantly greater detection performance than 18F-FDG PET/CT in detecting liver metastases in digestive system cancer and carcinoma.

Aim/Introduction: Fibroblast activation protein, characterized as a type II transmembrane glycoprotein, emerges as a significant target for radiolabeled imaging due to its increased expression in various cancer and inflammatory diseases. This research employed pharmacokinetic modeling to verify the effectiveness of simplified parameters for measuring [68Ga]Ga-FAPI-46 uptake. ***Materials and Methods:*** Ten patients with bile duct or pancreatic duct cancer were prospectively included (PANSCAN-1 study part A). Scans were performed on LAFOV PET/CT Biograph Quadra from 0 to 90 minutes post-injection (p.i) of ~200 MBq of [68Ga]Ga-FAPI-46. Arterial blood samples were drawn to establish calibrated

plasma input function extracted from both continuous arterial sampler and image derived input function from ascending aorta (IDIF). The kinetics of FAPI-positive lesions were characterized using conventional plasma input tissue-compartment models and simplified quantification methods were validated against the most preferred conventional model and outcome. ***Results:*** Data from 1 patient were not included due to discontinued scan acquisition over time and missing arterial sampling. Five patients had cholangiocarcinoma, 3 patients had pancreatic ductal adenocarcinoma and 1 patient had ampullary carcinoma. Twenty-one FAPI-positive lesions were evaluated. Blood sampling showed relatively stable plasma-to-whole blood ratio and no radiometabolites were detected. Time-activity curves (> 10 min p.i.) showed almost plateau for 12 uptakes and a declining shape for 9 lesions. Reversible 2-tissue-compartment showed most preferrable fits (81% based on Akaike information criteria). Volume of distribution using Logan linearization (VT_Logan) at 30-90 min p.i., target-to-whole blood activity concentration ratio (TBR) and weight-normalized standardized uptake value (SUVbw) at 80-90 min p.i. were highly correlated to VT obtained with full kinetic analysis using IDIF (respectively R2 = 0.97, R2 = 0.94 and R2 = 0.87). TBR and SUVbw at 60-70 min p.i. were also highly correlated to VT (respectively R2 = 0.93 for TBR and R2 = 0.86 for SUVbw), however correlation decreased with earlier intervals (respectively R2 = 0.79 for TBR and R2 = 0.82 for SUVbw at 20 to 30 minutes p.i). ***Conclusion:*** The kinetics of FAPI-positive lesions are most accurately depicted by a reversible 2-tissue-compartment model. SUVbw can be used as a simplified method to quantify [68Ga]Ga-FAPI-46 uptake with a start of acquisition time at 60 minutes p.i.

EPS-227

High Blood Glucose During F^{18} FDG PET CT - Is there a Sweet Solution?

K. Sabanayagam, *M. Millip, S. Arfa, B. Sanghera, M. Krishnamurthy;*
Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: High blood glucose level (BGL) can reduce ^{18}F FDG uptake in tumours and may reduce sensitivity of ^{18}F FDG PET CT studies. Patient preparation prior to the study includes at least 6 hours of fasting and ensuring the BGL is less than 8mmol /l or 144mg/l prior to ^{18}F FDG injection. BGL significantly >10mmol/l are encountered regularly, due to poor preparation or difficult glycaemic control in chronic diabetics, posing significant challenges with adverse impact of diagnostic delays and inconvenience of rescheduling patients. There are conflicting reports regarding the impact of high BGL on the diagnostic quality of the study and subsequent impact on management. This study assesses the impact of high BGL on the final report of the PET CT study. This was compared with histopathology, follow up imaging and consultations. ***Materials and Methods:*** 50 patients referred for ^{18}F FDG PET CT scans having high blood glucose level (>8mmol/l) prior to the study were included. The average uptake time was 64minutes. ^{18}F FDG uptake (SUVMax) within the primary, metastases, brain and liver were assessed. The report was reviewed for diagnosis and any inconclusion due to high BGL and its impact on patient management. Follow up was available for >6 months post imaging. Clinical indications included lung nodule assessment(14/50), colorectal cancer(10/50), Lymphoma and Melanoma(4/50). ***Results:*** The mean BGL was 11.4mmol/L (range 9 -29.1). The mean SUVMax in the primary tumour was 7.4 (0.76 -33) and for the metastases was 5.8 (1.4 - 17.8). The mean SUVMax Liver- 3.6 (2.6-5.46) and Brain - 7.2 (2.6-25.6). In 7 /50 patients (2 colorectal cancer, 1 Lymphoma, 1 GIST, 1 Myeloma, 1 Lung nodule and 1 Ureteric), tumour ^{18}F FDG uptake was reduced due to high BGL, whilst in the rest, 43/50, there was no effect. In the 7 patients, the uptake was of diagnostic level and did not affect the report, confirmed on patient follow-up. ***Conclusion:*** High BGL can affect ^{18}F FDG uptake in the tumour with potential to reduce sensitivity of the study. No significant impact seen regarding high BGL on the PET CT study report and patient management. Results are in keeping with the EANM guidelines which states FDG PET-scan's value outweighs concerns about fasting hyperglycaemia. ***References:*** Boellaard, R.,Delgado-Bolton, R., Oyen, W.J.,Giammarile, F., Tatsch, K.,Eschner, W., Verzijlbergen, F.J., Barrington, S.F., Pike, L.C.,Weber,W.A. and Stroobants, S., 2015. Estimation of LVEF and LV Volumes from Cardiac Gated ^{18}F-FDG PET Using Different Commercially Available Software

M. Al-Qabandi[1], *P. Galve[2,3,4], F. Hyafil[5], M. Bernardini[5];*
[1]Department of Nuclear Medicine, College of Medicine, Kuwait University, Kuwait, KUWAIT, [2]Paris Cardiovascular Research Center, Inserm University, Paris, FRANCE, [3]Nuclear Physics Group and IPARCOS, Complutense University of Madrid, Madrid, SPAIN, [4]Health Research Institute of the Hospital Clinico San Carlos, Madrid, SPAIN, [5]Department of Nuclear Medicine, European Hospital Georges Pompidou, Paris, FRANCE.

Aim/Introduction: Positron emission tomography (PET) is a sensitive, accurate, non-invasive diagnostic tool. The use of PET has been increasing for cardiac patients, especially those with myocarditis, endocarditis, and sarcoidosis. PET also helps determine inflammation and infection and assess myocardial viability in patients with heart failure and coronary artery disease considered for revascularization. PET can discriminate viable from scarred tissue in damaged myocardium. Gated ^{18}F-fluorodeoxyglucose (^{18}F-FDG) PET enables the study of metabolic properties of myocardial tissues and provides further information about global left ventricular function, wall thickening, and regional wall motion. This study aimed to quantify and compare left ventricular (LV) volume and ejection fraction (EF) using different commercially available software to assess myocardial viability in heart failure patients. ***Materials and Methods:*** Fifteen patients underwent electrocardiographically gated ^{18}F-FDG cardiac PET/CT in order to determine myocardial viability. Three commercially available software packages were used to obtain the left ventricular end-diastolic volume (EDV), end-systolic volume (ESV), and left ventricular ejection fraction (EF). The software packages used were Cedars-Sinai's Quantitative Automated Gated SPECT (QGS - Cedars-Sinai Medical Center), the Corridor4DM (4DM - INVIA, LLC) application (formerly known as 4DM-SPECT), and CardIQ (GE Healthcare) software. ***Results:*** The LVEF measured by QGS and CardIQ was not significantly different, while the values obtained from 4D-MSPECT were relatively higher. Among the various parameters analysed, the reconstruction algorithms Q.Clear with β-value = 1000 resulted in the highest LVEF variations, while Q.Clear with β-value = 300 had the lowest. ***Conclusion:*** Significant differences were found among the three image post-processing software packages, which could affect the prognostic results of the cardiac exam and patient management.

EPS-229

[18F]-piflufolastat used for PSMA-PET/CT imaging of patients presenting with first biochemical recurrence of prostate cancer: assessment of the agreement of per-region reading between an experienced nuclear medicine physician and a deep-learning-based software

M. Gauthé[1], *J. Richter[2], S. Balogova[3,4];*
[1]SCINTEP, Grenoble, FRANCE, [2]EXINI Diagnostics AB, Lund, SWEDEN, [3]Comenius University Bratislava, St. Elisabeth Oncology Insitute and Bory Hospital a.s., Bratislava, SLOVAKIA, [4]Hôpital Tenon GH AP.SU, Paris, FRANCE.

Aim/Introduction: Artificial intelligence-aided imaging is of increasing interest since it might improve diagnostic reading performance. We tested the per-region agreement in reading of [18F]-piflufolastat used for PSMA-PET/CT imaging of prostate cancer (PCa) patients presenting with first biochemical recurrence (1stBCR) between an experienced nuclear medicine physician (ENMP) and a deep-learning-based automated software (AI). ***Materials and Methods:*** PET/CTs from the phase III "PYTHON" study were used. Details on the AI and its automatic-detection-function, which has been developed to standardize quantification and reporting in PCa patients and not to flag lesions, have been previously published [1]. First, an ENMP read all the PET/CTs, blinded to the clinical data, and quoted the abnormal foci in agreement with the e-PSMA guidelines' 5-point scale, for several anatomical regions. Second, the AI automatic-detection-function was performed on the PET/CTs. Automatically detected foci were noted for the same anatomical regions as those in the ENMP reading. Uptakes in urinary, digestive or vascular structures, degenerative/traumatic bone lesions and ganglia were considered obvious irrelevant foci and excluded from the analysis. Uptakes whose volume was below 0.1 ml defined according to the PET/CTs acquisition parameters were also not considered. The per-region agreement between ENMP and AI readings was assessed using Cohen's kappa k-coefficient. Analysis was performed by considering equivocal findings by ENMP (e-PSMA score 3) positive for PCa. ***Results:*** Overall, 192 PET/CTs were analyzed. From AI-reading, a median of 17 obvious irrelevant foci per patient were excluded. Per-patient positivity rate for ENMP and AI was 71% and 80% respectively. ENMP and AI concordantly classified 149/192 (78%) PET/CTs but disagreed on the number of positive regions in 66 of them. There was strong agreement for the prostate bed (k=0.65), pelvic lymph nodes (k=0.69), paraaortic lymph nodes (k=0.64) and viscera (k=0.92); moderate agreement for lymph nodes above the diaphragm (k=0.46), rib cage (k=45) and pelvis (k=0.48); weak agreement for spine (k=0.39). ***Conclusion:*** We demonstrated an encouragingly strong agreement in several anatomical regions between the separate PET/CT readings by an ENMP and an AI used like a computer-aided-design device in patients presenting with PCa 1stBCR. A further combined ENMP-AI reading will be compared to a standard of truth to demonstrate the improved diagnostic performance provided by AI-aided imaging reading. ***References:*** 1. Development and validation of AI-driven PET/CT-based models and new imaging biomarkers to improve differential diagnosis of breast DLBCL and IDC

F. Liu, *W. Chen, X. Liu, S. Song;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: There is no effective way to differentiate breast lymphoma from breast cancer other than invasive pathology testing. We aimed to establish a multimodal artificial intelligence (AI) discrimination model and identified a robust predictive non-invasive digital imaging biomarker for the differential diagnosis of breast cancer and breast lymphoma. ***Materials and Methods:*** A total of 386 breast nodules from 279 breast diffuse large B-cell lymphoma (DLBCL) and invasive ductal carcinoma (IDC) patients with 18F-fluorodeoxyglucose (18F-FDG) positron emission tomography/computed tomography (PET/CT) were enrolled in our multi-center study. Patients with breast nodules from different centers were separated into internal and external cohorts. We have introduced a deep learning (DL) model extractor, which is trained on DLBCL and IDC datasets, combined with conventional radiomics workflow, to extract nodule-level features under different tumor slice views. Utilizing machine learning (ML) approaches, we integrated multimodal features into our models and employed local shapley and local interpretable model-agnostic explanations (LIME) to further interpret and gain clinician trust. ***Results:*** On the internal validation, our multimodal model (accuracy (ACC)=0.980, 95% confidence interval (CI)=0.957-0.991; area under the curve (AUC)=0.992, 95% CI= 0.946-0.998) outperformed unimodal models. On the external testing, the ACC and AUC were 0.975 (95% CI 0.913-0.993) and 0.996 (95% CI 0.972-0.999). Moreover, the optimal non-invasive digital imaging biomarker could distinguish between breast DLBCL and IDC, with an average ACC of 0.923±0.075 and 0.937±0.062 on the internal validation and external testing sets, respectively. ***Conclusion:*** Our study demonstrates that an AI-driven PET/CT based diagnostic differential model and non-invasive imaging biomarkers can effectively discriminate between DLBCL and IDC in the breast.

EPS-231

Enhancing Preoperative Diagnosis of Gliomas in 18F-FET PET-Negative Lesions: A Multiparametric MRI and MRS Approach Using Integrated PET/MR

X. Li[1,2], *J. Lu[1,2];*
[1]Department of Radiology and Nuclear Medicine, Xuanwu Hospital, Capital Medical University, Beijing, CHINA, [2]Beijing Key Laboratory of Magnetic Resonance Imaging and Brain Informatics, Beijing, CHINA.

Aim/Introduction: This study aims to assess the potential utility of multiparametric MRI with magnetic resonance spectroscopy (MRS) in the diagnosis of gliomas within 18F-FET PET-negative isolated cerebral lesions. ***Materials and Methods:*** Participants with isolated cerebral lesions suspected of gliomas by conventional MRI were prospectively recruited to perform a hybrid 18F-FET PET/MRI scan between March 2022 and September 2023. The lesions with negative 18F-FET PET findings were included. Multiparametric MRI features, including conventional MRI characteristics, apparent diffusion coefficient, cerebral blood flow, and MRS parameters, were quantified within the regions of interest. Logistic regression was performed to combine conventional and advanced MRI parameters for glioma identification. Area under the curve (AUC) and net reclassification improvement (NRI) were used to determine the diagnostic efficacy of gliomas. Spearman's

tests examined correlations between PET/MRI parameters and WHO grades. ***Results:*** Fifty-one participants (44.35 ± 27.15 years old, 26 males) with 37 gliomas, 8 demyelination lesions, and 6 metastases were evaluated. choline to creatine (Cho/Cr) ratio in gliomas were significantly higher than those in non-gliomas (2.21, 1.30, $p < 0.001$). Multiparametric MRI (AUC, 0.88) outperformed conventional MRI (AUC, 0.72) in differentiating gliomas from non-gliomas (NRI = 0.29, $p = 0.02$). Ch/Cr ($r = 0.44$, $p = 0.006$), choline to acetylaspartate (Cho/NAA) ($r = 0.33$, $p = 0.047$), and metabolic tumor volume ($r = 0.47$, $p = 0.003$) correlated with WHO grades in PET-negative gliomas. ***Conclusion:*** Multiparametric MRI with MRS demonstrates significant promise in enhancing the diagnosis and overall clinical management for 18F-FET PET-negative gliomas.

PET/CT Imaging of a_vB_6 Integrin to Monitor Radiation-Induced Pulmonary Fibrosis
C. Wieczorek Villas Boas, *W. C. Y. Lo, R. Clifford, L. Strong, A. Klaas, F. Grogan, C. Bergom, B. E. Rogers;*
Washington University School of Medicine, St. Louis, MO, UNITED STATES OF AMERICA.

Aim/Introduction: Cancer patients treated with radiation therapy in the thoracic region can develop radiation-induced pulmonary fibrosis (RIPF) [1]. The αvβ6 integrin plays a central role in RIPF pathogenesis by the activation of transforming growth factor-beta after radiation injury. We hypothesize that αvβ6 is an early marker of RIPF and that PET imaging of αvβ6 can predict RIPF onset or determine the efficacy of therapeutic interventions using [64Cu]Cu-DOTA-A20-K16R. ***Materials and Methods:*** C57BL/6 female mice (N=4) were administered 14 Gy in a single fraction to the right lung using an image-guided small animal radiation research platform, which is a model that leads to RIPF. Sham-treated mice were used as controls (N=4). At four, five, and six months post-irradiation, animals were administered 11.1 MBq of [64Cu]Cu-DOTA-A20-K16R, which has shown high affinity binding to αvβ6 [2]. Mice were imaged one hour after injection using a small animal PET/CT system (Mediso). Images were reconstructed, and the SUV mean was calculated. Lungs were harvested for immunohistochemistry (IHC) to determine fibrosis (trichrome) and expression of αvβ6 integrin. ***Results:*** PET images demonstrate radioactive uptake in the right lung at the site of irradiation, with increased uptake from four to six months. At month four, there was no statistical significance (P=0.08) between sham (SUV 0.13 ± 0.03) and irradiated mice (SUV 0.15± 0.01). At month five, the irradiated lung had greater uptake (0.18 ± 0.05) than the sham (0.11 ± 0.01) (P = 0.03). At month six, uptake in irradiated lung increased to 0.28 ± 0.02, while the sham had an SUV of 0.14 ± 0.05; this difference was significant (P = 0.0003). IHC demonstrated a low level of expression of αvβ6 integrin at month four that increased at months 5 and 6, thus matching the PET imaging. Additionally, fibrosis was mild in month four, with diffuse fibrosis in month six. ***Conclusion:*** We demonstrated that PET imaging of αvβ6 integrin using [64Cu]Cu-DOTA-A20-K16R is feasible for detecting RIPF, although we were not able to show αvβ6 expression prior to fibrosis. Nevertheless, this approach could be used to determine the efficacy of anti-RIPF therapies. ***References:*** 1.Puthawala, K., et al., Inhibition of Integrin αvβ6, an Activator of Latent Transforming Growth Factor-β, Prevents Radiation-induced Lung Fibrosis. OP-725
In vivo SPECT imaging of Fibroblast Activation Protein as a non-invasive biomarker of anti-fibrotic efficacy of Gp96 inhibition in idiopathic pulmonary fibrosis
B. Collin[1,2], *A. M. M. Dias[2], O. Burgy[3], M. Moreau[1], M. Claron[1], M. Guillemin[2], M. Monterrat[2], J. Simonet[2], A. Oudot[2], A. Helbling[2], F. Goirand[3,4], P. Bonniaud[3,4], P. Bellaye[3,2];*
[1]ICMUB UMR CNRS 6302 - University of Burgundy, Dijon, FRANCE, [2]IMATHERA, BIOSAND UMS INSERM 58 - CGFL, Dijon, FRANCE, [3]CTM UMR INSERM 1231, University of Burgundy, Dijon, FRANCE, [4]CHU François Mitterrand, Dijon, FRANCE.

Aim/Introduction: Idiopathic pulmonary fibrosis (IPF) is a progressive disease characterized by excessive production and deposition of extracellular matrix (ECM), leading to respiratory failure in patients. Under the influence of pro-fibrotic cytokines such as TGF-β1, lung cells acquire a myofibroblastic phenotype characterized by expression of Fibroblast Activation Protein (FAP)

and overproduction of ECM. Treatment options for IPF are limited, and can only delay disease progression without stopping it. Gp96 is an endoplasmic reticulum chaperone protein overexpressed during fibrosis, promoting membrane expression of numerous receptors involved in fibrogenesis. Inhibition of Gp96 appears to be an interesting therapeutic strategy in IPF, and we hypothesize that in vivo imaging of myofibroblasts via a probe targeting FAP could enable the monitoring of the efficacy of this type of treatment. ***Materials and Methods:*** C57BL/6 mice (male, 8 weeks old) received a single intratracheal administration of bleomycin (BLM, 1.5 mg/kg, n=14) or NaCl (n=14) as a control, then were treated or not with a Gp96 inhibitor (PU-WS13, 12.5 mg/kg, daily gavage, n=17)) or NaCl (n=16) from D8 to D22. Fibrosis was followed longitudinally by CT imaging at D8, D15 and D22. At D22, lungs and broncho-alveolar lavages (BALs) were recovered for collagen quantification (Sirius Red, Sircol and Ashcroft score), FAP immunostaining (IHC) and TGF-β1 assay (ELISA). In vitro, A549 cells stimulated with TGF-β1 (2 ng/mL, 24h) were treated or not with PU-WS13 (25/50 µM, 24h) to study FAP protein expression (WB) and protein-protein interactions between Gp96 and FAP (PLA). A FAP-specific imaging probe was developed from an anti-FAP antibody fragment (Fab) coupled to a bifunctional chelating agent (DOTAGA) for radiolabeling with indium-111 for single-photon emission computed tomography (SPECT) imaging. The [111In]In-DOTAGA-Fab-FAP probe was injected intravenously into C57BL/6 mice (100µL, 10MBq, 25µg). Mice underwent SPECT imaging at 1h, 4h and 24h post-injection. ***Results:*** In vitro, PU-WS13 decreased the interaction between Gp96 and FAP inducing its degradation. In vivo, our results demonstrated that PU-WS13 induced an inhibition of collagen accumulation, fibrous lesions on CT imaging, FAP and TGF-β1 expression induced by BLM. SPECT imaging showed a significant increase in [111In]In-DOTAGA-Fab-FAP uptake in the lungs of control fibrotic mice when compared to the PU-WS13 treated group. ***Conclusion:*** Gp96 inhibition represents an innovative anti-fibrotic strategy. In vivo imaging of myofibroblasts via the FAP protein appears capable of monitoring the efficacy of this therapy in our animal model.

OP-726

Autotaxin-Specific PET/CT Imaging using [18F]ATX-1905 for Progression Monitoring and Efficacy Evaluation in Preclinical Models with Pulmonary Fibrosis

X. Deng[1], *J. Liu[1], J. Zhou[1], Y. Shi[1], S. Song[1], J. Chen[2], Y. Li[2], B. Yu[1], S. H. Liang[2], X. Zhu[1];*
[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]Emory University, Atlanta, GA, UNITED STATES OF AMERICA.

Aim/Introduction: Idiopathic pulmonary fibrosis (IPF) poses a lethal threat with unpredictable advancement and scarce treatment avenues. Current diagnosis via high-resolution computed tomography (HRCT) may overlook initial deterioration signs of IPF, necessitating precise early-stage detection methods and continuous monitoring. Autotaxin (ATX) emerges as a crucial target due to its high expression in IPF-afflicted lungs, holding potential for positron emission tomography (PET) tracers to track fibrosis progression. This study aimed to assess the efficacy of [18F]ATX-1905 compared to [18F]FDG in diagnosing early fibrosis, monitoring disease evolution, and evaluating treatment response in a bleomycin-induced pulmonary fibrosis (BPF) mouse model. ***Materials and Methods:*** To establish a BPF mouse model, a single dose of bleomycin was administered via intratracheal delivery. To assess treatment efficacy, mice received oral administration of two commonly used drugs for IPF, pirfenidone or nintedanib, from Day 9 to Day 23 post-bleomycin administration. Lung tissues were collected from the mice for evaluation of pulmonary inflammation using hematoxylin-eosin (HE) staining, as well as assessment of fibrosis degree using Masson staining. ATX expression in the lungs of BPF mice was examined through enzyme-linked immunosorbent assay (ELISA). PET imaging with [18F]FDG and [18F]ATX-1905 was conducted at various disease stages or treatment phases. ***Results:*** The level of pulmonary fibrosis observed in the BPF mouse model corresponded with changes in ATX expression levels. Throughout the study, particularly evident at the early stage (Day 9), PET imaging showed that the uptake of [18F]ATX-1905 in the lungs of BPF mice surpassed that of the control group and remained consistently high, reflecting the sustained presence of severe pulmonary fibrosis. This heightened lung uptake was mitigated by pretreatment with the ATX inhibitor, PF-8380. Conversely, the lung uptake of [18F]FDG markedly increased, peaking at Day 15 (mid-term), and subsequently declined, potentially indicating reduced levels of inflammation. A two-week treatment regimen using either pirfenidone or nintedanib resulted in notable reductions of ATX expression levels and fibrosis degrees within lung tissues, based on ELISA and Masson staining, as evidenced by PET imaging with [18F]ATX-1905. Furthermore, uptakes of [18F]FDG also decreased following the treatment period. ***Conclusion:*** PET imaging with [18F]ATX-1905 demonstrated outstanding capabilities in early fibrosis detection, disease monitoring, and treatment assessment within the lungs of BPF mouse models. Its notable specificity for ATX expression and sensitivity to ATX alterations indicate its potential for monitoring diverse ATX expression levels in the lungs of IPF patients.

In vivo detection of C. difficile infection by immunoPET imaging using toxin-selective radiotracers

B. Salinas[1,2,3], *M. González Arjona[1], L. Cussó[1,3], L. Alcantara[4], P. Muñoz[1,4], M. Desco[1,5,3];*
[1]Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, SPAIN, [2]Universidad Carlos III de Madrid, Madrid, SPAIN, [3]Centro Nacional de Investigaciones Cardiovasculares, Madrid, SPAIN, [4]Hospital General Gregorio Marañón, Madrid, SPAIN, [5]CIBERSAM, ISCIII, Madrid, SPAIN.

Aim/Introduction: Clostridioides difficile infection (CDI) is the main leading cause of hospital acquired infections, increasing morbidity, hospitalization length and mortality of patients1,2. Conventional diagnostic tools, especially with low biomarker concentrations, may prove insufficient3,4. Our goal is to create a specific radiotracer to assess the diagnosis of CDI by Nuclear Imaging. We describe the labeling of the commercial antibody Bezlotoxumab5 (Bez), which is selective for ToxinB released by the bacteria, with clinical [89Zr]Zr to accurately identify active infectious foci in a CDI animal model ***Materials and Methods:*** Bezlotoxumab was conjugated with a 20-fold molar excess of p-SCN-Bz-DFO (30min, 37ºC, PD-10 column), and radiolabeled with 1.5 mCi of [89Zr]Zr (1h, RT, 100kDa-Amicon). In C57BL/6J mice (N=6), CDI was induced with a 10-day antibiotic regimen (cefoperazone 0.5mg/mL) followed by IP clindamycin (10mg/kg). Then, 106 CFUs C. diff (ribotype 027) were administered orogastrically. Animals with antibiotics but uninfected (N=5) and wild-type (WT) animals (N=5) served as dysbiosis (Dysb) and healthy controls respectively. 89Zr-DFO-Bez radiotracer was IV administered 24h post-infection (100 µCi), and PET/CT imaging was performed at 24h and 4d post-injection. Colons were harvested post-imaging for H&E histology and ex vivo biodistribution. ***Results:*** The synthesis of 89Zr-DFO-

Bez was successfully accomplished, with a high radiochemical yield of 67.9±18.3%, a purity level of 100% and a specific activity of 5.8±0.3 mCi/mg. PET/CT imaging confirms a specific and localized uptake of the radiotracer in the lumen of sections of the digestive system associated with the colonization of the bacteria (included colon), of the infected animals. In contrast, control groups exhibited uptake solely in excretion organs and circulatory system. Reduction of the longitude of the colon was observed only in CDI and Dysb animals. H&E histopathology confirmed a moderate CDI. Ex vivo biodistribution showed 2-fold higher uptake in CDI colons (4.0±0.9%ID/g) compared to WT (2.0±0.5%ID/g) and Dysb (2.0±1.7%ID/g). ***Conclusion:*** We have synthesized and characterized a C. difficile specific radiotracer based on commercial antibody Bezlotoxumab, 89Zr-DFO-Bez, with high radiochemical yield, purity and stability, which supports its use in in vivo studies. PET/CT imaging of 89Zr-DFO-Bez revealed a distinct and specific uptake in the colon of CDI animals, not observed in the other groups, and further confirmed by ex vivo biodistribution higher colon uptake in CDI models ***References:*** 1. Bartlett, J.G.; et al, New England journal of medicine 1978, 298, 531-534. 2. Magill SS, et al. New England Journal of Medicine. 2018;379(18):1732-44. 3. Debast SB, et al. Clin Microbiol Infect.

Novel reporter approach for highly specific longitudinal T-cell tracking via PET

M. Schottelius[1], *G. Giordano-Attianese[2], D. Viertl[3], M. Triboulet[2], L. Wendlinger[4], K. Ouchen[2], Y. Bonvin[3], M. Irving[2];*
[1]Centre Hospitalier Universitaire Vaudois (CHUV), University of Lausanne (UNIL) and Ludwig Institute, Lausanne, SWITZERLAND, [2]University of Lausanne (UNIL) and Ludwig Institute, Lausanne, SWITZERLAND, [3]Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, SWITZERLAND, [4]Centre Hospitalier Universitaire Vaudois (CHUV), Lausanne, SWITZERLAND.

Aim/Introduction: Cell-based immunotherapies (CART-cells, TILs) have shown great promise in the clinic, but the kinetics of distribution and expansion and the fate of transferred cells in patients are largely unknown. Non-invasive, longitudinal T-cell imaging can provide this missing information, given that the reporter system meets the following prerequisites: non-immunogenic human(ized) reporter protein, no physiological expression, high and stable expression on T-cells, and, ideally, availability of a clinically established reporter-targeted tracer with suitable in vivo characteristics. The h679-scFv/[68Ga]Ga-IMP288 system, previously employed in the context of a pretargeting strategy [1,2], combines all these features and was thus evaluated as a reporter system for longitudinal T-cell tracking using [68Ga]Ga-IMP288-PET. ***Materials and Methods:*** Jurkat T-cell lymphoma cells were transduced with a chimeric T-cell tracking receptor (CTTR-1) containing the h679-scFv using a lentiviral construct. CTTR-1 expression was confirmed using flow cytometry and in vitro [68Ga]Ga-IMP288 binding (1 nM, 37°C, 30 min). CTTR-1 expressing Jurkat cells (10 Mio) were injected both subcutaneously (SC) and intravenously (IV) into NSG mice, and [68Ga]Ga-IMP288 PET/CT was performed at different time points after cell transfer (SC: 1, 5 and 14d; IV: 28d). Moreover, a retroviral construct was used to transduce primary human T-cells with the h679-scFv (CTTR-2). ***Results:*** Transduction efficiency of Jurkat cells with CTTR-1 was >90%, resulting in in vitro binding of 64.7±3.2% of added [68Ga]Ga-IMP288 activity per 1Mio cells. In vivo [68Ga]Ga-IMP288 PET/CT allowed high-contrast visualization of SC and IV injected CTTR-1-Jurkat cells at all time points investigated. Complete absence of tracer accumulation in SC WT Jurkat tumors demonstrated the CTTR-1 specificity of [68Ga]Ga-IMP288 PET. In the IV model, extensive infiltration of the liver and bone marrow with CTTR-1-Jurkat cells after 28d was observed in [68Ga]Ga-IMP288 PET/CT and confirmed by ex vivo analyses. The retroviral transduction of primary human T-cells with CTTR-2 (3 donors) yielded transduction efficiencies of app. 35 and 20% in CD4 and CD8 T-cells, respectively, with in vitro binding of 53-69% and 8-23% of added [68Ga]Ga-IMP288 activity per 1Mio cells. ***Conclusion:*** Our proof-of-concept data clearly demonstrate the general feasibility of exploiting the established h679-scFv/[68Ga]Ga-IMP288 pretargeting approach as a reporter system for sensitive, high contrast imaging of CTTR-transduced T-cells. Its implementation in a preclinical CART-cell model to corroborate its great potential for clinical T cell tracking is currently ongoing. ***References:*** [1] C. Bodet-Milin et al., J. Nucl. Total body [18F]FDG PET/CT imaging in lung cancer mouse models links inflammation and shifts in brain metabolism to worse disease outcome

Ö. Özer, *M. Krisch, M. Homolya, H. Moll, E. Casanova, S. Gruenert, M. Hacker, C. Philippe, C. Vraka;*
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: In cancer metabolism studies, the circadian rhythm and chronic stress have been recognized as contributing factors to cancer development [1]. Two articles linked poor prognosis in head and neck cancer patients with stress [2] and lung cancer patients with high levels of chronic emotional stressors, such as anxiety and depression, through [18F]FDG neuroimaging [3]. This work investigates how inflammation and stress from disease burden manifests in brain uptake and is linked with a worse disease outcome in lung cancer mouse models. ***Materials and Methods:*** Lung cancer models were created in C57BL/6J (Wt) mice using orthotopic transplantation of KrasG12D mutated, p53 (KP) and A20 (KPA) deficient mouse lung cancer cells [4]. [18F]FDG was administered 30 days post-engraftment, following a 60-minute awake distribution, mice underwent µPET/CT scans under isoflurane anesthesia. Whole-body image segmentation and data analysis were conducted using PMOD and Ma-Benveniste-Mirrione brain atlas, normalising brain SUV values to total brain uptake. ***Results:*** KPA mice showed significant alterations in brain [18F]FDG metabolism: increase in basal forebrain septum and brain stem, and decrease in cortex region. Notably, decreases in brown adipose tissue (BAT) [18F]FDG uptake and white adipose tissue (WAT) volume was observed in KPA mice alongside of increases in thymus uptake and lymph node volume. Advanced disease state in KPA mice was confirmed by the significant increase in total lung uptake, increased lung and metabolic tumor volumes, lung weights and total lesion glycolysis (TLG). ***Conclusion:*** Higher inflammatory burden in KPA mice is associated with worse outcomes and impacts body composition and brain metabolism. The altered brain regions suggest a metabolic shift favoring survival functions over higher brain functions. This highlights the severe consequences of chronic inflammation on disease progression, showcasing metabolic and immune system adjustments as pivotal under stress. ***References:*** [1] Swanton C, Bernard E et al. Université Paris-Saclay, Hôpital Bicêtre, Service de génétique Moléculaire, Pharmacogénétique et Hormonologie, Le Kremlin Bicêtre, FRANCE.*

Aim/Introduction: Sex and age may account for pharmacokinetic (PK) variability. However, corresponding molecular determinants remain misunderstood. Organic anion-transporting polypeptides (OATPs) transporters are key determinants of the liver uptake and hepatobiliary elimination of many drugs. OATPs are also expressed in other tissues where their pharmacokinetic importance is not known. 11C-glyburide is a metabolically stable probe developed to study the hepatic OATP function in humans1. The objective of this study was to assess whether OATPs account for PK variability related to sex and ageing. ***Materials and Methods:*** The study was conducted in 16 healthy humans undergoing an 11C-glyburide whole-body PET acquisition in baseline condition. Ten of them underwent a second 11C-glyburide PET scan after infusion of rifampicin, a potent OATP inhibitor. Subjects were sorted according to their age and sex: males<30y (24.0±3.2y, n=7), males>50y (57.5±5.6y, n=4), and females>50y (60.6±2.4y, n=5). The transfer rate of 11C-glyburide (kuptake) from blood to the liver was estimated to describe OATP function. Tissue exposure was expressed as the area under the curve (AUC) of 11C-glyburide kinetics in selected organs and blood. Tissue distribution was expressed as AUCR=AUCtissue/AUCblood. ***Results:*** Rifampicin drastically decreased kuptake (-73±13%, $p<0.001$) and liver exposure (-50±10%, $p<0.001$) while significantly increasing blood exposure (+24±24%, $p<0.01$). Liver exposure was 42.6±18.4% higher ($p<0.05$) in females>50y compared with age-matched males, consistent with higher kuptake values ($p<0.05$), with negligible and non-significant difference in blood exposure ($p>0.05$). Sex differences were abolished in the presence of rifampicin. In males, neither liver, blood exposures nor kuptake were changed by ageing ($p<0.05$). For all subjects, kuptake was positively correlated with liver exposure ($p<0.01$, $R2=0.78$) and negatively correlated with blood exposure ($p<0.01$, $R2=0.40$) with an impact of OATP function (kuptake) 4-fold more pronounced for liver compared with blood exposure. In other organs, no significant difference in AUCR was observed between groups. ***Conclusion:*** OATP function predominates in the liver where it may drive important sex-related differences in liver exposure, which was not discernible from blood-based data. Therefore, classical plasma PK may miss sex differences in liver exposure to OATP substrates that may account for the higher prevalence of drug-induced liver injury in females. Conversely, neither was kuptake, liver exposure nor blood kinetics of 11C-glyburide affected by ageing. This suggests no or limited decline of OATP-mediated elimination with age. ***References:*** 1Marie et al. Aim/Introduction: Lutetium (177Lu) Vipivotide Tetraxetan (PluvictoTM), a Prostate-Specific Membrane Antigen (PSMA)-targeted radioligand therapeutic, has recently gained marketing approval for the treatment of metastatic castration-resistant prostate cancer. Despite the clinical benefit observed in the VISION Phase III trial, all 831 patients treated with the drug eventually relapsed.[1] Moreover, uptake in healthy tissues, such as salivary glands and kidneys, resulted in dose-limiting toxicities. Prostatic Acid Phosphatase (ACP3), a non-specific phosphomonoesterase that is virtually absent in healthy organs, including salivary glands and kidneys, shows elevated expression levels in most prostate cancer lesions (www.proteinatlas.org). Technetium-99m and Indium-111 labeled anti-ACP3 antibody fragments successfully accumulated in metastatic prostate cancer lesions in patients when administered intravenously at high doses.[2] Highly potent and specific ACP3 ligands may provide ideal targeting moieties for the selective delivery of diagnostic and therapeutic radionuclides to prostate cancer lesions. ***Materials and Methods:*** Two DNA-Encoded Chemical Libraries comprising ~5.8 million members were screened against recombinant human ACP3. Resulting hits were synthesized as DOTAGA and fluorescein conjugates to characterize binding to recombinant and cellular ACP3. Lutetium-177-labeled ligands were injected in tumor-bearing mice to assess their in vivo targeting performance and anti-cancer activity. ***Results:*** Several ligands (named ProX1, ProX2, and ProX3) were identified as highly potent small organic binders and inhibitors of human ACP3 as observed by enzymatic inhibition, fluorescence polarization and surface plasmon resonance measurements. The best tumor accumulation and residence time after intravenous injections in mice bearing HT-1080.hACP3 or PC3.hACP3 cancer lesions was observed for ProX1, also named OncoACP3 (i.e., >35 %ID/g, 72 hours after administration). Single injections of 177Lu-OncoACP3 cured cancer at low and well-tolerated doses (i.e., 5 and 20 MBq/mouse). ***Conclusion:*** Given its exceptional tumor-targeting performance and the lack of salivary glands and kidney uptake, OncoACP3 may overcome current limits of PSMA-based ligands for pharmacodelivery applications in prostate cancer patients. ***References:*** [1] Sartor O. Multi-Organ Segmentation on CT-free Total-Body Dynamic PET Scans

C. Clement[1], *S. Xue[1], X. Zhou[2], L. Li[2], R. Seifert[1], A. Rominger[1], J. Liu[2], K. Shi[1];*
[1]Inselspital, Universitätsspital Bern, Bern, SWITZERLAND,
[2]Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: The advancement of ultrasensitive, high-resolution, total-body (TB) PET/CT with an extended field of view has significantly broadened the scope of dynamic PET. However, discrepancies in temporal resolution between PET and CT pose challenges, potentially compromising quantitative accuracy. Moreover, the reliance on CT for organ segmentation can introduce errors in kinetic modelling. We aim to leverage the superior anatomical details provided by TB PET for attenuation correction (AC) and scatter correction (SC), coupled with frame-by-frame multi-organ segmentation, mitigating the effects of temporal resolution disparities and improving the precision of quantitative analyses. ***Materials and Methods:*** Deep learning algorithms were developed using static TB PET images from 430 patients scanned with the United Imaging uExplorer system. The algorithms were tested on twenty dynamic TB PET scans, each comprising 92 frames. A 3D UNet was initially trained using the nnU-Net framework [1] on non-attenuation and non-scatter corrected PET images to perform multi-organ segmentation. Ground-truth segmentation maps were generated from CT images with TotalSegmentator [2]. Subsequently, a dedicated decomposition-based network [3] was trained to handle AC and SC. For dynamic data, organ segmentations were predicted for each non-corrected frame using the segmentation network, followed by AC and SC using the decomposition network. The algorithms' performance was compared against manual segmentations refined by two physicians using Dice coefficients for each frame to assess the concordance between predicted dynamic organ segmentations and CT-based organ segmentations. ***Results:*** The trained model achieved an average Dice coefficient of 0.96 across all organs and dynamic frames. When applying the CT-based segmentation maps to the dynamic frames, an average Dice coefficient of 0.77 was attained in comparison. Table 1 depicts the Dice coefficients for each of the eight organs, comparing the outcomes from the trained model and the CT-based approach. ***Conclusion:*** The developed deep learning approach is effective for CT-free multi-organ segmentation, AC, and SC in dynamic TB PET scans, demonstrating potential to enhance accuracy and efficiency in dynamic PET imaging applications. ***References:*** [1] Isensee, Fabian et al. OP-733

Fully Automated FDG and PSMA Lesion Segmentation in PET Imaging via Deep Learning

M. Pires, *D. Ferrara, T. Beyer, L. K. Shiyam Sundar;*
QIMP Team, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Metabolic tumour volume (MTV) represents an emerging biomarker for patient prognosis in oncology. However manual delineation is untenable in clinical routine. Therefore, we introduce LION (Lesion segmentatiON), an open-source, automated tool designed for tumour delineation in [18F] FDG and [68Ga]PSMA PET scans. ***Materials and Methods:*** All the PET images and tumour delineations used for this study originate from the AutoPET-III challenge dataset. Separate models for each tracer were trained. The FDG model was trained on 914 PET scans and model performance was assessed on 52 PET scans. The training data (517M/397F) included 449 cases of lymphoma, melanoma, or lung cancer, and 465 negative findings. For the PSMA model, 250 prostate cancer PET images were used for training, while 50 were used to evaluate the model performance. The models were trained on PET images only, using the nnU-Net framework [1]. Baseline models were created using tumours as the sole target class. Subsequently, models with organ context were trained with the rationale of avoiding physiological uptake in both FDG and PSMA. Organ delineations were obtained using an established CT delineation approach [2] and were subsequently verified. The so-derived tissues were incorporated as additional target classes. Model performance was evaluated using DICE score, tumour detection rate, and Spearman correlation between reference and predicted MTV. ***Results:*** The addition of organ context significantly improved the performance of both models, by preventing the segmentation of healthy organs with high tracer uptake as tumours. In the FDG model, the DICE score improved from 0.46 to 0.74, while in the PSMA model, the DICE score improved from 0.57 to 0.68. The FDG model with organ context accurately identified 691 out of 899 (77%) malignant lesions. This model also showed a strong Spearman correlation of 0.94 between the predicted and reference MTV. Likewise, the PSMA model with organ context yielded a good detection rate by correctly identifying 1118/1325 (84%) tumours, together with a strong Spearman correlation between reference and predicted MTV of 0.98. ***Conclusion:*** The incorporation of organ context achieved state-of-the-art performance in tumour segmentation for two commonly used tracers, using only the PET image as input. ***References:*** [1] Isensee, F. et al. (2021). nnU-Net: a self-configuring method for deep learning-based biomedical image segmentation. Nature Methods, 18(2), 203-211.[2] Shiyam Sundar, L. K. et al. (2022). Deep-learning-based fully automatic malignant lesions segmentation in whole-body [^{68}Ga]Ga-PSMA PET/CT scans originates comparable results as expert-based identification and segmentation

F. Oliveira, *C. Constantino, Â. Silva, J. Castanheira, R. Oliveira, M. Machado, D. C. Costa;*
Champalimaud Foundation, Lisbon, PORTUGAL.

Aim/Introduction: This work aims to assess the feasibility and robustness of deep-learning-based fully automatic malignant lesion detection and segmentation on whole-body [68Ga]Ga-

PSMA PET/CT scans and their influence on disease characterization. ***Materials and Methods:*** A dataset of 355 whole-body [68Ga]Ga-PSMA PET/CT scans from patients with prostate cancer was used for training and testing a deep-learning-based network using the nnU-Net framework [1]. The architecture was a 3D U-Net with two channels (PET-PSMA and CT). The scans were performed in two different PET/CT scanners: Philips Vereos Digital and Philips Gemini TF16. 53% of the cases were related to staging and the other 47% to re-staging/assessment of response to therapy. The mean injected activity was 1.90±0.32MBq/kg and the scans started approximately 88±31 minutes post-injection. The training dataset contained 285 scans from 147 patients (some patients underwent early and/or late scans with the same injection, or underwent two follow-up scans). The testing dataset contained 70 scans from 70 patients not included in the training dataset. Manual lesion identification was performed by experienced nuclear medicine physicians and semi-automatically segmented based on a Bayesian method [2]. This was considered the gold standard. ***Results:*** From the 70 test scans, 52 were identified by the physicians as having suspected malignant lesions: 33 in the prostate/prostate site, 9 in the bones, 14 in the lymph nodes, and 2 in the seminal vesicle. The network had a sensitivity and specificity, respectively, of 94% and 78% for the detection of scans with malignant lesions, 97% and 95% for the detection of prostate/prostate site malignant lesions, 100% and 97% for the detection of scans with bone metastases, and 100% for the detection of scans with malignant lymph nodes. Regarding the quality of the voxelwise segmentation on the 52 scans with suspected malignant lesions, the median Dice coefficient was 0.73 (interquartile range [IQR]:0.56-0.88), the sensitivity was 76% (IQR:40%-93%), and the predictive positive value was 94% (IQR:77%-100%). ***Conclusion:*** The deep-learning-based solution herein implemented showed potential to be used in clinics. The detection of prostate malignant lesions or recurrence at the prostate site, bone metastases, and malignant lymph nodes was similar to the physicians' detection. The use of this network alone would give similar conclusions on the majority of the scans. Nevertheless, experienced nuclear medicine physicians' supervision and quality control are, at the moment, considered mandatory. ***References:*** [1]Isensee et al. Nature Methods 2021, DOI:10.1038/s41592-020-01008-z; [2]Constantino et al. J Digit Imaging 2023, DOI:10.1007/s10278-023-00823-y.

OP-735

Fully automated segmentation of lymphoma manifestations in the GHSG HD16, HD17 and HD18 trials

C. Clement[1], *J. Ferdinandus[2,3], S. Xue[1], H. Tharmaseelan[2,3], M. Lommen[2,3], P. Borchmann[2,3], A. Rominger[1], K. Shi[1], C. Kobe[2], R. Seifert[1];*
[1]Inselspital, Universitätsspital Bern, Bern, SWITZERLAND, [2]University Hospital Cologne, Cologne, GERMANY, [3]German Hodgkin Study Group (GHSG), Cologne, GERMANY.

Aim/Introduction: PET/CT is routinely used for staging newly diagnosed Hodgkin Lymphoma (HL), with previous analyses emphasizing the value of baseline metabolic tumor volume (MTV) to predict outcome. However, manual segmentation is time-consuming and labor-intensive. Therefore, we aimed to develop a fully automatic segmentation model for HL. ***Materials and Methods:*** We analyzed baseline PET/CT images obtained within the German Hodgkin Study Group HD16 (early favorable), HD17 (early unfavorable), and HD18 (advanced stage) trials, collected from 103 different sites between August 2008 and December 2016. Lesion annotations were manually delineated by an experienced nuclear medicine expert using a cut-off of SUV > 4. We then developed a deep learning-based 3D segmentation model using ^{18}F-FDG PET/CT imaging for automatic lesion segmentation with the nnU-Net framework. The model was validated on test datasets using voxel-based Dice scores and lesion-based metrics, including sensitivity, precision, and F1 score. Spearman's rank correlations were calculated to assess the consistency between predicted and ground-truth MTVs. ***Results:*** The study included 550 patients (mean age 35.2 ± 12.6 years; 305 men) with available baseline imaging. The 3D Residual Encoder UNet model was trained on 459 patients using patch sizes of 144 x 288 x 144 voxels. Across the entire test dataset (n=91, 918 lesions), the model attained a mean Dice Score of 0.88, a lesion sensitivity of 0.84, a lesion precision of 0.78, and a lesion F1 score of 0.77. In the HD16 test subset (n=19, 61 lesions), the model reached a Dice score of 0.86, a lesion sensitivity of 0.92, a lesion precision of 0.76, and a lesion F1 score of 0.80. In the HD17 test subset (n=17, 109 lesions), it achieved a Dice score of 0.91, a lesion sensitivity of 0.87, a lesion precision of 0.78, and a lesion F1 score of 0.81. In the HD18 test subset (n=55, 748 lesions), it achieved a Dice score of 0.87, a lesion sensitivity of 0.80, a lesion precision of 0.79, and a lesion F1 score of 0.75. There was a high correlation between MTVs derived from manual measurements and automatic segmentations (HD16: rho=0.98, p=1.7e-13; HD17: rho=0.98, p=2.0e-12; HD18: rho=0.95, p=7.6e-28). ***Conclusion:*** The fully automated segmentation of HL demonstrates high accuracy and a very strong correlation between MTVs across both early and advanced stages. Future work will focus on expanding the scope of the model to predict treatment response by including follow-up scans.

OP-736

Segmentation of cerebrum grey matter in [18F]FDG PET imaging using convolutional neural networks

M. Iláco[1,2], *F. Oliveira[1], C. Constantino[1], J. Fonseca[2], D. C. Costa[1];*
[1]Champalimaud Foundation, Lisboa, PORTUGAL,
[2]NOVA University, Lisboa, PORTUGAL.

Aim/Introduction: Precise quantification of grey matter uptake of [18F]FDG PET helps in the differential diagnosis of several neurological disorders. However, precise identification of grey matter typically requires an additional MRI scan. This study aims to assess the feasibility of fully automatic cerebrum grey matter segmentation based on [18F]FDG PET images and its influence on grey matter uptake quantification in the absence of MRI data. ***Materials and Methods:*** A dataset of 370 subjects was downloaded from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database. For each subject, there is a brain [18F]FDG PET and a structural MRI. 300 subjects were selected for training resulting in the following disease distribution: 62 with Alzheimer's disease (AD), 163 with mild cognitive impairment (MCI), 4 with subjective memory concerns (SMC), and 71 cognitively normal (CN). The test dataset contains 70 subjects: 20 with AD, 29 with MCI, 2 with SMC, and 19 CN. For automatic segmentation, a 3D U-Net was trained using the nnU-Net framework [1]. The gold standard segmentation used for training and testing was obtained from the subject's MRI scans using the toolbox Statistical Parametric Mapping (SPM) running in MATLAB. Image registration and quality control tasks were performed in the 3D Slicer software. Agreement between the grey matter segmentation performed by the network and the gold standard was assessed using the Dice similarity coefficient (DSC). The relative difference of the [18F]FDG uptake based on the masks obtained from the network and the MRI was measured to assess the influence of the segmentation on quantification.

Results: The median DSC in the test dataset was 0.79 (IQR: 0.75-0.82) and similar among CN, MCI and AD subjects (median DSC difference < 0.03). The mean absolute deviation in grey matter [18F]FDG uptake obtained from both mask types was 0.72%, with the highest deviation being lower than 1% for all scans in the test dataset. There were no clinically significant differences in the quantification of [18F]FDG PET cerebrum grey matter uptake values obtained between the two masks. ***Conclusion:*** We herein demonstrate that cerebrum grey matter segmentation based on [18F]FDG PET uptake is feasible and sufficiently reliable for quantification in patients with AD, despite the markedly grey matter reduced uptake (signal intensity). Further work is needed to confirm this methodology efficacy in other neurodegenerative diseases, overall and in specific brain regions of interest according to specific pathologies. ***References:*** [1] Isensee et al. OP-737

A deep learning-based automatic segmentation method on left ventricle in dynamic myocardial perfusion using a CZT-SPECT

Z. Xu[1], *C. Ko[1,2], C. Chen[1], Y. Wu[3,4,5];*
[1]Department of Biomedical Engineering, National Taiwan University, Taipei, TAIWAN, [2]Department of Nuclear Medicine, National Taiwan University Hospital, Taipei, TAIWAN, [3]Division of Cardiology, Cardiovascular Medical Center, and Department of Nuclear Medicine, Far Eastern Memorial Hospital, New Taipei City, TAIWAN, [4]School of Medicine, National Yang Ming Chiao Tung University, Taipei, TAIWAN, [5]Graduate Institute of Medicine, Yuan Ze University, Taoyuan, TAIWAN.

Aim/Introduction: Cadmium-zinc-telluride (CZT) cameras enable dynamic SPECT to evaluate regional myocardial blood flow and coronary flow reserve, and accurate left ventricle (LV) segmentation is crucial for evaluating myocardial perfusion. Nevertheless, accurate labelling of myocardium is challenging due to the high noise-to-signal ratio of dynamic SPECT, making manual annotation results infeasible to train artificial intelligence models. This study aimed to propose an automated segmentation approach in dynamic SPECT images integrating the shape information of static SPECT and image registration. ***Materials and Methods:*** The training set comprised 466 patients who underwent dipyridamole 99mTc-MIBI dynamic CZT-SPECT, and the static and dynamic external validation sets included 54 patients with manual labeling for static images and the averages of the last 180-sec of dynamic images. All images were manually labeled by two experienced nuclear physicians.With 5-fold cross validation, the proposed method was accomplished in two steps. The first step was to train a deep learning model, V-Net, for automated segmentation of LV on static SPECT. The second step was to register the LV segmented by the V-Net to the mean dynamic image of the last 180-sec. Registration was achieved by the SyN non-rigid registration method with the rotation angle constraints to reduce the probability of being trapped in an improper rotation. The non-rigid registration results of the static segmented LV were considered as the segmentation results of the dynamic SPECT images. ***Results:*** The average Dice of V-Net for the static myocardial segmentation was 0.96 in the internal test dataset and 0.95 in the external validation set, suggested that V-Net effectively provides high-quality myocardial segmentation of LV. Moreover, the average dice of the derived myocardial segmentation via registration for the external validation datasets of the dynamic SPECT was 0.85. To evaluate the quality of the registration results, the aligned myocardial regions of the static and dynamic images were assessed using three indices for the external validation dataset. These three indices were Pearson correlation coefficient, mutual information and structural similarity index measure, the results of which were 0.88 ($p<0.001$), 6.73, 0.69. While the reasonably high dice value indicated the accuracy of the segmentation results, three indices suggested that the aligned myocardial regions of LV be highly correlated and mutually similar. ***Conclusion:*** This study demonstrated that automatic 3D segmentation of dynamic image of LV could be effectively attained by non-rigidly registering the myocardium segmented from the static SPECT on to the mean dynamic images.

Deep-learning-based automated delineation and classification of metabolic tumor volume in non-small-cell lung cancer in [18F]FDG-PET/CT

P. Nikulin[1], *E. Fitis[2], F. Hofheinz[1], J. Kotzerke[3], C. Furth[4], H. Amthauer[4], O. Elicin[5], E. Stutz[5], R. Krcek[5], S. Zschaeck[2], J. van den Hoff[1,3];*
[1]Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY, [2]Charité – Universitätsmedizin Berlin, Klinik für Radioonkologie und Strahlentherapie, Berlin, GERMANY, [3]Universitätsklinikum Carl Gustav Carus, Klinik und Poliklinik für Nuklearmedizin, Dresden, GERMANY, [4]Charité – Universitätsmedizin Berlin, Klinik für Nuklearmedizin, Berlin, GERMANY, [5]Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: Patients with locally advanced non-small-cell lung cancer (NSCLC) have a high risk of developing distant metastases. It has been shown that applying immunotherapy after radiochemotherapy can significantly improve the prognosis for affected patients. In this context, biomarkers for individualized therapy escalation are urgently needed. One such biomarker could be the total metabolic volume of primary tumor and lymph node (LN) metastases (total tumor burden, TTB). However, delineation of tumor lesions with conventional methods is time consuming and error-prone, especially for the LN metastases. The goal of this study was to investigate feasibility of such delineation with deep learning methods. ***Materials and Methods:*** Automated delineation was performed with a 3D U-Net convolutional neural network (CNN) developed with the nnU-Net software package [1]. The default nnU-Net training parameters were modified to provide better training stability with small lesion targets as well as to better balance sensitivity vs. positive predictive value (PPV) of lesion detection. A dataset consisting of 517 [18F]FDG-PET/CT scans of NSCLC patients was used for the network training and testing following 5-fold cross-validation scheme. In these data, the ground truth labels were defined via manual delineation and labeling of primary tumor and metastases by an experienced physician. ***Results:*** The derived CNN models were capable of accurate delineation, achieving a mean (median) Dice similarity coefficient of 0.831 (0.891). The sensitivity and PPV of lesion detection was 0.974/0.829/0.887 and 0.963/0.741/0.824 for primary tumor/LN metastases/union of both, respectively. Accuracy of lesion classification as primary tumor or LN metastases was 92.1%. Manually and automatically derived TTBs were highly correlated with R2=0.96 and a mean absolute difference of 5.4 ml (after rejecting 1% of the outliers). ***Conclusion:*** In this work, we present CNN models able to perform delineation of and discrimination between primary tumor and lymph node metastases in NSCLC in [18F]FDG-PET/CT with only sporadic manual corrections required. This provides the ability to accelerate large-scale study data evaluation in quantitative PET and has potential for clinical

application. ***References:*** [1] Isensee, F., Jaeger, P.F., Kohl, S.A.A. et al. nnU-Net: a self-configuring method for deep learning-based biomedical image segmentation. Nat Methods 18, 203-211 (2021).

OP-739

Automatic detection of lesions by "artificial intelligence" in [18F]FDG PET/CT in clinical practice : what is the most efficient solution ?

M. Gambiez[1], *X. Palard-Novello[2], C. Guery[2], E. Marchal[1], M. Meyer[1], O. Humbert[3], A. Girard[1];*
[1]CHU Amiens-Picardie, Amiens, FRANCE, [2]CLCC Eugène Marquis, Rennes, FRANCE, [3]Centre Antoine Lacassage, Nice, FRANCE.

Aim/Introduction: Artificial intelligence (AI) algorithms have recently been commercialized to assist nuclear medicine physicians in lesion detection in clinical practice. The aim of this study was to evaluate the lesion detection performance on [18F]FDG PET/CT by two commercially available AI algorithms using a convolutional neural network (CNN), when used alone or in addition to a human reading. ***Materials and Methods:*** One hundred and fifty-one [18F]FDG PET/CT scans of patients managed for melanoma or lymphoma in 3 French centers were retrospectively analyzed. Lesion detection was performed according to four methods: manually (M1) ; by using a « PET Assisted Reporting System » (PARS) based on CNN trained on 629 patients with lymphoma and lung cancers (1), with a detection threshold at SUV 2.5 (M2) or PERCIST-like (M3) ; and by using a one-step U-net algorithm trained on 4906 patients with multiple neoplasias (M4) (2). All volumes of interest (VOIs) identified by each of the 4 methods were reviewed by an expert consensus. VOIs judged to correspond to neoplasic lesions related to the pathology studied were labeled "true positives" (TP). The sensitivities of detection methods were compared in pairs using Student's paired-sample t-test, as well as sensitivities of automated methods combined with human reading. ***Results:*** A total of 1,544 lesions were considered as the reference standard. The respective sensitivities one-step method (M4), PARS with a SUV threshold of 2.5 (M2) and PERCIST-like (M3), and the manual method (M1) were 95.7%, 60.2%, 44.3%, and 76.6%, respectively. When combining M4 with human detection (M1), its sensitivity reached 99.9%, significantly higher than that of any other method alone or combined. M4 reported the highest number (1435) of false-positive VOIs, compared with 837 for M2 and 151 for M3. ***Conclusion:*** The use of some clinically available AI algorithms could provide a robust safety net to physicians for lesion detection on [18F]FDG PET/CT, with more than 99% sensitivity. Its routine use is nevertheless currently limited by its high false-positive rate. ***References:*** 1) Nicolò Capobianco, Michel A. Meignan, et al. Multi-center Deep learning-based Lesion Segmentation in^{18}F-FDG PET/CT Imaging: Comparative Efficacy, Prognostic Insights, and Clinical Implications

S. Xue[1], *X. He[2], Y. Hu[2], S. Wang[2], M. Hacker[1], X. Li[1];*
[1]Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Evomics Medical Technology Co., Ltd., Shanghai, CHINA.

Aim/Introduction: Medical imaging analysis relies heavily on segmentation, a fundamental task that traditionally demands significant time and expertise for manual execution. Automatic or semi-automatic segmentation methods, particularly those based on deep learning (DL), offer substantial time and labor savings. However, many current medical image segmentation models are limited in their adaptability, especially in the context of PET imaging, which exhibits variability across different centers due to instrumentation and imaging protocol differences, alongside disease-specific biodistribution variations. Moreover, concerns persist regarding the reproducibility and clinical applicability of DL-driven segmentation tools, which often lack robust external dataset validation and clinical evaluation. ***Materials and Methods:*** We developed a DL-based whole-body lesion segmentation using a dataset of 2963 patients scanned with various scanners, undergoing 18F-FDG PET imaging for diseases including lymphoma, lung cancer, and melanoma, acquired from 5 centers. The developed model was tested on a separate dataset and evaluated for lesion detectability and segmentation accuracy against manual segmentations. Furthermore, we assessed the prognostic predictability using clinically relevant features extracted from PET imaging. ***Results:*** The developed model achieved a mean Dice score of 0.745 at the patient level and 0.816 at the voxel level. Bland-Altman analysis demonstrated good agreement between ground truth metabolic tumor volumes (MTV) and predicted MTV, with biases of -55.8 (-930.5, 819.0±1.96 SD) with 95% confidence intervals. Kaplan-Meier curve analysis showed that imaging features extracted from DL-segmentation and manual segmentation exhibited similar prognostic predictability (p=0.0011 for MTV, p=0.00019 for TLG). ***Conclusion:*** The developed DL-based tool has the potential to enhance lesion detectability and segmentation accuracy, offering a streamlined approach for image analysis. It stands to benefit effective patient management and facilitate personalized precision medicine.

Aim/Introduction: Fibroblast Activation Protein (FAP) has recently emerged as a promising pan-tumoural target for the delivery of diagnostic and therapeutic radio-conjugates. OncoFAP is a small organic ligand with high affinity for human FAP1,2. [68Ga]Ga-OncoFAP is currently being studied in a prospective, multicentre Phase I clinical trial (NCT05784597). The primary objective of this trial is to evaluate the safety; secondary objectives include definition of the kinetics, biodistribution and preliminary imaging findings evaluation. ***Materials and Methods:*** Up to 20 patients with a pathologically confirmed diagnosis of breast, oesophageal, pancreatic, or colorectal cancer are enrolled into two cohorts. Cohort A comprises 3 female and 3 male patients with an early stage tumour; cohort B comprises also patients with advanced/metastatic disease. All patients receive a single administration of 250 (225-275) MBq [68Ga]Ga-OncoFAP followed by PET/CT scans at 0-30, 60, and 120 min, using scanners with an EARL accreditation for 68Ga. Adverse events are assessed according to CTCAE v.5 criteria. Blood and urine samples are collected before and up to 120 min post-administration to analyse pharmacokinetics and excretion. Uptake in lesions and healthy organs is evaluated by SUVmax, SUVmean and tumour:organ ratio. ***Results:*** At the cut-off date of the 18th of April 2024, 17 patients (6 males, 11 females), median age 56 (46-76) years, have been enrolled. Seven (7) patients have a diagnosis of breast cancer, five (5) patients with pancreatic cancer, three (3) patients with oesophageal cancer, and two (2) patients with colorectal cancer. Six patients (3 males and 3 females) have been enrolled in cohort A. No adverse events related to administration of [68Ga]Ga-OncoFAP have been recorded. The maximum concentration in the blood was reached within 10 min of administration, followed by rapid clearance. Biodistribution and quantitative image analysis are currently ongoing. From the preliminary PET/CT scans evaluation resulted that all patients showed rapid and selective tumour uptake. Shortly after administration (0-30 min), SUVmax of the lesions was in the range 4.88-36.36. Healthy organs except for kidney and pancreas had an SUVmean below 5. Kidney uptake was mainly restricted to the urinary tract, and no significant uptake was observed in the kidney parenchyma. Increased uptake in the healthy pancreas was predominantly seen in patients with pancreatic cancer. ***Conclusion:*** [68Ga]Ga-OncoFAP was well tolerated and showed promising pharmacokinetics and uptake properties for PET imaging of a range of solid tumours. ***References:*** 1) Millul et al, PNAS, 2021, 118:16:e21018521182) Backhaus et al, EJNMMI, 2022, 49:1822.

OP-742

Enhanced Diagnostic and Therapeutic Potentials of 68Ga-LNC1013 and 177Lu-LNC1013 in Cancer Imaging and Radionuclide Therapy: A Comparative and Preclinical Study

P. Wang[1,2], *L. Zhao[3], F. Li[2], X. Su[1], J. Zhang[4], X. Chen[4]; [1]The First Affiliated Hospital, Zhejinag University School of Medicine, Hangzhou, CHINA, [2]Peking Union Medical College Hospital, Beijing, CHINA, [3]First Affiliated Hospital of Xiamen University, Xiamen, CHINA, [4]National University of Singapore, Singapore, SINGAPORE.*

Aim/Introduction: 68Ga-LNC1013 is a novel dimeric PET tracer designed for targeting the fibroblast activation protein (FAP), exhibiting prolonged retention in tumors. This study aims to evaluate the diagnostic superiority of 68Ga-LNC1013 PET/CT over ^{18}F-FDG PET/CT in detecting primary and metastatic cancer lesions and to explore the therapeutic potential of 177Lu-LNC1013 in a preclinical setting. ***Materials and Methods:*** In this comparative study, 33 cancer patients with 12 different malignancies underwent simultaneous 68Ga-LNC1013 and ^{18}F-FDG PET/CT imaging. The performance of these tracers was assessed through lesion detection rates and quantitative uptake values (SUVmax and TBR). Additionally, a subgroup underwent 68Ga-FAPI-04 PET/CT. Preclinical studies involving 177Lu-LNC1013 were conducted using CT-26-FAP cell-derived xenografts (CDXs) to assess its potential in radionuclide therapy through SPECT imaging and biodistribution studies. ***Results:*** In our comparative analysis, 68Ga-LNC1013 detected a total of 128 lesions across 33 patients, demonstrating enhanced capabilities over ^{18}F-FDG, which identified 116 lesions. Specifically, 68Ga-LNC1013 detected 25 primary or recurrent lesions compared to 22 by ^{18}F-FDG, and 20 liver metastases versus 17 by ^{18}F-FDG, showcasing its superior detection rates. Quantitative analysis revealed significantly higher SUVmax and TBR for 68Ga-LNC1013 in primary tumors (SUVmax: 12.8 ± 7.5 vs. 7.2 ± 5.6, $P < 0.001$; TBR: 9.7 ± 6.5 vs. 4.8 ± 4.1, $P = 0.001$) and liver metastases (SUVmax: 10.8 ± 3.4 vs. 5.6 ± 2.0, $P = 0.043$; TBR: 4.3 ± 3.4 vs. 2.3 ± 0.9, $P = 0.048$), indicating higher tumor uptake and improved image contrast. Preclinical SPECT imaging showed that 177Lu-LNC1013 achieved peak tumor uptake at 72 hours post-injection, followed by a gradual decrease, with minimal uptake in healthy tissues. This tracer demonstrated superior tumor growth inhibition compared to 177Lu-FAPI-46 and control groups in CDXs, suggesting effective radionuclide therapy potential. ***Conclusion:*** 68Ga-LNC1013 outperforms ^{18}F-FDG in the diagnostic imaging of diverse cancer types, providing higher contrast and detection sensitivity. The theranostic potential of this tracer series is further highlighted by the promising therapeutic outcomes of 177Lu-LNC1013 in preclinical models, setting the stage for advanced FAP-targeted theranostics in oncology.

In Vivo needs in Vitro - Subtype specificity of CXCR4 Theranostics in chemotherapy resistant Muscle Invasive Bladder Cancer within the Bladder BRIDGister.

R. Wirtz[1], *L. Kastner[2], E. Storz[2], M. von Brandenstein[2], F. Friedersdorff[3], D. Barski[4], T. Otto[4], M. Waldner[5], J. Graff[5], E. Veltrup[1], F. Linden[1], M. Fuss[1], R. Hake[6], S. Eidt[6], J. Roggisch[7], S. Koch[7], C. Rieger[2], T. Ecke[8], A. Heidenreich[2], L. Greifenstein[9], R. Baum[9]; [1]STRATIFYER Molcular Pathology GmbH, Cologne, GERMANY, [2]Dpt of Urology, University of Cologne, Cologne, GERMANY, [3]Dpt. of Urology, Evangelisches Krankenhaus Königin Elisabeth Herzberge, Berlin, GERMANY, [4]Dpt. of Urology, Rheinlandklinikum, Neuss, GERMANY, [5]Dpt. of Urology St. Elisabeth Hospital, Cologne, GERMANY, [6]Institute of Pathology at the St. Elisabeth Hospital, Cologne, GERMANY, [7]Institute of Pathology, HELIOS Hospital, Bad Saarow, GERMANY, [8]Dpt of Urology, HELIOS Hospital, Bad Saarow, GERMANY, [9]CURANOSTICUM Wiesbaden-Frankfurt, Wiesbaden, GERMANY.*

Aim/Introduction: Patients with MIBC achieving pathological complete response (pCR) upon neoadjuvant chemotherapy (NACT) have improved prognosis. Previously we did show that luminal tumours respond better to NACT, while FGFR1 expression is associated with chemoresistance . Interestingly, the expression of the radioligand target CXCR4 is found in chemoresistant,

stroma-associated tumours rather than luminal or basal tumours. The objective of this study was to prospectively validate the predictive value of molecular subtyping and target quantitation for selecting patients for PET/CT after intraluminal application of 68Ga-CXCR4 (via a transuretrhral catheter) and subsequent intravesical radioligand therapy ("RadioMolecularIncubator Theranostics"). ***Materials and Methods:*** Formalin-fixed paraffin embedded (FFPE) tissues from the first 100 TURB samples from the BladderBRIDGister molecular registry as well FFPE tissue from the first patients undergoing intravesical 68Ga-CXCR4-PET/CT were prospectively collected. RNA from FFPE tissues were extracted by commercial kits, relative gene expression subtyping markers (KRT5, KRT20, PPARG), ADC targets (TROP2, NECTIN4), CPI targets (PD-L1, PD-1, CTLA4) and radioligand targets (CXCR4, FAP) were analysed by standardized RT-qPCR systems (STRATIFYER Molecular Pathology GmbH, Cologne). Hierarchical clustering, Kruskal-Wallis, chi square and contingency tests were done by JMP 9.0.0 (SAS software). ***Results:*** Hierarchical clustering revealed three different clusters by combining target gene quantitation of ADC and theranostic drugs and subtyping markers with strong luminal and basal characteristics as defined by high mRNA expression of KRT20, PPARG and KRT5, respectively with high, intermediate and low expression of luminal target genes. In contrast, CXR4 mRNA expression dominated in non-luminal tumours with only minor expression in luminal tumours. To functionally validate subtype expression of CXCR4 expression, we instilled 68Ga-CXCR4 into the bladder of two advanced bladder cancer patients after failure of neoadjuvant Gem/Cis chemotherapy. 68Ga CXCR4 PET/CT clearly visualized the non-luminal MIBC invading the perivesical soft tissue. In contrast, 68Ga CXCR4 PET/CT was completely negative in the luminobasal MIBC. ***Conclusion:*** We functionally validated the relevance of mRNA-based assessment of bladder cancer subtype expression as well as CXCR4 target gene expression from tumour biopsies in vitro to select patients for effective subsequent theranostic approaches in vivo. Previously, we have shown that determining CXCR4 mRNA from TUR biopsies predicts non response to neoadjuvant chemotherapy. Here we show that non-luminal bladder cancer patients, not responding to neoadjuvant chemotherapy, might benefit best from theranostic 177Lu- or 90Y- CXCR4 radioligand therapies. Molecular subtyping of pretherapy tissue biopsies substantially contributes to precise patient selection for theranostics in bladder cancer when quantifying target gene expression.

OP-744

Comparative Evaluation of [18F]MFBG and [68Ga]Ga-DOTATATE as Imaging Biomarkers in Neuroblastoma

P. Wang[1,2], *F. Li[3], H. Jing[3], H. Zhuang[4], H. Zhang[3];*
[1]The first affiliated hospital Zhejiang University School of Medicine, Hangzhou, CHINA, [2]Peking Union Medical College Hospital, Beijing, CHINA, [3]Peking union medical college hospital, Beijing, CHINA, [4]Children's Hospital of Philadelphia University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, UNITED STATES OF AMERICA.

Aim/Introduction: The molecular radiotherapies, [131I]MIBG and [177Lu]LuDOTATATE, target the norepinephrine transporter (NET) and somatostatin receptor subtype 2 (SSTR-2), respectively, and are pivotal in treating metastatic neuroblastoma. This study aims to compare the anatomical distribution and tumor uptake of [18F]-meta-fluorobenzylguanidine ([18F]MFBG) and [68Ga]Ga-DOTATATE, which visualize NET and SSTR expressions, respectively, to select appropriate therapeutic interventions. ***Materials and Methods:*** In this prospective, single-center study, ten pediatric patients (mean age 5.6 ± 2.7 years) with neuroblastoma histories were assessed. Each patient underwent dual PET/CT imaging using [18F]MFBG and [68Ga]Ga-DOTATATE on the uMI Panorama PET/CT system, following specific tracer injections (0.05 mCi/kg) after intervals of 60-120 minutes for [18F]MFBG and 40-60 minutes for [68Ga]Ga-DOTATATE. Lesion count, Curie scores, and tumor uptake were recorded and compared, with a cap at ten lesions for diffuse or localized regions showing more extensive disease. ***Results:*** Two patients showed negative findings on both [18F]MFBG and [68Ga]Ga-DOTATATE studies. One patient (12.5%) was positive on [18F]MFBG but negative on [68Ga]Ga-DOTATATE, while seven patients showed positive findings on both modalities. The median Curie scores for [18F]MFBG (13.5, IQR: 2, 19) were higher than those for [68Ga]Ga-DOTATATE (median, 6, IQR: 2, 18), though not statistically significant ($p = 0.09$). [18F]MFBG identified 243 lesions, and [68Ga]Ga-DOTATATE detected 226 lesions ($p = 0.307$). Regionally, lesion detection was similar in several areas, while [18F]MFBG detected more lesions in T-spine (34 vs. 30), L-spine (34 vs. 30), upper arms(10 vs. 7), lower arms(2 vs. 0), and soft tissues(25 vs. 21); [68Ga]Ga-DOTATATE showed slightly more lesion detection in the chest (20 vs. 16). Bone/bone marrow metastases demonstrated lower uptake in [18F]MFBG (8.2 ± 7.8) compared to [68Ga]Ga-DOTATATE (9.9 ± 6.7); however, [18F]MFBG exhibited a higher tumor-to-background ratio (TBR) (12.6 ± 8.6 vs. 8.1 ± 5.3). ***Conclusion:*** Both [18F]MFBG and [68Ga]Ga-DOTATATE PET/CT scans demonstrated high lesion detection capabilities, providing complementary information crucial for comprehensive neuroblastoma assessment. The heterogeneous distribution of molecular targets highlighted by these scans suggests that a combined approach using both [131I]MIBG and [177Lu]LuDOTATATE therapies could potentially enhance therapeutic efficacy over using either modality alone.

OP-745

[18F]FDG PET/MRI in muscle-invasive bladder cancer (MIBC): role in staging and neoadjuvant response assessment

P. Mapelli[1], *C. Bezzi[1], A. Cigliola[2], A. Samanes Gajate[3], G. Brembilla[4], S. Ghezzo[1], V. Tateo[2], P. Scifo[3], C. Mercinelli[2], F. De Cobelli[4], A. Chiti[1], A. Necchi[5], M. Picchio[1];*

Aim/Introduction: An accurate staging of muscle-invasive bladder cancer (MIBC) is fundamental for prognosis and perioperative therapy planning. The rate of clinical complete response (cCRs) has increased thanks to neoadjuvant therapy (NAT). However, the definition of cCR is still debated. The aim of the present study is to investigate the diagnostic ability of [18F]FDG PET/MRI in MIBC primary tumour (T) and lymph nodes (LN) staging and its role in NAT response evaluation. ***Materials and Methods:*** Prospective study including 36 patients with MIBC candidate to NAT (2021-2023). All subjects underwent [18F]FDG PET/MRI before and after NAT. Treatments included: chemotherapy (N=4), immune-checkpoint inhibitors (N=2), chemo-immunotherapy (N=20), enzyme inhibitors (N=2) and sacituzumab govitecan (N=6). Radical cystectomy with pelvic lymph node dissection was performed in all patients, after completing NAT.Two Nuclear

Medicine physicians and a Radiologist reviewed [18F]FDG PET/MRI scans. [18F]FDG LN uptake and nacVI-RADS score were determined on Pre-NAT PET/MRI images. Balanced accuracy (bACC), sensitivity (SN), specificity (SP), positive and negative predictive values (PPV, NPV) were used to test the diagnostic accuracy of [18F]FDG PET/MRI in MIBC staging against pathological response on post- NAT scans. NAT response was assessed as: 1)complete (ypT0N0), 2) partial (ypT<2N0), and 3)no-response. Fisher's exact test and multinominal logistic regression were used to determine the prognostic significance in predicting NAT response. ***Results:*** In 10/36 patients (27.8%) pathological LN involvement was detected. LN [18F]FDG uptake at baseline was present in 5/36 patients and in 4/36 at post-NAT assessment. For T staging, [18F]FDG PET showed a bACC=54.35%, SN=8.7%, SP=100%, PPV=100% and NPV=38.24%, while for N staging a bACC=70%, SN=40%, SP=100%, PPV=100% and NPV=81.25%. For T staging, MRI showed a bACC=85.79%, SN=86.96%, SP=84.62%, PPV=90.91% and NPV=78.57%, while for N staging a bACC=77.77%, SN=90%, SP=65.4%, PPV=50% and NPV=94.91%. Regarding response, among NAT complete-, partial- or non- responders, a statistically significant difference in the frequencies of both pre- NAT [18F]FDG LN uptake (p=0.048) and nacVI-RADS (p=0.004) was observed, with higher frequencies of LN pathological [18F]FDG uptake and higher nacVI- RADS scores in non-responders. Conversely, only nacVI-RADS score predicted NAT pathologic response, according to multinominal logistic regression, with nacVI-RADS significantly differentiating complete response from partial (OR= 3.59, p=0.021) and no response (OR=4.68, p=0.003). ***Conclusion:*** [18F]FDG PET/MRI demonstrated overall good diagnostic accuracy in detecting MIBC, despite the low sensitivity of [18F]FDG PET in T and N staging. NacVI-RADS score showed a role in predicting NAT response, with potential implications in improving MIBC patients' quality of life.

OP-746

Diagnostic performance of ^{99m}Tc-Sestamibi SPECT/CT for the Characterization of Solid Renal Masses with standard of truth by Histopathology: Secondary Endpoint Analysis of a Prospective Study

V. Ludwig[1], *A. Holzgreve[1,2], J. Czernin[1], B. Shuch[3], J. Calais[1], L. Unterrainer[1,2];*
[1]Ahmanson Translational Theranostics Division, David Geffen School of Medicine, University of California Los Angeles (UCLA), Los Angeles, CA, UNITED STATES OF AMERICA, [2]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, [3]Department of Urology, Institute of Urologic Oncology, David Geffen School of Medicine, University of California Los Angeles (UCLA), Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: To evaluate the accuracy of 99mTc-Sestamibi SPECT/CT in differentiating aggressive/concerning kidney lesions (i.e. clear cell renal cell carcinoma (ccRCC) and papillary RCC (pRCC)) from indolent/non-concerning lesions (such as oncocytoma, low grade oncocytic RCC, chromophobe RCC (chRCC) and hybrid oncocytic chromophobe tumor (HOCT)). ***Materials and Methods:*** We report explorative data and a secondary objective analysis of a single-institution prospective, explorative, nonrandomized study (NCT03996850, IRB #18-001817) primarily investigating the impact of 99mTc-Sestamibi SPECT/CT on patient management. 73 patients (51 male, 22 female) who underwent 99mTc-Sestamibi SPECT/CT for the evaluation of a solid renal mass ≥1.5 cm diameter in the cT1N0M0 stage previously identified on CT and/or MRI (median of 61 days IQR 57 of imaging interval) were included in this analysis. Lesions on SPECT/CT were visually rated as either positive (non-concerning) or negative by one non-blinded reader. Positive lesions were further classified using a previously published uptake score ranging from 1-5 (with 1= uniformly high tumor uptake, 2= variable tumor uptake with areas of high uptake, 3= peripheral uptake with central photopenia, 4= definite tumoral uptake below surrounding renal parenchyma, and 5= uptake predominantly in the endophytic portion) [1]. In a subgroup of patients, SPECT/CT findings were compared to histopathology results (n=61; surgery performed median of 75 days IQR 79.5 after SPECT/CT). ***Results:*** A total of 73 99mTc-Sestamibi SPECT/CT scans were included with a total of 93 lesions (median diameter 2.4 cm). Visual analysis demonstrated 54 (58.1%) negative and 39 (41.9%) positive lesions. The following uptake scores were assigned to the positive lesions: score 1 (n=17, 43.6%), 2 (n=7, 17.9%), 3 (n=0), 4 (n=4, 10.3%), and 5 (n=11, 28.2%). Histopathological diagnosis was available in 61 cases (29 ccRCC, 5 pRCC, 3 chRCC, 1 HOCT, 14 oncocytomas and 9 low grade oncocytic RCC), i.e. n=34 aggressive/concerning lesions vs. n=27 indolent/non-concerning lesions. For the diagnosis of non-concerning kidney lesions using 99mTc-Sestamibi SPECT/CT, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy were 78%, 94%, 91%, 84% and 87%, respectively. ***Conclusion:*** 99mTc-Sestamibi SPECT/CT showed potential to non-invasively depict non-concerning solid renal masses when conventional imaging is indeterminate. 99mTc-Sestamibi SPECT/CT might facilitate patient selection for active surveillance. ***References:*** 1) Campbell et al. 99mTc-sestamibi SPECT/CT for the characterization of renal masses: a pictorial guide. The Role of [18F]FDG PET/CT for predicting histology and prognosis in patients with thymic lesions.

D. Pizzuto[1], *A. Castello[2], M. Chiappetta[3], M. Castellani[2], S. Annunziata[4], A. Campanella[3], G. Calabrese[3], M. Cattaneo[5], L. Rosso[5], F. Lococo[3], P. Mendogni[5];*
[1]Nuclear Medicine Unit, GSteP Radiopharmacy, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY, [2]Department of Nuclear Medicine, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, ITALY, [3]Thoracic Surgery, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, ITALY, [4]Nuclear Medicine Unit, GSteP Radiopharmacy, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Roma, ITALY, [5]Thoracic Surgery and Lung Transplantation, Fondazione IRCCS Ca' Granda, Milan, ITALY.

Aim/Introduction: The need of a non-invasive diagnostic tool able to predict the thymic epithelial tumors (TETs) aggressiveness would be necessary for an optimized stratification of risk which is essential for an effective therapeutic approach. CT and MRI usually fails to discriminate among different WHO histologic subtypes. Conversely, preliminary data suggest that PET metrics, i.e. SUVmax, could be able to distinguish among less and more aggressive TETs. We aimed to investigate whether FDG PET metabolic parameters were associated with histology and to assess their potential prognostic role in patients with resected thymic lesions. ***Materials and Methods:*** One hundred and sixteen patients (49/67 M/F; mean age 59.5 years) who underwent thymectomy and preoperative 18F-FDG PET/CT from 2012 to 2022 were retrospectively considered from two Hospitals (Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome and Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan). Associations between histology and metabolic parameters (i.e. SUVmax, SUVmean, SUVpeak, TLG, MTV, rPET,

qPET, tumor-to-mediastinum (T/M), SUVmax/Tcm ratios were examined. Progression-free-survival (PFS) was determined and compared using the Kaplan-Meier and the log-rank test. The median follow-up was 38 months (range 14-72 months). ***Results:*** Twenty-seven thymic hyperplasia, 41 low-risk thymomas (LRT, types A, AB, B1), and 48 high-risk thymomas (HRT, types B2, B3, carcinoma) were included. Metabolic parameters of HRT and LRT patients were significantly different, i.e. SUVmax (mean 4.8 [4.1-7.3] vs 4.5 [3.4-5.3], p<0.001), SUVmean (3 [2.3-4.6] vs 2.7 [2.2-3.3] p<0.001), SUVpeak (4 [3.2-6.4] vs 3.7 [2.8-4.6] p<0.001), rPET (2.1 [1.3-2.6] vs 1.4 [1.2-2.1] p<0.001), qPET (2 [1.4-2.8] vs 1.5 [1.1-2.6] p<0.001) and T/M (3.2 [2.1-4.6] vs 2.6 [1.8-2.3] p<0.001). TLG and MTV were significantly higher in patients with LRT than HRT (95.3 [23.2-210.1] vs 76.1 [32-284.9] p<0.001; 35 [11-74.8] vs 24.8 [9.6-48.3] p<0.001, respectively). Patients with SUVmax<4.3, as well as those with SUVmean and SUVpeak < 2.87 and 4.03, respectively, showed a longer PFS (p = 0.009, p= 0.05, and p=0.05). MTV, TLG, T/M, and SUVmax/Tcm were not associated with PFS. ***Conclusion:*** Preoperative PET metrics could help to differentiate thymic histotypes. SUVs-based parameters appear promising to predict recurrent disease.

OP-748

The role of $^{64}CuCl_2$ PET/CT in detecting and staging muscle-invasive bladder cancer. Comparison with contrast-enhanced CT and ^{18}F-FDG PET/CT.

F. Fiz[1], *B. Sambucco[2], A. Piccardo[1];*
[1]Ospedale Galliera, Genova, ITALY, [2]University of Genoa, Genova, ITALY.

Aim/Introduction: 64CuCl2 is a PET tracer of cancer metabolism with exclusive hepatic excretion and could be thus well-suited to stage muscle-invasive bladder cancer (MBC). In this study, we evaluated the feasibility of a 64CuCl2-based staging of patients with MBC; furthermore, we compared the diagnostic capability of this method with the current gold standards, i.e., contrast-enhanced CT (ceCT) and 18F-FDG PET/CT. ***Materials and Methods:*** We prospectively enrolled patients referred to our institution for pathology-confirmed MBC staging/re-staging between September 2021 and January 2023. All patients underwent ceCT, 18F-FDG, and 64CuCl2 PET/CT within a two-week period. Patient-based and lesion-based analyses (PBA and LBA, respectively) were carried out for all the potentially affected districts (overall, bladder wall, lymph nodes, skeleton, liver, lung, and pelvic soft tissue). ***Results:*** Forty-two patients (nine females) were enrolled. Thirty-six (86%) had evidence of disease, with a total of 353 disease sites. On PBA, ceCT and 64CuCl2 PET/CT showed higher sensitivity than ^{18}F-FDG PET/CT in detecting the primary tumour (p<0.001); moreover, 64CuCl2 PET/CT was slightly more sensitive than ^{18}F-FDG PET/CT in disclosing soft tissue lesions (p<0.05). Both PET methods were more specific and accurate than ceCT in classifying nodal lesions (p<0.05). On LBA, 64CuCl2 PET/CT outperformed 18F-FDG PET/CT and ceCT in detecting disease localisations overall (p<0.001), in the lymph nodes (p<0.01), in the skeleton (p<0.001), and in the soft tissue (p<0.05). ***Conclusion:*** 64CuCl2 PET/CT appears to be a sensitive modality to stage/re-stage MBC and might represent a "one-stop shop" diagnostic method in these scenarios.

A Retrospective Study of the Diagnostic Performance of $^{[18F]}$FDG PET-CT for Lymph Node Staging in Patients With Upper Tract Urothelial Carcinoma

R. Fridriksdottir[1,2], *I. Patras[3,2], J. Bobjer[3,2], A. Gerdtsson[3,2], F. Liedberg[3,2], E. Trägårdh[1,2];*
[1]Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital, Lund/Malmö, SWEDEN, [2]Department of Translational Medicine, Lund University, Malmö, SWEDEN, [3]Department of Urology, Skåne University Hospital, Malmö, SWEDEN.

Aim/Introduction: Upper tract urothelial carcinoma (UTUC) is a rare cancer and the diagnostic utility of $^{[18F]}$FDG PET-CT for preoperative lymph node staging in UTUC is somewhat unknown. The aim of this study is to assess the diagnostic accuracy of $^{[18F]}$FDG PET-CT for lymph node staging in patients with UTUC. ***Materials and Methods:*** Seventy-six patients (28 female; median age 72 [IQR 65-76] years) with UTUC in the renal pelvis and/or proximal ureter subjected to radical nephroureterectomy (RNU) and template-based lymph node dissection (LND) who had performed a preoperative $^{[18F]}$FDG PET-CT were retrospectively included in this study. Eleven patients received preoperative induction chemotherapy (IC), and for those patients the $^{[18F]}$FDG PET-CT included in the study was performed before initiating IC. LND was performed according to a predefined and side-specific fractionated anatomic template including paraaortal nodes for the left side and paraaortal/aortocaval/paracaval for the right side, divided into 10 anatomic areas1. Comparison of the $^{[18F]}$FDG PET-CT to the histopathology in the fractionated lymph node specimen was made on a patient level as well as for each predefined anatomic area. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV), likelihood ratios and accuracy were calculated in all patients and after excluding those receiving IC. ***Results:*** Out of 76 patients, 31 (41%) had lymph node involvement on $^{[18F]}$FDG PET-CT and 18 (24%) had confirmed lymph node involvement on histopathology. Analyses per patient for all patients (n=76) and after excluding patients who had received IC (n=65) showed: sensitivity 83% and 82%, specificity 72% and 79%, PPV 48% and 58%, NPV 93% and 93%, positive likelihood ratio 3.02 and 3.95, negative likelihood ratio 0.23 and 0.22, and accuracy 75% and 77%, respectively. The corresponding results of analyses per predefined anatomical areas (n=216 and n=203 excluding IC) showed: sensitivity 76% and 75%, specificity 90% and 93%, PPV 50% and 60%, NPV 97% and 97%, positive likelihood ratio 7.64 and 11.19, negative likelihood ratio 0.27 and 0.27, and accuracy 88% and 91%, respectively. ***Conclusion:*** Preoperative $^{[18F]}$FDG PET-CT has a high diagnostic accuracy for lymph node involvement in UTUC located in the renal pelvis and/or the proximal ureter. ***References:*** 1 Bobjer J et al. Location of Retroperitoneal Lymph Node Metastases in Upper Tract Urothelial Carcinoma: Results from a Prospective Lymph Node Mapping Study. Eur Urol Open Sci. 2023 Sep 27;57:37-44.

Multi-site, prospective trial evaluating FET-PET In Glioblastoma (FIG) Study (TROG 18.06): Central review of initial FET-PET biologic target volume delineation for radiation planning.

A. Scott[1,2], *R. Francis[3,4], S. Lee[1,2], E. Lau[1], A. Whitehead[5], O. Cook[5], N. Barry[6], M. A. Ebert[3,4], H. Gan[1,2], B. A. Moffat[7], G. Fitt[1], A. Moore[5], S. Ng[1], M. Pinkham[8], H. Evans[5], A. Rossi[5], R. Dykyj[5], D. L. Bailey[9,10], E. Koh[11,12];*
[1]Austin Health, Melbourne, AUSTRALIA, [2]Olivia Newton-John Cancer Research Institute, Melbourne, AUSTRALIA, [3]Sir Charles Gairdner Hospital, Perth, AUSTRALIA, [4]The University of Western Australia, Perth, AUSTRALIA, [5]TROG Cancer Research, Newcastle, AUSTRALIA, [6]University of Western Australia, Perth, AUSTRALIA, [7]University of Melbourne, Melbourne, AUSTRALIA, [8]Princess Alexandria Hospital, Brisbane, AUSTRALIA, [9]Royal North Shore Hospital, Sydney, AUSTRALIA, [10]University of Sydney, Sydney, AUSTRALIA, [11]Liverpool Hospital, Sydney, AUSTRALIA, [12]University of NSW, Sydney, AUSTRALIA.

Aim/Introduction: The FIG Study (TROG 18.06) is a prospective, multi-centre trial of O-(2-[18F]-fluoroethyl)-L-tyrosine Positron Emission Tomography (FET-PET) in glioblastoma patients. The primary study objectives are to: 1) determine the proportion of radiation treatment plans that are changed with incorporation of FET-PET imaging, and 2) determine in the post-therapy setting if FET-PET (vs MRI) can differentiate tumour recurrence/progression from pseudo-progression. We report on the progress of the trial, and the results of an assessment of the impact of central Nuclear Medicine physician (NMP) review of prospective FET-PET1 delineation of the biological target volume (BTV) for radiotherapy (RT) planning. ***Materials and Methods:*** Up to 210 adult GBM participants across 11 Australian sites will undergo FET-PET post-surgery/pre-chemo-RT [CRT] (FET-PET1), one month post CRT (FET-PET2) and at suspected progression (FET-PET3). Group 1 participants enter at timepoint 1 (FET-PET1 with MRI1), whilst Group 2 enter at timepoint 2. Adjuvant RT target volumes are derived per standard contrast MRI with hybrid post-hoc RT volumes created by incorporating the FET-PET1 NM-derived BTV utilising MiM version 7.0. All trial sites and NMP have passed credentialling which included three benchmarking cases involving BTV delineation. ***Results:*** Trial recruitment to date is 180 patients (n=117 Group 1 and n=63 Group 2) enrolled to date, with a target of 140 Group 1 patients. During trial credentialling, results demonstrated variations in FET-PET1-derived BTV in 25/72 (34.7%) including both 13 minor and 12 major deviations. During the prospective recruitment phase, to date, 26 of 30 participant FET-PET1 with BTV delineation cases across 11 sites have undergone central review. Of these, 5/26 (19%) requiring resubmission. Reasons for resubmission/protocol deviations have included: incorrect imaging sequence selection within the MiM workflow (two cases), both workflow issues and incorrect background ROI selection (one case); Static GTV overcontouring (one case) and both MiM workflow issues and Static GTV overcontouring (one case). All 5 cases passed central review after subsequent resubmission. ***Conclusion:*** The FIG trial will complete recruitment in 2024 with analyses planned at one year post CRT completion. Despite improvements in resubmission rates compared to the credentialling phase, central review of prospective FET-PET1-derived BTV delineation remains vitally important in ensuring BTV accuracy and protocol adherence. The FIG study is the largest prospective multi-site study of its kind addressing FET-PET's impact on adjuvant radiation planning and its role in management of pseudoprogression and prognostication.

OP-751

PET-based response assessment criteria for diffuse gliomas (PET RANO 1.0): application to ^{18}F-FDOPA PET imaging

G. Stien[1], *A. Zinsz[1], S. Ahrari[2,3], L. Taillandier[4,5], M. Blonski[4,5], L. Imbert[1,2,3], Z. Timothée[2,6], A. Verger[1,2,3];*
[1]Department of nuclear medicine, centre hospitalier universitaire de Nancy, Nancy, FRANCE, [2]IADI, U1254, Inserm, Université de Lorraine, Nancy, FRANCE, [3]Nancyclotep Imaging Platform, Université de Lorraine, Nancy, FRANCE, [4]Department of neuro-oncology, centre hospitalier universitaire de Nancy, Nancy, FRANCE, [5]Centre de Recherche en Automatique de Nancy CRAN, UMR 7039, Université de Lorraine, CNRS, Nancy, FRANCE, [6]CIC-IT 1433, Inserm, CHRU de Nancy, Université de Lorraine, Nancy, FRANCE.

Aim/Introduction: The Response Assessment in Neuro-Oncology (RANO) group recently reported the PET-based response assessment criteria for diffuse gliomas (PET RANO 1.0). The objective of this study was to evaluate these criteria for the amino-acid 18F-FDOPA radiotracer. ***Materials and Methods:*** Patients with histological confirmed glioma, having performed at least one baseline 18F-FDOPA PET scan at the diagnosis after the initial surgery (< 3 months post-surgery) or at recurrence (<3 months before the start of an adjuvant treatment) were retrospectively included. Three different tasks were evaluated according to different population: i. the number of lesion measurable, no-measurable, and non-measurable according to the PET RANO 1.0 criteria and the cases for which striatum physiological uptake was challenging to delineate the lesion in the overall population, ii. the direct comparison of PET RANO 1.0 criteria and the visual interpretation of two experts for patients with at least one follow-up PET scan, and iii. the diagnostic performances of PET RANO 1.0 criteria regarding 6 months progression-free (PFS-6) based on clinico-radiological follow-up and 12 months overall (OS-12) survivals for patients whom the follow-up PET scan was performed during or after a maximal time of 3 months after the end of the treatment. ***Results:*** Ninety patients (52.0±15.3 years old, 40 (44%) women) with a baseline 18F-FDOPA PET were included in this study (70 patients after the initial surgery and 20 patients at recurrence). Among these patients, they presented in average 1.18±0.66 lesion per patient with 10 (11%) patients presenting no-measurable, 3 (3%) non-measurable and 77 (86%) measurable diseases. The delineation of tumoral uptake was challenging due to the striatum physiological uptake in 16/81 (16%) patients. Among the 65 patients with at least one follow-up PET scan, the visual interpretation and the PET RANO 1.0 criteria showed a global concordance of 80% (coefficient κ=0.71), maximal for the mean tumor-to-background ratio (TBRmean) parameter (coefficient κ=0.66). Among the 44 patients (20 evaluating radio-chemotherapy with temozolomide ± bevacizumab, 16 with temozolomide or PCV chemotherapies and 8 other treatments) for whom the diagnostic performances could be calculated, PET RANO 1.0 criteria had respective accuracies of 70% and 73% for PFS-6 and OS-12 (vs. 73% and 80% respectively for the visual interpretation) with the TBRmean and MTV parameters showing the best accuracies. ***Conclusion:*** PET RANO 1.0 criteria are feasible with 18F-FDOPA PET imaging with diagnostic performances approaching those of the visual interpretation.

OP-752

The predictive potential of ^{18}F-FET PET in patients with post-surgical residual mass of high grade glioblastoma

***I. Laghai*[1],** *A. Martini[1], L. Fedeli[2], M. Betti[2], S. Scoccianti[3], S. Sestini[1]; [1]Nuclear Medicine Unit, Department of Diagnostic Imaging, Santo Stefano Hospital, Azienda U.S.L. Toscana Centro, Prato, ITALY, [2]Medical Physics Unit, Santo Stefano Hospital, Azienda U.S.L. Toscana Centro, Prato, ITALY, [3]Radiation Oncology Unit, Santa Maria Annunziata Hospital, Azienda U.S.L. Toscana Centro, Florence, ITALY.*

Aim/Introduction: to determine the diagnostic and predictive potential , in terms of overall (OS) and progression free survival (PFS), of ^{18}F-FET PET in patients with primary glioblastoma (GBM) after surgical resection and before radio-chemotherapy. ***Materials and Methods:*** 32 patients [(15 M;17 F; ≤ 50 y n=9 (28.1%); > 50 y n=23 (71.9%)] with GBM WHO3 n = 6 (18.7%) and WHO4 n = 26 (81.3%) associated with IDH mutation in n = 5 (15.6%) or MGMT methylated in n = 13 (40.6%) underwent a PET scan after surgical resection. Semi-quantitative parameters including tumor-to-brain ratios (TBRmax cut-off value > 1.6 for post-surgical residual mass), SUVmax, uptake volumes and metabolic tumour volumes (MTV) have been taken into account. Univariate analyses and Mantel-Cox log-rank test were used to identify independent variables associated with OS and PFS comparing differences in Kaplan-Meier survival curves (KM).Relationship between parameters was also investigated with Pearson correlation. ***Results:*** For OS and PFS (p = 0.005 - 0.0001), results showed high prediction value associated with the WHO grade, IDH mutation and MGMT methylated , age, and PET findings (TBR max, MTV, uptake volume). The Kaplan-Meier curve highlighted a longer OS and PFS for patients with GBM WHO3, age >50 y, IDH mutation (compared to tumor with wild type mutation), TBRmax (range 3.42 - 6.00), MTV (range 306640 - 15876) and volumes (range 7530 - 76660 cc) values respectively higher than the median cut-off values (4.02, 40245, 18035, respectively). A significant negative exponential correlation was found between PET parameters and both OS and PFS (p<0.0001). ***Conclusion:*** This preliminary work suggests that several clinical and molecular parameters, including molecular neuro-imaging findings, may predict PFS and OS in patients with GBM WHO3-4. A multimodal approach including FET-PET may improve the oncological outcome in glioma patients.

OP-753

[18F]FET PET and DCE MRI metrics in Childhood CNS Tumours

***H. Ismail*[1],** *M. Lundemann[2], T. A. Gerds[3], A. Sehested[4], R. Mathiasen[4], P. S. Wehner[5], O. M. Henriksen[2], J. Skjøth-Rasmussen[6], H. Broholm[7], I. Law[2,8], L. Marner[1,2,8]; [1]Department of Clinical Physiology and Nuclear Medicine, Copenhagen University Hospital Bispebjerg, Copenhagen, DENMARK, [2]Department of Clinical Physiology, Nuclear Medicine and PET, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK, [3]Department of Biostatistics, University of Copenhagen, Copenhagen, DENMARK, [4]Department of Paediatrics and Adolescent Medicine, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK, [5]Hans Christian Andersen Children's Hospital, Odense University Hospital, Odense, DENMARK, [6]Department of Neurosurgery, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK, [7]Department of Pathology, Copenhagen University Hospital Rigshospitalet, Copenhagen, DENMARK, [8]Department of Clinical Medicine, University of Copenhagen, Copenhagen, DENMARK.*

Aim/Introduction: Using magnetic resonance imaging (MRI) in childhood central nervous system (CNS) tumours, post-treatment identification of residual/recurrent tumours may be challenging. We have recently shown that addition of [18F] fluoro-ethyltyrosine ([18F]FET) PET increases accuracy in paediatric neuro-oncology compared to standard MRI*. In children with primary CNS tumours we assessed [18F]FET PET and advanced MRI metrics to discriminate 1) tumour from treatment effects and 2) high-grade from low-grade tumours. ***Materials and Methods:*** A total of 100 children (41 females, median age 9.8 years, range 0.1 - 19.2 years) with suspicion of primary paediatric CNS tumours were included consecutively and prospectively as previously described*. A total of 133 [18F]FET PET and MRI scans with dynamic acquisition (n=124) and with Dynamic Contrast Enhanced (DCE) perfusion MRI (n=100) were performed at time of diagnosis, recurrence, or before or after treatment. Suspicious lesions were delineated on the [18F]FET PET or alternatively on the MRI scans and maximal tumour-to-background ratio (TBRmax) and curve type (I: steady increasing, II: plateau or III: early peak and decreasing) were extracted. Delineations were transferred to the MRI, and blood volume fraction (BV) estimated using DCE as well as mean Apparent Diffusion Coefficient (ADC) were extracted. The reference standard of each lesion was operation, biopsy, or follow-up*. The abilities of each metric alone or in combination to discriminate tumour from treatment changes (TBRmax, VB) and high-grade from low-grade tumours (TBRmax, curve type, ADC, VB) were evaluated using both simple and multiple logistic regression, and the prediction performance was assessed using area under the curve (AUC), Brier Score and 200 steps of cross-validation. ***Results:*** TBRmax and BV discriminated tumour from treatment effects (crude odds ratio (OR):4.86, 95% confidence interval (CI):[1.87-12.61], p=0.0012 and OR:1.80, CI:[1.07-3.02], p=0.026, but combined only TBRmax was significant OR:4.24, CI:[1.54-11.61], p=0.0050 with AUC:75.6%, CI:[56.5-94.7] and Brier Score 15.8, CI:[11.7-19.9]. All four metrics combined (TBRmax, curve type, ADC, VB) showed the highest ability to discriminate high-grade tumours from low-grade tumours (AUC 81.2%, CI:[59.2-100.0] and Brier Score 13.8, CI:[8.3-19.3]), which was significantly better than e.g. TBRmax alone (p=0.029). ***Conclusion:*** The addition of BV measurements does not increase the ability to discriminative tumour from treatment effects compared to the [18F]FET PET metrics TBRmax alone. However, multimodal imaging using dynamic [18F]FET PET metrics combined with advanced MRI significantly increase the discrimination between high-grade and low-grade paediatric CNS tumours. ***References:*** *Marner et al. (2021) NeuroOncol. 23:2107-16.

Aim/Introduction: The current study aimed to evaluate the feasibility of non-invasive MRI, O-(2-^{18}F-Fluoroethyl)-L-Tyrosine (^{18}F-FET), and 68Ga-Pentixafor (Cixafor) PET to increase diagnostic accuracy and to improve the discrimination of treatment-emergent changes in low- and high-grade gliomas. ***Materials and Methods:*** Two separate databases including low- and high-grade gliomas considered in our analysis. In the first subgroup, 29 patients with recurrent glioblastoma underwent Cixafor PET/CT before/after tumor mass resection. The second subgroup included 11 patients with histopathologically proven brain tumor suspected of having recurrent changes 3-4 months after surgery who were referred for an ^{18}F-FET PET/CT scan. In addition, PET/MR image fusion for both Cixafor and ^{18}F-FET was performed. Moreover, for both PET probes, visual and semiquantitative calculation of image-derived metrics, including SUVmax and tumor-to-background ratios (TBR), were performed. ***Results:*** Among eleven patients referred to ^{18}F-FET PET/CT/MR imaging, nine cases (82%) had a positive MRI, six cases (55%) had a positive PET/CT and PET/MRI, and tumor recurrence was observed in 6 patients (55%). Sample follow-up indicated that accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were 64%, 85%, 25%, 67%, 50% for MRI alone and 91%, 85%, 100%, 100% and 80% for PET/CT/MRI, respectively. The results of 29 patients who underwent Cixafor PET/CT were also evaluated visually and semiquantitatively. Visual assessment of Cixafor PET images revealed that 27/29 cases were positive with a mean SUVmax of 3.92. 17.24% (5/29) of patients had WHO grade III pathologies (anaplastic oligodendroglioma/anaplastic astrocytoma). Three out of twenty-nine participants had a stereotactic biopsy. The interval time between biopsy and imaging was 14-38 days (mean 21.71 days). The mean SUVmax of WHO grade IV lesions was significantly higher than grade III (3.131 ± 3.01 vs. 1.99 ± 0.45) and the mean SUVmax of blood pool activity was reported as 1.277 at the superior sagittal sinus area. While the mean target-to-background ratio of grade IV patients was 29.45, all grade III gliomas showed lower lesion uptake than background activity considered at the contralateral cortex areas. ***Conclusion:*** This study concluded that Cixafor had a higher TBR than ^{18}F-FET PET, with the ability to bond with 177Lu-Pentixather. Cixafor imaging could improve recurrence detection.

OP-755

[68Ga]Ga-PSMA PET/CT as a survival indicator in patients with suspected brain tumors of glial origin - preliminary results of a prospective study.

K. Pelka[1,2], *K. Koczyk[3], L. Koperski[4], T. Dziedzic[3], A. Nowak[3], L. Królicki[1], P. Kunert[3], J. Kunikowska[1];*
[1]Nuclear Medicine Department, Medical University of Warsaw, Warsaw, POLAND, [2]Laboratory of Center for Preclinical Research, Department of Methodology, Medical University of Warsaw, Warsaw, POLAND, [3]Department of Neurosurgery, Medical University of Warsaw, Warsaw, POLAND, [4]Department of Pathology, Medical University of Warsaw, Warsaw, POLAND.

Aim/Introduction: PET/CT targeting prostate-specific membrane antigen (PSMA) is commonly used in patients with prostate cancer; however, this antigen has been found in other solid tumours, including primary brain tumours such as glioblastoma (GBM). The aim of this study was to evaluate the usefulness of PSMA PET/CT for prognosis in comparison with histopathological results. ***Materials and Methods:*** In this prospective study, we screened patients who were referred to the hospital for surgery, with suspected glioma based on previous imaging studies. The qualitative and quantitative results of [68Ga]Ga-PSMA PET/CT were analysed. Until then at least two years follow up was performed. The collected data were analysed via Kaplan-Meier estimators in terms of overall (OS) and progression free survival (PFS) ***Results:*** Forty-four patients met the inclusion criteria. Twenty of them had positive and twenty-four negative [68Ga]Ga-PSMA PET/CT scans. In quantitative analysis the tumour-to-backgroud (TBR) ratio higher than 44.2 was best for diagnosis GBM. We found a statistically significant difference in PFS and OS between positive and negative PSMA PET/CT study (median OS 294 and 556 (days) vs not reached in negative ones), same as in GBM vs non-GBM patients. Patients with positive PET/CT had similar survival rates as HGG patients, same as patients with positive TBR to those diagnosed with GBM. Interestingly, for patients diagnosed with GBM, a statistical difference was noted between OS for positive and negative test results of [68Ga]Ga-PSMA-11 PET/CT (288 days vs not reached) ***Conclusion:*** The presence of [68Ga]Ga-PSMA-11 accumulation in PET/CT study of brain tumours can be as good a prognostic factor as the histopathological result. The results seem interesting and promising, but require further analysis on a larger group of patients - especially regarding the prognosis of patients with finally diagnosed GBM.

Aim/Introduction: Machine learning (ML) models based on

radiomics analysis of amino-acid positron emission tomography (PET) imaging have demonstrated efficiency in predicting histo-molecular diagnoses of gliomas. However, their clinical validation on physician interpretation remain challenging. This study aimed to investigate whether the explainable radiomics model impacts nuclear physicians' interpretation of the aggressiveness of presumed glial lesions at diagnosis. ***Materials and Methods:*** Patients underwent static/dynamic 6-[18F]fluoro-L-dopa PET scans to characterize suspected glial lesions retrospectively in conventional magnetic resonance imaging (MRI). With a 75%/25% split for training/test sets, an ensemble ML model employing radiomics features extracted from static/dynamic parametric PET images was trained using cross-validation to assess lesion aggressiveness through histo-molecular diagnosis or clinico-radiological follow-up. Three explainable ML methods including Local Interpretable Model-agnostic Explanations (LIME), Anchor, and SHapley Additive exPlanations (SHAP) were conducted to generate patient-specific explanations. Test set samples were evaluated by eighteen physicians from eight different institutions. During the first phase, physicians analyzed studies exclusively through MRI and PET images. In the second phase, the same physicians reevaluated the studies using all available data, including predictions and explanations derived from the radiomics model. This study was registered on ClinicalTrials.gov (NCT04469244). ***Results:*** Eighty-five patients (54 [39-62] years old, 41 women) were selected. The diagnostic accuracy of physicians in the second phase was significantly improved compared to those of the first phase (0.775 (0.750, 0.802) vs. 0.717 (0.694, 0.737), p=0.007). The explainable radiomics model augmented physician agreement with a 22.72% increase in Fleiss' Kappa and significantly enhanced their decision-making confidence (p<0.001). Among all physicians, Anchor and SHAP demonstrated effectiveness in 75% and 72% of cases, respectively, both surpassing LIME (p≤0.001). ***Conclusion:*** Our results highlight the potential of an explainable radiomics model from amino-acid PET scans, as a diagnostic support tool for physicians to determine the aggressiveness of suspected glial lesions at diagnosis.

OP-757

Value of ^{11}C-MET PET/CT imaging model based on machine learning in predicting IDH1 mutation status in glioblastoma

Y. Pan, *H. Dang, B. Xu;*
Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: The mutation status of IDH is often associated with the prognosis and survival time of patients with glioblastoma. Imaging omics models based on 11C-MET PET/CT was constructed to distinguish IDH1 mutation status in glioblastoma patients, and to explore the application potential and accuracy of the machine learning prediction models. ***Materials and Methods:*** Clinical and imaging data were retrospectively collected from 157 patients with glioblastoma who underwent 11C-MET PET/CT. All patients underwent surgical resection of tumors in our unit, and IDH1 molecular pathologic detection was performed. The 157 patients were randomly divided into a training set and a validation set using an 8:2 ratio. Glioblastoma lesions in 157 patients were delineated as areas of interest (ROI) and PET features were extracted using threshold segmentation. LASSO regression and Spearman correlation analysis were used to screen the most predictive imaging features, and logistic regression (LR), support vector machine (SVM) and decision tree (DT) were used to construct an omics model to distinguish wild and mutant IDH1 cases. The diagnostic efficacy of the model was compared by calculating the area under receiver (AUC) operating characteristic curve (ROC), 95% confidence interval (CI), sensitivity, specificity, accuracy, and P-value of the model and by Delong test. ***Results:*** The comparison results of the diagnostic performance of the decision tree model, logistic regression model, and support vector machine model demonstrated that in the training set, the AUC was 0.910 (95% CI, 0.892~0.922), 0.697 (95% CI, 0.682~0.703), and 0.698 (95% CI, 0.684~0.705), respectively; while in the validation set, the AUC values were 0.805 (95% CI, 0.798~0.812), 0.740 (95% CI, 0.734~0745), and 0.764(95%CI,0752~0773),respectively. Delong test results indicated that compared to LR and SVM models(P < 0.05),the DT model exhibited superior classification performance. ***Conclusion:*** Decision tree prediction model based on 11C-MET PET/CT imaging can accurately predict IDH1 mutation status in glioblastoma, showing high diagnostic performance and potential clinical application value. This model provides strong imaging support for the personalized treatment of glioblastoma and helps guide clinical decision-making.

OP-758

Feasibility and tolerability of [^{131}I]I-PA monotherapy in progressive and recurrent high grade gliomas; an ongoing single institution case series.

N. Tolboom[1], *T. J. Snijders[1], T. Seute[1], M. Geurts[2], D. Brandsma[3], J. Dankbaar[1], F. Y. De Vos[1], A. J. A. T. Braat[1];*
[1]University Medical Centre Utrecht, Utrecht, NETHERLANDS,
[2]Erasmus MC Cancer Centre, Rotterdam, NETHERLANDS,
[3]Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Aim/Introduction: In a phase I-study, safety and tolerability of intravenous 4-L-[131I]iodo-phenylalanine ([^{131}I]I-PA, TLX101, Telix Pharmaceuticals) administered concurrently with second line external beam radiation therapy in patients with recurrent glioblastoma has been demonstrated, with encouraging preliminary efficacy data. Here we report a case series of patients with high grade gliomas treated with [131I]I-PA monotherapy. ***Materials and Methods:*** Patients with 1st or 2nd recurrence of high grade glioma who exhausted local and systemic treatments were referred to our outpatient clinic. Exclusion criteria were life expectancy <12 weeks and KPS <70. [18F]FET-PET was performed, with a minimum tumor-to-background ratio of 2,5 being considered adequate for therapy. [131I]I-PA monotherapy was given in an in-patient setting during 3-5 days, depending on emitted radiation levels, in accordance with local radiation safety legislation. Post-therapy SPECT scans were done after three days, clinical follow-up after each cycle, and follow up MRI 3 weeks after the second cycle. ***Results:*** In August 2021, and between September 2023 and April 2024, five patients (1 oligodendroglioma grade 3, 4 glioblastoma (according to WHO 2021 criteria)) were treated. Mean age was 52±7 years, 5 male. All patients received two cycles with 5 GBq [^{131}I]I-PA, mean time between treatments was 25 days±4. One second cycle was an experimental intra-arterial administration, all others were intravenous administrations. Treatments were well tolerated, without any treatment-related adverse effects. No effects on kidney-, liver- or bone marrow functions were seen. Adequate targeting was demonstrated visually on post therapy SPECT/CT in all patients. To date, two patients have passed away (pt 1 (overall survival (OS)11 months), pt 2 (OS 5 months). One patient is receiving best supportive care based on clinical symptoms and MRI (OS to date 6 months), and two patients are awaiting 3rd treatment (OS 4 and 3 months). ***Conclusion:*** In this ongoing case series of [^{31}I]I-PA monotherapy in recurrent high-grade gliomas, treatment was feasible and well tolerated. Adequate targeting was revealed at post-therapy SPECT imaging.

225Actinium and combined 225Actinium/177Lutetium-labelled (TANDEM) PSMA radioligand therapy (PRLT) in patients with metastatic castration resistant prostate cancer (mCRPC): A retrospective study on long-term adverse events and survival

***E. Perrone*[1],** *A. Mishra*[2], *A. Eismant*[2], *K. Ghai*[2], *L. Greifenstein*[2], *R. P. Baum*[2];
[1]*Università Cattolica del Sacro Cuore, Rome, ITALY,*
[2]*CURANOSTICUM Wiesbaden-Frankfurt, Center for Advanced Radiomolecular Precision Oncology, Wiesbaden, GERMANY.*

Aim/Introduction: 225Actinium-PSMA is an option in advanced mCRPC patients resistant to 177Lutetium-PRLT. Adequate protection is needed to avoid salivary glands' impairment. 225Ac-PSMA PRLT (as monotherapy and as 225Ac/177Lu-TANDEM) was analysed concerning safety/impact on salivary glands function as well as concerning overall survival (OS). ***Materials and Methods:*** Between December 2020 and February 2024, 80 patients (age range 43-88 years) received 225Ac-PSMA PRLT. Salivary gland protection was performed by retroauricular scopolamine patches from two days before to two hours after injection and by chewing a polyglutamate parotid gland protector according to Paganelli's protocol [1]. Patients with ≥1 follow-up visit (n=64) were considered for evaluating xerostomia, haematological, renal, and hepatic adverse events (grading according to CTCAE v.5.0). ***Results:*** Over 38 months, 132 225Ac-PSMA cycles were administered (4 225Ac-monotherapies, 128 225Ac/177Lu-TANDEM PRLTs). At the time of analysis, 42 patients had received one cycle, either monotherapy or TANDEM (1.7-10.2 MBq 225Ac); 23 patients had received two cycles (7-21 MBq 225Ac), and 15 patients had received ≥three cycles (11-28.7 MBq 225Ac). PRLT was generally well tolerated; flare pain was the most common acute adverse event (n=11), followed by nausea (n=7) and vomiting (n=3). During follow-up, 54 patients died (OS 5 days - 30 months), 26 patients are still alive (follow-up 2-36 months). After PTRL (vs. baseline), anaemia G1/G2 and G3 was observed in 67 and 15 patients (vs.53 and 7), respectively; one patient developed anaemia G4; leukopenia G1/G2 and G3 in 28 and 4 patients (vs.20 and 2); thrombocytopenia G1/G2 and G3/G4 in 24 and 14 patients (vs.20 and 5); renal impairment G1/G2 occurred in 16 patients (vs.10); liver alterations G1/G2 and G3 in 24 and 8 patients (vs.22 and 6), respectively. Before PRLT, 17 patients reported xerostomia G1/G2, and 22 patients after PRLT. ***Conclusion:*** This retrospective analysis demonstrates that 225Ac-PSMA PRLT is safe in terms of acute and chronic toxicity. Only few patients experienced G3/G4 long-term adverse events: 9 anaemia G3/G4, 2 leukocytopenia G3, and 9 thrombocytopenia G3/G4, which was generally associated to severe bone marrow involvement or previous chemotherapy. Renal insufficiency G3/G4 and hepatotoxicity G4 did not occur; two patients (one with liver metastases) developed hepatotoxicity G3. Only 5 patients complained about de-novo xerostomia G1/G2 after PRLT. Finally, 225Ac-PSMA PRLT shows promising OS in patients progressing after previous treatments, including 177Lu-PSMA PRLT (OS 2.5 years, follow-up time 3 years). ***References:*** [1] Paganelli G, Sarnelli A, Severi S, et al. EJNMMI, 2020;47(13):3008-3017. doi:10.1007/s00259-020-04856-1.

OP-760

[^{225}Ac]Ac-PSMA-617 Targeted Alpha Therapy in Metastatic Castration-Resistant Prostate Cancer: efficacy and treatment outcome

A. Ebrahimifard, *S. Bagheri, Q. Wang, F. Eilsberger, M. Luster, D. Librizzi, B. H. Yousefi;*
Philipps University Marburg, Marburg, GERMANY.

Aim/Introduction: Targeted Alpha Therapy (TAT) with [225Ac]Ac-PSMA has been introduced as a new treatment option for patients with metastatic castration-resistant prostate cancer (mCRPC) who have shown refractoriness to [177Lu]Lu-PSMA therapy. The efficacy and treatment outcomes after TAT were evaluated in a retrospective study through PSA level assessment and quantitative evaluation of post-treatment PSMA PET images. ***Materials and Methods:*** We evaluated the pre- and post-treatment [68Ga]Ga-PSMA-11 PET/CT images in patients treated with [225Ac]Ac-PSMA-617 after developing refractoriness to [177Lu]Lu-PSMA-617 therapy. Total tumor volume and organs at risk were segmented, and quantitative parameters were extracted. The efficacy and treatment outcome were evaluated using biochemical response, survival analysis, molecular tumor response, and disease control rate (DCR). ***Results:*** Twelve patients, with a total of 59 [68Ga]Ga-PSMA-11 PET/CT images, were included in the retrospective study. Based on biochemical response results, 8 out of 12 (67%) patients experienced a decline in PSA levels, with 7 out of 12 (58%) showing a >50% decrease and 3 out of 12 (25%) experiencing disease progression. According to the molecular tumor response evaluation using PET images, 7/12 patients (58.4%) had a partial response, 3/12 (25%) had stable disease, and 2 out of 12 (16.6%) showed disease progression. The DCR was 85.7%. An interesting finding was the correlation between total tumor volume reduction and decline in PSA levels (>50%), both of which were observed in 58% (7/12) of the patients. Moreover, the biochemical blood assessment of [177Lu]Lu-PSMA-617 and [225Ac]Ac-PSMA-617 therapies showed no significant effects of [225Ac]Ac-PSMA-617 on Alkaline phosphatase, creatinine, eGFR, hemoglobin, LDH, platelets, and WBC levels. ***Conclusion:*** The mCRPC presents a challenge in patient treatment management due to lower treatment output and efficacy. In this study, TAT with [225Ac]Ac-PSMA-617 showed promising treatment outcomes for mCRPC patients who no longer respond to [177Lu]Lu-PSMA-617 therapy. While the decline in PSA levels is commonly used to evaluate treatment efficacy, total tumor volume may help as a useful response parameter for assessing treatment efficacy. Interestingly, the biochemical blood assessment of [225Ac]Ac-PSMA-617 therapies showed no significant effects on Alkaline phosphatase, creatinine, eGFR, hemoglobin, LDH, platelets, and WBC levels

OP-761

Botulinum toxin plus transdermal scopolamine reduce salivary gland uptake of ^{225}Ac/^{177}Lu-PSMA ligands

***J. Zhang*[1,2,3],** *J. Mueller*[4], *X. Fan*[1,2], *T. Zhao*[1,2], *V. Jakobsson*[1,2,3], *R. P. Baum*[3,5];
[1]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE,* [2]*Theranostic Center of Excellence, National University of Singapore, Singapore, SINGAPORE,* [3]*International Centers for Precision Oncology, Wiesbaden, GERMANY,* [4]*Vivantes Klinikum Spandau,*

Academic Teaching Hospital Charité - Universitaetsmedizin Berlin, Berlin, GERMANY, [5]Department of Oncology and Hematology, Helios DKD Klinik, Wiesbaden, GERMANY.

Aim/Introduction: PSMA-targeted radioligand therapy (PRLT) holds promise for the treatment of advanced metastatic castration-resistant prostate cancer (mCRPC). However, salivary gland toxicity is a major dose-limiting adverse effect, especially when it comes to PRLT with alpha-emitting radionuclides such as 225Ac. In this study, we explored the use of Botulinum Toxin (BTX) to mitigate salivary gland uptake of PSMA radioligands. ***Materials and Methods:*** IncoA (Xeomin) was injected percutaneously into the right parotid and left submandibular glands under ultrasound control 3-4 weeks before scheduled 225Ac-PRLT. Transdermal scopolamine was applied during a period of 72 hours prior to PRLT. The SUVmean or SPECT counts were measured from pre-BTX and post-BTX images; ratios of non-injected/injected contralateral gland were calculated and compared pre and post-BTX. ***Results:*** Fourteen patients were included, of whom 2 received BTX twice before scheduled PRLT, of which patients received mean cumulative activity of 225Ac 11.89 ± 7.02 MBq. We found that gradually increasing BTX doses, either alone or in combination with scopolamine, effectively reduced salivary gland PSMA uptake, up to 170 units to the parotid and 80 units to the submandibular gland. No adverse side effects were associated with this treatment. No severe adverse events were observed. ***Conclusion:*** This study demonstrated proof-of-concept of using Botulinum Toxin for mitigating sialotoxicity during PRLT with alpha and beta-emitting radionuclides.

OP-762

The prognostic value of whole-body composition analysis in prostate cancer patients undergoing [^{177}Lu] PSMA radioligand therapy: A Proof of concept study using pretherapeutic [^{18F}]PSMA PET-CT

***W. Roll*[1],** *L. Plagwitz[2], J. Varghese[2], D. Ventura[1], K. Rahbar[1], P. Schindler[3];*
[1]Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY, [2]Institute of Medical Informatics, University of Münster, Münster, GERMANY, [3]Department of Radiology, University Hospital Münster, Münster, GERMANY.

Aim/Introduction: This retrospective study aims to develop a deep learning-based approach to whole-body CT segmentation out of standard [18F]PSMA-PET-CT to assess body composition in metastatic castration resistant prostate cancer (mCRPC) patients prior to [177Lu]PSMA radioligand therapy (RLT). Our goal is to go beyond standard [18F]PSMA-PET-based pretherapeutic assessment and identify additional body composition metrics out of the CT-component with predictive and prognostic value. ***Materials and Methods:*** We used a deep learning segmentation model to perform fully automated segmentation of subcutaneous fat, visceral fat, skeletal muscle, and L3 vertebrae from whole-body [18F]PSMA-PET-CT scans of n=92 prostate cancer patients before RLT. The proportions of subcutaneous fat to skeletal muscle and visceral fat to skeletal muscle are compared in detail, both on a 2D slice-by-slice basis (centered at L3) and across the entire 3D CT scan. Statistical analyses were conducted to correlate the parameter ratios of the segmented fat-to-skeletal-muscle composition with patient outcomes. For this purpose, the subjects were divided into two groups based on the median value of the tissue composition. ***Results:*** The automated segmentation model was useful for delineating subcutaneous fat, visceral fat, and skeletal muscle across diverse patient anatomies. Analyses revealed significant correlations between lower subcutaneous fat ratios and poorer therapeutic outcomes (subcutaneous fat volume / skeletal muscle volume; high: median OS: 17 months; low: median OS: 12 months; p=0.037) in the 3D model, suggesting these parameters as potential prognostic indicators. In both 2D and 3D formats, the ratio of visceral fat to skeletal muscle, as well as the ratio of subcutaneous fat to skeletal muscle in 2D, showed no significant differences. ***Conclusion:*** In this proof-of-principle study the implementation of a deep learning-based whole-body analysis provides a robust and detailed CT-based assessment of body composition in mCRPC patients undergoing RLT. Potential prognostic parameters have to be corroborated in larger prospective datasets and compared to [18F]PSMA-PET parameters.

OP-763

Comparison of ^{68}Ga-PSMA and ^{177}Lu-PSMA Total Metabolic Tumor Volume (TMTV) variations for monitoring metastatic castration-resistant prostate cancer in ^{177}Lu-PSMA therapy.

***C. Boursier*[1,2],** *T. Zaragori[1], J. Kunsch[1], P. Olivier[1,2], M. Claudin[1,2], P. Marie[1,2], M. Bros[1], M. Bordonne[1], A. Verger[1,2], G. Karcher[2], L. Imbert[1,2];*
[1]CHRU Nancy, Vandoeuvre-les-Nancy, FRANCE, [2]Nancyclotep Imaging Platform, Vandœuvre-lès-Nancy, FRANCE.

Aim/Introduction: Previous trials have shown that semi-quantitatively derived SUVmean from 68Ga-PSMA PET/CT imaging could predict the response to 177Lu-PSMA treatment. 177Lu-PSMA SPECT/CT imaging can be performed post-therapy, although recording times on conventional gamma-cameras are too long for routine clinical use. 360° CZT-SPECT cameras, however, enable high-speed whole-body SPECT recordings in only 18 minutes. This study aimed to determine whether the absolute quantification of 177Lu-PSMA scintigraphy provided by a 360° CZT-SPECT/CT system provides consistent results for monitoring metastatic castration-resistant prostate cancer. ***Materials and Methods:*** We included patients eligible for 177Lu-PSMA-617 treatment, who completed at least one treatment cycle, and for whom post-therapeutic 177Lu-PSMA-617 360° CZT SPECT/CT and 68Ga-PSMA-11 PET/CT imaging were acquired. PSA levels were measured before each cycle. Total metabolic tumor volume (TMTV) was segmented using an absolute threshold of 3 SUV followed by manual correction. Total lesion activity (TLA=TMTVxSUVmean) values were determined on 177Lu-PSMA-SPECT/CT images acquired 24 hours post-177Lu-PSMA-617 injection and on pre-injection 68Ga-PSMA-PET/CT images. SPECT/CT images from all cycles were collected, and additionally PET/CT images acquired from C1, C4, C6. A mixed-effects linear model was used to model the global relationship of PSA levels with SPECT and PET TLA variations during treatment cycles. Spearman correlation coefficients were computed between the inter-cycle differences (C1-C4 and C1-C6) of SPECT or PET TLA (ΔSPECTTLA or ΔPETTLA) versus those of PSA (ΔPSA). ***Results:*** Seventy-two patients were included (mean age: 71 ± 8 years), receiving an average of 7327 ± 338 MBq of 177Lu-PSMA per cycle. Forty-one patients received 4 cycles and 25 received 6 cycles. SPECT and PET TLA correlated globally with PSA levels at each cycle (R=0.57 and R=0.67 respectively for SPECT and PET). Moreover, the variation of disease burden according to PSA change in 177Lu-PSMA-SPECT/CT was at least as effective as 68Ga-PSMA-PET/CT with correlations of 0.76 and 0.65 respectively for C1-C4 ΔSPECTTLA and ΔPETTLA; and correlations of 0.74 and 0.68 for C1-C6 ΔSPECTTLA and ΔPETTLA . ***Conclusion:*** Quantitative 177Lu SPECT/CT imaging after each cycle of 177Lu-

PSMA-617 treatment enables the determination of TLA, strongly correlated with PSA and its variation during treatment. Results provided by a 360° CZT-camera seem at least as good as PSMA-PET/CT imaging for monitoring metastatic castration-resistant prostate cancer. The early assessment of treatment using these scintigraphic biomarkers, obtained without further radiotracer injection, and having procedure times fast enough for acceptable clinical routine, might contribute to optimizing the management of these patients.

OP-764

Assessment of Early Treatment Response with [^{177}Lu] PSMA Whole-Body-Scintigraphy Compared to Interim PSMA-PET

***D. Ventura*[1],** *P. Rassek*[1], *P. Schindler*[2], *B. H. Akkurt*[2], *L. Bredensteiner*[1], *M. Bögemann*[3], *K. Schlack*[3], *R. Seifert*[4], *M. Schäfers*[1], *W. Roll*[1], *K. Rahbar*[1];
[1]*Department of Nuclear Medicine, Münster, GERMANY,* [2]*Department of Radiology, Münster, GERMANY,* [3]*Department of Urology, Münster, GERMANY,* [4]*Department of Nuclear Medicine, Bern, SWITZERLAND.*

Aim/Introduction: PSMA-PET is an essential tool for patient selection prior to radioligand therapy (RLT), interim staging and follow up to monitor therapy. The value of post therapeutic whole-body scans (WBS) after injection off [177Lu]PSMA is underestimated. The aim of this study was to compare early response to treatment as assessed by post-therapeutic WBS with interim staging by PSMA-PET after 2 cycles to predict overall survival (OS). ***Materials and Methods:*** Patients with metastatic castration resistant prostate cancer, who received at least two cycles of RLT, and interim PSMA-PET were retrospectively evaluated. The PROMISE V2 framework was used to categorise PSMA expression and assess response to treatment. Response was defined as either disease control in responders (DCR) or disease progression in those failing to respond. ***Results:*** A total of 188 men treated with RLT between February 2015 and December 2021 were included. The comparison of various imaging modalities showed a robust and statistically significant correlation, as determined by the Cramer V test: e. g. response on WBS during second cycle compared to first interim PET ($c\varphi = 0.888$, $P < 0.001$, $n = 188$). The median follow-up time was 14.7 months (range: 3-63 months; 125 deaths occurred). Median OS was 14.5 months (95% CI: 11.9-15.9). Early response assessment was associated with a significantly better OS: e.g. DCR of second cycle WBS (24 vs 13 months, $P < 0.001$) with a HR of 2.81 ($P < 0.001$) or DCR of interim PET after 2 cycles (24 vs 11 months, $P < 0.001$) with a HR of 3.5 ($P < 0.001$). A decline of at least 50% in PSA levels after two cycles of RLT also indicates a significantly lower likelihood of death (26 vs 17 months, $P < 0.001$) with a HR of 1.92 ($P = 0.001$). ***Conclusion:*** Routinely acquired WBS after RLT with [177Lu]PSMA can be used for interim analysis with comparable results to PSMA-PET and can identify patients at risk of poor outcomes.

OP-765

A novel approach to predict overall survival in mCRPC patients treated with 177Lu PSMA therapy using radiomic features: A step toward unraveling the puzzle

***P. Singh*[1],** *Y. Khandelwal*[2], *A. H. Nazar*[3], *B. Jain*[2];
[1]*King George Medical University, Lucknow, INDIA,* [2]*All India Institute Of Medical Sciences, New Delhi, INDIA,* [3]*S.G.P.G.I., Lucknow, INDIA.*

Aim/Introduction: Radiomics, employing data mining and medical image analysis, is a novel technology generating significance for its potential in cancer diagnosis & response assessment.177 Lu-PSMA -617 is a recently approved therapeutic option for end-stage prostate cancer patients. Early prediction of progression-free survival may facilitate superior treatment strategies and enable early therapeutic adjustments, potentially reducing morbidity and enhancing survival outcomes in patients with advanced prostate carcinoma. Using a hybrid machine learning approach and a reliable tensor radiomic feature, the study aims to predict overall survival outcomes ***Materials and Methods:*** A total of 40 mCRPC patients treated with 177 Lu PSMA therapy where baseline and post-therapy SUV max, SUV mean, SUV peak, PSMA-derived tumor volume and total lesion PSMA were calculated and used for analysis. Tumor ROI on PSMA PET-CT scans were segmented using a region threshold approach, and Radiomic features (RFs) were extracted from them using MATLAB program. Response in PSMA-TV was assumed when a decline > 30% was present. Spearman's Rank correlation examined the relationship between RFs and OS, while univariate analysis assessed their role in predicting OS. Significant RFS ($p=0.005$) from univariate analysis were included in multivariate Cox regression to assess hazard ratio. ***Results:*** A total of 176 RFs including 2D and 3D features from baseline and follow-up scans done after 3 cycles of 177Lu PSMA therapy were extracted for each ROI in 40 patients. 67 3D texture features were chosen from the 176 risk factors for statistical analysis because 3D analysis covers the entire tumor volume, providing more precise capture of spatial heterogeneity. Univariate analysis identified 13 risk factors significantly correlated with OS, 7 of which were selected for COX regression. However, clinical stage emerged as a strong predictor of survival, with one risk factor from the multivariate analysis being highly predictive of overall survival. GLRLM percentage had a hazard ratio of 5.4 ($p=0.003$), signaling a fivefold rise in mortality risk ***Conclusion:*** This is noteworthy study where we have confirmed that the GLRLM percentage as a reliable indicator of overall survival, with a fivefold increase in the risk of death associated with higher values of this predictor. By contrasting features extracted from baseline and follow-up images, delta radiomics can identify early indicators of recurrence, metastasis, or mortality. Challenges inherent in clinical implementation of radiomics techniques include image standardization, registration, and data exchange. Further investigation is warranted to assess the robustness and clinical utility of radiomics features.

OP-766

99mTc-antigranulocyte scintigraphy for estimation of bone marrow reserve prior to PSMA-therapy in mCRPC patients

S. Kunte[1], *A. Delker*[1], ***M. Zacherl*[1],** *H. Schmid*[1], *G. T. Sheikh*[1], *V. Wenter*[1], *P. Bartenstein*[1], *N. Schmidt-Hegemann*[2], *J. Casuscelli*[3], *H. Ilhan*[4,5], *M. Unterrainer*[1,4], *L. M. Unterrainer*[1];
[1]*Department of Nuclear Medicine, LMU, München, GERMANY,* [2]*Department of Radiation Oncology, LMU, München, GERMANY,* [3]*Department of Urology, LMU, München, GERMANY,* [4]*Die Radiologie, München, GERMANY,* [5]*Department of Nuclear Medicine, LMU, Munich, GERMANY.*

Aim/Introduction: The development of PSMA radioligand therapy, which targets the surface protein PSMA present on prostate cancer cells, has transformed the approach to treating metastatic, castration-resistant prostate cancer (mCRPC). One limitation of RLT is the potential for the depletion of the bone marrow stem cell reserve. This is particularly relevant in patients who have experienced extensive osseous tumor load or have

undergone myelotoxic treatment, such as chemotherapy. The objective of this pilot study was to assess the potential of 99mTc-antigranulocyte scintigraphy as a tool for the estimation of bone marrow reserve prior to PSMA-therapy. ***Materials and Methods:*** A total of 10 patients diagnosed with mCRPC with extensive osseous tumour load on ^{18}F-PSMA PET/CT were included in the study. Prior to PSMA-therapy, all patients underwent 99mTc-antigranulocyte scintigraphy. The spatial overlap of osseous tumour burden and bone marrow was then compared between the two modalities.In instances where both images exhibited a low degree of spatial overlap, RLT was conducted. These patients underwent a laboratory analysis at four and eight weeks following the initial therapy cycle. ***Results:*** A spatial correlation between viable bone marrow and PSMA-positive metastases was not observed in nine of the ten patients. Two patients underwent 177Lu-PSMA-therapy, three underwent 225Ac-PSMA-therapy, and two underwent 225Ac-177Lutetium-PSMA-tandem-therapy. Due to acute contraindications, two patients did not receive PSMA-therapy. Overall, the laboratory analysis demonstrated stable results at four and eight weeks following the initial therapy cycle. The hemoglobin levels were 9.3 ± 2.3, 9.3 ± 2.0, and 9.6 ± 1.9 g/dL, respectively, while the white blood cell count was 4.0 ± 1.1 vs. 4.1 ± 1.3 vs. 4.2 ± 0.8 G/l; platelets: 147 ± 84.5 vs. 136.1 ± 59.6 vs. 130.0 ± 50.4 G/l; neutrophils: 2.6 ± 0.9, 2.8 ± 1.2, and 2.8 ± 1.2 g/l, respectively. ***Conclusion:*** PSMA-therapy appears to be a viable therapeutic option in patients presenting with spatial mismatch on PSMA PET/CT and 99mTc-antigranulocyte scintigraphy, despite extensive osseous tumor load. Dosimetry studies are currently in progress with the aim of determining the bone marrow doses to be administered in the included patients.

OP-767

Does Pre-Therapy PSA Influence ^{177}Lu-PSMA-617 Treatment Outcomes?

S. Fermawi, MD[1], *T. Buehner, PhD[1], S. Kalarn, DO[2], C. Sabottke, MD[2], A. Recio-Boiles, MD[3], B. Savir-Baruch, MD[1];*
[1]University of Arizona College of Medicine-Tucson, Department of Medical Imaging, Division of Nuclear, Tucson, AZ, UNITED STATES OF AMERICA, [2]University of Arizona College of Medicine-Tucson, Department of Medical Imaging, Tucson, AZ, UNITED STATES OF AMERICA, [3]University of Arizona College of Medicine-Tucson, Department of Medicine, Hematology and Medical Oncology, Tucson, AZ, UNITED STATES OF AMERICA.

Aim/Introduction: Patients with metastatic castration-resistant prostate cancer (mCRPC) who experience biochemical recurrence and who have previously received both androgen receptor pathway inhibition therapy and taxane-based chemotherapy are eligible for treatment with 177Lu-PSMA-617 in the USA. During treatment, the PSA level is used as a marker for radioligand therapy (RLT) therapy response. Treatment outcomes vary and are difficult to predict. Thus, our study aims to investigate factors influencing both treatment failure and success in patients with mCRPC undergoing therapy with 177Lu-PSMA-617. ***Materials and Methods:*** We retrospectively evaluated patients at our institution from December 2021 to December 2023 with mCRPC who completed or failed 177Lu-PSMA-617 therapy. The patients were divided into two groups; the treatment success group included those who received six cycles of 177Lu-PSMA-617 and demonstrated biochemical response, and the treatment failure group included those who discontinued their treatment before cycle six due to enrollment in hospice or biochemical failure. We utilized the REDCap database (hosted at the University of Arizona, Tucson, AZ, USA) for data collection and storage. Pre-therapy PSA level and kinetics were evaluated among the two groups. A p-value of <0.05 was considered statistically significant. ***Results:*** A total of 137 cycles of 177Lu-PSMA-617 therapy were administered to a cohort of 32 patients. The study cohort consisted of 13/32 (40.6%) in the success group and 19/32 (59.4%) in the treatment failure group. The success group demonstrated a lower pre-therapy mean PSA (90.7, ±114.8, p-value 0.006) (mean, SD), longer pre-therapy PSA doubling time (7.2 months, ±12.7, p-value 0.049), and lower pre-therapy PSA velocity (48, ±95.7, p-value 0.014). In contrast, the treatment failure group displayed a higher pre-therapy mean PSA (449.1, ± 547.3), shorter pre-therapy PSA doubling time (1.7, 4.9), and faster PSA velocity (600.7, ±888.7). ***Conclusion:*** Lower pre-therapy PSA, longer pre-therapy PSA doubling time, and lower pre-therapy PSA velocity may be potential indicators of 177Lu-PSMA-617 better treatment outcome in patients with mCRPC, as our treatment failure group demonstrated the opposite trends. Studying a larger patient cohort in the future may be beneficial to assess this patient population further.

SSTR PET/CT in patients with Ectopic Cushing syndrome - A retrospective single center experience

N. Damle[1], *A. Vishnu[1], C. Ganapathy[1], K. Chandekar[1], G. Priyanka[1], C. Bal[1], A. Venugopal[1], B. Attri[2], R. Reddy[2], N. Tandon[2], Y. Gupta[2], S. Chumber[3], G. Puri[3];*
[1]Department of Nuclear Medicine, All India Institute of Medical Sciences, New Delhi, INDIA, [2]Department of Endocrinology, Metabolism and Diabetes, All India Institute of Medical Sciences, New Delhi, INDIA, [3]Department of Surgical Disciplines, All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Ectopic ACTH hyperproduction can account for upto 10% of all cases of Cushing syndrome and, after excluding pituitary and adrenal causes, the ectopic source has to be looked for. We aimed to study the role of 68Ga-DOTANOC PET/CT in the detection of the culprit tumor in patients suspected to have ectopic ACTH production. ***Materials and Methods:*** Records of consecutive patients with biochemically proven Cushing syndrome and clinically suspected ectopic source who underwent 68Ga-DOTANOC PET/CT at our tertiary care institution between January 2019 and February 2024 were retrospectively reviewed. All patients were injected 3-4mCi 68Ga-DOTANOC intravenously and underwent whole-body PET/CT 30-40 minutes post-injection. Scanned images were interpreted by two nuclear physicians independently. 68Ga DOTANOC PET/CT findings were corroborated with clinical details. Histopathology details were reviewed for the patients who underwent surgery. Findings of biochemical and conventional imaging were also utilized for correlation. ***Results:*** 81 patients (24 men, 57 women; median age: 32 years) with biochemically proven Cushing syndrome were included in the final analysis. Mean ACTH levels at the time of study were 89 pg/mL (normal range: 7-63 pg/mL). 68Ga-DOTANOC PET/CT was positive for a lesion in 37/81 patients (45.6%), 15/37 (41%) were localized to the lungs, 5/37 (13.5 %) to

the pancreas, and 7/37 (18.9 %) to the thyroid, 4/36 cases were localized to the mediastinum (11%); 6/37 (16.2%) lesions were localized to other sites for the culprit lesions. In 35/37 patients where the lesion was localized, ACTH levels normalised after appropriate management. ***Conclusion:*** 68Ga-DOTANOC PET/CT proved to be a valuable modality in the workup of patients with suspected ECS by revealing the primary tumor in almost half of the cases. Identification of the culprit lesion is of vital importance in managing ECS, as surgical management could completely result in remission. Hence, 68Ga-DOTANOC PET/CT can be a useful non-invasive, imaging test for detection of the primary tumor in patients with suspected ECS.

EPS-233

Imaging with SSTR PET/CT in endocrine syndromes: Insights from a tertiary center experience

***C. Ganapathy*[1],** *N. Damle[1], K. Chandekar[1], M. Tripathi[1], C. Bal[1], G. Priyanka[1], D. Khan[1], A. Venugopal[1], N. Tandon[2], Y. Gupta[2], V. Jyotsna[2], S. Das[2], P. Namjoshi[2], S. Chumber[3], K. Kataria[3], P. Ranjan[3], G. Puri[3];*
[1]Department of Nuclear Medicine, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA, [2]Department of Endocrinology, Metabolism and Diabetes, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA, [3]Department of Surgical Disciplines, All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA.

Aim/Introduction: Multiple Endocrine Neoplasia (MEN) and Von-Hippel-Lindau (VHL) syndromes have autosomal dominant inheritance with high penetrance and typically involve organs/glands that have endocrine function. The aim of the present study is to evaluate the role of somatostatin receptor targeted imaging with 68Ga-DOTANOC PET/CT in patients with MEN and VHL syndromes. ***Materials and Methods:*** Data of consecutive patients, clinically suspected/diagnosed with MEN/VHL syndromes, who underwent 68Ga-DOTANOC PET/CT at our tertiary care institute from January 2017 to April 2024, was retrospectively reviewed. Histopathological data was assessed for patients undergoing biopsy/surgery, while clinical, biochemical and conventional imaging correlation was done for others. ***Results:*** 105 patients (37-men, 68-women) with MEN/VHL syndrome (35-MEN1, 34-MEN2A, 7-MEN2B, 29-VHL) underwent 170 68Ga-DOTANOC PET/CT scans: 44.7% (47/105) for baseline evaluation and 55.3% (58/105) for restaging/response assessment/surveillance. In patients with newly diagnosed MEN-1 syndrome (n=15, median age 30.4 years), parathyroid adenomas were universal (100%) followed by pancreatic NET (93.3%). 4/15 patients had all three major features of MEN-1 syndrome, i.e., parathyroid adenoma, pituitary adenoma and enteropancreatic NETs. 40% (8/20) of follow-up MEN-1 patients had new lesions on SSTR imaging, primarily pancreatic NETs (6/8). For newly diagnosed MEN-2 syndrome (n=15, median age 26 years), medullary thyroid carcinoma and pheochromocytoma were most common (73.3% each, 11/15), sometimes co-existent (46.7%, 7/15). Post-surgical MEN-2 patients showed local recurrence in 40% (8/20) on DOTANOC PET/CT, often in paratracheal lymph nodes (6/8). Additionally 6 MEN-2 patients with metastatic disease, undergoing systemic therapy with either TKIs or 177Lu-PRRT, underwent follow-up scans for treatment response. 17 suspected/diagnosed VHL patients (median age 31 years) underwent 68Ga-DOTANOC PET/CT for baseline evaluation, with the most common lesions detected being cerebellar hemangioblastoma and pheochromocytoma (unilateral=7, bilateral=3) in 10/17 (58.8%) patients each, followed by RCC in 3/17 (17.6%) patients. Two (11.8%) patients, had all the four major constituents of VHL detected, i.e., cerebellar hemangioblastoma, clear-cell renal cell carcinoma, retinal-angiomas and pheochromocytoma. Of the VHL patients who underwent post-surgical/treatment follow-up scans, 66.6% (8/12) showed residual disease, 25% (3/12) had no evidence of disease, while one patient (8.3%) had a new left adrenal pheochromocytoma. ***Conclusion:*** In the realm of patients afflicted with hereditary syndromes such as MEN/VHL, 68Ga-DOTANOC PET/CT emerges as a formidable one-stop hybrid imaging tool. It serves manifold objectives, encompassing the determination of baseline disease burden, the facilitation of post-surgical restaging, evaluating feasibility for PRRT therapy, treatment response, disease recurrence and surveillance.

EPS-234

Detection of parathyroid lesions and its impact on clinical management in primary hyperparathyroidism patients using PET-MRI with $^{[18F]}$Fluorocholine

***I. Sánchez Rodríguez*[1],** *V. Carrero-Vasquez[1], M. Suarez-Piñera[1], M. De Lama-Salvador[2], P. Moreno-Llorente[3], M. Cortés-Romera[1];*
[1]Nuclear Medicine Department. Bellvitge University Hospital, Barcelona, SPAIN, [2]Radiology Department. Bellvitge University Hospital, Barcelona, SPAIN, [3]Endocrine Surgery Department. Bellvitge University Hospital, Barcelona, SPAIN.

Aim/Introduction: Primary hyperparathyroidism (PHPT) is characterized by excessive production of parathyroid hormone (PTH) because of the hyperfunction of one or more parathyroid glands (PG). Its prevalence ranges from 0.1% to 0.3%. Diagnosis is clinical, and treatment involves surgical removal of affected PGs; hence, imaging tests are essential for detection and localization. Our objective is to evaluate the detectability of parathyroid lesions by PET/MRI and its impact on the clinical management of PHPT patients. To compare its detectability with PET/CT and the impact on clinical decision-making in cases with positive PET/MRI or negative PET/MRI. ***Materials and Methods:*** Prospective study of PHPT patients with suspected parathyroid adenoma and negative conventional imaging, referred for $^{[18F]}$fluorocholine PET study during 2023-2024. Twenty-one consecutive patients (13 females; 63 years [44-82]) were included. We performed two consecutive PET/MRI acquisitions (T1, T2, and STIR) and PET/CT with an intravenous contrast between 20 and 50 minutes after administering the radiopharmaceutical. Two nuclear medicine physicians and one radiologist reviewed all PET/MRI studies visually and semiquantitatively. The variables evaluated the clinical impact of both PET/CT and PET: decision for surgical intervention (SI) vs. follow-up taken in the multidisciplinary clinical committee. ***Results:*** PET/MRI was positive in 17/21 patients, in these cases: SI=13 patients (76.5%): adenoma confirmation=3, rest pending SI; and follow-up =2. Pending decision=2. PET/MRI-negative in 4 patients (19%), all decided for follow-up. There was discordance PET/MRI-positive - PET/CT-negative in 5 patients, in these cases: SI=3 patients (60%) and follow-up =1. Pending decision by the committee=1. ***Conclusion:*** PET/MRI was superior to PET/CT in detecting hyperfunctioning parathyroid adenomas with a greater clinical impact on therapeutic decision-making. These results endorse the utility of PET/MRI in PHPT patients. We need larger studies to demonstrate the efficacy of the technique and its contribution to the surgical approach in these patients.

EPS-235

Comparing PET-MRI and PET-CT with $^{[18F]}$Fluorocholine for Detecting Parathyroid Lesions in Primary Hyperparathyroidism Patients

***I. Sánchez Rodríguez*[1],** *V. Carrero-Vasquez[1], M. Suarez-Piñera[1], P.*

Moreno-Llorente[2], M. De Lama-Salvador[3], M. Cortés-Romera[1];
[1]Nuclear Medicine Department. Bellvitge University Hospital, Barcelona, SPAIN, [2]Endocrine Surgery Department. Bellvitge University Hospital, Barcelona, SPAIN, [3]Radiology Department. Bellvitge University Hospital, Barcelona, SPAIN.

Aim/Introduction: Primary hyperparathyroidism (PHPT) occurs when one or more parathyroid glands (PG) hyperfunction, resulting in the excessive production of parathyroid hormone (PTH). Its prevalence ranges from 0.1% to 0.3%. Diagnosis is clinical, and treatment involves surgical removal of affected PGs; hence, imaging tests are essential for detection. Our aim is to evaluate and compare the detectability of parathyroid lesions by PET/MRI and PET/CT with $^{[18F]}$fluorocholine. To assess interobserver agreement in PET/MRI analysis. ***Materials and Methods:*** Prospective study of 21 patients (13 females; 63 years [44-82]) with PHPT and suspected parathyroid adenoma who underwent $^{[18F]}$fluorocholine PET imaging during 2023-2024. Prior imaging tests were negative or inconclusive. We performed two consecutive PET/MRI acquisitions (T1, T2, and STIR) and PET/CT with an intravenous contrast between 20 and 50 minutes after administering the radiopharmaceutical. All PET/MRI studies were evaluated (visually and semiquantitatively) by two nuclear medicine physicians and one radiologist. ***Results:*** We performed PET/MRI in all 21 patients and found it to be positive in 17 patients (81%), with all 17 patients being positive in PET+MRI. PET/CT in 19/21 patients: positive in 13/19 patients (68%), of which 10 were positive in PET+CT; 2 only in PET; and 1 only in CT; detecting 16 lesions (11 patients with single lesion and 2 with multiple). Among the 19 patients with both PET/CT and PET/MRI, we found a detectability agreement in 14 patients (73.7%). SUVmax mean=6 (1.7-18.4). Interobserver agreement in both studies was very good. ***Conclusion:*** PET/MRI showed superiority over PET/CT in detecting hyperfunctioning parathyroid adenomas, especially in cases of multiple lesions. The high interobserver agreement and its high diagnostic accuracy, because of the availability of two techniques of high anatomical and metabolic diagnostic precision in a single scan, as well as low radiation dose, make PET/MRI a very useful technique in parathyroid lesion diagnosis.

EPS-236

Correlation Of SUV_{max} Obtained From SPECT/CT With Pathology And Laboratory Findings In Imaging Parathyroid Adenoma

A. Erdem[1], *A. İnanır[1], B. Bozca[1], D. Çayır[1,2], S. Demirtaş Şenlik[1], T. Taşkın Türkmenoğlu[3], N. Aydınbelge Dizdar[1], Ö. Özmen[1,2], A. Çınar[1];*
[1]Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]University of Health Science, Ankara, TÜRKIYE, [3]Ankara Etlik City Hospital, Department of Pathology, Ankara, TÜRKIYE.

Aim/Introduction: Primary hyperparathyroidism is an endocrine disorder characterized by hypercalcemia and high/inappropriate serum PTH levels. Diagnosis' made biochemically, and curative treatment is surgery. Detecting and accurately localizing parathyroid adenomas are crucial for treatment success. Parathyroid scintigraphy is an easily accessible, cost-effective method for this purpose. We aimed to compare the pinhole, planar, and SPECT/CT methods in the detection and localization of parathyroid adenoma, and to evaluate the relationship between the SUVmax value which obtained from the SPECT/CT and laboratory-cytopathology findings. ***Materials and Methods:*** Sixty patients with primary hyperparathyroidism referred to our clinic between February-December 2023, who underwent 99mTc-MIBI parathyroid scintigraphy using pinhole, planar, and SPECT/CT techniques, with at least one reported positive, and confirmed to have a single adenoma on pathology, were included. The images were re-evaluated by two nuclear medicine specialists and pathology specimens by a cytopathologist. SUVmax was calculated on the ROI drawn to the adenoma location in all patients on SPECT/CT, except for one whose SPECT/CT was negative. The relationship between SUVmax and laboratory findings, the pathological subtype, size and volume calculated with USG of the adenoma was evaluated. Pathologically cell types were grouped as oxyphilic-dominant, chief-cell-dominant, clear-cell-dominant; patterns were; follicular-dominant, trabecular-dominant, nest-dominant. Statistically significant value was accepted as $p < 0.05$. ***Results:*** The demographic and medical informations are shown in Table-1. There was no statistically significant difference between imaging methods for detecting adenoma, but the highest lesion detection was achieved with SPECT/CT. 7 patients were negative on USG; 1 was considered suspicious on pinhole and planar imaging, and 6 were evaluated as positive by all three methods. A correlation was observed between sizes and SUVmax values; SUVmax was significantly higher in adenomas >1 cm ($p<0.001$) (Table-2). There was a positive correlation between SUVmax and PTH and Ca levels ($p<0.001$). A positive correlation was also observed between the adenoma volume and SUVmax, PTH, and Ca levels ($p<0.001$). The distribution of adenoma subtypes and SUVmax values were as follows: chief-cell-dominant 83.3% (n=53), 6.6±9.3; oxyphil-cell-dominant 6.7% (n=4), 9.0±5.5; clear-cell-dominant 5% (n=3), 3.0±1.2. Though the subgroup lacked enough patients for statistical analysis, SUVmax was higher in the oxyphilic-dominant group. Larger volumes were observed in trabecular-dominant group ($p<0.05$). ***Conclusion:*** SPECT/CT is the most effective method for detecting parathyroid adenoma, and its combination with pinhole and planar imaging increases reliability. The SUVmax obtained from SPECT/CT is correlated with PTH and volume. Calculating the SUVmax can improve diagnostic accuracy.

EPS-237

Correlation between ^{18}F-Coline PET-CT and surgical localization of parathyroid adenomas in patients diagnosed with primary hyperparathyroidism: insights from our utilization of advanced digital imaging technology.

P. Daudén Oñate[1], *A. Ortega Candil[1], C. Rodriguez Rey[1], S. Ochagavia Camara[2], I. Dominguez Serrano[2], R. Cano Carrizal[3], P. Nespral Torres[1], G. Cuesta Domingo[1], M. Vaillant Lopez[1], M. Zapardiel Martínez-Falero[1], A. Berardinelli[1], P. Bascuñana[1], M. Cabrera Martin[1];*
[1]Nuclear Medicine Department, Hospital Clinico San Carlos, Madrid, SPAIN, [2]General Surgery Department, Hospital Clinico San Carlos, Madrid, SPAIN, [3]Cardiology Department, Hospital Infanta Sofía, Madrid, SPAIN.

Aim/Introduction: Minimally invasive parathyroidectomy in primary hyperparathyroidism (pHPT) depends on the precise preoperative localisation of adenomas. Digital equipment is more sensitive and capable of detecting smaller lesions than analogue equipment. We aimed to determine the concordance between ^{18}F-Fluorocholine in a digital PET-CT scanner and intraoperative findings in the localisation of parathyroid adenoma (PA) in patients with pHPT. ***Materials and Methods:*** Retrospective study of 191 patients with pHPT and negative/discordant conventional imaging tests, who underwent ^{18}F-Fluorocholine on digital PET-CT

between 2021-2024. Patients undergoing surgery up to the date of analysis were included, constituting a final sample of 62 patients. We defined four quadrants of PA location: upper right, lower right, upper left and lower left. A concordance analysis was performed using the Kappa index. ***Results:*** pHPT was caused by single adenoma in 54 (87.1%) patients. Mean age was 62.1±11.1 years, being more frequent in women (87.1%) and in the right lower quadrant (43.06%). The interval between PET-CT and surgery was 202±114 days. The mean lesion size was 8.46±5.43mm with mean SUVmax 8.98±4.42. Miami criteria were met, with a significant fall in intraoperative PTH (mean reduction 70.1%; 95% CI 64.8-75.4; p<0.001). Post-surgery calcaemia was also significantly reduced (-1.84mg/dl; 95% CI -2.24/-1.44; p<0.001). The overall agreement observed between surgical localisation and PET-CT localisation was 93.1%, with a Kappa index of 0.90 (95% CI 0.82-0.98; p<0.001). Agreement was higher in patients with single adenomas (Kappa index: 0.97; 95% CI: 0.92-1.00; p<0.001). ***Conclusion:*** The concordance between ^{18}F-Choline PET-CT findings and surgery in the localisation of PA is excellent in the new digital equipment, allowing for a minimally invasive surgical approach.

EPS-238

Digital PET/CT in patients with hiperparathyroidism and negative/inconclusive 99mTc-MIBI scintigraphy: first steps towards automatic structured reports.

A. Caresia Aróztegui[1], *A. Tomàs[1], M. Boronat De Ferrater[1], V. Vallejos[1], P. Moreno Santabarbara[2], J. Balibrea Del Castillo[2], J. Deportós Moreno[1], M. Salcedo Pujantell[1], M. Solà Suarez[1], S. Lafuente Carrasco[1], S. Ruiz Llama[3], J. Riba Jofré[4], P. Puyalto[5], A. Torres[2], G. Moragas Freixa[1];*

Hospital Universitari Germans Trias i Pujol, Badalona, SPAIN, [3]Radiopharmacy Unit. Hospital Universitari Germans Trias i Pujol, Badalona, SPAIN, [4]Radiophamarcy Unit. Hospital Universitari Germans Trias i Pujol, Badalona, SPAIN, [5]Radiology Department. Hospital Universitari Germans Trias i Pujol, Badalona, SPAIN.

Aim/Introduction: To create a local system that allows structuring, storing and translating of ^{18}F- fluorocholine Digital PET/CT findings of patients with hyperparathyroidism and negative/inconclusive 99mTc-MIBI scintigraphy-SPECT/CT into an automatic structured report. ***Materials and Methods:*** 27 consecutive patients with hyperparathyroidism and negative/inconclusive 99mTc-MIBI scintigraphy-SPECT/CT (22 negatives/5 inconclusives) were included. Age, parathyroid hormone (PTH), Calcium (Ca) and renal function were registered. All patients underwent a digital ^{18}F- fluorocholine PET/CT (Discovery MI Gen 2).A positive PET/CT result was defined as a lesion with focal uptake significantly higher than that of the regular thyroid tissue, either in orthotopic or ectopic parathyroid position. A semiautomatic VOI with PET/CT parameters was recorded for each finding (location, CT size, SUVmax and metabolic tumour value (MTV)). Using a Phyton-based script, data was structured and stored into a local file, from where calculations were extracted. In addition, this file included a customizable predesigned report template for different options (one lesion/multiple lesions, ectopic/orthotopic location) and quantitative data (CT size, SUVmax and MTV). ***Results:*** Data extracted from local file (PET/CT parameters): Errors in original data were easily detected (units or administration data) and corrected. Positive studies: 30 parathyroid lesions were detected in 23/27 patients (20 female, Mean age 66 (51-86). PET/CT detection rate was 85%. 19 patients had a single lesion, 4 patients had multiple lesions (2 had renal failure). Mean CT size 8.41 mm (3.8-27.5), MTV 1.25 (0.16-8.5) mm3, SUV max 4.52 (1.5-19). PTH 192 (111-545) pg/ml, Ca 10.7 (9.7-12.15) mg/dl.Negative Studies: 4 patients. 2 had spontaneous normalization of PTH over time, one patient had a fast clearance (faint uptake MIBI SPECT/CT, 135 pg/ml, Ca 9.7 mg/dl) and one patient had negative SPECT/CT and PET/CT scans (PTH 130 pg/ml, Ca 9.7 mg/dl).Reports: All positive studies were automatically translated into a structured report: 19 patients had single lesion (2 ectopic), 4 patients had multiple lesions (2 ectopic). ***Conclusion:*** In case of positive ^{18}F-fluorocholine PET/CT (85%), this self-designed Phyton-based script allowed an easy extraction, storage and translation of the registered PET/CT data into automatic structured reports.

EPS-239

Evaluating the efficacy of different VOI sizes in quantitative SPECT-CT analysis for Graves, Orbitopathy

I. Mihovk[1], *S. Barna[2,1], J. Varga[1], E. Nagy[3], I. Garai[2,1], L. Galuska[1];*
[1]Department of Nuclear Medicine and Translational Imaging, Institute of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY, [2]Scanomed, Debrecen, HUNGARY, [3]Division of Endocrinology, Department of Internal Medicine, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY.

Aim/Introduction: Graves' Orbitopathy (GO) can significantly impair the quality of life of patients even with mild disease, and in rare cases it can even lead to vision loss. Knowledge of the presence and severity of inflammatory activity in GO is essential for effective treatment and the monitoring of therapeutic response. The [99mTc]DTPA-SPECT scan, which has been used for this purpose for about 20 years, provides cost-effective, accurate information on the above-mentioned issues, and allows quantification of activity uptake (AU).However, manual ROI drawing is time-consuming, and its reproducibility is limited. Therefore, we retrospectively re-evaluated images from 99 SPECT-CT examinations, to determine whether spherical VOIs of 2 or 3 cm diameter provide better reproducibility and correlate well with the previously manually fitted ROI parameters, simplifying the assessment while maintaining reliability. ***Materials and Methods:*** From the DTPA SPECT/CT studies performed in our institute between 04/04/2021 and 05/05/2022, 99 examinations were randomly selected. SPECT/CT images of the skull were acquired 20 min after iv. administration of 400 MBq [99mTc]DTPA. SPECT parameters: 128 views, 15 seconds-per-view, 2.36 pixel size. CT parameters: 120kV, 40mAs, 1.5 pitch, 90/min speed, 1.25mm slice thickness.Image reconstruction was perfomed with 3D OSEM-RR, using 48 iterations, and 4 subsets. Similarly to our previous studies, the unit of measurement was x10-6 injected dose/mL. The placement of spherical VOIs into the retroorbital regions was performed independently by 3 nuclear medicine specialists. Inter-rater reproducibility (reliability) was measured using the intraclass correlation coefficient (ICC).The association between old and new uptake values was characterized by Pearson's correlation coefficient, and ordinary least products regression, OLPR (Ludbrook 2012) was applied to estimate the coefficients of linear relationship. ***Results:*** Spheres with a diameter of 2 cm showed better reproducibility than those with a diameter of 3 cm (ICC: 0.930 vs. 0.880). AU values in spheres with 2 cm diameter were higher than in larger VOIs. The difference was systematically bigger at elevated values. In terms of correlation with the previous method, we found that the AU in the larger spheres was closer to the old values. ***Conclusion:*** Although the AU values in the 3 cm VOIs were generally closer to those of the previously used method, since the placement of the smaller spheres is easier and

more reproducible, the use of 2 cm diameter is recommended for the routine measurement of inflammatory activity in GO.

EPS-240

SPECT/CT of thyroid nodules using a full ring CZT scanner in comparison to planar thyroid scintigraphy

D. Heute, *J. Heute, T. Harald;*
Nuklearmedizin Telfs, Telfs, AUSTRIA.

Aim/Introduction: Superimposition of hyper- or hypofunctioning thyroid nodules with extranodular thyroid tissue or adjacent thyroid nodules may cause problems in planar scintigraphy. SPECT/CT has been suggested as an alternative. The purpose of this study is to evaluate the use of novel solid state SPECT/CT general purpose gamma camera for discriminating hot and cold thyroid nodules from surrounding thyroid tissue in comparison with a planar dedicated thyroid camera. ***Materials and Methods:*** From November 2022 to March 2024 we investigated 129 patients (36 male, 93 female) and a number of 286 thyroid nodules with a mean diameter of 14.4 mm (SD 7.3 mm), ranging from 5 to 59 mm and a mean volume of 1.3 ml (SD 2.5 ml), ranging from 0.1 to 21.9 ml. All patients had been transferred to our institution for routine thyroid investigation and have given informed consent to use their data for research. After intravenous injection of 40 to 50 MBq Tc99m pertechnetate comparative images were taken with a new CZT SPECT/CT and a dedicated thyroid camera. The results were put into three categories of matches with increased (hot nodule), reduced (cold nodule) or indifferent uptake of Tc99m pertechnetate on one hand and four categories of mismatches on the other hand. The mismatches either showed an increased or a reduced uptake in SPECT/CT in comparison to the planar images or a change from slightly increased or reduced uptake into an indifferent image. ***Results:*** 149 of the 285 thyroid nodules investigated showed matching results (30 matching hot, 48 matching cold and 71 matching indifferent nodules). 139 nodules showed a mismatch between SPECT/CT and planar scintigraphy primarily having given equivocal results after planar imaging. 51 of these showed an increase of tracer uptake in SPECT/CT whereas 86 nodules were marked as cold nodules in SPECT/CT. The CZT SPECT/CT system with an extraordinary spatial resolution proved to be superior in detecting nodules small in diameter and volume. ***Conclusion:*** SPECT/CT seems to be more accurate in detecting hot and cold thyroid nodules than planar scintigraphy, especially when investigating small nodules. ***References:*** Schmidt D, Simmerl M, Kuwert T: Is there Incremental Value of SPECT/CT over Planar Imaging in the Assessment of Nodular Goiter by TC99m pertechnetate Scintigraphy? in JNM 2016, 57 (supplement 2) 1699.

EPS-241

^{18}F-FDG PET/CT thyroid uptake and thyroid dysfunction in patients undergoing immunotherapy: a correlation study

G. Follacchio, *B. Criscuoli, F. Corica, F. Chiumiento, C. Manni, F. Capoccetti;*
Nuclear Medicine Unit, Macerata Hospital, Italy, Macerata, ITALY.

Aim/Introduction: It is well-known that patients treated with immunotherapy for different types of cancer may develop therapy-related thyroid dysfunctions.Aim of the study was to evaluate the correlation between 18F-FDG thyroid uptake on PET/CT performed for treatment response assessment and thyroid function disorders in patients receiving immunotherapy. ***Materials and Methods:*** 18F-FDG PET/CT scans performed for response assessment in patients undergoing immunotherapy in the period 2018-2023 were retrospectively included. Each scan was evaluated by two independent readers in terms of response to treatment and qualitative analysis of thyroid uptake.Patients' data on thyroid function (TSH, fT3 and fT4 serum hormonal levels) were collected, if available, at baseline and by periodical measures during immunotherapy treatment. ***Results:*** 109 18F-FDG PET/CT scans from 88 consecutive patients with complete thyroid function data were evaluated (lung cancer n=46; malignant melanoma n=16; urothelial and bladder carcinoma=13; endometrial carcinoma n=4; breast cancer n=3; lymphoma n=3; laryngeal carcinoma n=2; colorectal cancer n=1).During treatment, 24/88 patients (27%) demonstrated an immunotherapy-related thyroid dysfunction, of whom 20/24 with hypothyroidism (83%) and 4/24 with hyperthyroidism (16%).In this subgroup of patients, a diffuse 18F-FDG thyroid uptake was observed in 10/24 cases (41%) and no significant 18F-FDG uptake in 14/24 patients.In 4/10 patients with diffuse 18F-FDG thyroid uptake and hypotiroidism functional pattern, we observed an initial correlation between the two variables, followed by a synchronous normalization of both 18F-FDG thyroid uptake and hormonal levels at successive controls.In terms of response assessment, these 4 patients showed complete metabolic response (2/4 patients) and partial metabolic response (2/4 patients). ***Conclusion:*** Besides its well-established role in treatment response assessment during immunotherapy, 18F-FDG PET/CT can also be useful to evaluate immunotherapy-related endocrine dysfunctions.In our series, a relevant percentage of patients receiving immunotherapy (27%) was affected by treatment-related thyroid dysfunction.In this subgroup of patients, concomitant diffuse 18F-FDG thyroid uptake was observed in 41% of patients.In a minor sample, we observed an initial correlation between diffuse 18F-FDG thyroid uptake and thyroid dysfunction, followed by a synchronous normalization of both parameters; this scenario was also associated to a complete/partial response to treatment. This trend is in line with larger data from literature suggesting that 18F-FDG thyroid uptake may represent an additional prognostic factor for treatment response in patients undergoing immunotherapy.Nevertheless, further studies with larger cohorts are needed to evaluate the predictive and prognostic value of 18F-FDG thyroid uptake in patients receiving immunotherapy.

EPS-242

F^{18}-FCH uptake in thyroid parenchymal diseases

M. Araz, *C. Soydal, B. Demir, G. S. İnal, A. G. Canpolat, N. Ö. Kucuk;*
Ankara University, Ankara, TÜRKIYE.

Aim/Introduction: Thyroid nodules may cause misinterpretation on F^{18}-Flurocholine (FCH) PET/CT performed for hyperparathyroidism.The effect of thyroid parenchymal disease on thyroidal uptake of F^{18}-FCH is still debatable. We aimed to investigate if underlying thyroid disease affects F^{18}-FCH uptake and if it is correlated with the status of disease. ***Materials and Methods:*** A total of 188patients who were referred to F^{18}-FCH PET/CT study between January2018-March2020 were retrospectively evaluated. The results of serum TSH,AntiTPO,AntiTg, thyroid ultrasonography were recorded. On F^{18}-FCH PET/CT images, visual grading on MIP images was performed(Grade 0: no visualisation of thyroid gland, grade 1:<skeletal muscle uptake, grade 2:≥skeletal muscle uptake and <salivary gland uptake, grade 3:≥salivary gland uptake). Difference between the uptake intensity of the two lobes is also noted. Uptake pattern is categorised as homogenous, heterogenous or diffusely increased. SUVmax,SUVmean and SUVpeak of thyroid are

calculated. Ultrasonographic findings are categorised as either normal or abnormal(thyroiditis, nodular/multinodular thyroid gland or both). Statistical analysis included Spearmans' correlation analysis of laboratory tests and SUV parameters and Mann-Whitney U Test to compare medians between groups. ***Results:*** Among 188 patients, 64 patients were excluded due to missing data and 3 patients due to previous thyroid surgery. A total of 121 patients (94M,27F,mean age:53,95,min:18,max:83) were included. According to ultrasonography findings, patients with a normal thyroid gland had lower levels of SUVmax,SUVmean and SUVpeak(p=0.013, p=0.012 and p=0.004). Patients with findings of chronic thyroiditis either with or without coexisting nodular disease, had higher levels of SUVmax, SUVmean and SUVpeak (p=0.008, p=0.012 and p=0.004).Median values of serum AntiTg and AntiTPO levels were significantly higher in Grade 2-3 patients compared to Grade 0-1(p=0.011 and p=0.014). Medians of serum TSH didn't differ. AntiTg levels were correlated with SUVmax, SUVmean and SUVpeak(p=0.015,p=0.039 and p=0,014). AntiTPO and TSH levels were not correlated with SUV. However, medians of SUVmax values were higher in hyperthyroidism compared to euthyroid patients (p=0.045). Median values of thyroid antibody levels didn't differ according to uptake pattern and the difference of intensity of uptake between two lobes of thyroid ***Conclusion:*** F^{18}-FCH uptake increases in case of thyroiditis and intensity of uptake is correlated with serum thyroid antibody titres. Serum TSH is not linearly correlated with F^{18}-FCH uptake,although F^{18}-FCH uptake intensity is found higher in hyperthyroidism.

EPS-243

Analysis of mental health disorders in patients treated with ^{131}I in metabolic therapy units: a multicenter study

A. Piñeiro[1], *T. Aroui Luquin[1], C. Mallón Araujo[2], M. Negre Busó[3], M. Muros de Fuentes[1];*
[1]Hospital Universitario Virgen de las Nieves, Granada, SPAIN, [2]Complexo Hospitalario Universitario de Santiago, Santiago de Compostela, SPAIN, [3]Hospital Universitari Dr. Josep Trueta, Girona, SPAIN.

Aim/Introduction: Assessment of mental health disorders (anxiety and depression) during treatment in metabolic therapy units. ***Materials and Methods:*** Multicenter study of 181 patients with differentiated thyroid cancer treated with 131I in spanish metabolic therapy units between 2020 and 2023. We have analyzed the presence of anxiety and depression symptoms. We assessed anxiety symptoms according to the validated Hamilton hetero-administered scale collected at admission and at medical discharge. This scale consists of 14 items, each defined by a series of symptoms, and measures both psychic anxiety (mental agitation and psychological distress) and somatic anxiety (physical complaints related to anxiety). We obtained phychic anxiety, somatic anxiety and global score. We assessed the presence of depression symptoms using the validated Beck's Depression Inventory at admission and at medical discharge. For this, the patients were categorized into five categories of depression (normal ups and downs, mild mood disturbance, borderline clinical depression, moderate depression, severe depression and extreme depression). ***Results:*** 181 patients with a mean age of 52.2+-16.23 years. No patient showed symptoms of severe anxiety on the Hamilton scale (>30 points). The patients showed anxiety values of 10.59 prior to admission and 8.45 upon discharge, (p=0.0001). The mean values of previous psychic anxiety were 6.12 and 4.80 at discharge (p=0.0001) and previous somatic anxiety values were 4.47 to 3.65 at discharge (p=0.0001). Regarding symptoms of depression, 27/181 showed mild mood disturbance, 16/181 borderline clinical depression and 10/181 moderate to extreme depression on the Beck depression inventory. Within the subgroup analysis, 10/16 patients (62.5%) with borderline clinical depression showed improvement at discharge: 7 of them showed a normal score and 3 patients a mild mood disturbance. ***Conclusion:*** Staying in the metabolic therapy units does not worsen the emotional state of patients treated with 131I (anxiety and depression). Despite the characteristics of the stay (isolation, treatment with radioactivity, etc.), the fact of undergoing treatment has a positive impact on the patients' psychic and somatic anxiety. In spite of the improvement of depression symptoms, there are no significant changes before and after therapy.

EPS-244

Increased BMI, diabetes, and decreased GFR are associated with prolonged effective half-life of ^{131}I in thyroid cancer patients

L. Kääriä[1], *M. Lapela[2], M. Seppänen[3], M. Högerman[4], J. Ruohola[2], A. Ålgars[2], T. Noponen[1];*
[1]Department of Clinical Physiology, Nuclear Medicine, Turku PET Centre and Medical Physics, Turku University Hospital and Wellbeing Services County of Southwest Finland, and University of Turku, Turku, FINLAND, [2]Department of Oncology, Turku University Hospital and Wellbeing Services County of Southwest Finland, Turku, FINLAND, [3]Department of Clinical Physiology, Nuclear Medicine and Turku PET Centre, Turku University Hospital and Wellbeing Services County of Southwest Finland, and University of Turku, Turku, FINLAND, [4]Department of Urology, Turku University Hospital and Wellbeing Services County of Southwest Finland, and University of Turku, Turku, FINLAND.

Aim/Introduction: We analysed external dose-rate signals of differentiated thyroid cancer (DTC) patients measured with remote dose-rate meters to study the effect of patient characteristics on the effective half-life (Teff) of 131I. The aim is to gain novel understanding of the clearance of 131I in DTC patients by investigating whether there is a relationship between patient's clinical characteristics and Teff. ***Materials and Methods:*** Altogether 110 low- and higher-risk DTC patients (74 females and 36 males) aged between 14 and 85 years who underwent postoperative radioiodine (RAI) therapy between September 2018 and February 2023 in Turku University Hospital were studied retrospectively. According to the clinical practice, all patients underwent total thyroidectomy and met the criteria for RAI. The external dose-rates were monitored continuously during radiation isolation period with a remote dose-rate meter fixed on the ceiling of the isolation room. Some patients received several RAI therapies during the study period and a total of 135 external dose-rate signals were analysed. Patient's movements in the isolation room affect measured dose-rate signals, and hence some of the measurement points were location corrected afterwards with factors obtained from the calibration measurements using a RAI capsule. Each patient's dose-rate signal was resampled and modelled with a monoexponential function. Teff was calculated from the fitted function. All 26 patient characteristics were considered in the statistical analysis. Generalized linear mixed model (GLMM) was used to analyse the association between Log Teff and patient characteristics. Model included age, body mass index (BMI), glomerular filtration rate (GFR), other comorbidities, thyroglobulin (TG), administered activity, and treatment cycle. Variables were selected based on previous studies and most significant for the model. ***Results:*** The mean Teff was 13.47 ± 5.43 h for all patients. Longer Teffs were associated with increased BMI (p=0.004), diabetes (p=0.007), and decreased GFR (p<0.001). We

also discovered that neither age nor subsequent RAI therapies significantly affect on the whole-body Teff (p=0.522 and p=0.414, respectively). ***Conclusion:*** Increased BMI, diabetes and decreased GFR prolong the whole-body Teff of 131I after RAI therapy. To our knowledge, this was the first study to show statistical significance between BMI, diabetes and Teff of DTC patients. These findings could be utilized in the optimization of personalized RAI therapies and enhancing radiation safety precautions in clinical practice.

EPS-245

Effects of radioactive iodine therapy on LH,FSH, AMH and menstrual cycle in women with thyroid carcinoma

A. Aghaee, *s. shafiei, s. zakavi, m. emadzadeh, e. askari; nuclear medicine research center,Mashhad university of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Differentiated thyroid carcinoma (DTC) is the most common endocrine malignancy. Total thyroidectomy with subsequent radioactive iodine therapy (RIT) followed by levothyroxine consumption is a routine approach to deal with DTC. Widespread use of RIT in patients with DTC has raised concerns about its potential adverse effects on female reproductive organs. We aimed to check the effects of postoperative RIT on menstrual symptoms and sex hormones in patients with DTC. ***Materials and Methods:*** Women in reproductive age with DTC admitted in Nuclear Medicine department from 2020 to 2021 were studied. The demographic and menstrual information was recorded at first presentation and follow-up visits. Blood samples were taken for measurement of follicle stimulating hormone (FSH), luteinizing hormone (LH), anti-Müllerian hormone (AMH), and estradiol at baseline, 6 and 12 months after RIT. ***Results:*** 77 women with DTC and mean age of 35 years were studied. Roughly half (50.4%) received high-dose RIT (i.e. ≥100 mCi administered radioiodine). No patient had distant metastasis. Dysmenorrhea was reported in 23 (29.9%) of the patients and flushing was seen in 6 (7.8%). The number of pads used during menstrual periods, the length of menstrual periods and its frequency decreased significantly 2 months after RIT and returned to baseline values one year after RIT. The LH, FSH, and estradiol levels has increased continuously 6 and 12 months after RIT. In contrast, the mean serum level of AMH was not changed compared to that of the pre-treatment level. The changes in sex hormones and menstrual cycles were not different between the low and high-dose RIT groups ($p > 0.1$). ***Conclusion:*** The serum levels of LH, FSH, and estradiol hormones increased after RIT for up to 12 months after RIT while the AMH levels were stable. The menstruations were adversely affected 2 months after radioactive iodine therapy regardless of the dose of radio-iodine and improved by 6 months.

EPS-246

Long-term outcomes of radioiodine therapy in differentiated thyroid cancer patients presenting with incomplete or indeterminate results

S. Nagy, *G. Sipka, S. Almarsomy, Z. Mikó, A. Bakos, I. Farkas, T. Czékus, L. Pávics, Z. Besenyi; University of Szeged, Department of Nuclear Medicine, Szeged, HUNGARY.*

Aim/Introduction: Differentiated thyroid cancer (DTC) presents significant challenges in treatment and monitoring due to its varied responses to radioiodine therapy (RAIT). This is particularly evident in cases falling into the category of incomplete or indeterminate dynamic risk assessment. Understanding the extended outcomes of RAIT beyond conventional follow-up periods is crucial for refining treatment strategies and improving patient care. ***Materials and Methods:*** This retrospective study aimed to comprehensively investigate the long-term outcomes of RAIT in DTC patients with incomplete or indeterminate responses one year post-treatment. The primary objective was to evaluate therapeutic efficacy, factors influencing prognosis, and the incidence of late side effects and mortality associated with RAIT. A cohort of 43 DTC patients with incomplete or indeterminate responses post-RAIT underwent rigorous evaluation following ATA guidelines. In total, 24 clinical-oncopathological parameters and 18 laboratory and imaging parameters were assessed to evaluate the therapeutic response. Statistical methods such as the McNemar test, chi-square test of group diversity, and multifactorial regression analysis were used to validate treatment outcomes and identify predictive factors. ***Results:*** The study revealed significant therapeutic success beyond one year (McNemar test, p=0.0001), with a notable increase in excellent responses upon final evaluation. Thyreoglobulin analysis revealed a noticeable trend: patients initially classified in the indeterminate group often transitioned into the incomplete response category by the final follow-up (McNemar test, p=0.011). Factorial analysis identified age, aggressive pathology, lymph node status, and perineural spread as significant predictors of therapeutic outcomes (Multiple Linear Regression, R2=0.63; F=3.41; p=0.003). While early side effects correlated with aggressive pathology and higher doses, late side effects and mortality displayed no association with RAIT factors, suggesting multifactorial determinants. ***Conclusion:*** This research provides valuable insights into the extended results of RAIT for DTC patients, particularly those with incomplete or indeterminate responses. Given the possibility of patients transitioning between different risk groups during therapy, it is advisable to maintain close follow-up even after one year, particularly for those with incomplete or indeterminate responses. These findings emphasise the significance of continuous monitoring and tailored interventions to maximise therapeutic effectiveness and patient care in DTC management. Further research is warranted to unravel the intricate interplay of factors affecting long-term outcomes and to refine treatment strategies accordingly.

EPS-247

The impact of risk factors ascertained at the surgery of the primary tumor on metastasis appearance and outcome of patients with papillary thyroid microcarcinoma (PTMC).

A. Marongiu[1], *S. Nuvoli[1], A. De Vito[2], A. Falchi[1], A. Mura[1], S. Vargiu[1], A. Spanu[1], G. Madeddu[1]; [1]Unit of Nuclear Medicine, University of Sassari, viale S. Pietro 8 - 0700 Sassari, Italy, Sassari, ITALY, [2]Unit of Infectious Diseases, University of Sassari, viale S. Pietro 8 - 0700 Sassari, Italy, Sassari, ITALY.*

Aim/Introduction: Most PTMCs with larger diameter of ≤10 mm have favorable long-term prognosis, but can also exhibit aggressive behavior when neck lymph node (LN) metastases are associated. However, the role of minimal extrathyroid tumor extension (mETE) is still discussed and it has been removed from AJCC 8th Edition because many authors reported no impact on metastasis appearance and disease-free survival (DFS). In PTMC patients, we investigated some risk factors influence on recurrences, metastases, and DFS during follow-up. ***Materials and Methods:*** We retrospectively enrolled 449 consecutive PTMC patients, 85 M and 364 F, 254 aged <55 and 195 ≥55 years who underwent total thyroidectomy and radioiodine ablation.

Risk factors were present in 164/449 patients, such as neck LN metastases, mETE and multifocality/multicentricity (M/M). In every case, eventual metastases were detected during follow-up using 131I-whole body scan (WBS) and SPECT/CT, ultrasound, needle biopsy, and serum thyroglobulin assay. The lesions were confirmed by histology; when surgery was not feasible, metastases were confirmed during about a ten-year follow-up by aforementioned exams. ***Results:*** During follow-up, metastases were ascertained in 47/449 patients (10.5%), 6 M and 41 F, 29 aged <55 and 18 ≥55 years. Globally, 85 metastases were ascertained, 73 in the neck and 12 at distance (3 lung, 5 mediastinum, 4 bone). Risk factors were discovered during surgery in 27/47 (57.4%) of patients who developed metastases; mETE was globally present in 14 patients, neck LN metastases in 12 and M/M in 14. Among the 402/449 patients who did not develop metastases, risk factors were ascertained in 137/402 cases (mETE in 25 patients, LN in 13 and M/M in 117). Comparing the different variables, at Cox regression multivariate analysis, neck LN metastases (9.38 [95%CI 3.75-23.45] p<0.001) and mETE (5.97 [95% CI 2.69-13.24] p<0.001), but not M/M, gender and age, were significantly associated with an increased risk of metastasis during follow-up. DFS was significantly (p<0.001) lower in the patients with both these risk factors than patients without risk factors. ***Conclusion:*** In the present study, neck LN metastases and mETE proved significant risk factors for metastasis appearance and DFS reduction in PTMC patients during follow-up. The data confirmed that neck LN metastases are indicators of PTMC aggressiveness, as reported in numerous studies; however, the same results have been obtained by mETE suggesting a reflection on its previous removal from AJCC 8th Edition. Active surveillance in the follow-up of PTMC patients with mETE should be recommended.

EPS-248

Possible restrictions of levothyroxine absorption in thyroid cancer patients

F. Eilsberger, *A. Schmidt, W. Bowl, D. Librizzi, M. Luster, A. Pfestroff;*
University Hospital Marburg, Marburg, GERMANY.

Aim/Introduction: In patients with thyroid carcinoma, optimal thyroid hormone control remains an essential component of tumor therapy. Suppressing TSH levels, are often an essential component of tumor therapy. However, there are several factors, such as the use of pantoprazole or gastrointestinal diseases, showing a negative impact on absorption of levothyroxine and resulting in higher levothyroxine doses to achieve the desired levels. ***Materials and Methods:*** We established a questionnaire with 16 variables on possible influencing factors (including pantoprazole intake, gastrointestinal diseases) in daily routine and initially analyzed the responses of 40 thyroid cancer patients. ***Results:*** Of the 40 patients aged between 22-87 years (median 53 years; 23 female, 17 male) who were on levothyroxine for 0.5-39 years (median 4.5 years), 20 patients reported suffering from concomitant diseases, 26 confirmed regular additional medication intake, of whom 10 were taking pantoprazole and 2 taking iron supplements in parallel. 14 patients indicated a time interval of additional medication intake between 0-12 hours (median 1.25 h). 20 respondents reported suffering from occasional and/or regular gastrointestinal complaints, 3 patients had undergone gastrointestinal tract surgery. ***Conclusion:*** The preliminary evaluation of our study on the presence of factors influencing the absorption of levothyroxine in thyroid cancer patients shows that the majority of patients have potentially influencing variables that are often hardly taken into account in routine clinical practice and can lead to a less than optimal setting. The treating physicians should be aware of such influencing factors. ***References:*** Virili C, Antonelli A, Santaguida MG, Benvenga S, Centanni M. Gastrointestinal malabsorption of thyroxine. Sequence of cancers - Thyroid carcinoma

B. Schemmer, *M. Essler;*
Uniklinik Bonn, Bonn, GERMANY.

Aim/Introduction: With longer patient survival, secondary, tertiary, etc. neoplasms are increasingly relevant to patient care and quality of life. However, are there any specific neoplasms following or primordial cancers leading to thyroid cancer that we should or could be aware of when treating patients? ***Materials and Methods:*** We searched the SEER Research Plus Data, 8 Registries, Nov 2023 Sub (1975-2021), released April 2024, based on the November 2023 submission. We limited our search to patients with a thyroid carcinoma at any time in their history regardless of sequence and considered any tumor during their lifetime. ***Results:*** A total of 10.648 patients were included. The most common primary was thyroid cancer (9.140) followed by breast cancer (324), melanoma (135) and prostate cancer. The most common secondary cancers irrespective of treatments were breast cancer (2.154), thyroid cancer (1,726), lung and bronchus cancer (900) and prostate cancer (872). The most common tertiary cancers were breast cancer (618), lung and bronchus cancer (350) and melanoma (268). The most common quaternary cancer was breast cancer (127), lung and bronchus cancer (103) followed by melanoma (96). Histologic variance was somewhat limited with papillary thyroid carcinomas (ICD-O-3 8260/3) accounting for 3.208 cases and (8050/3) with 2.116 cases, followed by papillary cancer of follicular variant (8340/3) with 2.112 cases, follicular adenocarcinoma with 688 cases (8330/3). Almost all following neoplasia's were limited to adenocarcinoma 8140/3, infiltrating duct carcinoma 8500/3, papillary carcinoma 8260/3 and papillary carcinoma of follicular variant 8340/3. All other histologies had case counts well below 100 cases except for the third sequential neoplasm where squamous cell carcinomas reached 123 cases. Comparing RIT to non-RIT patients for primary papillary thyroid carcinoma only (8260/3, 8340/3 and 8050/3) there were 2.687 (primary), 459, 74 and 6 sequential thyroid carcinomas compared to 4.085 (primary), 762, 122 and 29 in the non-RIT group with no significant differences between the groups. ***Conclusion:*** Thyroid carcinomas show limited histologic variance with regard to consecutive cancers. The most common sequential cancer is breast cancer followed by recurring thyroid cancer, lung and bronchus cancer as well as prostate cancer and melanoma. There was no significant difference between patients that received radioiodine for primary thyroid carcinoma and those that did not regarding thyroid carcinoma as a sequential cancer.

Stimulated thyroglobulin level in differentiated thyroid carcinoma: improvised role in guiding follow-up

K. Agrawal, *K. K. Kandula, P. Singh, K. K. Behera, G. K. Parida, P. S. S. Patro;*
AIIMS, Bhubaneswar, INDIA.

Aim/Introduction: Serum Thyroglobulin (Tg) is a well-established marker used in management of patients with differentiated thyroid cancers (DTC). High-sensitivity Tg tests are crucial in early detection of recurrence. Various guidelines including European

Society for Medical Oncology and the American Thyroid Association (ATA) recommends use of Tg for guiding management of the thyroid cancer patients. On follow up, stimulated Tg (STg) levels <1 ng/ml is defined as excellent response post RAI treatment. ATA suggests no need of follow up whole body radioiodine scan (WBIS) in patients with low risk of recurrence and STg <1ng/ml. We studied role of follow-up undetectable STg in DTC patients in all ATA risk categories. ***Materials and Methods:*** We retrospectively analyzed data of 378 DTC patients, who were referred to Nuclear Medicine department post thyroidectomy for further management. 31 patients with raised anti-Tg levels were excluded from study. Patients were divided into two groups, Group 1 with STg < 1 and Group 2 with STg value >1. The initial risk of recurrence in patient was assessed using ATA criteria and were stratified into low, intermediate and high-risk categories. The findings of WBIS on 6 month follow up post Radioiodine ablation/therapy was also analyzed in all six groups. The results were calculated in percentage. ***Results:*** A total of 347 patients (97 male and 250 female, mean age 38.03 years) were included in the study, of these 123 had low risk, 147 had intermediate risk while 77 patients had high risk. In all three-risk category with STg < 1 ng/ml and negative Anti-Tg, WBIS shows no abnormal uptake. In low-risk category, even though none of the patients showed any abnormal on WBIS, STg value was >1 ng/ml in 97 patients (Table 1). ***Conclusion:*** To summarize, the WBIS can be avoided at follow up in patients with STg less than 1 ng/ml and negative anti-Tg level in all risk category defined by ATA. This can safely avoid morbidity associated with achieving hypothyroid state for WBIS. ***References:***

EPS-251

Postoperative basal serum thyroglobuline (Tg) prior to radioiodine therapy as a predictive factor of recurrence in patients with differentiated thyroid cancer (DTC)

R. Nuñez-Muñoz, *M. Badiola Molinuevo, R. Valverde-Jorge, A. Esteban Figueruelo, Y. Carreres Ortega, M. Astudillo Sarmiento, A. Peña Fuentes, I. Vinagre Pérez, J. Lavilla, M. Jimenez-Alonso, J. Genollá Subirats, I. Fernández Tercero;*
Osakidetza, Bilbao, SPAIN.

Aim/Introduction: To assess the role of post-surgery serum thyroglobulin and prior to iodine-131 therapy as a prognostic factor for locoregional or distant recurrence. ***Materials and Methods:*** We conducted a retrospective study of 242 patients (81% women, 19% men, mean age: 50.5 ± 14.2 years) with differentiated thyroid cancer (90.9% papillary, 9.09% follicular), non-metastatic debut and treated with total thyroidectomy. 142 patients (58.7%) underwent lymphadenectomy (73.3% prophylactic, 26.7% therapeutic), 40.7% of which resulted in pathological lymphadenopathies. Serum TG was determined 6-8 weeks after surgery, using the Immunulite 2000 Siemens method, with a functional sensitivity of 0.5 ng/ml. All patients subsequently received iodine-131 therapy, followed by a post-treatment whole-body scan and cervicothoracic SPECT/CT acquired 7 days after radioiodine administration. Uptake was observed only in the thyroid bed in 88.8% of the studies and extrathyroid uptake in 8.26%. The median follow-up was 11 years (P25: 8.8, P75: 13.5). Data on both locoregional and distant recurrence were collected from the clinical history during follow-ups. Statistical software R Core Team version 4.0.1 was used for statistical analysis. Patients with positive antithyroglobulin antibodies were excluded. ***Results:*** 32 of the 242 patients (13%) presented recurrence (71.9% lymph node, 28.1% Bone/ Lung), with median time to recurrence of 1.41 years (P25: 0.65; P75: 3.97). Patients with relapse in follow-up presented a median serum TG value after surgery of 2.05 ng/ml, compared to 0.5 ng/ml of the non-recurrence patients. TG was categorized taking the value 2.6 ng/ml as a cut-off point, which corresponds to the P95 of the group of patients with no recurrence during follow-up. 14 (43.8%) of the patients who relapsed had post-surgery thyroglobulin values >2.6 ng/ml, compared to 4.3% (9/210) in the non-recurrence group. Performing a univariate analysis with this cut-off point, we have observed statistically significant differences between the patients who did relapse and those who did not ($p<0.001$). We observed that serum TG values >2.6 ng/ml implies a 17-fold higher risk of presenting recurrence (OR: 17.3, CI95% [6.6-45.6], AUC: 0.697 [0.582-0.812]). When applied a multivariate logistic regression model, post-surgery serum thyroglobulin was shown as an independent variable. ***Conclusion:*** Basal serum thyroglobulin after surgery and prior to radioiodine therapy is an independent predictive factor of recurrence in patients with DTC. A serum thyroglobulin value >2.6 ng/ml implies a 17 times higher risk of suffering a recurrence, either lymph node or distant metastasis. 43.7% of patients who relapsed had thyroglobulin values >2.6 ng/ml.

EPS-252

Real-world applicability of recent Thyroid Cancer Guidelines on ablation

P. Exadaktylou[1], *E. Giannoula[1], C. Melidis[2], N. Papadopoulos[1], K. Papadopoulou[1], A. Tsangaridi[1], P. Charalambous [1], G. Koukl[1], I. Katsadouros[1], E. Papanastasiou[1], S. Frangos[3], A. Doumas[1], I. Iakovou[1];*
[1]Second Academic Nuclear Medicine Department, "AHEPA" University hospital, Aristotle University of Thessaloniki, Thessaloniki, GREECE, [2]CAP Santé, Radiothérapie Clinique Maymard, BASTIA, FRANCE, [3]Nuclear Medicine Department, Bank of Cyprus Oncology Center (BOCOC), Nicosia, CYPRUS.

Aim/Introduction: Thyroid cancer (TC) is the most common endocrine malignancy. Intermediate and low risk patients constitute the majority of cases to be treated, to whom different approaches of Iodine-131 therapy (ablation) have been implemented. The uncertainty and inconclusiveness regarding the ideal management of low-risk TC patients, especially concerning ablation use, emphasises the pressing need for "real life" applicable guidelines (GLs), which will be able to ensure the best clinical practice. Recently, various Guidelines (GLs) have been published on whom should be ablated, when and under which circumstances. Our study compares 6 of these GLs with a given patient cohort. Additionally, we will evaluate each GL's quality via an independent tool (AGREE II). ***Materials and Methods:*** Our cohort included 336 patients who were ablated between 2010 and 2013 in two different hospitals onto whom the following 6 GLs were retrospectively implemented: 2009 and 2016 ATA, ETA, NICE, German and EANM/SNMMI. Each GL's quality has been evaluated by four experienced Nuclear Medicine doctors with the help of the AGREE II tool. ***Results:*** We show that a great variability exists among the GLs. ATA 2016 is a clear improvement of the ATA 2009, but present a large grey area of "probable ablation candidate" patients. ETA and NICE agree that only a small portion of our ablated patients would benefit from it and the AGREE II

tool shows a lack of applicability, but very good scores elsewhere. On the contrary, German and EANM/SNMMI GLs agree that most of our clinical decisions to ablate were correct and their AGREE II scores are the highest in all six domains. ***Conclusion:*** More accurate, clear and evidence-based GLs are needed, encouraging individualised and patient-centered management, for assuring a better prognosis and quality of life in TC patients.

Selective PET imaging using the Al^{18}F-labeled CXCR4 antagonist LY2510924: "Al^{18}F-NOTA-SC, the new kid on the block".
M. Spahn, *T. Van Loy, S. Celen, M. Koole, C. Deroose, D. Schols, W. Vanduffel, G. Bormans, F. Cleeren;*
KU Leuven, Leuven, BELGIUM.

Aim/Introduction: CXCR4 is overexpressed in various cancers such as multiple myeloma (MM). Here we evaluate [18F]AlF-NOTA-SC, an Al18F-labeled radiotracer derived from LY2510924 [1], for CXCR4 targeted imaging as an 18F-alternative for [68Ga]Ga-PentixaFor. The theranostic potential was assessed by co-injection with [177Lu]Lu-DOTA-BL02 [2]. ***Materials and Methods:*** The CXCR4 affinity (IC50) was assessed by incubating CXCR4 overexpressing Jurkat cells with the non-radioactive compounds and CXCL12AF647. The NOTA-SC peptide was labeled with [18F]AlF and radioactive cell-binding assays were conducted on high (U87.CD4.CXCR4), moderate (MM.1S) or non (U87.CD4) CXCR4-expressing cells. The biodistribution was assessed in naïve mice, tumor mice bearing both non-CXCR4 expressing (U87.CD4) and CXCR4 expressing (U87.CD4.CXCR4) subcutaneous tumors, and in a subcutaneous and systemic MM.1S mouse tumor model. Both dynamic µPET/CT (60 min) and ex vivo biodistribution (75 min p.i.) were performed with [18F]FDG µPET/CT scans as comparison. Further, a [18F]AlF-NOTA-SC PET/MRI study was performed in a non-human primate. The theranostic potential of [18F]AlF-NOTA-SC was assessed in a MM.1S subcutaneous tumor model by co-injecting it with [177Lu]Lu-DOTA-BL02 followed by ex vivo dual-label measurements. ***Results:*** IC50 values of 14.3±2.6nM and 8.6±1.1nM were obtained for [natF]AlF-NOTA-SC and [natGa]PentixaFor, respectively. [18F]AlF-NOTA-SC was labeled with a radiochemical yield of 28.4±6.7%, radiochemical purity of 98.6±0.7% and molar radioactivity of 16.4±3.4 GBq/µmol. The total-bound fraction on U87.CD4.CXCR4 cells resulted in 7.1±0.5% of administered activity (AMD3100 blocking by 58%) and 2.46±0.13% on MM.1S cells (AMD3100 blocking by 31%). The uptake in U87 cells without CXCR4 expression was below 1.5%, indicating CXCR4 specific uptake. [18F]AlF-NOTA-SC showed an excellent biodistribution with fast renal clearance. Furthermore, high uptake was observed in U87.CD4.CXCR4 (SUV 3.04±0.65) and in MM.1S tumors (SUV 1.95±0.06). [18F]AlF-NOTA-SC outperformed [18F]FDG and negligible uptake was measured in U87.CD4 tumors (SUV 0.04±0.00) or in the AMD3100 blocked condition (MM.1S, SUV 0.06). In the systemic MM.1S model [18F]AlF-NOTA-SC accumulated in multifocal lesions, e.g. femurs, spine and skull, similar to the pathogenesis in MM patients. Further, [18F]AlF-NOTA-SC showed an excellent biodistribution profile in the non-humane primate with fast renal clearance, a moderate uptake in the bone marrow and spleen and high uptake in kidneys and adrenal glands (physiological uptake) [3]. The co-injection with [177Lu]Lu-DOTA-BL02 showed comparable tumor uptake at 75 min p.i.(SUV[18F]AlF-NOTA-SC 3.06±0.48 vs. SUV[177Lu]Lu-DOTA-BL02 3.19±0.36). ***Conclusion:*** [18F]AlF-NOTA-SC showed CXCR4 specific tumor uptake and excellent pharmacokinetic profile. By outperforming [18F]FDG, [18F]AlF-NOTA-SC is a promising candidate for clinical translation. ***References:*** [1]Peng,2015;14(2):480-490. doi:10.1158/1535-7163.MCT-14-0850 [2]Kwon,2022;28(8):1628-1639. doi:10.1158/1078-0432.CCR-21-3284 [3]Gao,2023;62(3):267-271. doi:10.3760/cma.j.cn112138-20220609-00440.

OP-786
Disialoganglioside GD2 targeted PET-NIR imaging of high-risk children neuroblastoma with newly synthesized peptide
Y. Zhao, *G. Shao;*
Department of Nuclear Medicine, Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA.

Aim/Introduction: High-risk neuroblastoma is one main childhood cancer with great heterogeneity. It carries a neuroblastoma-specific antigen in the form of a glycolipid antigen known as

Disialoganglioside GD2 which serves as one promising target for immunotherapy. Comparing with GD2 targeted antibody, Peptide is easier to be structure modified, produced, easily to be labelled with imaging radionuclide 68Ga, 18F and be conjugated to near-infrared (NIR) fluorescent dye. Here, we synthesized one GD2 targeted peptide (GD2TP) and prepared a PET-NIR multimode imaging agent to evaluate high risk neuroblastoma metastasis and improve fluorescence-guided surgery. ***Materials and Methods:*** GD2BP were designed based on the structure of GD2 targeted antibody and prepared via solid phase peptide synthesis, mixed with TATA for cyclization and radiolabeled with 68Gallium or Cy5.5. In vitro cell binding affinity and specificity experiments of 68Ga/Cy5.5-GD2BP were performed in neuroblastoma tumor cells with varying levels of GD2 expression. Ex vivo biodistribution and Animal PET, NIR imaging of 68Ga/Cy5.5-GD2BP were performed in mice bearing SK-N-SH Neuroblastoma xenografts. Surgery navigation was performed based on the pre-operation PET-CT imaging and real-time NIR imaging. Tumor uptake of 68Ga/Cy5.5-GD2BP (percentage of injected dose, %ID/g) was compared with GD2 expression based on IHC results from tumor xenografts. ***Results:*** 68Ga-GD2BP was synthesized with high radiochemical purity. It was stable in PBS for 3 hours with radiochemical purity ranging from 96% to 98%. Cell binding specificity of 68Ga/Cy5.5-GD2BP was confirmed by GD2 blockage. Positive correlation was found between tumor cell uptake of 68Ga/Cy5.5-GD2BP and GD2 expression with R2 being 0.86. 68Ga-GD2BP was excreted rapidly via kidney and its retention in blood circulation was short. Tumor uptake of 68Ga-GD2BP (%ID/g) at 1h, 2h, 3h was (2.9±0.25), (3.8±0.7) (2.6±0.1) and (0.65±0.1 on 2h) at the block group. Tumor/normal tissues uptake ratio of Cy5.5-GD2BP at 2h post tail vein injection was (15±3.2) and NIR imaging proved that Cy5.5-GD2BP could successfully delineate the boundary between the tumor and normal tissues with high temporal and spatial resolution. ***Conclusion:*** 68Ga/Cy5.5-GD2BP, as one newly prepared GD2 targeted multimode imaging peptide, maybe promising for neuroblastoma GD2 expression evaluation, precision preoperative diagnosis and surgery navigation.

OP-787

Assessing αvβ6 Integrin Expression in Pancreatic, Head and Neck Carcinoma Using ^{68}Ga-Trivehexin PET/CT and its correlation with Immunohistochemistry.

D. Malik[1], *S. S. Das[1], P. Thakral[1], J. Simecek[2], N. Singh[1], N. Rana[1], M. Koley[1], J. Gupta[1], D. Thakrani[1], I. Sen[1];*
[1]Fortis Memorial Research Institute (FMRI), Gurugram, INDIA, [2]TRIMT, GmbH, Radeberg, GERMANY.

Aim/Introduction: αvβ6-integrin is exclusively expressed in epithelial cells and is upregulated in many carcinomas, such as head and neck squamous cell carcinoma (H&N-SCC) and Pancreatic Ductal Adenocarcinoma (PDAC). Expression of αvβ6 integrin is almost always tumour specific with surrounding normal stromal tissue not expressing αvβ6. Trivehexin is a recently synthesized improved trimerized αvβ6-integrin selective nanopeptide which can be used as a diagnostic agent after being labelled with a positron emitter like 68Gallium. This is a pilot study to assess the potential role of 68Ga-Trivehexin PET/CT in patients of H&N-SCC and PDAC and their correlation with level of αvβ6-integrin expression by the tumour tissue on IHC. ***Materials and Methods:*** 32 patients with suspected H&N-SCC (n=20), or PDAC (n=12) underwent whole-body 68Ga-Trivehexin PET/CT and 18F-FDG PET/CT scans on two separate days. All 32 patients underwent biopsy from the tumor site for histopathological diagnosis and IHC for αvβ6-integrin expression. The degree of αvβ6-integrin expression on IHC was scored using the immunoreactive score (IRS) and modified 4-point IRS classification. ***Results:*** The 68Ga-Trivehexin PET images demonstrated increased tracer uptake in primary as well as in metastatic lesions (mean SUVmax 5.9 ± 3.3) with good lesion delineation seen in 8/9 cases of PDACs. On the other hand, 18F-FDG PET/CT showed increased tracer uptake (mean SUVmax 6.2 ± 2.6) in the lesions in 7/9 cases of PDACs. Among various cases of H&N-SCC, increased uptake of 68Ga-Trivehexin (mean SUVmax 6.6 ± 4.5) and 18F-FDG (mean SUVmax 12.7 ± 6.7) were seen in 17/18 patients (one case of tracheal carcinoma showed no significant uptake of either tracer). The two cases of inflammatory changes with suspected disease recurrence, showed increased tracer uptake in 18F-FDG PET/CT (7.98 ± 3.1) and no significant uptake in 68Ga-Trivehexin PET/CT (2.2 ± 0.34). 68Ga-Trivehexin PET/CT showed positive uptake in 36/38 lesions positive for αvβ6 integrin expression on IHC with mean higher SUVmax seen in lesions with higher IRS score. 68Ga-Trivehexin SUV Max tumor showed a positive association with αvβ6 expression (correlation coefficient 0.6830) with significant p-value (p <0.0001). A higher sensitivity, specificity and accuracy of 68Ga-Trivehexin PET over 18F-FDG PET was seen for detection of primary and metastatic lesions. ***Conclusion:*** 68Ga-Trivehexin is a promising non-invasive molecular imaging agent for tumors expressing αvβ6 integrin, especially in cases where 18F-FDG PET/CT scan may be suboptimal due to its low uptake owing to low GLUT receptors, or due to its nonspecific uptake around tumor sites.

OP-788

The chirality in position 1 and 2 of DOTA-NOC determines affinity and subtype selectivity

F. Spinnler[1], *L. Del Pozzo[1], S. Zanger[1], S. Schulz[2], R. Mansi[1], M. Fani[1];*
[1]University Hospital Basel, Division of Radiopharmaceutical Chemistry, Basel, SWITZERLAND, [2]Institut für Pharmakologie und Toxikologie, Friedrich-Schiller-Universität Jena, Universitätsklinikum Jena, Jena, GERMANY.

Aim/Introduction: Radiolabeled somatostatin receptor subtype 2 (SST2) agonists (i.e. DOTA-TATE and DOTA-TOC) are clinically established. Recent trials indicated certain advantages of SST2 antagonists over agonists. A structural difference between SST2 antagonists and agonists is the inverted chirality in position 1 and 2 ((L-Phe1, D-Cys2) vs (D-Phe1, L-Cys2), respectively). However, such information is not available for analogs with multi-receptor selectivity. Herein we investigated how these configurations affects affinity, subtype selectivity and functional properties of DOTA-NOC (DOTA-D-Phe1-c(Cys2-1Nal3-D-Trp4-Lys5-Thr6-Cys7)-Thr(ol)8), a known SST2 and SST5 agonist. ***Materials and Methods:*** DOTA-NOC (D1,L2), and its diastereomers MRL18 (L1,D2: [Phe1,D-Cys2]-NOC), MRL18D (D1,D2: [D-Phe1,D-Cys2]-NOC) and MRL18L (L1,L2: [Phe1,Cys2]-NOC) were synthesized, conjugated to DOTA and labeled with Lu-177. Their affinity (IC50) was evaluated on HEK-SST2 and on CHO-SST5 membranes, using 125I-Tyr-SS-14. Their SST2 functionality was assessed using 7TM phosphorylation assay. Their cellular uptake and distribution were determined on HEK-SST2 cells. SPECT/CT images were acquired in HEK-SST2 and HEK-SST5 xenografts at 1h post-injection. ***Results:*** Compared to DOTA-NOC (IC50 = 0.36 and 13.8 nM for SST2 and SST5, respectively): a) Inversion of chirality to L1,D2 (DOTA-MRL18) resulted in reduced affinity for SST2 and loss of affinity for SST5 (IC50 = 4.9 and >1000 nM, respectively). b) Introduction of both D-amino acids (DOTA-MRL18D) resulted in massively reduced affinity for both subtypes (IC50 = 39 and 334 nM, respectively). c) Introduction of both L-amino acids (DOTA-MRL18L) led to

high SST2 and moderate SST5 affinity (IC50 = 0.66 and 49 nM, respectively). In line with the affinity data, high internalization was only observed for [177Lu]Lu-DOTA-NOC and [177Lu]Lu-DOTA-MRL18L (65 and 80% of added activity, at 4h/37°C, respectively), indicating agonism. [177Lu]Lu-DOTA-MRL18D had no uptake and [177Lu]Lu-DOTA-MRL18 had low total uptake (~15% at 4h/37°C), distributed equally between the cell surface and internalized fractions, indicating an impact on its agonism/antagonism functionality. However, in the 7TM phosphorylation assay DOTA-MRL18 and DOTA-MRL18L showed SST2 agonism similar to DOTA-NOC. SST2- and SST5-targeting in vivo, followed by SPECT/CT imaging, was in line with the affinity data. ***Conclusion:*** The inversion of chirality at position 1 and 2 does not switch the multi-receptor agonist DOTA-NOC to an antagonist. The results suggest that position 2 requires L2 configuration for sustaining SST5 affinity, while D1 and L1 configuration are both tolerated in position 1. Acknowledgement: We acknowledge ITM (Munich) for the financial support.

OP-789

Preclinical evaluation of FL-031, a novel vector for next generation SSTR2 targeting radioligand therapy for the treatment of SSTR2-positive cancers

J. Zhang, *J. Yang, T. Hu, Y. Xie, F. Liu;*
Full-Life Technologies, Shanghai, CHINA.

Aim/Introduction: Somatostatin receptor 2 (SSTR2) is frequently overexpressed in neuroendocrine tumors (NETs) and other solid tumors including small cell lung cancer (SCLC), making it a promising target for diagnostic imaging and radioligand therapy. Lutetium-177 labeled somatostatin analog 177Lu-DOTATATE has been approved for the treatment of gastroenteropancreatic (GEP)-NETs, while its efficacy in SCLC is currently being explored in clinical trials. This study evaluated the preclinical characteristics of a novel SSTR2-targeting radioligand 177Lu-FL-031, which was engineered leveraging our proprietary platform. 177Lu-FL-031 demonstrated favorable biodistribution profiles and promising anti-tumor activities compared with 177Lu-DOTATATE in multiple xenograft mouse models, including in SCLC xenograft models with moderate or low SSTR2 expression. ***Materials and Methods:*** Binding affinity, selectivity and cross-species activity of FL-031 was evaluated in 293T cells with exogenous SSTR2 expression. The biodistribution profile of 177Lu-labeled FL-031 was characterized by SPECT/CT and ex vivo biodistribution assays in mice bearing SSTR2-expressing tumor xenograft models. The anti-tumor activity of 177Lu-FL-031 was compared with 177Lu-DOTATATE in mice bearing different xenografts with a single administration of 18.5 or 37 MBq/mouse. ***Results:*** FL-031 showed a 10-fold higher affinity to SSTR2 overexpressing 293T cells compared with DOTATATE (IC50 0.8 nM vs. 9.3 nM). FL-031 was >500-fold selective for SSTR2 over all other SSTR family members and demonstrated cross species reactivity with comparable affinity to SSTR2 of human, mouse, rat, dog and pig. High and specific tumor uptake was observed for 177Lu-FL-031 in AR42J and NCI-H524 xenograft models, with rapid clearance from all normal organs. Importantly, 177Lu-FL-031 demonstrated significantly increased tumor uptake and improved tumor-to-kidney ratio compared with 177Lu-DOTATATE. Moreover, 177Lu-FL-031 exhibited improved in vivo anti-tumor activities in AR42J, NCI-H524 and NCI-H69 xenograft models compared with 177Lu-DOTATATE. No notable body weight loss was observed in these studies and complete regression was achieved in the SCLC NCI-H524 model. Furthermore, in a post-177Lu-DOTATATE model, 177Lu-FL-031 induced regression and exhibited significantly improved anti-tumor activity compared with retreatment by 177Lu-DOTATATE, suggesting that 177Lu-FL-031 may overcome the resistance to 177Lu-DOTATATE. ***Conclusion:*** FL-031 exhibited tight binding affinity and high selectivity towards SSTR2. 177Lu-FL-031 demonstrated improved biodistribution profile and anti-tumor activity compared with 177Lu-DOTATATE in multiple models. Collectively, FL-031 is a promising vector for radioligand therapy targeting SSTR2-positive cancers. As the next step of developing our next-generation SSTR2 targeting radionuclide drug conjugate (RDC), we plan to initiate studies to investigate FL-031 conjugated to the radionuclide Actinium-225.

OP-790

Caspase-3 selective peptide-based probes for imaging of tumour cell death.

L. Lauwerys[1], *L. Beroske[1], A. Solania[2], C. Vangestel[1,3], D. Wolan[2], P. Van der Veken[4], F. Elvas[1];*
[1]Molecular Imaging and Radiology (MIRA), University of Antwerp, Antwerp, BELGIUM, [2]Scripps research institute, La Jolla, CA, UNITED STATES OF AMERICA, [3]Department of Nuclear Medicine, Antwerp University Hospital (UZA), Antwerp, BELGIUM, [4]Laboratory of Medicinal Chemistry (UAMC), University of Antwerp, Antwerp, BELGIUM.

Aim/Introduction: The fact that many cancer treatments exert their effect by inducing tumour apoptosis allows the assessment of early response to therapy, which may improve patient outcomes. Multiple PET imaging radiotracers have been developed to image apoptosis. Among these, tracers targeting active caspase-3, the main executor of apoptosis, have shown low absolute tumour uptake and lack of selectivity. Therefore, the goal of this study was to design selective PET tracers for imaging caspase-3 activation, and to assess their value for the evaluation of response to cancer therapy. ***Materials and Methods:*** Caspase-3-selective activity-based probes (ABPs) were developed based on two selective inhibitors Ac-DW3-KE (Ac-3Pal-Asp-βhLeu-Phe-Asp-KE) and Ac-ATS010-KE (Ac-3Pal-Asp-Phe(F5)-Phe-Asp-KE) [1]. The binding kinetics (kinact/Ki) and selectivity of the probes to different caspases were determined experimentally by measuring the cleavage of fluorogenic substrates. Radiosynthesis was performed by click reaction with 18F-labelled prosthetic groups, and the lipophilicity and stability of the tracers were assessed. The most promising tracers were evaluated in an in vitro model of apoptosis. Subsequently, in vivo experiments allowed to assess the radiotracer biodistribution in healthy mice and tumour targeting in an in vivo colorectal cancer model treated with apoptosis-inducing targeted therapy. ***Results:*** All probes showed high caspase-3 selectivity, with the DW3-KE-based ABPs displaying slower kinetics than ATS010-KE-based ABPs. Therefore, subsequent ABPs were based on the Ac-ATS010-KE sequence, generating a library by introducing different N-terminal linkers. The linkers had a minor effect on selectivity and binding kinetics (Table 1). The radiotracers were synthesized with moderate radiochemical yield (6.4±3.1% to 12.37±10.85%) and purity (89.93±13.3% to 99.76±0.05%) and, the logD ranged from -0.42±0.18 to -2.58±0.01. The ABPs remained stable in mouse plasma in vitro (77-88% after 2h), however, in vivo less than 25% remained intact 1h post-injection (p.i.). All radiotracers showed mixed renal-hepatobiliary excretion. The least hydrophilic tracer [18F]MICA-316 showed an increased uptake in apoptotic HeLa cells in vitro (28.5±5.2%ID/g) compared to the caspase-3-deficient control group (7.53±1.53%ID/g, P=0.0097). In vivo, [18F]MICA-316 imaging showed limited tumour uptake and could not discriminate between treated (0.55±0.32 %ID/cc) and untreated (0.52±0.12%ID/cc) tumours 60 minutes p.i., despite being able

to bind caspase-3 in tumour homogenates. ***Conclusion:*** In conclusion, novel caspase-3-selective ABPs were developed, retaining the kinetic properties of the original inhibitors. [18F]MICA-316, was able to detect apoptosis in vitro, however, low tumour accumulation was observed in vivo. Future caspase-3-selective radiotracers will have higher stability and tumour accumulation. ***References:*** 1 Solania et al. ACS Chemical biology 2019.

OP-791

Synthesis and preclinical evaluation of 89Zr labeled Angiotensin peptide as a breast cancer imaging agent using PET.

S. Okarvi;
Cyclotron & Radiopharmaceutical; King Faisal Specialist Hospital and Research Centre, Riyadh, SAUDI ARABIA.

Aim/Introduction: Angiotensin (Ang) II, the main effector peptide of the renin-angiotensin system, has been implicated in diverse aspects of cancer progression, such as cell proliferation, cell migration, invasion, tumor angiogenesis, and metastasis. Ang-(1-7) is a biologically active heptapeptide generated mainly from AngII by the enzymatic activity of angiotensin-converting enzyme 2. AngII is known to play a critical role in breast cancer development by stimulating breast cancer cell proliferation and modulating tumor cell migration and invasion. AngII mediates its action through two G-protein coupled receptors, AT1 and AT2. Overexpression of AT1 receptor in breast cancer seems to promote tumor growth and angiogenesis, thus targeting AT1 receptor using AngII peptide would facilitate the detection of breast carcinoma. The goal of this study was to assess whether the peptide of the renin-angiotensin system, AngII holds the potential to target AT1 receptor overexpressing breast cancer. ***Materials and Methods:*** Zr-89 was produced using a solid target (89Y metal foil), beam energy of 13 MeV, and beam current of 15 µA. DOTA-coupled AngII peptide was synthesized by solid-phase peptide synthesis according to the Fmoc/HATU chemistry. Radiolabeling with 89Zr was achieved in the presence of ammonium acetate buffer and heating the mixture for 45 min. 89Zr-labeled AngII peptide was evaluated for its binding capacity with SUM159, a mesenchymal triple-negative breast cancer cell line. The normal pharmacokinetics was performed in balb/c mice and the tumor targeting study was done in nude mice with SUM159 tumors xenografts. ***Results:*** DOTA-AngII peptide showed high labeling efficiency (≥80%) with Zr-89. The stability of radiopeptide in plasma was high. 89Zr-AngII peptide showed nanomolar (45 nM) AT1 receptor-specific affinity. In vivo, biodistribution in mice showed rapid clearance of radiopeptide from the blood and excretion mainly by the renal route due to its hydrophilic nature. A low uptake of radioactivity was seen in the major organs including lungs, liver, stomach, spleen, and intestines (<4% ID/g) except for the kidneys. A high renal-urinary excretion was observed for the radiopeptide. In nude mice, 89Zr-DOTA-AngII peptide displayed good tumor targeting in vivo, with 2.07% ID/g of radioactivity found in the tumors at 90 min p.i. The receptor specificity of the radiopeptide was confirmed by the receptor-blocking assay. ***Conclusion:*** Our initial findings indicate that the 89Zr-DOTA-AngII peptide can be a useful imaging agent for breast cancer. This work proposes the potential of this innovative class of peptides for efficient targeting of breast cancer and warrants further investigation.

OP-792

NOTA/NOTAGA-conjugated bombesin analogs for visualization of GRPR-positive tumors after labelling with the PET radionuclide Ga-68

P. Kanellopoulos[1], *E. Bezverkhniaia[1], A. Abouzayed[1], U. Rosestrom[1], V. Tolmachev[2], A. Orlova[1];*
[1]Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, [2]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Gastrin releasing peptide receptor (GRPR) has attracted a lot of attention over the years as a biomolecular target for radiopharmaceutical development. Its overexpression in various malignancies, including prostate and breast cancer, plus its negligible expression in the surrounding healthy tissues, strongly support that choice. Despite the many attempts over the years, none GRPR-targeting radiopharmaceutical has find its way into the everyday clinical praxis. Therefore, we designed and present two diagnostic GRPR-targeting, NOTA/NODAGA-conjugated radiotracers based on the in vivo stable motif PEG2-[Sar11]RM26 [1]. Aiming for use with positron emission tomography (PET) for diagnostic purposes both radioligands were labelled with Ga-68 and evaluated both in vitro and in vivo. ***Materials and Methods:*** The two new radioligands were designed and labelled with Ga-68. Their in vitro GRPR-specificity, as well as their cellular uptake over time was evaluated in PC-3 cells. The receptor affinity for NOTA/NODAGA-PEG2-[Sar11] RM26 and NOTA-PEG2-RM26, after coupling with natGa, was evaluated in competition binding experiments against [125I] I-Tyr4-bombesin in alive PC-3 cells. The biodistribution profile, in vivo specificity and imaging for was evaluated in Balb/c nu/nu mice bearing PC-3 xenografts. ***Results:*** Both new peptides were successfully labelled with Ga-68, with radiochemical yields and purity exceeding 95%. Both NOTA-/NODAGA-PEG2-[Sar11]RM26 displayed high GRPR-specific uptake in PC-3 cells (NOTA: 18±1%; NODAGA: 22.2±0.9% of added activity), while retaining the typical radioantagonist profile (the bulk of associated activity remaining on the cell membrane). After loading the peptides with natGa, in competition binding experiments, they exhibit a nanomolar affinity (6.6 nM and 4.3 nM, respectively), similar to the highly affine, previously reported, [natGa]Ga-NOTA-PEG2-RM26 (4.3 nM) [2]. In vivo, they displayed rapid background clearance with blockable receptor-driven uptake in tumors and in GRPR-rich organs, like pancreas. Among the two, [68Ga]Ga-NODAGA-PEG2-[Sar11] RM26 holds an edge with a slightly higher tumor-uptake and lower background (Tumors 1 h pi: NOTA -14±2%IA/g, NODAGA - 17±3%IA/g; Pancreas: NOTA -10±2%IA/g, NODAGA - 8±1%IA/g; Muscle: NOTA - 0.27±0.08%IA/g, NODAGA - 0.13±0.02%IA/g). Tumor/blood ratios started at 16-30 and increased 3-fold, while tumor/liver was 30 at 1h with >2-fold increase 3h pi. ***Conclusion:*** Based on the performance of [68Ga]Ga-NOTA-PEG2-[Sar11]RM26 and [68Ga]Ga-NODAGA-PEG2-[Sar11]RM26, both are considered as very promising PET probes for detection GRPR-positive lesions, due to their high tumor-targeting capabilities. Among the two, the NODAGA-conjugated one has a slight advantage and it is considered strong candidates for clinical translation. ***References:*** [1] Abouzayed et al. Biomolecules 2023, 13 (7), 1134. [2] Varasteh et al. Bioconjugate Chem. 2013, 24 (7), 1144–1153.

OP-793

Structure-property investigation of RM26 bombesin analogues with different hydrophobicity: impact on GRPR binding and prostate cancer imaging

I. Zelepukin, *P. Kanellopoulos, E. O. Håkansson, E. Bezverkhniaia, A. Bitzios, L. Odell, U. Rosenström, A. Orlova;*
Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: The gastrin-releasing peptide receptor (GRPR) is overexpressed in multiple cancer types, including prostate, breast, lung, and colon tumours. RM26 bombesin analogue (d-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH2) labeled with Ga-68 was proposed for imaging of GRPR-positive tumours [1]. Binding to GRPR and imaging properties of RM26 strongly depends on structure of linker between RM26 and chelator for labeling. Herein, a series of RM26-based peptides N-terminally conjugated with NOTA via o-methylanisole (NOTA-oMA-RM26), m-methylanisole (NOTA-mMA-RM26), or o-ethyltoluene (NOTA-oET-RM26) spacers were radiolabelled with Ga-68 and evaluated in vitro and in vivo for GRPR targeting in comparison with NOTA-(PEG)2-RM26. ***Materials and Methods:*** Three RM26 peptide analogues were radiolabelled with 68Ga via NOTA chelators and purified with Sep-Pak C8 columns. Labelling stability was evaluated using iTLC and radio-HPLC analysis. In vitro binding specificity and cellular processing was evaluated using PC-3 cells, overexpressed GRPR. Biodistribution of [68Ga]Ga-labelled peptides and PET imaging was performed in BALB/c nu/nu mice bearing PC3 tumours. ***Results:*** Radiochemical purity of [68Ga]Ga-labelled RM26 analogues was above 95%, radiochemical yield was above 90% after conjugation and above 99% after purification step. [68Ga]Ga-NOTA-oMA-RM26 has shown almost 1.5-fold higher binding to PC3 cells, compared to other tested proteins. Binding of new peptides was GRPR specific and can be blocked by addition of 1000-fold excess of non-labelled NOTA-(PEG)2-RM26 protein. Biodistribution 2 h post intravenous injection has shown the highest uptake in pancreas, following by GRPR-expressing tumours and kidneys. Tumour uptake did not differ between analogues, almost 12% IA/g. Nevertheless, hydrophobic analogue [68Ga]Ga-NOTA-oET-RM26 demonstrated lower non-specific uptake in normal organs, namely, pancreas, lungs, liver and spleen. Activity uptake of all proteins in tumours, pancreas, and gastrointestinal tract could be blocked by co-injection of NOTA-(PEG)2-RM26 that supports GRPR-specific accumulation of new peptides. High uptake of peptides in liver and small intestine supposed involvement of hepatobiliary excretion in clearance of RM26 analogues. PET imaging was in agreement with biodistribution data and enable identification of PC3 tumour on the background of excreted peptide in small intestine. ***Conclusion:*** RM26 analogues with different spacers between targeting part and chelator can be easily radiolabelled with Ga-68 with high radiochemical yield and stability. After labelling proteins perceived specific binding to GRPR-overexpressed cells. [68Ga]Ga-NOTA-oET-RM26 showed reduced non-specific activity uptake in body. Nevertheless, inclusion of any of the proposed spacers to RM26 peptide increases its accumulation in small intestine, which is not favourable for PET imaging. ***References:*** 1. Mitran et al. International journal of oncology. 2016, 48(5), 2124-2134.

The consistency of guideline recommendations for the use of FDG PET/CT in oncology by ACR, NCCN, and EANM

Y. Xiong[1], *F. Cui[1], M. Su[1], T. He[2], X. He[3], F. Yang[4], H. Wang[2], W. Lu[3], Y. Liu[4], L. Li[5], R. Tian[1], X. Sun[5], Q. Li[1];*
[1]Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA, [2]Department of Nuclear Medicine, Panzhihua Central Hospital, Panzhihua, CHINA, [3]Department of Nuclear Medicine, Guangyuan Central Hospital, Guangyuan, CHINA, [4]Department of Nuclear Medicine, Ya'an People's Hospital, Ya'an, CHINA, [5]Chinese Evidence-Based Medicine Center, Cochrane China Center, and MAGIC China Center, West China Hospital, Sichuan University, Chengdu, CHINA.

Aim/Introduction: Reliable and consistent guideline recommendations improve the quality of practice. However, it is unclear whether guidelines recommendations for the appropriate use of FDG PET/CT vary between different specialties. Thus, we aim to compare recommendations for oncological FDG PET/CT indications from representative guidelines developed by the oncology group (National Comprehensive Cancer Network [NCCN]), the radiology group (American College of Radiology [ACR]), and the nuclear medicine group (European Association of Nuclear Medicine [EANM]), in order to examine consistency. ***Materials and Methods:*** We collected recommendations about the use of FDG PET/CT for oncological indications from guidelines developed by the NCCN and ACR, and compared them with those from the EANM guideline (Hossein Jadvar, J Nucl Med, 2017). ***Results:*** Recommendations for the use of FDG PET/CT for restaging and treatment response assessment in 7 cancers were compared (i.e., lymphoma, breast cancer, lung cancer, head and neck cancer, colorectal cancer, melanoma and sarcoma, presented as Table 1). Serious inconsistencies were observed for three indications (20%): breast cancer restaging for local recurrence, and colorectal cancer restaging and treatment response assessment, in which the use of FDG PET/CT was supported by the EANM, while explicitly recommended against by either the NCCN or the ACR. Potential inconsistencies were observed for 12 indications (80%): restaging and treatment response assessment for colorectal cancer, lymphoma, lung cancer, melanoma, and sarcoma, and treatment response assessment for breast cancer, in which the use of FDG PET/CT was supported by the EANM, while not mentioned under the corresponding indications by ACR. ***Conclusion:*** This is the first study to compare guidelines recommendations for FDG PET/CT indications developed by different specialties, and serious inconsistencies were noted in several indications. Efforts are needed to examine the underlying cause for inconsistent recommendations and to improve the quality of guideline recommendations for FDG PET/CT use.

OP-795

Quantitative accuracy of clinical PET systems in the UK (2019-2023)

A. Fenwick[1], *W. Heetun[1], D. Deidda[1], A. Robinson[1], K. Ferreira[1], D. Roddy[1], B. Sanghera[2], Ge-68 NEMA Phantom Audit;*
[1]National Physical Laboratory, Teddington, UNITED KINGDOM,
[2]St. Bartholomew's Hospital, London, UNITED KINGDOM.

Aim/Introduction: Quantitative accuracy in PET is a critical factor when considering multi-centre comparability. To assess the comparability of PET systems in the UK a specialised traceably calibrated solid phantom was designed and distributed to UK PET centres. ***Materials and Methods:*** The phantom was adapted from the NEMA NU-2 Image quality phantom which consists of 6 spheres ranging in size from 10 mm to 37 mm diameter. A 7th sphere with a 5 mm diameter was added to the phantom in a position optimised using monte carlo techniques. The phantom was prepared with a 68Ge spiked epoxy resin and a total activity of 99.0(30) MBq (@ k=2) with a sphere:background ratio of 4:1. The phantom was shipped to the test sites for measurement between 2019 and 2023 with images acquired using a decay-corrected acquisition time simulating a 3 min per bed position scan at each site. An additional scan with a single frame centred over the sphere axis was also obtained at most sites and list-mode data was collected. The phantom was periodically returned to to coordinating site and scanned to confirm stability of the phantom. Images were reconstructed using typical clinical protocols at the participating site, and image analysis was performed centrally by two independent operators. Results were calculated for quantitative accuracy of background and sphere activities and recovery coefficient curves were generated for each scan made. ***Results:*** The results show statistical agreement between centres with no site returning activity values more than 10 % from the reference values. Uncertainties were estimated for each site using statistical information from the scans and estimated values based on measurements performed at the coordinating site (NPL). Recovery coefficient curves were generated and compared to the EARL recommended values for 18F and 68Ga. ***Conclusion:*** The comparison exercise demonstrated equivalence between centres for typical activity measurements in a simple geometry. The exercise highlighted the lack of knowledge at participating centres in performing uncertainty analysis of PET measurements and future work should be performed in this area. Further work will be undertaken using the list mode data from this study and a harmonised reconstruction platform to minimise reconstruction influences on the dataset and harmonise uncertainty components.

OP-796

Validation of a Fully Automated Deep Learning (DL)-Assisted Analysis Pipeline for Quantification of PET/CT Image Data in a Medical Data Integration Center

S. Böhner[1], *R. Fischer[1], T. Fuchs[1], N. Hellwig[1], A. Hellwig[2], H. Albig[1], D. Schmidt[2], D. Waldmannstetter[1], D. Hellwig[2];*
[1]University Hospital Regensburg; Medical Data Integration Centre, Regensburg, GERMANY, [2]University Hospital Regensburg; Department of Nuclear Medicine, Regensburg, GERMANY.

Aim/Introduction: Nuclear medicine images are data and contain information suitable for automated analyses of physiological and biochemical processes. Here, we validated a prototypic analysis pipeline linked to a medical data integration center (DIC) of the German Medical Informatics Initiative (MII) for the automatic quantification of reference organs (aorta, liver, and bone marrow in L3 vertebra) in FDG PET/CT images. ***Materials and Methods:*** A Python script indexes molecular imaging series from PACS by extracting relevant DICOM metadata to be linked with case data in the searchable DIC database containing further clinical parameters and follow-up data. Exemplarily, we selected 74 consecutive cases with EARL-compliant FDG PET/CT for analysis in a Python-based pipeline. After voxel-resampling and SUV-scaled conversion to Nifti format, 104 organ regions were obtained from the CT component using the DL-tool TotalSegmentator [1] for PET quantification. To account for incongruent organ rims in PET and CT, CT-based segmentations underwent post-processing (demasking of cortical bone and erosion operations with optimized parameters). Physician supervised SUV measurements served as reference standard. ***Results:*** Indexing the image series expands the dataset in the DIC if procedure coding of imaging is missing or ambiguous. The EARL-compliant PET/CT images allow robust organ segmentation which takes 6-9 minutes per scan. Median SUVs in organ regions are less sensitive to shifts between PET and CT components than mean SUVs as shown by Bland-Altman analysis. The SUVs obtained from our pipeline are equivalent to conventional SUV measurements with a mean absolute error, correlation coefficient, linear slope, and intercept of 0.11, 0.92, 0.93, 0.09 in the aorta (analyzed volume: 6.5±4.0 mL), 0.1, 0.92, 1.0, 0.05 in the liver (332±337 mL), and 0.09, 0.99, 0.93, 0.1 in L3 (9.2±3.0 mL), respectively. ***Conclusion:*** The fully automated pipeline provides a robust and accurate quantification of PET data. CT-defined segmentations need proper post-processing prior to application for PET quantification to account for overlay inaccuracies. The use of median instead of mean SUVs results in more robust quantifications even if pathology (e.g. metastatic disease) is present in reference organs. Further prototype development aims at roll-out to the DIC sites at medical universities for both local operation and cross-site research. Its modular structure facilitates adaptation to local image archiving scenarios and integration of further analysis tools. Linking quantitative molecular imaging data to medical information in a DIC unlocks the large-scale use of image-based phenotyping for DIC-supported research with clinical and survival data. ***References:*** [1] DOI: 10.1148/ryai.230024

OP-797

Tracking of Ultra-Low Activity Sources in LAFOV PET Using Histo-Images

K. D. Vrakidis[1], *D. Bharkhada[2], M. Yaqub[1], R. Boellaard[1];*
[1]Amsterdam UMC, location VUmc, Amsterdam, NETHERLANDS, [2]Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Insight of cell homing and trafficking can be crucial for the development and evaluation of novel cell-based therapies. Cell tracking algorithms based on Positron emission tomography (PET) have been proposed to track over one hundred cells, each labeled with a few becquerels of activity. However, these methods have been primarily evaluated with preclinical scanners or Monte Carlo simulations. Stepping towards a clinical setting, in this study, we explore the feasibility of histo-image-based [1] tracking of ultra-low activity sources using a commercially available long axial field of view (LAFOV) PET system. ***Materials and Methods:*** 22Na point sources with activities of 6.4 (L), 22.8 (M), and 726 (H) kBq were positioned with a calibrated robotic arm that was placed at the edge of the axial FOV of the PET scanner. Series of list-mode PET acquisitions were performed with the point source(s) moving on predefined linear or spiral trajectories at various constant velocities of 0.31 (s), 10 (m), and 35.6 (f) mm/s.

To emulate clinically comparable attenuation and scatter effects, additional PET acquisitions were performed in the presence of two cylindrical phantoms, 70 cm long and 20 cm diameter each. From the acquired data, histo-images were generated to visualize the coincidence events in image space. Two observers assessed the visibility of the trajectories on the maximum intensity projections (MIPs) of the resulting histo-images. ***Results:*** Without an attenuation medium, the histo-image method yielded visually identifiable trajectories of all activity sources with all tested velocities. We obtained similar results with the attenuation medium, except in the cases of (s) and (m) velocities using the (L) activity source, where the trajectories were unable to be discerned from the background noise. ***Conclusion:*** The histo-image-based method was capable of generating discernable trajectories of ultra-low activity sources using a clinical LAFOV PET system. Therefore, a source localization method based on histo-images can potentially be suitable for cell tracking applications. Currently, we are developing the necessary tools to estimate the location and the motion of the sources from dynamic histo-images before starting clinical evaluations. ***References:*** [1] Matej S, Surti S, Jayanthi S, Daube-Witherspoon ME, Lewitt RM, Karp JS. FastPET: fast quantitative end-to-end deep learning reconstructions

M. Millardet[1,2], *D. Bharkhada[2], J. Raj[1], Y. Zheng[2], J. Schaefferkoetter[2], V. Panin[2], M. Conti[2], S. Matej[1];*
[1]Department of Radiology, University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA, [2]Siemens Medical Solutions USA, Inc., Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: End-to-end deep learning (DL) positron emission tomography (PET) reconstruction was first proposed in 2018, offering benefits such as rapid reconstructions, being particularly advantageous for dynamic studies requiring the reconstruction of numerous frames, and the prospect of real-time PET imaging. Whiteley et al. (2021) introduced a novel data representation called "histo-images" as the network's input, replacing traditional sinograms. Histo-images directly map the detected events to the spatial dimensions of the image and, thus, are well suited to be processed by convolutional neural networks. This paper was the first to enable DL reconstructions of full 3D images. Feng et al. and Ote and Hashimoto have since used multi-view histo-images — one histo-image per set of azimuthal angles. However, these studies have shown non-systematic bias and blurry reconstructions. Therefore, to our knowledge, an end-to-end neural network capable of providing quantitative results had yet to be presented. This work introduces the first end-to-end network capable of quantitative reconstructions. ***Materials and Methods:*** We achieved that by using a multi-view histo-image containing the attenuation correction factors as an additional input. We also trained our network against noisier but sharper targets since the network tends to smooth the provided target. ***Results:*** We significantly improved image quantification, with the absolute relative difference from OSEM being 2.3 % on average over 16 regions of interest. Our proposed method also removes some artefacts in the image. It exhibits higher contrast and lower noise than the clinical OSEM. The reconstruction takes 20 seconds for a long axial field of view scanner (image size 440 × 440 × 645) using a GPU NVIDIA RTX A6000 with 47.5 GB memory. Creating the attenuation histo-image takes 2 minutes and can be performed after the CT before the PET acquisition starts. The time required to produce a PET histo-image varies according to the number of events. It is around 2 minutes for a typical 10-minute FDG scan of 2.7 billion prompts. In a clinical setting, this can be performed during the acquisition process. As a result, the waiting time after the scan finishes is only 20 seconds compared to the 7 minutes with the clinical OSEM currently in use. For long dynamic studies involving 100 frames, the difference is substantial. ***Conclusion:*** This study introduces the first end-to-end deep-learning technique capable of performing quantitative reconstructions in nearly real-time.

Impact of different Patlak parametric imaging approaches with a long axial field-of-view (LAFOV) PET/CT in oncological patients

L. Pan, *C. Sachpekidis, A. Dimitrakopoulou-Strauss;*
German Cancer Research Center, Heidelberg, GERMANY.

Aim/Introduction: The recently introduced Long-Axial-Field-of-View (LAFOV) PET-CT scanners allow for the first-time whole-body dynamic- and parametric imaging. We, herein, aimed to evaluate whether Patlak imaging is feasible with the new LAFOV Biograph Vision Quadra PET/CT (Siemens Healthineers) system and whether it improves lesion detectability as compared with the 50-60-min standard uptake value (SUV) images. Furthermore, we investigated the differences between the direct and indirect parametric Patlak images and the impact of the time factor. ***Materials and Methods:*** 50 oncological patients with 346 tumor lesions were enrolled in the study. All patients underwent [18F]FDG PET/CT (skull to upper thigh). Four sets of images have been compared: short-time (30 minutes)-direct (STD) Patlak Ki images, short-time (30 minutes)-indirect (STI) and long-time (59.25 minutes)-indirect (LTI) Patlak Ki images, as well as 50-60-min SUV (sumSUV) images. All four sets of images were reviewed visually (qualitatively) by the reading physicians. Furthermore, 346 individual tumor lesions were quantitatively analyzed using the target-to-background (TBR) and contrast-to-noise ratio (CNR) metrics. ***Results:*** No significant differences were observed between the four approaches regarding the number of tumor lesions. However, we found three discordant results: a true positive liver lesion in all Patlak Ki images, a false positive liver lesion delineated only in LTI Ki which was a hemangioma according to MRI and a true negative example in a patient with an atelectasis next to a lung tumor. Quantitatively, parametric imaging showed that STD, STI and LTI Ki images had superior TBR in comparison with sumSUV images (2.9-, 3.3- and 4.3-fold mean increases in TBR, respectively). STD Ki images demonstrated 2.3-fold higher CNR in tumor lesions as compared with STI Ki images. Besides, TBR of LTI Ki was significantly higher than TBR of STD Ki in 306/346 lesions. ***Conclusion:*** Dynamic [18F]-FDG with the new LAFOV PET/CT scanner produces Patlak Ki images with better lesion contrast than SUV images but does not increase lesion detection rate. In few cases, Patlak images revealed discordant findings as compared to sumSUV and adds further useful clinical information. However, Patlak imaging does not increase lesion detection rate as compared with the sumSUV images. In addition, the TBR of LTI Ki images are significantly higher than STD Ki images. Our results demonstrate, that the time window used for Patlak reconstruction plays an important role than the use of (in)direct image reconstruction.

Whole-body Patlak Parameter Estimation of Deep Learning Time-of-Flight Enhanced Dynamic PET Scans

F. Kotasidis[1], *S. Wollenweber[2], M. Huellner[3], A. Maurer[3], R. Johnsen[2], F. P. Jansen[2], A. Mehranian[4];*
[1]GE HealthCare, Zurich, SWITZERLAND, [2]GE HealthCare, Waukesha, WI, UNITED STATES OF AMERICA,
[3]Department of Nuclear Medicine, University Hospital Zurich, University of Zurich, Zurich, SWITZERLAND,
[4]GE Healthcare, Oxford, UNITED KINGDOM.

Aim/Introduction: To investigate the performance of [18F]FDG deep learning-based time-of-flight (DLToF) models for image quality enhancement in non-ToF [18F]FDG whole-body dynamic (WBD) and Patlak parametric imaging. ***Materials and Methods:*** Three residual U-NET DL-ToF models with varying contrast and noise properties: low (L), medium (M) and high (H), and trained on [18F]FDG data to transform non-ToF block sequential regularized expectation maximization (BSREM) based images, towards their TOF counterpart, were used on 12 [18F]FDG WBD datasets acquired on a 30cm 6-ring ToF PET/CT system [1]. Dynamic datasets consisted of a 10-min single bed dynamic acquisition over the heart followed by a number of WBD passes (6±2 bed positions, 53±3sec/bed position) up to 62±5min post injection. The dynamic datasets were subsequently processed using Patlak graphical analysis and with an image-derived input function from the descending aorta. Quantitative regions of interest analysis was performed on lesions, lung, liver and aorta, using the dynamic series reconstructed with non-ToF BSREM, ToF BSREM as well as the inferenced images using the three DL-ToF models. Similar analysis was repeated on the derivative Ki and DV parametric images of the five dynamic image series, as well as on the weight average static image. ***Results:*** Lesion SUVmax (%) difference in non-ToF BSREM, and DLToF-L, -M and -H images with respect to reference ToF BSREM ones was as followed: for WBD images across passes -31±3, -38±3, -27±4, -15±4 for mean (and standard deviation), for Ki -30, -33, -26, -12, for distribution volume (DV) -23, -30, -23, -14 and for weight average static -30, -35, -27 and -18. Input function area under the curve (AUC) % error was -5.6, -7.8, -4.4 and -4.1, with the DLToF-H moving the AUC closer toward ToF amongst image series. Finally, for the liver SUVmean (%) difference for the WBD images across passes was -1.1, -1.7, -0.8, -1.9 for the mean (and standard deviation), for Ki -26, -21, -11, -2, for DV 10, 11, 6, 5 and weight average static -1, -2, -1 and -2. Lung SUVmean and liver SUVstd also showed ToF-like performance for the DLToF models, with predictable contrast and noise trade-offs across the three model strengths. ***Conclusion:*** DL-ToF models can be utilized in non-ToF [18F]FDG WBD acquisitions for the estimation of voxel-wise quantitative Patlak parametric maps, with the DLToF-H providing the most accurate estimate towards ToF kinetic parameter estimation. ***References:*** [1] Mehranian A et al. Parametric mapping of dynamic Ga-68 FAPI-46 PET data of 43 patients with pancreatic diseases: feasibility and diagnostic value

M. Röhrich[1,2], *I. von Goetze[1], H. Buchholz[1], U. Heger[2], M. Lang[2], J. Liermann[2], E. Gutjahr[3], M. Schreckenberger[1], U. Haberkorn[2];*
[1]University hospital Mainz, Mainz, GERMANY,
[2]University hospital Heidelberg, Heidelberg, GERMANY,
[3]University hospital Heidel, Heidelberg, GERMANY.

Aim/Introduction: Differential diagnoses of primary pancreatic lesions include pancreatic ductal adenocarcinomas (PDAC) and inflammatory lesions of the pancreas (ILP). Post pancreatectomy, differentiation of postoperative reactive tissue (PRT) and recurrent PDAC is a major challenge for oncological imaging. Static Ga-68 FAPI-PET-uptake is increased in all of these lesions with marked overlap in signal intensity, which hampers their FAPI-PET-based assessment. Here, we evaluated parametric mapping based on dynamic Ga-68 FAPI-46 PET with respect to assessment of pancreatic lesions in primary and post-operative scenarios. ***Materials and Methods:*** 43 Patients (26 primary, 17 recurrent) underwent static and dynamic 68 Ga-FAPI-PET/CT. Primary cases underwent surgical resection/biopsy after FAPI-PET imaging. Possible recurrences were classified according to CT- and clinical course (at least 18 months). Parametric maps (1 tissue compartment (1TC) and Logan plot (LP)) were generated with an image-based aortic input function using PMOD software. Pancreatic lesions were delineated on parametric and static maps and maximum signal intensities of different lesions were analyzed. ***Results:*** Histology revealed PDAC in 15 and ILP in 11 primary patients. In post-op setting, 9 cases were classified as recurrences and 8 cases as PRT. Differences in maximum signal intensity between PDAC and ILP were more pronounced in 1 TC (mean 12,37 vs. 7,99, p-value 0,019) and LP (mean 13,84 vs. 10,12, p-value 0,028 compared to static (mean 28,79 vs. 22,21, p-value 0,29) maps. With regard to the differentiation of recurrences versus postoperative tissue, static (mean 13,60 vs. 4,431, p-value 0,04) and LP (mean 4,23 versus 1,622, p-value 0,055) maps showed similarly marked, but 1TC only slight differences of their maximum signal intensities. ***Conclusion:*** Parametric mapping of dynamic Ga-68 FAPI-46 PET data has promising diagnostic potential for the assessment of pancreatic lesions.

OP-802

Validation of a Reversible Kinetic Model for 30-min Dynamic Whole-Body PET Imaging of the Total Distribution Volume

J. Rosenskjold Madsen[1,2], *P. B. Danielsen[3], A. H. Dias[1], L. C. Gormsen[1,2], A. B. Rodell[4], V. Panin[5], D. Pigg[5], O. L. Munk[1,2];*
[1]Department of Nuclear Medicine & PET, Aarhus University Hospital, Aarhus, DENMARK, [2]Department of Clinical Medicine, Aarhus University, Aarhus, DENMARK, [3]Department of Electrical and Computer Engineering, Aarhus University, Aarhus, DENMARK, [4]Siemens Healthcare A/S, Aarhus, DENMARK, [5]Siemens Medical Solutions USA, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: Dynamic whole-body (D-WB) PET/CT allows for multiparametric imaging with the irreversible Patlak model [1], but many organs require a reversible model for physiologically meaningful parametric imaging. The widely used reversible Logan Model (LM) requires complete dynamic tissue data and the full arterial input function to estimate the total distribution volume (Vt), which restricts Vt imaging to the scanner's axial field-of-view (FOV) and necessitates a long 70-min dynamic PET scan. This study validates a novel reversible Delayed Logan Model (DLM), only requiring late steady-state data and a scaled population-based input function (sPBIF). ***Materials and Methods:*** The DLM was validated using 20 patients examined with 18F-FDG using a 70-minute multiparametric PET acquisition protocol on a PET/CT scanner (26.3cm FOV, 214ps TOF). A deep learning model was used for automatic segmentation of selected organs in the chest region: spleen, kidneys, liver, pancreas, and lungs. Aorta image-derived input function (IDIF) was used to calculate a sPBIF [1]. Region-based kinetic analysis and voxel-based Vt imaging were conducted with LM (data: 0-70 min) and DLM (data: 40-70 min). The region-based LM kinetic analysis served as the gold standard.

Results: We found excellent agreement between Vt estimations in parametric images generated by DLM with IDIF and the gold standard with biases between [-3.8%; 2.1%]. Furthermore, there were no significant differences in any organs when using DLM with IDIF and DLM with sPBIF with biases between [0.9%; 2.3%]. In contrast, the traditional LM with IDIF generated Vt images that had significant biases between [-6.5%; -17.3%]. The Vt images generated by LM and DLM showed similar characteristics, but DLM images had fewer noise artifacts. ***Conclusion:*** The new DLM model allows multiparametric Vt imaging based on a clinically feasible 30-minute D-WB PET examination on a conventional PET/CT scanner. ***References:*** 1. Intraoperative beta-probe for pathological tissue detection in GEP-NET patients: a prospective Phase II Trial.

F. Mattana[1], *E. Bertani[2], F. Collamati[3], R. Mirabelli[3], E. Bonatto[1], L. L. Travaini[1], M. Ferrari[4], A. G. Di Dia[4], E. Pisa[5], N. Fusco[5], U. Fumagalli Romario[2], F. Ceci[1];*
[1]IEO European Institute of Oncology IRCCS, Nuclear Medicine, Milan, ITALY, [2]IEO European Institute of Oncology IRCCS, Division of Digestive Surgery, Milan, ITALY, [3]INFN National Institute of Nuclear Physics, Nuclear Physics, Rome, ITALY, [4]IEO European Institute of Oncology IRCCS, Medical Physics, Milan, ITALY, [5]IEO European Institute of Oncology IRCCS, Pathology, Milan, ITALY.

Aim/Introduction: Accurate localization of GEP-NETs lesions is crucial for successful radical surgery. Radioguided surgery (RGS) is recognized as an innovative and promising technique that could facilitate the identification of even the smallest lesions, improving the management of GEP-NET patients. The primary objective was to evaluate the diagnostic accuracy of the intra-operative positron detector (β-Probe) using pathology as the gold standard. ***Materials and Methods:*** This is a prospective, single-arm, single-center, non-interventional, registered phase II trial (NCT05448157). Inclusion criteria were:1)histological diagnosis of ileum GEP-NET; 2)positive 68Ga-DOTATOC PET/CT (SSR-PET) performed within the previous 4weeks; 3)>18yo. Exclusion criteria were:1)not eligible for a radical surgery; 2)SSR-PET not performed. Activity of 1.1 MBq/Kg of 68Ga-DOTATOC was intravenously administered in the surgery room. The in-vivo measurements with a β-Probe were performed by the surgeon using hand-held (for open-surgery procedures) or DROP-IN (for laparotomic procedures) devices. The tumor-to-background-ratio (TBR) was evaluated using real-time counts per second (CPS). Data derived from the SSR-PET, β-Probe and histopathological analysis were compared in an over-all analysis. ROC curve analysis was used to calculate the CPS cut-off with the highest accuracy. The absorbed dose of the surgeon has been measured using an electronic personal dosimeter (EPD). ***Results:*** We enrolled 26 patients from May 2022 to April 2024. A total of 209 specimens have been evaluated and surgically removed with a specificity, sensibility, PPV and NPN of 87%, 90%, 93%, 83% respectively, in comparison with the pathology results. When a single measurement taken on the omentum is used as a reference for the background specificity, sensibility, PPV and NPN were 82%, 81%, 89%, 69% respectively. The CPS cut-off with the higher performance was 1.3. No side effects have been observed during all procedures. The mean absorbed dose from the surgeon was 30 μSv (range 12-41 μSv). ***Conclusion:*** The intraoperative beta-probe showed higher accuracy in detecting pathological tissue compared to previously used gamma-probes. An additional advantage lies in using a measurement on the corresponding healthy tissue for background assessment, which significantly increases the accuracy compared to using a single measurement on the omentum. RGS with β-Probe can be considered as a useful approach in the management of GEP-NET patients. ***References:*** El Lakis M, Gianakou A, Nockel P, Wiseman D, Tirosh A, Quezado MA, Patel D, Nilubol N, Pacak K, Sadowski SM, Kebebew E. RADar reflector localIsatiOn-Scout for breast carcinOma, a prospective monocentric trial: RADIOSO trial

L. Travaini, *G. Pagani, S. Fracassi, M. Colandrea, A. Polizzi, P. Rocca, L. Gilardi, V. Galimberti, F. Mattana, M. Cuomo, B. Parducci, A. Di Dia, M. Mioradelli, F. Ceci;*
European Institute of Oncology, Milano, ITALY.

Aim/Introduction: Radio-guided occult lesion localization (ROLL) is the standard of care in non-palpable breast lesion localization in our Institute. Its main limitations are the necessity to have a nuclear medicine division, the radioexposure, the difficulty to localize two lesions in the same breast and its execution next to surgery. We designed a monocentric prospective observational study that aims to evaluate the impact of a new procedure of breast localization. SCOUT® Radar (Merit Medical) occult breast lesion Localization (SRL) exploits non-radioactive micropulse radar to provide real-time surgical localization. Primary endpoint is the rate of successful localization procedures. Secondary endpoints include the percentage of negative margins, the percentage of a second excision and the comparison of SCOUT® and ROLL. ***Materials and Methods:*** Inclusion criteria were: female gender, age 18-90 years old, pathological confirmed non-palpable breast lesions and referred for breast-conserving surgery. Exclusion criteria were suspected nickel allergy and any condition that may expose the individual to a higher risk or prevent the study from achieving full compliance or completion. ***Results:*** From June 2022 to March 2024, we evaluated 303 breast cancer patients. After a multidisciplinary tumor board consensus meeting 246 pts were considered eligible for SCOUT®. SRL was performed in 296 breast lesions: the majority (92%) in a monolateral breast lesion, under ultrasound guidance (97%). No adverse events have been reported by radiologists during positioning procedures. Among the patients included 190 have currently undergone radar-guided surgery. We observed a 99,6% success rate in localizing and harvesting the reflector during surgery. Confirmation was given by the presence of the reflector on the x-ray of the specimen or by the evaluation of the pathologist. There were no cases of re-intervention needed due to positive margins. Data analysis showed that the distance between the lesion and the margin is less than 1 mm in 2.5%. The use of radar technology has found

wide acceptance among clinicians: 98% of radiologist and 89% of surgeons declared themselves satisfied with the use of Scout® device. Among the patients, 89.7% declared themselves satisfied with the positioning procedure. ***Conclusion:*** SCOUT® Radar Localization System is a safe and reliable method in non-palpable breast lesions localization with a lower re-excision rate than wire-guided localization. Further benefits include high patient and clinician satisfaction, no radiation exposure, long-term positioning of the reflector in the breast and the possibility of placement of more than one reflector in patients with multifocal breast lesions.

Freehand [^{99m}Tc]Tc-PSMA SPECT for back-table margin assessment during prostate cancer surgery

G. Pisano[1,2], *A. Berrens[1,3], L. J. Slof[1], P. J. van Leeuwen[3], H. G. van der Poel[3,4], D. D. D. Rietbergen[1,3,5], F. W. B. van Leeuwen[1,3], M. N. van Oosterom[1,3];*
[1]Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Centre, Leiden, NETHERLANDS, [2]Section of Nuclear Medicine, University Department of Radiological Sciences and Haematology, Università Cattolica del Sacro Cuore, Rome, ITALY, [3]Department of Urology, Netherlands Cancer Institute–Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, [4]Department of Urology, Amsterdam University Medical Centre, Location VUmc, Amsterdam, NETHERLANDS, [5]Department of Nuclear Medicine, Leiden University Medical Centre, Leiden, NETHERLANDS.

Aim/Introduction: In prostate cancer care, prostate-specific membrane antigen (PSMA)-PET is increasingly being used to match patients to a personalized treatment plan. To enhance interventional precision in patients with local disease, ([99mTc]Tc-)PSMA-targeted surgery is currently explored [1]. While these studies tend to focus on intraoperative identification of nodal metastases, there is also need for margin assessment of the primary cancer site [2]. The aim of this study was to demonstrate how gantry-less freehand imaging can be used to generate high-end [99mTc]Tc-PSMA specimen scans. ***Materials and Methods:*** We included prostate cancer patients who, based on PSMA PET/CT and MRI, were selected for de novo robot-assisted [99mTc]Tc-PSMA targeted surgery (currently N=6 de novo surgeries performed). Following the excision of primary tumour and lymph nodes, three surgical samples were placed on a custom-built specimen tray, which presented a slot for excised tissues and integrated optical reference trackers. With this design, it allowed single-object scanning and focused field-of-view. To provide anatomical reference to SPECT scan, a handheld 3D surface scanner (16 frames per second, 0.5 mm resolution) was used. It employs patterns of structured white light that hit the specimens from different angles and positions. The scanner's camera captures light reflections distorted by the sample's surface, to obtain depth and distance data during surface acquisition. In this way, we were able to optically capture shape, texture and volume information of the excised specimens, creating accurate high-resolution three-dimensional models. Subsequently, freehand [99mTc]Tc-PSMA-SPECT scans were obtained using handheld gamma camera and freehandSPECT system [3]. ***Results:*** Back-table PSMA-imaging could be realized by integrating two existing 3D imaging technologies. The sequential morphologic and molecular imaging took approximately 3-4 minutes each. Registrations of surface and SPECT scans could be used to augment a video-view of specimens. The end result was a high-resolution model where ex vivo findings mirror in vivo measurements. Focal areas of intense [99mTc]Tc-PSMA uptake could be displayed, margins could be delineated and correlated with pre-operative imaging and histopathology. ***Conclusion:*** Hybrid [99mTc]Tc-PSMA specimen imaging is feasible by integration of readily available technologies. This strategy could help surgeons that already rely on [99mTc]Tc-PSMA for radioguided surgery, improving intraoperative surgical margin identification for frozen section confirmation. Thus, providing a single-tracer low radiation-dose strategy that fully aligns with surgical needs. ***References:*** 1] Berrens AC et al., Eur Urol Open Sci. 2023 2] Gandaglia G et al., Eur Urol. 2022 3] Engelen T et al., Am J Nucl Med Mol Imaging. 2015.

Our experience in Minimally Invasive Radioguided Parathyroidectomy

J. Cruz, *I. Blanco Saiz, A. Alomar Casanovas, A. Barrera Cerpa, P. Salvador Egea, E. Anda Apiñaniz, C. Villaprado Meza, N. Rudic Chipe, M. Ribelles Segura, P. Boya Roman, L. Paruta Araez, F. Lozada Delgado, A. Camarero Salazar, E. Goñi Gironés; Hospital Universitario de Navarra, Pamplona, SPAIN.*

Aim/Introduction: Aim: To evaluate the results after four years of Minimally Invasive Radioguided Parathyroidectomy protocol in our Centre Minimally Invasive Radioguided Parathyroidectomy (MIRP) is an effective technique since it requires a minimal incision with few complications and short surgical times. It also allows immediate verification of the resection of the parathyroid lesion and is especially of interest in patients with ectopic adenomas or a history of cervical surgery. However, there is large variability in the protocol followed in each hospital. We describe the experience obtained during the application of our own protocol. ***Materials and Methods:*** A prospective study was carried out consecutively including 158 patients with primary hyperparathyroidism who met surgical criteria and underwent MIRP at the same tertiary center between January 2020 and February 2024. All patients underwent preoperative morphofunctional confirmation with US and MIBI SPECT-CT±PET-CT. The procedure consisted of the intravenous administration of 185 MBq. 99mTc-MIBI, approximately one hour before surgery (in all cases, preoperative imaging was acquired at the Nuclear Medicine Department in this interval). Intraoperative localization was performed with a portable gamma camera and a gamma probe, and counts were registered during the procedure. Surgical success was evaluated by intraoperative biopsy. ***Results:*** The mean age was 61 ± 11.36 years with 122 (77.2%) women. Time from MIBI administration to surgery was 88 ± 25min. Successful surgical localization of the parathyroid lesion occurred in 154 patients (98.7%). Imaging acquired the day of the intervention allowed localization of a second lesion in 3 patients, which had not been identified in previous studies.The mean surgical time was 35± 19.56 minutes. The mean weight of the removed lesion was 1276 mg (IQR 1075). The observed count rate in skin was 246.83±74.10 counts per second, adenoma in vivo 308.41±107.86 cps, thyroid bed 197.92±58.14 cps, background 149.46±37.92 cps, and ex vivo adenoma 176.14±115.46 cps. Mean in vivo adenoma/thyroid ratio: 1.61 Mean in vivo adenoma / background ratio: 2.11 ***Conclusion:*** The protocol used allowed us to locate the parathyroid lesion in a high percentage of patients (due to a significant difference in the count rate lesion compared to thyroid and background). Furthermore, in three patients, a second parathyroid lesion (previously unknown) was identified on the day of the intervention, changing the surgical approach protocol. ***References:*** § Isabel Blanco Saiz, Pilar Salvador Egea, Enma Anda Apiñaniz, Nikola Rudic Chipe, Elena Goñi Girones. PET and optical dual-modality image-guided surgery in prostate cancer using ^{68}Ga- PSMA-IRDye800CW

M. Zhang, *W. Yang, F. Kang, J. Wang;*
Xijing Hospital, Xi'an, CHINA.

Aim/Introduction: Although there are many treatment options for prostate cancer, radical prostatectomy is still the most effective treatment method and the first choice for early patients. However, maximum safe resection of prostate cancer lesions remains a major challenge. In order to preserve normal tissue and function as much as possible during surgery, more sensitive and accurate surgical boundary detection technology is needed. In this study, we developed a PET/near-infrared fluorescence (NIRF) dual-mode molecular probe, 68Ga-PSMA-IRDye800CW, for accurate diagnosis and precise resection. ***Materials and Methods:*** PSMA-IRDye800CW was synthesized and labeled with 68Ga. The microPET imaging study was performed in 22Rv1 tumor model with 68Ga-PSMA-IRDye800CW at 0.5, 1 and 2 h post injection (p.i.). Fluorescence imaging study was conducted with the same model using PSMA-IRDye800CW at 1, 3, 8, 24 and 30 h p.i.. ***Results:*** PSMA-IRDye800CW was successfully synthesized with a molecular weight of 2270.6. The radiochemical purity of 68Ga-PSMA-IRDye800CW was greater than 97% after purification. In the PET imaging, the organs with the highest accumulation were kidneys and bladder. Tumors can be clearly visualized with the uptake of 5.62 ± 0.56, 7.02 ± 0.59 and 8.27 ± 0.42 ID%/g at 0.5, 1 and 2 h, respectively. The fluorescence imaging study demonstrated that the highest tumor uptake was achieved at 1h p.i., with the value of 4.97 ± 0.75. After that, the uptake of PSMA-IRDye 800CW in tumors gradually decreased, with the value of 4.63 ± 0.55, 3.27 ± 0.32, 3.03 ± 0.25, and 2.60 ± 0.36 at 3, 8, 24, and 30 h, respectively. ***Conclusion:*** In this study, we reported a PET/NIRF dual-mode molecular probe of 68Ga-PSMA-IRDye800CW, which has high tumor uptake in both PET and fluorescence imaging, and is expected to be used for accurate diagnosis and precise resection of prostate cancer.

Radio-Guided Localization of Small Pulmonary Nodules: Our Experience

A. Calatayud[1], *L. Barberán[1], M. Garrido[1], Z. Nogareda[1], M. Pombo[1], O. Rivas[1], E. Abou Jokh[1], M. Mallón[1], J. Gonzalez-Vara[1], J. García[2], A. Martínez[3], R. Varela[3], I. Abdulkader[4], V. Pubul[5];*
[1]Department of Nuclear Medicine, Hospital Clínico Universitario Santiago Compostela, Santiago de Compostela, SPAIN, [2]Department of Thoracic Surgery, Hospital Clínico Universitario Santiago Compostela, Santiago de Compostela, SPAIN, [3]Department of Radiology, Hospital Clínico Universitario Santiago Compostela, Santiago de Compostela, SPAIN, [4]Department of Histopathology, Hospital Clínico Universitario Santiago Compostela, Santiago de Compostela, SPAIN, [5]Head of the Department of Nuclear Medicine, Hospital Clínico Universitario Santiago Compostela, Santiago de Compostela, SPAIN.

Aim/Introduction: Recent advances in diagnostic imaging have improved the detection of pulmonary nodules, some of which are small or deeply located in the lung, presenting challenges for intraoperative detection. Consequently, minimally invasive surgery (MIS) may not be possible. We evaluated the effectiveness of radio-guided occult lesion localization (ROLL) with [99mTc]-MAA for the detection of pulmonary nodules in our institution. ***Materials and Methods:*** In this retrospective study, 35 patients requiring surgical resection of pulmonary nodules were included. ROLL with [99mTc]-MAA (37 MBq-0.1mL/0.2mL) was performed the day before MIS, with verification of radiopharmaceutical localization using SPECT-CT. Lesion size, resection margins, histology, postoperative complications and recurrences were analyzed. ***Results:*** Between July 2020 and April 2024, 35 patients (27 males, 8 females; mean age: 67.03 years) with millimetric and/or non-palpable potentially resectable pulmonary lesions underwent [99mTc]-MAA injection. Six patients had a history of Chronic Obstructive Pulmonary Disease (17.14%), thirty had an oncological history (85.71%) and nine had previous lung surgery (25.71%). Localization of the lesions was as follows: thirteen in the right upper lobe (34.21%), nine in the left upper lobe (23.68%), nine in the left lower lobe (23.68%), five in the right lower lobe (13.16%) and two in the middle lobe (5.26%), with a mean size of 9.54 mm on CT. All injected lesions were successfully localized intraoperatively. Multiple nodules were observed in four cases, two lesions detected in three patients and three lesions in one patient, the resection of these nodules was performed simultaneously without complications. SPECT-CT identified one case of pleural diffusion, which did not interfere with intraoperative localization. ROLL was repeated in two patients, one due to radiopharmaceutical retention in the injection needle and the other due to induced pneumothorax during marking. Twelve postsurgical complications (34.29%), not associated with the ROLL technique, were identified and categorized into mild and more severe adverse events. Mild complications included surgical wound infection (4 patients, 11.43%) and pleural effusion (3 patients, 8.57%), whereas more serious complications comprised haemorrhage (2 patients, 5.71%), respiratory failure (2 patients, 5.71%) and pneumothorax (1 patient, 2.86%). Pathological findings revealed seventeen patients with primary pulmonary lesions (48.57%), thirteen patients with metastases (37.14%), and five benign lesions (14.29%), all with clear margins. Eleven recurrences were recorded. ***Conclusion:*** Preoperative marking using the ROLL technique has been proven effective and safe for precise intraoperative localization of small pulmonary nodules.

Exploring Intra-Abdominal Nuclear Tomography: Robot-Assisted SPECT in Robotic Sentinel Lymph Node Surgery

S. Azargoshasb[1,2], *A. Berrens[3,2], L. J. Slof[1,2], B. Alp Çakal[4,5], T. Wendler[4,5], M. Sinaasappel[6], P. J. van Leeuwen[2], H. G. van der Poel[2,7], M. N. van Oosterom[1,2], F. W. B. van Leeuwen[1,2];*
[1]Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Cent, Leiden, NETHERLANDS, [2]Department of Urology, Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Amsterdam, the Netherlands, Amsterdam, NETHERLANDS, [3]Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS, [4]Chair for Diagnostic and Interventional Radiology, Faculty of Medicine, University of Augsburg, 86156 Augsburg, Germany, Augsburg, GERMANY, [5]Institute of Digital Medicine (IDM), University Hospital Augsburg, 86356 Neusaess, Germany, Augsburg, GERMANY, [6]Department of Clinical Physics and Instrumentation, Netherlands Cancer Institute, Amsterdam, The Netherlands, Amsterdam, NETHERLANDS, [7]Department of Urology, Amsterdam University Medical Centers, Amsterdam, The Netherlands, Amsterdam, NETHERLANDS.

Aim/Introduction: The introduction of the 'drop-in' gamma probe has transformed the way image-guided robotic surgery

can be performed. This probe is now instrumental for radioguided sentinel node (SN) procedures (i.e., in prostate, cervical, endometrial and bladder cancer). Where typical 'drop-in' gamma probe guidance is based on acoustical and numerical feedback, we set out to further refine surgical perception and decision-making by providing intraoperative 3D imaging. Using a video-tracked 'drop-in' probe we've developed, and clinically evaluated, a gantry-free robot-assisted tomographic imaging approach called robotic-SPECT. ***Materials and Methods:*** We included 10 prostate cancer patients undergoing robotic SN surgery with the hybrid tracer, Indocyanine green (ICG)-99mTc-nanoscan. Following initial SN identification via SPECT/CT their resection was enabled by a combination of 'drop-in' radioguidance and Firefly fluorescence detection. Uniquely the 3 notches in the CE-marked 'drop-in' gamma probe were fitted with 3 sterilizable tracking markers. Custom computer-vision tracking software was used to track the probe's position within the laparoscopic video feed, while recording the probe readings (counts/s). These data streams were processed with a MLEM reconstruction algorithm using a look-up table (LUT) method. The LUT was generated using nuclear Monte Carlo simulations of the detector. The MLEM reconstructions yielded a tomographic SPECT image of the tracer distribution within the volume-of-interest. An image that was overlayed on the laparoscopic view using a custom video-augmentation program. ***Results:*** In the preoperative SPECT/CT scans, a total of 28 SNs were identified, (median 3 per patient, IQR: 2-3). 'Drop-in' empowered robotic-SPECT proved to be feasible and helped to provide a unique 3D-insight into the SN locations. Augmented reality overlays facilitated efficient visualization of target locations within the surgical video feed. The 'drop-in' probe pursued 25 SNs and successfully traced all these nodes with a median count-rate of 290 counts/s. For superficial nodes (19) there was direct concordance between 'drop-in' radioguidance and Firefly fluorescence guidance. However, for the 6 SNs located deeper beneath the tissue-surface only radioguidance helped provide accurate target localization. Pathological evaluation indicated tumor metastases in 3 of the retrieved SNs. ***Conclusion:*** The novel robot-assisted SPECT method was successfully integrated into a real-life robotic surgery setting. The robotic-SPECT visualizations help enhance the target perception within the abdominal cavity. Combining intraoperative SPECT with hybrid tracers compliments superficial Firefly fluorescence imaging techniques.

OP-810

Employing Multispectral Fluorescence Imaging to Distinguish Lymphatic Drainage Patterns During (Sentinel) Lymph Node Dissection in Prostate Cancer

A. C. Berrens[1], *T. Buckle[2], M. N. van Oosterom[2], P. J. van Leeuwen[1], L. Slof[2], E. Wit[1], H. G. van der Poel[1], F. W. B. van Leeuwen[2];*
[1]Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS,
[2]Leiden University Medical Center, Leiden, NETHERLANDS.

Aim/Introduction: Only 10% of removed lymph nodes (LNs) during an extended pelvic lymph node dissection (ePLND) contain prostate cancer metastases, while the resulting lymph edematous complications are around 20-50%. To see if we could omit removal of LNs not related to the cancer (LN-sparing ePLND, if you may) we employed multicolor and multispectral fluorescence imaging to differentiate lymphatic drainage patterns from the primary cancer and healthy tissue. ***Materials and Methods:*** This prospective study (NCT05120973) included 16 patients who underwent robot assisted radical prostatectomy (RARP) + ePLND + a sentinel node (SN) procedure. For the latter, patients received intraprostatic administration of indocyanine green (ICG)-99mTechnetium-nanocolloid and underwent preoperative Single Photon Emission Computed Tomography (SPECT)/CT imaging. Prior to RARP, a second fluorescent dye (Fluorescein) was injected unilaterally in two deposits into the intradermis of the upper leg (n=8) or abdominal wall (n=8). In and ex vivo multispectral fluorescence imaging was performed using an integrated camera in the robotic system and a separate fluorescence laparoscope. Fluorescence data was correlated to histopathological findings. ***Results:*** A median of 6 SNs (interquartile range [IQR] 3-8) were identified per patient on both SPECT/CT and intraoperative ICG imaging. Fluorescein was visible in the ePLND-template (coming from the upper leg; cloquet 5/8 (62.5%), obturator fossa 4/8 (50%), external iliac 4/8 (50%), internal iliac 0/8 (0%) and coming from the abdominal wall; cloquet 7/8 (87.5%), obturator fossa 8/8 (100%), external iliac 6/8 (50%), internal iliac 3/8 (37.5%). Although SNs containing ICG were visible in the lymphatic regions containing Fluorescein, both colors only visibly co-accumulated in two lymph vessels. At pathology, Fluorescein was seen in 10/370 LNs, none of which overlapped with ICG and none were tumor positive. Additional administration of Fluorescein did not result in discomfort at the injection site or abnormal postoperative recovery. ***Conclusion:*** Multispectral fluorescence imaging was feasible during RARP+ePLND+SN. Although we did not encounter 'two-color-staining' in LNs and LNs containing Fluorescein were not tumor-positive, our initial in-human findings indicate that lymphatic drainage patterns of the prostate overlap with those of the lower limbs and abdominal wall. Further studies could determine feasibility of LN-sparing ePLND.

OP-811

Imaging Peritoneal Cancer Index versus surgical Peritoneal Cancer Index in patients with peritoneal metastases

G. Shankaramurthy, *K. Pramukh, N. Sandeep, G. Bharath, R. Sreekanth, A. Khan;*
Fortis hospital, Bengaluru, INDIA.

Aim/Introduction: To determine the accuracy of imaging Peritoneal carcinoma index (PCI) in comparison with surgical PCI to assess the feasibility of cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) in patients with metastatic peritoneal disease ***Materials and Methods:*** 30 patients with metastatic peritoneal disease who underwent F18 FDG PET-CT and laparoscopy within four weeks of F^{18} FDG PET-CT were assessed. Imaging PCI (iPCI) was assessed by two Nuclear Medicine Physicians and surgical PCI (sPCI) was assessed by two Surgical Oncologists via laparoscopy. When available comparison was done with pathological PCI(pPCI) ***Results:*** We included 14 (47 %), 5 (17%), 4(13%), 3 (10%) and 4 (13%) patients with carcinoma ovary, carcinoma colon, carcinoma rectum, carcinoma stomach and miscellaneous tumors respectively. Median imaging PCI score was 10 (IQR:5-26) while that of surgical PCI was 12 (IQR: 5-24). Wilcoxon sign rank test showed that there was no significant difference in the median scores of imaging and surgical PCI (p=0.55). 26 (86 %) patients had a diagnostic PCI score in the range of +/- 4 when compared to imaging PCI. The reasons for difference in each case were noted and discussed. Imaging PCI and diagnostic PCI were not in-line in 04 (14%) patients because of large ascites in 2 patients, miliary bowel surface deposit in 1 patient and sPCI was not correlated with pPCI in 1 patient. In 2 (7%) of these patients imaging PCI correlated with pathological PCI rather than sPCI. In 2 other patients PCI was more than 20 and CRS was not feasible. There was no significant difference in the impact on management guided by iPCI in comparison with sPCI

Conclusion: sPCI is considered more accurate than iPCI which aids in decision-making to continue with CRS-HIPEC. Our study shows that iPCI is accurate in accessing PCI and will guide to avoid diagnostic laproscopy, especially in patients with higher PCI

Drug library screens for identifying pharmaceuticals to enhance cancer response to radioligand therapy
M. Grzmil*[1]*, *L. Cantoni*[1,2]*, F. Mohr*[3]*, R. Schibli*[1,2]*, M. Schottelius*[4,5,6]*, M. Behe*[1]*;*
[1]Paul Scherrer Institute, Villigen PSI, SWITZERLAND, [2]Department of Chemistry and Applied Biosciences, ETH Zurich, Zurich, SWITZERLAND, [3]Pentixapharm AG, Würzburg, GERMANY, [4]Translational Radiopharmaceutical Sciences, Department of Nuclear Medicine and Department of Oncology, Centre Hospitalier Universitaire Vaudois (CHUV) and University of Lausanne (UNIL), Lausanne, SWITZERLAND, [5]AGORA, Pôle de recherche sur le cancer, Lausanne, SWITZERLAND, [6]SCCL Swiss Cancer Center Leman, Lausanne, SWITZERLAND.

Aim/Introduction: The development of molecular strategies to enhance cancer radiosensitivity or tumor uptake of radiopharmaceuticals, while sparing healthy organs, has immense potential to improve the efficacy and safety of radioligand therapy (RLT). Drug library screens represent a promising avenue for identifying pharmaceuticals that can enhance response to cancer therapy. To reveal new therapeutic opportunities for RLT, this study developed drug library screens and validated obtained results employing two models with radiolabeled minigastrin analog (PP-F11N) targeting cholecystokinin B receptor (CCKBR), and PentixaTher (PTH) targeting C-X-C-motif chemokine receptor 4 (CXCR4) positive cancer cells, respectively. ***Materials and Methods:*** Drug library screens, followed by proliferation, internalization, and viability assays, were conducted to identify compounds that increase uptake or cytotoxicity of [177Lu]Lu-PP-F11N and [177Lu]Lu-PTH in human epidermoid carcinoma A431 cells (which overexpress CCKBR) and CXCR4-positive T cell leukemia Jurkat cells, respectively. An A431/CCKBR xenograft mouse model was utilized for biodistribution, SPECT imaging, and in vivo validation of the therapeutic effect of [177Lu]Lu-PP-F11N in combination with identified inhibitors. Dissected tumors and organs were subjected to histological analysis. ***Results:*** A kinase inhibitor library screen comprising 80 inhibitors, followed by in vitro and in vivo validation studies, demonstrated the potential of the mammalian target of rapamycin complex 1 (mTORC1) inhibitor RAD001 (everolimus) to substantially improve tumor-specific uptake (fold 1.79) and therapeutic efficacy of [177Lu]Lu-PP-F11N in A431/CCKBR tumors without adverse effects [1, 2]. An FDA-approved drug library screen with 211 compounds in Jurkat cells identified 21 small-molecule inhibitors that significantly improved the cytotoxicity of [177Lu]Lu-PTH, with 5 compounds showing synergistic interaction. The correlation coefficients for the biological replicates ranged from 0.70 to 0.99, indicating high reproducibility of the established screens. Validation of 10 screen-identified inhibitors confirmed radiosensitizing potential of 6 compounds, including bosutinib, crizotinib, etoposide, everolimus, talazoparib, and YM-155. Development of the combinatory treatments in other cancer models is currently underway. ***Conclusion:*** Our research has

established and optimized drug library screen-based workflows suitable for identifying compounds for tumor radiosensitization and enhancing the uptake of radiolabeled ligands. This work supports and recommends further development of the screen-based discovery of novel combinatory treatments for efficacious and clinically feasible RLT in cancer. ***References:*** 1. Efficient α and ß- Radionuclide Therapy Targeting Fibroblast Activation Protein-α in a Fast-Growing Preclinical Tumour Model

H. Ceuppens[1], *A. Pombo Antunes[2], L. Navarro[2], T. Ertveldt[1], M. Berdal[2], S. Nagachinta[2], K. De Ridder[1], M. Keyaerts[1], N. Devoogdt[1,2], C. Goyvaerts[1], M. D'Huyvetter[1,2], K. Breckpot[1];*
[1]Vrije Universiteit Brussel, Brussels, BELGIUM,
[2]Precirix NV/SA, Brussels, BELGIUM.

Aim/Introduction: Targeted radionuclide therapy (TRT) is an emerging cancer treatment, exhibiting promising therapeutic efficacy across various cancer types. Single domain antibodies (sdAbs), characterized by their compact size, are attractive targeting moieties for TRT due to enhanced tumour penetration and rapid clearance from circulation, thereby minimizing systemic radioactivity exposure. We studied the therapeutic potential of TRT using fibroblast activation protein-α targeting sdAbs (4AH29) labelled with 225Ac or 131I to treat cancer in immunocompetent mice and explored its combination with programmed cell death ligand 1 (PD-L1) immune checkpoint blockade (ICB). ***Materials and Methods:*** Long-term biodistributions of [131I]I-GMIB-4AH29 and [225Ac]Ac-DOTA-4AH29 were determined up to 192 hours post-injection (p.i.) by ex vivo gamma counting. TC-1-FAP lung tumour-bearing C57BL/6 mice received 6 intravenous injections with 18.5 or 37 MBq of [131I]I-GMIB-4AH29, 5 or 20 kBq of [225Ac]Ac-DOTA-4AH29 or vehicle solution over a three-week period. Tumours of [225Ac]Ac-DOTA-4AH29 treated mice were isolated 22 days post-inoculation for flow cytometric analysis. [225Ac]Ac-DOTA-4AH29 treatment was repeated in combination with intraperitoneal injection of anti-PD-L1 or isotype control antibodies on days 8, 15 and 22. Animal welfare was monitored by measuring weights and tumour volumes. ***Results:*** Long-term biodistribution showed high tumour uptake of [131I]I-GMIB-4AH29 with 3.48 ± 0.45% IA/g 1h p.i. decreasing to 0.94 ± 0.13% IA/g after 24h. Tumour uptake of [225Ac]Ac-DOTA-4AH29 was high with 2.10 ± 0.49% IA/g 1h p.i. decreasing to 1.72 ± 0.18% IA/g after 24h. For both radionuclides, elevated kidney retention is seen early after tracer administration due to renal clearance, followed by fast clearance for [131I]I-GMIB-4AH29 while [225Ac]Ac-DOTA-4AH29 had a prolonged renal retention. Survival was significantly improved after treatment with low and high dose [131I]I-GMIB-4AH29 or [225Ac]Ac-DOTA-4AH29 compared to vehicle solution. When comparing treatment efficacy of [225Ac]Ac-DOTA-4AH29 versus [131I]I-GMIB-4AH29, tumour burden was significantly lower for [225Ac]Ac-DOTA-4AH29 treated mice on day 22 and mean survival was more beneficial with 39 days compared to 35.5 days. We observed significantly higher PD-L1 expression in tumours of mice treated with [225Ac]Ac-DOTA-4AH29 compared to vehicle solution on day 22. Therefore, we combined high dose [225Ac]Ac-DOTA-4AH29 with PD-L1 ICB showing delay in tumour growth compared to [225Ac]Ac-DOTA-4AH29 alone. ***Conclusion:*** [225Ac]Ac-DOTA-4AH29 and [131I]I-GMIB-4AH29 exhibit high and persistent tumour targeting, which translated into prolonged survival in mice bearing aggressive tumours. Moreover, we demonstrate the potential of combining [225Ac]Ac-DOTA-4AH29 with PD-L1 ICB, though further optimization of the treatment regimen is required to translate the delay in tumour growth to significantly improved survival.

EPS-255

Intra-patient comparison of normal organ uptake and biodistribution of the [^{68}Ga]FAPI-46 vs [^{18F}]FAPI-74 radiopharmaceutical

A. Deleu[1], *Z. Wimana[1], S. Lacroix[1], S. Vercauteren[1], C. Marin[1], B. Vanderlinden[1], P. Lavis[1], L. Taraji[1], A. Arçay Öztürk[1], P. Flamen[1], B. Bondue[1,2];*
[1]Hôpital Universitaire de Bruxelles (H.U.B), Brussels (Anderlecht), BELGIUM, [2]European Reference Network for Rare Pulmonary Diseases (ERN-LUNG), Frankfurt, GERMANY.

Aim/Introduction: The development of fibroblast activation protein inhibitor (FAPI) radiopharmaceuticals has opened doors for possible groundbreaking research into FAP as a stromal target in different oncologic and nononcologic pathologies. A range of FAPI ligands coupled to different radionuclides has emerged, all showing high lesion-to-background ratios. However, few studies have compared different FAPI radiopharmaceuticals regarding their biodistribution. The aim of this study is to compare the normal organ uptake and imaging properties of the [68Ga]FAPI-46 and the [18F]FAPI-74 radiopharmaceutical in an intra-patient study design. ***Materials and Methods:*** 5 patients underwent both a [68Ga]FAPI-46 and a [18F]FAPI-74 PET/CT with a maximum interval of 12 days between both exams. The activity injected was 3 MBq/kg for [18F]FAPI-74 (with a maximum of 300 MBq) and 2 MBq/kg for [68Ga]FAPI-46. On the 1 hour post injection images of both exams, volumes of interest (VOIs) were drawn in uniform regions of healthy tissues, blood pool sites and reactive uptake foci. VOI diameters ranged from 10 to 15 mm depending on the size of the target tissue. The FAPI uptake was visually analyzed and quantitative PET parameters (SUVmean, SUVmax) were compared using a paired samples t test. ***Results:*** Visual and statistical interpretation of the PET images revealed a significantly higher blood pool activity of [18F]FAPI-74 compared to [68Ga]FAPI-46 at both aortic and left ventricle regions. The p-value of the difference in uptake at the descending aortic VOI was 0,009 for SUVmean and 0,03 for SUVmax values. The spleen SUVmax ($p = 0,04$) and SUVmean ($p = 0,004$) was also significantly higher for [18F]FAPI-74 compared to [68Ga]FAPI-46. Other normal organs as well as reactive tissues showed similar uptake values. Furthermore, a non-negligible intestinal activity was detected at visual interpretation of the [18F]FAPI-74 PET/CT in some patients. Finally, tracer uptake in the nipple regions as well as in the gall bladder fundus was seen for both radiopharmaceuticals. ***Conclusion:*** [18F]FAPI-74 shows a significant higher blood pool activity and similar normal organ uptake values compared to [68Ga]FAPI-46 at 1 hour post injection, making it less appropriate for certain FAPI PET/CT indications such as cardiovascular diseases, as well as for early imaging acquisition protocols.

EPS-256

The impact of different cell models on the preclinical evaluation of FAP-targeting radiopharmaceuticals

C. D. van der Heide, *J. D. Campeiro, E. A. M. Ruigrok, L. van den Brink, S. U. Dalm;*
Department of Radiology & Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: Fibroblast activation protein (FAP) is an attractive cancer-specific biomarker for targeted radionuclide theranostics. Accordingly, FAP-targeting radiopharmaceuticals have shown clinical success for PET/CT imaging. Unfortunately, results with FAP-targeted radionuclide therapy (TRT) have been suboptimal to date. Preclinical research plays a key role in improving FAP-TRT efficacy and selecting the best FAP-targeting radiopharmaceutical for this purpose. For this, selecting an appropriate and clinically relevant tumor model is crucial. Although FAP is mainly expressed by cancer-associated fibroblasts and not by cancer cells, transduced human (hu) FAP-expressing cancer cells are often used as a model. To what extent these models are appropriate for studying FAP-targeting radionuclide theranostics remains unknown. Therefore, we aimed to compare tracer behavior in two commonly used FAP-transduced cancer cell lines (HT1080 (fibrosarcoma) and HEK293 (human embryonic kidney)), one endogenous FAP-expressing glioblastoma cell line (U87MG), and an endogenous FAP-expressing pancreatic stellate cell line (PS-1). ***Materials and Methods:*** Tracer uptake studies were performed by incubating cells with 1 nM 20MBq/nmol [111In]In-FAPI-46 or 10 nM RTX-1370S, a fluorescent FAP-targeting tracer (kindly provided by Ratio Therapeutics). Additionally, membrane-bound versus internalized [111In]In-FAPI-46 was separated using Glycine-NaCl and NaOH, respectively. Radioactivity was measured in a γ-counter and RTX-1370S was imaged by confocal microscopy. Moreover, [111In]In-FAPI-46 autoradiography was performed on HT1080huFAP, HEK293ThuFAP, and U87MG xenografts. Lastly, the expression of human (hu)FAP and murine (mu)FAP was analyzed by IHC and RT-qPCR. ***Results:*** HT1080huFAP had the highest [111In]In-FAPI-46 uptake in vitro (22.4%), followed by HEK293huFAP (17.3%). Unexpectedly, higher FAP expression did not result in higher uptake, as a more intense FAP staining and a 3.5-fold higher mRNA expression were observed for HEK293huFAP vs HT1080huFAP. U87MG and PS-1 demonstrated much lower [111In]In-FAPI-46 uptake (2.2% and 2.9%, respectively). Autoradiography studies indicated similar [111In]In-FAPI-46 binding to HT1080huFAP and HEK293huFAP (31.6% vs 32.6%, respectively), and contrary to in vitro uptake, a remarkable ex vivo binding to U87MG xenograft (15.4%). The presence of muFAP mRNA levels was measured in all xenografts, indicating radiotracer binding is partly facilitated by the infiltration of murine fibroblasts in this model. In addition, confocal microscopy demonstrated potent uptake of RTX-1370S, and while [111In]In-FAPI-46 was mainly internalized in all cell lines, membrane-bound RTX-1370S was visible in one cell line, illustrating that tracer localization can be impacted by the model. ***Conclusion:*** Our data shows that FAP (radio)tracer behavior is model specific and that, depending on the research question, appropriate model selection is crucial for evaluating and understanding FAP-targeting radiopharmaceuticals.

EPS-257

Oxidation-stress related PET imaging monitors therapeutic efficacy of combining PAPR inhibitor with immunotherapy in hepatocellular carcinoma treatment

F. Xiong[1], *Z. Han[2], Y. Yang[1], B. Zhang[1], P. Wang[1], Q. Chen[1], Z. Wang[1], S. Song[1], S. Zou[1], P. You[2], X. Zhu[1], B. Yu[1];*
[1]Department of Nuclear Medicine, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, CHINA, [2]Hubei University of Chinese Medicine, Wuhan, Hubei, CHINA.

Aim/Introduction: Combining poly ADP-ribose polymerase inhibitor (PAPRi), which simultaneously inhibits DNA-based excision repair and cystine transporter SLC7A11, with immunotherapy holds the potential to improve the efficacy of hepatocellular carcinoma (HCC) management. However, monitoring tumor response to the above therapeutic modality remains challenging. Herein, 5-[18F] Fluoroaminosubic acid ([18F]-FASu), an oxidation-stress related positron emission tomography (PET) tracer that targets SLC7A11, was used to assist in the early assessment of tumor responses post combination therapy of PAPRi and anti-PDL1 in Hepa1-6 cell-bearing C57BL/6 mice model. ***Materials and Methods:*** Thirty-two Hepa1-6 cell-bearing C57BL/6 mice were randomly divided into four groups. They were then administered with either a vehicle control, Olaparib (a PARPi) alone, anti-PDL1 alone, or a combination of Olaparib and anti-PDL1 treatment. The effects of treatment in each group were evaluated based on changes in tumor volume and Ki67 staining. Tumor response was further assessed in vivo using [18F]-FASu for PET/CT imaging. PET/CT imaging was performed at Day 8 and Day 10 by tail vein injection of [18F]-FASu and [18F]-FDG. The static images at 60 min p.i. were acquired for 10 min. We also analyzed the correlation between the percentage area of CD8-positive cells and images ***Results:*** The combination of PAPRi and anti-PDL1 had a significant therapeutic effect on tumors, with a statistically markedly difference at day 15. Meanwhile, the expression of the corresponding Ki67 was reduced in the combined treatment group compared to the control group. For [18F]-FASu PET/CT imaging data, SUVmax and Tumor-to-background ratio (TBR) were appreciably lower in the combination treatment group. However, no difference between groups was observed on [18F]-FDG. Pathological analysis at the corresponding time points showed a significant reduction in SLC7A11 expression in the combination treatment group, along with elevated CD8 expression within the tumor. In addition, the percentage of cell area with pathologically positive CD8 expression was negatively correlated with the SUVmax value of [18F]-FASu. ***Conclusion:*** Combination therapy with PAPRi and anti-PDL1 is a promising treatment for HCC. [18F]-FASu PET/CT imaging is powerful in assessing tumor immunity and response to immunotherapy in Hepa1-6 cell-bearing C57BL/6 mice model. This study supports future clinical application of [18F]-FASu PET/CT to guide HCC patients for precise PAPRi plus immunotherapy.

EPS-258

A Mathematical Model for the Investigation of Combined Treatment of Radiopharmaceutical Therapy and PARPi

M. Ryhiner[1], *Y. Song[2], C. V. Gomes Ferreira[1], J. Hong[1], A. Rominger[1], S. Kossatz[2], W. Weber[2], K. Shi[1];*
[1]University of Bern, Bern, SWITZERLAND, [2]Technical University of Munich, Munich, GERMANY.

Aim/Introduction: As radiopharmaceutical therapy (RPT

continues to evolve and the need for mathematical optimization techniques in cancer treatment planning grows, this study introduces a mathematical model that facilitates in silico investigations of combined treatments involving RPT and poly (ADP-ribose) polymerase inhibitors (PARPi). This model incorporates adaptations related to DNA damage response, such as homologous recombination deficiency (HRD) as a prognostic factor, and the radiosensitizing properties of PARPi. It aims to provide an accurate representation of phenotypical variations in radiobiological responses and enable patient-specific customization of therapeutic schedules. ***Materials and Methods:*** The proposed mathematical model uses probabilistic statuses as average to simulate cells in different stages of the cell cycle. It assesses the absorbed dose by DNA based on the decay of 177Lu in various cellular compartments, considering cellular geometry. The effect of PARPi is modeled by the accelerated conversion of single-strand breaks (SSBs) to double-strand breaks (DSBs) due to PARP-trapping in the S phase, while homologous recombination deficiency (HRD) is represented by defects in DSB repair in replicated DNA. The model predicts therapeutic outcomes based on the absorbed radioactive doses by DNA and the resulting radiobiological responses, with DNA DSBs being the critical determinant of cancer cell fate. The model parameters were calibrated using experimental data on cell culture. ***Results:*** Model calibration was performed according to treatment of NCI-H69 cells with 177Lu-DOTA-TOC and PARPi. Three days of PARPi monotherapy reduces cancer cell abundance by 32.3% (Olaparib) and 47.7% (Rucaparib). Rucaparib radiosensitization reduces tumor cells during lutetium therapy by 99.2% and 99.99% (HRD). Established model is used to compare simulated results with in vivo experiments where tumor xenografts are treated with lutetium therapy and radiosensitizers. Highest effect shows Talazoparib (21.9% per ng), followed by Rucaparib (70.2% per µg) and the DNA protein kinase inhibitor Nedisertib (48.3% per µg). Considering protocols of clinical trials, presented model predicts relative tumor shrinking after 14 days of Olaparib (250 mg) combination treatment according to the body weight of the patient (e.g. 60 kg: 99.6%; 90kg: 98.0%). ***Conclusion:*** This study presents a mathematical RPT model that is adjustable for conditions affecting cellular DNA damage response, whereby the effects of PARPi and HRD already are included. This model provides a tool for systematic exploration and optimization of clinical protocols. Further directions will involve enhancement of whole-tissue and whole-body considerations as well as PARPi concentration effects. This study marks a significant step towards the digital twin.

EPS-259

Side-by-side Assessment of $^{[18F]}$Olaparib and $^{[18F]}$Talazoparib for Next-generation PARP Imaging in an HR-Deficient Breast Cancer Xenograft Mouse Model

***S. Stotz*[1,2,3]**, *G. D. Bowden*[4,2,3], *B. J. Pichler*[2,3], *A. Maurer*[2,3];
[1]Department of Drug Design and Pharmacology, University of Copenhagen, Copenhagen, DENMARK, [2]Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, Eberhard Karls University, Tuebingen, GERMANY, [3]Cluster of Excellence iFIT (EXC 2180) "Image Guided and Functionally Instructed Tumor Therapies", Eberhard Karls University, Tuebingen, GERMANY, [4]Department of Radiology, University of Michigan, Ann Arbor, MI, UNITED STATES OF AMERICA.

Aim/Introduction: The clinical relevance of poly (ADP-ribose) polymerase (PARP) as an anti-cancer therapy target warrants the necessity for novel PARP imaging probes with enhanced performance. Isotopologically radiolabeled PARP inhibitors can serve as imaging probes and give insight into drug and target distribution. The first approved PARP inhibitor, olaparib, and the most potent, talazoparib, exhibit considerable differences in their mode of action.1 We preclinically compared 18F-labeled olaparib and talazoparib to assess how these differences influence compound biodistribution and PET imaging performance. ***Materials and Methods:*** $^{[18F]}$Olaparib and enantiomerically pure $^{[18F]}$talazoparib synthesized via previously published procedures.2,3 Binding to PARP1 was validated through uptake assays in HCC1937 cells. In vivo, NOD.CB17-Prkdcscid/J mice bearing HCC1937 xenografts (n=5) underwent PET imaging (1h dynamic immediately p.i. and 10 min static 2h p.i. of 12.6±0.6MBq $^{[18F]}$olaparib or 13.1±0.7MBq $^{[18F]}$talazoparib) and an anatomical MR scan. Both dynamic PET data and ex vivo by gamma-counting of selected organs were used for biodistribution analysis. Xenograft tissue was probed for PARP1 expression by immunofluorescence microscopy. ***Results:*** Both radiotracers exhibited excellent binding to HCC1937 cells in vitro, with over 99% blockability by non-radioactive talazoparib and olaparib. Notably, talazoparib significantly inhibited more radiotracer signal than olaparib in both cell-based and in vivo competition assays. In vivo, $^{[18F]}$olaparib showed less renal uptake compared to $^{[18F]}$talazoparib as indicated by a significant difference in absolute kidney uptake ($p < 0.0001$). Both exhibited rapid blood clearance (calculated blood half-lives: 2.2 min ($^{[18F]}$olaparib) and 3.3 min ($^{[18F]}$talazoparib). The majority of radiotracer signal localized in excretion-related abdominal tissues (liver, kidney, and intestine). Interestingly, significant differences in spleen ($p<0.0001$) and lung ($p=0.004$) uptake were observed, suggesting a potential secondary target of $^{[18F]}$talazoparib due to differential selectivity. The HCC1937 xenografts exhibited comparable $^{[18F]}$olaparib and $^{[18F]}$talazoparib signals over time, with mean tumor-to-muscle ratios of 2.3±0.7 and 1.82 ± 0.44, respectively, 3h p.i.. ***Conclusion:*** Both radiotracers displayed comparable tumor uptake; however, the variance in lung uptake may indicate additional binding of $^{[18F]}$talazoparib to other targets such as PARP5a and b. The distinct mode of action suggests that $^{[18F]}$talazoparib may offer new insights into studying PARP enzymes beyond PARP1.4 Our data support the feasibility of $^{[18F]}$olaparib and $^{[18F]}$talazoparib-PET in mice and advocate for further exploration of secondary targets for $^{[18F]}$talazoparib in genetically engineered tumor models and ultimately in patients. ***References:*** 1LaFargue et al., LancetOncol, 2019 2Bowden et al., OrgBiomolChem, 2021 3Bowden et al., JMedChem, 2021 4Carney et al., NatCommun, 2018

EPS-260

Early chemotherapeutic imaging response assessed by FDG-PET, T2-weighted and diffusion-weighted MRI in patient-derived endometrial cancer mouse models

***H. Espedal*[1,2]**, *J. M. Lyngstad*[2], *H. F. Berg*[2], *M. E. Hjelmeland*[2], *K. E. Fasmer*[3], *C. Krakstad*[2], *I. S. Haldorsen*[3,2];
[1]The University of Western Australia, Perth, AUSTRALIA, [2]University of Bergen, Bergen, NORWAY, [3]Haukeland University Hospital, Bergen, NORWAY.

Aim/Introduction: Chemotherapy with combined carboplatin and paclitaxel is often used as first-line treatment in advanced or recurrent endometrial cancer. Evaluation of treatment response routinely includes diagnostic imaging weeks to months after treatment, and the assessments are mostly based on changes in tumor size or appearance of new metastases. The aim of this study was to evaluate early chemotherapeutic response in two subcutaneous organoid-based patient-derived

(O-PDX) endometrial cancer models using T2-weighted (T2w) magnetic resonance imaging (MRI), diffusion-weighted (DW) MRI and dynamic fluorodeoxyglucose (FDG) positron emission tomography (PET). ***Materials and Methods:*** Mice had bilateral subcutaneous injections of chemotherapy-responding (nr=8 mice) or mixed/poor response (nm=7 mice) organoids from two different grade 3 endometrioid endometrial cancers. Mice were monitored biweekly by palpation and when the mean tumor size was >80 mm3, mice were randomized into treatment (combined carboplatin and paclitaxel, nr=8 tumors /nm=6 tumors) or control (saline, nr=8 tumors/nm=8 tumors) groups. The mice underwent T2-weighted MRI, DW-MRI and FDG-PET at baseline/day 0 (before start of treatment), at day 3 and at day 10/endpoint using a sequential PET-MRI small-animal scanner. All tumors were manually segmented on T2w-MRI, and tumor volume (vMRI) and mean tumor apparent diffusion coefficient (ADCmean) were measured. Standard uptake values (SUV) from the 10 most FDG-avid tumor voxels (SUV10) and tumor metabolic rate (MRFDG) were calculated from static and dynamic FDG-PET, respectively. At endpoint, cell density was calculated by semi-automatically counting tumor cells on hematoxylin and eosin (HE)-stained tissue sections. ***Results:*** In the responding model, tumor MRFDG was significantly lower on day 3 in the treatment- compared to the control group (p=0.03). At endpoint, MRFDG, SUV10, vMRI and cell density were significantly lower, whereas tumor ADCmean was significantly higher in the treatment groups vs. control group (p≤0.04), all suggesting treatment response. In the mixed-response model, vMRI and SUV10 were significantly lower in the treatment group compared to control at endpoint (p≤0.04), and tumor ADCmean was significantly higher in the treatment group (p=0.03), suggesting treatment response. Cell density tended to be lower in treated vs. control tumors (p=0.09). None of the imaging parameters were significantly different between the two groups in this model at the early timepoint (day 3). ***Conclusion:*** Multimodal imaging by MRI and dynamic FDG-PET is feasible for evaluating treatment response in subcutaneous preclinical endometrial cancer models. MRFDG from dynamic PET may particularly represent a promising imaging marker for detecting early treatment response following chemotherapy.

EPS-261

In Vitro Interaction Studies of PSMA-617 with Human ABC and SLC Transporters

H. Taş[1], *G. Bakos[1], U. Bauder-Wüst[1], M. Schäfer[2], Y. Remde[2], M. Roscher[2], M. Benešová-Schäfer[1];*
[1]German Cancer Research Center (DKFZ), Research Group Molecular Biology of Systemic Radiotherapy, Heidelberg, GERMANY, [2]German Cancer Research Center (DKFZ), Service Unit for Radiopharmaceuticals and Preclinical Trials, Heidelberg, GERMANY.

Aim/Introduction: Globally, advanced metastatic castration-resistant prostate cancer (mCRPC) remains a lethal challenge for patients and healthcare systems with low 5-year survival rates, desperately calling for improved treatment regimens. Many novel treatment modalities have arisen and, recently, [177Lu]Lu-PSMA-617 has been successfully approved by the FDA, MHRA, Health Canada and EMA as Pluvicto®. However, shortcomings remain as undesired radioligand uptakes in healthy salivary glands (SG) and kidneys, with much lower PSMA expression levels, account for main dose-limiting side-effects such as xerostomia and renal dysfunction. Non-PSMA-specific uptake mechanisms are hypothesized to factor in [1], which remain unclear and call for urgent elucidation. Recently, different ATP-binding cassette (ABC; BCRP, MDR1, MRP1, MRP4) and solute cassette (SLC; MATE1, MATE2-K, OAT1, OAT2v1, OAT3, OAT4) transporters have been verified in humans SGs and kidneys [2]. In this study, it was examined whether these ABC and SLC transporters account for the efflux and uptake of [177Lu]Lu- and [225Ac]Ac-PSMA-617 in SGs and kidneys. ***Materials and Methods:*** For in vitro transporter inhibition (ABC) and substrate (SLC) studies ([α,β-3H]Nal)Lu-PSMA-617 [3], an isotopologue of [177Lu]Lu-PSMA-617, was used as the test substance (TS) in HEK293, Sf9, CHO-K1 and MDCKII cell lines or vesicles expressing human ABC (BCRP, MDR1, MRP1 and MRP4) and SLC (MATE1, MATE2-K, OAT1, OAT2v1, OAT3, OAT4) transporters. Corresponding probe substrates and reference inhibitors were used as appropriate controls. ***Results:*** Vesicular transport inhibition (ABC) assays were conducted at two different TS concentrations (0.3, 3.0 nM) and indicated no significant inhibition as values remained far under 20%. Vesicular transport substrate (SLC) assays were conducted at two different TS concentrations (0.03, 0.3 nM) and incubation periods (2, 20 min) indicating no active accumulation of ([α,β-3H]Nal)Lu-PSMA-617 to any examined cell lines. The results were further verified by fold accumulation calculations. In all assays, positive control probe substrates and inhibitors worked as anticipated. ***Conclusion:*** Our results conclude that human ABC and SLC transporters do not contribute to the uptake and retention of [177Lu]Lu-PSMA-617 and [225Ac]Ac-PSMA-617 in healthy SGs and kidneys. Hypothesizing that molecular sizes, ionic charges and potential binding sites of PSMA-targeted ligands remain crucial in understanding non-PSMA-specific transport mechanisms, further investigations are mandatory in future instances. ***References:*** [1] Rupp et al., J. Nucl. Med. 2019, 60, 1270-1276. [2] Lapczuk-Romanska et al., Int. J. Mol. Sci. 2019, 20. [3] Bauder-Wüst et al., Appl. Radiat. Isotopes 2023, 197, 110819.

EPS-262

Validation of 6-bromo-7-[^{11}C]methylpurine for measuring the function of multidrug resistance-associated proteins in various human tissues using long axial-field-of-view PET/CT

M. Jackwerth;
Medical University of Vienna, Department for Clinical Pharmacology, Vienna, AUSTRIA.

Aim/Introduction: The adenosine triphosphate-binding cassette transporter multidrug resistance-associated protein 1 (MRP1) has a widespread tissue distribution. It effluxes various exogenous and endogenous compounds from cells and has been implicated in the pathophysiology of Alzheimer's and chronic respiratory disease. The novel radiotracer 6-bromo-7-[^{11}C]methylpurine ([^{11}C]BMP) has been used to measure MRP1 function in the mouse brain and lungs with PET. [^{11}C]BMP crosses cellular membranes by passive diffusion followed by intracellular conjugation with glutathione (GSH) and MRP1-mediated efflux of the radiolabelled GSH-conjugate. The aim of this first-in-human study was to validate [^{11}C]BMP for measuring the function of MRP1 and other MRP subtypes in various tissues. ***Materials and Methods:*** 13 healthy volunteers underwent dynamic whole-body PET-imaging on a long axial-field-of-view (LAFOV) PET/CT system (FOV:106 cm) after i.v. injection of [^{11}C]BMP (374±30 MBq). Seven subjects underwent a second [^{11}C]BMP PET scan after oral administration of the prototypical organic anion transporter inhibitor probenecid. Venous blood was collected during and urine after the PET scan and analysed with HPLC for GSH-conjugate conversion. Volumes of interest were outlined for the aorta descendens, lungs, cerebral cortex, kidneys, urinary bladder, liver, myocardium, and retina to extract time-activity curves (TACs). The elimination rate constant

(kE) for radioactivity washout from different organs was estimated by linear regression analysis of the natural logarithm-transformed organ TACs from 15 to 90 min after radiotracer injection. In addition, the renal plasma clearance (CLrenal, mL/min) of the radiolabelled GSH-conjugate was calculated. ***Results:*** At 5 min after [^{11}C]BMP administration, 64±6% of radioactivity in plasma represented the corresponding GSH-conjugate. Radioactivity was primarily excreted into the urinary bladder. In contrast to mice, radioactivity was very slowly eliminated from the human brain (cortex: kE: mouse: 1.3±0.06 1/h, human: 0.05±0.01 1/h). Following probenecid administration, kE values were significantly decreased in plasma (-40±10%), lungs (-18±12%), kidneys (-32±45%), liver (-19±13%), and retina (-57±28%), while no significant changes were found in the brain and myocardium. CLrenal of the radiolabelled GSH-conjugate was significantly decreased after probenecid administration (-63±19%). ***Conclusion:*** The use of LAFOV PET/CT enabled a simultaneous assessment of the function of MRP transporters with [^{11}C]BMP in various human tissues. Following administration of probenecid, radioactivity elimination was significantly decreased in the lungs, kidneys, liver, and retina, suggesting an involvement of different MRP subtypes. As opposed to mice, radioactivity was very slowly eliminated from the human brain, indicating substantial species differences in the abundance of transporters involved in the brain elimination of the radiolabelled GSH-conjugate.

EPS-263

Construction of multi-modal integrated probe targeting TfR and synergistic enhancement of immune response in triple negative breast cancer

B. Gu, *Z. Yang, X. Du, S. Song;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: This study aims to design a theranostic nanoprobe GA-Fe@Tf-131I and investigate its anti-tumor and enhanced immune therapy performances against triple-negative breast cancer (TNBC). ***Materials and Methods:*** GA-Fe@Tf-131I nanoprobe was prepared by a three-step method, and then a series of physical and chemical characterization were conducted on their morphology, structure, stability, etc. The targeting, therapeutic, immunosensitizing properties and biocompatibility of GA-Fe@Tf-131I nanoprobe were verified in vitro and in vivo. The anti-tumor activity and immune sensitization of GA-Fe@Tf-131I nanoprobe were investigated with TNBC tumor bearing mice. ***Results:*** The hydration particle size of GA-Fe@Tf-131I nanoprobe was 11.7 nm. MR T1 relaxation rate of GA-Fe@Tf-131I nanoprobe was 0.98 mmol·L-1·S-1. The photothermal conversion efficiency was about 66.84%. On the cellular level, CCK-8 assay showed that GA-Fe@Tf nanoprobe had no side effects, while labeled with radionuclide 131I or irradiated with NIR laser could kill TNBC cells. The results of cell radionuclide assays showed that GA-Fe@Tf-131I nanoprobe could specifically target TNBC cells. Calcein-AM/PI fluorescence experiment and Annexin V/PI apoptosis experiment results showed that a low temperature thermal (43°C) or a low dose of radionuclide (200 μCi/mL) could inhibit tumor growth, and the combined effect of both was better. Multimodal imaging showed that GA-Fe@Tf-131I nanoprobe could specifically aggregate in TNBC tumor tissue, and was mainly metabolized through liver and kidney. In vivo anti-tumor results showed that low temperature photothermal combined with low dose radionuclide treatment could effectively inhibit tumor growth and induce auto-immune response in collaboration with KN046. The contents of immunopositively regulated cells, such as DCs, CD4+ T and CD8+ T cells, in tumor tissue were significantly increased, while the number of immunonegatively regulated cells, such as Treg cells, decreased significantly. GA-Fe@Tf-131I nanoprobe had no obvious toxic and side effects on normal tissues and organs and functions, representing a good biocompatibility. ***Conclusion:*** The GA-Fe@Tf-131I nanoprobe prepared in this study has tumor-specific targeting performance, anti-tumor property and immune sensitization performance, and can be used for multi-modal imaging and multi-means treatment, which is expected to provide a new, effective and safe integrated nanoprobe for diagnosis and treatment of patients with TNBC.

EPS-264

Evaluating the immune response activation by targeted radionuclide therapy: towards a correlation between dose and response

J. Perrin[1], *N. Overdevest[1], G. Tamborino[1], J. Nonnekens[2];*
[1]Erasmus mc, rotterdam, NETHERLANDS,
[2]Erasmus mc, Rotterdam, NETHERLANDS.

Aim/Introduction: Targeted radionuclide therapy (TRT) consists of the injection of a radiolabeled vector targeting cancer cells. This allows the irradiation of the primary tumor and metastases while mostly sparing the healthy tissues. This led to clinical successes in neuroendocrine and prostate cancer for a proportion of the patients, but current treatments do not lead to cure. Furthermore, there is still little known about the immunogenic potential of TRT and thus whether it could synergize with immunotherapies which has shown potential for external beam radiotherapy. The aim of our study is to assess the immunogenicity of TRT using available literature data. ***Materials and Methods:*** Among the 1074 studies included in our search, 25 met inclusion criteria. To compare the large variety of TRT strategies used, the dose (rate) delivered at the tumor site in vivo or to cultured cells in vitro was calculated. Next, the correlation between the delivered dose (rate) and the % of change in various immune parameters between the control and TRT condition was evaluated. ***Results:*** A strong, significant correlation ($R>0.7$, $p<0.05$) was observed between early factors of the immune response, such as calreticulin tumor expression and TNF-α secretion, and the absorbed dose of TRT. Interestingly, a stronger correlation was observed when the dose rate was taken into account rather than the cumulated dose, suggesting the dose rate is better suited to predict TRT immunogenicity. Immune markers related to the tumor specific lysis also seemed to show a dose rate-dependent increase, however not enough data was available to establish a correlation. At the opposite, later immune parameters like CD8 or CD4 T cells tumor infiltrate did not show any correlation with the absorbed dose or dose rate. ***Conclusion:*** This highlights that TRT can be immunogenic, and a correlation with the dose (rate) is observed for some elements of the immune response. However, the various way of measuring each immune markers and the different time points used in literature introduce a bias in our analysis. This might explain why, even though some parameters are increased after TRT, no correlation with the dose is observed. Nevertheless, increased knowledge on which dose (rate) is necessary for TRT to modulate the immune microenvironment is crucial to move forward with immunotherapy combination. Further experiments aiming to understand the underlying mechanisms of the observed correlations will allow to identify which dose is best suited to induce immunogenic effects.

EPS-265

Potassium Channel Kv1.3 Targeted Immuno-PET Imaging for Diagnosing and Monitoring Active Rheumatoid Arthritis

S. Cheng, *X. Lan, D. Jiang;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, CHINA.

Aim/Introduction: Rheumatoid arthritis (RA) is a chronic inflammatory disease afflicting approximately 1% of the population worldwide. Current methods for diagnosing and monitoring early-stage RA have limited sensitivity and do not aid in identifying potential candidates for immune-mediated therapy. The Kv1.3 potassium channel plays a crucial role in regulating the activation of effector memory T lymphocytes (TEM cells), which are major drivers of inflammation in active RA(1). Herein, we developed and evaluated the potential of a new Kv1.3 targeting radiopharmaceutical, 68Ga-NOTA-AbKv1.3, in accurately monitoring and quantifying joint inflammation in a mouse model of RA. ***Materials and Methods:*** We developed a Kv1.3-targeted radiotracer by labeling gallium-68 (68Ga, T1/2=68 min) to an anti-Kv1.3 antibody (AbKv1.3) after its chelation with NOTA. After evaluating the radiolabeling yield, radiochemical purity, and stability, we performed micro-PET/CT imaging on DBA/1 mice with type II collagen-induced unilateral arthritis. Joint tissues were subsequently collected for further immunohistochemical and immunofluorescence staining. ***Results:*** 68Ga-NOTA-AbKv1.3 was synthesized with high radiolabeling yields and radiochemical purity. PET results reveled a significantly higher concentration of radioactivity in inflamed joints compared to normal joints at different time points. ROI analysis demonstrated that arthritis sites exhibited the highest uptake of 11.73 %ID/g at 4 h, while non-inflamed joints had only 1.55 %ID/g. Histological analysis further confirmed the distribution of T cells at the inflammatory sites and their high expression of Kv1.3 channels. ***Conclusion:*** We successfully developed 68Ga-labeled Kv1.3-targeting antibody probes. Targeting Kv1.3 expression in activated T cells enabled the visualization of active inflammation in arthritis joints. The results demonstrate the potential of 68Ga-NOTA-AbKv1.3 immuno-PET imaging for sensitively and accurately diagnosis of RA at early stage. ***References:*** (1) Wulff H, Castle NA, Pardo LA. Voltage-gated potassium channels as therapeutic targets. Nat Rev Drug Discov. 2009;8:982-1001.

EPS-266

Multi-time-point [18F]FDG-PET/CT for monitoring a combined anti-PD-L1/anti-CTLA-4 immunotherapy in a murine melanoma model with multiparametric immunohistochemical validation

M. Antons[1], *S. Kloiber-Langhorst[1], H. Hirner-Eppeneder[1], R. Schaefer[2], J. Stueckl[1], G. Palumbo[2], R. Oos[2], S. Lindner[2], S. Ziegler[2], M. Brendel[2], J. Ricke[1], M. Heimer[1], C. C. Cyran[1];*
[1]Department of Radiology, University Hospital, LMU Munich, Munich, GERMANY, [2]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY.

Aim/Introduction: Immune checkpoint inhibition (ICI) has shown promising results in malignant melanoma, but not all patients respond equally well, which necessitates early and accurate monitoring of immunotherapy response. [18F]FDG-PET/CT aids in characterizing therapy response beyond morphology, but validated imaging biomarkers of immunotherapy response are currently unavailable. Therefore, the aim of this study was to investigate a three-time point [18F]FDG-PET/CT protocol to monitor a combined anti-PD-1/anti-CTLA-4 immunotherapy in melanoma allografts. In vivo semi-quantitative PET parameters were validated by a multiparametric immunohistochemical reference standard as imaging biomarkers of therapy response. ***Materials and Methods:*** Melanoma cells (B16-F10) were injected subcutaneously into the left flank of C57BL/6 mice (n=40). 7 days post-inoculation, baseline [18F]FDG-PET/CT was conducted. Animals were randomized into two groups; the therapy group received 5 i.p.-injections of anti-PD-L1 and anti-CTLA-4 antibodies (20 µg/kg) on days 7, 9, 11, 13 and 15, while the control group received sham treatment. Follow-up PET/CT was performed on days 13 (FU1) and 19 (FU2). Tumor allografts were harvested at each time point for immunohistochemistry (CD8, Ki-67, TUNEL) to validate imaging parameters (MTV, SUVmax). ***Results:*** At FU1, a significantly lower MTV was observed in the therapy group than in the control group (0.12 ccm vs. 0.35 ccm, p= 0.017). At FU2, both MTV and SUVmax were significantly lower in the therapy than in the control group (MTV: 0.36 ccm vs. 1.01 ccm, p= 0.0012; SUVmax: 4.73 vs. 7.17, p= 0.000025). Ex vivo immunohistochemical validation at FU1 and FU2 showed significantly higher apoptosis in the therapy than in the control group (FU1: 43.85% vs. 14.71%, p= 0.028; FU2: 56.43% vs. 20.28%; p= 0.0000078) as well as a significantly higher number of CD8-positive cells at FU2 (225.83 vs. 55.3, p= 0.019). At FU1 and FU2, tumor cell proliferation was significantly lower in the therapy group than in the control group (FU1: 31.88% vs. 61.31%, p= 0.0042; FU2: 32.23% vs. 55.56%, p= 0.001). ***Conclusion:*** Multi-time point [18F]FDG-PET/CT allowed for the early non-invasive monitoring of a combined immunotherapy with anti-PD-1/anti-CTLA-4 in experimental melanomas, validated by multiparametric immunohistochemistry. The significantly lower tumor glucose metabolism was paralleled by significant pro-immunogenic, pro-apoptotic and anti-proliferative effects of the combined immunotherapy.

EPS-267

Reprogramming the tumor microenvironment by targeting tumor-associated macrophages with mannosylated liposomes that deliver zoledronic acid

G. Lee[1,2,3], *E. Cho[1,2,3], S. Oh[1,2,3], K. Kang[1,2,3], H. Youn[2,3,4];*
[1]Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [2]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [4]Cancer Imaging Center, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Immune checkpoint inhibitors (ICIs) are less effective in cold tumors characterized by a prevalence of M2-like, anti-inflammatory tumor-associated macrophages (TAMs). To address this, we developed mannosylated liposomes (M-lipo) to target M2-like TAMs and deliver zoledronic acid (ZA), which blocks M2-like polarization and promotes M1-like polarization. This study aims to evaluate the ability of ZA-encapsulated M-lipo (M-lipo/ZA) to modulate the tumor microenvironment (TME), transforming cold tumors into immunologically hot tumors to enhance ICI efficacy. ***Materials and Methods:*** Female C57BL/6 mice (8-week-old, n=10) were used for tumor inoculation. After subcutaneously inoculating Nanoluciferase-expressing MC38 (MC38-Nluc) into the left leg and B16F10 (B16F10-Nluc) into the right leg, the mice were then divided into two groups. For ZA treatment, mice received 2 mg/kg ZA, and for ICI combination therapy, they were given 100 µg/kg ZA and 1 mg/kg anti-PD-1 monoclonal antibody (mAb) every two days. TAMs were analyzed

using flow cytometry and immunohistochemistry. Liposomes and M-lipo were radiolabeled with 111In-NOTA-N3 for SPECT/CT imaging of mice which was acquired at time points. ***Results:*** In vitro flow cytometry and Western blot results demonstrated that treatment of RAW264.7 cells with M-lipo/ZA reduced CD206 and Arg1 (M2 marker) expression by more than half. In a mouse model, flow cytometry analysis showed that treatment of B16F10 ("cold") tissues with M-lipo/ZA resulted increased iNOS expression by 3.4% and decreased CD206 expression by 29.9% compared to controls. These indicate a similar percentage of TAMs as in MC38 ("hot") controls, suggesting the potential for converting cold tumors to hot tumors. This is consistent with immunohistochemistry showing a similar phenotype of TAM infiltration in these two groups. Tumor volumes of the M-lipo/ZA treatment group and ICI combination treatment group were significantly smaller than those of the control group ($P < 0.01$). Importantly, a high anti-tumor effects was confirmed even in cold tumors. SPECT/CT results showed hepatic uptake of M-lipo was too high to confirm tumor targeting, but the pattern of liposomes migration into tumor tissue was confirmed. Further research is needed by optimizing the conditions. ***Conclusion:*** M-lipo/ZA effectively targets TAMs in the TME and induces a phenotypic shift from M2 to M1, supporting its potential to enhance ICI responsiveness. It is worth noting that M-lipo exhibited a trend of improved inhibitory effect on the M2 polarization of macrophages compared to free ZA, which may be attributed to the dual function of active targeting and promoting polarization of mannosylated nanocarriers.

EPS-268

Detection of inflammation-related blood-brain barrier disorders using PET and MRI imaging - a pilot study

C. Hilbrig[1], *W. Sievert[2], C. Solbach[3], B. Baumann[2], M. Huber-Lang[2], A. J. Beer[1], V. Rasche[2], J. Loeffler[1];*
[1]Ulm University medical centre, departement of nuclear medicine, Ulm, GERMANY, [2]Ulm University, Ulm, GERMANY, [3]Ulm University medical centre, Ulm, GERMANY.

Aim/Introduction: Precise techniques for monitoring brain barrier dysfunction following a neuroinflammatory state after, e.g., traumatic brain injury are among the most important targets in both trauma research and care, as they pose the potential for organ dysfunction or even failure. While various blood markers have been investigated, some of which indicate the presence of blood brain barrier (BBB) dysfunction, they have proven insufficient to provide specific insights into the localization or severity of such dysfunction. In a transgenic mouse model displayed intracerebral neuroinflammation, initial attempts have been made to evaluate [89Zr]Zr-DFO-HSA as a potential radiotracer for non-invasive monitoring of brain barrier dysfunction by PET and MRI scans. ***Materials and Methods:*** The radioligand [89Zr]Zr-DFO-HSA was injected i.v. into mice exhibiting neuroinflammation (n = 3) and control mice (n = 4). PET and MR imaging were conducted to assess in vivo biodistribution of [89Zr]Zr-DFO-HSA over 24h. Subsequently, intracerebral accumulation of labeled HSA was verfied via ex vivo γ-counter analysis and autoradiography. Intracerebral morphological alterations were further assessed on a cellular level by histological staining analysis. The PET and MRI data were analyzed in PMOD, the statistical analysis in GraphPad Prism. Ver. 10 ***Results:*** Based on PET and MR imaging, a noticeably higher tracer signal was observed in the cerebellum region of the intervention mice. Quantitative analysis of the in vivo PET data revealed an elevated intracerebral tracer concentration over the measurement period in the neuroinflammatory mice (0.99 ± 0.08%IA/mL), compared to the control animals (0.81 ± 0.06%IA/mL), a trend further supported by ex vivo analysis. Autoradiography subsequently confirmed the PET findings, demonstrating an increased tracer signal within the cerebellum of the neuroinflammatory mice. ***Conclusion:*** The application of [89Zr]Zr-DFO-HSA has proven successful in monitoring BBB dysfunctions in a neuroinflammatory mouse model. PET and MRI data depicted a heightened concentration of labeled HSA, validating the anticipated alterations in BBB permeability linked to neuroinflammation. Beyond discerning differences in barrier permeability, the study highlighted the accumulation of the radiotracer in areas known to be most heavily influenced by neuroinflammation, the cerebellum. Consequently, the efficacy of labeled albumin as the radiotracer in this study highlighted its sensitivity in detecting BBB disruption and established it as a valuable tool for monitoring disease progression. The non-invasive nature of PET imaging with [89Zr]Zr-DFO-HSA enhances its translational potential and makes it a promising candidate for further preclinical investigations of various barrier disorders and possibly for future clinical applications.

EPS-269

Preclinical Evaluation of DNA Damage Response Inhibitors and ^{225}Ac-DOTA-girentuximab Combination Therapy

Z. Cao[1,2,3], *C. W. Wichmann[1,2,3], A. Ivashkevich[4], A. Zimmermann[5], C. Sirrenberg[5], H. Dahmen[5], N. Guo[1], F. E. Scott[1,2], M. Wheatcroft[4], A. M. Scott[1,2,3];*
[1]Olivia Newton-John Cancer Research Institute, Heidelberg, AUSTRALIA, [2]School of Cancer Medicine, La Trobe Univeristy, Bundoora, AUSTRALIA, [3]Department of Molecular Imaging and Therapy, Austin Health, Heidelberg, AUSTRALIA, [4]Telix Pharmaceuticals, Melbourne, AUSTRALIA, [5]Merck Healthcare KGaA, Darmstadt, GERMANY.

Aim/Introduction: Cancer cells can repair therapy-induced DNA damage through DNA Damage Response (DDR) mechanisms, leading to therapeutic resistance. DDR inhibitors (DDRi) have been developed to overcome this challenge. In the field of radioimmunotherapy, enhancing the biologic effect of radiation dose to tumour could widen the therapeutic window, and achieve greater responses to treatment and lower doses. This study aims to investigate anti-tumour effect of combining DDRi with 225Ac-DOTA-girentuximab that targets CAIX expressed by SK-RC-52 renal cancer cells. ***Materials and Methods:*** Girentuximab was conjugated with DOTA (1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid) chelator for 225Ac radiolabelling. To assess cytotoxicity, we performed clonogenic assays to determine half-maximal inhibitory concentration (IC50) values for 225Ac-DOTA-girentuximab and DDRi, specifically lartesertib targeting ataxia telangiectasia mutated protein (ATM) and peposertib targeting DNA-dependent protein kinase (DNA-PK). Levels of different molecular markers related to DDR were quantified by Meso Scale Discovery (MSD) and Luminex assays Additionally, we investigated the in vitro anti-tumour efficacy of the combined treatment comprising 225Ac-DOTA-girentuximab and DDRi. ***Results:*** Lartesertib and peposertib exhibited IC50 values of 3.543 µM and 0.7712 µM, respectively, for SK-RC-52 cells. The IC50 value for 225Ac-DOTA-girentuximab in SK-RC-52 cells was 0.1505 kBq/mL. Synergy mapping analysis of the clonogenic assays, which included the combination treatment of 225Ac-DOTA-girentuximab and lartesertib, revealed an additive effect. The combination of 225Ac-DOTA-girentuximab with peposertib, in contrast, exhibited a synergistic effect. Combination Index (CI) analysis revealed a CI value of 0.760 for the 225Ac-DOTA-girentuximab

+ peposertib combination therapy, corroborating the observed synergistic effect (defined by CI ≤ 0.8). The CI value for 225Ac-DOTA-girentuximab + lartesertib was 0.985, indicating an additive effect (defined by 0.8 < CI < 1.2). The MSD assay demonstrated a positive correlation between DNA-PK phosphorylation and the doses/treatment duration of 225Ac-DOTA-girentuximab. While increased phosphorylation of ATM and KRAB-associated protein (KAP) was also observed with higher doses and longer treatment durations of 225Ac-DOTA-girentuximab, the trend was less pronounced compared to phosphorylated DNA-PK. ***Conclusion:*** The combination of 225Ac-DOTA-girentuximab and DDRi proved to be more effective than either monotherapy alone. The synergistic effect was evident with 225Ac-DOTA-girentuximab + peposertib, whereas 225Ac-DOTA-girentuximab + lartesertib exhibited an additive effect. Analysis of DDR biomarkers indicated elevated levels of DNA-PK phosphorylation, with phosphorylated ATM showing a comparatively lesser increase. Future studies will be extended to in vivo models to determine the optimal dosing combination for potential human trials.

EPS-270

Development of Girentuximab as a theranostic tool in non-renal indications

A. Ivashkevich[1], *S. Belderbos[2], P. Provent[2], S. Gribble[1], M. P. Wheatcroft[1];*
[1]Telix Pharmaceuticals, Melbourne, AUSTRALIA,
[2]Oncodesign Services, Dijon, FRANCE.

Aim/Introduction: Girentuximab is a human antibody targeting carbonic anhydrase IX (CA9), intracellular pH maintaining enzyme. Its upregulation in the majority of renal cell carcinomas (RCC) as a result of inactivation of VHL oncogene creates pseudo-hypoxia, whereas CA9 upregulation in non-renal cancers is associated with tumour hypoxic state. The aim of this study was to validate DOTA-Girentuximab binding in multiple cell lines representative of non-renal indications of interest and test imaging and therapeutic potential of 177Lu-labelled Girentuximab in selected xenograft models. ***Materials and Methods:*** A range of cell lines representative of tumour types known to express CA9 were tested for binding to increasing concentrations of Girentuximab (GmAb) under hypoxia. Kd and Bmax were established. Nude mice carrying AsPc-1, FaDu and HT-29 xenografts were randomized into imaging/biodistribution (N = 4) and therapy (N = 6) groups, and treated with 20-22MBq or 9MBq of 177Lu-GmAb in imaging and therapy study arms respectively. Body weight and tumour volume were monitored up to 10-weeks post treatment in the therapy arm. SPECT imaging was performed at 24 and 72 hrs, and biodistribution was analysed ex vivo in heart, liver, spleen, kidneys, tumour and blood. Imaging results were quantified and correlated to the ex vivo biodistribution. ***Results:*** The imaging and biodistribution analysis of 177Lu-GmAb in Swiss Nude mice carrying FaDu, AsPc-1 and HT-29 xenografts demonstrated tumour targeting in AsPc-1 and HT-29 xenografts, accompanied by accumulation in main clearance organs as predicted based on radiolabelled antibody clearance. Ex vivo quantification of the % injected dose in the tumour confirmed the flow cytometry results , where highest uptake reaching ~30% at 72 hrs post-injection was detected in HT-29, and the lowest in FaDu xenografts. Remarkably, in therapy studies monitoring tumour volume and mice survival, treatment with 9MBq of 177Lu-GmAb resulted in inhibition of tumour growth in FaDu xenografts and extension of survival despite non-significant binding to tumour cells as determined with FACS and imaging. Both AsPc-1 and HT-29, characterised by relatively slow and rapid xenograft growth respectively, responded to the treatment, however responses in HT-29 xenografts were less pronounced despite highest levels of CA9 expression among tested three cell lines. ***Conclusion:*** The results support a potential of radiolabelled Girentuximab as a theranostic agent in non-renal cancer indications and demonstrate that in addition to efficient tumour targeting intrinsic tumour radiosensitivity or effects on tumour stroma might play a role in determining tumour responses.

EPS-271

Radiolabeling of embolization microspheres for SPECT/CT and PET/CT : feasibility on swine model.

Y. Mortaki[1,2,3], *V. Nail[1,2,3], P. Brige[3,4], P. Garrigue[1,2,3], V. VidalL[5,3,4], P. Habert[5,3,4], B. Guillet[1,2,3];*
[1]Radiopharmacy, Assistance Publique-Hôpitaux de Marseille, Marseille, FRANCE, [2]Aix-Marseille Universiy, INSERM 1263, INRAE 1260, C2VN, Marseille, FRANCE, [3]Aix Marseille University, CERIMED, Marseille, FRANCE, [4]Aix Marseille University, LIIE, Marseille, FRANCE, [5]nterventional Radiology Departement, Assistance publique des Hopitaux de Marseille, Marseille, FRANCE.

Aim/Introduction: Arterial embolization is a mini-invasive treatment for a wide range of vascular conditions such as hemorrhages, cancers treatment or vascular disorders. Even if this practice proved his efficient, the size of optimal embolization devices and the proportion of their off-target release are unknown. In this context, we aim to radiolabel various types and sizes of embolic microspheres (EM) to follow their biodistribution by SPECT/CT and PET/CT imaging. ***Materials and Methods:*** Cook PVA® (Cook Medical), Embosphères® (Merit Medical), Embozenes® (Varian) and DC Beads® (Boston Scientific) have been studied from 300 µm to 1300 µm. Radiolabelling was performed using technetium-99m (4GBq/2ml) reduced by 2 mg tin-chloride. Gallium-68 radiolabelling was conjugated via NODAGA-NHS-ester following the protocol [REF1]. The radiolabeling was carried out at room temperature for 10 minutes or 60 minutes respectively for gallium-68 and technecium-99m. Stability tests were performed for 4 hours (gallium-68) and 24 hours (technecium-99m) in human serum. SPECT/CT and PET/CT were performed at two hours post-injection after arterial splenic embolization in a swine model. Signals were quantified as injected dose (%ID). ***Results:*** For SPECT/CT radiolabelling ; radiochemical yields (RCY) of 33.4% for DC Beads® ; 19.0% for Cook PVA® ; 15.3% for Embozenes® and 10.6% for Embosphères® were observed. Followed these tests, RCY of 14.0%, 7.1%, and 11.3% for Embosphere® EMs respectively for 700 µm, 900 µm, and 1300 µm. The final radiochemical purity excedeed 90% for each batches. For both stabilities were superior to 80% for 4 or 24 hours in human serum. Optical analyses showed no difference between no-radiolabelled and radiolabelled EMs in term of size homogeneity; sphericity and roughness. Embozenes® 700 µm and 500 µm were selected for preclinical injection to SPECT/CT and PET/CT. In both cases, signal quantifications showed no off-target sites with 93 %ID and 92 %ID into the spleen. ***Conclusion:*** Radiolabeling and in vivo proof-of-concept have been considerate conclusive for both SPECT/CT and PET/CT imaging. These results raise the question of screening others radionuclides for monitoring interventional radiology practices, as well as potential perspectives for vectorized internal radiotherapy with adjustments of agents sides used according to the indications. ***References:*** 1-STRATEGIES FOR TARGETED AND IMAGE GUIDED DRUG DELIVERY FOR SOLID TUMOR THERAPY - Ayele Hailu Negussie

EPS-272

Brachytherapy-photothermal Therapy Integrated $^{32}P/Ag_2S$-loaded Microneedle Patches for Preventing Postoperative Recurrence and Infection of Melanoma

L. Hao;
Xiangya Hospital, Changsha, CHINA.

Aim/Introduction: Melanoma is one of the most common and lethal forms of skin cancer. Current treatment options for melanoma include surgery, chemotherapy, and radiotherapy. Unfortunately, traditional methods such as surgery and chemotherapy fall short in preventing postoperative recurrence, while radiotherapy is limited by factors like radiation dose and distance, resulting in low tumor absorption and toxicity to surrounding healthy tissues. Furthermore, postoperative bacterial infection can impede wound healing, exacerbating the dilemma in melanoma treatment. To address these constraints, this study synthesized Ag2S@Ca32P and employed microneedles (MNs) as delivery platforms. This enabled the direct delivery of high-dose β rays emitted by 32P to tumor area, achieving nuclide brachytherapy. Meanwhile, this approach synergized with the photothermal capability of Ag2S, significantly suppressing postoperative recurrence and infection of melanoma. ***Materials and Methods:*** This study explored the therapeutic effects of Ag2S@Ca32P MN at both cellular and animal levels. At cellular level, this study evaluated the cytotoxic effects of Ag2S@Ca32P via mechanisms like DNA damage and ROS production. At animal level, this study established animal models like primary melanoma, recurrent melanoma, and wound infection to assess its treatment effects on inhibiting postoperative recurrence and infection. Ultimately, this study delved the mechanisms involved in inducing tumor cell apoptosis, inhibiting postoperative recurrence, and wound healing using immunohistochemistry and other methodologies. ***Results:*** At cellular level, the dose of 32P at 100 μCi/mL resulted in a 70.45% cell death rate in tumor cells. When combined with photothermal therapy, 79.23% of tumor cells were killed. Immunofluorescence results of DNA damage and ROS generation showed that the group treated with 32P combined with Ag2S exhibited the most significant DNA damage and higher ROS production capabilities. When Ag2S@Ca32P was delivered to tumor area, 32P itself was able to conspicuously inhibited the growth and recurrence of melanoma. Of note, after combining with photothermal therapy, considerable reduction of tumor volume, inhibition of tumor postoperative recurrence, suppression of bacterial proliferation and facilitation of wound healing were observed. ***Conclusion:*** This study introduces a novel nuclide microneedle platform designed to prevent postoperative recurrence and infection in melanoma. The platform delivers 32P directly to the tumor, enabling effective brachytherapy. In addition, when radionuclide treatment is combined with photothermal therapy, it can further inhibit tumor recurrence, reduce bacterial infection and promote wound healing. In conclusion, this research offers a promising approach for addressing postoperative recurrence and infection in melanoma, demonstrating significant potential in the realm of nuclide therapy.

EPS-273

The study of multi-targets PET tracer on early monitoring ICI curative effect of lung cancer

J. Wang;
The First Affiliated Hospital of Air Force Military Medical University, Xi'an, CHINA.

Aim/Introduction: Immune checkpoint inhibitors (ICI) are considered one of the most promising new anti-cancer drugs. However, the efficacy of ICI varies greatly in different patients because of the complex immune microenvironment, in which the neutrophil/lymphocyte ratio may play a key role. Here, we hypothesized that imaging of granzyme B (GZB) with 68Ga-DOTA-grazytracer and myeloperoxidase (MPO) with 68Ga-NOTA-bis-5HT could predict the ICI responders of lung cancer, which are the effective protein of CD8+ T cell and the core protein of neutrophil trapping net (NETs), respectively. ***Materials and Methods:*** The radioactive labeling yield and radiochemical purity of 68Ga-DOTA-grazytracer and 68Ga-NOTA-bis-5HT were analyzed by HPLC. The stability in physiological saline and serum were evaluated and the Log P was determined to make sure the biological characteristics. Then, the LLC tumor-bearing mice were treated with PD-L1 mAb (200μg) every three days intraperitoneally. Then, the uptake before and after treatment were evaluated by double PET probes with micro-PET/CT. Meanwhile, the immunotherapy effect was analyzed by determining the volumes of tumor and the weight changes every 3 days. ***Results:*** The radioactive labeling yield of 68Ga-DOTA-grazytracer and 68Ga-NOTA-bis-5HT were 63% and 40%, and the radiochemical purity were>95% and>90%. They kept stability in salt and serum at 37°C within 4h. The lipid/water partition coefficient of the two tracers were -0.22±0.05 and -0.49±0.05, respectively, which showed the good hydrophilicity. The results of 68Ga-DOTA-grazytracer PET imaging showed that the PET signal value of tumor was increased after treatment ($P<0.05$), indicating that PD-L1 stimulated the release of GZB and activated immune system cytotoxicity. Meanwhile, the PET signal of 68Ga-NOTA-bis-5HT was correlated with tumor volume after PD-L1 treatment ($r=0.94$), which suggesting the potential of 68Ga-NOTA-bis-5HT to predict the tumor immunotherapy response. In addition, by monitoring the dynamic PET signal changes of GZB and MPO, it was found that the secretion of GZB and MPO were reached maximum value within 4h after the last treatment, and declined gradually, which provided new ideas for further combination therapy and clinical research. ***Conclusion:*** GZB expression in tumor was increased by PD-L1 stimulation and the change of MPO had the potential to predict the immunotherapy response of lung cancer. The GZB and MPO expression were limited by time. Molecular imaging of 68Ga-DOTA-grazytracer and 68Ga-NOTA-bis-5HT may help to predict the immune efficacy early and perfect the novel therapies.

The Emerging Role of [89Zr]Zr-DFO-Girentuximab PET/CT in Accurate Characterisation and Staging of ccRCC: early experience with three Patients
F. Gelardi[1,2], *L. Antunovic[2], A. Larcher[1,2], G. Musso[1,2], C. Re[1,2], F. Cei[1,2], F. Belladelli[1,2], A. Salonia[1,2], R. Luciano[1,2], N. Tenace[1,2], M. Olivieri[1,2], A. Savi[2], M. Sollini[1,2], A. Chiti[1,2];*
[1]Università Vita-Salute San Raffaele, Milano, ITALY,
[2]IRCCS Ospedale San Raffaele, Milano, ITALY.

Aim/Introduction: Accurate characterisation of solid renal masses using conventional imaging is a major challenge, often leading to unnecessary surgery in patients with benign lesions. Carbonic anhydrase IX (CAIX) is known to be overexpressed in clear cell renal cell carcinoma (ccRCC) and offers potential as either diagnostic and therapeutic target. Here we present the results of first three patients who underwent [89Zr]Zr-DFO-girentuximab PET/CT for renal mass characterisation and staging in our Institution. ***Materials and Methods:*** Three patients with renal lesions suspicious for ccRCC on morphological imaging, all candidates for radical nephrectomy, were enrolled. Pre-operative staging was performed using whole-body PET/CT with [89Zr]Zr-DFO-girentuximab under the compassionate use programme. In addition, ex-vivo microPET/CT imaging of the surgical specimen was performed in two patients showing increased tracer uptake in renal mass, who underwent surgery one week after injection of [89Zr]Zr-DFO-girentuximab. ***Results:*** All patients had a known renal mass suspicious for ccRCC. In addition, preoperative imaging revealed suspicious lymph nodes on CT in patients 1 and 2, while patient 3 had a suspicious alteration in the right tibia on bone scintigraphy. [89Zr]Zr-DFO-girentuximab PET/CT showed increased uptake in the renal lesion with no uptake in the locoregional lymph nodes in patients 1 and 2. Of note, a rib lesion was detected in patient 1, who underwent further assessment. Ex vivo imaging in patients 1 and 2 showed consistent increased uptake in the region of the tumour mass with no uptake in the normal renal parenchyma. In contrast, patient 3 showed no uptake in the renal mass and in the tibial lesion. Final pathology confirmed the diagnosis of ccRCC with high levels of CAIX expression in patients 1 and 2 (positive on PET imaging), with no evidence of spread to the omolateral lymph nodes or adrenal gland. Final pathology confirmed cromophobe RCC in patient 3 (negative on PET imaging). In addition, biopsy of the tibial lesion was found to be a benign alteration. ***Conclusion:*** [89Zr]Zr-DFO-girentuximab PET/CT is emerging as a promising tool for the accurate characterisation and staging of renal masses suspicious for ccRCC. This modality provides critical information to guide treatment strategies, improving overall clinical management with the advantage of whole-body imaging. In addition, the high specificity of CAIX targeting can identify ccRCC preoperatively, potentially sparing patients with benign renal masses from unnecessary surgery.

OP-825
An Extremely Rare MEN4 case with Multimodality Imaging
O. Kodaz, *G. Kaya, M. Tuncel, M. Caglar Tuncali;*
Hacettepe University Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Multiple endocrine neoplasia (MEN) is a syndrome characterized by endocrinological neoplasias in multiple region or organ in a patient. Subgroups defined as MEN1, MEN2(a), MEN3(2b), MEN4 and MEN5. Diagnosis is made by family history and genetic examinations, and more than one endocrinological neoplasia is shown. MEN4 is extremely rare and related to CDKN1B mutation. In our case, we discussed the patient diagnosed with MEN4 with various imaging modalities. ***Materials and Methods:*** We discuss Tc-99m-MIBI SPECT-CT, Ultrasound (US), FDG PET-CT, Somatostatin receptor (SSTR) PET-CT images of genetically proven rare MEN4 syndrome. ***Results:*** A 32-year-old male who had a family history of parathyroid adenoma was referred for parathyroid scintigraphy due to hypercalcemia and suspected hyperparathyroidism. Focal Tc-99m-MIBI retention

was detected at the inferior poles of both thyroid lobes and US showed two nodular lesion (24x18 mm and 9x5 mm). While evaluating CT part of SPECT-CT images, 3 lung nodules were detected incidentally. FDG PET-CT was performed to evaluate pulmonary nodules. Pulmonary nodules were not FDG avid but parathyroid lesion detected on the MIBI was unexpectedly FDG avid (SUVmax: 11.7). All of the findings were suspicious for MEN syndrome so i to evaluate adrenal glands, an abdomen MRI was done, and it was unremarkable at first sight except nodular lesion in vicinity of pancreas head. Thus, SSTR PET imaging was performed. Parathyroid lesions and pulmonary nodules showed low SSTR expression and multiple nodular peripancreatic lesions with high SSTR expression were detected (SUVmax: 168, not FDG avid). Hypophysis-MRI revealed pituitary microadenoma. Thereupon, genetic analysis for MEN syndrome was performed. Genetic analysis for MEN syndrome was performed. No mutations related to MEN and RET genes were found, but CDKN1B mutation was detected. The patient was diagnosed with MEN4 syndrome. Parathyroid lesions with intense FDG uptake could be related parathyroid adenoma with high mitotic activity or parathyroid carcinoma. Lung nodules are considered to be carcinoid tumors or less likely to be metastases. The lesions in the and around pancreas could be related to neuroendocrine neoplasia and paraganglioma respectively. ***Conclusion:*** The patient had a very rare MEN4 syndrome, and multimodality imaging solved many problems, but SSTR PET-CT was a real problem solver that revealed all of the suspicious lesions. Thus somatostatin receptor imaging (SSRI) may be a first-line modality for imaging MEN-related syndromes.

OP-826

Brain FDG-PET/CT through years as a marker of disease activity in CASPR2 limbic encephalitis: a case report

A. Monaci, *S. Cornacchini, V. Damato, E. Rosati, F. Montanini, L. Massacesi, V. Berti;*
University of Florence, Firenze, ITALY.

Aim/Introduction: Autoimmune encephalitis (AE) is a heterogeneous group of inflammatory diseases of the central nervous system characterised by an acute or subacute onset, inflammation of the brain parenchyma, rapidly progressive neurological dysfunction and positive laboratory tests for anti-neuronal antibodies, although a substantial percentage of patients may be seronegative. Currently, MRI is the main neuroimaging method for the diagnosis of AE, however, a significant number of AE do not show any MRI abnormalities. Hence, this case report aims to highlight how in these cases, FDG-PET/CT can be a valuable aid in supporting the diagnosis of AE. ***Materials and Methods:*** In 2014, a 60-year-old male presented with epileptic seizures characterized by pshyco-motor arrest and oro-buccal automatism. While brain MRI was normal, FDG-PET/CT scan showed the presence of an intensely hypermetabolic focality in the left temporo-mesial region, along with a smaller, less intense area in the same location but in the contralateral hemisphere. He was diagnosed with limbic encephalitis due to anti-CASPR2 antibodies, in acute phase. Initial treatments included plasmapheresis, corticosteroids, and Rituximab, leading to a dramatic improvement of the seizures, but mood changes and memory disturbances persisted. The FDG-PET/CT scan performed three months after the first one showed a marked reduction of hypermetabolism on the left temporo-mesial region and the disappearance of hypermetabolism on the right; then, despite the presence of residual fluctuating symptoms, follow-up FDG-PET/CT scans (eight in total) showed stable metabolism outcomes, consistent with a remission phase on imaging. In 2018 the patient experienced increased seizures with marked, subacute, cognitive decline and a new brain FDG-PET/CT revealed bilateral mesial temporal hypometabolism (relapse phase). Treatment with corticosteroids, cyclophosphamide and Tocilizumab led to a complete clinical remission with a concordant reduction of the FDG-PET/CT hypermetabolism. ***Results:*** This case illustrates the potential role that FDG-PET/CT could play in the diagnosis of autoimmune encephalitis and in follow-up, since the metabolic alterations shown on imaging seem to correlate with the patient's different disease phases (acute phase, remission, relapse) even when standard neuroimaging methods show no alteration. ***Conclusion:*** For this reason, we believe that FDG-PET is a valuable tool for the diagnosis and management of autoimmune encephalitis and should be included in the main criteria for the diagnostic work-up of patients with limbic AE.

OP-827

^{18}F-FDOPA negative insulinomas in paediatric population

R. Sajjan[1], *I. Banerjee[1], B. Sathyamurthi[1], S. Muthu[1], P. Manoharan[2], S. Kusuma B[1], I. Armstrong[1], S. Alam[1], L. Fletcher[1], R. Craigie[1], A. Cakstina[1], R. Gaspar[1];*
[1]Manchester University NHS Foundation Trust, Manchester, UNITED KINGDOM, [2]The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM.

Aim/Introduction: Insulinomas are pancreatic neuroendocrine tumours. Their occurrence in paediatric group is rare. They are usually benign, sporadic and solitary. They are often curative if successfully identified and surgically removed. Insulinomas are also expected to be ^{18}F-FDOPA avid. Our aim is to highlight that Insulinomas can be ^{18}F-FDOPA non avid. We here report three cases where ^{18}F-FDOPA PET scan did not show uptake in the lesion. ***Materials and Methods:*** We are one of the few centres in the world who perform ^{18}F-FDOPA studies for hyperinsulinemia in children. We here share 3 paediatric patients with suspected insulinomas who had ^{18}F-FDOPA PET scans,. Carbidopa was not administered to any of these children. The scan was performed at different time intervals starting from 5 minutes up to 60 minutes post tracer injection. The information on histology and patient outcome were obtained from electronic patient record system. All cases were reviewed by two Nuclear Medicine physicians and one paediatric radiologist. Comparison was made with other modalities of imaging such as MR. ***Results:*** All three children had MR scan prior to ^{18}F-FDOPA PET. Interestingly, all children had no uptake of ^{18}F-FDOPA in the insulinoma lesions and two of them were in fact photopenic. All three children underwent surgical resection. Insulinoma was confirmed in all of them histologically and underwent screening for MEN1 syndrome. One child is now 23 years of age with no requirement of medication. The other two children are being followed up, currently keeping well and not requiring medications. ***Conclusion:*** ^{18}F-FDOPA is recommended for diagnosing suspected congenital hyperinsulinism and other hypoglycaemic syndromes such as insulinomas. Large majority of insulinomas are known to be ^{18}F-FDOPA avid. This poster highlights limitation of ^{18}F-FDOPA PET in Insulinomas in paediatric age group and recognising that some insulinomas do not take up ^{18}F-FDOPA and in fact two of our cases were typically photopenic. More studies are required in future in the paediatric age group to assess the behaviour of insulinomas on functional imaging.

Aim/Introduction: Paraganglioma is a rare extra-adrenal neuroendocrine tumor. First line-diagnostic procedures involve CT and MRI imaging. While isolated paraganglioma are surgically treated, metastatic disease requires systemic treatments including radiometabolic therapy(RmT). Functional imaging PET/TC scan using different radionuclides allows a personalized therapy in a theragnostic approach. ***Materials and Methods:*** A 17-year-old male presents with drug-resistant dorsal pain. MRI investigation and CT scan showed a dorsal intracanal solid tissue from D3 to D5 with extracompartimental paravertebral extension, involving respective vertebral soma together with that of L2 with extension anterior to the left iliopsoas muscle(LIPM). He underwent surgical spinal stabilization and decompression at D2-D6 level. The diagnosis at biopsy was paraganglioma with focal nuclear pleomorphism, tumor necrosis and microfoci in bone, muscle and fibrocartilaginous tissue. He was referred to our nuclear medicine department to complete staging and treatment decision. ***Results:*** An initial ^{18}F-FDG PET/CT scan showed mild uptake in the paravertebral region at D4-D5 and L2 level and equivocal uptake anterior to the LIPM and bone marrow. Subsequent 68Ga-DOTANOC PET/CT revealed mild uptake at the same sites identified at ^{18}F-FDG PET/CT and additionally uptake anterior to the left kidney and LIPM and at the skeletal level of C1, occipital clivus and L3. Diagnostic (123)I-MIBG scintigraphy was performed to evaluate RmT feasibility. The latter showed uptake in the soma and paravertebral tissues of L2, multiple skeletal localisations(SL) (dorsolumbar spine, shoulder, iliac bones, femurs) and two areas close to the liver and heart wall. No paravertebral uptake at C1, clivus and D3-D5 levels. Included in an experimental protocol, 68Ga-FAPI PET/CT was performed with evidence of uptake in the abdominal lesion of the left flank/mesogastrium, paravertebral tissue(PT) of D4 and L2, multiple SL (frontal bone, basicranium, C1-C4, C7, D4-L5, ribs, left glenoid, humeri, sternum, sacrum, iliac bones, ischio-pubic branches and proximal femurs) and some para-aortic adenopathies. The patient underwent therapeutic 131I-MIBG with subsequent scintigraphic evidence of uptake in all lesions detected by FAPI-PET. Following finding of ALK mutation, the patient started Lorlatinib. A follow up CT scan, at 6 months, demonstrated a reduction of PT, adenopathies and structural changes of D7 to D12 and L5 vertebral soma. ***Conclusion:*** 68(Ga) FAPI-PET/CT showed the largest number of disease localisations compared to PET-FDG, PET-DOTANOC and diagnostic 123I-MIBG scintigraphy. This finding may play a role in the theragnostic use of FAPI in multi-metastic paraganglioma.

[68Ga]Ga-FAPI-46 PET/CT Impacts on Management of a Incidentally Detected Lung Adenocarcinoma, Upstaging Lymph Node Metastases Over Conventional [18F]F-FDG, Diagnostic CT and EBUS

E. Fortunati[1], *L. Zanoni[1], G. Cuzzani[2], C. Nanni[1], S. Emiliani[1], M. Ferrari[3], F. Giunchi[4], F. Antonacci[5], P. Solli[5], P. Candoli[3], S. Fanti[1,2];*
[1]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [2]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [3]Interventional Pulmonology Unit, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Pathology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [5]Thoracic Surgery, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: A 16 mm nodular lung lesion in the right inferior lobe was incidentally detected in a 57y.o. male patient, ex-smoker and without relevant and known diseases, undergoing diagnostic computed tomography(dCT). ***Materials and Methods:*** The patient was referred to our Centre for staging [18F] F-FDG PET/CT to evaluate the nodular lung lesion in the right inferior lobe and, in the suspect of lung cancer, enrolled to perform a subsequent [68Ga]Ga-FAPI-46 PET/CT(14days later) within an ongoing prospective monocentric investigational trial(EudraCTnumber:2021-006570-23). ***Results:*** [18F]F-FDG PET/CT detected significant uptake (SUVmax=4.2) only in the lung lesion, absent in lymph nodes(according to TNM8th: FDG-T1bN0). Interestingly, endobronchial ultrasound-guided biopsies resulted inconclusive in lung but positive for metastases of lung adenocarcinoma in right lower paratracheal(#4R), right interlobar peribronchial(#11R) and subcarinal(#7) lymph nodes (EBUS-TxN2). [68Ga]Ga-FAPI-46 PET/CT showed similar uptake in the lung lesion (SUVmax=3.6) and significant uptake in right prevascular (#3, SUVmax=5.7) and in the known metastatic lymph-nodes #4R (SUVmax=8.4), #11R (SUVmax=7.9) and #7 (SUVmax=4.2), but interestingly also in bilateral supraclavicular nodes (FAPI-T1bN3M0). A right supraclavicular lymph node soon became enlarged and suspicious at US, and was finally confirmed malignant (adenocarcinoma) at fine-needle-aspiration. FAPI correctly upstaged from T1bN0M0(dCT+FDG only) to T1bN3M0, excluding patient from surgery. The restaging after 6 months of Osimertinib(EGFR+) revealed a dimensional decrease of both T and N lesions at dCT, and residual faint FDG uptake in the lung lesion (SUVmax=4.2). ***Conclusion:*** It was preliminarily reported that FAPI has similar sensitivity to FDG for primary lung cancer, and overall a higher performance for metastases[1-3], although not frequently significantly changing TNM and patient management. This is an interesting example of upstaging N in lung adenocarcinoma, confirming the superior performance of experimental [68Ga] Ga-FAPI PET/CT over conventional [18F]F-FDG for the evaluation of lymph-nodal metastasis[4]. ***References:*** [1]Yang Q, Huang D, Wu J, et al. An Example of Higher Accuracy of [68Ga]Ga-FAPI-46 PET/CT in Staging Mediastinal Lymph Nodes Compared to [18F]F-FDG PET/CT in a Lung Cancer Patient

***E. Fortunati*[1],** *L. Zanoni*[1], *G. Cuzzani*[2], *C. Nanni*[1], *V. Cabitza*[1], *F. Natali*[3], *T. Galasso*[3], *F. Giunchi*[4], *F. Antonacci*[5], *P. Solli*[5], *P. Candoli*[3], *S. Fanti*[1,2];
[1]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [2]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [3]Interventional Pulmonology Unit, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Pathology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [5]Division of Thoracic Surgery, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: A 60 y.o. woman underwent a diagnostic-CT in order to investigate the onset of persistent cough, asthenia, weight loss, fever and hemoptysis. Diagnostic-CT revealed the presence of a voluminous lung lesion in the right superior lobe, which needed to be staged with PET/CT. ***Materials and Methods:*** She underwent a standard [18F]F-FDG PET/CT to stage the lung lesion in the right superior lobe and, after three days, an additional [68Ga]Ga-FAPI-46 PET/CT was performed, within an ongoing prospective monocentric investigational trial (EudraCT number: 2021-006570-23) conducted in our Nuclear Medicine Department. All images were acquired 60 minutes after the radiopharmaceutical injection, with a field-of-view from the vertex to the proximal thighs. ***Results:*** [18F]F-FDG PET/CT detected intense and inhomogeneous uptake (SUVmax=28.8) in correspondence of the known lung lesion in the right superior lobe, less intense in the lesion centre for possible necrotic phenomena. Significant uptake was also described respectively in right lower paratracheal (#4; SUVmax=4.3), subcarinal (#7, SUVmax=4.9) and right hilar (#10, SUVmax=8.9) lymph nodes,suggestive for metastases (T3N2M0). [68Ga]Ga-FAPI-46 PET/CT also confirmed the intense and inhomogeneous uptake of the lung lesion (SUVmax=22.5), but did not detect any significant lymph nodal uptake (T3N0M0). Endobronchial ultrasound-guided biopsies resulted positive in lung for squamous cell carcinoma but negative for metastasis in right lower paratracheal, subcarinal and right hilar lymph nodes. Surgery confirmed biopsies ***results:*** a poorly differentiated squamous cell carcinoma, with pleural, bronchial and vascular invasion was diagnosed, without lymph nodal involvement (pT3N0Mx). Subsequently, she started chemotherapy. Last diagnostic-CT, five months after surgery, excluded relapse. ***Conclusion:*** The correct evaluation of the mediastinal lymph nodes staging is of primary importance to select patient eligible for surgery. Recently, [68Ga]Ga-FAPI-46 PET/CT showed a better performance in discriminating lymph node metastasis compared to [18F]F-FDG PET/CT [1]. This case report is a clear example of the potential impact of [68Ga]Ga-FAPI-46 PET/CT for lymph node staging, which could cover a fundamental role in decreasing false-positive results before surgery. ***References:*** [1]Kang YK, Na KJ, Park J, et al. Triple whole-body cross-sectional imaging ([18F]FDG PET, [99mTc]Tc-HMDP SPECT, MRI) to successfully decrypt a "PPP syndrome" (Pancreatitis, Panniculitis, Polyarthritis)

***A. Bahloul*[1],** *F. Pontille*[2], *P. Augusto Gondim Teixeira*[3], *F. Paycha*[4];
[1]Nuclear Medicine department, Nancy Universitary Hospital, Nancy, FRANCE, [2]Internal Medicine and Clinical Immunology department, Nancy Universitary Hospital, Nancy, FRANCE, [3]Medical Imaging GUILLOZ department, Nancy Universitary Hospital, Nancy, FRANCE, [4]Nuclear Medicine department, Lariboisière Universitary Hospital, Paris, FRANCE.

Aim/Introduction: Patients with underlying pancreatic disease may develop extra pancreatic manifestations. The triad of pancreatitis, panniculitis, and polyarthritis, "PPP-syndrome", is rare and can be misdiagnosed. Depending on the nature of the underlying pancreatic condition, treatment can lead to complete remission, highlighting the importance of early diagnosis. ***Materials and Methods:*** A 55-yr-old man with medical history of alcoholism and previous episodes of alcoholic pancreatitis was admitted for peripheral bone pain worsening over time with heat, redness, and swelling of peripheral joints of upper and lower limbs. In addition, the patient presented many ill-defined inflammatory skin nodules suggestive of erythema nodosum. Biology tests elicited an increased CRP: 283 mg/mL and a hyperlipasemia (41000 U/L,N<53 U/L) without abdominal pain. The [18F]FDG PET scan exhibited multiple sites of hypermetabolic foci corresponding to skin nodules without pancreatic abnormal metabolism. A dual phase [99mTc]Tc-HMDP whole-body SPECT-CT demonstrated multiple areas of intense and irregular bone-seeking tracer uptake in the long bones of both extremities, both calcanei and several other tarsal bones, sparing axial skeleton. No obvious abnormal findings on twinned whole-body computed tomography were noted. These SPECT anomalies matched on MRI with areas of extensive intramedullary necrosis with multiple medullar foci of ill-defined, garland-like, T1-hypointense and T2 STIR-hyperintense lesions. ***Results:*** This pattern of abnormalities in triple whole-body cross-sectional imaging ([18F]FDG PET, [99mTc]Tc-HMDP SPECT, MRI) together with the presence of underlying pancreatic disease and a hyperlipasemia correctly pointed to pancreatitis, panniculitis, and polyarthritis syndrome, "PPP syndrome", and waived for the necessity of bone biopsy. Characteristic imaging anomalies in "PPP syndrome" include peripheral bilateral bone and joint increased uptake on whole-body 99mTc-HMDP SPECT with multiple intramedullary necrosis foci over peripheral long bones on MRI. In contrast, whole-body 18F-FDG PET shows faint metabolism of bone lesions. This syndrome is caused by the release of pancreatic enzymes into the systemic circulation (pancreatitis) with lipolysis of the subcutaneous tissue (panniculitis) and fat necrosis of bone marrow (polyarthritis). Suspicion of a pancreatic duct-vena cava fistula led to placement of a pancreatic endo-prosthesis resulting in significant regression of skeletal manifestations. ***Conclusion:*** We described a case of "PPP syndrome" in which pancreatitis with systemic release of pancreatic enzymes causes cutaneous and osteo-medullary fat necrosis. Diagnosis could be challenging because abdominal pain is often mild or lacking. However, multimodality whole-body imaging (FDG PET, bone SPECT, MRI) correctly pointed to the etiological diagnosis and obviated a bone biopsy, by displaying characteristic peripheral multiple intramedullary necrosis.

OP-832

Variable Patterns and Telltale Signs for Venous Thrombosis on Positron Emission Tomography

S. Kwok, *S. Wong, F. Choi;*
Pamela Youde Nethersole Eastern Hospital, Hong Kong, HONG KONG.

Aim/Introduction: [18F]Fluorodeoxyglucose (FDG) positron emission tomography-computed tomography (PET-CT) has become a standard investigation for various malignancies, which could be associated with a higher risk of venous thrombosis. There were some studies on the diagnostic performance of PET-CT on venous thrombosis (for example, detection of venous thrombosis by focal or linear FDG hyperactivity at or along venous structure, and differentiation between tumour thrombus and bland thrombus), but the available literature remains sparse and illustrations are limited particularly for venous thrombosis presenting with FDG hypoactivity. We aim to review imaging features of venous thrombosis and to identify specific patterns on FDG PET-CT. ***Materials and Methods:*** All PET-CT using FDG in a large regional hospital within a 3-year period were reviewed for concurrent presence of venous thrombosis, their associated imaging features and patterns, as well as their causes and outcomes. ***Results:*** We identified 40 out of 8647 (0.46%) cases confirmed or suspected to have concurrent venous thrombosis. Twenty-eight cases (70%) showed FDG hyperactivity in a focal or linear pattern at or along thrombosed veins, whereas four cases (10%) showed intraluminal FDG hypoactivity located within venous structure. The latter was depicted as a linear pattern of intravenous cold defect surrounded by blood-pool or vascular-wall FDG activity, thus conforming to an "FDG railway track" sign in the plane parallel to the vessel and an "FDG polo mint" sign in the plane perpendicular to it, which were also analogous to the findings originally described for diagnosing acute pulmonary embolism on computed tomography pulmonary angiography. One case (2.5%) showed a co-existence of FDG hyper- and hypoactivity pattern, and the remaining seven cases had no observable abnormal FDG activity pattern. All of the cases with intravenous cold defects were confirmed to have bland venous thrombosis, one of which could only be unravelled by FDG PET-CT after a false-negative doppler ultrasound study, and that illustrative PET-CT also had auxiliary imaging features of limb swelling, dermal and subcutaneous oedema. ***Conclusion:*** Venous thrombosis was found to have variable patterns of FDG hyper- or hypoactivity on PET-CT. Of note, the aforementioned "FDG railway track" and "FDG polo mint" were deemed to be telltale signs in revealing the presence of bland venous thrombosis. ***References:*** 1. Aim/Introduction: There is a high need to identify patients with glioblastoma who could benefit from novel immunomodulatory therapy approaches. PET imaging can be used to non-invasively characterize immune cells in the tumor microenvironment (TME) in living patients prior to therapy initiation. However, currently available radiotracers (i.e. translocator protein (TSPO) PET tracers) lack specificity as they bind to immune cells, tumor cells and endothelial cells. Hence, we aimed to develop an antibody-based radiotracers targeting the triggering receptor of myeloid cells 2 (TREM2) as a key biomarker of tumor associated microglia/macrophages (TAMs). ***Materials and Methods:*** A TREM2 antibody engineered with a monovalent-human transferrin receptor binding site in the Fc domain, known as the antibody transport vehicle (ATV:4D9) was covalently modified with pNCS-benzyl-NODAGA and labeled with copper-64. Syngeneic mouse models with implanted SB28 glioblastoma cells in wild-type mice (week-2) received PET imaging and cell sorting 20h after radiotracer injection. Autoradiography was performed in a subset of mice. Furthermore, we used an ATV-enabled radiolabeled human-specific TREM2 antibody (ATV:14D3) together with a transgenic mouse model expressing human TREM2. PET and autoradiography signals (tumor-to-background-ratio, TBR) as well as cellular specificity of radiolabeled ATV:TREM2 antibodies were benchmarked against TSPO PET. ***Results:*** ATV:4D9 TREM2 PET and autoradiography showed strong signals (PET TBR: 8.8 ± 0.4, autoradiography TBR: 14.9 ± 0.3) following circular distribution of TAMs in the infiltration zone. Cell sorting revealed strong selectivity of the radiolabeled TREM2 antibody for TAMs over tumor cells (16-fold) and other remaining cells (19-fold). Translation of copper-64 labeling to ATV:14D3 confirmed strong PET and autoradiography signals and TAM over tumor cell specificity (18-fold) in mice with human TREM2 expression. TREM2 PET outperformed TSPO PET by 20-fold in terms of TBR assessment of TAMs. ***Conclusion:*** PET imaging with radiolabeled ATV:TREM2 antibodies indicated high specificity for immune cells and facilitated sufficient targeting of TAMs within the TME. Successful performance of a human ATV:TREM2 antibody holds promise for translation towards imaging of patients with glioblastoma.

OP-843
Comparative assessment of nigrostriatal and mesolimbocortical D2 receptor binding after GABA(A) receptor and NMDA receptor agonist and antagonist treatment
S. Nikolaus[1], *H. Wittsack[1], M. Beu[1], C. Antke[1], H. Hautzel[2], E. Mamlins[1], G. Antoch[1], H. Müller[1], F. L. Giesel[1];*
[1]University Hospital Düsseldorf, Düsseldorf, GERMANY, [2]University Hospital Essen, Essen, GERMANY.

Aim/Introduction: GABA is the main inhibitory neurotransmitter in the CNS and believed to counteract the excitatory neurotransmitter glutamate (GLU). We assessed the impact of the GABA(A) receptor (R) agonist and antagonist muscimol (MUS) and bicucullin (BIC) and the NMDAR agonist and antagonist D-cycloserin (DCS) and amantadine (AMA) on regional D2R binding in the rat brain. ***Materials and Methods:*** In 70 rats, D2R binding was measured in baseline (BAS) and after injection of MUS (1 mg/kg), BIC (1 mg/kg), DCS (20 mg/kg) or AMA (40 mg/kg). Iodine-123-IBZM (26±4 MBq i.v.) was injected 30 min post-challenge. Imaging data were acquired 45 min later with the TierSPECT. The following regions (with a diameter ≥ FWHM of the TierSPECT) were defined on SPECT-MRI overlays: caudateputamen (CP), nucleus accumbens (NAC), substantia nigra/ventral tegmental area (SN/VTA), thalamus (THAL), frontal cortex (FC), motor cortex (MC), parietal cortex (PC), dorsal hippocampus (dHIPP) and ventral hippocampus (vHIPP). Estimations of the binding potentials (BPs) in BAS and post-challenge were obtained by computing ratios of the specifically bound compartments to the cerebellar

reference region. The regional BPs were normalized to BAS (BPn) and compared between groups. ***Results:*** BPn was reduced after MUS (A) relative to BIC in CP, NAC, FC, vHIPP, SN/VTA and THAL, (B) relative to AMA in PC, and (C) relative to DCS in CP, NAC, FC, MC, PC, dHIPP, vHIPP, SN/VTA and THAL. BPn was reduced after AMA (A) relative to DCS in CP, NAC, FC, MC, PC, dHIPP, vHIPP and THAL, and (B) relative to BIC in CP, NAC, SN/VTA and THAL. Moreover, BPn was reduced after BIC relative to DCS in PC and vHIPP. ***Conclusion:*** MUS exerted opposite effects relative to BIC and DCS throughout the nigrostriatal (NSS) and mesolimbocortical system (MSCS) with MUS increasing and BIC and DCS decreasing regional dopamine (DA) levels. In FC and MC, the impacts of MUS and BIC relative to BAS were similar. Also, the effects of AMA and DCS were opposed throughout NSS and MSCS with AMA increasing and DCS decreasing DA. However, in SN/VTA the impact relative to BAS was similar. AMA and BIC exerted opposite effects only at the site of origin and the primary projection areas of the NSS and MLCS with AMA increasing and BIC decreasing DA. GABA(A)R and NMDAR play differentiated, region-specific roles in regulating DA levels.

OP-844

Metabolic Imaging of the Brain and Brown Adipose Tissue as a Biomarker for Chronic Stress

M. Krisch[1], *J. L. Wilson[2], S. Macho-Maschler[3], O. Kulterer[1], P. Ettel[2], T. Wanek[1], C. Kuntner[1], Ö. Özer[1], R. Palme[3], T. Weichhart[2], C. Philippe[1], M. Hacker[1], C. Vraka[1];*
[1]Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA, [2]Center of Pathobiochemistry and Genetics, Institute of Medical Genetics, Medical University of Vienna, Vienna, AUSTRIA, [3]Department of Biomedical Sciences, University of Veterinary Medicine, Vienna, AUSTRIA.

Aim/Introduction: Assessing chronic stress and its impact on health and disease progression is a complex task in modern medicine. Previous studies have used $^{[18F]}$FDG as a biomarker for depression, anxiety, or chronic stress in cancer patients. However, they lack specific brain patterns and assessment in preclinical models, limiting their translational potential. In this study, we present a novel approach exploring $^{[18F]}$FDG and $^{[18F]}$FTHA to image glucose and free fatty acid metabolism of the brain and brown adipose tissue (BAT) as biomarkers for chronic stress in vivo. ***Materials and Methods:*** Female and male C57BL/6J mice were subjected to different chronic stressors, including cooling, restraint, and surgery (n = 6-8/group). Static µPET/CT scans (Siemens Inveon®) were performed on fasted mice under isoflurane anesthesia after a 60-minute distribution phase in an awakened state following i.v. administration of $^{[18F]}$FDG or $^{[18F]}$FTHA. Blood glucose and fecal corticosterone metabolites (FCM) were assessed throughout the experiments. Spatial and intensity normalization, segmentation, and quantification of images were performed with PMOD software and voxel-wise analysis was done with statistical parametric mapping (SPM12). ***Results:*** FCM levels were significantly increased in chronically stressed mice over one week of stress exposure, peaking after two to three days (109 → 213 ng/50 mg). We observed significantly higher $^{[18F]}$FDG uptake in BAT of mice that were chronically cooled (2.1 SUVmean) compared to mice that were chronically restrained (1.5 SUVmean) and not stressed (1.3 SUVmean). In the surgery group, $^{[18F]}$FDG uptake in BAT even showed a five-fold increase at one day post-surgery (8.1 SUVmean). Moreover, $^{[18F]}$FTHA showed a 1.5-fold increase (1.0 SUVmean) compared to pre-surgery scans (1.5 SUVmean, 0.7 SUVmean, respectively). Whole brain $^{[18F]}$FDG uptake was significantly decreased by 50% in all stressed animals, partly related to increased blood glucose levels. Using brain atlas analysis (M. Mirrione) and statistical parametric mapping, we saw significant stressor-specific differences in regional brain uptake, e.g., in the basal forebrain septum, olfactory bulb, and brain stem following chronic restraint and surgery. ***Conclusion:*** Our findings suggest that metabolic µPET/CT imaging could be a valuable tool for noninvasively assessing brain patterns in chronic stress models and a suitable translational tool for stress and disease research in mice. Moving forward, we will focus on investigating mechanistic differences in the brain-BAT axis of different stressors and plan to extend our research to investigate the effects of chronic stress in lung cancer mouse models.

OP-845

Synthesis and evaluation of novel α-synuclein targeting probes for PD PET Imaging

Y. Xu, *C. Wang, D. Pan, L. Wang, X. Wang, J. Yan, C. Chen, M. Yang; Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.*

Aim/Introduction: Accumulation of α-synuclein is a major hallmark of Parkinson's disease. The development of PET tracers to visualize aggregated α-synuclein is helpful for early diagnosis and treatment of Parkinson's disease. In this study, a series of novel radiolabeled small molecule compounds targeting α-synuclein was designed and synthesized. Also, their utility as α-synuclein imaging probes in the living body was evaluated. ***Materials and Methods:*** Small molecule compounds based on benzothiazole, benzodioxole, and oxadiazole scaffolds were prepared and labeled using Cu(II) mediated radiofluorination methods, respectively. The imaging properties of the tracers were primarily screened through PET imaging at A53T mice and normal mice. Then, in vivo, PET/MR imaging was further performed on rodents after the administration of the optimal tracer. The imaging properties of the probe were also investigated through biodistribution experiments as well as ex vivo autoradiography and pathological analysis. ***Results:*** 18F-labeled small molecule compounds were obtained with an average labeling yield of 10%, and the radiochemical purity was greater than 95%. Among these tracers, in vivo PET imaging revealed that more radioactivity was significantly detected in the brain of A53T mice than those of normal mice after administration of 18F labeled benzothiazole analog, 18F-YM1. Further PET/MR images in A53T mice revealed that 18F-YM1 retained in regions with abundant expression of aggregated α-synuclein, including the striatum, thalamus, hippocampus, etc. Quantitative analysis showed that the ratios of uptake values in these regions between A53T mice and normal mice were nearly 1.6 and 1.3 at 10 min and 30 min postinjection, respectively. Furthermore, ex vivo autoradiography and histological examination confirmed the possibility of detection of aggregated α-synuclein using 18F-YM1. A biodistribution study in normal mice found that 18F-YM1 displayed moderate uptake (2% ID/g at 5min postinjection) in the brain and gradually cleared (0.4% ID/g at 60min postinjection). Metabolite analysis showed that the radioactivity signals detected by PET scanners in the brain mainly originated from the parent compounds. ***Conclusion:*** The preclinical study demonstrated that the small molecule compound based on benzothiazole scaffold owned preferable imaging prosperities, including high targeting capacity, low non-specific uptake, and favorable pharmacokinetics, etc. It may be a new candidate for α-synuclein PET imaging, and further appropriate modification might be beneficial for improving the performance.

Development and Evaluation of [18F]FS9, Novel PET tracer for α-Synucleinopathies in PFF mouse model of Parkinson's Disease

B. Hooshyar Yousefi[1,2], *B. Uzuegbunam[3], S. Bagheri[4], W. Paslawski[5], J. Li[6], A. Rosenau[7], M. Henrich[7], P. Svenningsson[5], H. Ågren[6], M. Luster[8], W. Weber[9], T. Arzberger[10], D. Librizzi[1];*
[1]Department of Nuclear Medicine, Radiopharmacy Section, Philipps University Marburg, Marburg, GERMANY, [2]Core Facility Molecular Imaging, Center for Tumor Biology and Immunology, Philipps University Marburg, Marburg, GERMANY, [3]Department of Nuclear Medicine, Klinikum rechts der Isar, TUM, Munich, GERMANY, [4]Nuclear Medicine Department, Radiopharmacy section, Marburg, GERMANY, [5]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, SWEDEN, [6]Department of Physics and Astronomy, Uppsala University, Uppsala, SWEDEN, [7]Clinic for Psychiatry and Psychotherapy, Philipps University Marburg, Marburg, GERMANY, [8]Nuclear Medicine Department, Radiopharmacy section, Philipps University Marburg, Marburg, GERMANY, [9]Nuclear Medicine Department, Klinikum rechts der Isar, TUM, Munich, GERMANY, [10]Neurobiobank Munich, Ludwig-Maximilians-University of Munich, Munich, GERMANY.

Aim/Introduction: Development of a specific 18F-labeled PET tracer, based on diarylbisthiazole, with excellent binding affinity to α-synuclein fibrils (α-syn), admirable selectivity over Aβ and tau fibrils in addition to favorable brain uptake and pharmacokinetics (PK) as well as its in vitro and in vivo evaluation in post-mortem patient-brain and animal models of Parkinson's disease (PD). ***Materials and Methods:*** [18F]FS9 was chosen from several leads as a result of its promising preclinical results: binding affinity and selectivity to α-syn, biodistribution, metabolite analyses, lipophilicity, PK, Blood-Brain-Barrier permeability, postmortem autoradiography of human brain with α-Synucleinopathies, and PET imaging in mouse models. FS9 was then radiolabeled, purified and utilized directly within a longitudinal study of 90-minute dynamic PET/CT scans in 12-24 weeks post intrastriatal injection of preparation of mouse α-synuclein preformed fibrils (PFF) mice (n≥3) versus age-matched post intrastriatal injection of monomeric α-synuclein mice (ctrl, n≥3). The brain regions were segmented using the Ma-Benveniste-Mirrione mouse-brain template to evaluate uptake values, time activity curves, and parametric mapping analysis. The left stratum was considered a region of interest then the left ventricle was used for an arterial input function corrected with metabolite analyses through the parametric mapping analysis. Additionally, PFF and control mice brains were used for ex vivo immunohistochemical (IHC) confirmation. ***Results:*** [18F]FS9 shows high binding affinity (Ki 2nM), excellent selectivity toward Aβ plaques over NFT (>100 fold), suitable lipophilicity (logD=2.8±0.1), plasma protein binding 0.97± 0.12 and favorable pharmacokinetics (RCY 25±5% and Purity ≥99.5%). It shows high binding to α-synucleinopathies in patients´ brains versus no binding to healthy control brains also confirmed by IHC. Besides, it shows initial brain uptake >7 %ID/g (5 min p.i.) and fast washout from the brain, as well as exceptional stability in brain (t1/2 > 8h). It shows excellent PET results in the longitudinal study in PFF (SUV between 2.0-3.9) vs control with initial uptake >10%ID/g and fast washout down to 1%ID/g (90 min). The distribution volume ratio (DVR) PET is significantly higher on the left stratum of PFF brain (DVR 1.8-2.7 ml/cm3), versus no specific signal (DVR 0.8 ml/cm3) in control mice brain. ***Conclusion:*** The rational optimization helped us to develop the groundbreaking and highly desirable tracers as a tool to detect and quantify the presence, severity, and regional distribution of α-syn and its clinical manifestations in individuals with α-synucleinopathies. [18F]FS9 shows promising binding, selectivity and imaging properties encouraging us to further investigate it first in human study. ***References:*** The project is supported by ParkinsonFonds-Deutschland.

OP-847

Translational development of [18F]FC0324, a PET radiotracer for CB_2 receptors imaging

F. Caillé[1], *S. Auvity[1], B. Attili[2], M. Goislard[1], J. Cayla[1], F. Hinnen[1], S. Demphel[1], V. Brulon[1], M. Bottlaender[1], C. Leroy[1], G. Bormans[2], B. Kuhnast[1], M. Peyronneau[1];*
[1]CEA, Orsay, FRANCE, [2]KU, Leuven, BELGIUM.

Aim/Introduction: Upregulation of the cannabinoid type 2 receptors (CB2R) unveils pathological processes such as neuroinflammation. We have described [18F]FC0324 as a promising PET radiotracer to image CB2R. For clinical translation, we report in vivo PET imaging studies in hCB2-AAV local overexpressed rat model and in non-human primates (NHPs). ***Materials and Methods:*** [18F]FC0324 (33±5MBq) µPET scan (120min) were performed in hCB2-AAV rats (n=6), including blocking studies with i.p. injections of CB2-selective NE40 (1 and 10mg/kg). The standardized uptake values (SUV) were recorded in the right (ipsilateral) and left (contralateral) striata. Test-retest brain PET scans (120 min) after [18F]FC0324 injection (254±26MBq) were performed on four male rhesus NHPs (9.5±2.8kg). Whole brain and regional total volumes of distribution (VT) were estimated using a compartmental model including separate input function and compartment for radiometabolites. Competitions experiments with CB1-selective (rimonabant 1 mg/kg, n=1) and CB2-selective (FC0324 and NE40, 1 mg/kg n=1 each) compounds were performed. Whole-body PET-CT scans (212±18MBq, 70 min) were performed on 3 NHPs including after blocking by NE40 (1 mg/kg; n=1). Image analysis was performed using the PMOD software. Ex vivo (NHP and human microsomes) and in vivo NHP metabolism was explored. ***Results:*** [18F]FC0324 uptake in hCB2-AAV rats showed an 8-fold increase in the ispilateral striatum compared to the contralateral. Blocking with NE40 decreased the SUV in the right striatum up to 77%. Brain time-activity curves in NHPs displayed a fast distribution followed by a rapid washout. Brain radioactivity was homogenous, with no significant difference in regional VT. Whole brain VT was 0.86±0.22 mL.cm-3 with a within-subject variability of 4.2%. Competition studies did not show any significant modification of the regional [18F]FC0324 brain kinetics. Whole-body PET-CT display a high and specific uptake of the radiotracer in the spleen, a CB2R-rich organ. In vivo metabolism in NHP was relatively fast (16% parent at 60min) but should be highly reduced in humans as suggested by in vitro metabolism study (30% vs 5% at 60 min) ***Conclusion:*** [18F]FC0324 crosses the blood brain barrier and binds to hCB2R. [18F]FC0324 displays interesting kinetics with selectivity over the CB1R. Despite a fast but not detrimental metabolism, [18F]FC0324 is a promising tracer for CB2R clinical investigation in neuroinflammation.

OP-848

Advancing Antibody-Based Brain Pretargeted PET Imaging: Assessing a Novel ^{18}F-Labeled BBB-Penetrating Tetrazine and Strategies to Improve Brain-to-Blood Contrast

T. Gustavsson[1], *V. Shalgunov[1], S. Stotz[1], S. Lopes van den Broek[1], J. Niewoehner[2], L. Gobbi[3], M. Honer[4], T. Kustermann[4], U. M Battisti[1], M. M Herth[1];*
[1]Department of Drug Design and Pharmacology, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, DENMARK, [2]Roche Pharma Research and Early Development (pRED), Therapeutic Modalities, Roche Innovation Center Munich, Munich, GERMANY, [3]Roche Pharma Research and Early Development (pRED), Therapeutic Modalities, Roche Innovation Center Basel, Basel, SWITZERLAND, [4]Roche Pharma Research and Early Development (pRED), Neuroscience and Rare Disease, Roche Innovation Center Basel, Basel, SWITZERLAND.

Aim/Introduction: In this study, we evaluate whether an in-house developed blood-brain barrier (BBB) penetrable tetrazine (BBBTz) with rapid trans-cyclooctene (TCO) ligation kinetics can be used for brain pretargeted PET imaging. The BBBTz was tested in an amyloid-beta (Aβ) mouse model using a TCO-modified bispecific construct (TCO-bsAb) of the Aβ targeting antibody mAb31 connected to a single-chain Fab fragment of the BBB-penetrating antibody 8D3. Additionally, we explored the potential of using a masking-Tz to enhance the brain-to-blood contrast in brain pretargeted PET imaging. ***Materials and Methods:*** The bsAb was TCO-functionalized, and affinity for Aβ and mouse transferrin receptor (mTfR), as well as antibody integrity, were assessed by ELISA and size-exclusion HPLC. TCO load was determined by radio-SDS-PAGE. Aβ imaging was evaluated in 6-8 months old 5xFAD or age-matched wild-type (WT) mice. TCO-bsAb (40 nmol/kg), was administered intravenously, and after 72h, brains were extracted, frozen, and sectioned. Sections were incubated with [18F]BBBTz, and exposed to a phosphor imager screen. Specific binding of [18F]BBBTz in the brain was assessed by comparing Aβ-rich regions (cortex and thalamus) with an Aβ-lacking region (cerebellum). Aβ pathology was confirmed with thioflavin-S staining. Next, WT mice received 15 nmol/kg TCO-bsAb. After 3h, a polar, non-BBB penetrating masking-Tz was administered intravenously at a molar Tz:TCO ratio of 20:1 or 80:1, with saline as control. After 1.5h, [18F]BBBTz (5 MBq/mouse, 200 nmol/kg) was administered intravenously. Tissue uptake of [18F] BBBTz was measured ex vivo after 2h by gamma-counting and expressed as %ID/g tissue. ***Results:*** TCO-bsAb (10 TCOs/bsAb) exhibited minor affinity alteration to Aβ and mTfR, and no change in antibody integrity. On-section Tz-TCO ligation on 5xFAD brain sections revealed a [18F]BBBTz binding pattern colocalizing with Aβ pathology, yielding a cortical/thalamic-to-cerebellar ratio of 3-6. Conversely, in WT mice, no region-specific binding of [18F]BBBTz was detected, with a cortical/thalamic-to-cerebellar ratio of 1. Notably, mice treated with masking-Tz showed markedly reduced blood concentration (20:1, -90 %; 80:1, -91%) of [18F]BBBTz, while brain uptake was reduced to a minor degree when comparing 20:1 (-33%) and 80:1 (-43%) relative to control. This led to overall cerebrum-to-blood ratios relative to control improving by a factor of 6.97 (20:1) and 6.17 (80:1). ***Conclusion:*** Our newly developed BBBTz demonstrates significant promise in brain pretargeting by successfully transversing the BBB and ligating with TCO-bsAb in the brain. When combined with a peripheral masking-Tz, brain-to-blood contrast can dramatically be improved, underscoring the potential of masking agents in brain pretargeting.

Neuronal but not Astrocytic Tau Dominates the Signal Source of in vivo PET Signaling in 4-Repeat Tauopathies

J. Gnörich[1], *L. Slemann[1], S. Hummel[1], L. Bartos[1], C. Klaus[1], S. Kunte[1], L. Kunze[1], A. Englert[1], S. Katzdobler[1], C. Palleis[1], L. Beyer[1], T. van Eimeren[2], A. Drzezga[2], O. Sabri[3], H. Barthel[3], G. Respondek[4], J. Levin[1], G. Höglinger[1], J. Herms[1], L. Paeger[1], S. Roeber[1], N. Franzmeier[1], M. Brendel[1];*
[1]LMU Munich, Munich, GERMANY, [2]University Hospital Cologne, Cologne, GERMANY, [3]Department of Nuclear Medicine, Leipzig, GERMANY, [4]Hannover Medical School, Hannover, GERMANY.

Aim/Introduction: Tau-PET emerged as a valuable biomarker for the differentiation of the 4-repeat (4R) tauopathy progressive supranuclear palsy (PSP) from healthy and disease controls. However, the translation of in vitro 4R-tau binding to in vivo tau-PET signals is still unclear. ***Materials and Methods:*** We conducted a longitudinal [18F]PI-2620 PET/MRI study in a 4R-tau mouse model (PS19) and age matched wild-type mice (n=10 each). Next, we performed immunohistochemistry in a subset of these PS19 and wild-type mice (n=4 each) to characterize regional tau abundance and cellular contributions to tau pathology. Cell sorting after tau radiotracer injection was applied in another subset of PS19 and wild-type mice (n=5 each) to determine the cellular origin of tau-PET signals. A key experiment of the study consisted of a correlation analysis between regional [18F]PI-2620 tau-PET signals and abundance of fibrillary tau pathology in autopsy samples of patients with definite PSP (n=6) and disease controls (n=2). In this sample, we performed a quantitative correlation analysis between tau-PET binding, autoradiography binding and abundance of AT8-positive tau pathology. An additional autopsy sample of deceased patients with PSP with limited co-pathology (n=16) was used to determine the contribution of tau-positive neurons and tau-positive astrocytes to [18F]PI-2620 autoradiography signals. ***Results:*** We found elevated PET signals in presence of high neuronal but low astroglial tau. Furthermore, we a observed higher tracer uptake in single neurons compared to astrocytes of PS19 mice. Regional [18F]PI-2620 tau-PET signals in vivo correlated strongly with abundance of fibrillary tau in subsequent autopsy samples of PSP patients and disease controls. In an additional autopsy sample of deceased patients with PSP, tau-positive neurons with high AT8 density but not tau-positive astrocytes were the driver of [18F]PI-2620 autoradiography signals. ***Conclusion:*** In summary, neuronal tau constitutes the dominant signal source of tau-PET signal increases in 4R-tauopathies, yielding the capacity to translate to an in vivo signal.

Hoffmann-La Roche AG, Roche Pharma Research & Early Development, Neuroscience, Roche Innovation Center Basel, Basel, SWITZERLAND, [4]Munich Cluster for Systems Neurology (SyNergy), Munich, GERMANY, [5]F. Hoffmann-La Roche AG, Roche Pharma Research & Early Development, Roche Innovation Center Basel, Neuroscience & Rare Diseases (NRD) Translational Area, Discovery Neuroscience, Basel, SWITZERLAND.

Aim/Introduction: Neurodegeneration and accumulation

of amyloid-β plaques are two major hallmarks in Alzheimer's disease. There is evidence that amyloid-β can trigger neuronal hyperactivity but has also been found to be neurotoxic. Thus, we aimed to investigate the temporal and spatial association between amyloid-β plaque load and synaptic density in an amyloid-β mouse model. ***Materials and Methods:*** 26 APPSL70 and 15 C57Bl/6 mice underwent longitudinal PET-scans with 18F-UCB-H to define the synaptic vesicle protein 2A (Sv2a) density, as well as with 18F-florbetaben (FBB) to determine the amyloid-β plaque load. Statistical parametric mapping was performed to uncover similarities between the binding patterns of 18F-FBB and 18F-UCB-H. ***Results:*** As expected, we found a continuous longitudinal increase of FBB in APPSL70 mice with predominance in the frontal cortex from six to twelve months of age, resulting in a significantly higher 18F-FBB-PET in cortex ($p<0.0001$), hippocampus ($p<0.0001$), and thalamus ($p=0.0007$) of APPSL70 mice compared to C57Bl/6 mice at twelve months of age. Interestingly, we also found a significant increase in Sv2a PET signals of cortex ($p=0.023$) and thalamus ($p=0.032$), as well as a trend to significance in the hippocampus ($p=0.061$) of APPSL70 mice compared to C57Bl/6 mice at 12 months of age. Statistical parametric mapping revealed a similar pattern for differences in 18F-FBB and 18F-UCB-H binding. ***Conclusion:*** This study suggests a close temporal and spatial association between synaptic density and amyloid-β plaque load. Furthermore, we found a significant increase of 18F-UCB-H PET-signal. This adds to the observed hyperexcitability of neurons in close vicinity to amyloid-β plaques as described by Busche et al. (2008) for APP23xPS45 mice, here now shown in a longitudinal PET-imaging study in APPSL70 mice and connected with the amyloid-β plaque load as measured by 18F-FBB PET. ***References:*** Busche, M. Improving visual assessment of ^{18}F-Florbetaben PET scans through the adjunctive use of quantitation: A retrospective analysis in challenging close-to-pathology cases across 18 software methods.

***S. Bullich*[1],** *G. D. Kolinger[1], N. Roé-Vellvé[1], N. Koglin[1], A. Nelson[2], M. Diemling[3], J. Lilja[3], J. Gómez-González[4], L. Thurfjell[5], J. Koikkalainen[5], J. S. Lee[6], R. Mazza[7], V. Doré[8], P. Bourgeat[9], A. Whittington[10], R. Gunn[11], A. W. Stephens[1], A. Jovalekic[1];*
[1]Life Molecular Imaging GmbH, Berlin, GERMANY, [2]MIM Software Inc, Cleveland, OH, UNITED STATES OF AMERICA, [3]Hermes Medical Solutions, Stockholm, SWEDEN, [4]Qubiotech Health Intelligence, A Coruña, SPAIN, [5]Combinostics Oy, Tampere, FINLAND, [6]Brightonix Imaging Inc, Seoul, KOREA, REPUBLIC OF, [7]Nuclear Medicine Unit, G. Mazzini Hospital, Teramo, ITALY, [8]Department of Molecular Imaging & Therapy, Austin Health, Melbourne, AUSTRALIA, [9]CSIRO, Brisbane, AUSTRALIA, [10]Invicro, London, UNITED KINGDOM, [11]XingImaging - A Mitro Company, London, UNITED KINGDOM.

Aim/Introduction: Visual interpretation of 18F-Florbetaben PET is approved and reliable for assessing brain amyloid-beta (Aβ) deposition. However, PET images of patients with Aβ levels close-to-pathology thresholds can be challenging to read. This study assessed the robustness and added value of amyloid PET quantification in a sample of challenging scans with Aβ levels close-to-pathology thresholds. ***Materials and Methods:*** 18F-Florbetaben PET scans (n = 81) from end-of-life subjects with post-mortem histopathological confirmation of the presence or absence of Aβ neuritic plaques on a 4-point scale (Aβ-: none, sparse; Aβ+: moderate, frequent) were analysed. PET scans were visually assessed by 8 independent and blinded readers (3 experts and 5 newly trained readers). PET scans were quantified using 18 software methods excluding those cases that did not pass quality control. Sensitivity and specificity of quantitative and visual assessment were determined in the close-to-pathology threshold subpopulation (n=36) (i.e. Aβ load was sparse or moderate by Bielschowsky silver staining and/or immunohistochemistry, scans with none or frequent Aβ plaques were excluded). In this subpopulation, the frequency of discordant visual and quantitative assessments and their respective agreement with histopathology was assessed. ***Results:*** Sensitivity and specificity (mean±SD) across software packages in the close-to-pathology threshold subpopulation were 96±4% and 92±4%, respectively. Expert readers' sensitivity and specificity were 93±5% and 85±5%, respectively, newly trained readers had 93±7% and 68±25%, respectively. Across all possible pairs of readers and software methods (n=4896) where visual and quantitative assessment was discordant (n=412, 8.4%), quantitation agreed more often with histopathology than visual assessment. In the Aβ-positive discordant subset, readers correctly identified plaque presence, but quantification did not in 1.3% instances, while quantitation correctly identified plaque presence, but readers did not in 2.7% instances. In the Aβ-negative discordant subset, there were no instances in which readers correctly identified plaque absence, but quantification did not. Furthermore, quantitation correctly identified plaque absence in 4.4% instances where readers failed. ***Conclusion:*** This study demonstrated the excellent sensitivity and specificity of quantitative methods in close-to-pathology threshold cases, supporting their use as an adjunct to visual assessment in this population. A benefit of quantification in this challenging population was observed in newly trained readers to identify Aβ-negative scans.

OP-852

Comparing Models for Myocardial Blood Flow Quantification of Flurpiridaz F^{18} PET

M. Meddens, *M. E. Hol, A. J. A. T. Braat, H. W. A. M. de Jong; UMC Utrecht, Utrecht, NETHERLANDS.*

Aim/Introduction: Flurpiridaz F^{18} is a novel PET myocardial perfusion imaging tracer that is currently being evaluated in clinical trials. Its high first pass extraction and small positron range make it an ideal tracer for myocardial blood flow (MBF) quantification. Various models to quantify MBF from time activity curves (TAC) have been proposed. The aim of this study is to compare these models in terms of error in MBF estimation and goodness of fit on data from clinical scans. ***Materials and Methods:*** 10 min dynamic Flurpiridaz PET imaging was performed in 13 patients with suspected coronary artery disease (CAD) in a 1-day rest/

stress protocol using 110/240 MBq respectively. TACs from three coronary artery territories (LAD, LCX, RCA) and 17 segments (AHA model) were analyzed using a two tissue compartment model (2TC, [1]), one tissue compartment model (1TC) and Packard model (1TC with no efflux (k2=0) fitted only over the first 90s after injection, [2]). Standard error on fitted K1 (a measure for MBF) was compared and goodness of fit was evaluated using the Akaike information criterion with small sample size correction (AICc) which penalizes models with more parameters. ***Results:*** Mean K1 values for all patients and models combined were 0.87 and 2.09 ml/min/g for rest and stress scans respectively. The mean MBF per model deviated at maximum 5% from the overall mean. However, only the 2TC model resulted in outliers (K1 > mean+3SD): 1/39 for territories, 6/221 for segments. The standard error (SE) on the fitted K1 parameter was comparable for 2TC and Packard models but significantly lower for 1TC, especially for rest scans. Comparing the goodness of fit by means of the AICc showed that for territorial analysis 2TC, 1TC and Packard were preferred in 32%, 68% and 0% of exams. For segmental analysis this was 33%, 66% and 1% for 2TC, 1TC and Packard respectively. ***Conclusion:*** All three models can estimate MBF and result in comparable absolute values. The 2TC model was least robust, especially for noisier data from smaller ROIs. The Packard model was robust, but rarely the preferred model based on the AICc. Therefore 1TC seems to be the optimal model for MBF quantification. When using the 2TC model care should be taken to implement quality control for the fit result since this model can result in erroneous MBF estimation, especially for noisier TACs. ***References:*** [1] Nekolla et al. 2009; [2] Packard et al. 2014.

OP-853

From coarse to refined: Fully automated amyloid brain PET spatial normalization pipeline using Convolutional Neural Networks without MRI

C. Tang[1,2], *X. Sun[1,3], W. Ruan[1,3], X. Lan[1,3];*
[1]Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]First School of Clinical Medicine, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [3]Hubei Key Laboratory of Molecular Imaging, Wuhan, CHINA.

Aim/Introduction: Spatial normalization (SN) of Amyloid Brain PET images is crucial for tasks like amyloid burden quantification. Traditional methods rely on MRI images and require computation from scratch for each new registration process. Neural networks could store patterns of the PET images, significantly accelerating the registration process. However, manual coarse registration is still necessary beforehand to ensure approximate alignment of input images, since the raw input may undergo rotations, translations, or inversions. Therefore, we propose a fully automated pipeline based on convolutional neural networks (CNNs) to tackle challenges from coarse to refined registration, enabling rapid and accurate SN procedure of PET images to the MNI space. ***Materials and Methods:*** We introduce a multitask CNN that simultaneously predicts the anterior commissure's position and head directions for rigid transformations. We've enhanced the standard VoxelMorph algorithm with data augmentation and an Amyloid PET template, enabling refined registration through local displacement field predictions. SPM12 registration results serve as the Ground Truth to match the Centiloid Scale. We use WHUH (nPiB=115, nAV45=255) and ADNI-Patho (nPiB=13, nAV45=115) for training and validation, with external testing on the GAINN-PiB, GAINN-AV45, GAINN-FBB, and GAINN-Flutemetamol datasets. ***Results:*** Our multitask convolutional neural network predicts the anterior commissure position with an error of 5.31±3.46mm, 5.33±2.84mm, 4.46±2.06 mm, and 5.72±2.86mm, the anterior commissure-posterior commissure direction with an error of 5.31±3.62°, 5.43±4.16°, 5.38±3.61°, and 5.61±3.95°, and the anterior commissure-superior direction with an error of 4.60±2.44°, 5.04±3.72°, 5.19±3.56°, and 5.10±3.43° respectively on the testing dataset. Following the standard Centiloid procedure, we recalculated the PiB Centiloid Scale, achieving an R2 value of 0.99 compared with the result reported in the Centiloid paper. We also computed the SUVr suggested by the Centiloid project on the testing datasets, with an error of 3.55±2.42%, 3.92±3.23%, 4.07±2.83%, and 6.68±4.52% respectively. Compared to the standard SPM registration process, which takes an average of 170±18s per image and requires manual coarse registration beforehand, our automated SN pipeline requires no human intervention and registers images in an average time of 1.37±0.71s. ***Conclusion:*** Our fully automated normalization pipeline demonstrates excellent accuracy, aligns well with the Centiloid Scale, and exhibits good generalization performance across tracers. Our method can handle transformations including rotation, translation, and flipping in PET images, making it promising for application in fast, automated, and large-scale data normalization across centers, and scenarios where MRI images are not available.

OP-854

^{68}Ga-FAPI-04 PET/CT for cardiotoxicity visualization of cancer therapy: kill two birds with one stone

X. Yu, *L. Xu, J. Liu, Y. Chen;*
Renji Hospital affiliated with Shanghai Jiao Tong University, Shanghai, CHINA.

Aim/Introduction: The development of cancer therapy extends the survival time for cancer patients. However, exposure to corresponding therapy contributes to cardiac toxicity, which could compromise the quality life of cancer patients. While fibroblast activating protein inhibitor (FAPI) PET is increasingly utilized for cancer staging, its application for damaged myocardium induced by cancer therapy still needs to be investigated. ***Materials and Methods:*** The retrospective study included 35 patients who underwent 68Ga-FAPI-04 PET/CT between August 2021 and November 2023. All of them were examined pre- and post-cancer therapy. Cardiac FAPI uptake was analyzed based on the uptake location, pattern and value. Cardiovascular risk factors, cardiac serum biomarker, electrocardiogram (ECG) and left ventricular ejection fraction (LVEF) from transthoracic echocardiography (TTE) were also analyzed. Myocardial FAPI uptake was further assessed based on different cancer therapy classification and the corresponding cycles. ***Results:*** All 35 patients (22 men, 13 female; 58.7±12.3) were pathologically diagnosed as malignant. The baseline 68Ga-FAPI-04 PET/CT demonstrated FAPI-negative myocardium uptake, while FAPI-positive myocardium uptake was observed in 11 patients (31.4%) after cancer therapy. 2 out of 11 patients (18.2%) showed diffuse myocardial FAPI uptake pattern, 3 patients (27.3%) demonstrated focal on diffuse uptake pattern, and the other 6 patients (54.5%) presented focal uptake pattern. In addition, a total of 19 uptake lesions were identified. 8 lesions (42.1%) were located in interventricular septum, 5 lesions (26.3%) were in inferior wall, 3 lesions were (15.8%) in apical part, 2 lesions (10.5%) were in anterior wall, and the 1 remaining lesion (5.3%) was in lateral wall. The lesion SUVmax value was 3.6±1.6 and the tumor-to-background ratio (TBR) was 3.3±1.5. The linear regression analysis demonstrated both LVEF and smoking had a strong correlation with myocardial FAPI SUVmax value ($r = -0.72$, $p < 0.01$; $r = 0.61$, $p < 0.05$), while diabetes and BNP displayed the

moderate and weak correlation with SUVmax value respectively (r = 0.45, p < 0.01; r = 0.27, P < 0.05), whereas moderate correlation was demonstrated between TBR and LVEF (r = 0.52, P < 0.05). Additionally, myocardial FAPI uptake was more likely to occur after the second cycle (P < 0.05). ***Conclusion:*** 68Ga-FAPI-04 PET /CT could be the one-stop shop for cancer TNM staging and therapy evaluation, along with detecting therapy-induced cardiac damage.

OP-855

Findings from a medical algorithmic audit of a clinical decision support system for the detection of cardiac amyloidosis based on ^{99m}Tc-scintigraphy images

C. Spielvogel[1], *D. Haberl[1,2], K. Kluge[3], J. Ning[2,1], M. Hacker[1], C. Nitsche[4];*
[1]Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]Christian Doppler Laboratory for Applied Metabolomics, Vienna, AUSTRIA, [3]Medical University of Vienna, Vienna, AUSTRIA, [4]Division of Cardiology, Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Research on clinical decision support systems (CDSS) for medical imaging typically focuses on performance metrics, but even high-performing systems can fail when deployed in real-world clinical environments, potentially posing a danger to patients' lives. Therefore, thorough evaluation of CDSSs is essential for successful clinical implementation. This study conducted a medical algorithmic audit (MAA)(1) for a CDSS previously evaluated to have high diagnostic accuracy in detecting cardiac amyloidosis using bone scintigraphy imaging(2). The study aimed to critically assess the CDSS's robustness, safety, clinical applicability, and limitations. ***Materials and Methods:*** Overall, the MAA involved 22613 bone scintigraphy scans from 19453 patients across nine international medical centers. Imaging data included four 99mTc-tracers including DPD, HMDP, MDP, and PYP. Parameters related to patients, image acquisition, and predictions were gathered. The audit was conducted by a team of three nuclear medicine specialists, two artificial intelligence experts, and a cardiologist. The audit included scoping, mapping, artifact collection, testing, and reflection phases. The CDSS was tested for variations in tracers, imaging protocols, scanners, centers, and patient demographics, and failure modes were explored and quantified using a failure modes and effects analysis (FMEA). ***Results:*** The CDSS demonstrated robust performance across various scanners (AUC 0.933-1.000), tracers (0.925-1.000), centers (0.925-1.000), and demographic factors (0.985-0.996). Lower performances were consistently associated with two centers using substantially different imaging protocols including [99mTc]Tc-PYP. Systematic validation using images acquired after development of the AI system did not indicate data drift over time (p<0.05). In the exploratory error analysis, seven common failure modes were identified from 64 misclassifications (0.3%), with extracardiac uptake being the most frequent. As a consequence of intermediate findings of the MAA, an attention map validator algorithm was developed. This algorithm reduced false positives by 7/16 (44%). The FMEA assessed multiple clinical implementation scenarios, identifying the safest as integrating the CDSS in tandem with nuclear medicine physician reading, including alerts for positive detections. ***Conclusion:*** This audit highlighted the CDSS weaknesses and their mitigation, underscoring the importance of comprehensive evaluations of medical AI systems, especially in the context of real-world clinical environments. Through the MAA, we defined operational boundaries and conditions for safe CDSS Usage, facilitating clinical integration and emphasizing the need for ongoing improvement and monitoring of deployed medical AI-systems. We believe that the evaluation framework provided by the MAA can enable critical and systematic assessment, allowing for developing effective, reliable, and safe CDSSs in nuclear medicine. ***References:*** (1)Liu,-X.-et-al.-Lancet-Digit-Health (2022) (2)Spielvogel,-C.-P.-et-al.-Lancet-Digit-Health-(2024)

OP-856

Energy demands of resting state brain connectivity

Y. Mayr, *A. Lizarraga, I. Yakushev;*
Technical University of Munich, Department of Nuclear Medicine, Munich, GERMANY.

Aim/Introduction: Resting-state functional connectivity (rsFC) has been one of the most active research areas of systems neuroscience in the last 20 years. Intriguingly enough, it is still unclear if and how much energy rsFC demands, in general and relative to structural connectivity (SC). Previous studies reported that SC and rsFC were significantly correlated; SC was highly predictive of the presence and strength of rsFC, but SC could not be reliably inferred from rsFC; indirect SC accounted for some FC observed between regions lacking direct SC. ***Materials and Methods:*** We analyzed diffusion-tensor imaging (DWI), functional-magnetic-resonance-imaging (fMRI), and fluorodeoxyglucose (FDG) positron-emission-tomography (PET) data of 55 healthy, middle-aged individuals. Each subject underwent 2 identical scanning sessions. Images were spatially parcellated into 106 brain regions. SC was measured by probabilistic tractography. rsFC was estimated from fMRI data as Pearson correlation between blood-oxygen-level-dependent signals of each pair of regions. We fitted 3 sets of regression models: one set with SC as predictors, another with rsFC as predictors, and a third set with both SC and rsFC as predictors. Each set included 5 regression models, one linear and 4 non-linear. The complete dataset was split into a training (80%) and test set (20%), grouped by subject. All regression models were trained using the same training set, with 5-fold cross validation repeated 5 times. Mean and standard deviation of the adjusted R2 scores and root-mean-squared-error (RMSE) were reported as model performance metrics. ***Results:*** SC explained up to 74% variance in glucose metabolism. In contrast, rsFC explained only up to 29% variance. SC-based models significantly outperformed rsFC-based models across all regression models - the mean adj. R2 of each SC model was more than double that of its counterpart FC model, and the mean RMSE of each SC model was lower than its counterpart FC model. Critically, rsFC did not add to the predictive power when combined with SC. These results were reproducible. ***Conclusion:*** SC outperformed rsFC in predicting brain glucose metabolism across various model complexities, and rsFC did not provide additional predictive power. These results are in line with the view that white matter infrastructure is essential for maintaining the baseline level of brain function, and is the key consumer of energy at rest. Even if rsFC truly reflects indirect SC, these connections do not impact glucose metabolism, thus being energetically irrelevant. Our results question the unique role of rsFC for brain function at rest.

OP-857

Support vector machine classification of ^{18}F-FDG PET scans in ALS patients with and without C9orf72 mutations versus controls

C. Tang[1], *M. Koole[1], K. Van Laere[1,2], P. Van Damme[3,4], J. De Vocht[3,4];*
[1]Nuclear Medicine and Molecular Imaging, Imaging and Pathology, KU Leuven, Leuven, BELGIUM, [2]Division of Nuclear

Medicine, University Hospitals Leuven, Leuven, BELGIUM, [3]Laboratory for Neurobiology (VIB-KU Leuven), Department of Neurosciences, KU Leuven, Leuven, BELGIUM, [4]Division of Neurology, University Hospitals Leuven, Leuven, BELGIUM.

Aim/Introduction: Previous studies underscored the diagnostic value of 18F-FDG PET in Amyotrophic Lateral Sclerosis (ALS) (1), consistently revealing group-level differences between ALS patients and controls, and differences in cerebral glucose metabolism between patients with and without a C9orf72 repeat expansion (2, 3). Yet, refining diagnostic algorithms and managing inter-centre variability is imperative to improve the reliability and generalizability of diagnostic methods in ALS using 18F-FDG PET. In this study, we employed support vector machines (SVM) to further explore the diagnostic potential of 18F-FDG PET in ALS, and its ability to classify patients with or without C9orf72 mutations. ***Materials and Methods:*** 20 healthy controls (HC; 62.4 ± 6.2 y, 12F/8M), 46 ALS patients with a C9orf72 repeat expansion (C9-ALS; 57.9 ± 8.0 y, 20F/26M) and 182 sporadic ALS patients (sALS; 65.7 ± 10.7 y, 82 F/100 M) underwent a 18F-FDG PET scan, 30 - 60 min post injection. All patients were diagnosed by an experienced neurologist. 18F-FDG PET images were spatially normalized to MNI space and subsequently converted to vectors with unit length. Soft margin SVMs with the linear kernel (Python v3.9, scikit-learn v0.24.2) were trained with 10-fold cross-validation which was repeated over 10 times with subjects being randomly reshuffled. Class weights were applied to balance the group sizes. The trained SVM classifiers were evaluated by sensitivity, specificity, and accuracy. ***Results:*** The binary SVM resulted in an sensitivity (mean ± std) of 0.902 ± 0.011, specificity of 0.895 ± 0.015 and overall accuracy of 0.900 ± 0.010 for classification between C9-ALS and HC, and of 0.919 ± 0.005, 0.870 ± 0.024 and 0.914 ± 0.005 respectively between sALS and HC. For the SVM classification between C9-ALS and sALS, the accuracy was 0.709 ± 0.014 for C9-ALS and 0.740 ± 0.012 for sALS. ***Conclusion:*** Binary SVM classified 18F-FDG PET scans of HCs and ALS patients with high sensitivity. The classification between C9-ALS and sALS achieved accuracies higher than 0.700 for both classes, showing that the pattern of brain involvement in C9-ALS considerably differs from sALS. These findings underscore the evolving role of PET imaging in diagnosing ALS, and in elucidating its heterogeneity. However, to further ensure the robustness of our findings across diverse populations, validation in larger cohorts is essential. ***References:*** 1. L. Multimodal Deep Fusion of MRI and DaT Scans for unsupervised stratification of Parkinson's Disease

M. Inglese[1], *M. Ferrante[1], S. Caminiti[2], N. Toschi[1], Parkinson's Progression Markers Initiative (PPMI);*
[1]University of Rome Tor Vergata, Rome, ITALY,
[2]University of Pavia, Pavia, ITALY.

Aim/Introduction: Parkinson's disease (PD) is a progressive neurodegenerative disorder affecting over 6.2 million individuals worldwide [1]. The FP-CIT SPECT (DaT scan) is the most commonly used neuroimaging technique for PD diagnosis. This study aims to develop a deep learning model that synthesizes DaT scans using a multimodal approach, integrating structural information from T1-weighted MRIs, and to generate a low-dimensional representation of DaT images to facilitate unsupervised analysis and stratification of PD. ***Materials and Methods:*** Data were sourced from the Parkinson's Progression Markers Initiative, encompassing 145 healthy controls, 455 PD subjects, and 54 scans without evidence of dopaminergic deficit (SWEDD) with baseline structural T1-weighted MRI available. T1-weighted MRI and DaT scans were co-registered and normalized to MNI space. The BRATS-MRI generative diffusion model was adapted to process joint inputs of T1 and DaT scans, synthesizing DaT images and compressing them into a latent space. Evaluation metrics included mean squared error (MSE), normalized difference, contrast-to-noise ratio (CNR), and ROI-wise analysis in regions such as the putamen, caudate, hippocampus, amygdala and cingulate. An unsupervised clustering algorithm, optimized by the Calinski-Harabasz score, was employed to explore inherent variations within the PD spectrum. ***Results:*** The reconstructed DaT scans exhibited a low MSE (0.00065 ± 0.00078), indicating minimal intensity discrepancies. Normalized difference and CNR analyses confirmed unbiased reconstructions. No statistically significant differences were found in ROI-wise comparisons. The clustering algorithm discerned three distinct clusters: majority of healthy controls were categorized into one cluster and the majority of PD subjects into another. Interestingly, the majority of SWEDD subjects were grouped predominantly with the PD patients. This suggests that despite the lack of dopaminergic deficit, SWEDD subjects share certain imaging characteristics with the PD group, which might indicate a subset of PD or a different neurodegenerative trajectory. ***Conclusion:*** This study demonstrates the potential of a multimodal deep learning approach to synthesize DaT scans from T1-weighted MRIs and to derive meaningful low-dimensional embeddings for PD stratification. The inclusion of SWEDD subjects in the PD cluster underscores the complexity of neurodegenerative disease diagnosis and highlights the utility of this approach in potentially redefining neurodegenerative spectra. ***References:*** [1]Caminiti,doi:10.1002/mds.28818;[2] Rombach, https://doi.org/10.48550/arXiv.2112.10752

Aim/Introduction: Investigate effective tumor and safe healthy liver doses in radioembolization for colorectal cancer liver metastasis (CRLM) using multicompartment dosimetry. ***Materials***

and Methods: This multicenter retrospective single-arm study (NCT06030232), included adult patients with metastatic colorectal cancer (mCRC) treated using 90Y glass microspheres from January 2014 to December 2021 in 8 centers in Turkey. All 99mTc-MAA sessions data were reviewed and pretreatment dose estimations were performed centrally by using Simplicit90Y software. Mean tumor, perfused volume, normal and whole liver doses were calculated. Treatment response was evaluated by 18F-FDG PET images. Pre and posttreatment total lesion glycolysis (TLG)s were calculated from all lesions in the perfused liver volume. Metabolic tumor response was categorized as follows; A change in metabolic activity of -100% was considered a complete response (CR), -45% to -99% was considered a partial response (PR), +75% to -44% was considered stable disease (SD), and +75% was considered progressive disease (PD). The categories were subsequently grouped into objective response (CR + PR) and non-response (SD + PD). All adverse events were evaluated using the Common Terminology Criteria for Adverse Events (CTCAE) version 5. ***Results:*** 202 patients form 8 centers were recruited. Following exclusion of patients with suboptimal imaging for response evaluation or Tc-99m MAA dose calculations, 177 (112M; 64F, mean age:61,8±0.8) patients were included to the final analysis. Mean absorbed tumor doses of responder and non-responder patients were found significantly different (250.41±126.61 vs 106.28±41.17 p=0.001). A strong correlation was observed between mean absorbed tumor dose and response to treatment (p=0.001) (figure 1 and 2). In the ROC analyses cut-off values; 109.3 Gy (sens:68%, spec:73%, AUC: 0.728, p=0.001) for mean perfused volume dose and 151.9 Gy (sens:93%, spec:89%, AUC: 0.945, p=0.001) for mean absorbed tumor dose were calculated (figure 3). There was no difference between treatment response rates related to KRAS mutation status (60% vs 59%, p=0.97). In the multivariate regression model, the only predictive factor for response was mean absorbed tumor dose (p=0.001). Baseline CEA levels (p=0.66), Ca-19-9 levels (p=0.65), location of the primary tumor (right vs other) (p=0.66) and K-RAS mut vs wt (p=0.99) were not predictive of response. In the whole patient group while ALBI scores were upgraded in 38 (26%) patients after treatment, Grade 3 hepatotoxicity was seen in 1 patient representing with transient hyperbilirubinemia. ***Conclusion:*** In patients with CRLM delivery of at least 152 Gy dose to tumor strongly correlated with tumour metabolic response.

OP-861

Predictive value of [^{99m}Tc]Tc-MAA SPECT/CT personalised dosimetry in ^{90}Y radioembolization of hepatocellular carcinoma: DOSISPERE-01 post-hoc study

G. Keane[1], *X. Palard-Novello[2], J. Chalaye[3], B. Guiu[4], L. Tselikas[5], E. Boucher[6], K. Fowers[6], E. Garin[2], M. Lam[1];*
[1]UMCU, Utrecht, NETHERLANDS, [2]Centre de Lutte Contre le Cancer Eugène Marquis, Rennes, FRANCE, [3]Assistance Publique Hôpitaux de Paris, Paris, FRANCE, [4]Department of Radiology, St-Eloi University Hospital, Montpellier, FRANCE, [5]Department of Medical Imaging, Institut de Cancérologie Gustave Roussy, Paris, FRANCE, [6]Boston Scientific Corporation, Marlborough, MA, UNITED STATES OF AMERICA.

Aim/Introduction: The landmark DOSISPHERE-01 study underscored the importance of multi-compartmental dosimetry in radioembolization. Dosimetry-guided treatment planning relies on the predictive accuracy of [99mTc]Tc-MAA-SPECT/CT. The purpose of this work was to determine the agreement between tumour absorbed dose (TAD) and normal tissue absorbed dose (NTAD) measured pre and post-procedurally in the DOSISPHERE-01 study. ***Materials and Methods:*** A post-hoc, validation analysis of prospectively acquired data from the DOSISPHERE-01 study. Patients with pre-procedural [99mTc]Tc-MAA-SPECT/CT and 90Y imaging (Bremsstrahlung-SPECT/CT or 90Y-PET/CT) were eligible for inclusion. Pre and post-treatment dosimetry was performed using a multi-compartment method, using two distinct segmentation approaches: anatomic (CT/MRI-based) and functional ([99mTc]Tc-MAA count threshold-based). Association between predicted TAD and NTAD from pre-treatment dosimetry and actual delivered doses were assessed using Pearson's correlation coefficient (PCC) and Bland-Altman analysis. ***Results:*** For the anatomical workflow, 37 patients were evaluated. A strong correlation between simulation and therapy TAD and NTAD was noted (PCC of 0.92 and 0.78 respectively). TAD estimated from [99mTc]Tc-MAA-SPECT/CT was greater than that from 90Y imaging (7.7% increased) (mean:11.9Gy, 95% limits of agreement (LoA):-85.6Gy, 109.5Gy), and NTAD was lower (2.1% decreased) (mean:-8.2Gy, LoA:-72.4Gy, 56.0Gy). For the functional workflow, 42 patients were included. The PCC for TAD and NTAD was 0.88 and 0.74 respectively. The relative overestimation of [99mTc]Tc-MAA-SPECT/CT TAD compared to 90Y imaging (24.7% increased), (mean:48.3Gy LoA:-81.7Gy, 178.4Gy) and underestimation of NTAD (27.0% decreased) (mean:-27.0Gy, LoA:-91.3Gy, 37.3Gy) was greater for this workflow. ***Conclusion:*** A strong correlation between absorbed dose metrics from pre and post-procedural imaging was identified. An anatomical segmentation workflow exhibited closer agreement than a functional segmentation workflow.

OP-862

Interim AnalysisAssessment of Hypoxia Before Radioembolization Treatment With ^{18}F-FMISO PET (ARTE-MISO Trial):

C. Soydal, *B. Demir, E. C. Celebioglu, G. Sutcu, M. S. Bilgic, N. O. Kucuk;*
Ankara University Medical Faculty, Ankara, TÜRKIYE.

Aim/Introduction: Transarterial radioembolization (TARE) stands out as a prominent therapeutic option for primary and secondary liver tumors. Its primary mechanism of action involves radiation-induced injury. Hypoxia within the tumor microenvironment has been posited as one of the underlying mechanisms contributing to radiation resistance.In this pilot study, our objective was to analyze and quantify the extent of hypoxia within liver tumors and evaluate its impact on treatment response to TARE. ***Materials and Methods:*** Patients who received transarterial radioembolization (TARE) for liver tumors were included prospectively from August 2023, with planned completion in August 2024. This abstract presents the interim analysis of the study(ClinicalTrials.gov Identifier: NCT06027021), aimed at analyzing the effect of tumor hypoxia measured by ^{18}F-FMISO PET on the response to TARE. Within 4 weeks prior to TARE, all patients underwent ^{18}F-FMISO PET imaging. Maximum standardized uptake value (SUVmax) and mean standardized uptake value (SUVmean) of all VOIs were recorded for analysis. Tumor-to-muscle ratio (TMR) and tumor-to-blood pool ratio (TBpR) were calculated. Response to treatment was assessed radiologically and metabolically. ***Results:*** Total of 30 lesions from 11 patients (mean age: 57.8 ± 11.4, 8 males and 5 females) were included in the interim analysis. Following transarterial radioembolization (TARE), partial response (PR) was observed in 18 lesions (60%), complete response (CR) in 8 (27%), stable disease (SD) in 3 (10%), and progressive disease (PD) in

1 (3%) lesion.The median values of ^{18}F-FMISO SUVmax (p=0.2) and tumor-to-blood pool ratio (TBpR) (p=0.3) for responder and non-responder lesions did not show significant differences. However, the median tumor-to-muscle ratio (TMR) values differed significantly (median: 2.65, range: 0.5-5.1 vs. median: 3.15, range: 2.5-3.4, p=0.03) between the two groups.Cut-off values were calculated as follows: 3.0 for ^{18}F-FMISO SUVmax (sensitivity: 80%, specificity: 75%, AUC: 0.71, p=0.18), 1.62 for TMR (sensitivity: 77%, specificity: 100%, AUC: 0.89, p=0.01), and 1.79 for TBpR (sensitivity: 88%, specificity: 75%, AUC: 0.80, p=0.06) for predicting response to treatment. Based on the cut-off value for TMR, the treatment response rate was 100% for non-hypoxic tumors and 60% for hypoxic ones (p=0.02). ***Conclusion:*** The results of this analysis suggest that the evaluation of tumor hypoxia with ^{18}F-FMISO before treatment in patients undergoing TARE may have a potential role in predicting treatment response. Upon completion of the study, dose threshold values required to achieve response in hypoxic tumors will also be calculated with analysis of a larger number of lesions.

OP-863

Hepatobiliary Scintigraphy and Holmium-166 Radioembolization with Personalized Dosimetry for Hepatocellular Carcinoma: Feasibility of a One-day Evaluation including Simulation and Functional Assessment, and Functional Follow-up

B. Collette[1], *A. Bucalau[1], O. Renson[2], C. Cridelich[3], I. Vierasu[1], G. Verset[1], O. Debeir[2], R. Moreno-Reyes[1], P. Flamen[1];*
[1]HUB Hôpital Erasme - ULB, Brussels, BELGIUM, [2]ULB, Brussels, BELGIUM, [3]Université de Franche-Comté, Besançon, FRANCE.

Aim/Introduction: Personalized dosimetry increases the efficacy and safety of TARE (TransArterial RadioEmbolization). But recent publications tend to confirm that in an HCC (HepatoCellular Carcinoma) context, functional information is also crucial. First, our aim was to demonstrate the feasibility of a HBS (HepatoBiliary Scintigraphy) done just after a 166Ho (Holmium-166) scout simulation, correcting for the scatter. Then, we compared it with the follow-up by HBS. ***Materials and Methods:*** 21 patients suffering from HCC simulated with 166Ho-PLLA (Poly-L-Lactic Acid) « scout dose » were included, for a total of 24 simulations, leading to 24 baseline HBS (the week preceding the scout dose) and 24 post-scout HBS (just after the scout dose, the same day). Among those 21 patients, 15 were treated with 166Ho-PLLA, leading to 15 follow-up HBS (3 months after treatment). The HBS were conducted on our SPECT/CT system following well-documented acquisition parameters. Whole liver clearance calculation was done in our own software developed to automatize the post-processing and maximize the reproducibility. Local liver clearances were assessed combining anatomical information, functional information, and dosimetry, in current software's. To compare the 24 whole liver clearances before and after scout, a Student paired t-test was done (data being normally distributed). Then, whole liver clearances and non-treated liver clearances (based on a 60 Gy isodose curve segmentation) at the different time points were compared, including coefficients of determination calculation. ***Results:*** The t-test showed non-significant differences between the whole liver clearances before and just after the injection of the scout dose, with a p-value of 0.65. Distributions seem similar, but with a poor correlation (R2 = 0.6). Focusing on whole liver clearances comparison, baseline versus 3 months after TARE, we see less similar distributions with a mean decrease, and still a bad correlation (R2 = 0.66). It's quite the same when comparing post-scout and 3 months after TARE follow-up (R2 = 0.69). The correlations between the non-treated liver clearances, baseline versus post-scout, baseline versus 3 months after TARE follow-up, and post-scout versus 3 months after TARE follow-up, seem better (R2 = 0.71, R2 = 0.75, and R2 = 0.76 respectively). ***Conclusion:*** These results indicate that a HBS just after the injection of the scout dose is feasible and seems more accurate regarding the non-treated liver clearance than regarding the whole liver clearance. Compared to the baseline HBS, both allow good prediction of the non-treated (future remnant) liver clearance 3 months after TARE.

OP-864

Dosimetric-guided therapeutic efficacy of ^{177}Lu-tin colloid radio-synovectomy in patients with inflammatory knee joints conditions

N. Kumar, *S. Shamim, M. R. Meena, S. Yadav, R. Mittal, M. Ansari, R. Gupta;*
All India Institute of Medical Sciences, New Delhi, India, New Delhi, INDIA.

Aim/Introduction: Radiosynovectomy (RSV) uses the radionuclide loaded colloidal particles such as 177Lu-tin-colloid which are rapidly phagocytized by macrophages in the inflamed synovial membrane that leads to the reduction in the synovial inflammation. Our prior experience with 177Lu-tin colloid treatment in inflammatory arthritis patients showed promise, yet was restricted to intra-articular injection of empirical activity in a small cohort. Thus, present study is aimed to assess the therapeutic efficacy with dosimetrically estimated 177Lu-tin-colloid RSV in patients with chronic inflammatory knee joint conditions. ***Materials and Methods:*** Dosimetry of 177Lu-tin-colloid was adapted by absorbed dose profile given by Torres M. et al. Considering the S-Values (Gy/MBq*h) for 250 cm2 synovium area, 0.02 cm thickness of synovial lining cells, and assuming the complete radionuclide decays in the knee joint, the 90Y-dose equivalent therapeutic activity of 177Lu-tin colloid was estimated by varying the prescribed absorbed dose with severity of disease and administered intra-articularly to the inflamed knee joint. Blood pool bone scan and clinical parameters e.g. mobility score (0-3), pain score (0-10), analgesic score (0-6), tenderness score (0-3) and joint swelling score (0-3) were performed at baseline, 6, 12 and 24 month from RSV. The patients with > 50% decrease in the cumulative scores of clinical parameters from baseline and a return of blood pool activity to background (thigh) level were considered as responders to therapy. ***Results:*** A total of 62 knee joints in 58 patients with various inflammatory joints conditions like rheumatoid arthritis (24 joints), pigmented villonodular synovitis (12 joints), Hemophillic arthritis (9 joints), lipoma arborescens (5 joints), non-specific chronic synovitis (7 joints), spondyloarthritis (4 joints), psoriatic arthritis (1 joint), underwent intra-articular injection of dosimetrically estimated activity 1750-2220 MBq of 177Lu-tin-colloid to inflamed knee joint. Of 62 inflammatory knee joints, 48 joints (~77%) were considered as responder and 14 (~23%) as non-responders at 6-months. Of 48 joints, remission were seen in 41 joints (~85%), while 7 (~15%) had recurrences at 1 year duration. Further, long term follow-up at 2-years, 35 (~73%) had complete remission and 13 (~27%) had recurrence. There was significant reduction in blood pool activity as well as change in cumulative score of clinical parameters at 6, 12 and 24 months when compared with baseline ($p<0.05$). No lymphedema, infection, radio-necrosis, or any other serious adverse effects were observed in any patient. ***Conclusion:*** Dosimetrically-guided 177Lu-tin colloid RSV is useful treatment modality for long-term remission in patients of chronic inflammatory joints.

OP-865

The correlation between tumor dosimetry and clinical parameters with therapy response and overall survival in patients with hepatocellular carcinoma, who underwent transarterial radioembolization treatment

***M. Oflas*[1],** *D. Has Simsek*[1], *E. Isik*[1], *S. Kuyumcu*[1], *Z. Ozkan*[1], *A. Poyanli*[2], *B. Kovan*[1], *C. Turkmen*[1], *Y. Sanli*[1];
[1]*Istanbul Faculty Of Medicine Department Of Nuclear Medicine, Istanbul TÜRKIYE,* [2]*Istanbul Faculty Of Medicine Department Of Radiology, Istanbul, TÜRKIYE.*

Aim/Introduction: The aim is to determine the correlation between tumor dosimetry and clinical parameters with therapy response(TR) and overall survival(OS) in hepatocellular carcinoma(HCC) patients,who received transarterial radioembolization(TARE) treatment. ***Materials and Methods:*** The patients diagnosed with HCC were included in the study,who underwent TARE treatment with glass microspheres.BCLC stages, Child-Pugh, MELD and ALBI scores were obtained from the documentation of pre/post-treatment clinical,laboratory and radiological findings.Baseline SUVmax values were calculated from F^{18}-FDG PET/CT images.The TR was assessed according to mRECIST and PERCIST criteria based on MRI and/or F^{18}-FDG PET/CT scans obtained at 3-6 months.The patients were divided into four groups:complete response (CR),partial response(PR),stable disease(SD),progressive disease(PD).Multicompartment dosimetry data were calculated from hepatic artery perfusion SPECT/CT images.The relationship between clinical and dosimetry data with OS was ascertained by Kaplan Meier and Cox regression analyses. The threshold perfused tumor doses(PTD) for the prediction of 'CR' and'CR or PR'were determined by ROC analysis. ***Results:*** 71 patients were included into the study(Table-1).During the follow-up; CR was observed in 17 patients, PR in 25 patients ,SD in 10 patients and PD in 19 patients.OS was estimated as 19 months(11.74-26.26, %95 CI).While there was a significant correlation between the TR and OS,the highest OS was observed in the CR group(median:51 months) and the lowest OS in the PD group(median:9 months) (p=0.004)(Table-2). In the ROC analysis,the threshold PTD required for 'CR or PR' was calculated as 180 Gy (sensitivity %76, specificity %55; AUC: 0.677, p: 0.012).and the threshold PTD required for 'CR' was calculated as 232 Gy (sensitivity:%77, specificity: %60 AUC: 0.721, p:0.006).There was a statistically significant increase in OS in patients, who received a PTD above 180 Gy (36 vs 10 months, p<0.001)(Table-3).Likewise,the patients received a PTD above 232 Gy had statistically higher OS(36 vs 15 months, p=0.025). According to Cox regression multivariate analysis, PTD over 180 Gy (HR:3.2) was found to be the most significant indicator in predicting OS. ALBI degree (HR:3) and SUVmax value (HR:1.15) are other statistically significant parameters in predicting OS(Table-4). ***Conclusion:*** In this study,it has been determined that the 'CR or PR' may be predicted with a PTD above 180 Gy and 'CR' may be predicted with a PTD above 232 Gy.Furthermore,a statistically significant relationship between PTD and OS has been found. Although ALBI scores and baseline SUVmax values are important parameters for predicting OR and TR,the PTD has been identified as the most important determinant for achieving effective TR and higher OS.

OP-866

Interplay Between Radiomics Features of pre- and post-procedural SPECT and PET Imaging for the Prediction of Response to Selective Internal Radiation Therapy (SIRT) for Hepatocellular Carcinoma (HCC): Preliminary Analysis

***G. Rovera*[1],** *M. Finessi*[1], *M. Cioffi*[1], *S. Grimaldi*[1], *V. Giannini*[2], *R. Passera*[1], *R. Casoni*[1], *S. Morbelli*[1];
[1]*Nuclear Medicine, Department of Medical Sciences, AOU Città della Salute e della Scienza di Torino, Turin, ITALY,* [2]*Department of Surgical Sciences, University of Turin, Turin, ITALY.*

Aim/Introduction: SIRT efficacy is mainly related to a dose-response threshold; however, tumoral heterogeneity can potentially affect treatment response. This heterogeneity is only partially reflected by pre-SIRT structural imaging. Further insights might be provided by pre-/post-procedural Nuclear Medicine imaging with SPECT/CT and PET/CT respectively. We aimed to investigate the early predictive value of radiomic features extracted from pre- and post-procedural SPECT/CT and PET/CT. ***Materials and Methods:*** Retrospective data were collected on consecutive patients with liver-dominant HCC undergoing SIRT-treatment at the University of Turin (Oct 2014-Sept 2023) with a clinical follow-up ≥1 year. Target-lesions were segmented on pre/post-procedural SPECT/PET after coregistration with conventional imaging using Simplicit90YTM. Radiomic features were extracted with PyRadiomics, using a 95% resegmentation range for noise removal, a fixed bin-count (n=25) and native isotropic voxels (spacing=4). The prognostic value (overall survival-OS and progression-free survival-PFS) of radiomic features was tested using ROC curve and Kaplan-Meier analysis with log-rank test (threshold based on Youden-index). ***Results:*** 46 HCC patients were included (median follow-up of 18 months [IQR 10-39]). 91% (42/46) of patients had cirrhosis, 37% (17/46) neoplastic portal-vein trombosis. Child-Pugh classification as follows: A5 in 72% (33/46), A6 in 22% (10/46) and B7 in 6% (3/46). Bilirubin levels were > 1.1 mg/dl in 41% (19/46) patients. Pre- and post-procedural SPECT/CT and PET/CT images were available in 44 and 27 patients respectively. PET-derived Gray Level Dependence Matrix (GLDM) Large Dependence Low Gray Level Emphasis (LDLGLE) as measure of textural heterogeneity showed a correlation with target-lesion progression during follow-up (AUC 0.80), significantly predicting PFS (median PFS 10 months vs not reached, p=0.006). SPECT-derived LDLGLE reached an AUC of 0.68, with a significant impact on PFS distribution (median PFS 15 months vs not-reached, p=0.031). Finally, when considering whole-liver progression, SPECT-derived Gray Level Size Zone (GLSZM) Large Area High Gray Level Emphasis feature showed an AUC of 0.74, possibly related to the initial disease burden. PET textural heterogeneity metric LDLGLE also predicted OS (ROC AUC 0.82; median OS 11 months vs not reached, p=0.005). No SPECT features were able to predict OS (AUC<0.7 in all cases). ***Conclusion:*** Preliminary evidence in HCC patients undergoing SIRT treatment supports a potential role of SPECT and PET radiomic features in predicting treatment response and PFS, while only PET-derived features were able to predict OS. The next steps towards the development of a combined predictive/prognostic model will require the integration of clinical, dosimetric and pre-treatment CT/MR radiomic data.

OP-867

A novel approach to radioembolization dosimetry treatment planning using a hybrid [^{99m}Tc]Tc-MAA contrast enhanced SPECT/CT

G. Keane, *A. Braat, M. Smits, H. de Jong, R. Bruijnen, M. Lam; UMCU, Utrecht, NETHERLANDS.*

Aim/Introduction: Dosimetry treatment planning is integral to the radioembolization work-up. Current guidelines recommend volumes be segmented on baseline anatomical images (e.g. contrast-enhanced CT) and registered to the separately acquired SPECT/CT. However, this conventional method is limited by registration errors and potential interval progression. The aim of this study was to compare hybrid contrast enhanced SPECT/CT-based treatment planning with the conventional method. ***Materials and Methods:*** Hybrid contrast enhanced SPECT/CT was performed in 24 patients with hepatocellular carcinoma (HCC). Treatment planning followed both the conventional and updated workflow, where delineation was performed directly on the contrast enhanced SPECT/CT. Dosimetric and morphological differences between workflows were quantified using Simplicit90Y and MIM software, and evaluated by Bland-Altman analysis. ***Results:*** Direct delineation on contrast-enhanced SPECT/CT yielded higher tumour doses (10.5% increase; 95% limits of agreement [LoA]: -70.2 Gy, 130.5 Gy) and lower normal tissue doses (13.2% decrease; 95% LoA: -66.4Gy, 109.6Gy). Tumour (p=0.01) and normal tissue doses (p=0.02) differed significantly between workflows. Tumour volume increase between baseline CT and contrast enhanced SPECT/CT was 8.2% (95% LoA: -58.6 mL, 81.6mL). Morphological differences between segmentations created via the conventional and updated workflow (indicators of registration errors and interval progression) revealed the relative impact of these effects was greater for tumour volumes (mean DICE 0.6, mean Hausdorff distance 24.2mm) than whole liver volumes (mean DICE 0.8, mean Hausdorff distance 31.2mm). ***Conclusion:*** Hybrid contrast enhanced SPECT/CT based treatment planning improves target definition and dosimetry estimates.

OP-868

ALBI score affects Overall Survival (OS) in patients with hepatocellular carcinoma (HCC) treated with selective internal radiation therapy (SIRT)

M. Cioffi, *S. Grimaldi, M. Fronda, A. Doriguzzi Breatta, G. Rovera, R. Passera, P. Fonio, S. Morbelli, M. Finessi; Università di Torino, Torino, ITALY.*

Aim/Introduction: Optimising treatment application and selection is crucial in patients potentially eligible to SIRT. We aimed to evaluate the prognostic impact of baseline clinical features and treatment procedure, including liver function measured with albumin-bilirubin (ALBI) formula and dosing methods in HCC patients treated with SIRT. ***Materials and Methods:*** The study includes 82 consecutive patients with liver-dominant HCC treated with SIRT (90Y glass microspheres, TheraSphereTM) between October 2014 and September 2023. 25 patients were treated with standard dosimetry, while for remaining patients multi-compartment dosimetry was performed using Simplicit90YTM software. Impact of baseline patients characteristics including presence of portal vein thrombosis (PVT), Child Pugh score (CP), ALBI score, bilirubin levels, tumor size and prior loco-regional liver directed or systemic treatments was assessed through multivariable Cox proportional hazard model.Clinical outcome was evaluated in terms of objective response rate (ORR) and OS. Relationships between either tumor absorbed-dose (TAD) or normal tissue absorbed-dose (NTAD) and clinical outcomes was evaluated. ***Results:*** Median follow-up after treatment was 40.0 months (15.2-67.9); 69 patients (84%) presented cirrhosis, while 35 (43%) had neoplastic PVT. 47 patients (60.3%) had bilirubin levels up to 1.1 mg/dl and 31 (39.7%) over 1.11 mg/dl. 28 patients (44.4%) had an ALBI grade 1, while 35 (55.6%) an ALBI grade 2. Median TAD and NTAD were 471.9 Gy (365.3-632.6) and 27.4 Gy (13.0-45.4), respectively.At univariable analysis, only baseline ALBI score was found to be independent prognostic factor for OS after SIRT (p=0.001, respectively); furthermore, at Cox proportional hazards analysis, HR for death of ALBI 2 vs ALBI 1 was 10.54 (95% CI, 1.42-78.19, p=0.021), while, despite not significant, HR in patients with bilirubin levels over 1.1 mg/dl was 2.47 (0.69-8.89, p=0.166). Conversely, no significant association were found between OS and cirrhosis, tumor size and PVT. Difference in ORR between standard vs multi-compartment dosimetry did not reach significancy, however the use of standard dosimetry was associated to a lack of objective response (SD+PD) with a rate three times higher with respect to multi-compartment dosimetry: stratification into TAD subgroups (from < 200 Gy to ≥ 300 Gy) showed a linear association between ORR and higher TAD (p=0.022). ***Conclusion:*** ALBI score demonstrated to impact OS in HCC patients treated with SIRT thus going beyond a simple prediction of treatment-related toxicity. The present results are relevant for the selection of HCC patients for SIRT in a real-world clinical setting.

Assessment of 2-$^{[18F]}$FDG-PET/CT metrics in treatment-naive patients with bone and soft tissue sarcomas.

A. Basanta, *M. Romera, F. Mínguez, V. Betech, A. Fernández-González, G. Quincoces, E. Guillén, J. Arbizu, J. Rosales; Clínica Universidad de Navarra, Pamplona, SPAIN.*

Aim/Introduction: 2-$^{[18F]}$FDG-PET/CT (FDG-PET) has been used for determining the oncological stage, therapy response, and prognosis in patients with Bone Sarcoma (BS) and Soft Tissue Sarcoma (STS). The aim of our study is to evaluate the semiquantitative and volumetric parameters of FDG-PET in treatment-naive patients with BS and STS and analyze their distribution according to histological grading groups. ***Materials and Methods:*** We retrospectively included 66 patients (mean age 40 ± 20). Among them, thirty-two patients were diagnosed with Bone Sarcoma (BS) and thirty-four with Soft Tissue Sarcoma (STS). FDG-PET imaging was performed for initial staging in all patients. Classical semi-quantitative parameters such as SUVmax, SUVmean, TBR (Tumor SUVmax/Liver SUVmean), Metabolic Tumor Volume (MTV), and Total Lesion Glycolysis (TLG) in the primary tumor were obtained from FDG-PET scans. These FDG-PET parameters were analyzed across histopathological classification

groups. The grading of BS and STS was established based on histotype and by FNCLCC classification, categorized as follows: Grade I-low (G1), Grade II-intermediate (G2), and Grade 3-high (G3). ***Results:*** Patients with high-grade (G3) BS and STS statistically exhibited higher SUVmax, SUVmean, and TBRs. For SUVmax, a median of 6.98 (IQR: 4.31-14.62) was observed compared to a median of 4.41 [IQR: 2.70 - 8.98] in the G1-G2 group. The values for SUVmean and TBRs are summarized in Table 1. In the STS group, higher SUVmax values were noted in G3 with a median: 8.77 (IQR: 5.12-17.73) compared to G1-G2 with a median of 3.33 (IQR: 2.45-6.17; p<0.005). However, no significant differences were observed in the FDG-PET parameters among the histological BS subgroups. Patients with G1-G2 BS had significantly higher values in the FDG-PET parameters (SUVmax, SUVmean, and TBRs) when compared to G1-G2 STS. No significant differences were found among groups in terms of volumetric parameters (MTV and TLG). ***Conclusion:*** Our findings indicate that patients with high-grade (G3) BS and STS demonstrated significantly higher SUVmax, SUVmean, and TBRs compared to lower-grade tumors. Particularly in the STS group, elevated SUVmax values correlated with higher histological grades, suggesting a potential role of FDG-PET in prognostic assessment. These findings underscore the potential of FDG-PET as a valuable tool for assessing tumor characteristics and guiding treatment strategies in patients with BS and STS, particularly in the context of histological grading, but larger cohorts are warranted to validate these findings.

OP-871

To evaluate F^{18} FDG PET/CT based parameters in prediction of histopathological response to neoadjuvant chemotherapy in patients with Osteosarcoma

S. Maitra;
University College London Hospital, London, UNITED KINGDOM.

Aim/Introduction: To evaluate F^{18} FDG PET-CT based parameters in prediction of Histopathological Response to Neoadjuvant Chemotherapy in Patients with Osteosarcoma. ***Materials and Methods:*** 30 patients diagnosed with osteosarcoma who underwent FDG PET-CT scan at baseline and post neoadjuvant chemotherapy (NACT), followed by surgery (between 2011 - 2016) were assessed. The SUVmax , metabolic tumor volume (MTV) and total lesion glycolysis (TLG)of the primary lesion was recorded at baseline and post NACT along with post/pre NACT ratios. MTV was calculated with threshold of 45% SUVmax; MTV(45%)and by summing the volume of voxels with SUV higher than SUV 2; MTV(2). TLG(45%) and TLG(2) was calculated. Histopathological reports post-surgery were obtained, necrosis fractions and response was catalogued. Histopathological necrosis fractions (HNF) were correlated with post NACT parameters and post/pre NACT ratios. Receiver operating characteristic (ROC) curve analysis was done to determine cut off, sensitivity and specificity for post/pre NACT ratios which could predict good histopathological response from poor response. Post/pre NACT ratios were compared to find out better predictor of histopathological response. ***Results:*** 16 patients were good histopathological responders and 14 were poor histopathological responders. Post NACT SUVmax , MTV (2) , TLG(2) , post/pre NACT ratios of SUVmax, MTV (2), and TLG (2) showed difference between good and poor responders. Among post/pre NACT ratios, all parameters except MTV (45%) showed correlation with HNF. TLG (2) showed strong, MTV (2) ratio showed moderate and SUVmax ratio showed weak correlation. On post NACT PET- CT scan, absolute values of SUVmax and MTV (45 %) did not show correlation with HNF and MTV (2), TLG (2) and TLG (45 %) showed weak correlation. ROC curve analysis and comparing AUCs (area under curve), revealed MTV (2) ratio and TLG (2) ratio to be equally good predictors of histopathological response. MTV(2) ratio is a better predictor of histopathological response than SUVmax ratio. The sensitivity and specificity for predicting a good response was 92.8 % and 75 % using a MTV (2) ratio cut off of 0.17 and using a TLG (2) ratio cut off of 0.10. ***Conclusion:*** In our osteosarcoma population, the change in ^{18}F-FDG PET-CT based parameters post NACT were useful in predicting tumor response. The change in combined metabolic/volumetric parameters like MTV and TLG (measured at threshold of SUV 2) post NACT were better predictors of Histopathological response than change in the metabolic parameter, SUVmax post NACT.

OP-872

Radiomics-based Machine learning method for prediction of metastatic disease in soft tissue sarcoma

T. Singhal, *P. Singh, G. K. Parida, P. S. Patro, S. K. Barik, K. Agrawal; AIIMS Bhubaneswar, Bhubaneswar, INDIA.*

Aim/Introduction: Soft-tissue sarcomas(STS) are rare tumors with unpredictable clinical behavior. Distant metastasis(DM) occurs in about 25-30% of patients and ponders poor prognosis. A comprehensive approach, including surgery and chemoradiotherapy, is common and can improve survival rates provided complete excision of disease is possible. Thus, the preoperative assessment for metastatic disease is vital for prognosis and for formulating treatment strategy. However, available imaging including functional positron-emission tomography(PET)-CT imaging carries limited accuracy leading to unnecessary interventions. Thus, this study was carried out to model a non-invasive method to predict the likelihood of DM to assist in more tailored interventions only in cases with reasonably high pre-test likelihood. ***Materials and Methods:*** Patients with STS who underwent ^{18}F-FDG PET-CECT imaging were included in the study. Experienced Nuclear Medicine physicians manually delineated the regions of interest and high-dimensional radiomic features(RF) were extracted using LIFEx (v7.2). Univariate analysis was applied to each RF as well as metabolic parameters (SUVmax, MTV and TLG), using area under curve(AUC) of receiver operator curve(ROC) and p-value computed by Mann-Whitney-U test. p-value<0.05 was considered significant. Clinical ± imageological follow-up was taken as the gold standard. RF with an AUC>0.6 were further refined with least absolute shrinkage and operator(LASSO) algorithm. A support vector machine(SVM)-based MLM was developed using Rv.4.1.3, with 75% of data for training and 25% for validation. Model's performance was assessed using ROC curves and compared with metabolic parameters. ***Results:*** The study included 41 STS patients (30 males, median age-41, range: 2 months-74 years). Among these, 23 patients had metastatic disease on follow-up. A total of 134 RF were extracted from each ^{18}F FDG PET-CT image. Subsequently, Univariate analysis was performed which revealed 17 RF were statistically significant predictors of outcome. In multivariate analysis, the best SVM-LASSO model consisted of 9 RF (Table-1). The SVM-MLM achieved a sensitivity and specificity of 83.33% & 75% respectively with AUC of 0.917 compared to 78.3% & 50% for MTV at a cut-off of 92.5cm3 and 82.6% & 55.6% for TLG at a cut-off of 533 with an AUC of 0.688 and 0.703 respectively. Thus, SVM-MLM demonstrated superior performance compared to metabolic parameters with an overall accuracy of 80%. ***Conclusion:*** SVM-MLM can provide an efficient tool to predict the risk of metastases in STSs. This technique has

potential to assist in choosing the appropriate treatment for STSs and potentially improve patient survival.

OP-873

A registration pipeline for digitized histopathology and multimodality imaging in sarcoma

G. Kalisvaart, *A. Broersen, S. Lam, R. P. J. van den Ende, A. Navas Canete, K. van Langevelde, J. A. van der Hage, M. A. J. van de Sande, H. Gelderblom, J. Dijkstra, J. V. M. G. Bovee, L. de Geus-Oei, H. Bloem, W. Grootjans;*
Leiden University Medical Center, Leiden, NETHERLANDS.

Aim/Introduction: Despite growing interest, preoperative response monitoring in sarcomas during neoadjuvant therapy has not yet resulted in standardized response assessment and subsequent treatment personalisation. This is caused due to lack of understanding on relations between imaging features and tumour biology, complicated by considerable tumour heterogeneity in sarcomas. Here we develop and evaluate a methodological pipeline to spatially register digitized histological information with preoperative [18F]FDG-PET, CT, T1-, diffusion weighted-, and dynamic contrast enhanced MRI. ***Materials and Methods:*** We propose workflows for 6 different research settings; registration of bone sarcomas in retrospective (WF1), and in prospective settings without (WF2) or with fixating tumours in 3D-printed tumour moulds during pathological processing (WF3), and corresponding settings in soft-tissue sarcomas (STS); WF4, WF5 and WF6, respectively. For each workflow 2 patients were included forming a development cohort to test registration accuracy with Dice coefficients. Histology slides were digitized and annotated for viable and responsive tumour tissue. Slides were stitched and registered to preoperative images. Associations between imaging features and tissue types were assessed, quantitatively modelled and clustered in an unsupervised manner with hierarchal stochastic neighbour embedding (HSNE) to gain insight in tumour biology. Another 8 sarcomas were included to validate most accurate retrospective and prospective candidate workflows. ***Results:*** The developed methods showed good registration accuracy in WF1-3, WF5 and WF6 with average Dice coefficients being 0.86, 0.84, 0.89, 0.91, 0.93, respectively. Retrospective registration in STS (WF4) was considered not to be feasible due to tissue deformation. Several clusters of different tissue types could be identified with HSNE, showing added value of combining information from multiple imaging modalities. In predictive modelling, mean accuracies and areas under the curves for response were 0.73(±0.06) and 0.80(±0.07), respectively. [18F]FDG-PET was available in 10 patients and was the modality with highest importance for response classification in 60%. Interestingly, in 4 STS with histological response to radiotherapy, non-necrotic response, consisting of fibrosis, hyalinization, or cell maturation, showed higher SUV than viable tumour. In the 2 of these 4 patients that showed treatment-induced necrosis, necrosis showed lower average SUVs (1.0 in both) than viable tumour (4.3 and 4.4 in a liposarcoma and maligne nerve sheath tumour, respectively). ***Conclusion:*** Results suggest retrospective registration of bone sarcomas is feasible and use of 3D-printed moulds adds precision in both bone- and STS. The proposed pipeline allows to establish the relation between imaging and tumour biology and development of quantitative models explaining observed tumour heterogeneity.

OP-874

Development of a Deep Learning Model for Automated Measurement of Skeletal Muscle Mass in [18F]F-FDG PET/CT Scans

R. Nakamoto[1], *K. Fujimoto[2], R. Sakamoto[2], M. Yakami[1], T. Nobashi[1], H. Isoda[1], Y. Nakamoto[2];*
[1]Kyoto University Hospital, Kyoto, JAPAN,
[2]Kyoto University, Kyoto, JAPAN.

Aim/Introduction: In recent years, the reduction in muscle mass (sarcopenia) has garnered attention as a poor prognostic factor in various malignancies and resistance to treatments such as surgery, chemotherapy, and radiation therapy. Accurately measuring individual skeletal muscle mass is becoming increasingly important in the realization of personalized medicine. Thus, this study aimed to develop a deep learning model to automatically measure the muscle mass of anti-gravity muscles using whole-body CT scans from [18F]F-FDG PET/CT. ***Materials and Methods:*** This study included 209 individuals (148 males, 61 females) who underwent [18F]F-FDG PET/CT scans for cancer screening between January 2017 and April 2022 at Preemptive Medicine and Lifestyle Related Disease Research Center, Kyoto University Hospital. Muscle regions in the CT data of four PET/CT scans were manually labeled using the open-source software (3D Slicer), creating the training data. The open-source 3D segmentation model (nnUNET1) was trained with these data and then used to perform inference on the anti-gravity muscle areas in the remaining 205 CT data. The overlap (Dice coefficient) between the labeled regions and the inferred regions was calculated for the four training datasets. The Spearman correlation coefficient was calculated for skeletal muscle mass measurements between nnUNET and the bioelectrical impedance analysis device (InBody) for 209 subjects. ***Results:*** The average Dice coefficient was 0.973 ± 0.0085 (range 0.961-0.979). A board-certified nuclear medicine and radiology specialist extracted CT data randomly from 30 of the 205 participants after inference and confirmed that nnUNET could accurately infer anti-gravity muscle regions. The correlation coefficient between skeletal muscle mass measurements by nnUNET and InBody was 0.963. ***Conclusion:*** The study demonstrated that our 3D segmentation deep learning model could reasonably measure skeletal muscle mass from whole-body CT images in PET/CT scans. PET/CT is expected to become an increasingly important tool for personalized medicine, as it can acquire not only tumor accumulation values (SUVmax) from PET images, but also non-tumor parameters such as muscle mass that reflect individual patient characteristics from CT images.

PSMA expression and PSMA PET/CT imaging in advanced soft tissue sarcomas; potential for PSMA-targeted radioligand treatment? Interim results

F. Kleiburg[1,2], *T. van der Hulle[2], H. Gelderblom[2], M. Slingerland[2], F. M. Speetjens[2], L. J. A. C. Hawinkels[2], P. Dibbets-Schneider[2], F. H. P. van Velden[2], M. Pool[2], J. V. M. G. Bovée[2], L. Heijmen[2], L. de Geus-Oei[1,2,3];*
[1]University of Twente, Enschede, NETHERLANDS, [2]Leiden University Medical Center, Leiden, NETHERLANDS, [3]Delft University of Technology, Delft, NETHERLANDS.

Aim/Introduction: Although initially associated with prostate cancer, it is now known that PSMA expression is also present in

several other tumours, including soft tissue sarcomas. This study aimed to assess PSMA-tracer uptake on PSMA PET/CT imaging in advanced soft tissue sarcomas, to determine the feasibility of a large-scale trial investigating PSMA-targeted radioligand therapy in this patient population. ***Materials and Methods:*** This prospective single-centre feasibility trial, registered as NCT05522257 [1], included patients with advanced soft tissue sarcoma with measurable disease (lesion diameter > 1cm), WHO performance status 0-2 and either no systemic therapy in the previous 8 weeks or progressive disease on previous systemic therapy. First, immunohistochemical PSMA expression levels were determined on previously obtained biopsy material. In case of high PSMA expression [2], a [18F]-JK-PSMA-7 PSMA PET/CT was made with a fixed dose of 359 MBq [3]. Evident PSMA-tracer uptake was defined as SUVmax > 8. The progression criterium was set at evident tumoural PSMA-uptake in at least 6 out of 15 PET/CT scans. ***Results:*** To date, 24 patients with metastatic soft tissue sarcoma have been included. High PSMA expression was found in 11 patients (46%): 4/10 leiomyosarcomas, 2/5 liposarcomas, 3/4 undifferentiated sarcomas, 1/4 fibrosarcomas and 1/1 malignant peripheral nerve sheath tumour (MPNST). Five of these patients agreed to a [18F]-JK-PSMA-7 PET/CT scan: one patient (MPNST) had evident PSMA-uptake in multiple metastases (SUVmax = 16.7), three patients (leiomyosarcoma, liposarcoma and undifferentiated sarcoma) had moderate PSMA-uptake with SUVmax between 6-8, and one patient (leiomyosarcoma) had no PSMA-uptake above the background. ***Conclusion:*** Interim results from this still recruiting trial showed that almost half of metastatic soft tissue sarcomas had high PSMA expression, which was higher than expected based on previously published literature. Metastatic PSMA-tracer uptake was seen in 4 out of 5 patients, however, in 1 patient the SUVmax exceeded 8. More data are needed to draw conclusions about the implications for potential PSMA-targeted radioligand therapy in soft tissue sarcoma patients. Further results from this feasibility study will follow. ***References:*** [1] https://classic.clinicaltrials.gov/ct2/show/NCT05522257, [2] https://doi.org/10.18632%2Foncotarget.13994, [3] https://doi.org/10.1186%2Fs13550-019-0540-7

Ad-hoc analysis of [18F]FAPI-74 imaging in patients with sarcoma within an ongoing prospective basket-trial

E. Novruzov[1], *F. L. Giesel[1], Y. Mori[1], E. Mamlins[1], C. Antke[1], C. Pinto[2], C. Soza-Ried[3], H. Amaral[3], V. Kramer[3], R. Fernandez[4], L. Badinez[3];*
[1]Department of Nuclear Medicine, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Düsseldorf, GERMANY, [2]Departamento Anatomia Patologica, Hospital Sotero del Rio, Santiago, CHILE, [3]Instituto Radiooncológico Santiago INRAD, Santiago, CHILE, [4]Center for Nuclear Medicine and PET/CT Positronmed, Santiago, CHILE.

Aim/Introduction: Radiolabeled fibroblast activation protein (FAP) ligands, a novel class of tracers for PET/CT imaging, have demonstrated very promising results in various oncological, as well as in some benign, diseases with long-term potential to supplant the current pan-cancer agent [18F]FDG in some cancer types. In particular, sarcoma has been shown to overexpress fibroblast activation protein (FAP) on abundant cancer-associated fibroblasts within its surrounding microenvironment. Hence, we conducted an ad-hoc study from our ongoing prospective, basket-study with an intra-individual comparison of [18F]FAPI-74 and [18F]FDG, to investigate the diagnostic performance of FAP imaging in sarcoma. ***Materials and Methods:*** The cohort of this ad-hoc study included currently 6 biopsy-proven sarcoma patients with a median age of 57 (range 33 - 64) who underwent both [18F]FDG PET/CT with contrast-enhancement and [18F]FAPI-74 PET with low-dose CT for primary staging (n = 1) and therapy response control (n = 3) or re-staging due to suspected relapse (n = 2). We assessed the tracer uptake with metabolic parameters such as SUVmax and SUVmean. The tumor-to-background ratio (TBR) was derived by dividing the SUVmax of tumor lesions by the SUVmax of adipose tissue, skeletal muscle, and blood pool. Furthermore, we evaluated the metabolic tumor burden and its implications for the prognosis. ***Results:*** Overall, 10 lesions were detected in 6 patients including primary (n = 5) and distant organ metastases (n=5). Although the direct comparison of metabolic PET parameters in terms of SUV reveals a similar intensity of tracer uptake, the favorable background uptake leads to a superior TBR and better lesion delineation with FAPI imaging ***Conclusion:*** This ad-hoc investigation represents, to our best knowledge, the first, prospective, intra-individual investigation comparing [18F]FAPI-74 with [18F]FDG imaging in sarcoma with interesting results regarding prognostic implications of metabolic and volumetric analyses.

Response assessment to chemotherapy in multiple myeloma by[68]Ga-Pentixafor PET/CT: A comparative evaluation with[18]F-FDG PET/CT and IMWG based clinical response

H. Kaur, *S. Kumar, A. Watts, R. Kumar, S. Sreedharanunni, M. S. Sachdeva, P. Malhotra, B. Singh;*
PGIMER, CHANDIGARH, INDIA.

Aim/Introduction: Multiple myeloma (MM) is a complex oncological disorder known to overexpress CXCR4 receptors. These receptors are viewed as potential disease targets for theranostic applications in MM. In the present study, we investigated the diagnostic utility of 68Ga-Pentixafor PET/CT for initial disease evaluation and response assessment to chemotherapy on follow-up imaging. The results were compared with 18F-FDG PET/CT and IMWG based clinical response. ***Materials and Methods:*** Thirty newly diagnosed MM patients were recruited prospectively and their clinical details were recorded. All the patients underwent 68Ga-Pentixafor and 18F-FDG PET/CT at baseline and 6-mo post standard treatment regime. IMPETUS criterion was used for 18F-FDG PET/CT data and for 68Ga-Pentixafor PET/CT based response assessment on follow-up, EORTC guidelines were used. Patients were classified into different response categories according to IMWG response criteria. The clinical response was correlated with PET/CT based response. Cohen's kappa (K) was used to quantify the level of agreement. ***Results:*** Thirty (16 male: 14 female) treatment naive MM patients were enrolled having median age=55 years (range=34-81 years). Baseline 68Ga-Pentixafor PET/CT was positive in 29/30 patients (96.7%) and 18F-FDG PET/CT was positive in 24/30 patients (80.0%). 68Ga-Pentixafor PET/CT had significantly higher ($p<0.01$) mean SUVmax value than 18F-FDG PET/CT (12.3±11.9 vs. 4.5±2.9). As compared to 18F-FDG PET/CT, a significantly higher decrease in 68Ga-Pentixafor PET/CT mean SUVmax value in CR, VGPR and PR and increase in SUVmax in PD clinical response categories was noted. On evaluation of response in these patients, as per the IMWG criteria, 11 patients (36.7%) showed sCR, 6 CR (20.0%), 10 VGPR (33.3%), 2 PR (6.7%) and 1 PD (3.3%). Response assessment on 18F-FDG PET/CT demonstrated 17/24 (70.8%) having CR, 5/24 (20.8%) PR, 1/24 (4.2%) SD and 1/24 (4.2%) PD. Whereas, 68Ga-Pentixafor PET/CT based response classified 8/29 (27.6%) as CR, 18/29 (62.1%) PR, 1/29 (3.4%) SD and 2/29 (6.9%) PD. 68Ga-

Pentixafor PET/CT based response assessment showed higher agreement with IMWG response criteria (K= 0.43, p=0.001) vs. that of 18F-FDG PET/CT (K=0.27, p=0.04). ***Conclusion:*** 68Ga-Pentixafor PET/CT provided higher (by factor of 3.0) baseline mean SUVmax than 18F-FDG PET/CT and thus presented better image contrast and lesions' characterization. 68Ga-Pentixafor PET/CT was able to evaluate response in consonance with IMWG clinical response in a higher number of patients as compared to 18F-FDG PET/CT. The study findings demonstrated that the tracer uptake tied up with CXCR4 disease activity is a sensitive PET based biomarker for response evaluation to chemotherapy in MM.

A Phase I study of [18F]SYN2, a new PET perfusion tracer in healthy subjects

J. Knuuti[1], *M. Kobylecka[2], K. Kalliokoski[1], T. Tolvanen[1], S. Krajewski[3], L. Steczek[3], K. Gotowicz[3], J. Towpik[3], P. Kozanecki[3], J. Włostowska[3], M. Dziuk[4], L. Królicki[2], C. Kozanecki[2];*
[1]Turku University Hospital, Turku, FINLAND, [2]Medical University of Warsaw, Warsaw, POLAND, [3]Synektik SA, Warsaw, POLAND, [4]University of Warsaw, Warsaw, POLAND.

Aim/Introduction: The phase I clinical, a first-in-man, study aimed to assess safety profile, radiation dosimetry, and biodistribution of a new potential cardiac positron emission tomography (PET) perfusion tracer [18F]SYN2 (18F-labelled acridinium derivative) in healthy subjects. ***Materials and Methods:*** [18F]SYN2 intravenous administration with PET imaging was performed in healthy volunteers and sequential whole-body imaging was performed for 4 hours. Blood and urine samples were collected for up to 240 min. Safety follow-up visits took place at 2, 5 and 14 days after the administration. ***Results:*** 10 subjects (8 females and 2 males) completed all study procedures. The mean age was 38.1 ± 8.8 years, and the mean body mass index was 22.7 ± 3.0 kg/m2. The mean administered dose of radioactivity was 253 MBq (range: 240 - 258 MBq). There were no drug-related adverse events, and the tracer was well tolerated in all subjects. The mean whole-body effective radiation dose for [18F]SYN2 was 0.0195 mSv/MBq. The tracer was very rapidly taken up by myocardial wall and cleared up from plasma leading to good image quality already after minutes of tracer injection. The accumulation of [18F]SYN2 to left ventricle was 2.2-2.4 %ID/organ. ***Conclusion:*** Based on tracer safety profile, radiation dosimetry, and biodistribution [18F]SYN2 appears a promising agent for clinical PET myocardial perfusion imaging and further clinical studies are warranted.

OP-879

First experiences with ^{18}F-Flurpiridaz in clinical practice

M. E. Hol, *M. G. G. Hobbelink, A. J. A. T. Braat;*
UMC Utrecht, Utrecht, NETHERLANDS.

Aim/Introduction: 18F-flurpiridaz is a mitochondrial complex 1 tracer for cardiac perfusion imaging using positron emission tomography (PET). A second phase III trial has recently been published, in which 18F-flurpiridaz PET demonstrated a significantly higher sensitivity and noninferior specificity for detection of coronary artery disease (≥50% stenosis) in comparison with 99mTc-labeled single photon emission computed tomography (SPECT)1. When compared to readily available myocardial PET tracers (e.g. 82Rb and 13N-ammonia), 18F-flurpiridaz has multiple advantages, which has sparked interest for clinical practice1. Aim of this study was to assess the feasibility of 18F-flurpiridaz in real-world clinical practice. ***Materials and Methods:*** All patients referred for cardiac perfusion imaging between December 2022 and April 2024, and planned for 18F-flurpiridaz PET/CT were included. Patients underwent 18F-flurpiridaz PET scan, in accordance with the protocol of the second phase III trial1. 18F-flurpiridaz was provided on named-patient use basis. Prespecified 18F-flurpiridaz doses were 110 MBq for rest imaging and 240 MBq for stress imaging, with a 60-minute time interval between rest and stress imaging. All stress imaging was done using pharmacological stress with either adenosine (140 µg/kg/min, 6-minute continues infusion) or regadenoson (400 µg, slow administration). All dynamic and static images were analyzed in a dedicated software package for cardiac PET analysis (4DM, INVIA), in which motion correction and residual activity correction is implemented. Dynamic PET data at rest and pharmacological stress were integrated into a two-tissue-compartment model to effectuate myocardial blood flow quantification. Myocardial blood flow and myocardial flow reserve were used in the interpretation of the images. ***Results:*** A total of 100 patients with suspected coronary artery disease were scanned, of which 58 were male and 42 were female. The mean age was 65.5 years (range 34.6-84.9 years). In 46 patients findings were suspected of ischemia, both limited (<10% ischemia burden; 12 patients) and extensive (≥10% ischemia burden; 34 patients). A total of 26 patients went for coronary angiography (CAG) as a result of the abnormal findings on 18F-flurpiridaz PET. 19 out of 26 patients had confirmed obstructive coronary artery stenosis (>50%), whilst 7 did not. In 3 out of 7 negative CAG findings, patients were deemed to have microvascular disease by the treating cardiologist. ***Conclusion:*** This is the first real-world cohort of 100 patients demonstrating the clinical feasibility of 18F-flurpiridaz for routine clinical practice. ***References:*** 1Maddahi J,et al. Flurpiridaz F^{18} PET Myocardial Perfusion Imaging in Patients With Suspected Coronary Artery Disease. J Am Coll Cardiol. 2023;Oct,17;82(16):1598-1610.

OP-880

Association between reduced cerebral blood flow andmyocardial blood flowin patients with heart failure

C. Zheng[1], *Y. Cui[1], C. Sun[2], Y. Yang[3], X. Li[4], J. Lu[1];*
[1]Xuanwu Hospital, Capital Medical University, Beijing, CHINA, [2]Central Research Institute, UIH Group, Shanghai, CHINA, [3]Beijing United Imaging Research Institute of Intelligent Imaging, Beijing, CHINA, [4]Department of Nuclear Medicine Vienna General Hospital Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Heart failure (HF) is associated with an increased risk of cognitive impairment (CI), leading to a poor prognosis for patients, but the mechanisms underlying these alterations are unclear. The aim of this study was to investigate cerebral blood flow (CBF) alterations in patients with HF and their relationship with CI and myocardial blood flow (MBF). ***Materials and Methods:*** 33 HF patients caused by ischemic heart disease and 20 healthy volunteers underwent brain MR, 13N-NH3·H2O cardiac PET/MR scans and MMSE cognitive tests. MR sequences included T1WI for brain structure and arterial spin labelling (ASL)

sequence for brain perfusion. Quantitative MBF was calculated from dynamic 13N-NH3·H2O PET data. Two sample t-tests were performed between the patient and control data at voxel level and at ROI level (brain ROIs defined in the AAL brain atlas). A p-value < 0.05 after FDR multiple test correction was considered statistically significant. Correlations between CBF, cognitive score and MBF were accessed with generalized linear model and used age and sex as covariates. ***Results:*** Compared to the healthy control, the HF patients demonstrated reduced CBF in the thalamus, frontal, calcarine, cerebellum, hippocampus, parahippocampus, fusiform, temporal, cingulate post, and precuneus regions. Relative strong perfusion decrease was observed in the hippocampus and parahippocampus region. Similar perfusion differences are reflected by the comparison of brain area mean CBF. Decreased brain perfusion appears in both side of the hippocampus, calcarine, cuneus, lingual, precuneus, thalamus and the left temporal region. CBF in the right olfactory, paracentral lobule and rectus correlate with the MMSE score (slope -2.25, p=0.01; slope=-2.45, p=0.03; slope=-2.04, p=0.03). Correlation analysis also indicated significant correlation between the MBF of the left circumflex artery territory and the regional CBF in the left angular, precuneus, post cingulum, middle temporal gyrus, right precuneus, thalamus, middle frontal orbital gyrus. The MBF of the right coronary artery territory correlated significantly with the regional CBF in the left middle temporal gyrus, angular, post cingulum, right middle frontal orbital gyrus, precuneus, and post cingulum. ***Conclusion:*** HF patients exhibit widespread CBF decrease in multiple brain regions, and a correlation with CI, suggesting that chronic cerebral hypoperfusion due to reduced MBF may be an important cause of the CI in patients.

OP-881

Sex Differences in the Brain-Heart Axis in the Setting of Acute Mental Stress

N. Mikail[1], *A. Rossi[1], S. Bengs[1], A. Portmann[1], P. Gebert[1], A. Haider[1], V. Treyer[1], A. G. Gennari[2], A. P. Pazhenkottil[1], C. E. Gebhard[3], R. R. Buechel[1], G. G. Camici[4], R. von Kaenel[5], V. Regitz-Zagrosek[6], P. A. Kaufmann[1], C. Gebhard[1];*
[1]University Hospital of Zurich, Department of Nuclear Medicine, Zurich, SWITZERLAND, [2]Department of Neuropediatrics, University Children's Hospital Zurich, 75, 8032, Zurich, Switzerland., Zurich, SWITZERLAND, [3]Intensive Care Unit, Department of Acute Medicine, University Hospital Basel, University of Basel, Basel, Switzerland., Basel, SWITZERLAND, [4]Center for Molecular Cardiology, University of Zürich, Schlieren, Switzerland., Schlieren, SWITZERLAND, [5]Department of Consultation-Liaison Psychiatry and Psychosomatic Medicine, University Hospital Zürich, University of Zurich, Zurich, Switzerland., Zurich, SWITZERLAND, [6]Institute of Gender in Medicine (GiM), Charité-Universitätsmedizin Berlin, Berlin, Germany, Zurich, SWITZERLAND.

Aim/Introduction: The steady progress achieved in the management of cardiovascular diseases (CVD) has less benefited women than men, suggesting sex-specific mechanisms in CVD. The role of mental stress in CVD is increasingly acknowledged, with an established correlation between fluor-18-fluorodeoxyglucose ([18F]FDG) uptake in the amygdala, a surrogate for stress-related neural activity (SNA), and adverse cardiovascular events, likely involving the hypothalamus-pituitary-adrenal (HPA) axis and the sympathetic nervous system (SNS). The aim of this prospective study was to investigate the existence of sex differences in 1) the amygdala and myocardial responses, as well as 2) the HPA and SNS responses to acute mental stress. ***Materials and Methods:*** Healthy volunteers (50% women), aged 50-75 years, were prospectively recruited at the University Hospital Zurich and investigated with positron emission tomography/magnetic resonance (PET/MR), using two radiotracers: [18F]-FDG to explore the amygdala metabolism, and [13N]ammonia ([13N]NH3) to explore the amygdala and myocardial perfusion. Acute mental stress was triggered using two mental stress tests: the Trier Social Stress Test (TSST) while undergoing [18F]FDG PET/MR, and the Montreal Imaging Stress Task (MIST) while being explored with [13N]NH3 PET/MR. The primary endpoint consisted of sex differences in SNA, defined as the ratio between [18F]FDG uptake (as mean standard uptake value, SUVmean) in the amygdala and a reference region, i.e., the cerebellum. Secondary endpoints included sex differences in i) amygdala perfusion (using [13N]NH3), ii) myocardial blood flow (MBF) and flow reserve (MFR), iii) salivary cortisol response to stress (a surrogate for HPA axis activation), and iv) the heart rate response (HRR) to stress (a surrogate for SNS activation). ***Results:*** Sixty-four healthy volunteers (32 women), aged 59.8±5.8, were included. Following the TSST, SNA was significantly higher in women than in men (SNA=0.7530 in women vs. 0.7173 in men, p<0.001). Amygdala perfusion showed a significant decrease during the stress part of the MIST in females (ΔAmygdalaperfusion=-0.0181 [-0.0267; -0.0094], p<0.001) and a trend toward a decrease in men (ΔAmygdalaperfusion=-0.0086 [-0.0177; 0.0005], p=0.064). MBF at rest was significantly higher in women than men (p=0.019), however, the MFR did not significantly differ between sexes (p=0.537). Conversely, the cortisol response to stress was significantly increased in men (p=0.034) but not in women (p= 0.465), while the HRR was greater in women than men (p= 0.049). ***Conclusion:*** Amygdala response to acute mental stress is more pronounced in women than men and triggers predominantly the SNS in the former and the HPA axis in the latter.

OP-882

The perfusion response to adenosine in the brain, liver, spleen, kidneys, skeletal muscles, and pancreas as measured using total-body PET

H. Kärpijoki[1], *J. Tuisku[1], S. Palonen[1], S. Nesterov[1], T. Maaniitty[2], A. Saraste[2], L. Nummenmaa[1], J. Knuuti[2];*
[1]The University of Turku, Turku, FINLAND, [2]Turku University Hospital, Turku, FINLAND.

Aim/Introduction: Adenosine is routinely used as a pharmacological stressor in myocardial perfusion imaging. However, its effects on other organs have been less well-studied. The aim of this study was to investigate the effect of adenosine on body organs using [15O]H2O and total-body PET. ***Materials and Methods:*** Patients (n=25) underwent total-body [15O]H2O PET perfusion imaging with and without adenosine stress (140 µg/kg/min). Two patients were excluded because of technical problems in the analysis. K1-derived absolute perfusion values were measured using a single-tissue-compartment model. Segmentation of the organs was done using the CT-based total segmentation method. The brain was segmented using a dedicated brain model for the averaged brain. The input function was derived from the descending aorta. Bonferroni corrected p-values from paired comparisons are reported. ***Results:*** In addition to myocardial perfusion, the mean perfusion in the studied organs was mildly increased only in the liver (at rest median 0.42 [25th-75th percentiles 0.32-0.55] mL/g/min, during stress 0.58 [0.32-0.86] mL/g/min; stress/rest ratio 1.34 [0.97-1.87], p-value for rest vs. stress 0.052). In contrast, perfusion decreased in the brain white matter (rest 0.38 [0.36-0.47] mL/g/min, stress 0.33 [0.28-0.37] mL/g/min, stress/rest ratio 0.77 [0.75-0.93], p<0.0001) and grey matter (rest

0.46 [0.41-0.51] mL/g/min, stress 0.37 [0.32-0.41] mL/g/min, stress/rest ratio 0.77 [0.70-0.90], p<0.00001), spleen (rest 1.25 [0.96-1.39] mL/g/min, stress 0.27 [0.23-0.37] mL/g/min, stress/rest ratio 0.26 [0.20-0.34], p<0.00001) and kidneys (rest 0.95 [0.82-1.06] mL/g/min, stress 0.67 [0.50-0.81] mL/g/min, stress/rest ratio 0.66 [0.49-0.91], p<0.001). In skeletal muscles and pancreas, the differences in perfusion were not statistically significant. ***Conclusion:*** The perfusion response to adenosine appears to be organ-specific. In the heart and liver, perfusion is increased, but in the brain, spleen, and kidneys, it is reduced. At the same time, no significant difference was detected in skeletal muscle and pancreas.

OP-883

Effect of Age and Sex on LV Stress-MBF and Cardiac Output Reserve Using ^{15}O-water PET

P. Svanström, *K. Eggers, J. Sigfridsson, H. Harms, T. Kero, M. Lubberink, J. Sörensen;*
Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Global left ventricular (LV) myocardial blood flow measured with 15O-water PET myocardial perfusion imaging (MPI) during adenosine-induced hyperemia (stress-MBF) has high prognostic value for future cardiac adverse events. Additionally, adenosine increases heart rate and cardiac output (CO) by a neuronal effect, secondary to peripheral vasodilation. Little is known about the association of stress-MBF and hemodynamic responses towards age and sex. We therefore aimed to determine the impact of age and sex on cardiac and peripheral vascular adenosine responses in a large cohort. ***Materials and Methods:*** We retrospectively identified clinical patients referred to rest/adenosine stress 15O-water PET MPI due to suspected coronary artery disease (CAD) at a single center. Patients with known heart failure or CAD, major adverse cardiac events (MACE) or significant perfusion defects (defined as stress defects with a size ≥5% of the LV, MBF ≤2.3 mL/min/g within the defect and a relative flow reserve of <0.69) were excluded. Stress-MBF and CO reserve were measured using aQuant Research (Medtrace). The association of LV stress-MBF and CO reserve towards age and sex was evaluated using linear regression (ANCOVA). ***Results:*** A total of 783 patients with suspected CAD were identified and MACE were recorded during a median follow-up of 3.6 years. 326 patients (60% women) remained after exclusion criteria were applied, median age 66 years (interquartile range: 59-73, range 21-87). For LV stress-MBF vs age, linear regression of stress-MBF resulted in the equations: y (mL/min/g)=4.17-0.019*Age for men (P=0.002) and y=5.77-0.032*Age for women (P<0.0001). Both slope and intercept differed between sexes (P<0.0001). For age groups of 20-49, 50-69 and ≥70 years, men had LV stress-MBF of 3.25, 3.11, and 2.58 mL/min/g and women of 4.42, 3.89, and 3.29 mL/min/g respectively. For CO percentage increase versus age, the equations were %=160-0.62*Age for men and %=175-0.80*Age for women (both P<0.0001). Intercept was higher for women (P=0.003), but slopes were similar (P>0.05). Using these equations, the CO reserve was abolished at age 95 for both sexes. ***Conclusion:*** Ageing blunted both cardiac and systemic effects of adenosine among low-risk subjects with chest pain and normal PET MPI. Women had higher stress-MBF than men even at older age, but female stress-MBF declined faster with increasing age. Age also decreased CO reserve, but at similar rates for both sexes.

OP-884

The relative prognostic value of coronary plaque burden and myocardial perfusion according to the length of follow-up

T. Maaniitty[1], *R. Jukema[2], J. Dahdal[2], P. van Diemen[2], I. Stenström[1], P. G. Raijmakers[2], R. Sprengers[2], N. Planken[2], P. Knaapen[2], J. J. Bax[3], A. Saraste[1], J. Knuuti[1], I. Danad[2];*
[1]Turku University Hospital, Turku, FINLAND, [2]Amsterdam University Medical Center, Amsterdam, NETHERLANDS, [3]Leiden University Medical Center, Leiden, NETHERLANDS.

Aim/Introduction: Non-invasive anatomical and functional imaging modalities enable risk stratification in chronic coronary artery disease (CAD), but there is limited knowledge about the relative prognostic impact of anatomical and functional information according to the length of follow-up. We evaluated the prognostic value of quantitatively measured coronary atherosclerotic plaque burden and stress myocardial blood flow (MBF) at short, intermediate, and long-term follow-up. ***Materials and Methods:*** A pooled cohort of 1385 patients (median age 63 years, 54% male) from two academic medical centers underwent coronary computed tomography angiography (CCTA) and [15O] H2O positron emission tomography (PET) myocardial perfusion imaging for suspected chronic CAD. Coronary plaque burden was measured as percent atheroma volume (PAV). Lowest regional stress MBF (ml/g/min) was measured as an average of two adjacent segments. The endpoint was a composite of all-cause mortality, myocardial infarction, and unstable angina pectoris. Multivariable Cox regression models were constructed for short, intermediate, and long-term, with truncation of follow-up at 3, 6, and 9 years, respectively. Hazard ratios (HR) were adjusted for significant clinical predictors of outcome (age, sex, hypertension, diabetes). ***Results:*** Until 3, 6, and 9 years of follow-up, 72 (5%), 131 (9%), and 167 (12%) patients experienced the composite endpoint, respectively. There was a moderate inverse correlation between PAV and lowest regional stress MBF (ρ=-0.44; p<0.001). After adjusting for clinical variables, PAV was a predictor of outcome in 3, 6, and 9-year follow-up (at 9 year: HR=1.04 (95%CI 1.03-1.05) per 1% increase, p<0.001). Similarly, lowest regional stress MBF was an adjusted predictor of outcome in 3, 6, and 9-year follow-up (at 9 year: HR=1.03 (1.01-1.05) per 0.1 ml/g/min decrease, p<0.001). When PAV and lowest regional stress MBF were incorporated into same multivariable models, both were independent predictors of outcome at 3-year follow-up (PAV: HR=1.04 (1.02-1.06), p<0.001; MBF: HR=1.04 (1.00-1.07), p=0.026) and at 6-year follow-up (PAV: HR=1.03 (1.02-1.05), p<0.001; MBF: HR=1.03 (1.00-1.05), p=0.024). In contrast, at 9-year follow-up, only PAV was an independent predictor of outcome whereas regional stress MBF was not (PAV: HR=1.03 (1.02-1.05), p<0.001; MBF: HR=1.01 (1.00-1.03), p=0.138). However, regional stress MBF became statistically significant (HR 1.03 (1.01-1.05), p=0.015) after exclusion of 281 (20%) patients undergoing early (6-month) myocardial revascularization. ***Conclusion:*** Both coronary plaque burden and myocardial perfusion are associated with adverse clinical outcome. The relative prognostic impact of myocardial perfusion may decrease during long-term follow-up, but myocardial revascularization appears as a potential confounder.

OP-885

Quantification of Plaque Burden over Stenosis Severity Improves the Detection of Myocardial Ischemia by Coronary Computed Tomography Angiography

T. Kero[1], *S. Bär[2,3], A. Saraste[2,4], J. J. Bax[5], J. Knuuti[2], T. Maaniitty[2,6];*
[1]Department of Surgical Sciences/Nuclear Medicine &

PET, Uppsala University, Uppsala, SWEDEN, [2]Turku PET Centre, Turku University Hospital, University of Turku, Turku, FINLAND, [3]Department of Cardiology, Bern University Hospital Inselspital, Bern, SWITZERLAND, [4]Heart Center, Turku University Hospital, University of Turku, Turku, FINLAND, [5]Department of Cardiology, Leiden University Medical Center, Leiden, NETHERLANDS, [6]Department of Clinical Physiology, Nuclear Medicine, and PET, Turku, FINLAND.

Aim/Introduction: In symptomatic patients undergoing coronary computed tomography angiography (CCTA) for suspected coronary artery disease (CAD) we assessed, if plaque burden and morphology, as determined by Artificial Intelligence-guided Quantitative Computed Tomography (AI-QCT), in addition to luminal narrowing and clinical risk factors offered incremental value for the identification of myocardial ischemia, as defined by hybrid CCTA/15O-water PET. ***Materials and Methods:*** This study evaluated patients who underwent CCTA for suspected CAD together with 15O-water PET myocardial perfusion imaging in case of ≥50% visual stenosis. CCTA scans were subsequently analysed using AI-QCT with percent total (TPB), calcified (CPB), noncalcified plaque burden (NCPB) and maximum diameter stenosis. Logistic regression was used to determine variables related to ischemia and test two multivariable models for prediction of ischemia; Model 1: clinical + stenosis ≥50% and Model 2: clinical + stenosis ≥50% + plaque burden. The Models´ performance were compared with area under the receiver operating characteristic curves (AUC). Test characteristics for ischemia was compared for (a) stenosis ≥50% and (b) intermediate stenosis+ plaque burden. For the latter, patients were classified non-ischemic for stenosis <30% and ischemic for stenosis >70%. Patients with 30-70% stenosis were classified ischemic if the plaque burden exceeded a binary optimal threshold to predict ischemia according to the method of Youden and non-ischemic if plaque burden was below. ***Results:*** 2145 patients were analysed by AI-QCT. TPB and NCPB had equal discriminative ability for ischemia on top of clinical variables and ≥50% stenosis (AUC 0.91 for both, ns) whereas CPB was inferior (AUC 0.89, p<0.0001 in comparison with TPB model) and TPB was chosen for subsequent analysis. TPB on top of clinical variables and ≥50% stenosis improved the prediction of ischemia (Model 1 AUC=0.87 and Model 2 AUC=0.91, p<0.001). Sensitivity, specificity, positive and negative predictive values and AUC for ischemia of stenosis ≥50% were (a): 75%, 88%, 57%, 94% and 0.81. The optimal TPB threshold to predict ischemia in intermediate stenosis was ≥12.2%. The test characteristics of intermediate stenosis +TPB 12.2% (p-value vs. (a)) were (b): 76% (p=0.008), 91% (<0.001), 64% (<0.001), 95% (<0.001), 0.84 (p=0.048). ***Conclusion:*** The addition of total plaque burden and non-calcified plaque burden by AI-QCT to clinical variables and ≥50% stenosis improved the detection of myocardial ischemia. Furthermore, applying a total plaque burden threshold of 12.2% in patients with intermediate stenosis improved the diagnostic accuracy as compared to the traditional ≥50% stenosis approach.

OP-886

The association between coronary plaque burden and coronary plaque inflammation, as assessed by ^{68}Ga-DOTATATE PET/CT in primary prevention

R. Oostveen, *N. S. Nurmohamed, J. M. Kraaijenhof, C. Y. Y. Beverloo, N. M. J. Hanssen, E. S. G. Stroes, H. J. Verberne; Amsterdam UMC, Amsterdam, NETHERLANDS.*

Aim/Introduction: 68Ga-DOTATATE is a positron emission tomography (PET) radiotracer with a high affinity for the somatostatin receptor subtype 2 (SSTR2), commonly expressed on activated macrophages (M1). 68Ga-DOTATATE therefore holds promise as a specific marker for atherosclerotic lesion inflammation. In this study, we evaluated the association between coronary artery disease (CAD) as assessed by coronary computed tomography angiography (CCTA) and 68Ga-DOTATATE PET/CT uptake as a surrogate marker for coronary plaque inflammation. ***Materials and Methods:*** We performed 68Ga-DOTATATE PET/CT in volunteers aged >50 years, who recently (within 78 weeks of screening) underwent CCTA. Forty participants with no history of cardiovascular disease or revascularization were included with either no or minimal (CAD-RADS 0-1) or extensive CAD (CAD-RADS 4) in a 1:1 ratio matched by age and sex. Image analyses were performed by a blinded observer. A target-to-background ratio (TBRmax) was determined based on the standardized uptake value (SUVmax) in the coronary arteries, and SUVmean within the blood pool of the superior vena cava. Multivariable linear models were used to evaluate the relation between CAD presence and TBRmax on a per patient (linear regression) and a per-vessel level (mixed effects linear regression). ***Results:*** The study included 40 primary prevention participants, 34 male, with a mean age of 64.75 ± 5.86. Mean low density lipoprotein (LDL) cholesterol was 2.66 ± 0.99, median high sensitivity C-reactive protein (hsCRP) was 0.80 [0.60, 1.92], and 16 (40%) participants were on statin therapy. The median TBRmax was 2.06 [1.59, 3.08]. In the multivariable analysis, extensive CAD resulted in a 0.881 higher TBRmax (95% CI: 0.062, 1.700; p=0.042), whereas the use of statin resulted in a numerically lower TBRmax (-0.862, 95% CI: -1.705, -0.019; p=0.053) on a per patient level. On a per-vessel level, the mixed linear effects model confirmed a higher TBRmax in extensive CAD and a lower TBRmax in statin use. ***Conclusion:*** Our findings demonstrate a positive association between plaque burden and 68Ga-DOTATATE uptake within coronary arteries in a primary prevention population. These findings underscore the potential of 68Ga-DOTATATE, as a specific marker for coronary inflammation.

Safety and Outcome of Retreatment with [^{177}Lu]Lu-PSMA-I&T Radioligand Therapy (PRLT) in Metastatic Castration Resistant Prostate Cancer

G. Santo[1,2], *G. Di Santo[1], A. Sviridenko[1], M. Kiasatdolatabadi[1], S. Bayerschmidt[1], L. Wirth[1], F. Scherbauer[1], P. Lehmann[1], E. von Guggenberg[1], C. Decristoforo[1], I. Virgolini[1]; [1]Department of Nuclear Medicine, Medical University of Innsbruck, Innsbruck, AUSTRIA, [2]"Magna Graecia" University of Catanzaro, Catanzaro, ITALY.*

Aim/Introduction: Abundant evidence exists that 177Lu-PRLT prolongs survival in mCRPC patients with only minor side effects. The approved treatment regimen is based on a fixed activity of 7.4 GBq, injected 6-8 weeks apart for up to 6 cycles. The purpose of this study was to assess the safety and outcome of re-challenge [177Lu]Lu-PSMA-I&T in patients who progressed after response

to initial treatment. ***Materials and Methods:*** We retrospectively included 18 patients who underwent re-challenge with [177Lu]Lu-PSMA-I&T. All patients presented with i) disease control after intial treatment ii) [68Ga]Ga-PSMA-11 PET/CT confirming the presence of PSMA-positive metastases iii) ECOG-performance status 0-1. Adverse events were graded according to CTACE v5.0. Response was assessed by PSA classified according to Prostate Cancer Working Group 3 recommendation. For patients who underwent restaging with [68Ga]Ga-PSMA-11 PET/CT, imaging response was categorized according to adapted PERCIST v1.0. In patients with discordant [68Ga]Ga-PSMA-11 PET/CT and PSA, other available imaging modalities were evaluated to confirm disease status. Overall survival (OS) was calculated from the first cycle of initial PRLT and re-challenge PRLT, respectively, until last patient contact or death. ***Results:*** Patients were initially treated with a median of 5 cycles (range 4-7; median cumulative activity 38,4 GBq) and were re-challenged after a median of 9 months (range 3-13). Each patient received a median of 4 (range 2-7) re-challenge cycles (median cumulative activity 26,1 GBq). During both treatment periods, none of the patients experienced life-threatening G4 adverse events. Grade 3 adverse events included one only case of renal failure. In 8/18 patients long-term toxicities were G3 anemia (n=3) and G4 renal insufficiency (n=2). PSA-response was seen in 56% (n=10/18) patients. In 12/18 patients re-staged by imaging, 7 (58%) patients showed disease control, one mixed response, and 4 progression. After a median follow-up time of 25 months (range 14-44) 10 patients died, 7 were still alive and 1 were lost at follow-up. The median OS calculated was 29 months (95%CI 14,3 - 43,7 months) for the first treatment and 11 months (95%CI 8,1 - 13,8 months) for first re-challenge course. ***Conclusion:*** More than half of patients continue to respond to re-challenge PRLT. Our analysis suggests that re-treatment may prolong survival in selected patients, with an acceptable safety profile.

EPS-275

Implementation of 177Lu-PSMA-617 Dosimetry Based on 360° CZT Whole-Body SPECT/CT and Collapsed Cone Superposition: A Comparison with Organ S-values and Local Deposition Method

A. Terro[1], *S. Perret[1], D. Tonnelet[2], A. Dumouchel[2], A. Edet-Sanson[1,2], P. Bohn[1,2], P. Vera[1,2], P. Decazes[1,2], A. Dieudonné[1,2];*
[1]LITIS-Quantif,University of Rouen, Rouen, FRANCE, [2]Nuclear Medicine Department, Henri Becquerel Center, Rouen, FRANCE.

Aim/Introduction: Today, dosimetry in patient undergoing 177Lu-PSMA-617 therapy for metastatic castration resistant prostate cancer (mCRPC) is complex and non-standardized. SIMPLE-DOSE is an automated patient-specific whole-body dosimetry software implementing collapsed cone superposition (CCS). We aimed to compare dosimetry values using SIMPLE-DOSE to dosimetry values using organ S-values (OSV) implemented in MIRDcalc [1] and local deposition method (LDM). ***Materials and Methods:*** 10 patients with mCRPC who received first infusion of 7.4 GBq of 177Lu-PSMA-617, underwent at day 3 ± 2 days whole-body SPECT/CT on VERITON-CT (Spectrum Dynamics, Israel). SIMPLE-DOSE implements a deep-learning-based organ segmentation nnU-Net [2] and CCS to compute the absorbed dose taking into account tissue densities [3]. Activity concentration in Bq/mL and masses for seven organs were derived from SIMPLE-DOSE's segmentation process to serve as an input in the OSV approach (MIRDcalc). For the LDM approach, SPECT/CT was converted to dose-rate maps with an energy deposition coefficient of 147 keV/Bq. Local density was provided by the CT. ***Results:*** Median (InterQuartile Range (IQR)) dose rate in mGy.h-1 for kidneys, liver, spleen, salivary glands, pancreas, lungs and bone marrow were respectively 7.4 (3.45), 1.08 (0.63), 0.92 (0.89), 4.5 (4.07), 1.01 (1.53), 0.8 (0.48), 0.32 (1.2). The organ-wise comparison with MIRDcalc showed a median (IQR) difference of 2.41% (1.4%), 2.85% (3.4%), 3.96% (4.2%), 4.88% (10.5%), 10.9% (3.2%), 21% (12.61%), 32% (10.7%) respectively. The voxel-wise comparison with LDM showed a median (IQR) symmetric mean absolute percentage deviation (sMAPD) of 31.2% (8.77%). Respectively 46%, 25% and 12.5% of voxels within the body had differences greater than or equal to 5%, 10%, 20%. The computation time for the whole process with SIMPLE-DOSE was between 2.5 and 3.5 minutes. ***Conclusion:*** Compared with MIRDcalc and LDM, dose rate calculations using CCS resulted in significant differences in dosimetry, especially when considering specific organs. Further comparisons with Monte Carlo simulations and correlations with organ toxicity are currently underway. SIMPLE-DOSE, an automatic, fast, and user-friendly dosimetry software, is available for testing at Oncometer3D.com. ***References:*** [1] Kesner AL, Carter LM, Ramos JCO, et al. Theranostic Application of ^{68}Ga/^{177}Lu-LNC1011: A Novel Long-Circulating PSMA Probe for Metastatic Castration-Resistant Prostate Cancer

J. Wang[1], *R. Wang[1], X. Chen[2], J. Zhang[2];*
[1]the Department of Nuclear Medicine, Peking Union Medical College Hospital, Beijing, CHINA, [2]Department of Diagnostic Radiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, SINGAPORE.

Aim/Introduction: Utilizing albumin binders to enhance tumor uptake is a strategy to improve the therapeutic efficacy of PSMA-targeted treatments. However, maintaining diagnostic capabilities while ensuring low bone marrow toxicity is challenging. LNC1011 (D-Dan-Phe-PSMA) is a novel long-circulating PSMA probe based on a weak albumin-binding dansyl group. Preliminary animal studies have shown its potential to balance diagnostic and therapeutic efficacy. This study aims to conduct preliminary human distribution and dynamic imaging research of [68Ga]Ga-LNC1011 and [177Lu]Lu-LNC1011 in mCRPC patients, exploring uptake characteristics in tumors and organs, and to investigate its diagnostic and therapeutic efficacy as a theranostic probe. ***Materials and Methods:*** This study initially enrolled six mCRPC patients for dynamic PET/CT imaging using [68Ga]Ga-LNC1011 at time points of 10, 20, 30, 40, 60, 90, 110, and 150 minutes post-administration of [68Ga]Ga-LNC1011. Additionally, 3 patients underwent 1 and 2-hour [68Ga]Ga-PSMA-11 imaging within one week for comparison. In the therapeutic aspect, the study included 12 mCRPC patients who underwent SPECT imaging at multiple time points after the administration of [177Lu]Lu-LNC1011 at 2h, 4h, 24h, 48h, 72h, 120h, and 168h. The 12 patients were divided into three groups, receiving doses of 1.85 GBq , 2.78 GBq , and 3.7 GBq of [177Lu]Lu-LNC1011, respectively, for two treatment cycles. The therapeutic efficacy assessment post-treatment was based on the Response Evaluation Criteria In PSMA-Imaging

(RECIP 1.0) for molecular imaging efficacy evaluation. ***Results:*** PET images at multiple time points showed notably high early uptake in the cardiac blood pool at 10 min, with evident tumor uptake observed at the same time. Compared to [68Ga]Ga-PSMA-11, which detected 35 lesions in three patients, [68Ga]Ga-LNC1011 detected an equivalent number of lesions. High tumor uptake was observed in the time-activity curves, with SUVmax values showing a continuous increasing trend. Kidney uptake was highest among other organs, with a gradual increasing trend. SPECT imaging at multiple time points for [177Lu]Lu-LNC1011 showed significant tumor uptake at 168 hours. After two treatment cycles, two patients reached progressive disease (PD), while eight patients achieved stable disease (SD), and two patients attained partial response (PR) based on RECIP 1.0 criteria. ***Conclusion:*** [68Ga]Ga-LNC1011 demonstrated non-inferior diagnostic efficacy compared to [68Ga]Ga-PSMA-11, with early tumor uptake observed. Combined with [177Lu]Lu-LNC1011 SPECT, prolonged retention of the imaging agent in the tumor was suggested. Additionally, [177Lu]Lu-LNC1011 exhibited promising therapeutic efficacy after two cycles of treatment. Therefore, LNC1011 serves as a promising theranostic probe.

Characterize the Effective Half-Life for Instant Single Time Point Dosimetry using Machine Learning

C. Gomes Ferreira[1], *S. Xue[1], A. Gafita[2], J. Hu[1], R. Seifert[1], L. Mercolli[1], J. Brosch-Lenz[3], J. Hong[1], M. Ryhiner[1], Y. Chen[1], S. Ziegler[4], A. Afshar-Oromieh[1], A. Rominger[1], M. Eiber[5], T. Lima[6], K. Shi[1];*
[1]Department of Nuclear Medicine, Inselspital, Bern, SWITZERLAND, [2]Ahmanson Translational Theranostics Division, University of California Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA, [3]Department of Nuclear Medicine, Technical University Munich, Munich, GERMANY, [4]Department of Nuclear Medicine, University Hospital, Munich, GERMANY, [5]Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY, [6]Department of Radiology and Nuclear Medicine, LUKS, Luzern, SWITZERLAND.

Aim/Introduction: Single time point (STP) image-based dosimetry presents a more convenient approach for clinical practice in radiopharmaceutical therapy (RPT) compared to conventional multiple time point (MTP) image-based dosimetry. Despite significant advancements, STP methods still pose challenges in routine clinical settings due to the need for strict and late timing in data acquisition. A new concept of instant single time point (iSTP) dosimetry is introduced in this preliminary study, achieved by predicting the effective half-life (Teff) of organs using machine learning (ML) applied on pre-therapy (PET and clinical) data. ***Materials and Methods:*** An ML model was developed to predict Teff based on patient characteristics derived from pre-therapy PET scans and clinical values. The time-integrated activities were then calculated from the predicted Teff and the STP measurements to estimate the absorbed dose. For the proof of concept, we focused on the left and right kidneys, liver, and spleen. Retrospective data from two centers using different PSMA-targeting radiopharmaceutical were included. Patients from the first center underwent [177Lu]Lu-PSMA I&T RPT (n=22 patients, 42 cycles) following pre-therapy [68Ga]Ga-PSMA-11 PET imaging. Patients from the second center received [177Lu]Lu-PSMA-617 (n=12 patients, only first cycle) following pre-therapy $^{[18F]}$F-PSMA-1007 PET imaging. The results using the iSTP method were compared to the MTP and the previously proposed Hänscheid methods. ***Results:*** The ML model, utilizing pre-cycle PET/CT data from both centers, achieved mean errors (ME) below 2% for [177Lu]Lu-PSMA I&T and 17% for [177Lu]Lu-PSMA-617, across both kidneys, liver, and spleen. Our iSTP method showed satisfactory results at 2 h, 20 h, 43 h, and 69 h time points, significantly outperforming the Hänscheid method at 2 h ($p<0.001$), where dosimetry is not feasible. Statistical analysis indicated that at 2 h and 20 h, our method performed better or was comparable to Hänscheid's best STP results. When using only initial PET/CT data from before the first cycle to predict Teff for subsequent cycles, [177Lu]Lu-PSMA I&T dosimetry demonstrated that, despite some variations, most cycles showed no significant differences across scenarios. Although the model using the second center data was less accurate compared to the first center, these results with PSMA-617 demonstrate the generalisability of our method. ***Conclusion:*** The preliminary results on two different PSMA RPT tracers confirmed the potential of iSTP in achieving accurate image-based dosimetry shortly and flexibly after the patient received its RPT. This proposed method may expedite the application of dosimetry in broader contexts, such as outpatient treatment.

EPS-278

Actinium-225 PSMA-617 therapy in metastatic castration resistant prostate cancer - Single center retrospective study

V. Gunasekaran, *S. Kumar, A. Sood, P. Aggarwal, B. R. Mittal; Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) radioligand therapy (RLT) is a novel treatment modality for metastatic castration-resistant prostate cancer (mCRPC). Actinium-225 (^{225}Ac), an alpha-emitter, has higher efficacy than beta-emitters and hence superior therapeutic option for mCRPC. This study aimed to evaluate the survival and safety of ^{225}Ac-PSMA-617 RLT in heavily pretreated mCRPC patients. ***Materials and Methods:*** This single center retrospective study included 15 mCRPC patients who had progressive disease with standard line of therapies, including Lutetium-177 (^{177}Lu) PSMA-617 RLT and were eventually treated with at least ≥1 cycle of ^{225}Ac-PSMA-617 RLT. Overall survival (OS), progression free survival (PFS), prostate specific antigen (PSA) response and treatment related adverse effects using common terminology criteria for adverse events (CTCAE) v5.0 grading system were assessed. ***Results:*** Among the 15 heavily pretreated mCRPC patients (mean age: 63.3 years, range: 52-78), median cumulative dose of 7.4 MBq (IQR 3.73-10.3) of ^{225}Ac-PSMA-617 RLT was administered intravenously over 36 cycles (median two cycles). All 15 patients had skeletal metastases, whereas lymph node and visceral metastases were seen in 12 and 4 (liver - 2 and lungs - 2) patients respectively. Pretreatment included androgen deprivation therapy (n=15), androgen receptor pathway inhibitors (Abiraterone: 9; Enzalutamide: 8), taxane based chemotherapies (Docetaxel: 15; Cabazitaxel: 3) and ^{177}Lu-PSMA RLT (n=8). Median follow-up duration was 9·0 months (IQR 2·0-40.0). Median baseline PSA was 158 ng/mL (IQR 7.67-1590). The median PFS and median OS were 20.9 months (95% CI 3.5-49.0) and 9.0 months (95% CI 2.7-15.2) respectively. 5/15 patients (33%) demonstrated PSA fall of >50%. Along the course of ^{225}Ac-PSMA-617 RLT, PSA fall >50%, from 1st to 4th cycles, was noted in 33%, 27%, 6.7% and 0 patients respectively. ^{177}Lu PSMA-617 naive patients had higher median OS than those pretreated with ^{177}Lu-PSMA-617 (19.7 vs 7.5 months). However, only borderline statistical significance was observed (p=0.063). In terms of adverse effects,

grade 1/2 xerostomia (10/15 patients, 67%) and fatigue (7/15 patients, 47%) were two most common adverse events in post-therapy period. Only four patients had grade 3 adverse events (xerostomia requiring nasogastric tube feeds in 1; anemia in 1; thrombocytopenia in 1; and nephrotoxicity requiring dialysis in 1). ***Conclusion:*** ^{225}Ac-PSMA-617 RLT is an efficacious therapeutic agent for mCRPC patients in whom standard lines of approved agents are exhausted. Xerostomia is the most common side-effect, however grade ≥3 adverse events are less encountered. So, overall ^{225}Ac-PSMA-617 RLT appears to be safe and well-tolerated in mCRPC patients.

EPS-279

PSMA radioligand therapy does not select for PSMA-negative tumor cells

Y. Song[1,2], *S. Y. Kwon[3], I. Rauscher[2], C. D'Alessandria[2], M. Eiber[2], W. Weber[2];*
[1]Department of Nuclear Medicine, Union Hospital, Tongji Medica College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]Department of Nuclear Medicine, Klinikum rechts der Isar, Technische Universität München, Munich, GERMANY, [3]Department of Nuclear Medicine, Chonnam National University Hwasun Hospital, Jeonnam, KOREA, REPUBLIC OF.

Aim/Introduction: PSMA radioligand therapy (RLT) has become an established palliative therapy for metastatic castration-resistant prostate cancer (mCRPC). However, virtually all tumors recur after treatment. This study investigated if RLT selects for tumor cells that no longer express PSMA. ***Materials and Methods:*** Radiation doses to PSMA positive and negative cells in cell clusters of varying sizes were calculated with MIRDcell. In addition, we searched an institutional database of 379 consecutive mCRPC patients for patients who achieved an exceptional response to PSMA RLT with Lu-177-PSMA I&T, defined as a decline of PSA by at least 90%. PSMA expression of metastases as assessed by SUVmax was compared between the PET scan before RLT and the PET scan at the time of relapse. ***Results:*** Simulations of densely packed clusters of prostate cancer cells showed that the self-dose (i.e., the radiation that PSMA-expressing cells receive from the radioligand that they have accumulated) is only 2.5% of the total dose (self-dose and cross-dose from neighboring cells) for spherical clusters as small as 1.0 mm. Differences between self- and cross-dose were smaller when PSMA-expressing cells were not densely packed, but under many scenarios, cross-dose remained dominant. This suggested that PSMA-negative cells in a metastasis that shows radioligand uptake on PET may not have a survival advantage. This hypothesis was confirmed by an analysis of 29 patients with an exceptional response to RLT. In 69 PSMA-positive lesions that showed a marked decrease in uptake/disappearance after therapy followed by an increase in uptake/relapse, there was no significant decrease in PSMA expression at the time of relapse compared to baseline (SUVmax 22.07±14.12 vs. 19.55±13.45, P=0.81; or SUVmax 22.58±12.15 vs. 17.70±11.57, P=0.76). ***Conclusion:*** In contrast to other targeted cancer therapies such as CAR-T cells or protein kinase inhibitors, PSMA RLT does not appear to select for cancer cells that lack target expression. Thus, retreatment with PSMA RLT at the time of relapse can often be a valid treatment option.

EPS-280

Quantitative ^{18}F-DCFPyL(PSMA) SUV_{max} Cutoff Values May Distinguish Prostate Cancer from Benign Tissue

L. Lindenberg[1], *E. Huang[2], E. Mena[1], B. Turkbey[1], G. Brown[1], F. I. Lin[1], G. R. Berenji[3], I. Sonni[3], G. Ulaner[4], E. Bergvall[5], K. Prasad[6], M. Lindenberg[7], P. Pinto[8], A. Lindenberg[5], R. Madan[9], F. Karzai[9], K. Patel[10], D. Citrin[10], P. Choyke[1];*
[1]Molecular Imaging Branch, National Cancer Institute, Bethesda, MD, UNITED STATES OF AMERICA, [2]Biometric Research Program, Division of Cancer Treatment and Diagnosis, NCI, Bethesda, MD, UNITED STATES OF AMERICA, [3]VA Greater Los Angeles Health Care System, Los Angeles, CA, UNITED STATES OF AMERICA, [4]Hoag Family Cancer Institute, Irvine, CA, UNITED STATES OF AMERICA, [5]Alexander T. Augusta Military Medical Center, Ft Belvoir, VA, UNITED STATES OF AMERICA, [6]Walter Reed National Military Medical Center, Bethesda, MD, UNITED STATES OF AMERICA, [7]Drexel University, Philadelphia, PA, UNITED STATES OF AMERICA, [8]Urologic Oncology Branch, NCI, Bethesda, MD, UNITED STATES OF AMERICA, [9]Genitourinary Malignancies Branch, NCI, Bethesda, MD, UNITED STATES OF AMERICA, [10]Radiation Oncology Branch, NCI, Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: Quantitative 18F-PSMA PET/CT may be useful distinguishing prostate cancer from benign activity with PET parameter cutoff values correlated to histopathologic diagnosis. ***Materials and Methods:*** This is a retrospective multi-institutional analysis of men who underwent 18F-DCFPyL (PSMA) imaging and subsequent histopathologic diagnosis. Participants underwent a PET/CT, two hours post-injection of 6 mCi (222 MBq) 18F-DCFPyL and subsequent tissue sampling a median of 28 days later (min-max: 1-172 days). Regions of interest (ROIs) were drawn to anatomically match tissue location. Quantified parameters included standardized uptake value (SUV)max/mean, total lesion uptake (TLU) and lesion volume. Liver and spleen ROIs served as reference for normalization ratios. PET positivity for lesions was visually assessed as uptake distinct from background. Univariate associations were evaluated via generalized linear mixed models and the Benjamini-Hochberg procedure was used to adjust for multiple testing. Cutoff values were determined by maximizing the Youden index. ***Results:*** In this preliminary subset assessment, 85 men, (median age of 67) from the National Cancer Institute were evaluated (median PSA: 4.37 ng/mL [min: 0.02, max: 464]). Thirty-four had metastatic disease, 14 had localized disease/treatment-naïve, and 37 had biochemical recurrence after primary treatment. Prior to imaging, 18 had a history of prostatectomy, 25 had radiation treatment and 15 had both prostatectomy and radiation therapy, with 17 men on androgen therapy within 6 months before or during the PSMA scan. One hundred and sixty-five histopathologic specimens (malignant [n=96]; benign [n=69]) were available for PET comparison (in-gland [n=40]; extra-prostatic [n=125]). For all lesions, there were strong associations between quantitative PET measurement and probability of malignancy: SUVmax/mean, tumor:liver , tumor:spleen, PET positivity, TLU, TLU:spleen, and TLU:liver (p-value < 0.001). Proposed optimal cutoffs included 4.14 for SUVmax (sensitivity 0.761, specificity 0.917),1.28 for tumor:spleen (sensitivity 0.667, specificity 0.917), and 0.664 for tumor:liver, (sensitivity 0.696, specificity 0.944). For the subset of in-gland lesions, imaging factors with the strongest relationship to malignancy included SUVmax/mean, tumor:liver, tumor:spleen and PET positivity (p-value <0.001). Grade Group 5 was highly associated with PET positivity, SUVmax/mean, tumor:liver, and tumor: spleen (p=value<0.001). Proposed prostate lesion cutoffs include: 3.95 for SUVmax (sensitivity 0.875, specificity 0.910), 1.19 for tumor:spleen (sensitivity 0.750, specificity 0.955), and 0.686 for tumor:liver (sensitivity 0.750, specificity 0.909). ***Conclusion:*** Quantitative 18F-PSMA imaging may improve ability to discriminate between benign and malignant lesions, especially when indeterminate. Further analysis is ongoing to validate the suggested cutoffs in this preliminary, hypothesis-generating study.

EPS-281

To evaluate the detection rate of local and whole-body recurrence by integrated ^{18}F-PSMA PET/MR assessment of prostate cancer patients treated with prostatectomy with very low biochemical recurrence (< 0.5 ng/ml). Therapeutic implications.

J. Garcia, *A. Compte, J. Pastor, S. Mourelo, L. Mont, L. Pinilla, P. Cozar, M. Soler, P. Bassa, E. Llinares, E. Valls, T. Blanch, E. Riera, J. Ferrer;*
CETIR ASCIRES Grupo biomédico, Barcelona, SPAIN.

Aim/Introduction: To analyse the efficacy of integrated assessment of ^{18}F-PSMA.1007 PET/MRI on the early detection of local recurrence (LR) for prostate cancer patients with PSA levels <0.5 ng/ml after radical prostatectomy. To assess the location of recurrence so that therapy may be tailored to patient. ***Materials and Methods:*** Prospective study including 35 patients with prostate cancer (PCa), who were referred for a ^{18}F-PSMA.1007A PET/MR after prostatectomy with a very initial PSA value increase. Simultaneous acquisition in a PET/MRI hybrid equipment (SIGNA-GE), 1 hour after administration of 370±10%MBq of ^{18}F-PSMA.1007: Prostate selective imaging (20min): Multiparametric PET+MRI (MRImp): DIXON,T1,T2,diffusion, post-Gadolinium sequence. Whole body image (30min): PET+MRI: DIXON,T1,T2,diffusion,STIR sequences. A Nuclear Physician and a Radiologist jointly reviewed the studies: In order to assess LR, the "Prostate Imaging for Recurrence Reporting" system was used on MRI, as well as the Likert scale on the PET prostate imaging. The remaining lesions were classified as N1 and M1a. ***Results:*** PET/MRI was negative in 10 patients (28.6%) and positive in 25 (71.4%). RL was detected in 15 patients (42.9%): in 2 (5.7%) MRI was superior; in 3 (8.6%) PET was superior; integrated PET/MRI showed improved results in 5 patients (14.3%) for the detection of LR. Location of recurrences: LR in 11 patients (44.0%); N1 in 10 (40.0%); LR+N1(8.0%) in 2; LR+N1+M1a in 2 (8.0%). In 20 patients (80%) the PET/MRI findings allowed radioguided radiotherapy implementation (11 on LR, and 9 on N1), whereas hormonal treatment was decided in 5 patients (20%) due to multimetastases/spread disease. ***Conclusion:*** ^{18}F-PSMA.1007 PET/MRI increased by 14.3% the detection rate of LR in patients with PCa after prostatectomy and with PSA levels <0.5ng/ml, with a high detection rate of N1+M1a (71.4%), thus allowing radioguided radiotherapy in 80% of patients. ***References:*** JR Garcia, A Compte, M Buxeda, et al. EPS-282

Exploring the use of PRIMARY Score in favourable intermediate risk Prostate Cancer: analysis about the correlation with pathological upstaging after radical prostatectomy

L. Muraglia[1], *P. Guglielmo[2], J. Jandric[1], Z. Roberta[3], M. Rodari[1], E. Lopci[1], L. Evangelista[1,4];*
[1]Nuclear Medicine Unit, IRCCS Humanitas Research Hospital Rozzano, Milan, ITALY, [2]Nuclear Medicine Department, Veneto Institute of Oncology IOV - IRCCS, Padova, ITALY, [3]Nuclear Medicine Specialization School, Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Milan, ITALY, [4]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, Milan, ITALY.

Aim/Introduction: The aim of our retrospective, single center study is to establish a correlation between PRIMARY score calculated on ^{18}F-PSMA-1007 PET/CT scan performed for staging favourable intermediate risk prostate cancer (PCa) and pathological evaluation after radical prostatectomy. ***Materials and Methods:*** We retrospectively enrolled 54 patients diagnosed with favourable intermediate risk PCa (Gleason Score 3+4; ISUP Grade 2) after biopsy procedure, who underwent ^{18}F-PSMA-1007 PET/CT to stage the disease and were referred to surgery as primary treatment at our institution. PSMA PET were revised by two experienced readers and PRIMARY score was calculated. Data about pathological assessment were collected and statistically combined with PSMA-PET results. ***Results:*** Patients were stratified into two groups based on PRIMARY Score results. Of 54 patients enrolled, 28 (51,9%) were classified as Group 1: PRIMARY Score 1,2 or 3, median PSA 6,2 ng/ml; 26 (48,1%) were classified as Group 2: PRIMARY Score 4 or 5, median PSA 9,3 ng/ml. After pathological evaluation of the prostate surgical specimen 15 patients (27,8%) were upstaged to unfavourable intermediate risk. Among them, 4 patients (14,3%) belonged to Group 1 and 11 patients (42,3%) to Group 2. Despite the limitations derived from a small population, PRIMARY Score 4,5 was significantly correlated with pathological upstaging after surgery through Chi-Square Test (Chi-Square Value=5,179; p=0,0229). ***Conclusion:*** Our results are harmonious with the current literature on this subject, confirming the importance of a correct interpretation of intra-prostatic PSMA uptake and furtherly validating the accuracy of PRIMARY Score. There's more to be discovered about PSMA PET and its role as a game changer in the management of prostate cancer both in surgical and in active surveillance approaches, therefore our analysis is worth to be deepened in larger prospective trials. ***References:*** Emmett L, Papa N, Buteau J, Ho B, Liu V, Roberts M, Thompson J, Moon D, Sheehan-Dare G, Alghazo O, Agrawal S, Murphy D, Stricker P, Hope TA, Hofman MS. The PRIMARY Score: Using Intraprostatic 68Ga-PSMA PET/CT Patterns to Optimize Prostate Cancer Diagnosis. J Nucl Med. 2022 Nov;63(11):1644-1650. doi: 10.2967/jnumed.121.263448. Epub 2022 Mar 17. ^{212}Pb SPECT/CT Clinical Imaging for Routine Biodistribution and Dosimetry of Targeted Alpha Therapy

M. Griffiths[1], *L. Campbell[1], M. Latter[1], S. E. Rose[2], S. G. Puttick[2], W. Tieu[2], K. Kuan[2], S. Taylor[2], A. Karmann[2], D. Wyld[1], A. Hansen[3], S. Ngai[3], D. Pattison[1];*
[1]Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA, [2]AdvanCell, Sydney, AUSTRALIA, [3]Princess Alexandra Hospital, Brisbane, AUSTRALIA.

Aim/Introduction: Aim/Introduction 212Pb-based Targeted Alpha Therapy (212Pb-TAT) shows great promise. We have developed a SPECT/CT acquisition protocol for routine biodistribution and dosimetry imaging in patients with metastatic castration resistant prostate cancer (mCRPC) following the administration of a novel PSMA-targeted-therapy, [212Pb] Pb-ADVC001. ***Materials and Methods:*** SPECT/CT dosimetry imaging series have been acquired at 90 minutes, 4, 20 and 24-28 hours post injection (p.i.) of 60 MBq [212Pb] Pb-ADVC001 in

four patients. Confirmatory treatment localisation imaging has been acquired at 90 minutes for the subsequent 3 cycles in each patient. The images were acquired on a gamma camera using HE collimators, 30 minutes per bed position (30s/projection, 120 projections over 360 degrees) for 2 bed positions to include the salivary glands and kidneys. To maximise efficiency, 6 energy windows were used for two triple-energy window acquisitions (78 keV ± 20% with 20% scatter [31% abundance] and 239 keV ± 10% with 10% scatter [43% abundance]. Equal weighting was applied to each scatter window during scatter and attenuation corrected reconstruction. Each photo peak was reconstructed separately, and the resultant images summed. ***Results:*** [212Pb] Pb-ADVC001 SPECT CT imaging was feasible in all patients. 212Pb progeny have high energy emissions (208Tl 2.6 MeV 35%) which cause significant scatter from the patient and the lead collimator leading to a reconstruction artefact along the collimator orbit path. This artefact dominates the count statistics of the transaxial images which was reduced with filtering and is trimmed for creation of MIP images. A Gaussian 12 filter was applied for visual localisation, and unfiltered reconstructions were used for dosimetry analysis. [212Pb] Pb-ADVC001 uptake showed concordance with location of PSMA-expressing disease on $^{[18F]}$DCFPyL or [68Ga]Ga-PSMA-11 PET imaging. Uptake in tumour lesions at 90 min p.i. was seen in all patients, and tumour retention was observed over 24h, while uptake in kidneys decreased significantly after 5h p.i.. Notably, [212Pb] Pb-ADVC001 uptake in the salivary glands was low and comparable to background level. Normal organ absorbed dose estimates were derived from the serial acquisitions. ***Conclusion:*** 212Pb SPECT/CT imaging allows confirmation of TAT biodistribution and permits TAT dose estimates, assuming no progeny redistribution.

EPS-284

Characteristics, tolerance and effectiveness of patients aged more or less than 75 years treated with [177Lu]Lu-PSMA-617 as part of France's early access program

***D. Tonnelet*[1], *J. Farce*[2], *L. Agrigoroaie*[3], *C. Merlin*[4], *A. Cottereau*[5], *S. Chêne*[6], *C. Bailly*[7], *M. Bros*[8], *L. Mourey*[9], *M. Lacombe*[10];**
[1]Henri Becquerel Cancer Centre, Rouen, FRANCE, [2]Centre Eugène Marquis, Rennes, FRANCE, [3]Institut Gustave Roussy, Villejuif, FRANCE, [4]Centre Jean Perrin, Clermont-Ferrand, FRANCE, [5]Hôpital Cochin, AP-HP, Université Paris Cité, Paris, FRANCE, [6]Advanced Accelerator Applications, Rueil-Malmaison, FRANCE, [7]Centre Hospitalier Universitaire, Nantes, FRANCE, [8]Centre Hospitalier Régional et Universitaire, Nancy, FRANCE, [9]Institut Universitaire du Cancer de Toulouse, Toulouse, FRANCE, [10]Institut de Cancérologie de l'Ouest, Angers, FRANCE.

Aim/Introduction: [177Lu]Lu-PSMA-617 (Lu-PSMA) is a new treatment for metastatic castration-resistant prostate cancer (mCRPC) expressing PSMA, available in France since December 2021 as part of France's early access program in patients who previously received at least one line of taxane chemotherapy and one new generation hormonal therapy. Its safety profile in the elderly is not known. This retrospective analysis compares the characteristics, safety and efficacy of Lu-PSMA in all patients aged >75 years old (yo) treated in France as part of early access program compared to patients ≤75yo. ***Materials and Methods:*** From 01.12.2021 to 31.01.2024, 1696 patients were included. The recommended administration schedule was 6 intravenous injections of Lu-PSMA (7.4 GBq) every 6 weeks. Patients characteristics and safety data were collected during the 6 follow-up visits. ***Results:*** 645 patients >75yo (39.7%) and 981 patients ≤75yo (60.3%) were included. Patients ≤75yo and patients >75yo had the following characteristics: ECOG score [0-1] 84.1% vs 89.2% (p<0.001); Median PSA 64.5 ng/ml vs 52.6 ng/ml (p=0.23); metastases by site: bone 92.9% vs 93.9% (p=0.42); lymph nodes 57.8% vs 61.5% (p=0.14); hepatic 9.8% vs 8.9% (p=0.54); number of systemic treatment lines ≥ 3 77.5% vs 78.4%; pain management by opioids 21.6% vs 31.3% (p<0.001) respectively. Over a period of effectiveness defined by a first cycle of treatment between 01.12.2021 and 30.04.2023, 790 underwent clinical, biological and radiological evaluations, of whom 294 patients >75yo (37.2%). Median follow-up time period was around 7 months. The median time to imaging PFS was not statistically different 6.93mo [5.78 - 7.66] for patients ≤75yo vs 7.98mo [6.11 - 8.21] for pt>75yo. 82.9% of patients >75yo and 80.8% of patients ≤75yo had a controlled PSA level (decrease or stabilization). 82.9% of patients>75yo and 80.8% of patients ≤75yo had a controlled PSA level (decrease or stabilization). Over this same period, 85 patients ≤75yo and 68 patients>75yo had dose adaptation (p=0.039). There was no significant difference between the 2 populations regarding reasons for discontinuing treatment, progression of the disease, or serious adverse events related or not to the treatment and death. ***Conclusion:*** Analysis of the French National data of patients treated with Lu-PSMA for mCRPC shows few differences for patients >75yo compared to patients ≤75 yo concerning patients characteristics and safety. Also, no differences in terms of radiological and biological response was observed. These data suggest that age alone should not preclude the use of Lu-PSMA in patients >75yo.

EPS-285

Can We Predict the Response to Lu177-PSMA Therapy and Progression-Free Survival Using Ga68-PSMA and F^{18}-FDG PET/CT Parameters in Prostate Cancer?

S. Aksu, *G. Uçmak, B. B. Demirel;*
Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: The aim of our study is to investigate clinical, pathological, Ga68-PSMA and F^{18}-FDG PET/CT parameters that can predict Lutetium177-Prostate-Specific Membrane Antigen(Lu177-PSMA) treatment response and progression-free survival(PFS) in patients with prostate cancer prior to therapy. ***Materials and Methods:*** 38 patients with metastatic castration-resistant prostate cancer who received Lu177-PSMA therapy were included in our study. Demographic characteristics and pathology-laboratory findings[total Prostate Specific Antigen(PSA), pre-treatment and 2nd month total PSA difference(ΔPSA)] were recorded. The parameters of Ga68-PSMA and F^{18}-FDG PET/CT[Maximum standardized uptake value(FSUVmax), mean SUV(FSUVmean), metabolic tumor volume(MTV), and total lesion glycolysis(TLG) for F^{18}-FDG PET/CT; maximum SUV(PSUVmax), mean SUV(PSUVmean), PSMA-Tumor Volume(PSMA-TV), and Total Lesion-PSMA(TL-PSMA) for Ga68-PSMA PET/CT) of the lesion with the highest PSMA expression on pre-treatment Ga68-PSMA PET/CT examination were recorded. PFS was defined as the interval between the date of the first treatment dose and the date of the second consecutive increase in total PSA. Logistic regression analysis was conducted to identify factors predicting the response to Lu177-PSMA therapy, and Kaplan-Meier analysis was performed to determine factors affecting progression-free survival. ***Results:*** The clinical-pathological characteristics of the 38 patients are presented in Table 1. Treatment response was observed in 26(68%) of the 38 patients. The mean progression-free survival time observed was 7

months(range: 3-15 months). A statistically significant relationship was found between treatment response and the ratio of bone PSUVmax to liver PSUVmax(p=0.024) and the ratio of bone PSUVmax to parotid PSUVmax(p=0.018). In the univariate analysis conducted to determine factors predicting treatment response, the bone FSUVmax/PSUVmax ratio(p=0.047,ORR: 0.03, C.I. 0.001-0.950), bone FSUVmean/PSUVmean ratio(p=0.042,ORR: 0.029, C.I. 0.001-0.881), and pre-treatment LDH level(p=0.029,ORR: 0.989, C.I. 0.980-0.999) were found to be significant. However, they were not significant in the multivariate analysis. The impact of bone PSMA-TV(p=0.008), bone FSUVmax/PSUVmax ratio(p=0.004), bone FSUVmean/PSUVmean ratio(p=0.005), bone MTV(p=0.022), TLG(p=0.024), and ΔPSA value(p=0.013) on PFS was found to be significant. In the ROC analysis, the cut-off value for bone PSMA-TV was determined to be 3.03 ml(sensitivity: 80%, specificity: 73%), indicating that patients with PSMA-TV <3.03 ml had longer PFS(≥7 months). ***Conclusion:*** In prostate cancer, it has been found that low bone PSMA-TV, low bone FSUVmax, FSUVmean, MTV, TLG parameters before Lu-177 PSMA therapy and high ΔPSA value after the 1st dose are associated with longer PFS. Consequently, we would like to emphasize the importance of evaluating both the tumor volume of lesions in Ga68-PSMA PET/CT and F^{18}-FDG PET/CT parameters in predicting prognosis before Lu177-PSMA therapy.

EPS-286

The correlation between PSMA PET/CT uptake and [^{177}Lu]Lu-PSMA-I&T absorbed dose in Metastatic Castration-Resistant Prostate Cancer Patients.

V. Kalloe, *E. C. Owers, M. M. de Boer, E. Rijkhorst, E. A. Aalbersberg, M. Dotinga;*
Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS.

Aim/Introduction: Patients with metastatic castration-resistant prostate cancer (mCRPC) might be excluded from PSMA-targeted radioligand therapy due to anticipated limited therapeutic efficacy if their tumours show less than 1.5 times the uptake in their liver on PSMA PET/CT.[1] The mean absorbed dose (MAD) in tumour lesions and normal tissues is likely associated with therapeutic efficacy and toxicity, respectively.[2] A strong correlation between PSMA PET uptake and [177Lu]Lu-PSMA absorbed dose potentially enhances patient selection as treatment outcomes and toxicity are more predictable. Our objective was to correlate the SUVmean value on PSMA PET to the MAD of tumours after the first cycle of [177Lu]Lu-PSMA-I&T therapy, stratifying for different radiotracers. ***Materials and Methods:*** mCRPC patients who underwent [177Lu]Lu-PSMA-I&T therapy from October 2020 till January 2023 were retrospectively included. Patients who had not undergone an EARL-accredited PSMA PET/CT scan within 2 months prior to treatment were excluded. PSMA PET/CT scans were performed using [18F]F-PSMA-JK-7, [18F]F-PSMA-1007 or [68Ga]Ga-PSMA-11. All patients received 7.4 GBq [177Lu]Lu-PSMA I&T and underwent SPECT/CT scans at 24 and 168 hours post-administration. In target lesions, a volume of interest (sphere of 20 mm diameter) was delineated around the voxel exhibiting the highest SUV or uptake for PET and SPECT, respectively. MADs were assessed using a mono-exponential fit. Correlations between SUVmean and MAD in tumours were analysed for bone, lymph node and other lesions. Additionally, we investigated differences among the different PSMA PET radiotracers. ***Results:*** 46 mCRPC patients with a total of 132 target lesions were included. For bone lesions, a moderate correlation was observed between SUVmean and MAD (N=66, r=0.54, p<0.01). Among the radiotracers, [18F]F-PSMA-JK-7 exhibited the strongest correlation (N=37, r=0.872, p<0.01), surpassing [18F]F-PSMA-1007 (N=12, r=0.12, p=0.75) and [68Ga]Ga-PSMA-11 (N=22, r=0.39, p<0.08). Lymph node lesions exhibited a moderate correlation (N=42, r=0.562, p<0.01). [68Ga]Ga-PSMA-11 demonstrated the strongest correlation (N=13, r=0.718, p=0.01) in comparison to [18F]F-PSMA-JK-7 (N=22, r=0.614, p<0.01) and [18F]F-PSMA-1007 (N=7, r=0.2, p=0.8). For other lesions, the overall correlation was strong (N=21, r=0.753, p<0.01). [18F]F-PSMA-JK-7 exhibited a very strong correlation (N=9, r=0.967, p<0.01) while [68Ga]Ga-PSMA-11 showed a moderate/strong correlation (N=11, r=0.71, p<0.02). ***Conclusion:*** While there was an overall moderate correlation seen for all tumour lesions, [18F]F-PSMA-JK-7 generally demonstrated stronger correlations across bone and other non-lymph node lesions. These findings suggest that if PSMA PET-guided prediction models for radiation dose or treatment outcomes are developed, radiotracer selection is crucial. ***References:*** [1]Hofman et al. EPS-287

Quantitative Evaluation of PET/CT and SPECT/CT-based Dosimetry following Yttrium-90 Radioembolization

S. Kappadath, *C. Henry, B. Lopez, A. Mahvash;*
University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Following 90Y-radioembolization (90Y-RE), 90Y-PET/CT and 90Y-SPECT/CT imaging provide the means to calculate the voxelized absorbed dose distribution. Given the widespread use of the two imaging modalities and lack of well-established standardized dosimetry protocols for 90Y-RE, there is a clinical need to systematically investigate the performance of voxel-based dosimetry between them. The aim of this work is to quantitatively analyze and compare 90Y-PET/CT and 90Y-SPECT/CT-based dosimetry following 90Y-RE. ***Materials and Methods:*** 90Y-PET/CT and 90Y-SPECT/CT imaging was acquired for 35 patients following 90Y-RE with glass-microspheres for the treatment of unresectable hepatocellular carcinoma (as part of a prospective clinical trial, RAPY90D, NCT03896646). Dosimetry was performed using the local deposition method with known activity and the mean dose (Dmean) was calculated for perfused liver volumes (PV), tumors (T), and perfused normal livers (NL). Additionally, the absorbed dose to x% of the volume (Dx, x ∈ [5%, 10%, ∈, 95%]) and the volume receiving y Gy (Vy, y ∈ [10 Gy, 20 Gy, ∈, 200 Gy]) were calculated for T and NL, respectively. Dose metrics were compared using linear regression, Bland-Altman analysis, and statistical testing. ***Results:*** Both 90Y-SPECT/CT and 90Y-PET/CT-based tumor Dmean were strongly correlated (R2≥0.90) with Dx, excluding metrics on the extrema. Intra-modality comparisons of various Dx and Vy metrics yielded statistically significant differences (ANOVA, p<0.001) for both 90Y-PET/CT and 90Y-SPECT/CT. Based on statistical testing, only Dx metrics separated by greater than 20-30% coverage, and only Vy metrics separated by greater than 40-70 Gy, reported significant differences. For PV, there was a strong correlation (R2≥0.99) between Dmean derived separately from 90Y-PET/CT and 90Y-SPECT/CT imaging. The strength of the correlation was slightly reduced for T and NL with R2=0.91 and R2=0.95, respectively. For PV, the mean bias ± standard error (SE) and 95% limits of agreement (LOA) between Dmean from the two modalities was effectively zero with -0.8±0.4% (±2.5%). For T and NL, the mean bias ± SE (±LOA) was -14.5±3.7% (±24.1%) and 9.4±4.7% (±27.4%), respectively. ***Conclusion:*** The strong correlation between Dmean and Dx suggests information from multiple dose metrics (e.g., D70 and Dmean) is largely redundant when establishing dose-response relationships in 90Y-RE. Dmean

is highly correlated between 90Y-PET/CT and 90Y-SPECT/CT-based dosimetry, for all liver VOIs. Relative to 90Y-SPECT/CT, 90Y-PET/CT, on average, yielded larger Dmean to tumors (14%) and smaller Dmean to perfused normal livers (9%). Absorbed dose differences for perfused liver volumes between 90Y-SPECT/CT and 90Y-PET/CT were negligible.

EPS-288

Holmium-166 transarterial radioembolization in unresectable, early-stage hepatocellular carcinoma; a prospective, single-arm, open label, multicenter phase II study: HOMIE-166 Study Protocol

M. Zacherl[1], *M. P. Fabritius[2], D. Puhr-Westerheide[2], M. Seidensticker[2], M. Uder[3], P. Dietrich[3], W. Weber[4], U. Ehmer[5], A. Geier[6], M. Laßmann[7], J. Mayerle[8], A. Kandulski[9], H. J. Schlitt[10], K. Menhart[11], C. Lapa[12], T. Kröncke[13], R. Kickuth[14], J. Ricke[2];*

Aim/Introduction: Holmium-166 transarterial radioembolization (Ho-166 TARE) is a promising modality for the treatment of hepatocellular carcinoma (HCC), given the unique characteristics of holmium, allowing careful patient selection and personalized dosimetry treatment planning. Further clinical evidence is needed to evaluate the safety and efficacy of Ho-166 TARE in the treatment of early-stage HCC. The primary objective is to evaluate the efficacy of Ho-166 TARE in HCC patients with limited tumor burden, well preserved liver function and performance status, and ineligible for liver transplantation and/or liver resection. The secondary objectives are to analyse response rates, time to event outcomes, safety-toxicity, liver function, biodistribution/dosimetry and quality of life. Additionally, magnetic resonance (MR)-based dosimetry will be assessed as an exploratory objective. ***Materials and Methods:*** This is a prospective, single-arm, open-label, multicenter study with Ho-166 TARE. Patients with unresectable HCC with a single nodule ≤ 8 cm or up to three nodules with a diameter of ≤ 5 cm (each) will be recruited. Patients eligible for liver transplantation can still be included in the setting of bridge to transplant. It is expected a sample size of 65 evaluable patients to be recruited. The primary efficacy endpoint is defined as confirmed objective response rate (ORR) by localized mRECIST assessed by blinded independent central review. The secondary endpoints are best ORR based on localized mRECIST, best and confirmed ORR based on mRECIST, Duration of Response (DoR) ≥ 6 months based on localized mRECIST and mRECIST, time to progression, progression-free survival (PFS), hepatic PFS, liver transplantation rate, liver resection rate, overall survival, adverse events and MR-based dosimetry. Additionally, magnetic resonance (MR)-based dosimetry endpoints will be analysed. This study will also provide further evidence on the dose-response relationship of Ho-166 TARE in early HCC. Patients will be followed up regularly until 24 months post treatment with Ho-166 microspheres. After that, patients will be followed for survival follow-up every 6 months until death or 60 months, whichever comes first. ***Conclusion:*** Personalised dosimetry treatment planning in TARE holds the promise of future improvement of treatment efficacy and safety. The unique imaging properties of Ho-166 microspheres will support such developments. This study will confirm the safety and efficacy of Ho-166 TARE in this patient population.

EPS-289

The impact of non-target lesions on dosimetry calculations in Y-90 microsphere liver radioembolization

B. Ince, *N. Yeyin, M. T. Bodur, A. Namazova, O. E. Şahin, K. Sönmezoğlu, H. B. Sayman;*
Istanbul University-Cerrahpasa, Istanbul, TÜRKIYE.

Aim/Introduction: There are some studies based on mean whole healthy liver parenchymal absorbed dose (WHLPD) values to determine the maximum safe dose for patients in Y-90 microsphere transarterial radioembolization (TARE) treatment (1). Although non-target space occupied liver lesions (outside the perfused area) do not affect the doses absorbed by perfused targeted healthy parenchyma, subtracting them from liver parenchyma volume during dosimetry calculations would impact the dose received by healthy parenchyma of the whole liver since they might have a considerable volume. In this study, the impact of subtracting non-target lesions (NTL) from the liver volume on the average dose received by whole healthy liver parenchyma was investigated in dosimetry calculations. ***Materials and Methods:*** Twenty-five patients who underwent Y-90 TARE between July 2018 and March 2024 were studied. Post-treatment regional imaging was performed with PET/MRI within 24 hours. Multi-compartment dosimetry was performed using Simplicit90Ytm software on the post-treatment PET/MRI images by delineating volumes of interests (VOIs) for the whole liver, perfused area, targeted tumor, and healthy parenchyma of the perfused area. Additionally, VOIs for NTL were delineated for each patient and subtracted from the whole liver parenchyma followed by a second dosimetry calculation. ***Results:*** The mean administered Y-90 activity was 2.4 ± 1.6 GBq. The mean volumes of the whole liver, target tumor, and NTL were 1923.4 ± 726.2 cm^3, 311.7 ± 485.3 cm^3 and 120.6 ± 152.8 cm^3, respectively. When NTL were subtracted, the mean healthy parenchymal volume of the whole liver was 1491.1 ± 298.5 cm^3, compared to 1611.7 ± 381.4 cm^3 without subtraction. The mean WHLPD value was significantly higher when the subtraction of NTL is performed (34.0 ± 15.7 Gy versus 31.9 ± 15.2 Gy; $p < 0.01$), giving an increase value between 0.5% and 39.9%. ***Conclusion:*** Incorporating NTL in dosimetry of Y-90 TARE leads to a more accurate volume calculation and dose estimation to the whole healthy liver parenchyma. We found that this approach results statistically significant increase of mean dose comparing to NTL non-subtracted calculation. Therefore, taking NTL into account to the dosimetry aids to a better determination of the maximum safe dose for the patients undergoing Y-90 TARE, especially in those with high NTL volumes. ***References:*** 1. Efficacy And Safety of Repeated TARE Treatments with Extended Shelf Life Y90 Glass Microspheres in Colorectal Cancers : A Single-Center Experience

Z. Balaban Genc[1], *S. Kesim[2], E. Soydemir[3], K. Niftaliyeva[1], T. Kıssa[1], N. Filizoglu[2], S. Cetin[1], A. Eroglu[1], O. Kostek[4], E. Akdeniz[5], H. Turoglu[1], T. Erdil[1], T. Ones[1];*
[1]Marmara University Pendik Training and Research Hospital, Nuclear Medicine Department, Istanbul, TÜRKIYE, [2]Kartal Dr. Lutfi Kırdar City Hospital, Nuclear Medicine Department, Istanbul, TÜRKIYE, [3]Marmara University Pendik Training and Research Hospital, Radiology Department, Istanbul, TÜRKIYE, [4]Marmara University Pendik Training and Research Hospital, Medical Oncology Department, Istanbul, TÜRKIYE, [5]Marmara University Pendik Training and Research Hospital, Department of Medical Education, Istanbul, TÜRKIYE.

Aim/Introduction: When planning TARE treatment for liver malignancies, multiple treatment sessions may be required due to the presence of large tumoral lesions, heterogeneity in the distribution of glass microspheres, and specially bilobar disease. In this study, we aimed to evaluate the efficacy of treatments with quantitative parameters of pre/post-treatment $^{[18F]}$F-FDG PET/CT imaging and assess the safety and side effect profile in patients with metastatic colorectal cancer (mCRC) who underwent repeated sessions of TARE with Extended shelf life (ExSL) 90Y glass-microspheres. ***Materials and Methods:*** A total of 62 TARE sessions involving 37 patients were included, with a minimum of 2 and a maximum of 6 sessions per patient. Multicompartmental dosimetry was performed using Simplicity90YTM software. "Baseline" and "follow-up" MTV and TLG values were calculated by pre-post treatment $^{[18F]}$F-FDG PET/CT imaging. Absorbed dose values for unit MTV/TLG were calculated as (Gray/MTV) x100 and (Gray/TLG)x100, respectively. The metabolic tumor response was categorized as follows: "Complete Response-CR", "Partial Response-PR", "Stable Disease-StD", "Progressive Disease-PD", "Disease Control Rate-DCR" and "Objective Response Rate-ORR". Time from diagnosis to death, time from the first treatment session to death (overall survival-OS) and progression-free survival (PFS) were determined. Adverse events were recorded using the CTCAE v5.0 criteria. ***Results:*** For 62 treatments, CR was observed in 8 cases, PR in 25 cases, StD in 22 cases, and PD in 7 cases. The DCR (CR+PR+StD) was 88.7% and the ORR (CR+PR) was 53.2%, with median OS of 12.7 months and median PFS of 9.3 months. The median number of microspheres reaching the liver was found to be statistically higher in CR and PR cases compared to StH and PD cases (p=0.021). When the patients were classified as treatment-responders and non-responders, a statistically significant increase in the time from diagnosis to death was observed in the treatment-responders group (p=0.034, HR=1.977, 95% CI: 1.055-3.707). When the patients who received two sessions of TARE treatment were classified as treatment responders and non-responders, OS was higher in the responders group (p=0.025, HR=0.35, 95% CI: 0.14-0.874). In the dose-toxicity profile analyses, one patient developed REILD, and another patient developed RECHT. The clinical manifestations in these two patients occurred after the third TARE sessions. ***Conclusion:*** Our single-center study has demonstrated, for the first time, evidence of the therapeutic effectiveness and contribution to OS of repeated treatments and safety in terms of the dose-toxicity profile of ExSL 90Y glass-microspheres in mCRC patients who received multiple sessions.

EPS-291

Efficacy and tolerance results of high-dose radiation segmentectomy with resin microspheres.

J. Montalvá Pastor, *J. Orcajo Rincon, L. Reguera Berenguer, J. Ardila Mantilla, M. Casallas Cepeda, S. Salcedo Cortés, I. Gómez Fernández, A. Mari Hualde, R. Pérez Pascual, E. Ardila Manjarrez, D. Zamudio Rodriguez, A. Guzmán Cruz, J. Alonso Farto;*
Hospital General Universitario Gregorio Marañón, Madrid, SPAIN.

Aim/Introduction: Radiation segmentectomy (RS) is a supraselective liver radioembolization procedure, aimed at small lesions, confined to one or two liver segments, with radical therapeutic intent. Standardized dosimetric guidelines are based on results from cohorts treated with glass microspheres. The aim of the present study is to demonstrate the feasibility of performing supraselective procedures with resin microspheres, using ablative doses and to describe both therapeutic results, in terms of radiological response, and adverse effects. ***Materials and Methods:*** Retrospective, descriptive study, which included lesions treated with RS through administration of resin microspheres and use of ablative doses, in the period between April 2021 and September 2023. Response monitoring was carried out by CT scan one and three months after the procedure, using mRECIST criteria, classifying the type of response as complete, partial and progression.By reviewing the clinical history, the adverse effects related to the procedure and the most relevant dosimetric data were collected, such as the theoretical tumor absorbed dose and final absorbed dose, calculated using voxel-based dosimetry software, D50 and D70, extracted from the dose/volume histogram, angiosome tumor volume and number of segments included. ***Results:*** 30 hepatocellular carcinoma lesions (HCC) were included with a mean tumor size of 34,33mm and mean angiosome volume of 340,04cc. 83,33% of the procedures included a single segment and 16,67% included two liver segments. The calculated mean target dose was 377,78Gy (median 400Gy). The mean final calculated absorbed dose on 90Y-PET/CT image was 429,53Gy, with D50 and D70 values of 401,9 and 303,3Gy respectively. 73,33% of the lesions showed complete radiological response, 20% partial response and 6,66% progression. As adverse effects, only one patient was recorded with liver abscesses secondary to the procedure, resolved by antibiotic therapy. ***Conclusion:*** RS with high-dose resin microspheres is a safe and well-tolerated procedure in patients with small HCC, achieving a complete response of up to 73,33%.

EPS-292

Radiation protection during liver surgery shortly after SIRT: Interactive visualization of radiation on the liver surface for individualized planning.

L. Stegger[1], *F. Eilers[2], F. Schaeg[1], C. Duhme[2], H. Morgül[3], M. Köhler[4], P. Houben[3], M. Masthoff[4], A. Wegener[5], N. Razlaw[1], K. Rahbar[1], F. Büther[1], X. Jiang[2];*
[1]University Hospital Münster, Department of Nuclear Medicine, Münster, GERMANY, [2]University of Münster, Department of Computer Science, Münster, GERMANY, [3]University Hospital Münster, Department of General, Visceral and Transplant Surgery, Münster, GERMANY, [4]University Hospital Münster, Department of Radiology, Münster, GERMANY, [5]University of Münster, Department of Mathematics, Münster, GERMANY.

Aim/Introduction: Liver surgery shortly after radioembolization (SIRT) with 90Y microspheres may be indicated. However, the surgical personnel has to be spared from excessive radiation exposure. Since 90Y predominantly emits beta radiation with about a cm range, the particle distribution inside the liver

and especially the distance of 90Y from its surface determines radiation exposure of the personnel touching the liver surface. Instead of using a blanket waiting time for the decay of 90Y before surgery, an individual visualization of radiation on the liver surface (spatial and temporal) is proposed. This may allow for earlier surgery and may even guide the surgery itself (hand placement, radiation shielding sheets and gloves). The clinical potential of this approach was assessed by experienced transplantation surgeons. ***Materials and Methods:*** Patients underwent simultaneous 90Y-PET/MRI imaging of the liver after SIRT. PET emission data were acquired for twenty minutes in one bed position, standard liver MRI sequences were acquired concurrently. The reconstructed PET images were convolved with a dose-point-kernel to obtain the dose distribution. The open-source software framework Voreen (1) was adapted and used for the visualization of the distribution of radiation on the liver surface, together with MR-derived liver anatomy and adjacent anatomical structures such as vessels that may serve as anatomical landmarks during surgery. Two experienced transplant surgeons were acquainted with the visualization method (3 patients with unifocal, oligofocal and disseminated tumor) and given a questionnaire asking for their assessment of its clinical applicability. ***Results:*** An interactive visualization that satisfies the specifications set out at the start of the project was successfully realized within the Voreen framework. A user can explore the rendered data in 3D, he can explore the decay over time and he can set radiation threshold levels on the liver surface. The transplant surgeons assessed that the method can be applicable and of worth in the clinical setting. ***Conclusion:*** Individual visualization of radiation on the liver surface may be a suitable method to safeguard safe and early surgery, e.g. liver transplantation, after SIRT. This warrants further refinement, validation and practical implementation of the method. Careful consideration has to be given to the fact that the liver changes shape when manipulated during surgery in contrast to static imaging used for this first proof of concept. ***References:*** (1) Drees D, Leistikow S, Jiang X, Linsen L. Does the number of microspheres impact the treatment efficacy in ^{90}Y Transarterial Radioembolization?

M. Olivieri[1,2], *A. Savi[1], E. di Gaeta[1], C. Canevari[1], P. Magnani[1], G. Matassa[1], F. Calabrese[1,2], S. Gusmini[1], A. Casadei-Gardini[1,2], L. Aldrighetti[1,2], F. De Cobelli[1,2], A. Chiti[1,2];*
[1]IRCCS San Raffaele Scientific Institute, Milan, ITALY,
[2]Vita-Salute San Raffaele University, Milan, ITALY.

Aim/Introduction: In 90Y trans arterial radioembolization (TARE) considerable variability exists in clinical outcomes, prompting investigations into factors influencing treatment response. Among these factors, the number of spheres administered has garnered significant interest. Aim of this study is to determine the impact of the number of particles on the treatment efficacy. ***Materials and Methods:*** A total of 23 patients with 31 HCC lesions treated with TARE was considered in this single-institution retrospective study.The modified Response Evaluation Criteria in Solid Tumors (mRecist) was used to evaluate the tumor response on contrast enhanced CT performed at 3 months after radioembolization. Post-TARE 90Y-PET/CT was used to calculate the mean absorbed tumor dose (TD) with the voxel dosimetry approach and the Equivalent Uniform Dose (EUD) to take into account the dose distribution heterogeneity. For each patient, tumor particle density (particles/mL) and tumor-to-normal ratio (TN) were determined on 90Y-PET/CT. The 90Y resin microspheres vial contains approximately 44.48X106 particles and only an aliquot is necessary to obtained the calculated activity to be injected, therefore the number of particles delivered to the tumor was calculated as: (44.48x106 x Delivered Activity within the Tumor Region[GBq])/(3[GBq]at the time of calibration on calibration day x 2-treatment time (hours after calibration)/64.1). The tumor particle density was obtained by dividing this value for the tumor volume. The TN was calculated as the ratio between the activity within the tumor and normal liver volume of interests. To assess the impact of TD, EUD, tumor particle density and TN on tumor response, a multivariate analysis was performed. ***Results:*** Tumor volumes ranged from 6.48 to 732 mL (median 72.83 mL). On the basis of Barcelona Clinical Liver Cancer (BCLC) classification, 5 patients were BCLC A, 13 BCLC B, 5 BCLC C; 24 of 31 target lesions (77%) exhibited partial/complete response. Mean TD and EUD were 322±179 Gy and 199.96±87.71 Gy respectively. Evaluation of the 90Y-PET/CT provided a mean particle density of 65885±33901 particles/mL and a mean TN of 1.84±0.93. Multivariate analysis showed that local tumor response was significantly predicted by EUD (p=0.03), mean particle density (p=0.02), TN (p =0.007), but not by TD (p =0.15). ***Conclusion:*** An accurate choice of the number of resin spheres can significantly impact treatment planning and patient outcomes, offering a tailored approach to radioembolization therapy.

[^{3}H]PiB was not a useful radio ligand for the biding assay using magnetically isolated myelin

K. Kato[1], *R. Harada[2,3], T. Kumamoto[4], S. Furumoto[3];*
[1]National Institute of Neuroscience, Kodaira, JAPAN,
[2]Tohoku Medical and Pharmaceutical University, Sendai, JAPAN, [3]Tohoku University, Sendai, JAPAN,
[4]Hiroshima University, Hiroshima, JAPAN.

Aim/Introduction: in vivo imaging of myelin sheaths is significant for the clinical diagnosis of multiple sclerosis (MS). PET tracer visualizing myelin plays crucial role for this purpose. Seeking the compounds with high affinity to myelin is a first step to develop myelin imaging tracers and displacement binding assay using a radioactive ligand is typical technique to assess the affinity of compounds. PiB is a well known amyloid tracer and binds to white matter, where myelin is most abundant. In this

regard, PiB has been considered to bind basic myelin protein. We decided to use 3H-labeled PiB as a radio ligand of binding assay to the myelin which was isolated by magnetic beads. ***Materials and Methods:*** Myelin fractions from mouse brain (6-week-male, whole brain except cerebellum) were prepared using a commercially available tissue dissociation kits and myelin isolation beads according to the manufacturer's protocol. The molar activity and radiochemical purity of [3H]PiB used in the experiments were 2.96 TBq/mmol and 99%, respectively. MeDAS was synthesized in accordance with reference 1. Isolated myelin fractions were placed on the slide glass and dried. The myelin fractions were incubated with MeDAS (10 μM), a fluorescent compound with high affinity for myelin, to confirm the presence of myelin. In vitro binding assay of [3H]PiB (1 nM) was performed against the isolated myelin fractions. Non-specific binding was defined in the presence of unlabeled PiB (1 μM). ***Results:*** MeDAS-positive structures were observed on the myelin fractions. The result indicated the isolated myelin would be usable for displacement binding assay. In vitro binding assay of [3H]PiB indicated that significant specific binding was not detected on the myelin fractions although [3H]PiB preserved high specific binding for the synthetic Aβ40 fibrils. ***Conclusion:*** We prepared magnetically isolated myelin fractions for the displacement binding assay. Fluorescent MeDAS stain was observed but specific binding of [3H]PiB was not detected on the myelin fractions. As a result, we did not use [3H]PiB as a radio ligand for the biding assay. ***References:*** 1. Wu C. et al, J. Med. Chem. 2008 51, 6682.

EP-0002

In Vitro Study on DNA Damage Induction by Targeted Radionuclide and External Radiotherapy compared to DNA Damage Simulation using GEANT4 DNA

R. Winter[1,2], *U. Bauder-Wüst[1], M. Schäfer[3], Y. Remde[3], M. Roscher[3], R. Lopez Perez[4], M. Benesova-Schäfer[1];*
[1]German Cancer Research Center, Translational Radiotheranostics, Heidelberg, GERMANY, [2]Heidelberg University, Faculty of Physics and Astronomy, Heidelberg, GERMANY, [3]German Cancer Research Center, Service Unit Radiopharmaceuticals und Preclinical Studies, Heidelberg, GERMANY, [4]German Cancer Research Center, Clinical Cooperation Unit Molecular and Radiation Oncology, Heidelberg, GERMANY.

Aim/Introduction: Targeted radionuclide therapy (TRNT) has recently emerged as a highly effective treatment option for cancer patients with metastatic disease who do not respond to conventional therapies. Targeted Alpha Therapy (TαT) is the most effective TRNT, as α-particles induce complex DNA damage (DD) and are less prone to resistance development. Nevertheless, little is known about DD induction and repair after TRNT. Furthermore, successful treatment requires accurate, model-based estimation of the administered dose. Therefore, these processes are studied with α-emitters (225Ac, 227Th, 223Ra) and a β--emitter (177Lu) along with external photon radiation for reference. GEANT4-DNA will be used for the model comparison with radiobiological data. ***Materials and Methods:*** The prostate cancer cell lines PC3 (PSMA-), LNCaP and C4-2 (PSMA+) were incubated with either free, non-complexed radionuclides or with targeted, radiolabeled PSMA-ligands for 1 or 4 hours at the following activity ranges: 1-100 kBq (α-emitters) and 100-5000 kBq (β--emitter). External radiation doses of 0.5-2.5 Gy were applied to additional samples. DNA double-strand breaks were visualized via immunofluorescent staining of γH2AX and data analyzed for DD dependency on radionuclide and dose. The membrane-bound and internalized fraction of the total activity was quantified in a complementary cell assay. ***Results:*** Analysis of mean γH2AX foci/nucleus revealed a two orders of magnitude higher potency of α-emitters than β--emitters in DD induction. 223Ra caused higher DD than 227Th due to the increased frequency of emitted α-particles. While the signal intensity of the foci increased linearly with dose in all treatments, the area showed a greater expansion for α-emitters than for photons and β--emitters. In addition, radionuclides specifically administered in targeted radiopharmaceuticals did not induce significantly higher DD. This could be related to the non-specific binding of non-complexed radionuclides to the cell membrane, which account for up to 30 % of the total activity. ***Conclusion:*** The results emphasize the differences between the therapies based on α- and β--emitters. They provide a solid base for estimating the therapeutically effective dose and enable a better comprehension of DD induction. In particular, the differences in DD induction of non-complexed versus targeted radionuclides were studied. In future, Monte Carlo modelling of DD is essential to validate the experimental data and to clarify the effects of radionuclide distribution. Therefore, a GEANT4-DNA simulation based on a single-cell model to mimic the DD and γH2AX foci will be performed.

EP-0003

Investigation of Photodynamic Therapy Promoted by Cherenkov Light Activated Photosensitizers - New Aspects and Revelations

L. Hübinger[1], *K. Wetzig[1], R. Runge[1], H. Hartmann[1], F. Tillner[2], K. Tietze[1], J. Kotzerke[1];*
[1]Klinik und Poliklinik für Nuklearmedizin Dresden, Dresden, GERMANY, [2]Klinik und Poliklinik für Strahlentherapie und Radioonkologie, Dresden, GERMANY.

Aim/Introduction: Photodynamic therapy (PDT) is based on the activation of photosensitizers (PSs) by light. The disadvantage of this method is the low penetration depth of the light. Therefore, it was investigated whether radionuclide-induced Cherenkov light (CL) could also induce this effect, allowing therapy deep within the body. ***Materials and Methods:*** The CL sources are the nuclear medicine relevant radionuclide Re-188 (1.5 GBq) and the 15 MV photons from a linear accelerator, which were used to irradiate FaDu, B16 and 4T1 tumor cells for 24 hours or a few minutes, respectively. The CL generated by Re-188 was detected using a CCD camera and a microtiter plate reader. Psoralen or trioxsalen dissolved in DMSO was used as PS. The phototoxic effect was evaluated by colony formation assays and compared with control samples not exposed to CL. The effect of the PSs was verified by DNA gel electrophoresis on plasmid DNA. Other ongoing studies are investigating the effect of the PSs on plasmid DNA activated by CL generated by the linear accelerator setup. ***Results:*** The CL produced by Re-188 and its shielding were confirmed using a CCD camera and the CL spectrum was recorded using a microtiter plate reader, showing the expected peak in UVA wavelengths. An absorbance measurement shows that daylight does not induce a psoralen/trioxsalen reaction. There is reduced cell viability for CL-irradiated cells compared to controls for both PSs, although this is statistically significant due to large fluctuations of the cell experiments. This challenge is addressed with upcoming plasmid DNA experiments. Gel electrophoresis showed an enhanced effect of trioxsalen compared to psoralen. ***Conclusion:*** The expected therapeutic effect of CL-activated PSs in radionuclide therapy could only be demonstrated on a non-significant basis in cells. The plasmid DNA data should shed light on this.

EP-0004

In vitro studio of affinity of 18F-NaF vs 99mTc-DPD for amyloidosis cardiac imaging

L. Canziani, *L. Lodola, G. Manfrinato, G. Pepe;*
Fondazione IRCCS Policlinico San Matteo, Pavia, ITALY.

Aim/Introduction: Cardiac amyloidosis (CA) consists of a group of diseases characterized by a deposition of insoluble and misfolded proteins in the myocardium. Technetium labelled bone seeker phosphonate such as DPD,PYP and HMP are recognized as highly accurate for the non-invasive diagnosis of transthyretin (ATTR) cardiac amyloidosis. 18F-fluoride ($^{[18F]}$NaF) is a radionuclide approved for bone metabolism studies in Positron Emission Tomography (PET), that raise our interest as a potential ATTR diagnosis tool. $^{[18F]}$NaF benefits from the improved spatial resolution of PET imaging, offering superior imaging characteristics and quantification capabilities. These features could potentially lead to better diagnostic performance, especially in the early stages of the disease. To date, few data are available about the actual affinity of $^{[18F]}$NaF for fibrils. The aim of this study was to evaluate, as an essential preliminary step for planning a future clinical study, the in vitro affinity of $^{[18F]}$NaF for synthetic fibrils, in comparison with [99mTc]Tc-DPD. ***Materials and Methods:*** Amyloid fibrils were generated dissolving 10 mg of insulin in an aqueous solution of HCl (pH 2.0) and incubating the solution at 55°C to induce fibril formation. Ten vials were prepared, each with 120 uL of fibril preparation. In five vials, increasing amounts of $^{[18F]}$NaF (50, 100, 200, 500, 1000 kBq) were added and brought to a volume of 2 mL with saline solution. In other five vials, increasing amounts of [99mTc]Tc-DPD (50, 100, 200, 500, 1000 kBq) were added and brought to a volume of 2 mL with saline solution. As per protocol for bone acquisition, the $^{[18F]}$NaF vials were incubated for 60 min, while the [99mTc]Tc-DPD vials were incubated up to 180 min. Labelling yield was subsequently evaluated using ITLC-SG and acetonitrile and water (9:1) as mobile phase for $^{[18F]}$NaF, and TLC silica gel and acetone and methanol (1:1) for [99mTc]Tc-DPD. ***Results:*** The binding kinetics of both [99mTc]Tc-DPD and $^{[18F]}$NaF followed a specific-type pattern even if at different concentration, characterized by a sigmoidal shape suggestive of a BET isotherm model. Notably, at the same concentration $^{[18F]}$NaF exhibited a higher affinity than [99mTc]Tc-DPD. ***Conclusion:*** Our findings suggest that $^{[18F]}$NaF may possess superior binding ability for amyloid fibrils compared to [99mTc]Tc-DPD. Potentially it could provide to be a more effective tracer for cardiac amyloidosis imaging. Further in vitro and clinical investigations are needed to validate the diagnostic utility of $^{[18F]}$NaF in comparison to [99mTc]Tc-DPD and to elucidate its role in clinical practice.

EP-0005

Harnessing Pentafluorophenyl Esters for the Site-Selective Bioconjugation of a HER2-Targeted Radioimmunoconjugate

S. Delaney, *W. Kao, M. A. Cornejo, B. M. Zeglis;*
The City University of New York, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: Site-selective bioconjugations facilitate the creation of well-defined radioimmunoconjugates. However, none of the extant strategies for site-selective bioconjugation are as procedurally or logistically simple as stochastic methods, creating a barrier to clinical translation. Bhat et al. demonstrated that amine-reactive fluorophenolic esters preferentially react with the Lys-188 (K188) residues in the constant region of the kappa light chain of mAbs [1]. We previously reported an approach to site-selective bioconjugation based K188 residue modifications with pentafluorophenyl ester (PFP)-bearing azides and the subsequent attachment of cargoes via the strain-promoted azide-alkyne cycloaddition [2]. However, this method still requires two steps. Herein, we describe our efforts to streamline this process into one reaction. We have synthesized a PFP-bearing variant of desferrioxamine (DFO) to modify the K188 residues of pertuzumab. Then, the site-selectively modified immunoconjugate was labeled with the positron-emitting radiometal zirconium-89 (t1/2 ~3.3 d) to produce the radioimmunoconjugate, [89Zr]Zr-DFOPFP-pertuzumab, which exhibited excellent in vitro behavior. ***Materials and Methods:*** Fe-N-succinyl-DFO-PFP was prepared and characterized via mass spectrometry and UV-Vis spectroscopy [3]. Following the removal of iron, site-selective bioconjugation was achieved by incubating N-succinyl-DFO-PFP (10 eq.) with pertuzumab (19 h, 4 °C). The resulting immunoconjugate — DFOPFP-pertuzumab — was purified via size-exclusion chromatography, analyzed via LC-MS analysis, and radiolabeled to produce [89Zr]Zr-DFOPFP-pertuzumab. Stability measurements were taken every 24 h via radio-instant thin layer chromatography (5 days), and immunoreactivity was determined using HER2-coated magnetic beads. Additionally, a HER2-expressing SK-OV-3 tumor was grown in vivo, cryogenically frozen, cut, and subjected to immunofluorescence staining with DFOPFP-pertuzumab and goat anti-human IgG Alexa-488. ***Results:*** Mass spectrometry confirmed the synthesis of N-succinyl-DFO (m/z ~661.4), and UV-Vis spectroscopy revealed the formation of metalated Fe-N-succinyl-DFO-PFP (absorbance ~430 nm). Following bioconjugation, SDS-PAGE demonstrated selective labeling of the light chain on the mAb. In addition, LC-MS experiments confirmed selectivity towards the light chain and revealed a degree-of-labeling of ~1.0 DFO/mAb. [89Zr]Zr-DFOPFP-pertuzumab was produced in >97% radiochemical yield, remained >96% and 86% stable over 5 days in PBS and human serum, respectively, and boasted an immunoreactive fraction of >0.85. Immunofluorescence staining revealed high binding to HER2-expressing SK-OV-3 tumor tissue. ***Conclusion:*** In this investigation, we have improved upon our previously validated site-selective bioconjugation strategy based on pentafluorophenyl esters to create a HER2-targeted radioimmunoconjugate with excellent in vitro properties. Our next steps involve evaluating the in vivo performance [89Zr]Zr-DFOPFP-pertuzumab in a murine model of breast cancer. ***References:*** Bhat. US2012/0201809A1. 2014.Sarrett. Bioconjug Chem. 2022.Verel. J Nucl Med. 2003.

EP-0006

Assessment of (S)-LW223 binding affinity to TSPO in rs6971 genotyped human brain tissue

M. MacAskill[1], *L. J. N. Waddell[2], V. J. M. Reid[1], D. E. Newby[1], S. L. Pimlott[2], A. Sutherland[2], A. A. S. Tavares[1];*
[1]University of Edinburgh, Edinburgh, UNITED KINGDOM,
[2]University of Glasgow, Glasgow, UNITED KINGDOM.

Aim/Introduction: The 18kDa Translocator protein (TSPO) is a molecular imaging target for the investigation of inflammation across many sites throughout the body. Over the past several decades, multiple radiotracers have been developed but the majority are limited by considerable interindividual binding variability in humans caused by genetic polymorphism (rs6971). We have developed a novel TSPO ligand, $^{[18F]}$LW223, which is the first fluorinated TSPO radiotracer with binding in human tissue independent of the rs6971 polymorphism [1] and has now entered

clinical translation. Both [18F]LW223 and [11C]PK11195 possess chiral amide side-chains with R-configuration. [11C](R)-PK11195 is known to be insensitive to the rs6971 genetic polymorphism and has higher affinity to TSPO than [11C](S)-PK11195. We hypothesise that, as is the case with PK11195, (S)-LW223 will have a lower affinity to TSPO than its R-enantiomer, but will also be insensitive to the rs6971 genetic polymorphism. ***Materials and Methods:*** Eighteen genotyped and frozen human frontal cortex samples were obtained from the UK Brain Bank Network, representing n=6 high affinity binders (HAB), n=6 mixed affinity binders (MAB) and n=6 low affinity binders (LAB). A homogenised brain tissue solution was prepared for each sample and the binding affinity of (S)-LW223 was then assessed using a [3H]PK11195 competition binding assay as previously described [1]. Specific binding was calculated relative to a full blocking control. Both one-site and two-site fitting for specific binding was assessed, with one-site being the preferred option for all datasets. Individual one-site specific binding was used to calculate the Ki across each genotype and the overall population, and average one-site specific binding across each genotype was used to calculate the LAB:HAB ratio. ***Results:*** Across all samples, the average (S)-LW223 affinity (Ki) was 4.5± 0.7 nM (mean± SEM). This binding affinity to TSPO is 7.5 lower than that of (R)-LW223 which has been previously reported (0.6 nM) [1]. There was no difference in (S)-LW223 affinity between HAB vs. LAB (p= 0.53, unpaired t test). The average LAB:HAB ratio was 1.5. ***Conclusion:*** The TSPO binding affinity of (S)-LW223 is lower than that of (R)-LW223. Like (R)-LW223, (S)-LW223 is not sensitive to the rs6971 genetic polymorphism suggesting that structure, and not chirality, of the side chain is important for polymorphism insensitivity. Overall, (R)-LW223 remains the superior enantiomer for TSPO binding. ***References:*** 1. MacAskill MG, et al. Quantification of Macrophage-Driven Inflammation During Myocardial Infarction with 18 F-LW223, a Novel TSPO Radiotracer with Binding Independent of the rs6971 Human Polymorphism. Selection of Living Kidney Donors with measured Glomerular Filtration Rate using 99mTc-DTPA compared to creatinine estimated equations

A. Khelifa, *A. Talbi;*
Bab El Oued Hospital, Algiers, ALGERIA.

Aim/Introduction: Accurate assessment of kidney function in living kidney donors is crucial prior to surgery. The aim of this study was to demonstrate the value of measured Glomerular Filtration Rate using 99mTc-DTPA (mGFRDTPA) in living kidney donors compared to creatinine estimated equations, Modification of Diet in Renal Disease (MDRD, eGFRMDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD-Epi, eGFRCKD-Epi) for a best selection of potential kidney candidates. ***Materials and Methods:*** mGFRDTPA were performed in kidney donors candidates after intravenous injection of 37 MBq 99mTc-DTPA, followed by two blood samples at 2h and 4h post-injection according to BNMS Guidelines. Creatinine was measured in all candidates and the estimated creatinine eGFR calculated by MDRD and CKD Epi equations. mGFRDTPA was compared to the eGFRMDRD and eGFRCKD-Epi and the donors selected for the protocol transplantation according to their mGFRDTPA when superior or equal to 80ml/min/1.73m2 ***Results:*** 342 kidney donors (194 women 56,7%,148 men 43,3% mean age 50,06±11,80). The mGFRDTPA was 90,13±20,3 ml/min/1.73m2, eGFRMDRD 89,96±23,5 ml/min/1.73m2, eGFRCKD-Epi 93,97±18,11 ml/min/1.73m2. The mean creatinine was at 8,5±1,9, BMI at 26,10 Kg/m2 A total of 235 patients (68,7%) achieved a mGFRDTPA ≥ 80ml/min/1.73m2, selected into the transplant protocol. mGFRDTPA rejected 107 donors (31,3%) mDFGDTPA and eGFRMDRD were concordant in 68,42% of the population and discordant in 31,57%, with 69 donors rejected by eGFRMDRD but selected with DTPA. mDFGDTPA and eGFRCKD-Epi were concordant in 71,63% of the population and discordant in 28,36%, 34 donors rejected by eGFRCKD-Epi and selected with DTPA. CKD-EPI is better than MDRD to assess renal function in selecting kidney living donors as recommended by the nephrology societies, but mGFRDTPA is still recommended for such important impact clinical decisions, when facing doubt in assessing renal function such as aged donors or suspicious estimated GFR ***Conclusion:*** Measured GFR in assessing renal function mGFRDTPA is a gold standard method in the selection of potential kidney donors candidates compared to eGFR equations with an impact on the transplant decision, but mGFRDTPA requires indications adapted to this population. ***References:*** 1- Fleming JS, Zivanovic MA, Blake GM, Burniston M, Cosgriff PS. Comparing tumor cell intrinsic mechanisms governing response/resistance to^{177}Lu- and^{212}Pb-PSMA therapy

K. Lückerath[1], *D. Howard[1], M. Staniszewska[1], F. Liu[2], V. von Kiedrowski[1], R. Hübner[1], E. Deniz[1], S. Rose[2], S. Puttick[2], K. Herrmann[1], T. Kryza[2];*
[1]University Hospital Essen, Essen, GERMANY,
[2]AdvanCell, Brisbane, AUSTRALIA.

Aim/Introduction: 177Lu-PSMA has revolutionized prostate cancer (PC) treatment, but a substantial fraction of patients does not respond to radioligand therapy (RLT). Using in vitro models, we comparatively investigate tumor cell intrinsic mechanisms governing responses to 177Lu-PSMA617 and the emerging alpha-emitter 212Pb-PSMA. ***Materials and Methods:*** Using different PSMA-expressing PC cell models (PSMA-high, PSMA-low, PSMA-high and p53 loss), we determined the half-lethal activities for 177Lu- and 212Pb-PSMA (clonogenic assay). We analyzed DNA damage induction and repair kinetics (γH2A.X), cell cycle distribution (PI FACS), and the molecular changes in response to 177Lu- and 212Pb-PSMA therapy (RNA-seq) at low (half-lethal) and high activities over time. ***Results:*** RLT efficacy expectedly depended on PSMA-levels and p53 status, with PSMA-high cells responding better than PSMA-low cells, and p53-intact cells responding better than p53-KO cells. Low and high activities of 177Lu-PSMA resulted in rapidly repaired DNA damage, similar to external beam radiotherapy, but without cell cycle arrest - suggesting an opportunity for combination therapies that exploit 177Lu-induced DNA damage concurrent with RLT administration. In contrast, 212Pb-PSMA induced more sustained DNA damage that was accompanied by the activation of multiple signaling pathways including DNA damage response signaling with activation of non-homologous end joining as DNA repair pathway, p53 signaling, telomere and oxidative stress induced senescence, cell cycle checkpoints, and immunoregulation. Thereby, signatures related to DNA damage repair, cell cycle arrest and senescence were enriched early after treatment (24 h), and DNA damage repair, senescence and cell death signalling predominated after 48 h. Late responses (day 6) included activation of pathways related to DNA damage repair, DNA

fragmentation, antigen processing, and Toll-like receptor activation. ***Conclusion:*** The current study comparing the responses of PC cells to 177Lu- and 212Pb-PSMA sheds light on the complexity of tumor cell intrinsic mechanisms influencing the efficacy of RLT and suggests distinct modes of action for the two radioligands, with potential implications for combination therapies. In vivo validation of these results is warranted and ongoing.

EP-0009

Evaluation of radiation sensitivity by monitoring DNA double-strand breaks and cell cycle in prostate cancer cell lines

H. Jung[1,2,3];
[1]Department of Biomedical Sciences, Seoul National University Graduate School, Seoul, KOREA, REPUBLIC OF, [2]Department of Nuclear medicine, Cancer Imaging Center, Seoul National University, Seoul, KOREA, REPUBLIC OF, [3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Recently, various radiopharmaceuticals and radiotherapy have been developed. The anti-cancer effect of external beam radiation varies depending on the radiation exposure dose, and although much basic research has been conducted on this, much research is still needed to identify biological changes according to the distribution of absorbed dose in the body. In this study, we aim to evaluate radio-sensitivity by measuring the effect of absorbed dose distribution, observing DNA double-strand breaks and monitoring cell cycle changes in prostate cancer cell lines expressing high levels of PSMA. ***Materials and Methods:*** LNCaP, C4-2, and VCaP were used as PSMA positive cells, and PC3 was used as PSMA negative cells. Real-time quantitative reverse transcription PCR (qRT-PCR) and Western blotting was performed to determine androgen receptor (AR) and PSMA expression. Cell lines were exposed to 137Cs irradiator. Dose dependence of DNA damage was monitored through immunofluorescence staining of γH2AX and 53BP1 as double-strand break markers. Cell cycle changes by radiation (3, 6, 9 Gy), flow cytometry was performed after Propidium iodide (PI) staining. ***Results:*** Levels of gene expression of AR and PSMA in LNCaP, C4-2, and VCaP were significantly higher in both qRT-PCR and immunoblots compared to PC-3 cells. When they exposed to 2 Gy irradiation, the number of 53BP1 and rH2AX foci were reduced by half at 2 to 4 hours. When cells were exposed to 6 Gy, the number of 53BP1 and rH2AX foci decreased after 48 h in PSMA-positive cell lines, but the number of 53BP1 and rH2AX foci increased over time in PC-3. G2/M cell cycle arrest in PC-3 showed a time-dependent increase up to 48 hours after exposure to 6 Gy and 9 Gy doses, whereas no significant increase was seen in PC-3 exposed to 3 Gy. G2/M cell cycle arrest was 3- to 6-fold lower in PSMA-positive LNCaP and C4-2 compared to PC-3. Additionally, differences in treatment effectiveness appear in the absorbed dose distribution within the tumor ***Conclusion:*** These results suggest that cells expressing PSMA and AR are more resistant to radiation compared to control cells. This study is expected to provide important information when comparing differences in treatment effects according to absorbed dose distribution in future treatment using radiopharmaceuticals labeled with alpha- and beta-emitting radioisotopes.

EP-0010

Spheroids as Promising Models to Investigate Peptide-Based Targeted Radionuclide Therapy

L. Ali[1], *I. Galeano[2], S. Bodin[1,3], F. Cavelier[4], G. Siegfried[2], E. Hindié[5], M. Khatib[2], C. Morgat[1,3];*
[1]University of Bordeaux, UMR CNRS 5287, INCIA, F-33400 Talence, France, BORDEAUX, FRANCE, [2]RyTME, Bordeaux Institute of Oncology (BRIC)-UMR1312 Inserm, B2 Ouest, Allée Geoffroy St Hilaire CS50023, 33615, Pessac, France, BORDEAUX, FRANCE, [3]Department of Nuclear Medicine, University Hospital of Bordeaux, F-33076 Bordeaux, France, Bordeaux, FRANCE, [4]Institut des Biomolécules Max Mousseron IBMM, UMR 5247 Pôle Chimie Balard, 1919, route de Mende, 34093, Montpelier Cedex 5, France, Montpelier, FRANCE, [5]Institut Universitaire de France (IUF), F-75000 Paris, France, BORDEAUX, FRANCE.

Aim/Introduction: Targeted radionuclide therapy (TRT) is recognized as a valuable option for selective irradiation of metastases using Lutetium-177 (177Lu) ligands. However, its efficacy varies greatly depending on the size of irradiated lesions, a parameter that cannot be studied on 2D monolayer cells models. Therefore, the objective of this work was therefore to assess the dynamic and efficacy of TRT in singles cells versus larger multicellular constructs for 177Lu-TRT peptide ligands. The neurotensin receptor-1 (NTS1) was selected as a target. ***Materials and Methods:*** HT-29, Colorectal Adenocarcinoma cells that overexpressing NTS1, were grown as monolayer cells, in Roswell Park Memorial Institute (RPMI)1640 Medium supplemented with 10% fetal bovine serum, and as spheroids, in spheroids medium consists of Dulbecco's Modified Eagle Medium F12 (DMEM F12) medium (with Glutamine, without Antibiotic nor serum), with 0,4% Methylcellulose and supplemented with B-27 (50X), N-2 (100X), hEGF (10µg/ml) (human Epidermal Growth Factor) and hBFGF (25µg/ml) (Fibroblast Growth Factor-Basic human). For monolayer cells (2D), 5000 cells were seeded the day before the experiment. Whereas for spheroids (3D), 5000 cells were used to generate spheroids 3 days before the experiment. Next, [177Lu]Lu-JMV6659, a radiolabelled NTS1-agonist previously developed by our consortium1, was applied at increasing concentrations. Both 2D and 3D cells were exposed to radioactivity for 4h. Uptake and therapeutic efficacy (viability) were monitored. Next, monolayers and spheroids were characterized in terms of size, $^{[18F]}$-FDG uptake, and HIF1α expression. ***Results:*** [177Lu]Lu-JMV6659 showed an uptake of 25111 ± 4231 Bq in monolayer cells vs 13808 ± 2772 Bq in spheroids at 20MBq/mL. Consequently, the therapeutic efficacy was better in monolayer cells (IC50 = 6.4 MBq/mL vs > 100MBq/mL for spheroids). Spheroids were much larger than the monolayer cells. $^{[18F]}$-FDG uptake was 1.03% added dose (AD)/µg of protein for spheroids vs. 0.079 % AD/µg of protein for monolayer cells. There was no difference in HIF1α expression between the two models, as determined by western blotting. ***Conclusion:*** Spheroids stands as a versatile and promising platform for studying the radiobiology and pharmacodynamic of peptide-based TRT in single cells and multicellular constructs. ***References:*** 1: Silicon-Containing Neurotensin Analogues as Radiopharmaceuticals for NTS1-Positive Tumors Imaging. Exploring ^{135}La-DOTA-hEGF as a Promising Candidate for Targeted Radionuclide Therapy in Glioblastoma

A. Nielsen[1], *K. S. Pedersen[2], V. S. Gammelsrød[1,3], K. Ravn[2], Q. Tang[2], H. Thisgaard[1,3], A. I. Jensen[2];*
[1]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]The Hevesy Laboratory, Department of Health Technology, Technical University of Denmark, Roskilde, DENMARK, [3]Department of Clinical Research, University of Southern Denmark, Odense, DENMARK.

Aim/Introduction: Glioblastoma is the most common and aggressive form of brain cancer. The current treatment is inefficient and eventually leads to death in all cases. Thus, the demand for novel therapeutic approaches for glioblastoma patients is paramount. The epidermal growth factor receptor (EGFR) is overexpressed in approximately 55% of glioblastoma patients and possesses a promising target for targeted radionuclide therapy. Here, we produced lanthanum-135, a favorable Auger electron emitter, and radiolabeled human epidermal growth factor (hEGF) with lanthanum-135 to furnish 135La-DOTA-hEGF. We subsequently investigated the in vitro potential of 135La-DOTA-hEGF in glioblastoma cells. ***Materials and Methods:*** Lanthanum-135 was produced by irradiation of pressed enriched [135Ba]BaCO3 and Al (1:2, w/w) targets with a 16.5 MeV GE PETtrace cyclotron and purified by a simple procedure, as previously described [1]. DOTA was non-specifically conjugated to available amines on hEGF via an activated NHS-ester. DOTA-hEGF (11-22 nmol, 0.6 DOTA per hEGF) was radiolabeled with lanthanum-135 (up to 2.0 GBq) for 1.5 h at 95 oC at pH 5.5 in NH4OAc buffer. Cellular kinetics and subcellular distribution were assessed utilizing the EGFR-expressing glioblastoma cell line LN229. ***Results:*** At EOB, 1.62 ± 0.18 GBq lanthanum-135 was produced per target after 4 hours of irradiation in an effective molar activity of 79.6 ± 25.3 MBq/nmol measured via DOTA titration. 135La-DOTA-hEGF was radiosynthesized in activities up to 1.1 GBq in non-decay corrected RCYs of approximately 50-55% and apparent molar activities around 40-45 MBq/nmol. 135La-DOTA-hEGF demonstrated EGFR-specific uptake in LN229 cells with 9.9 ± 1.16 %, 13.3 ± 2.2 %, and 17.0 ± 4.1 % internalization after 1, 2 and 4 hours of incubation, respectively, and high cellular retention at 69 ± 5.8 % after 24 hours of incubation. ***Conclusion:*** We report development and synthesis of 135La-DOTA-hEGF in moderate RCY at good activity levels and molar activities. Further, we report EGFR-specific cellular uptake and retention. The 135La-DOTA-hEGF reported herein is suitable for preclinical in vitro and in vivo efficacy studies, paving the way for further studies into its suitability as a candidate for targeted radionuclide therapy for glioblstoma. ***References:*** [1] K. S. Pedersen, et al., Applied Radiation and Isotopes, 2023, 192, 110612.

EP-0012

TSPO ligands regulate HK activity by affecting TSPO dimer formation and TSPO-VDAC1 binding

C. An[1,2,3], *S. Lee[1,3], K. Kang[1,2,3], H. Youn[1,3];*
[1]Department of Nuclear Medicine, Cancer Imaging Center, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [2]Department of Biomedical Sciences, Seoul National University Graduate School, Seoul, KOREA, REPUBLIC OF, [3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Binding of hexokinase II (HKII), which is highly expressed in tumor cells, to mitochondrial voltage-gated anion channel 1 (VDAC1) increases the activity of HKII, resulting increased FDG uptake. Translocation protein-18 kDa (TSPO), which functions in a dimeric form, exists in the mitochondrial outer membrane and is known to bind to the VDAC1 protein. However, the effect of the binding of TSPO and VDAC1 on HKII activity is not clearly understood. The purpose of this study was to investigate whether inhibition of binding between TSPO dimers and VDAC1 could regulate FDG uptake by affecting the activity of HKII. ***Materials and Methods:*** 293FT (Human embryonic kidney), MCF7 and MDA-MB-231(human breast cancer) cell lines were used. PK11195 known as a TSPO antagonist used to inhibit TSPO-VDAC1 interaction. SDS-PAGE and native-PAGE were performed to identify the monomeric and multimeric expression of TSPO, VDAC1 and HKII. Co-Immunoprecipitation (Co-IP), Bimolecular Fluorescence Complementation (BiFC) and fluorescence resonance energy transfer (FRET) imaging were performed to observe protein-protein interactions. The hexokinase activity was measured with hexokinase assay kit (Abcam). ***Results:*** Multimeric expression of TSPO, VDAC1, and HKII was observed in normal cells, 293FT, and breast cancer cell lines (MCF7 and MDA-MB-231). No significant differences were observed in the multimeric expression of TSPO and VDAC1 when treated with PK11195. Through BiFC-FRET (Venus-mCerulean) fluorescence signals and Co-IP, a decrease in the interaction between TSPO dimer and VDAC1 and an increase in VDAC1-HKII binding were observed after PK11195 treatment, and the interaction of TSPO-VDAC1-HKII was confirmed. When PK11195 was treated in transfected breast cancer cells, we observed a decrease in FRET signal in cells co-expressing TSPO dimer-VDAC1 dimer. Additionally, in breast cancer cells treated with PK11195, a 1.5-fold increase in the amount of HKII bound to VDAC1 was observed in mitochondrial fraction isolation, and an increase was also observed in Co-IP. This is consistent with the 1.36-fold increase in measured hexokinase activity in breast cancer cells treated with PK11195. ***Conclusion:*** We showed that the interaction of the TPSO-VDAC1-HKII complex can lead to changes in HKII activity. These data suggest that reduction of TSPO dimer-VDAC1 assembly by TSPO ligand increases binding of HKII and VDAC1 and causes activation of HKII, which may also affect FDG uptake.

EP-0013

Development and in vitro characterization of [3H]GMC-058 as radioligand for imaging parkinsonian-related proteinopathies

A. Varrone[1], *V. Sousoa[2], M. Mugnaini[3], S. Biesinger[3], D. Sunnemark[4], S. Finnema[5], M. Schou[1];*
[1]Karolinska Institutet, Department of Clinical Neuroscience, Centre for Psychiatry Research, Stockholm, SWEDEN, [2]Karolinska Institutet, Department of Clinical Neuroscience, Division of Imaging Core Facilities, Stockholm, SWEDEN, [3]Molecular & Imaging Biomarkers, AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, GERMANY, [4]Offspring Biosciences, Södertälje, SWEDEN, [5]AbbVie, Neuroscience, Translational Imaging, North Chicago, IL, UNITED STATES OF AMERICA.

Aim/Introduction: PET imaging of α-synuclein (α-syn) pathology in Parkinson's disease (PD) and related movement disorders is a clinical unmet need. Recent studies with newly developed PET tracers [18F]ACI-12589 (1) and [18F]SPAL-T-06 (2) have shown promising results in patients with multiple system atrophy (MSA). However, there is still need for a PET tracer able to image α-syn pathology in PD. The aim of this study was to develop and characterize in vitro a PET radioligand for imaging aggregated α-syn in tissue from different proteinopathies ***Materials and Methods:*** A library of 78 small molecules was developed based on available information

from the public domain. Four optimization cycles were performed with in vitro binding assays using recombinant α-syn fibrils and brain homogenates from Alzheimer´s disease (AD) donors enriched with either tau of A-β pathology. Criteria for selection were Ki for α-syn < 30 nM and Ki for tau and A-β > 200 nM. Three compounds, GMC-073, GMC-098, and GMC-058 fulfilled the pre-defined criteria and were radiolabelled with 3H. Brain tissue from control donors and from patients with different proteinopathies was used for autoradiography (ARG) studies on fresh-frozen tissue sections and paraffine embedded tissue microarrays (TMAs). Emulsion ARG in TMAs was used to study the co-localization of ARG signal with α-syn, p-tau and A-β pathology measured with immunohistochemistry. ***Results:*** The three 3H-labelled compounds were initially evaluated in tissue sections from the cingulate cortex of healthy controls. [3H]GMC-073 (Ki for α-syn: 8 nM) and [3HGMC-098 (Ki for α-syn: 9.7 nM) displayed displaceable binding (likely off-target) in control tissue, whereas [3H]GMC-058 (Ki for α-syn: 22.5 nM) displayed negligible displaceable binding in the cingulate cortex and was considered for further evaluation. ARG studies in TMAs showed specific binding (mean±SEM) of [3H] GMC-058 in synucleinopathies (PD: 520±29 fmol/mg and MSA: 670±79 fmol/mg), as well as in cerebral amyloid angiopathy (CAA: 522±49 fmol/mg), AD (508±62 fmol/mg) and 4R tauopathies (PSP: 703±8 fmol/mg and CBD: 821±155 fmol/mg), in all cases higher than in controls (278±16 fmol/mg). Emulsion ARG showed that the binding of [3H]GMC-058 co-localised with α-syn inclusions in PD and MSA, with dense A-β plaques in CAA and AD, and with p-tau inclusions in PSP and CBD. ***Conclusion:*** [3H]GMC-058 is a novel radioligand displaying moderate in vitro affinity for aggregated α-syn, with an in vitro profile also suitable for imaging tau pathology in 4R tauopathies. ***References:*** 1. Nat Commun 14, 6750 (2023). https://doi.org/10.1038/s41467-023-42305-3; 2. Mov Disord. 2022 Oct;37(10):2159-2161. doi: 10.1002/mds.29186.

EP-0014

Enhanced visualization of metabolic changes in colorectal cancer organoids: a multimodal imaging approach

Z. Jiang[1], *K. Draganić[2], M. Hacker[1], E. Patronas[1];*
[1]Department of Biomedical Imaging and Image-Guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [2]MedUni Vienna · Clinical Institute of Pathology Bachelor of Science, Vienna, AUSTRIA.

Aim/Introduction: In cancer research, tumor organoids serve as the key tools for bridging the gap between in vitro models and clinical applications. Despite their great research potential, challenges remain in visualizing and quantifying metabolic changes. Our study employs a multimodal imaging approach that combines traditional autoradiography with modern co-registration techniques and optical coherence tomography (OCT) to enhance the visualization of FDG uptake in colorectal cancer (CRC) organoids . ***Materials and Methods:*** We developed a novel imaging method that combines autoradiography with OCT to enhance the visualization of clinical radiotracers in tumor organoids while providing 3D morphological information. We applied 5-fluorouracil (5-FU) at concentrations of 1 µM and 2.06 µM, the latter reflecting the IC50 value, to CRC organoids to assess the effects of chemotherapy on FDG uptake. Autoradiography was used to measure FDG uptake before and after drug treatment, providing a quantitative analysis of metabolic changes. To overcome the limitations of traditional 2D autoradiography and gain more detailed insights, we prepared 5 µm-thick frozen sections of the treated organoids,autoradiographically imaged each layer of the section, and constructed 3D models. This technique was then combined with OCT imaging to provide a more comprehensive view of the metabolic activity and structural integrity of the organism. This technique, along with OCT imaging, allowed for a more comprehensive visualization of both the metabolic activity and the structural integrity of the organoids. ***Results:*** Our findings indicate that the multimodal imaging technique provides superior resolution compared to standard PET scans and effectively captures the glycolytic activity of the originating tumor tissues. This suggests that tumor organoids can accurately replicate the metabolic behavior of their respective tumors and serve as predictive models for therapeutic responses. Our findings revealed a significant reduction in FDG uptake following treatment with 5-FU, indicating a decrease in metabolic activity. This reduction was dose-dependent, with more pronounced effects observed at the higher concentration of 2.06 µM, derived from the IC50 value. The combined use of autoradiography and OCT confirmed that the areas with reduced FDG uptake correlated with regions showing structural changes and increased cell death in the organoids. ***Conclusion:*** This method, which combines autoradiography with OCT for visualizing and quantifying FDG uptake in tumor organoids, not only enhances our understanding of the metabolic impact of chemotherapy but also supports the development of more effective cancer treatments by facilitating precise monitoring of therapeutic responses at the cellular level.

Administration of antipsychotic drug induces recovery of the impaired glutamatergic system in Alzheimer's disease

K. Lee, *H. Lee, H. Kim, S. Oh, Y. Son, K. Kang, K. Nam, J. Choi;*
Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Patients with Alzheimer's disease (AD) suffer from cognitive dysfunction often accompanied by psychotic symptoms. Therefore, to understand the pathology of AD, it is necessary to understand the relationship between cognitive dysfunction and psychotic symptoms. The glutamatergic system in the central nervous system, known for close links to learning and memory, is of particular interest. However, there exists limited research on the impact of anti-psychotic drugs on the glutamate system. This prompts our current study, where we aim to explore the effects of an antipsychotic drug on the glutamate system in an AD animal model, utilizing functional molecular imaging. ***Materials and Methods:*** We used aripiprazole as an anti-psychotic drug and used transgenic 5xFAD mice as an amyloid pathology-based AD animal model. The female 5xFAD mice were classified into a wild-type, a vehicle control group, and an aripiprazole-treated group (n = 6 for each group) at the age of 5 months. Then, the aripiprazole-treated group was administered aripiprazole intraperitoneally at a dose of 1 mg/kg every day, and the vehicle group was administered only solvents from 5 months to 7 months of age. Then, a novel object recognition test

was performed to evaluate the non-spatial working memory. Glutamate PET images were acquired using a specific radiotracer (i.e., [18F]FPEB) for a metabotropic glutamate receptor 5 (mGlur5) at 8 months of age. Finally, after imaging studies were completed, immunohistochemistry was performed. ***Results:*** In a behavioral test, the vehicle group showed a lower preference for the novel object than the WT group (p = 0.0236). However, the aripiprazole-treated 5xFAD group displayed a significantly increased preference for novel objects compared to the vehicle group (p = 0.0236). In a mGluR5 PET, brain uptakes in the vehicle group were 19-20% lower than that in WT mice (p-value in cortex = 0.0048, striatum = 0.0079, and hippocampus = 0.0012). However, the aripiprazole-treated 5xFAD group displayed 7-8% higher brain uptakes compared with vehicle treated group (p-value in cortex = 0.3028, striatum = 0.3693, and hippocampus = 0.3093) and lower uptakes than that of the WT group (aripiprazole-treated 5xFAD group (p-value in cortex = 0.0941, striatum = 0.1137, and hippocampus = 0.0245). In the immunohistochemistry experiments, aripiprazole administration resulted in inhibiting the down-regulation of mGluR5 in 5xFAD. ***Conclusion:*** From this study, we found that the administration of aripiprazole alleviates memory impairment and induces recovery of glutamatergic system.

New Phantom for Brain Imaging Standardization: first experience with full digital PET/CT

***L. Fedeli*[1],** *A. Martini[2], B. Alfano[3], M. Pirozzi[4], U. Guerra[5], C. Mazzeo[2], A. Chincarini[6], M. Quarantelli[3], L. Mansi[7], S. Sestini[2];*
[1]S.O.C. Fisica Sanitaria Prato Pistoia Azienda USL Toscana Centro, Prato, ITALY, [2]S.O.C. Medicina Nucleare Azienda USL Toscana Centro, Prato, ITALY, [3]CNR, Napoli, ITALY, [4]Brain Imaging Lab, Università Campania, Napoli, ITALY, [5]IRCSS Fatebenefratelli, Brescia, ITALY, [6]INFN, Genova, ITALY, [7]CIRPS, Napoli, ITALY.

Aim/Introduction: Characterization of PET scanner is mandatory to evaluate performances and optimize acquisition brain protocols. This can be achieved by using NEMA or anthropomorphic phantoms. The advantage of latter phantom is a better simulation of in-vivo clinical setting. ***Materials and Methods:*** New anthropomorphic brain phantom (StepBrain, Human Shape Technologies s.r.l.) was proposed for standardization among different PET-CT scanners. The phantom includes three different compartments: human grey (cortex, GM; striatum, STR) and white matter (WM) which can be filled with different concentrations of radioactive. The physical model was obtained using a rapid prototyping technique applied to a digital model derived from a dataset of 1.5 T MRI images of a 38-year-old normal volunteer, composed of 3mm thick slices. T1-, PD- and T2-weighted spin-echo images were obtained and segmented into GW, WM, and STR using a multi-parametric technique; compartment cavities separated by walls of 0.75mm thick were made. ***Results:*** STR, WM, GM volumes are of 14.6, 407 and 714ml respectively. Automatic rotating support was designed to ensure homogeneous mixing within each compartment. Healthy FDG PET scan and three Amyloid (AMY) PET scans (negative, doubtful, positive) were simulated by adding ^{18}F-FDG in WM for each of four acquisition (from 4 up to 19 kBq/ml) without changing the radioactive in GM and STR. This allowed the following GM/WM (2.86 for FDG PET scan and 0.77, 0.5, 0.29 for each AMY-PET scan) and STR/GM (1.03) ratios. Acquisitions were performed with full digital PET/CT (Biograph Vision 600, Siemens) in list mode and several parameters were considered including scan time (ST 1-6min), image matrix (IM 440x440 and 256x256), iteration number (ITER 30-120), presence/absence of TOF and PSF, gaussian filter (GF 1-4mm). Analysis was performed considering VOIs (3mm diameter) in WM, GM and STR. Qualitatively best image quality was considering IM 440x440, ST 6min, ITER 120 and GS 2mm, with TOF and PSF correction; ratio GM/WM (mean/SD): 3.3/0.3 for FDG scan; 0.84/0.05, 0.60/0.07 and 0.40/0.04 for AMY scans. Concentration assessment was more accurate without PSF correction, ratio GM/WM (mean/SD): 3.0/0.2 for FDG scan; 0.79/0.06, 0.56/0.06 and 0.032/0.02 for AMY scans. Considering ST <3min) the best assessment was reducing ITER to 60. ***Conclusion:*** Preliminary results show feasibility of this new 3D printed anthropomorphic brain phantom to quantify scanner parameters effect on image quality to optimize acquisition protocol to be used in clinical setting and homogenize acquisition protocols among different scanners for comparative purposes in multicentre studies.

EP-0017

Site-specific antibody labeling for brain PET using sortase-mediated ligation

***S. Lopes van den Broek*[1],** *E. Schlein[1], K. Laurell[1], J. Eriksson[2], A. Godec[1], G. Hultqvist[1], S. Syvänen[1], D. Sehlin[1];*
[1]Uppsala University, Uppsala, SWEDEN,
[2]Uppsala University Hospital, Uppsala, SWEDEN.

Aim/Introduction: Antibodies are attractive radioligands for positron emission tomography (PET) due to their high selectivity and specificity. However, their large size prevents antibodies from penetrating the blood-brain barrier (BBB) and reach targets within the brain. We have therefore developed bispecific antibodies that, next to the target of interest, also bind to the transferrin receptor, which mediates active transport across the BBB. This project aims to site-specifically radiolabel brain-penetrating antibodies through sortase-mediated ligation. This allows for controlled, reproducible and irreversible modifications improving clinical translation and has been evaluated for direct labeling and pretargeting. ***Materials and Methods:*** Bispecific anti-amyloid β (Aβ) antibodies with 1 or 3 sortase recognition motifs were produced in CHO cells. Wildtype (WT) Sortase A (SrtA) and mutated sortase (SrtA 7M) were produced in-house in E. Coli. Antibodies were conjugated to a fluorescent probe (AF680-Gly3) or a trans-cyclooctene (TCO-PEG3-Gly3) with a polyglycine chain using both variants of SrtA. Conjugates were purified with CaptureSelect affinity chromatography and reaction efficiency was monitored using SDS-PAGE. TCO-conjugated antibody was further reacted with a fluorine-18 labeled tetrazine ([18F]-Tz). Affinity was evaluated with ELISA and immunohistochemistry. Brain uptake and Aβ targeting of antibodies radiolabeled with iodine-125 or fluorine-18 was evaluated ex vivo in WT and Aβ expressing AppNL-G-F mice. ***Results:*** Antibodies with 1 or 3 sortase recognition motifs were produced in large quantities. WT SrtA and mutated sortase - SrtA 7M - were produced in-house and the catalytic activity of WT SrtA and SrtA 7M was monitored between 30 min and 24 h. Full conversion was obtained after 1 h and reversibility was observed after 4 h. SrtA 7M showed improved catalytic activity and less reversibility than WT SrtA. No reduction in affinity was observed after the conjugations. Radiolabeled antibodies showed high brain retention in AppNL-G-F compared to WT mice three days after injection and 18F-labeling of the antibodies was achieved by clicking 18F-Tz to TCO-antibody. Co-localization of the modified antibodies with Aβ plaques was confirmed with immunostaining. ***Conclusion:*** Successful site-specific antibody labeling was achieved through sortase-mediated ligation after one hour with SrtA 7M as the preferred sortase. Using antibodies with 1 and 3 sortase recognition motifs, either 1 or 3 tags could be attached without impaired brain uptake or target affinity, allowing

increased and controlled molar activities for radiolabeling. This versatile method can be used for either direct labeling or pretargeted imaging by attaching a pretargeting vector (e.g. TCO) to the antibody.

Aim/Introduction: Reactive astrocytes and activated microglia contribute to progression of neurodegenerative diseases such as Alzheimer's disease and Parkinson's disease1. Reactive astrocytes are known to overexpress monoamine oxidase-B (MAO-B). A novel radiotracer [18F]-(S)-(2-methylpyrid-5-yl)-6-[(3-fluoro-2-hydroxy) propoxy]quinoline ([18F]SMBT-1) effectively targets MAO-B. We report the synthesis, characterisation, subsequent radiolabelling and imaging of a rat model overexpressing MAO-B in response to a traumatic brain injury. ***Conclusion:*** Synthesis of the SMBT-1 precursor for radiolabelling was achieved in good yields, then successfully radiolabelled with 18fluoride in high radiochemical yield to afford the radiotracer [18F]SMBT-1. Imaging of a rat model following unilateral fluid percussion injury showed increased uptake in the affected hippocampus. ***Materials and Methods:*** Following the described literature methods1, we synthesised, then fully characterised the SMBT-1 precursor (2S)-3-((2-(6-methylpyridin-3-yl)quinolin-6-yl)oxy)-2-((tetrahydro-2H-pyran-2-yl)oxy)propyl 4-methylbenzenesulfonate for radiolabeling with 18fluoride ion (18F). Synthesis commenced with ring opening and protection of the chiral epoxide S-glycidyl tosylate, followed by TBS protection of the alcohol and debenzylation in preparation for the Mitsunobu reaction with 2-chloroquinolin-6-ol. Suzuki coupling was performed using the 2-methylpyridine boronic acid, followed by desilylation of the alcohol then reprotection using 3,4-dihydro-2H-pyran. Cold reference standard (S)-SMBT-1 and its enantiomer (R)-SMBT-1 were also prepared. Radiolabelling was performed using the iPHASE FlexLab with 37-74 GBq 18fluoride ion obtained from a 16.5 MeV GE PETtrace cyclotron. Imaging was performed at two weeks following lateral fluid percussion injury in an adult rat model using a nanoScan PET/CT scanner (Mediso, Hungary). Sixty second images were reconstructed with correction for scatter, attenuation and dead-time using the Tera-tomo 3D algorithm. The PET scan was manually co-registered to the Walxholm 80 um MRI atlas with time-activity curves extracted. ***Results:*** Synthetic intermediates were obtained in 52%-78% yields and in >95% purity. 18Fluoride radiolabelling was achieved in 25-30% radiochemical yield (non-decay corrected) and > 99% radiochemical purity by HPLC. Time activity curves were generated and show rapid washout but differential retention (15 mins onwards) particularly in regions known to contain high concentrations of monoaminergic neurons. There is also increased retention in the cortex and hippocampus, sites of reactive astrogliosis post injury. ***Conclusion:*** Synthesis of the SMBT-1 precursor for radiolabelling was achieved in good yields, then successfully radiolabelled with 18fluoride in high radiochemical yield to afford the radiotracer [18F]SMBT-1. Imaging of a rat model following unilateral fluid percussion injury showed increased uptake in the affected hippocampus. ***References:*** 1. Harada, R, Hayakawa, Y, Ezura, M, et al. 18F-SMBT-1: A selective and reversible PET tracer for Monoamine Oxidase-B imaging J.Nuc. Med.2021;62(2):253-8.

^{89}Zr-Immuno-PET as an alternative to radioiodinated bispecific BBB-shuttles targeting alpha-synuclein in a murine seeding model.

T. Wuensche[1,2], *P. Pereira[1,2], A. Windhorst[1,2], K. Bjerregaard-Andersen[3], F. Sotty[3], P. Kallunki[3], A. Jensen[3], B. Bang-Andersen[3], G. A.M.S. van Dongen[1,2], W. Beaino[1,2], D. Vugts[1,2];*
[1]Amsterdam UMC location Vrije Universiteit Amsterdam, dept Radiology & Nuclear Medicine, Amsterdam, NETHERLANDS, [2]Amsterdam Neuroscience, Brain imaging, Amsterdam, NETHERLANDS, [3]H. Lundbeck A/S, Copenhagen, DENMARK.

Aim/Introduction: PET imaging could be valuable for evaluating brain delivery and target engagement of biologicals targeting alpha-synuclein, a pathological hallmark of Parkinson's disease. 89Zr-immuno-PET, using the octadentate chelator DFO*, has emerged to visualize therapeutic antibodies that utilize transferrin-mediated transcytosis to cross the BBB.1 Specific uptake of 89Zr- or 124I-labeled anti-alpha-synuclein BBB-shuttles has been demonstrated in a mouse model of extracellular alpha-synuclein fibril deposition.2,3 The 124I-labeled compound showed no specific uptake in a transgenic mouse model expressing intra-neural alpha-synuclein.2 Here, the residualizing PET nuclide 89Zr was explored as an alternative to non-residualizing iodine for imaging intraneural alpha-synuclein. ***Materials and Methods:*** Anti-alpha-synuclein monoclonal antibody HLu-3 was engineered with an 8D3 moiety targeting the murine transferrin receptor 1. HLu-3-scFab8D3 was conjugated with DFO*-NCS and radiolabeled with 89Zr. The radioconjugate was evaluated in an alpha-synuclein seeding model with intraneuronal aggregates, established by intracranial injection of sonicated pre-formed fibrils (4µg/2µL) into both striata of F28tg-mice overexpressing human wild-type alpha-synuclein. Untreated F28tg-mice and C57Bl6wt-mice served as controls. One month post-surgery, 1mg/kg [89Zr] Zr-DFO*-HLu-3-scFab8D3 was injected (4-6MBq/mouse; n=10). Blood sampling and PET imaging up to 168hrs post-injection (p.i.) were performed, followed by biodistribution, autoradiography and immunofluorescence. ***Results:*** The radioconjugate was produced in sufficient radiochemical yields and purity. Blood sampling revealed no significant difference between the three groups. No differences in brain uptake was observed for [89Zr] Zr-HLu-3-scFab8D3 in seeded F28tg-mice compared to F28tg-mice 72hrs and 168hrs p.i., while C57Bl6wt-mice revealed lower brain uptake at 72hrs p.i.. Ex vivo brain uptake 168hrs p.i. confirmed these findings. No significant difference between the cortex and the cerebellum was detected in the PET data. Ex vivo autoradiography revealed a higher uptake in the cortex of all three groups. However, quantification showed a comparable cortex-to-cerebellum ratio, indicating no correlation with alpha-synuclein-specific target engagement. Immunostaining of seeded F28tg-mice revealed sufficient intraneural alpha-synuclein pathology but no corresponding antibody accumulation. ***Conclusion:*** No difference in brain uptake of [89Zr]Zr-DFO*-GM285-scFab8D3 was observed between seeded and control mice. Immunostaining further demonstrated no co-localization of the antibody and alpha-synuclein pathology. While Roshanbin et al. proposed that the residualizing properties of 89Zr could offer a better alternative than radioiodine for visualizing intracellular deposits2,

these results underscore the ongoing challenge of imaging intraneural inclusions. This project received funding from the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant agreement No 813528. ***References:*** 1Wuensche et al., Theranostics 20222Roshanbin et al., Neuropharmacology 20223Wuensche et al., NuclMedBiol 2023

EP-0020

Dynamics of the effects of ketamine on synaptic density: a SV2A PET study in a mouse model of depression

C. Corvo[1], *S. Goutal[1], I. Mendez-David[2], M. Goislard[1], S. Amargier[1], S. Leterrier[1], C. Leroy[1], D. J. David[2], N. Tournier[1];*
[1]Université Paris-Saclay, Inserm, CNRS, CEA, Laboratoire d'Imagerie Biomédicale Multimodale (BioMaps), Service Hospitalier Frédéric Joliot, Orsay, FRANCE, [2]Faculté de Pharmacie, Université Paris Saclay, MOOD, CESP, Saclay, FRANCE.

Aim/Introduction: The prolonged onset of action (2 to 4 weeks) of classical antidepressant drugs is a public health problem. Ketamine (Ket) is now prescribed as a rapid-acting antidepressant, showing effects within hours. However, it's mechanism of action remains unclear and may involve synaptogenesis. We hypothesized that i) the dynamics of Ket' effects on synaptogenesis could be non-invasively monitored using [^{11}C]UCB-J PET imaging, a radioligand targeting SV2A, a marker of synaptic density, and ii) depression may impact this dynamics. ***Materials and Methods:*** To mimic depressive disorders in mice, corticosterone was administered for at least 28 days in water (35µg/mL; CORT model) versus vehicle in naïve controls (VEH). Mice from each group (CORT and VEH) were then injected with either a single dose of Ket (10mg/kg, i.p) or 3 injections 48h apart, corresponding to the clinical scheme regimen in patients. Brain [^{11}C]UCB-J PET imaging (n=5-8 per group) was performed either 24h after the single dose (Ket24h; CORTKet24h), or 1 week (Ket1w; CORTKet1w) or 3 weeks (Ket3w; CORTKet3w) after the last injection of the 3-doses regimen. MicroPET acquisition (dynamic, 90min) was performed under isoflurane anesthesia. Time Activity Curves (TACs) were extracted from selected brain regions delineated from a mouse brain template, and from the left-heart ventricle to determine the image derived input function (IDIF). In additional mice, the proportion of plasma radiometabolites vs time was determined under each condition. Volumes of distribution (VT, Logan plot method and metabolite-corrected IDIFcorr) were determined to estimate the regional brain distribution of [^{11}C]UCB-J. ***Results:*** No mortality was observed in any of the groups. VT was decreased (whole brain; $p < 0,05$) in the CORT group compared to the VEH group. VT didn't change 24h after a single dose of Ket in either the CORT or the VEH groups. One week after the last dose of ketamine, VT was increased in the cortex, thalamus, striatum and cerebellum ($p < 0,05$) of the Ket1w group, but not in the CORTKet1w. Three weeks after the last dose of ketamine, VT was increased in both the Ket3w and the CORTKet3w. At each time-point, VT was lower in CORTKet mice compared with VEH-Ket mice (whole brain, $p < 0,05$). ***Conclusion:*** These results shows that ketamine progressively increases synaptic density in the healthy brain. This effect appears to be slower in the depressed brain. The disease state may thus impact the dynamics of ketamine on synaptogenesis.

EP-0021

Myocardial ^{18}F-FDG uptake quantitatively predicts hypoxic tolerance in calorie restrictive rats via visualizing glucose-fat acid metabolism shifting

X. Zhou, *W. Yang, F. Kang, J. Wang;*
department of nuclear medicine, Xi'an, CHINA.

Aim/Introduction: Hypoxia is an important pathogenic factor for ischemic and hypoxic diseases such as ischemic heart diseases (IHDs) and acute high-altitude diseases (AHAD). Calorie restriction (CR) may rapidly improve hypoxia tolerance by myocardial metabolic transformation which has great prospects. However, the lack of non-invasive and reliable quantitative approach to predict the improvement restricts the development and application of it, due to the individual differences and lagging evaluation methods. 18F-FDG PET/CT can continuously visualize and accurately quantifies the glucose metabolism in the myocardium, which is expected to predict the improvement of hypoxia tolerance by detecting metabolic transformations. This study aims to establish and validate an imaging scheme for quantitative predicting the improvement of acute hypoxia tolerance based on metabolic transformation. ***Materials and Methods:*** Male SD rats were randomly divided into different diet and altitude groups. The self-developed low-pressure chamber system was used to simulate the hypoxic environment at an altitude of 7620m (25,000ft). PET/CT was used to quantify myocardial 18F-FDG uptake levels. The myocardial metabolic pattern were analyzed by targeted metabolomics/lipidomics, serological test and WB. Echocardiography, HE staining and TEM was used to assess cardiac function, changes in myocardial fiber and mitochondrial morphology. ***Results:*** Fasting and ketogenic diet pretreatment significantly increased the 24h survival rate of acute hypoxic rats. Metabolomics, lipidomics, serological test and WB showed that the myocardial metabolic pattern was significantly changed. SUV ratio of myocardial 18F-FDG uptake decreased significantly with the fasting and ketogenic diet duration. It was highly correlated with the quantitative results of metabolites detected by metabolomics, and could precisely characterize the metabolic transformation. SUV ratio was significantly correlated with the 24h survival rate of fasting and ketogenic diet rats under hypoxic environment ($P<0.01$, $R2=0.8956, 0.7722$). The regression equations were $y=-18.29x+93.23$ and $y=-15.77x+81.45$. The survival rate of fasting rats could be effectively predicted by the equation, and the bias was less than 7.13%. SUV ratio was also significantly correlated with the levels of blood glucose, blood ketones and free fatty acids. WB, TEM and echocardiography confirmed that fasting can up-regulate autophagy, reduce mitochondrial and myocardial tissue damage caused by acute hypoxia, and protect cardiac function. ***Conclusion:*** Calorie restriction strategies effectively enhance hypoxia tolerance in rats and lead to significant myocardial metabolic transformation. Myocardial 18F-FDG PET/CT imaging can accurately predict the improvement of hypoxia tolerance by quantitatively identifying of myocardial metabolic transformation in fasting and ketogenic diet rats.

EP-0022

Cardiac hybrid metabolic imaging by multi-nuclear positron emission tomography-magnetic resonance imaging (PET/MRI) (^{23}Na/^{1}H) in radiation-induced cardiotoxicity: evaluation of the effect of dapagliflozin

H. Rida[1], *M. Guetlin[1,2], C. Simard[1], M. Naveau[3], P. Dupont[1], M. Joubert[1,2], A. Manrique[1,4];*
[1]Cyceron UR4650 PSIR, Université Caen Normandie, Caen, FRANCE, [2]Diabetology, CHU de Caen, Caen, FRANCE, [3]UAR3408/US50 Cyceron, CNRS, INSERM, Université Caen Normandie, Caen, FRANCE, [4]Nuclear Medicine, CHU de Caen, Caen, FRANCE.

Aim/Introduction: Sodium-glucose co-transporter 2 (SGLT2) inhibitors decrease glucose and sodium reabsorption in the kidney and improve prognosis in patients with heart failure.

We hypothesized that dapagliflozin might decrease tissue sodium content and glucose metabolism in a murine model of radiation-induced cardiotoxicity. ***Materials and Methods:*** Thirty-seven Sprague Dawley rats were prospectively randomized to dapagliflozin treatment (Dapa, n=19) or Placebo (n=18) 3 months after a 10 Gy cardiac irradiation using a micro-irradiator (X-RAD 225Cx, Precision X-ray Inc.). A Control group (n=5) consisted of non-irradiated animals. The Dapa group received Dapagliflozin for 6 weeks at a dose of 1.5 mg/kg/day. After 6 weeks of treatment, tissue sodium content in the skin, the pectoral muscle, and the heart was non-invasively assessed using 23Na-MRI with a 1H/23Na surface coil, and cardiac glucose metabolism was assessed by dynamic $^{[18F]}$ fluorodeoxyglucose (FDG) PET using a 7-T PET/MRI system (Bruker BioSpin). Left ventricular function was evaluated by echocardiography. Group comparisons were conducted using ANOVA. ***Results:*** After 6 weeks of treatment, systolic left ventricular function was preserved in all groups, as espected (fractional shortening in Dapa: 40±1.8%, Placebo: 42±1.3%, Control: 40.3±1.83%, p=0.7406). Sodium MRI signal was decreased in the muscle in Dapa (630.71±220.88 AU) compared to Placebo (848.56±277.92 AU, p=0.0362), without difference compared to Control (686.57±119.10 AU, p=0.6997). In addition, muscle sodium content was similar in Placebo and Control (848.56±277.92 AU vs. 686.57±119.10 AU, respectively, p=0.2074). In the skin, no significant difference was noted in Dapa (877.89±179.98 AU) vs. Placebo (1102.2±396.81 AU, p=0.0946), and vs. Control (771.5716±85.46 AU, p=0.5742). There was no significant difference in skin sodium content between Placebo and Control (1102.2±396.81 AU vs. 771.5716±85.46 AU, respectively, p=0,0522). In the myocardium, the sodium signal was increased in Placebo (766.8798±372.72 AU) compared to Control (340.83±85.46 AU, p=0.0112) but was non-significantly different in Dapa (530.303±209.94 AU) vs. Control (340.83±85.46 AU, p= 0.30) and vs. Placebo (766.8798±372.72 AU, p=0,0696). Finally, 18F-FDG PET showed a significant decrease in myocardial glucose uptake after dapagliflozin treatment compared to placebo. The 18F-FDG influx rate (Ki) was 0.021±0.01 min-1 in Dapa vs. 0.037±0.02 min-1 in Placebo (p = 0.0219), without significant difference when compared to Control (Ki= 0.039 min-1, p=0.1227). However, the Ki was similar in Placebo and Control (0.037±0.02 min-1 vs. 0.039 min-1 , respectively, p=0,9595). ***Conclusion:*** Cardiac myocardial sodium content was increased after cardiac irradiation, suggesting an increased sodium content. Dapagliflozin treatment resulted in a decrease in both sodium signal and cardiac glucose metabolism.

EP-0023

[^{11}C]PiB Brain Retention is not Affected by Antibody Binding to Amyloid-Beta

S. Syvänen[1], *M. Xiong[1], A. Dahlen[1], S. Roshanbin[1], E. Wik[1], X. Aguilar[1], J. Eriksson[2], D. Sehlin[1];*
[1]Uppsala University, Uppsala, SWEDEN, [2]Uppsala University and Uppsala Hospital PET centre, Uppsala, SWEDEN.

Aim/Introduction: The reduction of amyloid-beta (Aβ) plaques in Alzheimer's disease (AD) patients following treatment with anti-Aβ antibodies like lecanemab is evidenced by a substantially decreased signal in amyloid positron emission tomography (PET) imaging. Yet, this decline in PET signals has not corresponded to a similar notable improvement in cognitive function among AD patients. Several factors could account for this, including the brief duration of treatment and the advanced disease stages of the patients. However, an aspect that remains unexplored, addressed in this study, is whether the interaction of antibodies with amyloid plaques hampers the binding of amyloid-PET ligands. This could create a misleading impression of Aβ clearance from the brain. ***Materials and Methods:*** In the present study, tg-ArcSwe mice (n=22), a mouse model of AD, received three injections of RmAb158, the murine version of lecanemab, or phosphate-buffered saline (PBS) over two weeks. The treatment regimen was designed to maximize RmAb158 binding to Aβ plaques without actual plaque removal. Three days after the last RmAb158 administration, mice were given an intravenous injection of the amyloid-PET radioligand [^{11}C]PiB, followed by isolation of brain tissue at 40 min. Brain sections were immediately prepared and studied by autoradiography. Total Aβ1-40, total Aβ1-42, soluble Aβ aggregate, and microglial protein TREM2 concentrations were determined in brain homogenates. ***Results:*** Autoradiography showed that RmAb158- and PBS-treated mice displayed similar [^{11}C]PiB binding. Moreover, the total Aβ1-40 levels, representing the major Aβ species of plaques in the tg-ArcSwe model, as well as TREM2 levels, were similar in both groups. Interestingly, the concentration of soluble Aβ aggregates, which are considered the primary target of RmAb158, was decreased in the RmAb158-treated group, along with a small but significant decrease in the total Aβ1-42 levels. In tg-ArcSwe mice, Aβ1-42 is typically located at the outer border of the insoluble Aβ plaques, often referred to as the 'halo'. Thus, RmAb158 is more likely to initially interact with Aβ1-42 than with Aβ1-40, primarily due to greater accessibility. ***Conclusion:*** This study suggests that the binding of [^{11}C]PiB to Aβ reflects the presence of Aβ plaques in the brain. This is consistent with the interpretation of amyloid-PET in clinical investigations involving anti-Aβ antibodies. Nonetheless, [^{11}C]PiB PET was not able to identify early treatment effects on soluble Aβ aggregates or Aβ1-42 levels.

EP-0024

Highly activated microglia drive FDG-PET signal changes across neurodegenerative disease models and aging

S. Wagner[1], *L. M. Bartos[1], V. Zenatti[2], D. Prtvar[2], S. Fixemer[2], C. Klaus[2], J. Herms[3,2,4], L. Paeger[2], M. Prestel[2], S. Tahirovic[2], M. Brendel[1,2,4];*
[1]Department of Nuclear Medicine, University Hospital of Munich, LMU Munich, Munich, GERMANY, [2]German Center for Neurodegenerative Diseases, Munich, GERMANY, [3]Center for Neuropathology and Prion Research, Faculty of Medicine, LMU Munich, Munich, GERMANY, [4]Munich Cluster for Systems Neurology, Munich, GERMANY.

Aim/Introduction: Previous studies have shown that microglia activation states determine brain ^{18}F-FDG-PET signal changes in mice. This study aims to investigate the impact of microglia activation on FDG-PET signals across distinct mouse models of neurodegenerative disorders and aging. ***Materials and Methods:*** C57BL/6 (WT), a model of microglial cholesterol dyshomeostasis (Npc1), and two amyloid mouse models (APPki and APPPS1) were injected with 40MBq at the age of 3 months, 7 months and 12 months of age. After a dynamic 45 minute FDG-PET scan, the brain was collected and dissociated, followed by isolation of microglia with immunomagnetic cell sorting. Microglia were then separated into three subsets based on their activation level (CLEC7A low/medium/high) and the cell count as well as radioactivity in the samples were determined to calculate FDG uptake per single cell. FDG uptake was compared between models and microglia subsets. ***Results:*** WT mice showed a moderate increase of FDG-PET signals with age, which was consistent with increasing FDG uptake per single microglia cell with age. No

difference of cellular FDG uptake was observed across microglia subsets with low, medium and high activation in WT mice. During aging, both amyloid models showed a significant higher FDG-PET signal increase compared to WT mice. On the cellular level, higher FDG uptake per microglial cell of the CLEC7A-high subset was detected relative to WT (+37%, p=0.02). Contrary, Npc1 mice, showed a significant decrease in FDG-PET signals with age and had lower FDG uptake per single microglial cell in all age groups (-67%, p=0.01). Correlation between cellular uptake and FDG-PET across all models and ages revealed that FDG-PET changes were determined by highly activated microglia (CLEC7A-high, r=0.437, p=0.0001), but not by homeostatic microglia (CLEC7A-low, r=0.095, p=0.388). ***Conclusion:*** Cell sorting after in vivo FDG injection in mice allows assessment of microglia glucose uptake in subsets with different activation state. Highly activated microglia do not consistently show increased FDG uptake, but they are the driver of FDG-PET signal changes across disease models and ages.

Aim/Introduction: Animal models of Alzheimer's Disease (AD) are useful to understand the underlying pathophysiological process of this illness and to test new treatments; nevertheless, sex and age-related differences in brain glucose consumption between controls and Tx animals are not fully characterized. This work aims to perform a semi-quantitative evaluation of the [18F]FDG uptake in whole brain structures of elderly rats, including a transgenic model of AD and controls. ***Materials and Methods:*** MicroPET imaging was performed in elderly (21 months old) transgenic TgF344-AD (TgAD) rats (5 male, 8 female) and wild-type (WT) Fisher 344 rats (9 male, 9 female). Imaging was performed in a Focus 120 microPET scanner. [18F]FDG (29 ± 8 MBq) was intravenously administered via the tail vain while animals were under anesthesia (2-3% isoflurane). Prior to imaging rats were fasted for 12-18 h. After 60 min of biodistribution an static scan of 10 min was acquired. Images were reconstructed with a 2D ordered subset expectation maximization algorithm (2D-OSEM) with a voxel size of 0.86 x 0.86 x 0.79 mm3, including all corrections but attenuation. MicroPET images were normalized to the W. Schiffer rat space implemented in PMOD 3.7 software and the standardized uptake value (SUV) of each atlas brain region was computed to compare between groups. ***Results:*** No significant statistical differences of FDG-uptake between male and female WT rats were found in cortical and nor subcortical regions; nevertheless, female TgAD rats showed and increased SUV [18F]FDG-uptake in cortical regions (7.6 ±1.2) compared with TgAD and WT males (6.5 ± 1.1, 6.7 ± 1.2), and also with WT females (6.2±1.1). In subcortical regions, including the hippocampus, the amygdala, and the thalamus, TgAD males showed lower SUV [18F]FDG-uptake values (5.2±0.9) compared with TgAD and WT females (5.9±1.1, 5.6 ± 1) and WT male (5.7 ± 1.3) rats. ***Conclusion:*** Statistically significant differences of [18F] FDG-uptake in cortical (female TgAD vs other groups (p< 0.05)) and subcortical regions were found between groups (male TgAD vs other groups (p< 0.05)). Project supported by UNAM-DGAPA PAPIIT-IT201623.

Decreased opioid receptor availability and impaired neurometabolic coupling as a signature of morphine tolerance in rats: a multitracer PET study

A. Soyer[1], *S. Leterrier[1], F. Caillé[1], M. Goislard[1], S. Amargier-Barrial[1], C. Leroy[1], W. Saba[1], G. Dal-Bo[2], K. Thibault[2], S. Goutal[1], N. Tournier[1];*
[1]Laboratoire d'Imagerie Biomédicale Multimodale (BioMaps), Orsay, FRANCE, [2]Institut de Recherche Biomédicale des Armées (IRBA), Bretigny-sur-Orge, FRANCE.

Aim/Introduction: The development of tolerance and dependence to opioid drugs is the cornerstone of the current opioid crisis. Buprenorphine (BUP) is a potent but partial agonist of μ-opioid receptor (MOR), so that full receptor occupancy can be safely achieved with limited risk for respiratory depression. Functional neuroimaging techniques, combined with behavioral assessments, are needed to untangle the impact of tolerance on the pharmacological response to opioid. This study investigated the interplay between the MOR system, brain metabolism and behavior in the development of morphine tolerance. ***Materials and Methods:*** Sprague-Dawley rats received morphine daily to induce tolerance (n=10; 15 mg/kg/day) vs control rats (morphine-naïve animals). Behavioral pain sensitization was tested using the hot plate test after 2-days of withdrawal (Day 8), without (vehicle) or after injection of BUP (0.1 mg/kg, s.c), a dose that occupies 100% of available MOR (1). First, availability of MOR was assessed using [11C]BUP-PET imaging. Microdose [11C]BUP was i.v. injected followed by 90 min brain PET acquisition (tolerant rats n=4; control rats n=4). In other rats, [18F]FDG-PET experiments were performed in tolerant rats 30 min vs control after injection of unlabeled BUP (0.1 mg/kg, n=5, or vehicle (n=6). ***Results:*** In morphine-treated rats, after 2 days-withdrawal, BUP failed to induce analgesia compared to the control group (p<.001), thus confirming opioid tolerance. Compared with control rats, brain distribution (SUV) of [11C]BUP in tolerant rats was lower in most brain regions (p<.01) except in the cerebellum (p>.05). This difference was also observed when using the SUVR (cerebellum) as outcome parameter. Compared with control rats, morphine tolerance decreased the baseline uptake of [18F]FDG in most brain regions except in the cerebellum (p>.05). Significance was reached in the thalamus, cortex, striatum and midbrain (p<.01). In control rats, the pharmacological challenge using unlabeled BUP decreased the uptake of [18F]FDG in most brain regions except the cerebellum. The decrease in [18F]FDG uptake after the BUP challenged in tolerant rats was significantly lower (p<.05), suggesting attenuated pharmacological response. ***Conclusion:*** This study highlights the relevance of the BUP pharmacological challenge, associated with [18F]FDG-PET and MOR mapping, as a multitracer approach to explore the attenuated neurovascular coupling associated with morphine tolerance. This strategy may be used to evaluate protocols to mitigate the

development of opioid tolerance or restoring sensitivity to opioids.

EP-0027

Pre-Clinical Assessment of Cardiac P-glycoprotein Function In Vivo with [18F]MC225 PET Imaging

W. Liu[1], *P. Mossel[2], J. Sijbesma[1], J. Doorduin[1], M. Dannenberg[3], V. Schwach[3], R. H. J. A. Slart[1], G. Luurtsema[1];*
[1]Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, [2]Leiden University Medical Center, Leiden, NETHERLANDS, [3]Department of Applied Stem Cell Technologies, TechMed Centre, University of Twente, Enschede, NETHERLANDS.

Aim/Introduction: Drug transporter P-glycoprotein (P-gp), an essential efflux pump, is crucial for the transport and interaction of various drugs. Several cardiovascular drugs are defined as P-gp substrates. Changes in P-gp function may limit the effective distribution and bioavailability of these drugs. The functionality of P-gp can be affected by several factors such as modulators, drugs (e.g. chemotherapeutics), age, gender, and pathological conditions. [18F]MC225 is a promising radiopharmaceutical for assessing P-gp function at the human blood-brain barrier (BBB). Given that several cardiovascular drugs are P-gp substrates, it is of interest is to study cardiac P-gp functionality in vivo with Positron emission tomography (PET). In this pre-clinical rat study, [18F]MC225-PET was tested for the first time for its potential to assess cardiac P-gp function. ***Materials and Methods:*** [18F]MC225 (27.13±12.17 MBq) was injected intravenously into rats. The rats were randomly assigned to two groups. One group received 6 mg/kg tariquidar (n=4) to inhibit P-gp. The control group was administered only the vehicle solution (n=3). Dynamic small animal PET imaging with cardiac gating was performed for 60-minutes, followed by ex vivo biodistribution of all organs. All samples were weighted, and radioactivity was counted in a gamma counter. Additionally, as a control experiment, in vitro assay using immunofluorescent staining to indicate the presence of P-gp expression in heart tissues. ***Results:*** In the 40-60-minute frame interval, standardized uptake values (SUV) of the heart were significantly higher in the tariquidar group (Mean ± SD: 0.60 ± 0.12) when compared to the control group (0.47 ± 0.07) (p=0.03). The area under the time-activity curves and the SUV values of the time-activity curves were also higher in tariquidar treated rats, but this was not statistically significant. The tissue uptake of [18F]MC225 as measured ex vivo was significantly different between the two groups in multiple organs (table 1). Uptake of [18F]MC225 in the heart was higher trend in tariquidar treated rats, but not statistically significant. ***Conclusion:*** In this study, a novel PET radiotracer [18F]MC225 was applied for the first time to evaluate P-gp function in rat hearts. The findings suggest that [18F]MC225-PET imaging is promising for assessing the functionality of P-gp. In the future, [18F]MC225-PET may possess the capability to predict the cardiac bioavailability of pharmaceutical agents as well as provide precise, individualized insights for therapeutic optimization, but also the effect of cardiotoxic agents.

EP-0028

The Innovative Curcumin Analog EF-24, Radiolabelled with Gallium-68 Demonstrated Substantial Binding Affinity to Synthetic b-amyloid Fibrils, Indicating Diagnostic Utility for Neurodegenerative Diseases.

G. Papadakis[1], *K. Marias[2], E. Saloustrou[1], V. K. Giannakaki[1], A. Shegani[1];*
[1]Hybrid Molecular Imaging Unit (HMIU), Foundation for Research and Technology Hellas (FORTH), HERAKLION, GREECE, [2]Computational Biomedicine Laboratory (CBML), Foundation for Research and Technology Hellas (FORTH), Heraklion, GREECE.

Aim/Introduction: Curcuminoids labeled with fluorine-18 or technetium-99m have been reported to exhibit significant binding affinity for β-amyloid plaques. Curcumin derivatives were successfully radiolabelled with the positron-emitter Gallium-68, showing high affinity for synthetic β-amyloid fibrils [1]. EF-24 is an innovative synthetic curcumin analog with enhanced bioavailability and bioactivity presenting several biological activities, including neuroprotection. Aim of the current study was to successfully synthesize and characterize Gallium-68 EF-24 complex and explore its potential binding affinity to synthetic β-amyloid fibrils. ***Materials and Methods:*** Initially, DTC-EF-24 was synthesized and complexed with Gallium to form [Ga(DTC-EF-24)2]+. DTC-EF-24 was also radio-labeled with Gallium-68. The radio isotope was produced by reacting 68Ga3+ from a 68Ge/68Ga generator with 1mg/mL DTC-EF-24 solution. Reaction parameters (precursor amount, reaction temperature, and pH) were optimized to obtain high and reproducible radiochemical yield and purity. Quality controls and stability studies were performed by radio-TLC. Amyloid-beta (Aβ) fibrils were prepared and incubated with the labeled complex. The binding affinity was estimated according to methods previously published1. Displacement tests with an EF-24 solution were performed to evaluate specificity and interaction dynamics. ***Results:*** Synthesis and complexation of EF-24 with Gallium-68 were confirmed via comprehensive spectroscopic methods. Radiochemical purity (RCP) of 68Ga-complex was >95%, under best radio-labeling conditions. The identity of the [68Ga][Ga(DTC-EF-24)2]+ complex was confirmed by coelution with the equivalent natGa-complex in RP-HPLC analysis. The 68Ga-complex showed high and comparable stability to transchelation and transmetalation when challenged with DTPA solution or 0.9% NaCl solution or human serum. In allcases, the percentage of the intact complex remained >90% over 120 min of incubation. The [68Ga][Ga(DTC-EF-24)2]+ complex showed in vitro significant binding affinity to synthetic Aβ fibrils, retaining 91.5 ± 2.0% radioactivity, markedly higher than the control. These results indicate the diagnostic potentialof EF-24 complex in targeting amyloid-beta structures, a critical pathophysiologic feature in neurodegenerative diseases. ***Conclusion:*** The cureent study descirbes the potential of 68Ga labeled EF-24 complexes as diagnostic tools in neurodegenerative diseases. The specificity towards amyloid-beta fibrils provides the groundwork for advanced in vivo studies, potentially revolutionizing diagnostic approaches in molecular imaging for these disorders. Furthermore, given the neuroprotective role of curcumin analogs, the potential therapeutic effect of these novel compounds needs to be explored. ***References:*** [1] Asti Mattia et al, 'Synthesis and characterization of 68Ga-labeled curcumin and curcuminoid complexes as potential radiotracers for imaging of cancer and Alzheimer's Disease',Inorganic Chemistry , 2014 May 19/53, 4922-33.

EP-0029

Synthesis and Preliminary Evaluation of [18F]-EF-24, a novel synthetic curcumin analog, for PET Imaging of β-Amyloid Plaques in Alzheimer's Disease.

***G. Papadakis*[1],** *M. Sagnou[2], N. Pirmettis[3], E. Saloustrou[1], I. Pirmettis[3], V. Giannakaki[1], K. Marias[4], M. Pelecanou[2], A. Shegani[1]; [1]Hybrid Molecular Imaging Unit (HMIU), Foundation for Research and Technology Hellas (FORTH), HERAKLION, GREECE, [2]Institute of Biosciences & Applications, National Centre for Scientific Research "Demokritos (NCSRD)., ATHENS, GREECE, [3]Institute of Nuclear & Radiological Sciences and Technology, Energy & Safety (INRASTES), National Centre of Scientific Research "Demokritos" NCSRD"., Athens, GREECE, [4]Computational Biomedicine Laboratory (CBML), Foundation for Research and Technology Hellas (FORTH), Heraklion, GREECE.*

Aim/Introduction: The innovative synthetic curcumin analog EF-24 presents enhanced bioavailability, and bioactivity while exhibiting neuroprotective properties [1]. Natural curcumin is a promising agent due to its various bioactivities, including antioxidant, anti-inflammatory, anti-cancer and neuroprotective activities. Curcumin and curcuminoids complexes labeled with fluorine-18 or technetium-99m have demonstrated significant binding affinity for β-amyloid plaques encountered in Alzheimer's disease (AD) [2]. Aim of the current study was to successfully radiolabel EF-24 with [18F] and explore t its diagnostic potential as a radiotracer for imaging amyloid plaques, aiming to enhance diagnostic accuracy in AD. ***Materials and Methods:*** Radiolabeling of EF-24 was achieved using a boronic acid precursor, copper (II) trifluoromethanesulfonate, and pyridine in DMF in two steps. Radiochemical purity and yield were assessed by radio-TLC and radio-HPLC. Stability studies were conducted in PBS and serum, with assessments up to 4 hours post-synthesis. Synthetic β-amyloid fibrils were utilized to evaluate binding affinity. Ongoing in vivo imaging studies employing micro-PET/MRI (simulatenous PET and MRI acquisition) and biodistribution studies in healthy and Alzheimer's disease model mice will further investigate the tracer's distribution and binding capabilities. ***Results:*** [18F]-EF-24 was synthesized with low radiochemical yield (10-15%) but high purity (>95%), showing substantial stability in PBS and serum, remaining intact for up to 4 hours. Preliminary in vitro studies indicated significant binding to synthetic β-amyloid fibrils, with a retention of 89 ± 4.0% radioactivity. Early results from in vivo studies are promising, supporting further investigation. ***Conclusion:*** Synthesis and early evaluation of [18F]-EF-24 suggest its potential as a specific and stable PET imaging agent for β-amyloid plaques in Alzheimer's disease. The radiotracer's stability in biological media and strong affinity for amyloid fibrils underscore its potential clinical relevance. The outcomes of ongoing in vivo studies are anticipated to provide critical insights into the tracer's diagnostic utility, while the potential neuroprotective effective of the compoynd will also be explored.

A Novel Bis-boron Tracer for Amino Acid PET Imaging

Y. Pu, *L. Jin, L. Lu, C. Liu, C. Cai, Y. Chen, M. Lei, B. Shan; Boomray Pharmaceuticals Co., Ltd., Suzhou, CHINA.*

Aim/Introduction: Amino acid PET imaging enables a more accurate neuro-oncology diagnosis, especially in clinically equivocal situations. Boramino acid, as a novel class of amino acid analogue, has been developed for amino-acid-transporter-mediated PET imaging. This study aims to develop a novel boramino acid, BR-02 which incorporates two boron atoms, for brain tumor imaging. ***Materials and Methods:*** BR-02 was radiolabeled with fluorine-18 through the 18F-19F isotope exchange reaction and subsequently purified using semi-preparative HPLC. Preclinical studies for IND application, including pharmacology, pharmacokinetics, and toxicology studies, were fully performed. To identify the mechanism of action, a LAT1 high-expressing cell strain, HEK293/LAT1, was constructed. PET imaging of 13 xenograft models was performed. Both in vitro and in vivo pharmacokinetics studies, including an internal dose assessment based on biodistribution study, were conducted. The toxicological profile of BR-02 was evaluated in a series of toxicology studies, including single-dose toxicity, repeat-dose toxicity, genotoxicity, and local tolerance. ***Results:*** A sterile and non-pyrogenic solution with a radioactivity concentration of 10-24 mCi/mL was manufactured using a fully automatic radiopharmaceutical synthesizer. In the pharmacology study, the HEK293/LAT1 tumor uptake of BR-02 was significantly higher than that of HEK293/mock. The PET imaging study of 11 xenograft models demonstrated that the tumor uptake had a significant positive correlation with the LAT1 mRNA and protein expression levels, indicating that BR-02 could be transported and accumulated in the tumor through the LAT1 transporter. PET imaging studies of the U87MG orthotopic xenograft mouse model and the LLC brain metastasis mouse model demonstrated that BR-02 had excellent brain tumor targeting and imaging capabilities. After intravenous injection, BR-02 was mainly distributed in the kidneys and pancreas and was excreted in the urine. The effective doses converted from SD rats to adult men (4.98-9.95 mSv) and adult women (6.22-12.43 mSv) at the intended clinical dose were considered safe for clinical PET imaging. The safety margin was about 1000 times the clinical equivalent dose, and no further signs of toxicity concerning were noted in other toxicity studies. ***Conclusion:*** IND-enabling studies for a novel boramino acid PET imaging tracer were performed and demonstrated an acceptable safety profile, thereby allowing BR-02 to proceed to clinical trials.

EP-0032

Bicycle Radionuclide Conjugates for radioisotope delivery to solid tumors

G. Mudd, *A. R. Regupathy, J. Lahdenranta, F. Wood, B. Blakeman, P. Huxley;*
BicycleTx Ltd, Cambridge, UNITED KINGDOM.

Aim/Introduction: Bicycle molecules are a novel peptide-based modality consisting of constrained short peptides stabilized in a bi-cyclic structure using a central chemical scaffold. De

novo identification of Bicycle peptides that bind to biological targets, including proteins overexpressed in tumors, can be performed using the Bicycle phage display platform. One such target is MT1-MMP, a protein which is overexpressed in a number of cancers including lung, esophageal and pancreatic. We are developing Bicycle Radionuclide Conjugates (BRCs), in which Bicycle molecules are employed as targeting vectors to deliver radioisotopes to tumors for cancer imaging and targeted radionuclide therapy. The inherent properties of Bicycle molecules, namely their small size (compared to biologics) and hydrophilic nature, make them an ideal modality for radionuclide delivery. These characteristics, combined with exquisite binding specificity and high binding affinity, allow for rapid delivery to tumor and effective penetration, resulting in high accumulation of payload in the tumor. Their short biological half-life allows high contrast imaging at early timepoints and limits the exposure of normal tissue to payload. (1-4) ***Materials and Methods:*** In vitro cell binding assays were used to establish BRC binding properties. Mouse cell line derived xenograft models were used to determine organ distribution via imaging or ex vivo counting. ***Results:*** BRCs that demonstrate ideal properties for imaging, namely high tumor accumulation and rapid clearance from plasma, were identified across a number of targets and tumor models. Lead optimization of a MT1-MMP targeting BRC series labelled with Lead-212 resulted in compounds with improved biodistribution profiles, including more favorable tumor to kidney ratios, rendering them suitable for therapeutic application. ***Conclusion:*** As radiotheranostic approaches become widely employed in clinical oncology practices, the need for novel targets is well recognized. The Bicycle platform is a powerful tool for de novo identification of high quality binders to important cancer targets, with ideal properties for radionuclide delivery. The ability to optimize biodistribution properties of BRCs, particularly reducing kidney uptake, has been demonstrated, positioning Bicycle molecules as a potentially exciting new modality for targeted radionuclide therapy. ***References:*** 1. EP-0034

Impact of pentadecanoic acid conjugation to ^{111}In/^{225}Ac-RGD peptide on pharmacokinetics and therapeutic effects

M. Yoshimoto[1], *S. Wada[2], Y. Yoshii[3], A. Inaki[1], H. Fujii[1];*
[1]Division of Functional Imaging, EPOC, National. Cancer Center, Kashiwa, JAPAN, [2]Department of Bioorganic Chemistry, Faculty of Pharmacy, Osaka Medical and Pharmaceutical University, Takatsuki, JAPAN, [3]LinqMed Inc., chuo-ku, JAPAN.

Aim/Introduction: Too rapid clearance of peptides is unsuitable for peptide receptor radionuclide therapy. To overcome this, we developed RGD peptides with pentadecanoic acid (PD) as an albumin binding moiety. In this study, we investigated the pharmacokinetics and therapeutic effects of radiolabeled PD conjugated RGD peptides. ***Materials and Methods:*** We synthesized PD-K(DOTA)-c(RGDfK) (PD-K(DOTA)-RGD) and PD-K(DOTA)-E[c(RGDfK)]2 (PD-K(DOTA)-RGD2). To estimate the binding ability to albumin, PD-K(111In-DOTA)-RGD and PD-K(111In-DOTA)-RGD2 were incubated with human serum albumin (HAS), respectively. In comparison, 111In-DOTA-c(RGDfK) (111In-DOTA-RGD) and 111In-DOTA-E-[c(RGDfK)]2 (111In-DOTA-RGD2) without the albumin binding moieties were also evaluated. The albumin fraction was recovered by ultrafiltration using the Amicon Ultra-0.5 (NMWL: 50 kDa) and its radioactivity was measured. The percentage of the albumin binding for the incubated radioactivity was calculated. In U-87 MG xenograft mice, the biodistribution of 111In labeled RGD peptides was determined at 1, 4, and 24 h after the injection. In the therapeutic experiment, PD-K(225Ac-DOTA)-RGD (20, 40 kBq/mouse) was injected. Body weight and tumor size were measured. Hematological, hepatic, and renal toxicity was also examined at the end of the experiment. ***Results:*** Conjugation of PD to RGD peptides significantly increased the binding ability to HSA while there isn't almost the binding of 111In-DOTA-RGD and 111In-DOTA-RGD2 to HSA. The HSA binding of PD-K(111In-DOTA)-RGD was higher than that of PD-K(111In-DOTA)-RGD2. The biodistribution experiment indicated that the PD conjugation significantly increased the radioactivity in the blood and tumor and slowed the clearance. At 4 h after the injection, the blood radioactivity of PD-K(111In-DOTA)-RGD and PD-K(111In-DOTA)-RGD2 was 5.80 and 1.29 %ID/g, respectively while that of 111In-DOTA-RGD and 111In-DOTA-RGD2 was less than 0.1 %ID/g. The tumor uptake of PD-K(111In-DOTA)-RGD was 9.96 at 4 h and 10.68 %ID/g at 24 h after injection. That of PD-K(111In-DOTA)-RGD2 was 8.59 at 4 h and 5.12 %ID/g at 24 h after injection. In the therapeutic experiment using BxPC-3 xenograft mice, PD-K(225Ac-DOTA)-RGD successfully suppressed tumor growth. Median survival times are 48 days for control 70 days for 20 kBq, and 83 days for 40 kBq of PD-K(225Ac-DOTA)-RGD. The hepatic toxicity dose-dependently appeared though the renal toxicity was not obvious. ***Conclusion:*** In this study, the conjugation of PD to DOTA-c(RGDfK) successfully improved the pharmacokinetics of DOTA-c(RGDfK), leading to the prolonged blood circulation and the higher tumor uptake. In addition, PD-K(225Ac-DOTA)-RGD inhibited the tumor growth. These results suggested that PD-K(111In/225Ac-DOTA)-RGD has great potential for radiotheranostics of pancreatic cancers.

EP-0035

Radiosynthesis and quality control of ^{99m}Tc -Temozolomide: a preliminary study.

S. Tayal[1,2], *R. Kapoor[3], D. K. Dhawan[2], V. D. Chadha[2];*
[1]Mahamana Pandit Madan Mohan Malaviya Cancer Centre, A unit of Tata Memorial Centre, Varanasi, INDIA, [2]Panjab University, Chandigarh, INDIA, [3]Post Graduate Institute of Medical Education & Research, Chandigarh, INDIA.

Aim/Introduction: Nuclear medicine imaging makes use of 18F-FDG-PET as a valuable tool for diagnosis, therapy-monitoring and prognostication of glioma, but 18F-FDG is also picked up by inflammatory or infectious cells leading to its limitation and also requires cyclotron for its production. Therefore, as an alternate, SPECT-CT based radionuclide (99mTc) is to be exploited for various logistic and technical benefits. The present study aims to radio-synthesise and perform physicochemical characterisation of 99mTc-temozolomide, an alkylating agent, widely used for treating primary and recurrent high-grade gliomas. ***Materials and Methods:*** Radiolabeling of temozolomide with 99mTc was standardized using stannous chloride (SnCl2) reduction method. Various physical conditions viz: concentration of reaction constituents, incubation time, pH, and temperature were optimized to obtain maximum binding of 99mTc with the drug. Percentage protein binding, in-vitro stability and lipophilicity were also assessed. The radiochemical purity of 99mTc- temozolomide was estimated by instant thin layer chromatography (ITLC) and electrophoretic mobility of radiocomplex was assessed using paper electrophoresis. C6 cell lines were used to evaluate cytotoxicity of various concentration of radio-complex after incubating for 24 hours using MTT reagent, while haemoglobin

release assay was performed to test cytotoxicity on erythrocyte membrane. ***Results:*** 99mTc-Temozolomide radiocomplex exhibited maximum radiolabelling yield at 1:1 ratio of SnCl2 and temozolomide when incubated with 500µCi activity of pertechnetate, at 21°C for 10 minutes at pH of 5.5. Rf value of 0.1 was obtained in acetone medium for the bound radiocompex. Average protein binding was 7.03%, in vitro stability was > 90 % up to 6 hours and lipophilicity was high, as indicated by Log P o/w value (≥1.52). The net charge of the radiocomplex was observed to be zero from the electrophoresis run. MTT analysis showed that the viable population decreased gradually with increasing concentration and there was minimal haemolytic activity at the various concentration ranging from 12.5µg to 50µg of temozolomide. ***Conclusion:*** The developed radiocomplex exhibited a high labelling efficiency of ≥ 90% and holds the potential for its bioevaluation as radionuclide probe for glioma imaging at preclinical level and to be assertive for its clinical evaluation.

EP-0036

Impact of molar mass of FAPI on ^{68}Ga/^{177}Lu-FAPI PET imaging and radiotherapy for targeting murine FAP in wildtype tumor cell line derived xenograft

L. Liu, *Y. Shi, S. He, J. Yang, S. song, D. Wang, Z. Wang, H. Zhou, B. Yu, X. Zhu;*
Department of Nuclear Medicine, Tongji hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Since FAP is highly expressed in tumor stroma in various epidermal-derived cancers, FAP-targeted diagnosis and treatment have shown great potentials in preclinic and clinic for tumor theranostics. However, in preclinic, tumor-bearing mice hold relatively low absolute FAP expression level compared to cancer patients, leading to obstacles in detecting FAP expression using FAP-targeted PET as radiopharmaceuticals with higher specific activity is needed. So far there has been no study to make sure the impact of administration molar mass of radiolabeled FAPI on murine FAP-targeted theranostics in wildtype cell line derived xenograft. ***Materials and Methods:*** Specific activity of synthesized 68Ga/177Lu-FAPI-04 was measured by radioHPLC. 68Ga-FAPI-04 was administrated to wildtype 4T1 tumor-bearing mice with various molars of FAPI-04, followed by static PET scanning. Sigmoidal curves were simulated to analyze the correlation of SUVmax and administration molar mass of FAPI-04. Similarly, 177Lu-FAPI-04 with different molars of FAPI-04 and same dose of radioactivity was injected to 4T1 tumor-bearing mice for treatment. ***Results:*** Simulation results revealed the gradient blocking effect of FAPI-04 in 68Ga-FAPI-04 PET imaging. Correlation of SUV of tumor and other organs and administration molar mass fit standard Sigmoidal model (Top tumor SUVmax 0.86; Bottom tumor SUVmax 0.13; IC50 7.71 nmol/kg). Different tumor inhibition effect of 177Lu-FAPI-04 also validated the impact of administration molar mass of FAPI-04 on therapeutic effect that tumor inhibition was seen with treatment of 30 MBq/0.2 nmol 177Lu-FAPI-04 but 30MBq/1 nmol. ***Conclusion:*** The administration molar mass of 68Ga/177Lu-FAPI-04 shall apparently influence FAP-targeted imaging results and therapeutic effect. It's never careful enough to take it in consideration when apply radiolabeled FAP ligands to FAP-targeted PET imaging and radiotherapy in preclinical situation.

EP-0037

Development of porphyrin functionalized nanodroplets for cancer theranostics

K. Ogawa[1], *K. Tamamura[1], M. Munekane[1], N. Ramzi[1], K. Mishiro[1], T. Fuchigami[1], Y. Inaba[1], X. Hu[2], R. Jastrzęb[3], K. Ninomiya[1];*
[1]Kanazawa University, Kanazawa, JAPAN, [2]Shanghai University, Shanghai, CHINA, [3]Adam Mickiewicz University, Poznan, POLAND.

Aim/Introduction: It is known that porphyrins highly accumulate in cancer cells compared to normal cells. Therefore, surface conjugation of porphyrins to nanomaterials could improve the selective overall nanoparticles localization toward cancers. Meanwhile, phase shift nanodroplets that contain a low-boiling point liquid perfluorocarbon core have been used for ultrasound imaging agents and drug delivery carriers. Recently, ultrasound-triggered agents for sonodynamic therapy (SDT) have gained attention due to their non-invasiveness and ability to penetrate deeply seated tumors. In this study, the designed nanodroplets that encapsulate the low-boiling point liquid perfluorocarbon and IR-780 dye, with surface conjugation of 111In-labeled porphyrin derivative ([111In]In-DTPA-TPP), for theranostics were synthesized and evaluated by in vitro and in vivo experiments. ***Materials and Methods:*** [111In]In-DTPA-cysteamine-nanodroplets, which is 111In-labeled nanodroplets without porphyrin as a control, and [111In]In-DTPA-TPP-nanodroplets were synthesized by a simple chelation reaction of [111In]InCl3 with DTPA moiety of nanodroplets. Cellular uptake experiments in Colon 26 cells and biodistribution experiments in Colon 26 tumor-bearing mice of [111In]In-DTPA-cysteamine-nanodroplets and [111In]In-DTPA-TPP-nanodroplets were performed. SPECT imaging experiments were performed after injection of [111In]In-DTPA-TPP-nanodroplets. SDT of DTPA-TPP-nanodroplets was performed. ***Results:*** The cellular uptake of [111In]In-DTPA-TPP-nanodroplets was significantly higher than [111In]In-DTPA-cysteamine-nanodroplets. Biodistribution experiments revealed a higher accumulation in the tumor of mice injected with [111In]In-DTPA-TPP nanodroplets compared to [111In]In-DTPA-cysteamine-nanodroplets. Moreover, the accumulation of [111In]In-DTPA-TPP nanodroplets in the tumor was visualized by SPECT imaging. Sonodynamic therapeutic experiments revealed that DTPA-TPP-nanodroplets with a single ultrasound irradiation onto the tumor area significantly inhibited tumor growth. ***Conclusion:*** These results indicate that [111In]In-DTPA-TPP nanodroplets would be promising cancer theranostic agents.

Standardized analyses of static and dynamic fluorodeoxyglucose PET/CT images in patient-derived orthotopic mouse models of endometrial cancer

J. Lyngstad[1,2], *H. F. Berg[3,4], T. Fonnes[3], C. Krakstad[3,4], I. S. Haldorsen[1,2], H. Espedal[1,5,6];*
[1]Mohn Medical Imaging and Visualization Centre, Department of Radiology, Haukeland University Hospital, Bergen, NORWAY, [2]Department of Clinical Medicine, University of Bergen, Bergen, NORWAY, [3]Centre for Cancer Biomarkers, Department of Clinical Science, University of Bergen, Bergen, NORWAY, [4]Department of Obstetrics and Gynecology, Haukeland University Hospital, Bergen, NORWAY, [5]Deparment of Clinical Medicine, University of Bergen, Bergen, NORWAY, [6]Western Australia National Imaging Facility, Centre for Microscopy, Characterization and Analysis, The University of Western Australia, Perth, AUSTRALIA.

Aim/Introduction: Fluorodeoxyglucose (FDG)-PET/CT imaging allows non-invasive tumor characterization

and longitudinal monitoring in patient-derived orthotopic xenograft (PDX) models. Standards for analyzing FDG-PET/CT experiments in PDX models of endometrial cancer are lacking, which is challenging for the reproducibility and clinical translation. We report and compare standard and novel tumor metabolic parameters in preclinical PDX endometrial cancer models and explore whether the tumor parameters differ according to PDX model/histology/treatment group. ***Materials and Methods:*** The studied mice (n=63) comprised three cohorts including both endometrioid (EEC) and non-endometrioid (non-EEC) subtypes. Cohort 1 (C1) (n=43) consisted of treatment naive mice: PDX: n=13 (EECG2: n=3; EECG3: n=10) and organoid (O)-PDX: n=30 (clear cell: n=3; serous: n=1; EECG1: n=1; EECG2: n=1; EECG3: n=24) imaged with FDG PET/CT at endpoint. Cohort 2 (C2) (n=10) comprised O-PDX mice (EECG3) imaged with FDG-PET/CT at endpoint after treatment with carboplatin (n=5) or saline (control; n=5). Cohort 3 (C3) (n=23) comprised PDX mice (EECG3) imaged with FDG-PET/CT at endpoint following treatment with trastuzumab (n=7), paclitaxel (n=8) or saline (control; n=8). The following metabolic imaging parameters were extracted from all tumors; maximum/peak/mean/10 most intense voxels standardized uptake values (SUVMAX, SUVPEAK, SUVMEAN, SUV10) metabolic tumor volume, total lesion glycolysis, max tumor-background ratio (TBRMAX) and dynamic parameter tumor influx rate (KI). ***Results:*** All mice were successfully imaged by PET/CT depicting uterine FDG avid tumor uptake. Treatment naive mice (C1) had a mean/median [SD] tumor SUVMAX of 4.5/4.4 [1.1]. There were no significant differences in tumor metabolic parameters for the different histological subtypes or between PDX and O-PDX. The metabolic tumor parameters SUVMAX, SUVPEAK, SUV10 and SUVMEAN, were all strongly positively correlated with each other (coefficient RS= 0.91-0.97; $p<0.001$). In C2 median SUVMAX/TBRMAX/SUVPEAK/SUV10 values were similar in the treatment group (SUVMAX/TBRMAX /SUVPEAK/SUV10 = 5.1/10.2/4.4/4.9) vs. control group (median SUVMAX/TBRMAX/SUVPEAK/SUV10 = 5.6/11.2/4.9/5.3) ($p\geq0.17$). The median for the dynamic parameter KI was 0.0719 and 0.0533 ml/cm3/min for the carboplatin and control group, respectively ($p\geq0.81$). In C3, median SUVMAX/TBRMAX/SUVPEAK/SUV10 values were similar in trastuzumab (3.9/7.8/3.6/3.7) vs. paclitaxel (4.3/8.9/3.7/4.1) vs. control group (4.7/8.8/3.9/4.6) ($p\geq0.137$); median KI was 0.0489/0.0533 and 0.0595 ml/cm3/min for the trastuzumab, paclitaxel and control group respectively ($p\geq0.514$). ***Conclusion:*** We report quantitative FDG tumor uptake from a range of endometrial cancer models using conventional and novel parameters, which provides an important baseline for analyses in future preclinical studies. Incorporating multiple imaging timepoints and increasing the sample size may increase the strength of future treatment studies.

EP-0039

Construction of Novel Radionuclide Labeled Molecular Imaging Probes Targeting EGFR

L. Bai, *H. Cheng, S. Song;*
Department of Nuclear Medicine, Cancer Hospital of Fudan University, Shanghai, CHINA.

Aim/Introduction: PET tracers based on small molecule structures are simple to prepare and easier to mass produce. Currently, 18F-labeled epidermal growth factor receptor (EGFR) probes have shown good visualization effect, but there is no molecule based on 68Ga-labeled EGFR small molecules with good visualization effect. DOTA, as a chelating agent of 68Ga, can be 177Lu-labeled for therapeutic purposes. We designed EGFR tyrosine kinase inhibitor (TKI) probe [68Ga/177Lu]-Pip-Gefitinib for EGFR-Sensitive (19del/L858R) tumors. We conducted preclinical evaluation and application of the probe after using 68Ga labeling in order to instantly assess and monitor EGFR gene expression of tumor, guiding clinical dosing, and to explore the therapeutic effect after 177Lu labeling. ***Materials and Methods:*** The structures were screened by computerized molecular docking experiments and other methods, 68Ga and 177Lu labelling conditions were explored, cellular uptake and PET/CT imaging of the corresponding hormonal murine models were performed in cell lines validated for different EGFR expression, and then in vivo distribution and metabolism were evaluated. ***Results:*** 68Ga-Pip-Gefitinib had significantly high uptake in the NSCLC cell lines HCC827 and PC-9, and the human colon cancer cell line HCT116 (19del/L858R high-expressing cell line), and low uptake in A549 (19del/L858R low-expressing cell line), and compared to the pre-existing 68Ga-labelled EGFR probes, there were lower intestinal uptake and performed better in PET/CT. We have now demonstrated the stability of 177Lu labelling in vivo and ex vivo, and will further complete the experiments of SPECT/CT and therapy after 177Lu labelling. ***Conclusion:*** PET/CT of [68Ga/177Lu]-Pip-Gefitinib is capable of demonstrating EGFR expression status and is expected to provide non-invasive immediate clinical screening and long-term monitoring of EGFR-TKI-applicable patient populations, and is expected to guide clinical nuclide therapy.

EP-0040

^{68}Ga/^{177}Lu-labeled theranostic pair targeting fibroblast activation protein with high tumor uptake and retention

J. Huang, *X. Zhang, G. Tang;*
Department of Nuclear Medicine, Nanfang Hospital, Southern Medical University, GuangZhou, CHINA.

Aim/Introduction: Radiotheranostics allows pre-treatment diagnosis, radionuclide therapy, and post-treatment evaluation using specific radiopharmaceuticals [1, 2]. Fibroblast activation protein (FAP) is specifically expressed on cancer-associated fibroblasts in over 90% of tumors and considered a promising target for cancer theranostics [3, 4]. ***Materials and Methods:*** We developed a novel FAP-targeting ligand DOTA-FAPT and labeled it with gallium-68 and lutetium-177 as a theranostic pair. FAP-positive A549-FAP cells were used for in vitro specific binding evaluation of [68Ga]Ga/[177Lu]Lu-FAPT. Micro-PET/CT scans were performed on A549-FAP and U87MG tumor-bearing mice to compare the in vivo pharmacokinetic properties and tumor uptake between [68Ga]Ga-FAPT and [68Ga]Ga-FAPI-04. Biodistribution and therapeutic efficacy evaluation of [177Lu]Lu-FAPT were conducted on A549-FAP tumor-bearing mice. Lastly, primary clinical studies were conducted on patient with lung cancer. ***Results:*** [68Ga]Ga/[177Lu]Lu-FAPT exhibited high stability and hydrophily, as well as strong affinity to the FAP target (IC50 = 0.42 nM). PET/CT showed that [68Ga]Ga-FAPT had remarkably higher tumor uptake and prolonged tumor retention in A549-FAP and U87MG tumor xenografts compared to [68Ga]Ga-FAPI-04 with favorable in vivo pharmacokinetic properties. Therapeutic studies showed that [177Lu]Lu-FAPT had higher tumor accumulation compared to [177Lu]Lu-FAPI-04, leading to stronger tumor growth inhibition. The therapeutic efficacy of [177Lu]Lu-FAPT was dose-dependent, with 37 Mbq of [177Lu]Lu-FAPT had higher tumor growth inhibition and longer

median survival compared to 18.5 Mbq of [177Lu]Lu-FAPT. The safety of [177Lu]Lu-FAPT radiotherapy was also demonstrated by internal dose assessment and monitoring of mice in the treatment group. PET/CT imaging of [68Ga]Ga-FAPT in patient with lung cancer showed higher uptake in both primary lesion and metastatic lymph nodes compared to [18F]FDG. ***Conclusion:*** [68Ga]Ga/[177Lu]Lu-FAPT exhibit enhanced tumor visualization and stronger anti-tumor efficacy compared to [68Ga]Ga/[177Lu]Lu-FAPI-04. The preclinical study and primary clinical study show that 68Ga/177Lu-labeled DOTA-FAPT is a theranostic pair with a broad application prospect. ***References:*** 1.Aboagye EO, Barwick TD, Haberkorn U. Elucidating the cellular responses and mechanism of action of ^{177}Lu-based radioligand therapy

G. Sastre-Moreno[1], *A. Thapa[2], M. Ranzani[2], S. Hindupur[1], A. Cicconi[2], A. Kristian[1], B. Schacher Engstler[1], C. Hartnagel[1], D. Gorses[1], E. Simon[1], F. Schaeffer[1], J. Reber[1], L. Barys[1], L. Deberle[1], M. Walter[1], R. Destefani[1], E. Elinati[2], N. Shao[2], J. Barlow[2], A. Galbiati[2], D. Grande[2], E. Rajendra[2], N. Martin[2], K. Koler[2], S. Menon[2], G. Smith[2], T. Schmelzle[1], M. Reschke[1], H. Robinson*[2], M. Cortés-Cros*[1];*
[1]Novartis Biomedical Research, Basel, SWITZERLAND,
[2]Artios Pharma Limited, Cambridge, UNITED KINGDOM.

Aim/Introduction: Radioligand therapy (RLT) holds outstanding potential for the treatment of multiple cancer types, particularly those at advanced stage, with high effectiveness and tolerability. Among the expanding repertoire of RLT modalities, 177Lu-PSMA-RLT and 177Lu-Dotatate-RLT stand out as FDA-approved treatments for PSMA-positive metastatic castration-resistant prostate cancer (mCRPC) and somatostatin receptor-positive gastroenteropancreatic neuroendocrine tumors (GEP-NETs) respectively. Despite their clinical success, treated patients often lack durable responses, with complete cure being infrequent. A better understanding of the mechanism of action of 177Lu-RLT and the cellular responses induced by this treatment could unveil novel opportunities for the improvement of therapy and outcome for patients. ***Materials and Methods:*** The phenotypes and cellular responses induced by 177Lu-RLT were assessed in multiple cell lines by several experimental approaches, including viability assays, immunofluorescence and flow cytometry. Additionally, "DDR-ome" targeted genetic screens as well as pharmacological screens were conducted using cells treated with 177Lu-radioligands to unravel its mechanism of action and potential combination partners. ***Results:*** 177Lu-RLT-treated cell lines show induction of multiple DNA Damage Response (DDR) markers, with those indicative of double-strand break (DSB) repair by either non-homologous end-joining (NHEJ) or homologous recombination (HR) being particularly prominent. 177Lu-RLT induced other phenotypes characteristic of genomic instability such as cell-cycle alterations, accumulation of micronuclei and cell death. In agreement with published reports, we show that either the knock-out or chemical inhibition of NHEJ core factors such as the catalytic subunit of DNA-PK (PRKDC) renders cells sensitive to 177Lu-RLT and combination of both agents provides a beneficial tumor growth inhibition in vivo. Additionally, our targeted screens also suggest that DSBs are the most cytotoxic form of 177Lu-RLT-induced DNA damage and have identified novel targets for development of radiosensitizers. We will also show data from the pharmacologic screens including PARP inhibitors and correlate genetic and pharmacological results. ***Conclusion:*** Our work provides better understanding of the cellular responses to 177Lu-based RLT and pinpoints NHEJ as a critical pathway promoting survival to this treatment, which could set the basis for novel combination therapies.

EP-0042

Preparation and Application of Novel ^{68}Ga-labeled Nucleic Acid Aptamers Targeting c-Met

X. Liu;
Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: c-Met is a membrane receptor protein with tyrosine kinase activity that is activated by its physiologic ligand, hepatocyte growth factor (HGF). Once activated, this protein stimulates a series of intracellular signaling pathways, such as those associated with proliferation, motility, and invasive migration of cancer cells. Early c-Met targeting molecule was 64Cu-NOTA-rh-HGF. In 2008-2012 monoclonal antibodies targeting c-Met or its ligand (HGF) were labelled with 89Zr, peptides labelled with 18F, 64Cu and 68Ga and small molecules labelled with 11C and 18F. Unfortunately, despite the availability of such a large number of nucleotide-labelled tracers, only one is currently involved in clinical trials for pet applications. There is a lack of aptamer-based imaging probes, and we have developed an aptamer-based molecular imaging probe by utilizing the unique properties of aptamer. SELEX technology has proven to be a powerful and effective aptamer screening program. Aptamers are composed of DNA or RNA (primarily DNA) and are functionally equivalent to traditional antibodies, with the advantages of small size, flexible structure, ease of synthesis, versatile chemical modifications, high stability and lack of immunogenicity. In this study, we developed a molecular imaging probe with a c-Met aptamer for targeted imaging of positive tumours. Next, we successfully prepared an aptamer-based PET/CT imaging probe, named [68Ga] Ga-NOTA-SL1. ***Materials and Methods:*** First, we successfully labeled [68Ga] Ga-NOTA-SL1 and conducted Radio-HPLC and circular dichroism for validation. Next, flow cytometry, fluorescence confocal microscopy, and cellular uptake studies were performed at the cellular level. We utilized PC-9, HCC827, and HCT116 cell lines for subcutaneous implantation in mice. PET/CT scans were performed when the tumor size reached 0.5-1 cm, and at the end of the imaging, mouse tissues were collected to measure gamma values and calculate %ID. ***Results:*** Through the above experiments, it was demonstrated that [68Ga] Ga-NOTA-SL1 was successfully labeled and had good binding at the cellular level, and it was further demonstrated in PET/CT and biodistribution experiments that [68Ga] Ga-NOTA-SL1 could be specifically bound in c-Met expressing cells with good targeting properties. ***Conclusion:*** Our study explored the feasibility of c-Met imaging probes. Despite this limitation, [68Ga] Ga-NOTA-SL1 can illuminate tumors and is expected to allow for prognostic assessment and development of effective treatment strategies for patients in the future.

EP-0043

Construction of a novel PET tracer for targeting EGFR mutation

S. Liu, *F. Liu, Z. Yang;*
Peking University Cancer Hospital & Institute, Beijing, CHINA.

Aim/Introduction: With activating mutations in the EGFR kinase domain, activation occurs in the absence of a ligand, leading to tumor cell proliferation and growth. The most detected mutation in the EGFR tyrosine kinase domain includes exon 19 deletion. In advanced-stage disease, molecular targeted therapy, such as tyrosine kinase inhibitors is the standard first-line treatment for patients with these identified driver mutations. In this project, a novel 18F labeled TKI-PET probe was developed to target EGFR Del19 mutation and monitor mutation status. ***Materials and Methods:*** $^{[18F]}$F-LF50 was radiolabeled with one-step radiosynthesis. Quality control was verified by Radio-HPLC. In micro-PET/CT imaging, $^{[18F]}$F-LF50 probe were researched in bearing HCC827 xenografts mouse models (Del 19), bearing H1975 xenografts mouse models (L858R/T790M) and bearing A549 xenografts mouse models (EGFR wild type). ***Results:*** The radiochemical purity of $^{[18F]}$F-LF50 was over 99%. In immunohistochemistry, HCC827 tumor exhibited Del19 mutation while H1975 and A549 didn't. In micro-PET/CT imaging, $^{[18F]}$F-LF50 showed better aggregation in HCC827 tumor (SUVmax: 0.86 ± 0.03 at 30min), compared with H1975 tumor (SUVmax: 0.56 ± 0.03 at 30min) and A549 tumor (SUVmax: 0.38 ± 0.01 at 30min). This probe was eliminated through intestinal tract rapidly. ***Conclusion:*** $^{[18F]}$F-LF50 exhibited good characteristics of targeting HCC827 tumor, which showed 18F-LF50 was powerful to target EGFR del 19 mutation and potential to apply in monitoring EGFR mutation status in NSCLC patients.

EP-0044

Radiopharmaceutical-mediated in situ excitation of naphthalocyanine for deep tumor therapy

X. Su, *J. Li;*
Department of Nuclear Medicine, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, CHINA.

Aim/Introduction: Naphthalocyanine-based agents exhibit huge potential in imagimh-guided tumor photodynamic therapy (PDT). However, their PDT effect still remains restricted due to the poor tissue-penetrating performance of external laser.1 Based on our previous explorations that utilize radionuclide-emitted Cerenkov radiation (CR) as internal light source for tumor optical imaging and PDT,2-3 silicon naphthalocyanine (SiNC) nano-photosensitizers (NPSs) are rationally designed and constructed to achieve CR-induced PDT without the limitation of penetration depth. ***Materials and Methods:*** SiNC NPSs were prepared via the one-step assembly of SiNC and poly(ethylene glycol)-block-poly(ε-caprolactone) (PEG-PCL) using solvent evaporating method. The CR energy transfer and CR-induced 1O2 generation of SiNC NPSs was confirmed via the IVIS imaging system and fluorescence detention method based on SODG probe, respectively. Standard CCK8 assay was applied to evaluate the dark cytotoxicity and CR-PDT effect of SiNC NPSs at the cell level. Under the visualization guidance of living fluorescence imaging of SiNC NPSs and positron emission tomography (PET) imaging of 18F-FDG, the in vivo tumor treatment was performed on the 4T1 tumor-bearing mice model with the biosafety investigations compromising the body weight measurements and H&E histological staining analysis. ***Results:*** The obtained SiNC NPSs with the size of around 15 nm displayed strong optical absorption in the UV region (< 400 nm), indicating they were responsive to the UV-weighted CR emission. Under the excitation of CR emitted by 18F, SiNC NPSs enabled significant 1O2 generation to induce cancer cell death via type II PDT pathway based on the CR energy transfer progress. Due to the enhanced penetration and retention effect, living fluorescence imaging proved the remarkable tumor-targeting behavior SiNC NPSs, reaching the highest tumor accumulation at 8 h post-injection. Finally, in vivo antitumor experiment demonstrated that the sequential administration of SiNC NPSs (3mg/kg) and clinical PET tumor radiotracer (18F-FDG, 0.8 mCi) was capable of inhibiting the growth of subcutaneous 4T1 tumors, simultaneously causing negligible side effect towards health organs. ***Conclusion:*** Collectively, we firstly demonstrated the feasibility of activating silicon SiNC NPSs using CR within body for efficient tumor PDT, aiming at advancing and enriching the phototherapy application of naphthalocyanine-based agents, as well further expanding the tool box of CR-PDT to synergistically combine nuclear medicine and nanomedicine for the augment of therapeutic benefits. ***References:*** (1) Chem Mater, 2015, 27, 6155–6165. Development of [^{64}Cu]Cu-Albumin-Glutamate-Urea-Lysine/Fluorescence Complex as an Image-Guided Surgery Agent for PSMA-Expressing Prostate Cancer

Y. Chung[1], *J. Kim[1], J. Kim[2], Y. Shin[2], M. Suh[2], J. Park[1,2,3], R. Yoo[2,4], Y. Lee[5], K. Lee[5], Y. Lee[1,2,3];*
[1]Department of Nuclear Medicine, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [2]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [3]Institute of Radiation Medicine, Medical Research Center, Seoul National University College of, Seoul, KOREA, REPUBLIC OF, [4]Biomedical Research Institute, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [5]Division of RI application, Korea Institute of Radiological and Medical Sciences (KIRAMS), Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Positive surgical margins in radical prostatectomy specimens occur in 11-48% of cases, increasing the risk of recurrence. To address this, our research group developed a PSMA-targeting albumin-fluorescent complex, aiming to enhance surgical precision and reduce positive surgical margins. ***Materials and Methods:*** To synthesize the PSMA-targeting albumin-fluorescent complex (Alb-GUL/ICG), human serum albumin was conjugated with DBCO-NHS ester (DBCO) and Glutamate-Urea-Lysine (GUL) with azide. The degree of functionalization (DOF) for DBCO and GUL was assessed using Matrix-Assisted Laser Desorption Ionization Time-of-Flight (MALDI-TOF). After masking excess DBCO molecules, Alb-GUL was mixed with indocyanine green (ICG) to form Alb-GUL/ICG. This conjugate, along with a control Alb/ICG, was evaluated for cellular uptake in LNCaP and 22Rv1 cells using confocal microscopy. In vivo PET studies were performed to compare the biodistribution profiles and tumor-targeting efficacy of [64Cu]Cu-Alb/ICG and [64Cu]Cu-Alb-GUL/ICG, aiming to determine the optimal injection time. Further, in vivo fluorescence was obtained using IVIS imaging in 22Rv1 tumor models. ***Results:*** The DOF of DBCO and GUL as 11.2 and 5.3, respectively. In vitro 22Rv1 and LNCaP cell fluorescence signal was approximately 2 times and 10 times stronger in Alb-GUL/ICG than in Alb/ICG, respectively. In the in vivo biodistribution study, [64Cu]Cu-Alb-GUL/ICG showed faster blood clearance through liver compared with [64Cu]Cu-Alb/ICG. Time-activity curve showed, the tumor-to-blood ratio of [64Cu]Cu-Alb-GUL/ICG was highest at

24 h, showing 38% increase over [64Cu]Cu-Alb/ICG. In vivo 22Rv1 tumor fluorescence signal was enhanced by 36% in Alb-GUL/ICG compare to Alb/ICG, 24 hours post-injection. ***Conclusion:*** Alb-GUL/ICG demonstrated superior uptake in PSMA expressing tumors in vitro and in vivo, highlighting its enhanced targeting efficacy with a higher tumor-to-blood ratio. Consequently, Alb-GUL/ICG shows promise as an effective image-guided surgery agent for prostatectomy, potentially reducing the incidence of positive surgical margins. ***References:*** Park, Ji Yong, et al. Non-invasive visualization of HER2 expression using ^{68}Ga and ^{177}Lu labeled anti-HER2 antibody fragments

C. Li*[1]*, *B. Li[2], P. Liu[2], Z. Wei[2], X. Chen[2], J. Zhang[2];*
[1]Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, CHINA, [2]National University of Singapore, Singapore, SINGAPORE.

Aim/Introduction: The oncogenic potential and activation of human epidermal growth factor receptor 2 (HER2) have been confirmed in various human malignancies, most notably in breast cancer and gastric/esophageal junction cancer. Therapeutic agents targeting HER2 have significantly improved the prognosis of patients with HER2+ cancers. This study designed four antibody fragments targeting Trop2, which were labeled with radionuclides 68Ga and 177Lu for immunoPET and SPECT imaging, respectively, aiming to achieve rapid and accurate assessment of HER2 expression and distribution. ***Materials and Methods:*** We developed F(ab) and F(ab')2 fragments based on the sequence of patuzumab using antibody engineering techniques. Additionally, we coupled these fragments with the albumin binding domain (ABD) to construct F(ab)-ABD and F(ab')2-ABD fragments. Using transfection technology, we obtained a murine colorectal cancer cell line CT26 overexpressing human HER2 (CT26-HER2) and established the murine tumor models. The antibody fragments were first conjugated with the chelator p-SCN-Bn-DOTA at a molar ratio of 1:20, followed by purification using ultrafiltration tubes. The conjugates were then labeled with 68Ga and 177Lu and purified using a PD-10 column. The radiochemical purity was analyzed using radio thin-layer chromatography (radio-TLC). The 68Ga and 177Lu labeled antibody fragments were used for PET and SPECT imaging respectively in the CT26-HER2 tumor models. ***Results:*** The molecular weights of the antibody fragments F(ab), F(ab)-ABD, F(ab')2, and F(ab')2-ABD were approximately 50 kDa, 65 kDa, 100 kDa, and 115 kDa, respectively. The radiochemical purity of antibody fragments labeled with 68Ga and 177Lu was more than 95%. The tumors were clearly visible in immunoPET imaging with 68Ga-DOTA-F(ab)-ABD, 68Ga-DOTA-F(ab')2, and 68Ga-DOTA-F(ab')2-ABD from 2 h to 6 h, and the tumor uptake increased over time. However, 68Ga-DOTA-F(ab) likely experienced rapid glomerular filtration, resulting in no significant tumor uptake (n = 3). Subsequent SPECT imaging showed peak tumor uptake of 177Lu-DOTA-F(ab)-ABD at about 6.34 ± 1.22 %ID/g at 48 h postinjection, and that of 177Lu-DOTA-F(ab')2-ABD about 5.18 ± 1.51 %ID/g at 24 h postinjection (n = 3). The tumor uptake of 177Lu-DOTA-F(ab')2 was lower, peaking at 10 h postinjection with only about 1.79 ± 0.97 %ID/g. Uptakes in the heart, liver, and kidneys gradually decreased over time. Antibody fragments conjugated to ABD showed more retention in the heart and liver. ***Conclusion:*** Radionuclides-labeled HER2-targeted antibody fragments linked to ABD accumulated more in tumors, providing clearer tumor imaging. How to better balance the clearance and targeting ability of antibody fragments in vivo needs to be further explored.

Ga-68-Labelling of a Tetrahydroquinoline-Based Ligand for PET Imaging of C-X-C Chemokine Receptor Type 4 in Animal Models of Glioblastoma (GBM)

P. Suwattananuruk*[1,2,3]*, *S. Yaset[4], A. Kanasuwan[4], C. Chotipanich[4], A. Moldes-Anaya[3], R. Sundset[3,5], P. Rojsitthisak[1,2], M. Kranz[3], O. Vajragupta[1,2];*
[1]Department of Food and Pharmaceutical Chemistry and Center of Excellence in Natural Products for Ageing and Chronic Diseases, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, THAILAND, [2]Molecular Probes for Imaging Research Network, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, THAILAND, [3]PET Imaging Center, University Hospital of North Norway, Tromso, NORWAY, [4]National Cyclotron and PET Centre, Chulabhorn Hospital, Bangkok, THAILAND, [5]Department of Clinical Medicine, Nuclear Medicine and Radiation Biology Research Group, UiT the Arctic University of Norway, Tromso, NORWAY.

Aim/Introduction: The C-X-C chemokine receptor type 4 (CXCR4) is a promising target for cancer therapy, given its elevated expression in cancer cells during metastasis. This study aimed to develop a novel positron emission tomography (PET) radiotracer, [68Ga]Ga-TD-01, for CXCR4 imaging. To achieve this goal, we have tuned the molecular scaffold of the potent CXCR4 antagonist TIQ152 by conjugation with a chelator to make it suitable for 68Ga radiolabeling. ***Materials and Methods:*** A five-step synthesis process was employed to conjugate the amine functional group of TIQ15 with p-NCSBz-DOTA, to obtain the TD-01 precursor at a moderate yield of 60%. TD-01 was subsequently radiolabeled with 68Ga using 0.1 M ammonium acetate at 90°C for 15 minutes. Furthermore, 1-hour dynamic small animal PET/MRI in GL261-luc2 bearing mice (n=6) was performed, and brain tumor uptake was assessed through advanced pharmacokinetic analyses. Blocking studies involved pre-administration of TIQ15 (10 mg/kg) 10 minutes before PET start. ***Results:*** [68Ga]Ga-TD-01 exhibited a radiochemical yield (RCY) of 36.33± 1.50% (E.O.S.), with a radiochemical purity (RCP) >99% and a molar activity (Am) of 55.79±1.96 GBq/μmol. The radiotracer showed in vitro stability in PBS and human plasma for over 4 hours. Biodistribution studies in healthy animals revealed favorable kinetics for subsequent PET pharmacokinetic modeling and moderate brain uptake was observed indicating BBB penetrability. The highest uptake was found in the kidneys, liver and intestines, indicating a renal-hepatic excretion pattern. Importantly, [68Ga]Ga-TD-01 uptake in GBM-bearing mice significantly decreased upon competition with TIQ15, indicating high specificity. ***Conclusion:*** The newly developed CXCR4 PET tracer, [68Ga]Ga-TD-01, exhibited high affinity for CXCR4, excellent in vitro stability, and favorable pharmacokinetics, suggesting it as a promising candidate for the in vivo characterization of CXCR4 expression in GBM with potential for further development as a tool in cancer diagnostics. ***References:*** Valarie MT, Huanyu Z, Brooke MK, et al. Discovery of tetrahydroisoquinoline-based CXCR4 antagonists. ACS Med Chem Lett. 2013;4(11):1025-30.

Utilizing the chicken chorioallantoic membrane model to assess CXCR4 targeting agents for cancer therapy using multimodal imaging

***V. Prex*[1]**, *A. Gilg*[2], *V. Rasche*[3], *J. Münch*[2], *A. Beer*[1], *M. Harms*[2], *J. Löffler*[1];
[1]*Ulm University Medical Center, Department of Nuclear Medicine, Ulm, GERMANY,* [2]*Ulm University Medical Center, Institute for Molecular Virology, Ulm, GERMANY,* [3]*Ulm University Medical Center, Core Facility Small Animal Imaging, Ulm, GERMANY.*

Aim/Introduction: The chemokine receptor CXCR4 is upregulated in numerous diseases including cancer, rendering it an attractive target for drug development. Given this premise, our aim is to assess the stability and biodistribution for derivatives of the endogenous peptide inhibitor of CXCR4 (EPI-X4). In addition to the already non-invasive PET-MR approach we also want to consult the principles of replace, reduce and refine (3R) to explore the applicability of the chorioallantoic membrane (CAM) model in this context, comparing the data with findings from mouse experiments. ***Materials and Methods:*** First, we tested the stability of the EPI-X4 derivatives ex vivo by spiking them into plasma samples obtained from humans, mice, and chicken embryos. Retained activity of the spiked peptide samples was evaluated using an antibody replacement assay. Then compounds were labelled with the PET nuclide Zrirkonium-89 via DFO and intravascularly injected into mice and chicken embryos to comparably visualize the distribution by MRI and PET. Furthermore, tumor xenografts of CXCR4-positive cell line TZM-bl, along with HCT-116, were established in both models to assess specific tumor-binding of the peptides. The cell line PC-3, characterized by low CXCR4 expression levels, served as a negative control. ***Results:*** Ex vivo, the peptide derivative EPI-X4 JM#21 exhibits considerable instability in plasma samples of all species, with faster inactivation in mouse plasma than in chicken and human plasma. Accordingly, no retained activity was observed already 10min after injection in the CAM model, which is comparable to data obtained in mice. Furthermore, by using PET and MR imaging, we showed that EPI-X4 JM#21 is rapidly excreted within 24h in the CAM model, with signal primarily in the allantois (4.8 %IA/ml), serving as the equivalent of the bladder. Similarly, in mice the activity was primarily observed in the kidneys (2.0 %IA/ml) and bladder (16.9 %IA/ml). In contrast, the stability optimized and lipid-modified EPI-X4 JM#143 exhibited a circulation half-life of several hours in mice and in the CAM model with accumulation in the lungs (8.5 %IA/ml) and the liver (4.0 %IA/ml) of the tested mice. ***Conclusion:*** Given the consistent results observed with the EPI-X4 derivative JM#21 in the different species, the CAM model emerges as a feasible alternative for studying peptide distribution and tumor-targeting in vivo. In the future we plan to use the CAM model to evaluate further optimized EPI-X4 derivatives to identify the most promising candidate for cancer therapy.

ImmunoPET imaging of Trop2 for PSMA-Negative Prostate Cancer

***X. Long*[1]**, *W. Wei*[2], *X. Lan*[1], *D. Jiang*[1];
[1]*Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, CHINA,* [2]*Department of Nuclear Medicine, Institute of Clinical Nuclear Medicine, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA.*

Aim/Introduction: Prostate cancer is the second most significant contributor to male cancer mortality. PSMA-PET/CT imaging has promise in detecting prostate cancer without invasive procedures, however it has limits for patients with low PSMA expression. Trophoblast cell surface antigen 2 (TROP2), a transmembrane glycoprotein, is strongly associated with the progression of solid tumors, including prostate cancer. It has the potential to be a target for PSMA-negative prostate cancer. The aim of this work is to evaluate the value of a TROP2-targeted molecular imaging strategy in the diagnosis of PSMA-negative prostate cancer. ***Materials and Methods:*** Flow cytometry and Western blot were used to detect the expression of Trop2 and PSMA in prostate cancer cell lines. The TROP2-specific single domain antibody (T4) was labeled with gallium-68 (68Ga, T1/2 = 68 min) following NOTA chelator conjugation. The diagnostic value of [68Ga]Ga-NOTA-T4 was extensively evaluated by immunoPET imaging, biodistribution studies, and immunohistochemical staining on PSMA-negative xenograft models. ***Results:*** TROP2 was overexpressed in PSMA-negative prostate cancer cell lines. [68Ga]Ga-NOTA-T4 was developed with good radiochemical yield and radiochemical purity. PET/CT imaging demonstrated that [68Ga]Ga-NOTA-T4 specifically accumulated in PSMA-negative PC3 tumors with a high contrast, while [68Ga]Ga-PSMA-617 did not. Immunohistochemical staining also confirmed the strong expression of TROP2 in PC3 tumors. ***Conclusion:*** We have reported the potential for using TROP-2 to detect PSMA-negative prostate cancer and developed a radiolabeled nanobody tracer [68Ga]Ga-NOTA-T4 to specifically image TROP-2 expressing prostate cancer with high contrast. These results support further studies on TROP-2 as a therapeutic and diagnostic target for PSMA-negative prostate cancer.

EP-0050

Brain FDG clearance and brain SUV, but not brain glucose consumption, decrease with increasing tumour burden and blood glucose level

J. Livingstone, *D. Mukherjee, M. Berovic, A. Peters;
King's College Hospital NHS Foundation Trust, London, UNITED KINGDOM.*

Aim/Introduction: In FDG PET/CT, brain SUV correlates exponentially with blood glucose level (BGL) with exponential constant of -0.1 mmol/l-1, similar to the corresponding constant for tumours that can be derived from the study of Lindholm et al (JNM 1993) that showed tumour SUV decreasing in response to an increase in BGL. Brain is therefore a surrogate for tumour. Division of brain SUV by blood pool SUV gives an approximation of brain FDG clearance (CI). Viglianti et al (Radiology 2018) showed that such division abolished correlation between brain SUV and tumour metabolic burden. The aim of the study was to compare relationships of brain SUV and CI with BGL between patients with near-normal scans and patients with widespread disease to throw further light on BGL, tumour burden and brain SUV. ***Materials and Methods:*** Retrospective analysis was undertaken on FDG/PET scans of 100 patients with normal or near-normal scans (no/low group) and 100 with abnormal scans showing tumour FDG uptake. Of these 100, 29 had disease and/or marrow infiltration too widespread to measure tumour burden. ROIs were placed over cerebellum, liver, and ascending aorta (AA). Brain SUVmax was divided by AA SUVmax, giving CI. Since brain glucose consumption (MRglu) is constant (=CI*BGL), CI shows a hyperbolic relationship with BGL. The reciprocal of CI was plotted against BGL. Brain SUVmax and CI were then corrected to BGL of 5 mmol/l using their derived relationships with BGL. ***Results:***

Liver SUVmax did not correlate with BGL in either group or was different between them. Brain SUVmax decreased exponentially against BGL with constants of -0.12 and -0.057 mmol/l-1 in no/low and widespread disease groups, respectively. 1/CI showed slightly non-linear relationships with BGL. They were therefore fitted with second order polynomials. Mean brain SUVmax corrected for BGL was 9.7±2.5 and 7.9±2.0 ($p<0.001$) in no/low and widespread disease groups, respectively, while CI corrected for BGL using the polynomial equations was 5.2 and 4.5 ($p<0.01$). (These relationships are non-linear because of unphosphorylated FDG in the brain distribution volume.) In contrast, there was no difference in MRglu. ***Conclusion:*** Tumour SUV is influenced by tumour burden and BGL, which, when increased, decrease tumour SUV. Dividing brain SUV by blood pool SUV, giving CI, does not, however, abolish the dependence of brain SUV on BGL, despite constancy in MRglu. Because it's FDG handling more closely resembles that of tumours, brain is more appropriate than liver as reference tissue for tumours.

EP-0051

Multifunctional Organic Melanin Nanoparticles for Multimodal Imaging Guided Combination Cancer Therapy

L. Wen, *X. Lan, Y. Zhang, D. Jiang;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, CHINA.

Aim/Introduction: Radionuclide therapy is an effective method for cancer precise medicine. However, the uneven dose distribution and rapid metabolism of nuclides limit the effective killing of tumors. To overcome the limitations of radionuclide therapeutic approaches, combining different therapeutic strategies to treat cancer has manifested great promise in basic and clinical research. Herein, a biocompatible melanin nanoprobe with a highly specific fibroblasts activated protein (denoted as FAM) is developed for magnetic resonance (MR) /photoacoustic (PA)/positron emission tomography (PET) multimodal imaging guided combination cancer therapy. ***Materials and Methods:*** We prepared a multifunctional organic melanin nanoparticles (FMNs) coupled with the small molecule FAP inhibitor (FAPI) with excellent biocompatibility and biodegradability. Additionally, Near-infrared -absorbing FMNs chelated positron nuclide 64Cu and efficiently chelated the paramagnetic metal Mn2+ are used for enhanced the imaging effect of PAI, PET/CT, MRI, respectively. We simultaneously utilized beta-emitting radionuclides 131I to FMNs for radionuclide therapy and photothermal therapy. ***Results:*** In vivo MR/PA/PET multimodal imaging confirms effective tumor accumulation of FMNs. NIR-triggered PTT in combination with 131I-FMNs-based radioisotope therapy is achieved in our animal tumor model experiments, in which a remarkable synergistic antitumor effect is observed compared to monotherapies. Toxicology studies further indicate that 131I-FMNs-Laser induces no appreciable toxicity to mice at the treatment dose. Immunohistochemical staining for confirmed tumor tissue damaged, reduced tumor cell proliferation following treatment and less collagen fibers and significantly apoptosis in the tumor tissues. ***Conclusion:*** In this study, MR/PA/PET trimodal imaging allows more accurate diagnosis and imaging-guided therapy than single modality alone, and FMNs demonstrated significant antitumor efficacy for radionuclide therapy and photothermal therapy. It exhibits strong potential for clinical translation, providing a promising synergistic therapy of cancer. ***References:*** 1.Lin J, Wang M, Hu H, et al. Multimodal-Imaging-Guided Cancer Phototherapy by Versatile Biomimetic Theranostics with UV and γ-Irradiation Protection. Adv Mater. 2016, 28:3273-3279.2.Xia L, Meng X, Wen L, et al. A Highly Specific Multiple Enhancement Theranostic Nanoprobe for PET/MRI/PAI Image-Guided Radioisotope Combined Photothermal Therapy in Prostate Cancer. Small. 2021, 17:e2100378.

EP-0053

Targeting Fibroblast Activation Protein using Radioactively Tagged Sibrotuzumab

A. Ingham[1], *R. De Gregorio[1], T. Viray[1], A. Loor[1], M. Harris[2], J. S. Lewis[1];*
[1]Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES OF AMERICA, [2]Clarity Pharmaceuticals, Eveleigh, AUSTRALIA.

Aim/Introduction: Fibroblast activation protein (FAP) has emerged as a promising target in the stroma of many epithelial tumours due to its expression on cancer-associated fibroblasts.1 Despite the success of imaging FAP with radioactively tagged fibroblast activation protein inhibitors (FAPIs), these small molecules can have limited therapeutic response due to their short residence time at the tumour.2 To improve upon the pharmacokinetics necessary for therapy, we have designed a two-stage project based on the antibody sibrotuzumab.3 The first stage requires validating that sibrotuzumab can image FAP with a high retention over several days, using [89Zr]Zr4+ and [64Cu]Cu2+. In the second stage, we aim to conjugate sibrotuzumab to [67Cu]Cu2+ and determine its effectiveness as a radiotherapeutic agent. ***Materials and Methods:*** PANC-1 and U87MG cell lines were cultured for radioligand binding assays and in vivo studies.4 Sibrotuzumab was conjugated with deferoxamine (DFO) and subsequently radiolabeled with [89Zr]Zr4+. [89Zr]Zr-DFO-sibrotuzumab was also used in magnetic bead binding studies to determine whether there was cross-reactivity between human and murine FAP. In the in vivo studies, each mouse was administered ~1.5 MBq of [89Zr]Zr-DFO-sibrotuzumab. Positron emission tomography/computed tomography (PET/CT) images were obtained at 24 and 144 h for the U87MG xenografted mice, while biodistribution studies were carried out over several days for PANC-1 and U87MG xenografted mice. ***Results:*** In vitro studies showed [89Zr]Zr-DFO-sibrotuzumab did not bind to PANC-1 cells; however, there was low, selective uptake (~3%) in U87MG cells. In the magnetic bead binding studies, the antibody was found to bind to human FAP and not murine FAP. As a negative control, PANC-1 xenografted mice had ~5 %IA/g of [89Zr]Zr-deferoxamine-sibrotuzumab in their tumours between 24 and 72 h. Encouragingly, in U87MG xenografted mice, the radiopharmaceutical achieved >20 %IA/g in tumours from 24 to 144 h, and no high uptake (>10 %IA/g) observed in any off-target organs. Conjugation of [64/67Cu]Cu2+ radioisotopes to sibrotuzumab is currently in-progress. ***Conclusion:*** [89Zr]Zr-DFO-sibrotuzumab had high uptake and retention at the tumour site of mice xenografted with U87MG cells. Given its promising pharmacokinetics, development of therapeutic radionuclide sibrotuzumab conjugates are in progress to assess its ability as a theranostic agent. ***References:*** 1. EP-0054

Immuno-PET imaging using a Cu-64 labeled GD2-specific antibody in osteosarcoma

Y. Ha, *H. Lee, H. Park, K. Lee, K. Kim;*
Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Osteosarcoma (OS) is a representative primary malignant tumor of the bone, in which normal bone tissue is destroyed by tumor cells, forming a mass, and spreading to surrounding tissues. When it metastasizes through the blood to the lungs or other bones, the 5-year survival rate is 20-30%, indicating a poor prognosis. Although advancements in surgical techniques and the development of effective chemotherapeutic drugs have improved overall patient survival, there is still a limitation of more effective treatment options for OS. Disialoganglioside GD2 is known to be overexpressed on the surface of some cancer cells, including OS, in contrast to normal tissues where expression is limited. Therefore, GD2 has a high value as an effective target for the diagnosis and treatment of OS using radiolabeled tracers. The purpose of this study is to evaluate the potential of an anti-GD2 antibody, hu14.18, for targeted imaging in OS xenograft mouse model. ***Materials and Methods:*** The hu14.18 was conjugated with p-SCN-Bn-NOTA at a molar ratio of 1:20 and labeled with Cu-64. The stability of Cu-64 labeled hu14.18 (Cu-64-NOTA-hu14.18) were tested in human and mouse serum. GD2 expression was measured by flow cytometric analysis in various OS cells. Cell binding study of Cu-64-NOTA-hu14.18 was performed to confirm the specific binding according to the GD2 expression level. Small animal PET imaging was performed at 24, 48 and 72 hours after an injection of approximately 7.4 MBq Cu-64-NOTA-hu14.18 in a GD2-positive OS cell (G-292) xenograft mouse model. ***Results:*** Cu-64-NOTA-hu14.18 was prepared with high radiolabeling yield and radiochemical purity and showed high stability. Flow cytometric and cell binding analysis showed that GD2 expression was highest in G-292 cells among several OS cell lines. High uptake in GD2 expressing tumors was observed in Cu-64-NOTA-hu14.18 PET images obtained from the G-292 tumor xenografted mouse model. ***Conclusion:*** Cu-64-NOTA-hu14.18 was shown to successfully target GD2 both in vitro and in vivo. Immuno-PET using Cu-64-NOTA-hu14.18 can non-invasively visualize the extent of GD2 expression in OS and may be an excellent strategy for planning GD2-targeted therapy in OS and monitoring treatment effectiveness.

EP-0055

Interleukin-4 Receptor Targeted Immuno-SPECT Imaging Visualizes Tumor-associated Macrophages in vivo.

M. Hu, *D. Zheng, Y. Wang, Y. Zhang, D. Jiang, X. Lan;*
Wuhan Union hospital, Wuhan, CHINA.

Aim/Introduction: Within the tumor microenvironment, the interplay between macrophages and tumor cells, alongside other immune cells, profoundly impacts tumor progression, metastasis, and the efficacy of immunotherapy. The Interleukin-4 receptor (IL-4r), a G-protein-coupled receptor predominantly found on immune cell membranes, serves as a specific biomarker for inflammatory diseases, and has recently emerged as a marker for inhibitory macrophages within the tumor immune microenvironment. In this study, IL-4r-targeted monoclonal antibody-based probe was constructed and evaluated in syngeneic models to verify its feasibility tracking tumor associated macrophages (TAMs), following cross-validation of molecular biology techniques. ***Materials and Methods:*** An anti-IL-4r monoclonal antibody (mAbIL-4r)-based radiotracer, 99mTc-HYNIC-mAbIL-4r, was developed through technetium-99 (99mTc, T1/2=6.0h) labeling after chelation with HYNIC. The radiolabeling yield, radiochemical purity and stability were verified. Western blot analysis confirmed IL-4r expression levels in various tumor cells (Panc2: Pancreatic cancer; CT26: Colon cancer; Siha: Cervical squamous-cell carcinoma; PC12: Adrenal pheochromocytoma). SPECT imaging and biodistribution were performed to evaluate IL-4r-tageted immune cells of 99mTc-HYNIC-mAbIL-4r. Immunofluorescence imaging and flow cytometry served as cross-validation methods for co-location of IL-4r expression. ***Results:*** 99mTc-HYNIC-mAbIL-4r was synthesized with high radiolabeling yields of 88.7% and radiochemical purity of 93.3%, alongside excellent radio-stability. The probe exhibited significant differential tumor uptake across varied IL-4r expression xenograft models, with consistent blood radioactivity levels. We then evaluated the image of 99mTc-HYNIC-mAbIL-4r in Panc2 and CT26 syngeneic models, after low tumor IL-4r expression proved by western blot. 99mTc-HYNIC-mAbIL-4r was primarily accumulated in the hearts, livers and spleens and remained in the blood pool for over 24 hours, which is consistent with long-cycle physiological characteristics of antibody. Both models demonstrated peak tumor-to-muscle uptake ratios at 36 hours post-injection (Panc2: 4.37±0.44; CT26: 4.08±0.40). Immunofluorescence imaging and flow cytometry corroborated high IL-4r expression in TAMs, particularly the M2 subtype of activated macrophages. ***Conclusion:*** This study successfully developed a 99mTc-labeled IL-4r-targeting antibody probe, effectively delineating IL-4r expression in preclinical tumor-bearing models via Immuno-SPECT. The findings shed light on the heterogeneity of macrophage activation and warrant further exploration for a comprehensive understanding of immuno-oncology, focusing on TAMs and their implications in tumor development and treatment response.

EP-0056

Preclinical development of a novel nanobody GPA33 tracer of [^{68}Ga]Ga-NOTA-WWH374 in colorectal cancer

C. Zheng[1], *X. Long[1], W. Wei[2], X. Lan[1,3], D. Jiang[1];*
[1]Huazhong University of Science and Technology, Wuhan, CHINA, [2]Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, CHINA, [3]Wuhan Union Hospital, Wuhan, CHINA.

Aim/Introduction: Glycoprotein A33 (GPA33) is a protein encoded by the GPA33 gene in humans. It is overexpressed in more than 95% of human colorectal cancers (CRC). The aim of this study is to identify a GPA33-targeted nanobody and to demonstrate its application in the imaging of CRC using immuno-positron emission tomography (immunoPET). ***Materials and Methods:*** The expression of GPA33 in CRC was verified by immunohistochemistry. The expression of GPA33 in colorectal cancer cell lines was investigated by flow cytometry. To construct immunoPET imaging probes of CRC subcutaneous xenografts, a nanobody targeting GPA33 was designed and labelled with gallium-68 (68Ga, T1/2 = 1.1 h). A GPA33-expressing cell-derived colorectal cancer model was used to evaluate the agent. ***Results:*** GPA33 was overexpressed in human CRC cells. Generation of a GPA33-specific nanobody, WWH374, was successful, and its in vitro binding properties were found to be excellent. Utilization of [68Ga]Ga-NOTA-WWH374 in immunoPET imaging was found to enable clear delineation of a subcutaneous tumor in cell-derived models of CRC. The diagnostic capability of [68Ga]

Ga-NOTA-WWH374 (0.50 ± 0.05 MBq, n = 4) was evaluated in mice bearing subcutaneous LS174T CRC cell-derived xenograft. The microPET/CT imaging results demonstrated the ability to sharply delineate the tumor at 2 h post-injection of [68Ga]Ga-NOTA-WWH374. The results of the region of interest (ROI) quantitative analysis demonstrated that the highest enrichment of [68Ga]Ga-NOTA-WWH374 was observed in the kidney, with a value of 41.30 ± 6.26%ID/g. The tumor uptake value was 2.87 ± 0.67%ID/g (n = 4). The subsequent biodistribution analysis data demonstrated the same trend of organ uptake as that observed in the ROI results. The highest accumulation was observed in the kidneys, with a value of 204.48 ± 42.35%ID/g. The tumor uptake value was 5.68 ± 1.15%ID/g (n = 4). ***Conclusion:*** In conclusion, we conducted preclinical development of a novel GPA33-targeted nanobody, which enabled to the non-invasive visualization of the malignancy of colorectal cancer using immunoPET imaging in a subcutaneous model.

EP-0057

^{68}Ga-NaGdF$_4$-RGD nanoprobesfor PET/MR Dual-Modal Imagingof cancer in Vivo

L. Kang[1], *S. Wu[2], W. Li[3], Q. Yang[1], L. Song[1], W. Huang[1], B. Cui[4], Y. Xu[3], J. Lu[4], Y. Zou[2], Y. Hou[3];*
[1]Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA, [2]Peking University First Hospital, Beijing, CHINA, [3]College of Life Science and Technology, Beijing University of Chemical Technology, Beijing, CHINA, [4]Xuanwu Hospital of Capital Medical University, Beijing, CHINA.

Aim/Introduction: The 68Ga-c(RGDCK) peptide PEGylated NaGdF4 nanoparticles (68Ga-NaGdF4-RGD) as a novel multi-modal imaging agent were developed for tumor-targeting PET/MR imaging of various tumors. ***Materials and Methods:*** Their biocompatibility and binding specificity were evaluated through in vitro and in vivo experiments The in vivo tumor targeting of the NaGdF4-RGD was demonstrated by taking T1 MR images in a model mouse with liver tumor, and the signals of tumor from PET imaging. The distribution and metabolism of the nanoprobes in the mice were examined by PET and MRI imaging. The in vivo PET/MR multimodal simultaneous imaging capability of 68Ga-NaGdF4-RGD nanoparticles was validated by a wider variety of tumor models. Additionally, the relationship between the targeting effect and integrin αvβ3 expression levels was explored. ***Results:*** The 68Ga-NaGdF4-RGD exhibit long-term serum stability after labeling with nuclides. The in vivo tumor targeting of the 68Ga-NaGdF4-RGD was demonstrated by taking T1 MR images and PET in a model mouse with liver tumor. The maximum standardized uptake value (SUVmax) of tumor radioactivity was 1.84 ± 0.30 and the biodistribution of the tumor was 5.12 ± 0.42 %ID/g at 3 hours after the injection of 68Ga-NaGdF4-RGD nanoparticles. In MRI imaging, the MRI signals of subcutaneous and orthotopic tumors of Hepa 1-6 after injection of NaGdF4-RGD nanoprobe were significantly higher than those of the corresponding NaGdF4 group ($P < 0.05$). This study employed NaGdF4-RGD nanoprobes to effectively reveal the persistent accumulation and blood redistribution properties of nanoparticles in liver tumors. PET/MR imaging verified the tumoral uptake was positively correlated with the expression level of integrin αvβ3. Three hours after injection, the ratios of radioactive uptake in tumors to muscle were 7.91 ± 2.17 for Renca, 6.18 ± 1.51 for Hepa 1-6, and 3.50 ± 1.48 for 4T1. ***Conclusion:*** The fact suggested that 68Ga-NaGdF4-RGD probes possessed satisfying tumor-specific targeting ability and should be the potential tumor-targeting multi-modal imaging agent. The nanoparticles permitted for synchronized PET/MR scanning and precise multimodal imaging fusion in various tumor models, both temporally and spatially. Additionally, the level of enrichment of the nanoprobes was found to reflect the expression level of integrin αvβ3 in tumors.

EP-0058

Preclinical evaluation of novel theranostic heterodimeric ligands [^{68}Ga]Ga/[^{177}Lu]Lu-DOTA-FAPI-BPsfor tumor bone metastasis

Y. Deng[1], *W. Jin[2], Z. Zhang[1], X. Wang[1], R. Zhao[1];*
[1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China, CHINA, [2]Beijing Normal University, Beijing, China, CHINA.

Aim/Introduction: The rising incidence of bone metastases poses challenges to cancer patient survival. Bone metastasis-induced skeletal-related events (SREs) significantly impact patient survival. Bisphosphonates (BPs), targeted bone imaging agents, have been widely used in clinical bone scanning, while fibroblast activation protein inhibitors (FAPIs) offer advantages in several cancer clinical diagnosis and therapy. To address the integrated diagnostic and therapeutic needs of tumor bone metastasis, this study designed two novel heterodimeric ligands, DOTA-FAPI-BPs (DFP-1, DFP-2) to improve the retention time in tumor, especially in the bone metastasis. ***Materials and Methods:*** Comparative evaluations were conducted between 68Ga and 177Lu-labeled DFP1, DFP2, and FAPI-04, including stability, lipophilicity, cellular uptake/internalization assays, hydroxyapatite binding, and PET/CT imaging studies in tumor-bearing and normal mice. PET/CT imaging utilized Pmod 4.4 for organ delineation and data post-processing, with statistical analyses performed using GraphPad Prism 8. ***Results:*** Synthesis of the desired heterodimeric ligands DFP-1, DFP-2 were effectively accomplished. Labeling with either [68Ga]GaCl3 and [177Lu]LuCl3 in the sodium acetate buffer (pH 4-5) at 95°C in 10 min produced [68Ga]Ga/[177Lu]Lu-DFP-1/2 with high yields and excellent radiochemical purities (>95%). [68Ga]Ga-DFP-1/2 showed high stability in PBS until 2 h and [177Lu]Lu-DFP-1/2 is stable until 5 days in PBS. All [68Ga]Ga/[177Lu]Lu-DFP-1/2 indicated lipophilicity. [68Ga]Ga/[177Lu]Lu-DFP-1/2 exhibiting significantly higher hydroxyapatite binding rates (> 90%) compared to [68Ga]Ga/[177Lu]Lu-FAPI-04 (< 10%). Furthermore, [68Ga]Ga-DFP-2 displayed increased high internalization/uptake in U87MG cells up to 2h (uptake: 4.22 % ID/106 cells), while both [177Lu]Lu-DFP-1/2 showed sustained internalization/uptake in U87MG cells up to 24h (uptake: 5.87 % ID/106 cells and 8.98 % ID/106 cells, respectively), significantly surpassing [177Lu]Lu-FAPI-04 at 24h (uptake: 0.65 % ID/106 cells, respectively). PET/CT imaging of [68Ga]Ga-DFP-1/2 revealed high uptake and prolonged retention in A549-FAP bone tumor (30 min: 2.85% ID/g and 2.57% ID/g; 60 min: 3.02% ID/g and 2.57% ID/g, respectively), contrasting with the rapid decrease in uptake observed with [68Ga]Ga-FAPI-04 (30 min: 3.68 % ID/g and 60 min: 1.99% ID/g, respectively). ***Conclusion:*** Our study successfully synthesized and evaluated novel heterodimeric ligands DFP-1 and DFP-2 for their potential application in the integrated diagnostic and therapeutic management of tumor bone metastasis.

EP-0059

Radiotracer Evaluation in the Chick Embryo Tumour Bearing Brain: A Feasibility Study

S. Krause[1], *A. Florea[2], C. Choi[1], W. A. Worthoff[1], A. Heinzel[1,3], S. Fischer[1], B. Neumaier[1], N. J. Shah[1,4,5], P. Lohmann[1,2], F. M. Mottaghy[2,5], K. J. Langen[1,2], C. Stegmayr[1,2];*
[1]Institute of Neuroscience and Medicine (INM-4; INM-5; INM-11), Forschungszentrum Jülich, Jülich, GERMANY, [2]Dept. of Nuclear Medicine, RWTH University Hospital Aachen, Aachen, GERMANY, [3]Dept. for Nuclear Medicine, Martin Luther University Halle-Wittenberg, Halle (Saale), GERMANY, [4]Dept. of Neurology, RWTH University Aachen, Aachen, GERMANY, [5]JARA - BRAIN - Translational Medicine, Aachen, GERMANY.

Aim/Introduction: In addition to traditional rodent models for preclinical research, the chick embryo model has gained attention for radiotracer evaluation. Previous studies investigated tumours on the chick chorioallantoic membrane, however, radiotracer imaging of intracerebral chick embryo tumours has not yet been evaluated. ***Materials and Methods:*** Fertilized chick eggs were incubated at 37.8°C with 54% humidity for 18-20 days. On developmental day 5, a window was cut in the eggshell to access the embryo, and human U87 glioblastoma or U87-IDH1 mutant glioma cells were implanted into the developing chick brain. Solid tumours were detectable with magnetic resonance imaging (MRI) after 12-14 days, and the tumour bearing embryos were chosen for next-day radiotracer evaluation. Blood-brain-barrier disruption was shown either with contrast agent injection for MRI, or ex vivo with injection of Evans blue dye. O-(2-$^{[18F]}$fluoroethyl)-L-tyrosine ($^{[18F]}$-FET) (n=3), 3,4-dihydroxy-6-$^{[18F]}$-fluoro-L-phenylalanine ($^{[18F]}$-FDOPA) (n=3), or [68Ga]-labelled quinoline-based small molecule fibroblast activation protein inhibitor ([68Ga]-FAPI-46) (n=4) was injected intravenously, and the chick embryos were sacrificed 60 minutes post injection. Cryosections of the tumour bearing brains were produced and evaluated by autoradiography and immunohistochemistry. In some chick embryos, micro positron emission tomography (µPET) was performed in addition to autoradiography. ***Results:*** The intracerebral implantation technique resulted in the formation of solid tumours with a success rate of 48% (n = 85). For the evaluated radiotracers, the tumour-to-brain ratios (TBR) derived from ex vivo autoradiography as well as the tracer kinetics derived from µPET for intracerebral chick embryo tumours were comparable to those previously reported in rodents and patients; the mean $^{[18F]}$-FET TBRs were 1.7 ± 0.5 for intracerebral chick embryo tumours, 2.2 ± 0.4 for rodents [1] and 2.0 ± 0.5 for patients [2]. Further, similar elimination pathways and $^{[18F]}$-FET clearance through hepatic/pancreatic and urinary excretion could be shown with whole-body µPET imaging. ***Conclusion:*** Intracerebral tumours in the chick embryo offer a fast and reliable model for the evaluation of radiotracer uptake, accumulation, and kinetics. Our results indicate a high comparability of chick embryo intracerebral tumour imaging to xenograft rodent models and brain tumour patients. ***References:*** [1] Stegmayr C, Bandelow U, Oliveira D et al. In Vivo Characterization of TMTH-Sulfoximine (TMTHSI)-Based Linker for the Development of Antibody-Tracer Conjugates

J. Man[1], *B. Weijers-Verduin[1], D. G. de Heer[1], N. A. van Ogtrop[1], P. M. Pereira[1], W. Beaino[1], M. Timmers[2], R. Liskamp[2], C. J. F. Rijcken[2], M. van Egmond[3,4], G. A. M. S. van Dongen[1], D. J. Vugts[1];*
[1]Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Radiology and Nuclear Medicine, Amsterdam, NETHERLANDS, [2]Cristal Therapeutics, Maastricht, NETHERLANDS, [3]Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Molecular Cell Biology and Immunology, Cancer Centre Amsterdam – Amsterdam Institute for Infection and Immunity, Amsterdam, NETHERLANDS, [4]Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Surgery, Cancer Centre Amsterdam, Amsterdam, NETHERLANDS.

Aim/Introduction: Antibody-drug conjugates (ADCs) typically consist of a monoclonal antibody (mAb) and a payload that are coupled to each other by a linker system. The classical linkers however are far from being ideal often due to their hydrophobic nature and/or poor reactivity. Recently, a new strain-promoted azide-alkyne cycloaddition (SPAAC) reagent with higher reactivity and hydrophilicity, called TMTH-Sulfoximine (TMTHSI), was developed. Here, as a first proof of principle, the applicability of TMTHSI as a linker for the coupling of a radiolabelled tracer to mAb for diagnostic imaging was investigated with 89Zr-labeled deferoxamine (DFO) and trastuzumab as a model antibody. ***Materials and Methods:*** The in vitro stability and in vivo tumour targeting of 89Zr-DFO-TMTHSI-trastuzumab were evaluated along with 89Zr-DFO-trastuzumab coupled via direct conjugation of a commonly used SPAAC reagent DBCO. Azide-modified trastuzumab was conjugated to DFO-TMTHSI or commercial DFO-DBCO, whereas its unmodified counterpart was used to conjugate commercial DFO-NCS. The mAb-linker-DFO complex was then radiolabelled with 89Zr. In vitro linker stability was determined by evaluating products formulated in 0.9% NaCl or histidine/sucrose buffer at 4°C. At various time points, aliquots were taken and analysed for radiochemical purity by SE-HPLC. In parallel, the biodistribution of the conjugates was assessed in NCI-N87 tumour-bearing nude mice over time. ***Results:*** 89Zr-DFO-TMTHSI-trastuzumab and 89Zr-DFO-DBCO-trastuzumab were more stable in vitro than their NCS-based counterpart under all conditions. Both TMTHSI- and DBCO-based conjugates remained ≥96% intact after 168h incubation at 4°C, irrespective of the buffer used for formulation. Contrastingly, only 80% and 90% intact NCS-based conjugate was left after 168h incubation in 0.9% NaCl and histidine/sucrose buffer, respectively. Biodistribution revealed that the highest uptake was in tumour tissue (about 25 %ID/g). In healthy tissue, tracer uptake was less than 10%ID/g, except for the spleen and bones. 89Zr-DFO-NCS-trastuzumab showed an increased spleen uptake over time resulting in ~11%ID/g at 144h. Little to no difference in spleen uptake was observed over time in DBCO- and TMTHSI-based conjugates (~5% and 4%ID/g at 144h, respectively). PET imaging revealed biodistribution patterns comparable to the ex vivo findings. ***Conclusion:*** Our findings support the use of TMTHSI for the development of antibody-tracer conjugate that can subsequently be used for diagnostic PET imaging. This development allows us to evaluate the in vivo performance of TMTHSI-based conjugates with different payloads and payload-to-antibody ratios, aiming to design ADCs with an optimal therapeutic index.

EP-0061

Inhibition of OXPHOS reduces tumor hypoxia and induces metabolic rewiring as measured by [18F]FDG

D. Boreel, *A. P. M. Beerkens, J. P. W. Peters, M. Boswinkel, G. J. Adema, P. N. Span, J. Bussink, S. Heskamp; Radboudumc, Nijmegen, NETHERLANDS.*

Aim/Introduction: Limited diffusion and increased consumption of oxygen leads to chronic hypoxia in most solid malignancies. Scarcity of oxygen is known to induce radioresistance, but also leads to a more immunosuppressive microenvironment and immunotherapy resistance. By the inhibition of OXPHOS, using mitochondrial inhibitor IACS-010759, we hypothesize that the oxygen demand of the tumor can be decreased. In turn this might lead to a durable normalization of the oxygen concentration, increased therapy efficacy, but potentially also affects metabolism of normal tissues. ***Materials and Methods:*** The effect of IACS-010759 on tumor hypoxia and glucose metabolism was investigated in spheroids and mouse tumor models. Spheroids were produced of murine tumor cells (B16ova, MC38 and MOC1.3D5) containing a hypoxia responsive element (HRE)-eGFP. Using a Live-Cell Analysis System, fluorescence of spheroids was measured over time as an indicator for hypoxia. Glucose uptake of spheroids treated with IACS-010759 was measured using [18F]FDG uptake assays (150kBq/spheroid). Furthermore, C57BL/6 mice bearing B16ova, MC38 or MOC1.3D5 tumors were treated with IACS-010759 (10mg/kg) for 4 consecutive days. Before sacrifice mice were injected with [18F]FDG (10MBq) and pimonidazole. [18F]FDG uptake in tumor and healthy tissue was measured by ex vivo activity counting. Hypoxic fraction was determined by immunohistochemical staining of pimonidazole. ***Results:*** B16ova, MC38 and MOC1.3D5 spheroids containing a HRE-eGFP construct showed fluorescent cores indicating hypoxia. OXPHOS inhibitor IACS-010759 reduced hypoxia in these spheroids at 3 hours post treatment while [18F]FDG uptake was significantly increased (all $P<0.001$). Treatment of mice with IACS-010759 resulted in a reduction of pimonidazole on B16ova, MC38 and MOC1.3D5 tumors sections (all $P<0.05$). Blood glucose levels were not altered, but serum lactate was significantly increased following treatment with IACS-010759 (8.5±1.7mM vs. 12.7±1.4mM). Moreover, [18F] FDG uptake in several healthy organs was significantly increased. ***Conclusion:*** We showed that inhibition of OXPHOS can reduce hypoxia in spheroids and tumors, potentially increasing radio and immunotherapy efficacy. Furthermore, we show tumor cells are metabolically plastic and switch their metabolism from OXPHOS to glycolysis when OXPHOS is pharmacologically inhibited, resulting in increased glucose uptake in tumor cell spheroids. In vivo we observed increased serum lactate levels and increased [18F] FDG uptake in several healthy tissues, but not in the tumor. These systemic effects call for caution when administering OXPHOS inhibitors in a clinical setting, which is in line with adverse effects observed in clinical trials. More selective tumor targeting or less potent OXPHOS inhibitors might be a solution to reduce toxicity.

EP-0062

Development of a Folate-conjugated Albumin/ICG Complex for Preoperative Targeting in Image-Guided agent of Uterine Cancer Metastasis

J. Kim[1,2], *J. Park[1,3,4], Y. Chung[1,2], J. Kim[3], R. Yoo[3,5], Y. Shin[3], Y. Lee[6], K. Lee[6], Y. Lee[1,7,8];*
[1]Department of Nuclear Medicine, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [2]The Interdisciplinary Program of Cancer Biology, Seoul, KOREA, REPUBLIC OF, [3]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [4]Institute of Radiation Medicine, Medical Research Center, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [5]Biomedical Research Institute, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [6]Division of RI application, Korea Institute of Radiological and Medical Sciences (KIRAMS), Seoul, KOREA, REPUBLIC OF, [7]. Institute of Radiation Medicine, Medical Research Center, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [8]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Endometrial cancer originates in the lining of the uterus and can potentially metastasize to distant areas such as the lymph nodes in the cervix, abdomen or groin. The use of fluorescence-guided surgery based on indocyanine green (ICG) for sentinel lymph node (SLN) removal is used as a standard procedure for staging evaluation during uterine cancer surgery, despite the absence of targeting ability and washout issues. Therefore, this study aims to develop a contrast agent with enhanced in vivo compatibility and cancer-targeting capabilities to improve diagnostic accuracy while minimizing the need for extensive resection. ***Materials and Methods:*** Folate was conjugated to albumin through click chemistry (Alb-Fol), and quantified by Matrix-assisted Laser Desorption Ionization Time-of-Flight (MALDI-TOF). To determine the optimal concentration of ICG, it was mixed with Alb-Fol at various molar ratios (Alb-Fol/ICG), and analyzed using in vivo imaging system (IVIS). In vitro studies with KB cells were performed to measure binding affinity of folate through cell uptake and binding assays. For in vivo study, [64Cu]Cu- Alb/ICG and [64Cu]Cu- Alb-Fol /ICG were intravenously injected into mouse model with peritoneal tumor and IVIS and PET images were obtained at various intervals. After 24 hours, the tumors were excised, and the images from before and after surgery were compared. ***Results:*** The degree of functionalization (DOF) of folate was 3 (Alb-Fol3), and the optimal ratio of ICG was 2.5 to albumin. Cell uptake experiments based on the number of folate moieties, Alb-Fol3/ICG showed the highest uptake, with a Kd value of 36.9 nM. In vivo study, fluorescence and PET images were observed in metastatic cancers within the abdominal cavity, including intestines, uterus, pancreas and peritoneum. After excision, it was confirmed that fluorescence signals did not remain in organs except the kidneys. ***Conclusion:*** In this study, an optimized Alb-Fol3/ICG complex was developed to specifically target primary and lymph node metastatic endometrial cancer, aiming to minimize resection surgery. In a peritoneal metastasis model, it was observed that the retention time increased compared to conventional ICG and Alb/ICG complexes. Particularly, Alb-Fol3/ICG was found to be concentrated at the tumor site after 24 hours, suggesting its potential for effective operation using fluorescence imaging.

EP-0063

Preclinical assessment of ^{68}Ga-labeled CD38 Peptide for PET Imaging of pharmacokinetics in multiple myeloma

L. Kang[1], *Q. Yang[1], L. Song[1], W. Huang[1], X. Sun[1], T. Wang[1], Z. Wang[2];*
[1]Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA, [2]National Center for Nanoscience and Technology of China, Beijing, CHINA.

Aim/Introduction: Multiple myeloma (MM) is a heterogeneous disease with different clinical manifestations and prognosis. Despite conventional chemotherapy and radiotherapy, MM is

highly aggressive. CD38 is highly expressed on the surface of MM cells, making it a characteristic tumor biological target of MM. CD38-targeted peptide, PF381, can overcome limitations of antibodies and achieve precise imaging of tumor sites, providing the possibility for early diagnosis of tumors and dynamic monitoring of immunotherapy. In this study, the diagnosis role of 68Ga-labeled PF381, biodistribution and dosimetry were investigated in tumor-bearing models. ***Materials and Methods:*** After obtaining amino acid sequence through screening of combinatorial chemistry peptide library based on microchip, we synthesized CD38 peptide, PF381, by solid phase synthesis using standard Fmoc scheme. Surface plasmon resonance (SPR) method was used to detect the affinity between PF381 and human CD38 protein. Relative CD38 expression in H929, 8226, U266 and K562 cell lines was assessed using western blot. PF381 was conjugated with 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) for radiolabeling with 68Ga (t1/2 = 67.7 min). PET imaging was performed after injection of 68Ga-PF381 after the lymphoma tumor-bearing murine model was established. Further, we conducted biodistribution analysis 30 minutes after injection to analyze the differences in radioactive distribution and uptake of CD38 positive tumor H929 and negative tumor U266. ***Results:*** The SPR signal of PF381 gradually increased with the increase of protein concentration, and the KD value reached 10-8 M, indicating that PF381 has a strong affinity for CD38. For HPLC, the radiolabeling efficiency of 68Ga-PF381 was nearly 70%. PET imaging of 68Ga-PF381 showed that, significant radioactive concentration was observed 30 minutes after injection in H929 tumor model, and lasted until 80 minutes . In U266 tumor model, no significant radioactive concentration was observed at all time points. The above results of imaging suggest the high uptake of tumors from radiolabeled PF381. The biodistribution results showed that the uptake of H929 tumors (0.75 ± 0.03%ID/g) is higher than that of U266 tumors (0.26 ± 0.08%ID/g, P<0.01), which was consistent with PET imaging results. ***Conclusion:*** We developed a novel peptide targeting CD38 and proved 68Ga-labeled PF381 had rapid targeting and good tumor penetration ability. Therefore, 68Ga-labeled PF381 could achieve high sensitivity in vivo imaging of multiple myeloma.

EP-0064

Development of ^{68}Ga-DOTA-BP1 peptide PET tracer for detecting BCMA expression in multiple myeloma

L. Kang, *L. Song, Q. Yang, W. Huang, X. Sun, T. Wang;*
Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA.

Aim/Introduction: Evaluating multiple myeloma on a systemic scale in a noninvasive, dynamic, and validated manner holds significant clinical importance. B-cell maturation antigen (BCMA) has emerged as a promising focal point for diagnosing and treating multiple myeloma (MM). Therefore, the development of effective non-invasive methods for detecting BCMA-overexpressing lesions is crucial for screening and evaluating the efficacy of patients undergoing BCMA-targeted therapies. ***Materials and Methods:*** We employed a high-throughput microarray chip strategy to screen BCMA-targeting peptides from a one-bead-one-compound peptide library. The dissociation constants (KD) of the peptide ligands from BCMA proteins were determined using surface plasmon resonance imaging (SPRi). Specificity and affinity of the peptides were assessed by flow cytometry. BP1 coupled to 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA) was 68Ga-labeled, and negative control (NC) peptide served as a control. After establishing BCMA-positive (H929) and BCMA-negative (K562) subcutaneous tumor models, 68Ga-labeled targeted BCMA peptides were injected. Subsequent PET imaging, biodistribution, and immunohistochemical staining studies were conducted to assess the imaging utility of 68Ga-DOTA-BP1 in BCMA tumor models. ***Results:*** SPR and flow cytometry confirmed the specific affinity of BP1 for BCMA. 68Ga-DOTA-BP1 had a radiolabeling rate of over 99%. The maximum intensity projection (MIP) results revealed that, in the H929 tumor model, the radiation concentration of 68Ga-DOTA-BP1 was detectable immediately 10 minutes after injection, with a sustained high uptake observed from 10 to 60 minutes. Conversely, in the K562 tumor model, no significant radioactive concentration was observed. Furthermore, the uptake of 68Ga-DOTA-BP1 in H929 tumors surpassed that of 68Ga-DOTA-NC at all time points. Biodistribution findings at 20 minutes post-injection supported the PET imaging outcomes. The uptake of the BP1 probe was notably greater in H929 tumors (3.48 ± 0.68 %ID/g) than in K562 tumors (1.51 ± 0.26 %ID/g) and also exceeded the negative peptide uptake in H929 tumors (0.98 ± 0.50 %ID/g, P<0.05). The analysis of immunofluorescence staining revealed significantly elevated levels of BCMA expression in H929 tumors, characterized by a pronounced green intensity. Conversely, BCMA expression was observed to be lower in K562 tumors. The histopathological staining results aligned perfectly with the aforementioned imaging data, collectively affirming the robust BCMA targeting affinity of BP1. ***Conclusion:*** 68Ga-DOTA-BP1 displayed substantial and rapid tumor uptake in a BCMA-positive multiple myeloma model. These results suggest that 68Ga-DOTA-BP1 has the potential to identify BCMA expression levels for diagnosing BCMA-related tumors. In conclusion, 68Ga-DOTA-BP1 can rapidly and accurately delineate tumors, making it an ideal tool.

EP-0065

Before-after Study of FAPI-04 and the Leading FAP-targeting Radioligands in the Same Mouse

X. Cui[1]***,*** *Z. Liu*[2]*;*
[1]Changping Lab, Beijing, CHINA, [2]Peking University, Beijing, CHINA.

Aim/Introduction: Recently, we reported a novel modality called covalent targeted radioligand (CTR), which was installed with a sulphur (VI)-fluoride exchange (SuFEx) chemistry-based linker and successfully prevented the excessively fast tumour clearance on fibroblast activated protein (FAP). However, in previous work, FAPI-04 was the only control and no comparative evaluation of other reported leading FAP radioligands was performed. Therefore, we performed a before-and-after study with FAPI-04 in the same mice to robustly compare representative leading FAP radioligands, including our hit (CTR-FAPI). ***Materials and Methods:*** The interaction types of 177Lu-labelled FAP-radioligands were assessed by SDS-PAGE-autoradioluminography tandem assay. HT-1080-FAP cell uptake kinetic profiles of 68Ga-labelled FAP radioligands were then obtained. 68Ga-FAPI-04 was used as an 'internal standard' for comparison of various 68Ga-labelled FAP radioligands in identical cell-derived or patient-derived xenografts (CDX or PDX) based on PET/CT imaging. The SPECT/CT imaging of 177Lu-labelled FAP-radioligands was finally performed to study the dosimetry. ***Results:*** Among the leading FAP-radioligands, e.g. FAP-2286, only CTR-FAPI showed persistent FAP ligation (over 90% ligation yields and at least 144 h covalent binding with FAP). 68Ga-CTR-FAPI also showed higher and faster tumour uptake in cells. 68Ga-PET/CT imaging in the same CDX or PDX mice verified that the CTR-

FAPI had the highest tumour uptake and tumour-to-normal ratio. In addition, 177Lu-SPECT/CT imaging demonstrated a superior dosimetry profile for CTR-FAPI. ***Conclusion:*** The study indicated that covalent engineering based on SuFEx is a competitive strategy to improve tumour uptake and prolong residence time. Further clinical evaluation of 177Lu-CTR-FAPI is underway and this strategy is being applied to other targets.

EP-0066

Clinical potential of ananobody-based PET radiotracer^{68}Ga-TOHP-CD3813 for myeloma imaging

L. Kang, *W. Huang, Q. Yang, L. Song, X. Sun, T. Wang;*
Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA.

Aim/Introduction: Daratumumab (DARA) is an anti-CD38 monoclonal antibody for the treatment of multiple myeloma (MM). The tumor CD38 expression level is one of the important factors in determining the efficacy of DARA treatment. Therefore, there is an urgent clinical need for a noninvasive tool to evaluate the CD38 levels in cancer patients before DARA treatment. In this study, we prepared a new molecular imaging probe 68Ga-TOHP-CD3813, the 68Ga-labeled nanobody CD3813, for noninvasive imaging of CD38 expression by PET/CT. ***Materials and Methods:*** Nanobodies were genetically engineered to contain a tag (LPETG) at their C-terminus, which could be recognized by sortase A. Preparation of the 68Ga-nanobody by site-specific labeling. In vitro, fluorescein dye conjugated CD3813 was used to evaluate the cellular uptake. CD38-positive Ramos cells and CD38-negative U266 cells were implanted subcutaneously to build lymphoma murine models. Serial small animal PET imaging was performed after injection of 68Ga-TOHP-CD3813. PET data were analyzed by drawing ROI. Biodistribution study and histological staining were performed at the end of time point. ***Results:*** SDS-PAGE results showed that the molecular weight of CD3813 was about 15 kDa. Fluorescein dye conjugated CD3813 bound with cell membrane, observed by microscopy. After conjugated with TOHP, the CD3813 were labeled with 68Ga (labeling yield > 95%). PET imaging showed 68Ga-TOHP-CD3813 had a rapid and high tumor uptake as early as 1 h post-injection (0.21 ± 0.03 %ID/g) and reached the peak at 2 h (0.26 ± 0.05 %ID/g) in Ramos model (n = 4). In addition, 68Ga-TOHP-CD3813 had very low uptake in the U266 model. Biodistribution results at 2 h post-injection verified the PET imaging results. Finally, immunofluorescent staining confirmed the Ramos tumor showed strong expression of CD38. ***Conclusion:*** 68Ga-TOHP-CD3813 is a promising PET radiotracer for imaging the CD38-positive tumors and has clinical potential as a molecular imaging tool for evaluation of the CD38 expression level in patients before DARA treatment.

EP-0067

Development of a ^{68}Ga-labeled molecular probe targeting insulinoma based on glucagon-like peptide-1 receptor antagonists

T. Li, *Y. Wu, Y. Luo;*
Department of Nuclear Medicine, Peking Union Medical College Hospital, Beijing, CHINA.

Aim/Introduction: Insulinoma is a rare type of neuroendocrine tumor that still lacks an effective diagnostic approach[1]. Glucagon-like peptide-1 receptor (GLP-1R) exhibits significant upregulation in insulinomas[2]. In 2014, our group conducted the first clinical trial of a positron emitting nuclide labelled exendin-4 in localizing insulinomas. However, owing to the agonistic nature of Exendin-4 towards GLP-1R, a variable reduction in blood glucose levels ensues post-administration of 68Ga-NOTA-exendin-4 in insulinoma patients, thereby accentuating the associated risk. Consequently, we pioneered the synthesis of 68Ga-NOTA-exendin (9-39), a GLP-1R antagonist, aimed at enhancing tracer safety and facilitating positron emission tomography (PET) imaging in mouse models of insulinoma. ***Materials and Methods:*** Exendin (9-39) was synthesized by peptide solid-phase synthesis[3], and the bifunctional chelator 1,4,7-triazacyclononane-N,N,N-triacetic acid (NOTA) was modified at the N-terminus (Asp) and different lysine (Lys) sites of the peptide to construct Lys12-NOTA-Exendin (9-39), Lys27-NOTA-Exendin (9-39) and Asp09-NOTA-Exendin (9-39) probe precursors. 68Ga-NOTA-exendin (9-39) was obtained by reacting with 68Ga-GaCl3 solution. Radiochemical purity (RCP) was analyzed by radio-HPLC. Subsequently, the stability, affinity, selectivity, and pharmacokinetics of the probes were investigated to evaluate the performance of the novel molecular probes. ***Results:*** The RCP of 68Ga-NOTA-Exendin (9-39) modified at three different amino acid sites exceeded 90% and their 24-hour serum stability reached 95%. The dissociation constant (Kd) of GLP-1R was approximately 1 μM. Subsequently, probes were injected into tumor-bearing mice via the tail vein. It was observed that 68Ga-Asp09-NOTA-Exendin (9-39) exhibited significant accumulation in the tumor tissue within 1 h, predominantly excreted through the kidneys and bladder. In the blocking group, administered with a 100-fold excess of Asp09-NOTA-Exendin (9-39) precursor, there was no discernible enrichment of tumor tissue. Furthermore, 68Ga-Lys12-NOTA-Exendin (9-39) and 68Ga-Lys27-NOTA-Exendin (9-39) did not exhibit significant accumulation in tumor regions. ***Conclusion:*** We have devised a pioneering PET probe utilizing the GLP-1R antagonist, demonstrating effective tumor tissue accumulation. Notably, its administration does not precipitate hypoglycemia in patients, suggesting a promising clinical potential for this probe. ***References:*** [1] SADA A, et al. Malignant Insulinoma: A Rare Form of Neuroendocrine Tumor [J]. World journal of surgery, 2020, 44(7): 2288-94. [2] KöRNER M, et al. Modification of the tumor microenvironments (TME) induced by [^{177}Lu]Lu-LNC1004

S. So[1,2,3], *H. Oh[1,3], J. Kim[1,2,3], S. Lee[1,3], M. Kim[1,2,3], J. Lee[1,3], K. Kang[1,3,2], G. Cheon[1,4,3], H. Youn[1,3];*
[1]Department of Nuclear Medicine, Cancer Imaging Center, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [2]Department of Biomedical Sciences, Seoul National University Graduate School, Seoul, KOREA, REPUBLIC OF, [3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF, [4]Department of Molecular Medicine and Biopharmaceutical Science, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Cancer-associated fibroblasts (CAFs) has a crucial role in tumor microenvironment (TME) and driving tumor progression. Fibroblast activation protein (FAP) has been regarded as one of the promising targets for molecular imaging and targeted therapy as FAP overexpression in CAFs has been reported over 90% of human epithelial carcinomas. In this study,

we aimed to evaluate the changes of TME by the specific delivery of internal radiation targeting FAP as a theranostics tool. ***Materials and Methods:*** The HT1080-hFAP cell line was established by transfection with the recombinant lentiviral plasmid expressing human FAP (hFAP). The expression of hFAP in HT1080 cells was detected by qRT-PCR and Western blotting. HT1080-hFAP cells were transplanted into female Balb/c-nude mice (6-weeks-old). LNC1004 (Evans Blue conjugated FAP Inhibitor) was kindly provided by Dr. Xiaoyuan (Shawn) Chen. Radiolabled-LNC1004 with [177Lu]Lu and [68Ga]Ga were injected intravenously into the tail vein. Subsequently, the animals that underwent SPECT/CT imaging were sacrificed, and tumors were extracted for FACS and IHC. ***Results:*** On qRT-PCR and Western blot analysis, approximately 100,000-fold and around 22-fold higher hFAP expression was observed in HT1080-hFAP compared to the control, HT1080. The uptake of [68Ga]Ga-LNC1004 peaked at 3 hours, and measured at 6.96 ± 2.86 %ID/g. [177Lu]Lu-LNC1004 exhibited signals in the heart and bladder at 1 hour, with observable uptake in HT1080-hFAP cells starting at 8 hours, reaching its peak at 48 hours. FACS results showed that the proportion of B cells increased 1.4 times in the treatment group compared to the control group, while myeloid-derived suppressor cells (MDSC), which have an immunosuppressive function, decreased slightly by about 1.2 times in the treatment group. IHC was performed to evaluate the changes in Programmed death-ligand 1 (PD-L1) expression, a key player in tumor immune evasion, showing a decrease following internal radiation therapy. ***Conclusion:*** LNC1004 retained the HT1080-hFAP tumor for a sufficient duration allowing internal radiation to induce modifying the tumor microenvironment, compared to the other FAPI probes with rapid clearance. In this study, [68Ga]Ga-LNC1004 was suitable for imaging and [177Lu]Lu-LNC1004 treatment seemed to promote B cell infiltration and deprivation of MDSC. Whereas it decreased the expression of PD-L1, known as induce T cell exhaustion and immune tolerance. These findings suggest that [68Ga]Ga/ [177Lu]Lu-LNC1004 can be used as a theranostic pair to modify the tumor microenvironment.

EP-0069

Development and preclinical evaluation of a novel radioimmunoconjugate targeting BCMA in multiple myeloma.

N. Mourot[1,2], *S. Anguille[2], T. Van den Wyngaert[1], F. Elvas[1];*
[1]Molecular Imaging and Radiology (MIRA), University of Antwerp, Wiljrik, BELGIUM, [2]Laboratory of Experimental Hematology, University of Antwerp, Wiljrik, BELGIUM.

Aim/Introduction: Multiple myeloma (MM) is characterized by the abnormal proliferation of plasma cells within the bone marrow (BM). Considerable advances over the years have improved the diagnosis, management, and treatment of MM patients. Nevertheless, patients still relapse, indicating the presence of residual disease below the level of detection. The B-cell maturation antigen (BCMA) is a transmembrane glycoprotein involved in the proliferation and maturation of plasma cells. Importantly, BCMA is selectively expressed on the surface of malignant plasma cells in most MM cases. We aimed to develop an anti-BCMA ImmunoPET imaging strategy to visualize the expression of BCMA in MM. ***Materials and Methods:*** We designed a novel radioimmunoconjugate targeting BCMA based on belantamab (GSK2857914). This antibody (Ab) was first conjugated at different molar excess (4- and 20-fold), to the bifunctional chelator DFO* (DFO*-pPhe-NCS), and its affinity was evaluated by indirect ELISA. Subsequently, the Ab conjugate was radiolabelled with 89Zr and purified, as reported previously.1 Quality control was performed by size exclusion chromatography-high performance liquid chromatography (SEC-HPLC) and instant thin-layer chromatography (iTLC). The radioimmunoconjugate was further characterized in vitro using BCMA-transduced K562 and wild-type K562 (for nonspecific binding) cells to determine the immunoreactive fraction, the binding affinity, and the internalization kinetics. BCMA expression and binding of Ab conjugates were assessed using Fluorescence Activated Cell Sorting (FACS). ***Results:*** We have selected the DFO*-Belantamab conjugate (4-fold excess), showing the highest affinity for BCMA, with a dissociation constant (Kd) of 0.53 ± 0.01 nM and a preserved affinity compared to the native belantamab (Kd~ 0.28 ± 0.02 nM). FACS results confirmed BCMA expression of the BCMA-K562 cell line and specific binding of the immunoconjugate. [89Zr]Zr-DFO*-Belantamab was obtained with a non-decay corrected radiochemical yield of 90%, >95% radiochemical purity and 74.37 ± 14.7 MBq/mg specific activity (at end of production). The radiotracer remained stable over 7 days with a radiochemical purity >80%. In vitro assays demonstrated good affinity (Kd = 4.01 ± 0.63 nM) and immunoreactivity (about 52%) of the radioimmunoconjugate. [89Zr]Zr-DFO*-Belantamab showed slow internalization in BCMA+ K562 cells, which was maximum at 24 hours (18.2%). ***Conclusion:*** [89Zr]Zr-DFO*-Belantamab was successfully produced and showed favorable stability and binding affinity, supporting further validation as a potential novel immunoPET imaging agent of BCMA expression for in vivo studies. ***References:*** 1. Dewulf, Jonatan et al. "Immuno-PET Molecular Imaging of RANKL in Cancer." Cancers vol. 13,9 2166. 30 Apr. 2021, doi:10.3390/cancers13092166.

EP-0070

Exploring the therapeutic potential of BNCT for soft tissue sarcomas using F^{18}-FBPA PET/CT.

K. Isohashi[1], *K. Ono[2];*
[1]Osaka University, Suita, JAPAN, [2]Osaka Medical and Pharmaceutical University, Tatsuki, JAPAN.

Aim/Introduction: Boron neutron capture therapy (BNCT) destroys tumor cells using high-LET alpha particles and Li nuclei produced by the nuclear reaction between neutrons and boron (10B). Successful BNCT requires tumor-selective uptake of 4-10B-boron-l-phenylalanine (10B-BPA), and PET can be used with 10B-boron-2-18F-fluoro-l-phenylalanine (18F-FBPA) to estimate the amount of 10B-BPA in the tumor. This study investigated the accumulation of 10B-BPA in soft-tissue sarcomas, which are radioresistant tumors, and the possible therapeutic effect of BNCT with 18F-FBPA PET/CT. ***Materials and Methods:*** Nine patients with soft-tissue sarcoma who underwent 18F-FBPA PET/CT prior to surgery were included (6 males, 3 females; mean age ± SD, 67 ± 14 years). Tumor uptake was quantified by measuring the maximum standardized uptake value (SUV max) and tumor/blood radioactivity ratio (T/B ratio). SUV max and T/B ratio were compared with histopathological grade and Ki-67 expression, respectively. Sarcoma grading was performed using the French Federation of Cancer Centres Sarcoma Group (FNCLCC) and Ki-67 was measured using MIB-1 immunohistochemistry. ***Results:*** Six patients had FNCLCC grade III and three had FNCLCC grade II. SUV max was 4.7 ± 0.8 for grade III and 3.0 ± 0.5 for grade II, with a statistically significant difference between them ($P < 0.05$). SUV max and T/B ratio were significantly correlated with Ki-67 respectively ($P < 0.05$). T/B ratios were 3.8 ± 0.8 for grade III and 2.6 ± 0.5 for grade II. These are T/B ratios of 2.0 or higher, indicating

a potential therapeutic effect of BNCT. ***Conclusion:*** Soft-tissue sarcomas of grade II or higher can be expected to benefit from treatment with BNCT.

EP-0071

Site-specific ^{68}Ga-labeled nanobody for PET imaging of CEACAM5 expression in preclinical tumor models

Z. Deng, *Z. Yang;*
Peking University Cancer Hospital & Institute, Beijing, CHINA.

Aim/Introduction: Here, we aim to identify a nanobody targeting CEACAM5 and demonstrate its application in positron emission tomography (PET) imaging in non-small cell lung cancer (NSCLC). ***Materials and Methods:*** The CEACAM5 expression and localization of H3122, H2228, PC9, HCC827 and H1975 were confirmed by western blotting, flow cytometry and immunofluorescence. [68Ga]Ga-NB41 was synthesized by site-specifically conjugating [68Ga]Ga with 1,4,7-triazacyclononane-1,4,7-triacetic acid (NOTA) and purified with a PD-10 column. Quality control, metabolic characteristics and cellular uptake were performed on [68Ga] Ga-NB41 to analyze the probe properties. Crucially, small-animal PET imaging and biodistribution studies were performed in CEA-over expressed H3122 and CEA-low expressed H1975 tumor models. ***Results:*** CEACAM5 was highly expressed in H3122, successively decreasing in H2228, PC9, and HCC827 cells, and no expression in H1975. The radiochemical purity was over 99% when purified by PD-10 column and maintained over 90% in saline or 5% human serum albumin over 3h. [68Ga] Ga-NB41 showed significantly higher uptake in CEACAM5 high-expression cells than that in CEACAM5 low-expression cells.The biological half-life of distribution and clearance phases were 2.067 min and 52.81 min, respectively. In vivo immunoPET imaging showed that the probe had high tumor targeting ability in CEACAM5 positive tumors and increased accumulation of H3122 tumors within 3h, manifesting good retention effect, compared with the control. Similarly, the biodistribution of the probe showed high accumulation in H3122 tumor with the uptake of 5.71±1.09 ID%/g, which was much higher than that in H1975 (0.32 ± 0.17 ID% / g, P <0.001). Besides, the uptake of H3122 tumor could be specifically blocked (2.70 ± 0.27 ID% / g, P=0.02) when co-injected with 50 μg cold precursor, while the uptake of H1975 had no significant change (0.37±0.03 ID%/g,P=0.68). ***Conclusion:*** [68Ga]Ga-NB41 bears high targeting ability and specificity for CEACAM5, and shows great potential in the diagnostic detection of CEACAM5-positive tumors. The development of radioactive probes may provide new ideas for the precise diagnosis of tumors and the formulation of subsequent clinical treatment plans.

EP-0072

Development and Evaluation of [^{68}Ga]Ga-DOTA-COL Peptide Tracer for Probing Collagen Damage

P. Wang, *Q. Chen, B. Zhang, Y. Yang, F. Xiong, Z. Wang, S. Cheng, X. Zhu, B. Yu;*
Department of Nuclear Medicine, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Local ablation of hepatocellular carcinoma (HCC) is one of the major paradigms in clinical treatment, which confronts the challenge of interpretation of post-ablation imaging. As the extracellular matrix (ECM), including a large amount of collagen deposition,the generation of the damaged collagen is accompanied by the ablation procedures simultaneously. Furthermore, collagen damage leads to ECM changes exerting tumor-promoting functions. Thus, characterization of the damaged collagen status shows the potential to predict tumor response post local ablation. Herein, we designed a peptide-based PET tracer [68Ga]Ga-DOTA-COL for probing collagen damage. This study aims to evaluate the feasibility of [68Ga]Ga-DOTA-COL PET tracer for detecting collagen damage in the percutaneous ethanol injection (PEI) ablation model. ***Materials and Methods:*** We synthesized a collagen-targeted molecular imaging probe, [68Ga]Ga-DOTA-COL, which was efficiently prepared manually and performed a series of in vitro and in vivo assays to test its specificity. Pharmacokinetics and biodistribution studies of [68Ga]Ga-DOTA-COL in the KM mice and hepa1-6 tumor-bearing mice, respectively. Next, longitudinal [68Ga]Ga-DOTA-COL PET imaging detected tumor response in hepa1-6 tumor-bearing mice post PEI. H&E and immunohistochemical staining analyzed the pathological features ***Results:*** [68Ga]Ga-DOTA-COL was prepared within 30 min, with a radiochemical purity of over 99%. [68Ga]Ga- DOTA-COL was rapidly cleared from the body. The pharmacokinetics of [68Ga]Ga-DOTA-COL in mice showed a two-phase decay with a very short distribution phase half-life of 0.46 minutes and an elimination phase half-life of 12.08 minutes. In Hepa1-6 tumor xenografts, tumor uptake of [68Ga]-DOTA-COL in the PEI treatment group was significantly higher than the control group at 1 h after injection (SUVmax: 0.36 ± 0.047 and 0.14 ± 0.035, p = 0.00626). H&E results showed the lesion degree of tumor tissue was reduced in the PEI treatment group compared with the control group. IHC demonstrated that Ki67 was lower in the PEI treatment group than in the control group on day 5, indicating high-level accumulation [68Ga]Ga-DOTA-COL was positively correlated with the PEI-damaged lesions. Interestingly, we found that the probes had longer tumor retention times in the PEI-treated group compared to the control group and the ratio of Tumor/Muscle at 4 h after injection (9.06 ± 2.21 vs. 4.78 ± 1.60). ***Conclusion:*** Our results demonstrated the feasibility of [68Ga]Ga-DOTA-COL for monitoring collagen damage in the PEI ablation model. The clinical application of this new PET tracer will be explored to evaluate the HCC response in interventional oncology in future research.

Ga-68-Labelling of Tetrahydroquinoline-Based Compound as a PET Tracer for C-X-C Chemokine Receptor Type 4 Imaging

S. Yaset[1,2,3], *P. Suwattananuruk[1,3], A. Kanasuwan[2], S. Sriwongta[1,3,4], C. Chotipanich[2], P. Rojsitthisak[1,3], O. Vajragupta[1,3];*
[1]Department of Food and Pharmaceutical Chemistry and Center of Excellence in Natural Products for Ageing and Chronic Diseases, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, THAILAND, [2]National Cyclotron and PET Centre, Chulabhorn Hospital, Bangkok, THAILAND, [3]Molecular Probes for Imaging Research Network, Faculty of Pharmaceutical Sciences, Chulalongkorn University, Bangkok, THAILAND, [4]Faculty of Radiological Technology, Rangsit University, Pathum Thani, THAILAND.

Aim/Introduction: The C-X-C chemokine-receptor type 4 (CXCR4) is an emerging target for cancer drug development due to its high expression in cancer cells, particularly during metastasis. This study aimed to develop a new PET tracer for CXCR4 imaging. The potent tetrahydroquinoline-based CXCR4 antagonist, TIQ15 (IC50 = 5 nM)1, was selected as a tracer to prepare a bifunctional chelator (BFC) for Ga-68 labeling. ***Materials and Methods:*** TN-01, a BFC for Ga-68 labeling, was synthesized by conjugating TIQ15 with p-NCS-Bz-NODA-

GA. Semi-preparative HPLC was utilized to purify TN-01, and spectroscopy methods (IR, NMR, and HRMS) were employed to determine its structure. Ga-68 was directly radiolabeled onto BFC for 15 minutes at 70°C in 0.1 M ammonium acetate. The resulting [68Ga]Ga-TN-01 was purified using an HLB SPE cartridge and analyzed by a C-18 column with a mobile phase solution of 0.1% TFA in water and 0.1% TFA in ACN in gradient mode (85-50:15-50). The radiochemical yield and purity were assessed by radio-TLC and radio-HPLC. Stability was evaluated under three different conditions: normal saline pH 7.5, 0.01 M phosphate-buffered saline (PBS) pH 7.4, and human plasma. ***Results:*** The synthesis of the bifunctional chelator TN-01 was successfully achieved with a moderately high yield of 70%, and its assigned structure was confirmed to match the designed structure. The radiochemical yield of [68Ga]Ga-TN-01 was 41.33±2.00%, with a radiochemical purity exceeding 95% and a molar activity of 54.82±2.40 GBq/μmol. Stability studies demonstrated that the radiochemical purity of [68Ga]Ga-TN-01 remained above 97% at 4 hours under all tested conditions. ***Conclusion:*** This study presents an efficient method for 68Ga-radiolabeling of a bifunctional chelator targeting CXCR4. The resulting [68Ga]Ga-TN-01 is poised for further preclinical investigations, including biodistribution and localization studies, to validate its clinical potential for cancer diagnosis. ***References:*** Valarie MT, Huanyu Z, Brooke MK, et al. Discovery of tetrahydroisoquinoline-based CXCR4 antagonists. ACS Med Chem Lett. 2013;4(11):1025-1030.

EP-0074

Evaluation of 89Zr-DFO-T21 in immuno-PET imaging of A549 xenograft models with high TIM3 expression

J. Tao, *Z. Zeng, Z. Yang, H. Zhu;*
Peking University Cancer Hospital, Beijing, CHINA.

Aim/Introduction: T cell immunoglobulin and mucin domain 3 (TIM3) is one of the most researched immune checkpoints after CTLA-4 and PD-1and is considered a promising target in tumor immunotherapy. The purpose of this study is to provide guidance for the noninvasive detection and targeted therapy of TIM3 in tumor microenvironment. ***Materials and Methods:*** Humanized TIM3-targeted monoclonal antibody T21 was radiolabeled with 89Zr to obtain 89Zr-DFO-T21 probe. Flow cytometry and western blot were used to verify the expression of TIM3 on the surface of human lung cancer cells A549. In vitro the affinity of the 89Zr-DFO-T21 probe was evaluated by comparing the uptake of A549 and A549-TIM3 cells to the TIM3 target, and the stability of the probe was assessed in PBS and 5% HSA solution. The biodiversity distribution, metabolic characteristics of 89Zr-DFO-T21were performed, and then 89Zr-DFO-T21 was injected intravenously in the tail and then subjected to static whole-body positron emission tomography (PET) scanning by Micro-PET/CT for 10 minutes at 2, 24, 48, 72 and 96 h, respectively, and the images were quantified by region of interest (ROI) to obtain the maximum uptake value (SUVmax). ***Results:*** In this study, 89Zr-DFO-T21 probe was successfully prepared. A549-TIM3 cells showed high TIM3 expression, while A549 cells showed low expression of TIM3. The radiochemical purity was over 95% and maintained over 80% in saline or 5% Human Serum Albumin for more than 72 h. The Kd value of 89Zr-DFO-T21 to TIM3 protein was 24 nM. Compared with the blockade group or the A549-negative group, the results of cell uptake showed that the 89Zr-DFO-T21 probe was significantly specific for TIM3. The biological half-life of distribution and clearance phases were 2.23 h and 35.18 h, respectively. The effective dose of 89Zr-DFO-T21 estimated from the biodistribution data was 0.0125 mSv/MBq. The results of small animal PET showed that the uptake of 89Zr-DFO-T21 probe in the A549-TIM3 model reached the maximum absolute uptake value at 48 h (SUVmax =11.96 ± 0.01). ***Conclusion:*** The 89Zr-DFO-T21 probe developed in this study showed obvious targeting specificity with TIM3 in vitro and in vitro evaluation. The development of 89Zr-DFO-T21 may provide new insights for the regulation of TME and the formulation of precision diagnosis and treatment programs for tumors.

EP-0075

TNBC Theranostics by Intracellular TRPV1 Radioligands Trapping. Proof of Concept

N. Elkadri[1], *A. Heesch[2], M. Bauwens[3], S. Sahnoun[2], F. Mottaghy[2], M. Sadeghzadeh[2];*
[1]Faculty of Medicine of Tunis, University Tunis El Manar, Tunis, TUNISIA, [2]Nuclear Medicine Department, University Hospital Aachen, RWTH Aachen University, Aachen, GERMANY, [3]Department of Radiology and Nuclear Medicine, Maastricht University Medical Center (MUMC+), Maastricht, NETHERLANDS.

Aim/Introduction: Triple-Negative Breast Cancer (TNBC) has a poor prognosis with missing effective targeted therapies. Within this context, the exploration of novel treatment avenues is of paramount importance. Transient Receptor Potential cation channel subfamily V member 1 (TRPV1) is overexpressed in TNBC subtypes, mainly intracellular with specific pattern, especially by the endoplasmic reticulum and the Golgi apparatus. The 6-iodonordihydrocapsaicin was described as a potent ligand of TRPV1 (IC50=10±2.1nM). The aim of this study was to develop the synthesis of [131I]-6-iodonordihydtrocapsacin ([131I]INDC) and to make first proof of concept of intracellular TRPV1 radioligand trapping as a new approach in the field of TNBC theranostics. ***Materials and Methods:*** Nordihydrocapsaicin (NDC) was radioiodinated by electrophilic substitution of iodine-131 with the hydrogen atom in position 6 of the aromatic ring by using chloramine-T. Purification of [131I]INDC was performed by Semi-Preparative HPLC followed by C18 cartridge. Radiochemical stability of [131I]INDC was assayed by Radio-HPLC in saline 0.9%, human serum, and cell culture media. Expression and subcellular localization of TRPV1 were assessed by immunocytochemistry (ICC) in three cell lines: MDA-MB-231, 4T1 and MCF10A. Microautoradiography with hematoxylin & eosin staining (MAR H&E) of these three cells lines was performed after incubation for four hours with [131I]INDC. Microdosimetry was simulated using MIRDcell 3.13 for beta emission spectrum of iodine-131 and 4T1 adherent cells. ***Results:*** A radiolabelling yield of about 70% was obtained for [131I]INDC, with a radiochemical purity of over 95%. After formulation of [131I]INDC in 10% Ethanol in saline 0.9%, the radiotracer was found to be stable over 94% up to 120 h, and over 90% up to 24 h in human serum and 4T1/MDA-MB-231 growth media. As determined by ICC, expression of TRPV1 receptor was high in 4T1, located mostly intracellular around the nucleus, moderate in MDA-MB231 cells and non-specific in MCF10A cells. MAR H&E showed high intracellular uptake for 4T1 cells, moderate for MDA-MB-231 and non-specific for MCF10A. Microdosimetry simulation of [131I]INDC for 4T1 cells predicted absorbed doses delivered of at least 2 Gy to 90% of cells. ***Conclusion:*** In this study, we tentatively demonstrated initial in vitro indications of TRPV1 radioligands potentially being trapped intracellularly in TNBC cell lines. The radiotracer [131I]INDC was successfully synthesized with high radiolabeling yield and radiochemical purity. We confirmed the intracellular overexpression of TRPV1 receptor by ICC in 4T1 and MDA-MB-231 cell lines. Microdosimetry simulation predicted high in vitro delivered absorbed doses to these TNBC cell lines.

EP-0076

Preclinical Evaluation of a α-Fucosidase in therapy inducedsenescence, by[18F]FEtFuc PET

N. Trautwein[1,2], *J. Cotton[2], F. Reche Pérez[2], L. Zender[3], C. la Fougère[1], B. Pichler[2];*
[1]Nuclearmedicin Tuebingen, Tübingen, GERMANY,
[2]Werner-Siemens-Imaging Center, Tübingen, GERMANY,
[3]Internal Medicine VIII, Tübingen, GERMANY.

Aim/Introduction: Cellular senescence is a robust stress-induced state of cell cycle arrest and is reported to be accompanied by an increase in the expression of α-fucosidase. It has been widely observed that chemotherapy can drive tumor cells into therapy-induced senescence (TIS). While growth arrest is seen as a positive treatment outcome, senescent cells often harbor resistance to cytostatic drugs, rendering further treatments ineffective. Drugs that can selectively kill (senolytics) and modify the secretory phenotype (senomorphics) of senescent cells are already in development, but have side-effects. We thus present [18F]FEtFuc, an α-fucoside PET-tracer for the visualization of senescence. ***Materials and Methods:*** Three different models of TIS were used. In a CRC cell line (HCT116), senescence was induced by doxorubicin. In two HCC cell lines (Nras and AMp19), senescence was induced by a ribosomal checkpoint inhibitor (RCI). In-vitro, senescence was confirmed by X-Gal and expression levels of α-fucosidase were evaluated by qPCR and Westernblot. [18F]FEtFuc uptake was measured in a gamma counter in the three senescence models as well as an α-fucosidase overexpressing HCT116 cell line (Fuca). In vivo, tumor cells were injected s.c. and senescence was induced. After i.v. [18F]FEtFuc injection, dynamic PET (55 min) and anatomical MRI were performed for all senescence models and Fuca. All animals were scarified after in vivo imaging and tumor tissue was extracted and sliced for autoradiography, H&E and X-Gal staining. ***Results:*** All cell lines showed a significant increase of α-fucosidase mRNA after senescence induction, further confirmed by Western Blot. In vitro measurements showed a significantly higher [18F]FEtFuc uptake in all senescence models as well as in the Fuca cell line. The uptake was 1.9-fold higher in HCT116 senescent cells, 1.7-fold higher for the Nras and 5.0-fold higher for the AMp19 senescent cells. Fuca cells showed a 2.1-fold higher uptake then control HCT116 cells. In vivo, a significantly higher [18F]FEtFuc uptake was measured in all senescent tumors. The mean uptake in %ID/cc at 15-25 min for the senescent vs. control tumors was: 3.1±1.2 vs 1.8±0.3 for HCT116; 5.2±0.7 vs. 3.8±0.5 for Nras; 4.2±1.2 vs. 2.5±0.5 for AMp19. X-Gal staining confirmed senescence induction in all cell lines. ***Conclusion:*** α-Fucosidase is a robust biomarker in these senescence models and [18F]FEtFuc demonstrates its ability to visualize this cellular condition. This new approach offers an innovative system to detect senescence in vivoand could help for a better understanding of the intertumoral heterogeneity, as well as treatment related changes.

EP-0077

Synthesis and Evaluation of ^{68}Ga-D75CM-NODAGA, which enables Sentinel Lymph Node (SLN) Detection with PET.

G. Papadakis[1], *I. Pirmettis[2], M. Papadopoulos[2], N. Pirmettis[2], A. Shegani[1];*
[1]Hybrid Molecular Imaging Unit (HMIU), Foundation for Research and Technology Hellas (FORTH), Heraklion, GREECE, [2]Institute of Nuclear & Radiological Sciences and Technology, Energy & Safety (INRASTES), National Centre of Scientific Research "Demokritos" NCSRD", Athens, GREECE.

Aim/Introduction: Sentinel lymph node detection (SLND) and subsequent SLN-biopsy is vital for the accurate tumor management, serving as a key determinant in cancer staging and guiding treatment strategies by reducing unnecessary lymphadenectomy. Aim of the current study was to develop and rigorously evaluate the potential utility in SLND of the 68Ga-D75CM-NODAGA, a mannosylated dextran derivative radio-labeled with 68Ga. By employing state-of-the-art radiochemistry techniques and cutting-edge pre-clinical PET/MRI technology,enabling simultaneous PET and MRI acquisition, we aimed to develop and assess a novel imaging agent that will enable highly accurate SLND with PET. ***Materials and Methods:*** The mannosylated compound D75CM was synthesized, followed by the coupling with the succinimidyl ester of NODAGA. Specifically, a reaction of a 75 KD dextran with allyl bromide yielded the intermediate allyl dextran with about 40% coupling. Addition of cysteine to allyldextran resulted in the dextran-S-cysteine derivative D75C. This compound was mannosylated (approx. 65%) by coupling to the in situ activated cyanomethyltetraacetyl-1-thio-D-mannopyranoside. Subsequently, the reaction of the succinimidylester of NODAGA with free amine groups resulted in the formation of the final compound. Purification of the compound has been performed by ultrafiltration. Labeling was achieved by adding 0.5 mL 68GaCl3 to a 100 μL solution of the NODAGA mannosylated dextran and incubating at 40oC for 20 mins. Quality control and stability studies were performed by radio-TLC and radio-HPLC. The biological evaluation was performed by biodistribution and imaging studies in Swiss albino mice after subcutaneous injection in the footpad. ***Results:*** The preliminary biological testing of the 68Ga complex showed high accumulation in the popliteal lymph node (4.09 % ID) and fast injection site clearance (40.61 %/ID) at 120 min p.i. This data is comparable with our previous data1 indicating that the attachment of NODAGA chelator did not alter its biodistribution. Furthermore, a dynamic imaging study using microPET/MRI (enabling simultaneous PET and MRI acquisition; Bruker USA) confirmed the rapid elimination rate from the injection site. ***Conclusion:*** A novel 68Ga-based PET tracer for SLN detection has been developed and evaluated by our group. The innovative 68Ga-labeled D75CM-NODAGA compound showed favorable imaging perfomance as a novel PET imaging agent for SLND, providing the evidence for further evaluation in both the pre-clinical and clinical setting. ***References:*** 1. SYL3C aptamer-engineered DNA tetrahedrons for diagnosing imaging of colorectal cancer via dual PET and fluorescence imaging

Z. Huang[1], *P. Li[1], X. Duan[2], Y. Li[1], M. Li[3], D. Jiang[4], J. Li[5];*
[1]Inner Mongolia Medical University, Inner Mongolia, CHINA, [2]Department of Gastroenterology, The Affiliated Hospital of Inner Mongolia Medical University, Inner Mongolia, CHINA, [3]Union hospital, Huazhong University of Science and Technology, Wuhan, CHINA, [4]Huazhong University of Science and Technology, Wuhan, CHINA, [5]Department of Nuclear Medicine, The Affiliated Hospital of Inner Mongolia Medical University, Inner Mongolia, CHINA.

Aim/Introduction: Colorectal cancer (CRC) is one of the diseases with high morbidity and mortality rates. Since early-stage CRC is treated surgically with a cure rate of 90%, how to achieve early diagnosis has become one of the urgent problems to be solved.

SYL3C is a DNA aptamer that can bind Epithelial Cell Adhesion Molecule (EpCam)with high selectivity, which is widely expressed in colorectal cancer cells. DNA tetrahedron (DTN) has emerged as a highly promising nanodrug delivery system owning to high stability, structural designability and explicit biosafety. In this study, we choose fluorescent motif Cy7 and gallium-68 to modifie SYL3C aptamer-engineered DTN for targeted dual imaging modalities, positron emission tomography (PET) and fluorescence, which both non-invasive and real-time imaging on the internal structure at the molecular level, to enhance the early detection and treatment monitoring of colorectal cancer. ***Materials and Methods:*** We designed and synthesized the Cy7-DTN-SYL3C via one-step annealing and click chemistry. Following in vitro stability and cytotoxicity examination, we injected the probe into HT-29 tumor-bearing BALB/c nude mice and performed in vivo fluorescence imaging at different time points and sacrificed the mice at 24 h for biodistribution analysis. Subsequently We obtained 68Ga-NOTA-DTN-SYL3C according to base complementary pairing and injected it intravenously into HT-29 tumor-bearing mice to obtain metabolic information of tumor tissues to perform precise quantification. Imaging data were quantitatively analyzed to evaluate the targeting efficiency and biodistribution. ***Results:*** Cy7-DTN-SYL3C and 68Ga-NOTA-DTN-SYL3C were found to be stable and non-toxic in vitro. In vivo imaging experiments, we found that SYL3C aptamer-engineered DNA tetrahedrons is mainly metabolized by the kidneys and liver. The average fluorescence radiant efficiency of tumor was 6.8 ×10 8 (p/s/cm2/sr)/(μW/cm2) in tumor regions, which is about 1.6 - 2.9 folds targeted performance enhancement and the time of tumor retention in vivo prolonged about 8 - 10 hours compare with the control. Quantitative region of interest (ROI) analysis showed that tumor uptake was 1.4±0.8%ID/g (n=3), and biodistribution analysis confirmed the same conclusion as ROI, indicating that the tumor tissue has a considerable degree of uptake. ***Conclusion:*** The use of SYL3C aptamer-engineered DNA tetrahedrons represents a novel and promising approach for targeted dual imaging of colorectal cancer. It facilitates both early tumor detection and efficacy assessment due to its high specificity and dual imaging capabilities. The translation of this technology into clinical trials and its adaptation to other biomarker-specific cancers will be explored in future work.

EP-0079

Development of $^{[Cu-64]}$RTX-1363S, a high-affinity ligand for FAP-targeted PET imaging

S. Hillier[1], *K. Tully[1], E. Ruigrok[2], S. Kazerounian[1], S. DiMagno[1], S. Ponnala[1], K. Orcutt[1], A. Amor-Coarasa[1], N. Monks[1], M. Friebe[1], A. Novicki[1], J. Hesterman[1], S. U. Dalm[2], J. Hoppin[1], J. Babich[1];*
[1]Ratio Therapeutics, Boston, MA, UNITED STATES OF AMERICA, [2]Erasmus Medical Center, Rotterdam, NETHERLANDS.

Aim/Introduction: Fibroblast activation protein-α (FAP) is recognized as a pivotal target in molecular imaging, important in oncology and inflammatory and fibrotic diseases due to its presence in cancer-associated fibroblasts and activated fibroblasts. RTX-1363S, a tri-functional small molecule identified using the Trillium™ platform, integrates a FAP-binding ligand, a pharmacokinetic-modulating albumin-binding moiety, and a chelator for incorporation of radiometals. This high affinity FAP ligand, radiolabeled with Cu-64, Ga-68, and [F-18]AlF, enables specific PET imaging of FAP expressing tissues. ***Materials and Methods:*** The affinity of RTX-1363S and [Cu-nat]RTX-1363S for human FAP was determined by surface plasmon resonance (SPR). Specificity was evaluated against related prolyl peptidases in enzyme assays. Biodistribution of [Cu-67]RTX-1363S in U-87 MG xenograft mice was determined by SPECT/CT imaging and ex vivo gamma counting at 1, 3, and 24 hours post-injection. Biodistribution of $^{[Cu-64]}$RTX-1363S in male and female Sprague-Dawley rats (n=3/sex/time point) was investigated to project human tissue radiation absorbed dosimetry using the %kg/g scaling method. Toxicity was assessed in Sprague-Dawley rats and off-target interactions were assessed with the SafetyScan47 panel. ***Results:*** RTX-1363S and [Cu-nat]RTX-1363S displayed high affinity for human FAP by SPR with dissociation constants (KD) of 0.0123 ± 0.003 nM and 0.0211 ± 0.004 nM, respectively. IC50 values for [Cu-nat]RTX-1363S were >10 μM for human DPPIV and 2.76 ± 0.79 nM for human PREP, demonstrating minimal cross-reactivity with other prolyl peptidases. SPECT/CT imaging showed significant tumor retention in mice, with [Cu-67]RTX-1363S achieving peak tumor accumulation at 1 h post-injection. Tumor:blood, tumor:kidney and tumor:muscle ratios at 1 h were 15.4, 6.3 and 14.1, respectively. In rats, $^{[Cu-64]}$RTX-1363S demonstrated rapid clearance through the kidneys, with >80% decrease in blood concentration by 24 h. The projected effective doses for $^{[Cu-64]}$RTX-1363S in human males and females was estimated to be 31.2 and 17.1 μSv/MBq, respectively. At >100x the anticipated human dose, RTX-1363S produced no toxic side effects in rats. No significant results (defined as >50% inhibition at 10 μM concentration) were observed across a functional panel of 47 targets/pathways commonly implicated in adverse drug reactions. ***Conclusion:*** RTX-1363S is a selective, high affinity FAP inhibitor that demonstrates favorable biodistribution to the tumor and rapid background clearance allowing for early tumor imaging. These data, combined with the clean safety profile, underscore the potential of $^{[Cu-64]}$RTX-1363S for clinical PET imaging of FAP-expressing tissues to provide insights into both cancerous and fibrotic diseases.

^{177}Lu-Labeled GPC3-Targeted Antibodies: In Vivo Behavior and Therapeutic Potential in Hepatocellular Carcinoma

Z. Lin, *X. Zhang, Y. Feng, W. Song, Y. Gai, R. An, Y. Zhang, X. Lan;*
Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Hepatocellular carcinoma (HCC) poses a significant global health threat with high cancer-related mortality due to late diagnosis and limited therapy options. Targeted radionuclide therapy, focusing on specific tumor markers, shows promise for cancer treatment. Glypican-3 (GPC3), highly expressed in HCC but absent in healthy liver tissue, is a potential target for HCC therapy. In this study, we developed three 177Lu-labeled GPC3-targeted antibodies (full-length, Fab, and scFv) to explore their potential for HCC theranostics. ***Materials and Methods:*** The GPC3-targeted antibodies were labeled with 177Lu after conjugation with p-SCN-Bn-DOTA. BALB/c nude mice with Hep3B xenografts received intravenous injections of 18.5 MBq probes. SPECT/CT scans were conducted at various time-points for full-length antibody (6 h, 12 h, and day 1-7), Fab and scFv (2 h, 6 h, 12h, day 1 and 2). Ex vivo biodistribution experiments were conducted at the final time point, and blood biochemistry assessed short-term toxicity. ***Results:*** Three 177Lu-labeled GPC3-targeted antibodies were successfully synthesized with high radiochemical purity. SPECT/CT imaging delineated distinct in vivo behaviors of these probes. For 177Lu-DOTA-aGPC3-Fab and 177Lu-DOTA-aGPC3-scFv, rapid accumulation was evident in Hep3B tumors at 2 hours p.i., peaking at 5.4 ± 0.8 %ID/g and 4.1 ± 0.8 %ID/g by 6 hours p.i., respectively. These probes demonstrated rapid

clearance from the blood, leading to notably high tumor-to-blood ratios, approximately 15. However, a decline in tumor uptake was observed after 6 hours. In contrast, 177Lu-DOTA-aGPC3-mAb displayed a different in vivo behavior, primarily accumulating in the blood during the early phase. Tumor accumulation commenced at 6 hours, steadily rising and reaching its peak at 12.6 ± 1.3 %ID/g by day 2. Even by day 7, the uptake in the tumor remained notably high, at 4.37 ± 0.7 %ID/g. Ex vivo biodistribution studies confirmed the findings from SPECT imaging. Blood biochemistry analysis revealed no significant differences compare to the control group. ***Conclusion:*** We successfully developed three 177Lu-labeled GPC3-specific antibodies with high radiochemical purity. SPECT imaging confirmed their robust GPC3-targeting capabilities and observed distinct in vivo dynamics among them. Short-term toxicity assessment revealed no significant adverse effects, indicating their favorable safety profile. Moving forward, our focus will shift towards comprehensive evaluations of their therapeutic efficacy and safety in preclinical models, aiming to further elucidate their clinical potential.

EP-0081

Prostate-Specific Membrane Antigen (PSMA) expression in primary and metastatic kidney cancer (UroCCR-65 study).

***S. Binzaqr*[1]**, *D. Kryza*[2,3], *A. Giraudet*[4], *J. Bernhard*[5], *M. Gross-GOUPIL*[6], *M. Yacoub*[7], *G. Margue*[5], *E. Hindié*[1,8,9], *C. Morgat*[1,8];
[1]*Department of Nuclear Medicine, University Hospital of Bordeaux, Bordeaux, FRANCE,* [2]*2 Hospices Civils de Lyon, 69437 Lyon, France, Lyon, FRANCE,* [3]*Univ. Lyon - Université Claude Bernard Lyon 1, Lyon, FRANCE,* [4]*Center of Nuclear Medicine Lumen, Lyon, FRANCE,* [5]*Department of Urology, University Hospital of Bordeaux, Bordeaux, FRANCE,* [6]*Department of Medical Oncology, University Hospital of Bordeaux, Bordeaux, FRANCE,* [7]*Department of Pathology, University Hospital of Bordeaux, Bordeaux, FRANCE,* [8]*University of Bordeaux, Talence, FRANCE,* [9]*Institut Universitaire de France (IUF), Paris, FRANCE.*

Aim/Introduction: Renal cell carcinoma (RCC) accounts for more than 90% of renal tumors and about 15% of patients have metastatic disease at initial diagnosis. Prostate-specific membrane antigen (PSMA) has been shown to be over-expressed in the neo-vasculature of renal tumors. However, there is no study investigating the pattern of PSMA expression in primary RCC and metastases. The objective of this work was therefore to study, using autoradiography, PSMA expression in a panel of primary RCC and biopsies from RCC metastases. ***Materials and Methods:*** 60 frozen samples of renal cancer, 30 primaries and 30 metastases, were available from the UroCCR project (NCT03293563). PSMA expression was assessed using [177Lu]Lu-PSMA-617 as binding agent and the specific binding was calculated for each sample (1000 fold excess of the PSMA inhibitor PMPA was used to assess non-specific binding). Samples were then dichotomized in low PSMA expression (specific binding 1-10%) and high PSMA expression (specific binding 11-100%) for statistical analysis. A patient suffering from metastatic clear cell RCC (ccRCC) was also injected with [68Ga]Ga-PSMA-11 to evaluate PSMA expression on the known pleural lesions. ***Results:*** Samples from 44 patients were available and suitable for autoradiography processing, including 19 patients for primary renal cell carcinoma (9 ccRCC, 7 papillary RCC and 3 chromophobe RCC) and 25 for metastatic renal cell carcinoma (24 ccRCC and one eosinophilic cell carcinoma (NOS) not otherwise specified). The mean specific binding was 28.9 ± 40.4% for primary renal cancer and 65.0 ± 38.9% for metastasis. There were no association between PSMA specific binding and histology parameters in primary tumors such as pT, histological types and WHO/ISUP grade (p>0.05). A significant increase in PSMA-specific binding was depicted in metastatic samples (p=0.0037)(Figure 1). The patient suffering from metastatic ccRCC and imaged with [68Ga]Ga-PSMA-11 PET/CT showed high PSMA uptake on known pleural lesions. An occult femoral metastasis was also diagnosed (Figure 2). ***Conclusion:*** PSMA is significantly over-expressed in metastases of RCC, here mainly represented by ccRCC. ***References:*** 1. Schollhammer R, Quintyn Ranty M-L, de Clermont Gallerande H, Cavelier F, Valverde IE, Vimont D, et al. Theranostics of Primary Prostate Cancer: Beyond PSMA and GRP-R. Cancers. 2023;15:2345.

EP-0082

PET imaging to evaluate activated immune cells in hypoxia-enhanced immunotherapy for malignant tumors

X. Wang, *H. Fang, W. Hu, Y. Feng, M. Li, X. Zhang, Y. Zhang, R. An, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Currently, immunotherapy faces limitations due to its poor therapeutic efficacy and the absence of reliable methods for evaluating treatment responses. Herein, we aimed to enhance immunotherapy efficacy by ameliorating the hypoxic tumor environment and subsequently augmenting immune cell activity at the tumor site. Granzyme B targeted PET imaging was employed to monitor changes in activated immune cell, assessing the response to immunotherapy efficacy in vivo. ***Materials and Methods:*** Lung cancer cell membranes were obtained to coat on the surface of highly oxygenated perfluocarbon for tumor homologous targeting. Tumor hypoxia was monitored via in vitro immunofluorescence staining. Immunotherapy was conducted at 24 h post-injection of a biomimetic homologous-targeted oxygen-delivery system into xenografts. The efficacy of immunotherapy was evaluated using 68Ga-NOTA-GZP PET imaging and ex vivo biodistribution analysis. PET/CT scanning was performed 1 h after probe injection. Immunohistochemical analysis further validated the relationship between tumor uptake of 68Ga-NOTA-GZP and the expression level of CD8, CD3, TNF-α, INF-γ, and PD-1. ***Results:*** In vitro tumor hypoxia detection revealed significantly lower fluorescence intensity representing hypoxia in the oxygen-enhanced group compared to other groups ($P < 0.001$), indicating significant hypoxia relief. The initial labeling yield of 68Ga-NOTA-GZP was 99.99%, after 3 h of incubation with PBS, the labeling yield remained >99%. As for 68Ga-NOTA-GZP PET imaging after immunotherapy, the hypoxia-improved group exhibited the highest tumor site uptake (0.89 ± 0.13%ID/g) compared with the control group (0.32 ± 0.07 %ID/g) ($P < 0.01$). Additionally, the hypoxia-improved group demonstrated much higher tumor-to-blood ratios (T/B) and tumor-to-muscle ratios (T/M) than the control groups ($P < 0.05$). Biodistribution analysis at 2 h post-injection of 68Ga-NOTA-GZP revealed significantly higher accumulation in the hypoxia-improved tumor group (0.56 ± 0.03 %ID/g) compared to the control group (0.32 ± 0.06 %D/g,$P < 0.05$). High expression of CD8, CD3, TNF-α, and INF-γ were observed in the hypoxia-improved group, while control

groups showed moderate expression level. Quantitative analysis indicated a positive correlation between tumor uptake and the expression levels of CD8, CD3, TNF-α, and INF-γ, with no obvious correlation observed with PD-1 expression. ***Conclusion:*** We successfully improved the hypoxia of tumor microenvironment. Both the in vitro immunofluorescence staining and in vivo granzyme B targeted PET imaging confirmed enhanced activity of immune cells at tumor sites after improving the hypoxia. This study provided a new direction for enhancing the efficacy of tumor immunotherapy, and a non-invasive imaging method for therapeutic efficacy evaluation.

Applied Medical Research Center (CIMA), Pamplona, SPAIN, [3]Advanced Therapies Group for Pediatric Solid Tumors. Applied Medical Research Center (CIMA)., Pamplona, SPAIN, [4]Translational Molecular Imaging Unit (UNIMTRA). Nuclear Medicine Department. University Clinic of Navarra, Pamplona, SPAIN, [5]Nuclear Medicine Department. University Clinic of Navarra, Pamplona, SPAIN, [6]Radiopharmacy Unit. Nuclear Medicine Department. University Clinic of Navarra, Madrid, SPAIN.

Aim/Introduction: Midline diffuse glioma (DMG) is a highly aggressive pediatric brain tumor and a leading cause of childhood cancer-related death. These tumors are incurable, which increases the need for effective therapies. It has been demonstrated that blocking TIM-3 (cellular receptor 2 for hepatitis A virus) in diffuse intrinsic pontine glioma models promotes regression and antitumor immune memory, prolonging disease-free survival. Intratumoral treatment in the spinal cord is not recommended, so alternative administration via cerebrospinal fluid in the brain ventricles has been proposed. The objective of this work is to evaluate this administration route in a murine model of DMG in the spinal cord using imaging techniques and ex vivo analysis with the anti-TIM3 antibody radiolabeled with technetium-99m. ***Materials and Methods:*** The antibody radiolabeling (BioXCell InVivoMAb 1mg) was performed by reducing technetium-99m with SnCl2 [40µl SnCl2·2H2O (1mg/ml)]. Three µl of 99mTc-TIM-3(26,2±1,1MBq) were administered intraventricularly to male albino C57 mice, and MicroSPECT/CT images were acquired at 0.5, 2, 4, and 20 hours post-administration. At 20 hours, animals were euthanised, organs excised and radioactivity quantified using a Gamma Counter. ***Results:*** Radiochemical Purity (radioTLC) in all cases was greater than 98%. In vivo and ex vivo biodistribution studies demonstrated that the anti-TIM-3 antibody drains along the spinal canal, reaching the tumor area within the first half-hour post-administration. At longer times (20 h), uptake remained stable. ***Conclusion:*** The anti-TIM3 antibody can be directly radiolabeled with technetium-99m with good yields. Biodistribution studies showed that the anti-TIM-3 antibody rapidly drains (30 min) along the spinal cord using this administration route and remains stable in the tumor lesion (20h), opening up the future possibility of its application in patients through an Ommaya catheter. Further work will be expanded through differential studies with L-[methyl-11C]-methionine to accurately delineate the tumoral area, as well as labeling of the anti-TIM3 antibody with gallium-67 to study its behavior over longer periods. ***References:*** Cancer Cell 2023 Nov 13;41(11):1911-1926.

EP-0084

^{18}F radiolabeled lipid-shell microbubbles for simultaneous PET/US imaging: radiolabeling and first in vivo studies

J. Ariztia[1], *A. Dauba[1], A. Novell[1], D. Kereselidze[1], A. Delalande[2], J. Gennisson[1], C. Truillet[1], B. Kuhnast[1];*
[1]Université Paris-Saclay, CEA, CNRS, Inserm, BioMaps, Orsay, FRANCE, [2]CBM, UPR 4301 CNRS, Orléans, FRANCE.

Aim/Introduction: Positron Emission Tomography (PET) is a gold standard method for molecular, metabolic and quantitative imaging of relevant biomarkers.1 Ultrasound (US) is a real-time imaging modality for anatomical and functional imaging. Their combination will allow to study the microbubble biodistribution and quantification. To leverage the best profit of both modalities, lipid-shell microbubbles (µB) will be radiolabeled with fluorine-18. ***Materials and Methods:*** Biotin-avidin strategy2: The biotin-derivative precursor was radiofluorinated at 160ºC for 5 min on a (Trasis AIO). Then, the avidin was coupled with the 18F-biotin and purified by size-exclusion chromatography. Finally, the microbubbles were incubated with the ^{18}F-avidin complex (PBS, 10 min) to obtain de 18F-µB. As proof of concept, images of the liver were co-registered with a microPET scanner and a US transducer placed in the field of view of the scanner. Click chemistry strategies: the radiolabelled compounds $^{[18F]}$-FPyZIDE3 and $^{[18F]}$-FPyTCO were obtained in DMSO for 5 min at 160ºC or 15 min at 50ºC respectively (Trasis AIO). The SPAAC click reaction was performed between $^{[18F]}$-FPyZIDE and DBCO-liposomes/DBCO-µB in water/DMSO for 60 min. For the IEEDA strategy, the click reaction with $^{[18F]}$-FPyTCO and 3,6-di(4-pyridinyl)-1,2,4,5-tetrazin (as model compound) and MeTz-µB was tested. ***Results:*** Biotin avidin strategy: 18F-biotin derivative was obtained with 49% yield and 230±28 GBq/µmol m.a.. 18F-biotin incubation with avidin followed by NAP-10 purification allowed recovering 96% of 18F-biotinavidin complex. The obtained 18F-µB were injected in healthy mice. The images showed the colocalization of the radioactive signal and the contrast of µB in the liver after 2 min p.i.. After 15 min a renal elimination of the radioactive microbbubles/lipids was observed. Click Chemistry strategies: $^{[18F]}$-FPyZIDE was obtained with 56% yield and 491±2 GBq/µmol m.a.. The optimized SPAAC conditions allowed us to obtain the 18F-DBCO-µB with good yields (over 97%) and ready to inject. For the IEDDA, the radiolabeled $^{[18F]}$-FPyTCO was obtained with 35% yield. The click reaction with the model compound 3,6-di(4-pyridinyl)-1,2,4,5-tetrazin and MeTz-µB showed <40% and 0% conversion respectively. ***Conclusion:*** Lipid-shell-biotinylated microbubbles were successfully radiofluorinated using the bioinspired avidin-biotin strategy. The obtained microbubbles were tested on healthy mice establishing a proof of concept of microbubble radiofluorination and simultaneous PET/US imaging registration. The SPAAC reaction allowed to obtain 18F-µB with 97% radiochemical purity ready to inject.This chemical approach will be transferred to in vivo bimodal PET/US imaging. ***References:*** [1] Springer International Publishing: Cham, 2016/207, 177-205. Comprehensive Preclinical Study and Administration Protocol for ^{177}Lu-FAP-2286: Validation, Tumor Uptake, and Dosimetry Investigations

A. Abolhosseini Shahrnoy, *H. Khoshhosn, S. Mazidi, M. Pirdadeh-Beiranvand, R. Nami, N. Soltani, M. Safari, G. Paranideh; Pars Isotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: This study aimed to validate the process and methods for the production and quality control of 177Lu-FAP-2286. Additionally, a comprehensive preclinical investigation was conducted using xenograft models to assess tumor uptake through PET/CT imaging with 68Ga-FAP-2286. Furthermore, biodistribution studies in BALB/c mice and dosimetry investigations for 177Lu-FAP-2286 were performed, including the administration of amino acids and furosemide. ***Materials and Methods:*** The production and quality control of 177Lu-FAP-2286 were validated through a series of established processes and methods. Preclinical studies were conducted using 4T1, MCF-7, C6, and HEK-293 cell xenograft models in mice and rats. PET/CT imaging with 68Ga-FAP-2286 was utilized to investigate tumor uptake. Biodistribution studies were carried out in BALB/c mice, and dosimetry investigations included the administration of amino acids and furosemide, with a focus on kidney blockage using lysine and arginine. ***Results:*** The use of both lysine and arginine for kidney blockage, in combination with furosemide, resulted in significantly lower background activity in normal organs. PET/CT imaging revealed promising tumor uptake of 68Ga-FAP-2286. Biodistribution studies in BALB/c mice provided valuable insights into the distribution of 177Lu-FAP-2286. Dosimetry investigations yielded important data on the administration of amino acids and furosemide in relation to 177Lu-FAP-2286. ***Conclusion:*** The validation of production and quality control processes for 177Lu-FAP-2286, along with the comprehensive preclinical studies and dosimetry investigations, demonstrate the potential for effective clinical translation. The use of lysine and arginine for kidney blockage, in combination with furosemide, shows promise in minimizing background activity in normal organs.

^{68}Ga/^{177}Lu labeled bivalent imaging agents targeting hypoxia and PSMA in tumors

Y. Luo[1], *W. Jin[1], R. Wang[1], H. Hong[1], R. Zhao[1], L. Yan[1], Y. Huang[1], J. Qiao[1], L. Zhu[1], H. Kung[2];*
[1]Key Laboratory of Radiopharmaceuticals, Ministry of Education, College of Chemistry, Beijing Normal University, Beijing, CHINA, [2]Department of Radiology, University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) overexpressed in prostate cancer cells, is an attractive target for prostate cancer diagnosis and therapy. Hypoxia is prevalent in nearly all solid tumor types, and various radioligands based on nitroimidazole can enter through passive diffusion and be trapped inside hypoxic cells. Integrating the nitroimidazole group into the structure of PSMA-targeted radiopharmaceutical holds the potential to enhance tumor uptake and retention. Based on this, we synthesized a series of bivalent nitroimidazole (NI)-PSMA agents (compound 1 - 8) incorporating a hypoxia-sensitive moiety (2-nitroimidazole) and a PSMA-targeting group (glutamate-urea-lysine, GUL). We also added different chelators (AAZTA, HBED-CC, and DOTA) for labeling with various nuclides (such as Ga-68, F-18, Lu-177, etc.). ***Materials and Methods:*** Precursor ligands, 1 - 8, were synthesized and labeled with [68Ga]Ga(III) or [177Lu]Lu(III). Radiochemical purity (RCP) and in vitro stability of the radioligands were determined by radio-HPLC and radio-TLC. In vitro cell uptake studies and competitive binding assays were conducted using PSMA-positive 22Rv1-FOLH1-oe cells. PET/CT imaging, SPECT/CT imaging, and biodistribution studies were performed in 22Rv1 tumor-bearing mice. ***Results:*** [68Ga]Ga-1 to 8 and [177Lu]Lu-8 were efficiently labeled with radiochemical purity > 95%. Among the [68Ga]Ga-complexes, [68Ga]Ga-8 ([68Ga]Ga-AAZTA-NI-PSMA-093) demonstrated superior properties in both in vitro and in vivo experiments. Under normoxic conditions, [68Ga]Ga-8 exhibited comparable cellular uptake and internalization to [68Ga]Ga-PSMA-093 and [68Ga]Ga-AAZTA-PSMA-093. However, compared to the nitroimidazole (NI)-free ligand ([68Ga]Ga-AAZTA-PSMA-093), [68Ga]Ga-8 demonstrated significantly higher cellular accumulation under hypoxic conditions than under normoxic conditions ($P < 0.05$), indicating the advantageous hypoxia-selective trapping conferred by the introduction of nitroimidazole group. Micro PET/CT imaging at 60 min post-injection demonstrated that [68Ga]Ga-8 displayed higher tumor uptake (SUVmax: 2.01 vs 1.53) and tumor-to-muscle ratio (T/M: 34.4 vs 9.15) compared to [68Ga]Ga-PSMA-11. Furthermore, compared to [68Ga]Ga-PSMA-093 (tumor SUVmax: 2.36, T/M: 21.9), [68Ga]Ga-8 also demonstrated excellent image contrast. Micro SPECT/CT imaging at 24 h post-injection revealed that [177Lu]Lu-8 exhibited excellent accumulation and retention in the tumor, along with rapid clearance from non-target tissues, comparable to [177Lu]Lu-PSMA-617. In biodistribution studies, [68Ga]Ga-8 demonstrated similar tumor uptake to [177Lu]Lu-8 (11.73 ± 3.96 vs 11.73 ± 3.98 %ID/g) and T/M ratio (15.07 ± 2.22 vs 13.45 ± 2.41) at 60 min post-injection, respectively. ***Conclusion:*** Preliminary studies indicate that [68Ga]Ga/[177Lu]Lu-8 ([68Ga]Ga/[177Lu]Lu-AAZTA-NI-PSMA-093) may be a promising bivalent agent targeting hypoxia and PSMA binding for diagnosis and radiotherapy. Clinical application is currently under investigation.

EP-0087

Exploring Mycoplasma pneumoniae persistence in murine tumors through radiolabeling with [^{111}In]In-oxinate and in vivo imaging with SPECT/CT.

M. Collantes[1], *I. Rodríguez-Arce[2], F. Pareja[3], M. Ecay[1], G. Quincoces[3], L. Serrano Pubul[2], I. Peñuelas[1,3];*
[1]Translational Molecular Imaging Unit (UNIMTRA), Nuclear Medicine Department, Clínica Universidad de Navarra, Pamplona, SPAIN, [2]Centre for Genomic Regulation (CRG), Barcelona, SPAIN, [3]Radiopharmacy Unit, Department of Nuclear Medicine, Clinica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: Mycoplasma pneumoniae (Mpn) is believed to persist within lung tumors, suggesting its potential as a biotherapeutic agent to deliver treatments for this type of cancer. Our objective was to radiolabel an engineered non-pathogenic strain of Mpn (MpnCV8) with [111In]In-oxinate to evaluate its infective dynamics and persistence in a murine lung adenocarcinoma model using in vivo SPECT/CT imaging. ***Materials and Methods:*** In vitro feasibility of Mpn radiolabeling was assessed by incubating Mpn WT and CV8 strains (10E10 CFUs, n=2) with [111In]In-oxinate (≈6MBq, 37ºC, 15') and quantifying the uptake in a gamma-counter. The infection dynamics was studied in healthy mice by intratracheal administration of either free [111In]In-oxinate (control, n=3, 0.8Mbq/100µL) or 111In-MpnCV8 (10E07 or 10E08 CFU, n=3 per group, 0.9MBq/100µL). SPECT/CT images were acquired at 1,24,48,72, and 96h post-administration, and signal quantification performed by drawing VOIs in the lungs, calculating signal percentage relative to the

1h. A lung metastasis model (n=6) was created by intratracheal administration of 1x106 A549 cells, allowing tumors to grow for three weeks. Then, 10E7 111In-MpnCV8 were administered, and simultaneous SPECT/PET/CT images of Mpn biodistribution and [18F]FDG uptake in the tumors were acquired at 1,48,72 and 96h. ***Results:*** Mpn was radiolabelled in vitro with [111In]In-oxinate with high efficiency (>70%). In healthy animals, signal decrease in the lungs was faster in mice infected with 10E7CFUs compared to 10E8CFUs during the first 72h, showing a similar retention at 96h (≈55%). Free 111In-oxine showed different biodistribution with significantly more retention at late times (77±2% at 96h). In mice with lung tumors, 111In-MpnCV8 persistence was also significantly higher after 72h compared to healthy animals with a final overall retention of 73±6% at 96h. Simultaneous SPECT/PET/CT images showed preferential distribution of 111In-MpnCV8 in the tumor periphery over time, with consistent mismatch with [18F] FDG uptake in all the tumors. ***Conclusion:*** Radiolabeling of Mpn with [111In]In-oxinate is an effective method for in vivo tracking of its lung infection dynamics by SPECT/CT. The results seem to indicate that the 111In-MpnCV8 strain is capable of persisting in the tumors of the murine model to a greater extent over time as compared to healthy parenchyma, potentially modulating tumor metabolism. Molecular imaging techniques can aid in studying the distribution and biology of Mpn in lung tumors, providing insights into its potential as a biotherapeutic agent for this disease.

EP-0088

Novel generation of dimer based GRPR-targeting radioligands for breast cancer imaging and therapy.

P. Paraiso[1], *C. H. M. van Deurzen[2], Y. Seimbille[1];*
[1]Department of Radiology and Nuclear Medicine, Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, NETHERLANDS, [2]Department of Pathology, Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, NETHERLANDS.

Aim/Introduction: The 2 most promising GRPR-targeted radioantagonists, RM2 and NeoBOMB1, have already been applied for breast tumor imaging. Nevertheless, their limited metabolic stability, caused mainly by the neutral endopeptidase, limits their in vivo performance and tumor-to-background contrast can be enhanced. Therefore, two novel dimeric radioligands were developed to improve accumulation in GRPR positive tumors. ***Materials and Methods:*** To design RM2-based dimers, different platforms were investigated to conjugate the two GRPR-targeting moieties and the bifunctional chelator. Thus, the hdPP-01 homodimer was synthesized via a 2-cyanobenzothiazole (CBT)/1,2-aminothiol click reaction, while the hdPP-02 dimer was prepared from a 1,3,5-triazine core. Labeling with 111In was carried out at 95 °C for 20 min in a solution containing ascorbic/gentisic acids (50 mM), sodium acetate (2.5 M) and L-methionine (50 mM). Affinity (IC50) to GRPR was determined using T-47D cells. In addition, cell uptake/internalization (37 °C, 60 min), lipophilicity (logD7.4) and in vitro metabolic stability in phosphate-buffered saline (PBS), murine serum (MS) and human serum (HS) were carried out. In vivo microSPECT/CT imaging studies, as well as biodistribution, are underway in GRPR tumor-bearing NMRI nude mice to confirm the potential of our dimers. ***Results:*** The novel homodimers, hdPP-01 and hdPP-02, were synthesized, purified and quantitatively radiolabeled with 111In (RCY> 99%, RCP> 98%). The radiolabeled complexes showed high hydrophilicity ([111In]In-RM2: -2.36 ± 0.02, [111In]In-hdPP-01: -2.13 ± 0.07, [111In]In-hdPP-02: -2.27 ± 0.04). They exhibited very good overall stability (> 90%) in HS and PBS at 37 °C for 24 h and an increased stability in MS compared to the monomeric RM2 (> 32% for the dimers vs. 12% for [111In]In-RM2 at 24 h). In vitro binding affinity studies resulted in nanomolar IC50 values for GRPR ([111In]In-RM2: 1.60 ± 0.17, [111In]In-hdPP-01: 3.69 ± 0.53, [111In]In-hdPP-02: 1.07 ± 0.13). Uptake and internalization studies showed increased overall uptake of the radiolabeled dimers compared to RM2 (overall uptake of [111In]In-RM2: 11.42 ± 0.77%, [111In]In-hdPP-01: 13.58 ± 1.15%, [111In]In-hdPP-02: 16.77 ± 0.83%), with loss of the antagonistic properties (increased internalized fraction). ***Conclusion:*** Based on their improved metabolic stability and very promising overall data, the novel GRPR-targeted homodimers might have the potential to outperform the current gold standards among GRPR-targeted ligands (RM2, NeoBOMB1) for targeted radiotherapy in breast cancer. These compounds are currently being evaluated in in vivo studies in tumor bearing mice.

EP-0089

Preclinical evaluation of Cadherin 3 (CDH3) -targeted alpha radiopharmaceutical therapy, ^{225}Ac-PPMX-T002 for the treatment of solid cancer

S. Hagiwara[1], *M. Kajita[2], K. Orihara[2], Y. Funase[2], K. Suzuki[2], S. Usuda[3], A. Nambu[3], H. Haba[3];*
[1]Perseus Proteomics Inc., Tokyo, JAPAN, [2]PDRadiopharma Inc., Chiba, JAPAN, [3]RIKEN, Wako, JAPAN.

Aim/Introduction: Radiopharmaceutical therapy (RPT) typically uses an antibody to deliver primarily β- or α-particle emitting radionuclide to malignant cells in primary or metastatic tumors, selectively localizing it without affecting tissues that do not express the target antigen. CDH3, one of cadherin family, is associated with a more aggressive cancer cell phenotype and expressed minimally in normal adult human tissues. Thus, anti-CDH3 antibody is a promising tool for RPT against several solid cancer overexpressing CDH3 such as head and neck, ovarian, pancreatic and lung cancer. A phase 1 clinical trial of a radiolabeled anti-CDH3 antibody, yttrium-90 (90Y)-PPMX-T002 (former called FF-21101) has demonstrated the safety profile of the RPT with some early signs of antitumor activity (NCT02454010)1. On the other hands, anti-CDH3 antibody with more biologically effective warhead would be desirable for stronger efficacy leading to more benefit to patients. The linear energy transfer of α particles in tissue are much larger than that of β particles and can inflict much more damage to DNA in cancer cells. Here we report the preclinical efficacy data of actinium-225 (225Ac)-PPMX-T002 in comparison with 90Y-PPMX-T002. ***Materials and Methods:*** PPMX-T002 was labeled with 90Y or 225Ac via DOTA (1,4,7,10-tetraaza-cyclododecane-1,4,7,10-tetraacetic acid). The radiolabeled antibody was intravenously administered once into xenograft mouse with human pancreatic adenocarcinoma cell line HPAF-II. Biodistribution of 225Ac-PPMX-T002 was estimated by counting the radioactivity of the isolated each organ over time after the single administration. The maximum tolerated dose (MTD) of those antibodies was evaluated by measurement of the body weight. The efficacy was assessed by measuring tumor size and survival time xenograft mouse model. ***Results:*** Remarkable

tumor accumulation of 225Ac-PPMX-T002 was observed in the mouse xenograft model. The tumor uptake was 45.4 % ID/g on 7 days after dosing. MTD of 90Y- and 225Ac-PPMX-T002 was estimated to be 308 kBq/g or 1.42 kBq/g, respectively. The single administration of 225Ac-PPMX-T002 resulted in the complete inhibition of tumor growth at MTD or half dose of MTD without the regrowth of tumor during the experimental periods while 90Y-PPMX-T002 showed only partial inhibitory effects at MTD. Survival time analysis also demonstrated that 225Ac-PPMX-T002 has the remarkable efficacy, and superior to 90Y-PPMX-T002. ***Conclusion:*** 225Ac-PPMX-T002 RPT exhibited high anti-tumor efficacy with tolerable toxicity in animal experiments, suggesting the potential human clinical application. ***References:*** 1 Clin Cancer Res (2020) 26 (22): 5830-5842.

EP-0090

Therapeutic potential of a lead-212 labeled anti-PTK7 antibody in mice with intraperitoneal ovarian cancer

K. Lindland[1,2,3], *R. G. Li[3], M. M. Malenge[3], C. Hinrichs[3], S. M. Dragovic[3], A. Juzeniene[2,1], S. Westrøm[3], T. B. Bønsdorff[3];*
[1]University of Oslo, Oslo, NORWAY, [2]Oslo University Hospital, Oslo, NORWAY, [3]Oncoinvent AS, Oslo, NORWAY.

Aim/Introduction: The transmembrane protein tyrosine kinase 7 (PTK7) is overexpressed in multiple cancer types, including ovarian cancer, making it of interest for molecularly targeted therapy. The current study was performed to evaluate the therapeutic potential of a novel chimeric anti-PTK7 monoclonal antibody, chOI-1, labelled with the in vivo alpha particle generator lead-212 (212Pb). To the best of our knowledge, there are no other reports on the potential for radionuclide therapy targeting PTK7. ***Materials and Methods:*** The affinity of chOI-1 variants for human PTK7 was evaluated by surface plasmon resonance (SPR) and binding to human ovarian cancer Skov-3-luc cells examined by flow cytometry. chOI-1 antibodies were conjugated to TCMC and radiolabelled with 212Pb. Radiochemical purity (RCP) and immunoreactive fraction (IRF) of the radiolabelled antibodies was determined by iTLC and one point cell assay, respectively. Therapeutic potential of [212Pb]Pb-TCMC-chOI-1 was evaluated in athymic nude mice inoculated intraperitoneally (i.p.) with 5×106 Skov-3-luc cells. The mice were treated i.p. 3 days post cell inoculation with saline, chOI-1 alone, 211 kBq or 384 kBq [212Pb]Pb-TCMC-hIgG, or 180 kBq or 405 kBq [212Pb]Pb-TCMC-chOI-1, at a constant antibody amount (10 µg), n=8 for each group. The animals were euthanised on day 52-53 and all i.p. tumours collected and weighed. ***Results:*** SPR analysis demonstrated KD values of 0.3 nM for chOI-1 against human PTK7. Flow cytometry confirmed the binding of chOI-1 to the Skov-3-luc cell line, with a KD of 16.9±2.8 nM. The RCP of [212Pb]Pb-TCMC-chOI-1 was ≥98% and cell experiments showed that the binding properties were retained after radiolabelling, with an IRF on Skov-3-luc cells of 66.3±4.4%. The average i.p. tumour weight was reduced 4-167-fold in the groups receiving [212Pb]Pb-TCMC-chOI-1 (0.003±0.005 g for 180 kBq; 0.007±0.010 g for 405 kBq) compared to controls. The difference was statistically significant ($p<0.009$) when compared to the saline (0.5±0.3 g) and chOI-1 group (0.4±0.2 g) but not versus the groups given unspecific [212Pb]Pb-TCMC-hIgG (0.12±0.09 g for 211 kBq; 0.03±0.02 g for 384 kBq). However, the tumour burden favoured treatment with [212Pb]Pb-TCMC-chOI-1. Amongst the sixteen [212Pb]Pb-TCMC-chOI-1 treated mice, no animal had a total tumour burden above 0.03 g, whereas 63% (10 of 16) of the mice given [212Pb]Pb-TCMC-hIgG did. ***Conclusion:*** The results from this study warrant further investigation of [212Pb]Pb-TCMC-chOI-1 as a candidate for targeted radionuclide therapy in PTK7-expressing ovarian cancer.

EP-0091

SSTR2-targeted peptide-drug conjugates for the selective inhibition of PARP1

L. Koller[1], *S. Gosh[2], C. Kitzberger[1], W. A. Weber[1], A. Azhdarinia[2], S. Kossatz[1];*
[1]University Hospital rechts der Isar, Department of Nuclear Medicine, Munich, GERMANY, [2]The University of Texas Health Science Center at Houston, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Peptide receptor radiotherapy (PRRT) targets cancer cells using radiolabelled peptides, but the clinical response is limited, with inevitable disease progression. It has been postulated that the DNA damaging effect of radiotherapy can be potentiated by simultaneous inhibition of DNA repair, e.g. using poly-ADP-ribose-polymerase 1/2 (PARP1/2) inhibitors (PARPi). However, the off-tumour accumulation of PARPi into rapidly proliferating healthy cells can lead to dose limiting side effects, especially in combination therapy settings. We propose a strategy for the selective delivery of PARPi via peptide-drug-conjugates to limit the synthetic lethality of combination therapies to SSTR2-expressing tumour cells and increase the therapeutic index of PARPi/PRRT combination therapy in neuroendocrine tumours. ***Materials and Methods:*** Four SSTR2-targeted rucaparib (ruc) conjugates bearing a custom cyclen analogue for radiolabelling and a glutathione cleavable disulfide linker for intracellular ruc release were synthesized via solid phase peptide synthesis. We determined hydrophilicity (logD7.4) and cell uptake using 68Ga-labelled analogues of the drug conjugates. SSTR2-mediated ruc-delivery was assessed via fluorescence microscopy and flow cytometry. SSTR2-dependent cytotoxicity was determined via AlamarBlue assays. Furthermore, we performed PET imaging with two of the compounds in SSTR2-positive H69 xenograft-bearing mice. ***Results:*** The 68Ga-labelled compounds showed logD7.4 values between −2.58±0.04 and −2.10±0.19. We observed receptor-mediated cell uptake of [68Ga]Ga-Ruc-(PEG)4-TATE that was similar to [68Ga]Ga-DOTA-TATE after 60 min in AR42J (10.89±4.01% vs. 14.55±2.54%) and H69 cells (9.24±2.76% vs. 10.56±0.27%). Using the intrinsic fluorescence of rucaparib, we were able to confirm internalization into SSTR2-expressing cells, whereas minimal uptake was found in SSTR2-negative cells. Viability of SSTR2-expressing H69 cells was reduced after 72 h of treatment with 5 µM of either Ruc-TOC or Ruc-(PEG)4-TATE to 67.6±27.1% and 72.5±1.9%, respectively, as compared to untreated cells and SSTR2-negative HCT116-WT cells (viability >95%). Comparable treatment with free rucaparib reduced cell viability of H69 cells (44.8±4.67%) as well as of HCT116-WT cells (72.9±13.2%). Ruc-TOC and Ruc-(PEG)4-TATE showed specific accumulation in H69 tumours in vivo as determined via PET/MR imaging at 60 min post injection, with uptake values of 2.2 %ID/g and 2.7 %ID/g, respectively. The compounds were excreted renally and showed kidney uptake of 3.7 %ID/g and 2.9 %ID/g, respectively, while all other organs showed low uptake. ***Conclusion:*** We successfully synthesized multiple SSTR2-targeting rucaparib conjugates and observed efficient targeting and cell killing in vitro. SSTR2-dependent uptake was further demonstrated in preliminary in vivo evaluations along with favorable biodistribution and clearance profiles.

EP-0092

[$^{58m/55}$Co]Co-DOTA-hEGF as a novel theranostic pair with efficacy in targeted Auger-electron therapy of glioblastoma

V. S. Gammelsrød[1,2], *S. H. Abild[1,2], A. Y. Nielsen[1], C. A. Poulsen[1], J. D. Ewald[3,2], C. Baun[1], C. G. T. Pedersen[1], M. C. S. Andersen[4], Q. Tang[5], M. Woolley[6], B. W. Kristensen[7,2], B. Halle[4,2], B. B. Olsen[1,2], J. H. Dam[1,2], A. I. Jensen[5], H. Thisgaard[1,2];*
[1]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]Department of Clinical Research, University of Southern Denmark, Odense, DENMARK, [3]Department of Pathology, Odense University Hospital, Denmark, Odense, DENMARK, [4]Department of Neurosurgery, Odense University Hospital, Odense, DENMARK, [5]The Hevesy Laboratory, Department of Health Technology, Technical University of Denmark, Risø, DENMARK, [6]Renishaw Neuro Solutions Ltd, Gloucestershire, UNITED KINGDOM, [7]Department of Pathology, Odense University Hospital, Odense, DENMARK.

Aim/Introduction: Glioblastoma is the most common and aggressive primary brain tumour with a median survival of <16 months. The epidermal growth factor receptor (EGFR) is overexpressed in approximately 55% of glioblastomas, making it a highly relevant target. We present the development and preclinical evaluation of the theranostic pair [58m/55Co]Co-DOTA-hEGF for EGFR-targeted Auger-electron radiotherapy of glioblastoma. Cobalt-58m is a highly relevant radionuclide for emerging Auger-electron radiotherapy with favourable dosimetric properties, suitable half-life (9 h), and feasible production. ***Materials and Methods:*** Cobalt-58m and cobalt-55 were produced on a PETtrace cyclotron. DOTA-conjugated hEGF was radiolabelled with cobalt-58m, cobalt-55, or cobalt-57 by 2 min microwave heating. Cellular kinetics and distribution were measured with [57Co]Co-DOTA-hEGF in EGFR-positive LN229 glioblastoma cells, and A431 carcinoma cells. In vitro viability assessment of [58mCo]Co-DOTA-hEGF was performed using RealTime-Glo. In vivo kinetics of [57Co]Co-DOTA-hEGF was evaluated after intracranial administration in orthotopic glioblastoma-bearing rats by SPECT/CT and ex vivo biodistribution. In vivo therapeutic efficacy of [58mCo]Co-DOTA-hEGF was evaluated in the same rat model (n=6/group) following intracranial injection of 125±5 MBq. Side effects were assessed by blood and histological analyses. Large-brain intracranial distribution was evaluated in pigs infused with [55Co]Co-DOTA-hEGF administered through intracranial administration or convection-enhanced delivery (CED) for 3 hours during dynamic PET/MRI. ***Results:*** [58mCo]Co-DOTA-hEGF and [55Co]Co-DOTA-hEGF were labelled in high yields (98.8±0.6% and 93±6.2%, respectively) and radiochemical purities (95±2.7% and 89.3±0.6%, respectively) with apparent molar activities up to 67.4 MBq/nmol and 10 MBq/nmol. In vitro, [57Co]Co-DOTA-hEGF showed an EGFR-specific uptake (21-84%, 4 h) in both cell lines with rapid internalisation. 56-70% of the activity remained in the cells after 24 h. Up to 14.6% of the cell-associated activity was translocated to the nucleus where Auger-electrons are most effective. Consequently, cell viability was impaired by [58mCo]Co-DOTA-hEGF in a dose-dependent manner in both cell lines. Similarly, significant therapeutic efficacy was demonstrated in glioblastoma-bearing rats with 67% survival of [58mCo]Co-DOTA-hEGF-treated rats 90 days after therapy, with 0% survival of untreated rats and 17% of DOTA-hEGF (vehicle) treated rats. No adverse effects were detected. [57Co]Co-DOTA-hEGF was strongly retained in the brain of glioblastoma-bearing rats with little-to-no uptake outside of the brain. In pig studies, a broad intracranial large-brain distribution was observed by CED administration of [55Co]Co-DOTA-hEGF. ***Conclusion:*** We report excellent efficacy and wide intracranial distribution in a large-brain model of the novel theranostic Auger-electron radiotherapy pair [58m/55Co]Co-DOTA-hEGF. Our results warrant clinical translation for image-guided EGFR-targeted therapy of glioblastoma, via intracranial CED administration.

EP-0093

PARP1-targeted alpha therapy enhances target expression

H. Babazada[1], *P. Martorano[1], H. Lee[1], S. B. Gitto[1], C. N. Ihewulezi[1], M. Samanta[2], V. Batra[2,1], J. M. Maris[2,1], M. D. Farwell[1], D. A. Pryma[1,3];*
[1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, UNITED STATES OF AMERICA, [3]Abramson Cancer Center at the University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.

Aim/Introduction: Alpha particle therapy has high relative biologic effectiveness but does not always result in targeted cell kill. Cells damaged, but not destroyed, by therapy represent an important vector for relapsed and potentially treatment resistant disease if the sublethal therapy inhibits target expression. We hypothesized that targeting activated PARP1, a DNA damage repair enzyme, could increase target expression in sublethally damaged cells as the DNA damage from treatment would induce PARP1 expression. This could potentially enhance the efficacy of fractionated therapy. [^{18F}]FTT is a PET/CT probe that binds to active PARP1 based on the PARP inhibitor rucaparib. [211At]PTT is an alpha-emitting analog. We aimed to test whether [211At]PTT therapy would increase PARP1 expression as measured by [^{18F}]FTT PET/CT and immunofluorescence. ***Materials and Methods:*** IMR-05 (neuroblastoma) flank xenografts were established in female NSG mice (n=3 per group). Two weeks after implantation, imaging of activated PARP1 expression was performed with [^{18F}]FTT PET/CT (10-minute scan 60 minutes after injection). The next day, 370 kBq [211At]PTT was administered IV. PET/CT was repeated at 2 and 6 days after treatment. Regions of interest were drawn around tumors and %ID/g was measured, corrected for decay. Comparisons were evaluated using a paired t test. After imaging, tumors were resected, frozen, and sectioned for immunofluorescence for PARP1 and gammaH2AX, with Hoechst 33342 used to counterstain the nuclei. ***Results:*** Tumor uptake of [^{18F}]FTT increased 25.4% from baseline to day 2 ($p<0.05$), with a decrease back towards baseline by day 6. Indeed, there was no significant difference in uptake at day 6 compared to baseline ($p=0.55$). Immunofluorescence confirms a similar degree of baseline nuclear PARP1 expression at baseline and day 6 with minimal gammaH2AX staining at baseline. On day 2, there is significant gammaH2AX staining with overlapping increase in PARP1 staining. ***Conclusion:*** PARP1-targeted alpha radiopharmaceutical therapy causes a transient increase in nuclear activated PARP1 expression in neuroblastoma xenografts. This creates the potential for fractionated therapy to potentially enhance the therapeutic ratio.

EP-0094

Prostate-specific Membrane Antigen-Targeted Radionuclide Therapy as a Novel Therapeutic Approach in a Syngeneic Immunocompetent Murine Model for Oral Squamous Cell Carcinoma

M. Henrotte[1,2], *D. Creytens[1,2], F. De Vos[1], B. Descamps[1], L. Devisscher[1], W. Huvenne[1,2], K. Kersemans[2], S. Neyt[1], C. Vanhove[1], J. Debacker[1,3,4];*
[1]Ghent University, Ghent, BELGIUM, [2]Ghent University Hospital, Ghent, BELGIUM, [3]Vrije Universiteit Brussel (VUB), Brussels, BELGIUM, [4]Vrije Universiteit Brussel (VUB), Universitair Ziekenhuis Brussel (UZ Brussel), Brussels, BELGIUM.

Aim/Introduction: The prostate-specific membrane antigen (PSMA) is a clinically implemented target for patients with metastatic castration-resistant prostate cancer. However, its expression on tumour-associated neovasculature also makes PSMA a promising target in other malignancies, such as oral squamous cell carcinoma (OSCC). We aimed to assess the effects of PSMA-targeted radionuclide therapy (TRNT) with [177Lu]Lu-PSMA-I&T on tumour growth in a syngeneic orthotopic immunocompetent murine model for OSCC. ***Materials and Methods:*** MOC-1 oral squamous carcinoma cells were cultured and injected (7.5 × 105 in a 15 µL DMEM/15 µL Corning® Matrigel® Matrix mixture) into the left anterior lateral tongue of adult male C57BL/6J mice (n = 13). Eleven days after inoculation, mice within the treatment group (n = 5) received a mean (± SD) single intravenous dose of 152 ± 6 MBq [177Lu]Lu-PSMA-I&T in ≤ 200 µL; animals in the control group (n = 8) received 200 µL of phosphate-buffered saline intravenously. Animals were weighed and caliper measurements-based tumour volumes were calculated twice weekly during 5 weeks. After sacrification, formalin-fixed, paraffin-embedded tumour tissue sections were stained with haematoxylin-eosin and immunohistochemically evaluated for PSMA and endothelial marker CD31. Growth rates were calculated between sequential volume measurements, and between each volume measurement and baseline volume. ***Results:*** In the group treated with [177Lu]Lu-PSMA-I&T, tumour growth was initially restained, with a significantly lower mean volume compared to the control group 4 days after treatment (p = 0.039). In the treatment group, mean volume initially decreased and was significantly lower 6 days after treatment (p = 0.042). The suppressive effect on tumour growth stagnated one week after treatment, whereafter mean volume increased again. However, mean volume remained significantly lower (p = 0.012-0.040) in the treatment group until 30 days after treatment. Growth rates based on sequential volume measurements did not differ significantly between the two groups, but growth rates based on volume measurements compared to baseline did between 10-21 days after treatment (p = 0.003-0.015). ***Conclusion:*** This study is the first to investigate the effects of PSMA-TRNT in an immunocompetent murine model for orthotopically induced OSCC. Our results suggest that a single intravenous dose of c. 150 MBq [177Lu]Lu-PSMA-I&T not only temporarily impeded tumour growth, but also decreased tumour volume in the MOC-1 model. This highlights the potential of PSMA as a novel target for TRNT in mice with OSCC, and advocates further trials with radionuclide therapy in OSCC with regards to dosage and regimen optimisation.

EP-0095

Targeting ATM reverses radioiodine resistance in differentiated thyroid cancer via genotoxic stresses

X. Qiu[1,2], *Y. Pang[1], C. Ma[1];*
[1]Department of Nuclear Medicine, Shanghai Tenth People's Hospital, Tongji University School of Medicine, Shanghai, CHINA, [2]Tongji University, Shanghai, CHINA.

Aim/Introduction: Ataxia-telangiectasia mutated (ATM) is a mutated gene associated with ataxia-telangiectasia disease, encoding a serine/threonine protein kinase. ATM plays a crucial role in maintaining genomic stability by participating in DNA damage repair and cell cycle regulation. It has been implicated in the oncogenesis of various tumors. However, its expression status and clinical significance in thyroid cancer (TC) remain poorly understood. This study aimed to elucidate ATM's role in TC progression and assess its potential as a therapeutic target for TC. ***Materials and Methods:*** Formalin-fixed, paraffin-embedded excised papillary thyroid cancer (PTC) tumor tissue microarrays (TMA) were subjected to immunohistochemistry (IHC) to analyze ATM protein expression levels in PTC. Single-cell transcriptomic and genetic alteration data from patients with various TC subtypes were utilized to examine ATM expression trends across TC subtypes. In vitro, cultured PTC cell lines were used to investigate the mechanism of radioactive iodine (RAI)-131I-induced PTC cell death via RNA sequencing (RNA-seq), immunofluorescence staining, comet assay, and flow cytometry. The synergistic anti-tumor effect of ATM inhibitor and 131I was assessed through CCK8, clone formation, and flow cytometry assays. Furthermore, an in vivo xenograft mouse model of PTC was established to validate the radio-sensitizing effect of ATM inhibitors. ***Results:*** TMA analysis demonstrated heightened ATM expression in radioiodine-resistance (RAI-R) PTC compared to normal PTC in both primary tumors and metastatic lymph node samples. Single-cell analysis revealed a direct correlation between ATM expression levels and the progression of TC malignancy, with increased levels observed in anaplastic thyroid carcinoma (ATC) compared to PTC and normal thyroid tissue. RNA-seq analysis following 131I radiation exposure indicated activation of the DNA damage response (DDR) pathway and cell cycle arrest. Both in vivo and in vitro experiments supported the potential of ATM inhibition to enhance PTC sensitivity to 131I therapy, leading to tumor cell apoptosis via cell cycle regulation. ***Conclusion:*** ATM expression is correlated with the degree of TC malignancy and may play a role in the development of RAI-R by regulating the cell cycle. Additionally, ATM could serve as a therapeutic target for RAI-R in differentiated thyroid cancer (DTC) through genotoxic mechanisms.

EP-0097

Preclinical Evaluation of a Novel Clearing Agent-Independent Approach for Pretargeted Alpha Therapy with ^{212}Pb.

S. Frost[1,2], *A. Haas[3], A. Pichard[2,4], A. Mouchotte[2,4], A. Colmont[2,4], J. Torgue[5], S. Colombetti[2], C. Klein[2], P. Umaña[2];*
[1]Roche Innovation Center Welwyn, Welwyn Garden City, UNITED KINGDOM, [2]Roche Innovation Center Zurich, Schlieren, SWITZERLAND, [3]Roche Innovation Center Munich, Penzberg, GERMANY, [4]Institut Roche, Boulogne-Billancourt, FRANCE, [5]Orano Med LLC, Plano, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Over the years, various pretargeted radioimmunotherapy (PRIT) modalities have been proposed to improve the therapeutic window of systemic radiotherapy. These approaches typically involve a tumour-targeting bispecific antibody (BsAb) that distributes within target tissue, followed by a small radiolabelled molecule that efficiently binds pretargeted sites or is rapidly excreted. An intermediate step is often needed to clear or neutralise circulating pretargeting antibodies that

could otherwise capture the radioligand off-tumour. PRIT thereby minimises healthy tissue exposure while increasing the tumour absorbed dose, which is particularly impactful using short-lived radionuclides such as 212Pb (t1/2 = 10.6 h). However, the logistical complexity and added safety risks of incorporating clearing agents pose challenges to the clinical implementation of PRIT. We therefore developed a novel two-step, clearing agent-independent PRIT regimen for carcinoembryonic antigen (CEA)-positive tumours, involving a complementary bispecific antibody pair and a 212Pb radioligand. Efficacy and tolerability of this two-step PRIT approach were compared with a corresponding three-step PRIT scheme. ***Materials and Methods:*** Mice bearing subcutaneous CEA-expressing BxPC3 xenografts received the two pretargeting antibodies with specificity for CEA and a split high-affinity sub-pM 1,4,7,10-Tetrakis(carbamoylmethyl)1,4,7,10-tetraazacyclododecane (DOTAM) binder: one antibody carrying the VH and the other the VL domain. Tumour-bound, these split VH and VL domains assemble to form the complete binder for the radiolabelled effector molecule 212Pb-DOTAM, administered 7 days later. Another group of mice received a pretargeting CEA-DOTAM BsAb with a complete 212Pb-DOTAM binder. After 7 days, circulating BsAb was neutralised using a dextran-based clearing agent, followed by 212Pb-DOTAM after 24 hours. Two- and three-step CEA-PRIT were compared in terms of 212Pb biodistribution, tumour growth inhibition, and tolerability after three treatment cycles of 0.74 MBq. ***Results:*** Two- and three-step CEA-PRIT significantly and comparably delayed tumour growth, with mild transient body weight loss. Excellent 212Pb tumour specificity was confirmed, with an average tumour uptake of 25-30% of the injected activity per gram of tissue (IA/g) at 24 h p.i. for two-step PRIT and 36-45% IA/g for three-step PRIT, while the blood and kidney retention was <0.5% IA/g and <2 %IA/g, respectively, for both regimens. ***Conclusion:*** Therapeutic efficacy was demonstrated for the novel two-step CEA-PRIT approach, with biodistribution and tolerability data confirming preferential retention of 212Pb-DOTAM in tumours rather than in circulation, suggesting that the logistically complex three-step regimen is obsolete. Translation of this optimised approach to a phase I trial is anticipated, offering potential improvements in the clinical implementation of PRIT.

EP-0098

Combination therapy of benfo-oxythiamine and Luetium-177-PSMA radionuclide therapy in a preclinical prostate cancer model

S. Wolfshöfer[1], *M. Gast[1], N. Beindorff[1], S. Stintzing[1], R. P. Baum[2], P. Grabowski[1];*
[1]Charité - University Medicine Berlin, Berlin, GERMANY,
[2]Curanosticum, Wiesbaden, GERMANY.

Aim/Introduction: Prostate cancer is the second most common cancer in men, as well as the most common cause of cancer-associated deaths in men. Therapy options include surgery, androgen deprivation therapy (ADT), chemotherapy and radioligand therapy. The outlook for patients with localized disease is positive, but metastatic castration-resistant prostate cancer (mCRPC) remains a lethal diagnosis. Therefore, there is a need for new and improved therapeutic approaches. Tumor-specific metabolic reprogramming is widely accepted as an emerging hallmark of cancer. In later stages of prostate cancer, when numerous mutations are accumulated, the Warburg effect is exhibited in tumor cells and causes a high glucose uptake. Thus, targeting cancer the cell metabolism can be a promising strategy for the improvement of prostate cancer therapy. Here, we investigate the anti-cancer potential of benfo-oxythiamine (BOT), a vitamin B1 mimetic, in combination with prostate-specific membrane antigen (PSMA) directed radionuclide therapy (PRLT) in vitro. ***Materials and Methods:*** The anti-proliferative potential of BOT or Oxythiamin (OT) together with ADT was quantified by MTT assay in the PSMA-expressing prostate cancer cell lines LNCaP and LNCaP C4-2. The influence of BOT or OT treatment on androgen receptor (AR) and PSMA protein levels was determined in western blot experiments. Growth inhibitory effects of radioligand therapy with Lutetium-177-PSMA I&T in combination with BOT were assessed by colony formation assay. ***Results:*** BOT and OT reduced cell viability in both investigated prostate cancer cell lines in a dose-dependent manner: BOT displayed a half-inhibitory concentration of 1.1 mM in LNCaP cells and 1.2 mM in LNCaP C4-2 cells. OT had approximately 7-fold higher half-inhibitory concentration in both, LNCaP cells (7.9 mM) and LNCaP C42 cells (9.1 mM). In protein extracts, PSMA levels were reduced in OT treated LNCaP C4-2 cells in comparison to BOT treated cells. Treatment with BOT or OT in combination with ADT increased AR levels in comparison to ADT treatment alone. BOT treatment significantly reduced colony formation capacity of LNCaP C4-2 cells alone, as well as in addition to PRLT. ***Conclusion:*** The thiamine mimetics BOT and OT can reduce growth of prostate cancer cell lines in vitro. We confirmed an additive effect of BOT treatment in combination with Lutetium-177-PSMA I&T in a PSMA expressing prostate cancer cell line. Further investigation of the involved molecular processes could provide a rationale for the evaluation of the therapeutic potential of combinatory treatment of nutraceutical compounds together with radionuclides in prostate cancer.

EP-0099

Targeting the DNA Damage Response Boosts Radiopharmaceutical Therapy Efficacy in Castration-Resistant Prostate Cancer

M. Bio Idrissou[1], *J. Tromp[1], A. Carston[1], E. Santos[1], Y. Medina[1], O. Kwon[1], H. Comas Rojas[1], L. Lambert[1], A. Pinchuk[2], B. Bednarz[1], G. Iyer[3], R. Hernandez[1];*
[1]Department of Medical Physics, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA,
[2]Department of Radiology, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA,
[3]Department of Human Oncology, University of Wisconsin-Madison, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: 177Lu-PSMA-617 radiopharmaceutical therapy (RPT) is an encouraging treatment for men with metastatic castration-resistant prostate cancer (CRPC). However, half of the treated patients do not respond, and progression is inevitable. Thus, to enhance the radiobiological effect of RPT, we pharmacologically disrupted the DNA damage response (DDR) of CRPC cells through combined poly-(ADP-ribose) polymerase 1 (PARP1) and bromodomain and extra terminal (BET) proteins inhibition. ***Materials and Methods:*** We developed ART-101, a longer-acting PSMA-targeting molecule with superior pharmacology than PSMA-617, and employed 177Lu-ART-101 for our combination studies. In vitro, cytotoxicity was determined in PC3-PIP, LNCaP, and 22Rv1 cells treated with 0.3 nM-1 mM Talazoparib (TAZ: PARPi), JQ1 or ABBV-075 (BETi), or combinations. IC50s were determined, and combination effects were evaluated between treatments using established synergy models. Expression changes in the DDR gene (ex. BRCA1/2 and RAD51) were measured 24h-post treatment with BETi by qPCR. In addition, Monte Carlo-based in vitro 177Lu dosimetry estimates

enabled the determination of the absorbed dose-survival response relationship and the combination effects of RPT+BETi. In vivo, 8-week-old male nude mice (N= 5-10) bearing PC3-PIP xenografts received daily oral (for 14 days) TAZ (0.5 mg/kg), ABBV-075 (1 mg/kg), TAZ+ABBV-075, or intravenous 177Lu-ART-101 (18.5 or 37 MBq) alone or combined with TAZ, ABBV-075 or TAZ+ABBV-075. Tumor growth, overall survival, and toxicity were monitored thrice weekly ***Results:*** ABBV-075 showed nanomolar cytotoxic IC50s (100-300 nM) in all cell lines. Interestingly, only 22Rv1 cells responded to TAZ (IC50= 0.4 μM). Synergistic effects were observed for some TAZ+JQ1 combinations in LNCaP and 22Rv1 (CI>10; HAS and Loewe models). Treatments with BETi (0.3 and 3 μM) led to the downregulation of DDR genes BRCA1/2 and RAD51 in all cells: 1.6- to 50-fold difference between treated cells and control. Combination treatments of 177Lu with TAZ/BETi or TAZ+BETi resulted in enhanced cytotoxicity compared to either treatment alone, supporting the purported mechanism of cooperation between 177Lu and DDR disruption. In vivo, 177Lu-ART-101 alone or combined with TAZ/ABBV-075 or TAZ+ABBV-075 demonstrated a strong tumor growth inhibition compared to single-arm treatments. Notably, 177Lu-ART-101 exhibited stronger antitumor effects than 177Lu-PSMA-617, suggesting a potential for an injected-activity de-escalation when combined with DDR inhibitors, thus improving the overall safety of the combination treatment. ***Conclusion:*** Our studies demonstrate the potential of pharmacological DDR inhibition to boost radiobiological response in CRPC. Our preclinical data strongly supports the clinical feasibility of combining TAZ and ABBV-075, two clinical-stage drugs, and RPT in CRPC patients.

EP-0100

[177Lu]Lu-AKIR001 Inhibits Growth of Pancreatic Tumour Xenografts

A. Gustafsson[1], *A. Lundgren Mortensen[1,2], R. K. Selvaraju[3], F. Frejd[1], M. Nestor[1];*
[1]Department of Immunology, Genetics and Pathology, Science for Life Laboratory (SciLifeLab), Uppsala University, Uppsala, SWEDEN, [2]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, SWEDEN, [3]Department of Medicinal Chemistry, BMC, Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Despite therapeutic advancements during the last decades, only a modest increase in overall survival has been seen for pancreatic ductal adenocarcinoma (PDAC) patients. PDAC is refractory to both immuno-, and chemotherapy as well as external beam radiation, surgical resection is currently the only possibility to cure patients. Unfortunately, that is only feasible for the minority that present with local disease. Molecular radiotherapy has the potential to overcome these challenges, and could target both metastases and micrometastases, hopefully returning the cancer to an operable state. This study aimed to assess the anti-CD44v6 antibody AKIR001 labelled with 177Lu as treatment for PDAC, both alone and combined with chemotherapy. ***Materials and Methods:*** chemotherapy.Four PDAC cell lines were evaluated in vitro for CD44v6 expression and specific uptake of [177Lu]Lu-AKIR001. Sensitivity towards paclitaxel and gemcitabine was determined for the BxPC3 cell line. Biodistribution as well as therapeutic effects were studied in Balb/c nu/nu mice bearing BxPC3 tumour xenografts. The therapy study included five treatment groups: PBS control, [177Lu]Lu-AKIR001 monotherapy (4 MBq and 12 MBq), paclitaxel monotherapy, and combination (4 MBq [177Lu]Lu-AKIR001 with paclitaxel). SPECT imaging was conducted to confirm tumour uptake and continuous monitoring of haematoxicity was performed by blood sampling during the study. ***Results:*** All cell lines demonstrated specific [177Lu]Lu-AKIR001 uptake, but BxPC3 had the highest CD44v6 expression and was selected for further experiments. BxPC3 was more sensitive to paclitaxel than gemcitabine (IC50 1.74 vs. IC50 13.50), warranting the choice of paclitaxel for the combination therapy. High and specific tumour uptake in vivo was confirmed by biodistribution (>100%ID/g tissue 96h post-injection) and SPECT imaging. Paclitaxel monotherapy resulted in a modestly increased median survival compared to controls (20 days vs. 13.5 days). At day 46 post-treatment, the percentage tumour-free animals was 80% with 12 MBq, 60% with 4 MBq, and 25% with combination therapy. A slight decrease in white blood cells was observed after treatment with 12 MBq and combination, but levels were quickly restored to baseline. ***Conclusion:*** In conclusion, [177Lu]Lu-AKIR001 monotherapy inhibited tumour growth in vivo and led to prolonged survival without signs of severe haematoxicity, but paclitaxel did not increase the effect. [177Lu]Lu-AKIR001 may be a feasible treatment option for PDAC in the future, but further investigation and optimization of doses and suitable combinations is required.

EP-0101

Evaluation of [^{177}Lu]Lu-radiolabelled bombesin antagonists as potential candidates for GRPR-targeting therapeutic use in prostate cancer

A. Bitzios[1], *P. Kanellopoulos[2], E. Bezverkhniaia[2], I. Zelepukin[2], V. Tolmachev[3], A. Orlova[1];*
[1]Dpt. of Medicinal Chemistry (UU), Uppsala, SWEDEN, [2]Dpt. of Medicinal Chemistry -(UU), Uppsala, SWEDEN, [3]Dpt.of Immunology,Genetics and Pathology (IGP), Uppsala, SWEDEN.

Aim/Introduction: Gastrin releasing peptide receptor (GRPR) belongs to the bombesin receptor family and is frequently overexpressed in prostate cancer. This study is focused on evaluation of the following analogs: AU-RM26-M2 (DOTAGA-PEG2-Pip-[Sar11]RM26), AU-RM26-M4 (DOTAGA-Arg-Arg-Pip-[Sar11]RM26), AU-SAR-M1 (DOTAGA-AMA-Dig-D-Phe-Gln-Trp-Val-Sar-His-Leu-NHEt) and AU-SAR-M2 (DOTAGA-Arg-AMA-Dig-D-Phe-Gln-Trp-Val-Sar-His-Leu-NHEt) labeled with the therapeutic radionuclide Lu-177.These analogs have been previously chosen as potential radiotherapeutic agents(1,2). ***Materials and Methods:*** After labelling with Lu-177 the radiolabeled analogs were compared in vitro and in vivo. The specificity and cellular uptake over time were tested in PC-3 cells.For in vivo stability, blood from healthy NMRI mice (with/without NEP inhibitor saccubitril pretreatment), was collected 5min pi and analyzed with radio-HPLC. The biodistribution profile of labeled antagonists was tested in PC3 xenografed Balb/c nu/nu mice (pretreated with saccubitril) 4h and 23h pi. ***Results:*** All tested peptides were labeled with Lu-177 with high radiochemical yields (>98%) and high radiochemical purity (>97%). The radiolabeled analogs showed high affinity and specificity for GRPR in vitro. High activity uptake in PC-3 cells demonstrating a typical cellular internalization pattern for radioantagonists. In murine peripheral blood, pre-treatment with saccubitril resulted in a substantial increase of the intact peptide (stability improvement: 13-21%, reaching >80%). All peptides had rapid renal clearance from blood and non-GRPR-expressing tissues. Tumor's activity uptake 4h pi was the highest for [177Lu]Lu-AU-RM26-M4 (19.6%IA/g), followed by [177Lu]Lu-AU-SAR-M1 and [177Lu]Lu-AU-SAR-M2 (16.2 and 15.1%IA/g), and the lowest for [177Lu]Lu-AU-RM26-M2 (4.7%IA/g). Retention of activity in tumors was the best for [177Lu]Lu-AU-RM26-M4 (13.5%IA/g 23h pi). Activity uptake in GRPR-expressing organs (pancreas, stomach and small intestines) didn't show any significant difference. At

23h pi, all healthy tissues, except kidney, demonstrated activity uptake much below uptake in tumors. The highest ratio between AUCs (4-23 h pi) for tumors and kidneys was found for [177Lu]Lu-AU-SAR-M1 (5.4-fold). Under GRPR blocking all analogs showed significant decrease in tumor uptake.[177Lu]Lu-AU-RM26-M4 had the highest kidney uptake at 4h pi (6.1%IA/g), but there was no statistical difference between analogs at 23h ***Conclusion:*** Four new GRPR antagonistic analogues were labeled with Lu-177 and tested on the utility for GRPR-targeting radiotherapy. [177Lu]Lu-AU-RM26-M4, [177Lu]Lu-AU-SAR-M1, and [177Lu]Lu-AU-SAR-M2 demonstrated favorable properties for therapeutic radioligand, i.e. rapid clearance, high in vivo stability, high specific uptake in tumors, and low uptake in excretory organs. Based on tumor retention ratios and the lowest kidney uptake, [177Lu]Lu-AU-SAR-M2 is considered the most promising for a follow up therapy study. ***References:*** (1) Kanellopoulos et al. Development of Pb-203 Labeled SSTR-Targeting Peptides as Surrogates for Pb-212 Labeled Radiopharmaceuticals

J. Byun[1,2,3], *J. Paeng[1], D. Lee[4], Y. Kim[1,3], R. Yoo[1], Y. Lee[1], K. Kang[1,2,3], M. Schultz[5], G. Cheon[1,2];*
[1]Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [2]Department of Biomedical Sciences, Seoul National University, Seoul, KOREA, REPUBLIC OF, [3]Cancer Research Institute, Seoul National University, Seoul, KOREA, REPUBLIC OF, [4]Department of Physics and Chemistry, Korea Military Academy, Seoul, KOREA, REPUBLIC OF, [5]Perspective Therapeutics Inc, Coralville, IA, UNITED STATES OF AMERICA.

Aim/Introduction: Somatostatin receptor subtype 2 (SSTR2) is a key target molecule for peptide receptor radionuclide therapy (PRRT) in neuroendocrine tumors (NET). This study aims to assess the feasibility of Pb-203 labeled peptides as surrogates for Pb-212 labeled radiopharmaceuticals. ***Materials and Methods:*** SSTR2 agonists (i.e., DOTATATE, PSC-PEG2-TOC) and antagonists (i.e., DOTA-LM3, DOTA-PEG2-LM3) were radiolabeled with Pb-203 and evaluated to identify the most promising candidate for PRRT. The labeling efficiency and stability (in saline, human serum; up to 48 h) of the Pb-203 labeled peptides were determined using radio instant thin layer chromatography-silica gel (iTLC-SG) with 0.1 M citric acid, 50% acetonitrile and 75% MeOH as mobile phases. In vivo SPECT/CT imaging and biodistribution studies with the administrations of 203Pb-DOTATATE and 203Pb-PSC-PEG2-TOC were conducted in normal mice (tumor free) to evaluate the initial pharmacokinetics of the radiopharmaceutical candidates. In a separate study, 68Ga-DOTATOC PET/MRI and 177Lu-DOTATATE SPECT/CT imaging was performed in AR42J (SSTR2 positive) and MDA-MB-231 (SSTR2 negative) tumor-bearing mice for the baseline evaluation of NET mouse models. ***Results:*** Excellent radiochemical purity (>98%) was observed for all investigated Pb-203-labeled peptides (DOTATATE, PSC-PEG2-TOC, DOTA-LM3, and DOTA-PEG2-LM3). The stability of the radiopeptides in both saline and human serum was higher than 95% for 48 hours at 37°C. Initial in vivo imaging data suggested that 203Pb-PSC-PEG2-TOC exhibited rapid excretion via the kidneys, with significantly lower retention, compared to 203Pb-DOTATATE for 48 hour (1.18 vs. 2.59%ID/g). In addition, the imaging data using the AR42J-bearing mouse model confirmed the specific tumor uptake of 68Ga-DOTATOC and 177Lu-DOTATATE (15.07 ± 6.05 for AR42J tumors vs. 2.19 ± 0.49 for MDA-MB-231 tumors; 68Ga-DOTATOC; $P < 0.001$). ***Conclusion:*** The SSTR2-targeting peptides investigated exhibited excellent radiolabeling performance and stability with Pb-203. The imaging data suggested the feasibility of using Pb-203-labeled radiopharmaceuticals as surrogates for Pb-212 counterparts, potentially enabling Pb-203 image-guided Pb-212 therapy for NET. Further studies will be followed to evaluate thetherapeutic potential of Pb-212-labeled radiopharmaceutical candidates in NET mouse models.

EP-0103

Multimodality imaging with SPECT/CT and BLI to analyze the efficacy of hepatitis B vaccine candidates

M. Kim[1,2,3], *H. Kim[1], S. Lee[1,3], K. Kang[1,2,3], H. Youn[1,3];*
[1]Department of Nuclear Medicine, Cancer Imaging Center, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [2]Department of Biomedical Sciences, Seoul National University Graduate School, Seoul, KOREA, REPUBLIC OF, [3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: : To prevent Hepatitis B virus (HBV) infection, the large hepatitis B virus antigen (L-HBsAg), a protein on the surface of HBVs, is used as an antigen, but its effect alone is insignificant. In order to strengthen the immune response, it is common to use antigens and adjuvants together in vaccine candidates, so various adjuvants are being developed. For vaccine candidates consisting of antigens and adjuvants, antigen distribution is important in evaluating vaccine efficacy. Therefore, in this study, SPECT/CT was used to image vaccine candidates and track the distribution of antigens according to different adjuvant compositions. ***Materials and Methods:*** L-HBsAg was labeled with radioactive iodine (125I-L-HBsAg). C57BL6.Albino mice was inoculated with 125I-L-HBsAg or/and Pam3CSK4 or/and Poly(I:C) via intramuscular injection. 125I labeled L-HBsAg was monitored using animal SPECT/CT. To visualize the dynamics of immune cells following vaccination, splenocytes of luciferase transgenic mice were intravenously injected into B6.Albino. Bioluminescence imaging (BLI) signals were acquired using an IVIS 100 System. ***Results:*** Comparing the signal strength and persistence of 125I-L-HBsAg at the injection site after vaccination using SPECT/CT, the mixture of L-HBsAg, Pam3CSK4 and Poly(I:C) administrated group remained highly expressed until 5 days. As a result of visualizing the dynamics of immune cells with BLI after vaccination, the highest expression was seen at the injection site on day 6. Compared to L-HBsAg alone, 3.09 and 4.43-fold higher BLI signals were observed in the group inoculated with one or two types of adjuvants. [유-1] At the spleen, 1.75- and 2-fold higher BLI signals were observed, respectively. In the right inguinal lymph node, the BLI signal from splenocytes of antigen/adjuvants mixture remained higher than antigen alone at all time point. and was 4.73 fold higher on the day 6. In addition, when two adjuvant mixture were administered, IFN- γ secreting cells were observed to be 16 times more than antigen only, and the total IgG response was also observed to be 12 times higher. The increase of luciferase+CD45+ cells demonstrated higher immune responses and increased function in both T and B cells. ***Conclusion:*** PECT/CT with iodine-labeled antigen and BLI of immune cell dynamics allowed successful evaluation of the efficacy of adjuvants in vaccine candidates. In this study, we confirmed that TLR-associated adjuvant to promote immune responses induced more effective immune response than using HBsAg alone.

Application of TSPO-specific ^{18}F-GE180 PET for the prediction of propacetamol-induced acute liver failure

***D. Kim*[1]**, *H. Yoon*[2], *B. Kim*[2], *B. Moon*[2], *S. Kang*[2];
[1]*Department of Emergency Medicine, College of Medicine, The Catholic University of Korea, Incheon, KOREA, REPUBLIC OF,* [2]*Department of Nuclear Medicine, College of Medicine, Ewha Womans University, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Acetaminophen overdose frequently leads to acute liver failure (ALF). Predicting fatal disease progression is crucial for effective therapeutic planning. Translocator protein (TSPO), formerly known as peripheral benzodiazepine receptor, plays a pivotal role in molecular transport, oxidative stress, apoptosis, and energy metabolism. In this study, we aimed to assess whether earlier diagnosis of ALF is feasible using TSPO PET with 18F-GE180. ***Materials and Methods:*** ALF was induced in mice by intraperitoneal administration of propacetamol (a prodrug form of acetaminophen) at a lethal dose of 1500 mg/kg. 18F-GE180 PET images were acquired after 3 hours, and mean standardized uptake values (SUVav) of the liver were determined. TSPO expression levels were assessed using real-time polymerase chain reaction and Western blotting analysis, including histological analysis. ***Results:*** The liver SUVav in the group receiving the lethal dose of propacetamol showed a significant increase compared to the control group ($p = 0.001$ by Mann-Whitney test). During the 48-hour observation period, 6 of the 11 mice did not survive while 5 survived. The liver SUVav in the non-survived group demonstrated a significant increase compared to the survived group ($p = 0.045$ by Mann-Whitney test). Furthermore, both mRNA and protein levels of TSPO were elevated in the ALF group. Immunohistochemistry in the liver of propacetamol-induced liver failure group showed significantly higher TSPO protein expression than the control group. ***Conclusion:*** The TSPO-specific 18F-GE180 PET enabled visualization of propacetamol-induced ALF through TSPO overexpression. These findings highlight the potential utility of hepatic uptake by TSPO PET as a non-invasive imaging biomarker for the early stages of ALF. ***References:*** 1. Aim/Introduction: Due to high prevalence of cancer in all around the world, early imaging of tumor sites is very important step in their successful treatment. Tumor stroma comprises a significant mass (> 90%) of solid tumors and FAP is highly expressed in that environment without being found in healthy tissues, the strategic targeting of FAP emerges has gained more interest in recent researches. FAP is a key role in feeding, removing waste products from tumors and their evading from immune system (1-2). In present study, we aim to introduce a new FAPI labeled 68Gallium which can detect various cancers. ***Materials and Methods:*** A new cyclic peptide targeting FAP was designed and synthesized using solid phase method. The 68Ga-labeling process was done via DOTA conjugated to the peptide. After quality control of the prepared tracer, the preclinical pharmacokinetic was determined in HEK-293 xenograft Nude mice with biodistribution study and positron emission tomography-computed tomography (PET/CT scan). ***Results:*** The 68Ga-labeled FAPI was achieved with high radiochemical purity (RCP> 99%) and stability during 3 hours in saline and human plasma. The accumulation of 68Ga-FAPI in HEK-293 tumor sites was significantly increased during 4 hours post injection. The radioactivity in non-target tissues was decreased, so that the tumor/blood and tumor/liver ratio were more than four times within this time. Moreover, the amount activity in tumor was not significantly changed after 24 hours. Finally, PET/CT scans in HEK-293 tumor-bearing mice model revealed high tracer uptake in the tumor sites. ***Conclusion:*** The new 68Ga-FAPI is a promising agent which has improved the kinetic behavior and retention properties compared with 68Ga-labeled diagnostic FAPI tracers. Further studies on its therapeutic application in different cancers are ongoing. ***References:*** 1) Roustaei H, Kiamanesh Z, Askari E, Sadeghi R, Aryana K, Treglia G. EP-0106

Preclinical imaging evaluation of a bispecific antibody targeting hPD1/CTLA4 using humanized mice

X. Hou;
Peking University Cancer Hospital, Beijing, CHINA.

Aim/Introduction: At present, with the discovery of immune checkpoint, immune checkpoint immunotherapy has been successful in the clinical treatment of cancer, the lack of an efficient way to screen patients who are responsive to immunotherapy challenges PD1/CTLA4-targeting cancer treatment. Immunotherapeutic efficacy cannot be clearly determined by peripheral blood analyses, tissue gene markers or CT/MR value. Here, we used radionuclide 124I to label the PD1/CTLA4 double-targeted antibody cardonilizumab (AK104) and imaging to detect the distribution of PD1/ CTLA4-positive cells in PD1/CTLA4 humanized mice. Here, we used a radionuclide and imaging techniques to investigate the novel dual targeted

antibody cadonilimab (AK104) in PD1/CTLA4-positive cells in vivo. ***Materials and Methods:*** In this study, N-Bromosuccinimide (NBS) was used as an oxidant and labeled with AK104 (~200 kDa) using nat/124/125I, the high quality [nat/124/125I]I-AK104 was purified by a dimensional exclusion column (PD-10). After the binding ability of AK104 to PD1/CTLA4 protein was determined, the Kd value of AK104 uptake by PD1/ CTLA4-positive cells was determined with anti-PD1 monoclonal antibody (AK105) and anti-CTLA4 monoclonal antibody as control groups. Afterwards, the PD1/CTLA4 dual humanized mouse model with hPDL1 MC38 cells inoculated into the armpit was subjected to tail vein injection of 124I-AK104 for biological distribution and imaging experiments. The maximum standard uptake value (SUVmax) of organs in the imaging group of mice was determined. Finally, the distribution of PD1/CTLA4 positive cells was detected by immunohistochemistry and multicolor immunofluorescence assay. ***Results:*** The 124I-AK104 showed high radiochemical purity and specific activity . There was no significant difference in the ability of AK104 and natI-AK104 to bind PD1/CTLA4 proteins. The immuno-PET results showed that 124I-AK104 exhibited strong PD1/CTLA4 targeting in humanized mice, not only at the tumor site but also in the spleen. Compared with AK105 and anti-CTLA4 mAb imaging, 124I-AK104 imaging has excellent SUVmax at the tumor site and a higher tumor to non-tumor (T/NT) ratio. IHC and coimmunofluorescence staining results showed that all tumor sites in the imaging group mice contained PD1/CTLA4 positive cells. The dosimetry estimation study showed that the effective dose of 124I-AK104 is 0.112 mSv/MBq. ***Conclusion:*** The results demonstrated the potential of translating 124I-AK104 into a method for screening patients who benefit from immunotherapy and the efficacy, as well as the feasibility, of this method was verified by immuno-PET imaging of humanized mice.

EP-0107

Inhibition Study of Specific Met/Trk Kinase Inhibitor L009 on In Situ Liver Tumor Animal Model

D. Guifang, *G. Ruolan;*
Academy of Military Medical Sciences, Beijing, CHINA.

Aim/Introduction: To investigate the inhibitory effect of a novel small molecule compound L009 targeting Met and Trk kinases specifically on the BALB/c nude mouse liver in situ tumor model. ***Materials and Methods:*** IVIS Spectrum CT imaging system (PekinElmer); BALB/c nude mice purchased from Beijing Vital River Laboratory Animal Technology Co., Ltd., maintained at 25℃ with a 12-hour light/dark cycle and 55% humidity, fed with sterile water and feed. The breeding conditions and experimental procedures complied with the requirements of animal protection regulations. Hep G2 liver tumor cells were infected with pCDH-luc2-GFP plasmid lentivirus to construct the BALB/c nude mouse liver in situ tumor model. Three days after surgery, nude mice were randomly divided into three groups (N=10). The model control group was given blank solvent (0.5% CMC-Na), the experimental group was given L009 (48 mg/kg), and the positive control group was given Sorafenib (50 mg/kg), administered twice daily for 3 weeks. Bioluminescence imaging technology was used to detect the luminescence intensity of tumor cells in the livers of animals in different groups. ***Results:*** After 21 days of continuous administration, the fluorescence intensities in the liver in situ of the model control group, L009 treatment group, and Sorafenib positive control group were 2.59±5.57×109 p/sec, 2.70±2.03×108 p/sec, and 2.70±2.03×108 p/sec, respectively. The calculated inhibition rates of L009 treatment group and Sorafenib positive control group on nude mouse liver in situ tumors were 78.34±39.44% and 75.76±20.65%, respectively (P>0.05). ***Conclusion:*** The small molecule targeting Met/Trk kinases inhibitor L009 has a good inhibitory effect on BALB/c nude mouse liver in situ tumors, with inhibition effects similar to the positive drug Sorafenib.

EP-0108

Development of a novel ^{68}Ga labeled FAPI-PET tracer for molecular imagingof cancer-associated fibroblasts

H. Seo[1], *J. Byun[1], R. Yoo[2], G. An[3], J. Gim[3], S. Lee[3], J. Jeong[3], Y. Lee[1];*
[1]Seoul National University, Seoul, KOREA, REPUBLIC OF, [2]Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [3]Cellbion, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Fibroblast activation protein (FAP) is overexpressed in stroma tissues of most cancers including breast, lung, colorectal and gastrointestinal cancer and low expression in normal tissues making it an ideal target to inhibit tumor cell growth[1,2]. A variety of quinolone based FAP inhibitors (FAPi) were extensively studied and showed promising results as SPECT/PET imaging agents. However, short residence time in tumor microenvironment limits the use of these compounds for radiotherapy. In this study, we have developed a FAPi conjugated NOTA derivative (CB0006NT), labeled it with 68Ga under mild reaction condition and studied the feasibilities of [68Ga]Ga-CB0006NT radiotracer as potential PET imaging agent for detecting cancer-associated fibroblasts (CAFs) which the hope to improve the tumor retention and low normal tissue uptake. ***Materials and Methods:*** A wide variety of labeling conditions were studied, including effect of pH, temperature and amount of NOTA-FAPi (CB0006NT) and incubation time on radiolabeling efficacy using radio-TLC (ITLC-SG/0.1 M citric acid). The in-vitro serum stability with [68Ga]Ga-CB0006NT in a 37°C shaking incubator for 4 h was tested. In-vivo distribution of [68Ga]Ga-CB0006NT was conducted in normal mice and PET/MR image was acquired after 1 h post-injection of [68Ga]Ga-CB0006NT (3.7 MBq/100 µL). ***Results:*** Under optimized conditions (CB0006NT; 40 µg, 45 nmol; 0.1 M acetate buffer, pH 5, 200µL; incubation time, 10 min at RT) [68Ga]Ga-CB0006NT was obtained in high radiochemical efficiency (≥99%). The in vitro stability of [68Ga]Ga-CB0006NT was performed in human serum and demonstrated high stability up to the time period under investigation (4 h). The [68Ga]Ga-CB0006NT showed high uptake rapidly extracted through the intestine and no uptake was observed in normal tissue which showed its normal distribution profile. ***Conclusion:*** In conclusion, we synthesized CB0006NT and optimized radiolabeling conditions of [68Ga]Ga-CB0006NT and in vivo distribution in normal mice. Further studies in animal xenograft are in progress to check the uptake in tumor sites. [68Ga]Ga-CB0006NT was expected to contribute to the CAFs diagnostic agents targeting various diseases related to cancer. ***References:*** [1] Fitzgerald AA and Weiner LM. The role of fibroblast activation protein in health and malignancy. Cancer Metastasis Rev 2020;39:783-803. [2] Kalaei Z, Manafi-Farid R, Rashidi B, Kiani FK, Zarei A, Fathi M, et al. EP-0109

Count Rate Performance of Pre-Clinical SPECT/CT With Next Generation Multi-Pinhole Collimators

A. Drews[1], *A. Jones[1], L. Vass[1], K. Sunassee[1], M. Kovacs[2], T. H. Witney[1], P. K. Marsden[1], L. Livieratos[3,1];*
[1]School of Biomedical Engineering & Imaging Sciences,

King's College London, St Thomas' Hospital, London, UNITED KINGDOM, [2]Mediso Medical Imaging Systems, Budapest, HUNGARY, [3]Department of Nuclear Medicine, Guy's and St Thomas' NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: System deadtime behaviour is an important performance marker for preclinical Single Photon Emission Computed Tomography (SPECT) devices which can inform and optimise imaging protocols. ***Materials and Methods:*** Here we report phantom-based system count rate linearity measurements for a preclinical dual modality SPECT/CT system equipped with novel low- and high-energy multi-pinhole (MPH) collimators (16 pinholes per collimator). Measurements were performed with point- and cylinder sources (Ø1mm and Ø10mm x 10mm length) across an activity range from ~200 MBq to <0.1 MBq for 99mTc and 18F. For 99mTc, standard-energy MPH mouse whole body collimators (up to 300 keV) were used, while for 18F next generation high-energy MPH collimators were used. Data were acquired in list mode until at least 105 counts were acquired per time frame. The detected count rate as a function of input activity, as well as reconstructed image uniformity in the case of cylinder sources, were analysed for a +/-20% energy window centred at 140.5 keV for 99mTc and at 511.0 keV for 18F. Data were reconstructed with an ordered subset expectation maximization (OSEM) algorithm. ***Results:*** For both radionuclides and collimator sets, the measured count rate was linear over the range tested. Count rate showed zero losses up until 100 MBq, with a loss of 10% only occurring at 200 MBq for 99mTc. Total activity determined from reconstructed images mapped against input activity was linear for the same range and matched decay-corrected values from calibrated well-counter measurements with <5% error below 100 MBq for 99mTc. Reconstructed image uniformity of cylinder sources was largely maintained across the range of input activities and only degraded at low input activities of <1MBq as a result of low count noise. ***Conclusion:*** We conclude that the chosen preclinical multi-pinhole SPECT system provides excellent count rate linearity for the test conditions (point sources in air, distributed source in scatter) for both 99mTc and 18F over a significantly wider range than typical activities (~10-25 MBq) currently used in the pre-clinical setting.

EP-0110

The snail Lissachatina fulica as a model for lungworm pathogenesis using radio-labeled parasites

J. van de Sanden[1], *A. Dusch[2], M. Bernsen[1], F. A. Verburg[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]Institut für Parasitologie Justus-Liebig-Universität Gießen, Gießen, GERMANY.*

Aim/Introduction: In Europe, lungworm parasites such as Angiostrongylus vasorum and Crenosoma striatum pose significant threats to both wildlife and domesticated canids. In tropical regions the varieties Angiostrongylus cantonensis and Angiostrongylus costaricensis, which can infect mammals, including humans, can even cause the deadly disease Angiostrongyliasis. With the interconnectedness through global trade and travel, and the ongoing impacts of climate change, the incidence of these diseases is projected to rise in Europe. This study introduces an innovative method for studying parasite pathogenesis by employing the gastropod Lissachatina fulica as a model organism for intentional infection and radiolabeled parasite larvae for in imaging of larva/parasite migration. ***Materials and Methods:*** The larvae of Crenosoma striatum and Angiostrongylus vasorum were acquired through isolation using a modified Baermann-Wetzel technique on infected hedgehog and canid feces. For infection we used doses of 500 - 2000 larvae. These parasites were then incubated with 50 MBq 18F-FDG in 4 ml 0.9% NaCl solution at room temperature for 30 minutes. Subsequently, the larvae underwent washing via centrifugation for 5 minutes at 3500 rpm to remove the supernatant, followed by resuspension in a physiological salt solution at 0.9%. The gastropods received orally administered radio-labeled parasites and were immobilized via cooling. Following this, three subjects were subjected to PET/CT scans immediately and after a 2-hour migration period. Post-scanning, the gastropods were cryo-euthanized and artificially digested in a low pH environment to simulate predator-prey interactions and to confirm the location of the parasites. The number of parasites per organ was quantified and compared against the PET/CT results. ***Results:*** Both A. vasorum and C. striatum exhibited a consistent ability to undergo incubation with FDG. The result of the incubations yielded an activity between (32.5 -72 Bq/Larvae). PET/CT images revealed hotspots primarily in the snail's digestive tract immediately post-feeding indicating limited larval dispersal at that stage. At 2 hours post-feeding, displayed a more widespread distribution throughout the gastropod's body indicative of larval migration. Analysis of digested samples revealed confirmed accumulation of larvae in certain organs, especially albumen gland and hepatopancreas, although at lower levels than after a infection without radiolabeling. The latter might indicate that the 18F-FDG illicits an adverse effect on the parasites. ***Conclusion:*** Our findings highlight the robustness of A. vasorum and C. striatum in incubating with FDG, with notable uptake observed even after washing. PET/CT images revealed dynamic changes in parasite distribution over time, indicating potential avenues for further investigation.

EP-0111

Optimization of the scanning protocol for patients with primary and secondary tumors according to PET-CT with ^{18}F-FET

E. Gromova, *G. Kataeva, K. Kovalev, A. Dikanov, D. Susin; LDC MIBS, Saint-Petersburg, RUSSIAN FEDERATION.*

Aim/Introduction: PET-CT with 18F-FET is an important nuclear medicine technique in monitoring the treatment of patients with brain tumors. According to EANM guidelines the standard protocol PET-CT with FET is static scanning from 20 to 40 minutes after injection.We studied 117 patients from 8 to 73 years with foci of pathological hyperfixation FET in brain. Of these, 74 patients were diagnosed with glioma of varying degrees of malignancy, 43 patients had secondary brain damage, 51 patients did not receive any treatment; 66 patients received different types of treatment, including surgery, radiation, and chemotherapy. ***Materials and Methods:*** PET-CT protocol: start scanning 20 min after injection; scanning time is 20 minutes in list-mode; reconstruction of data: from 20 to 40 - «standard», from 20 to 30 - «early» and from 30 to 40 minutes - «late» images. The assessment was carried out using a semi-quantitative method - with the calculation of SUV

max and SUV peak in the lesion and contralateral intact cortex, as well as the ratios of TBR max and TBR peak. ***Results:*** Based on a comparison of «early» and «late» images it was found that regardless of the type of tumor and the type of treatment performed in the lesions the values of all parameters do not differ significantly while in the cortex in «late» images the values of SUV max and SUV peak is significantly higher and accordingly TBR values are significantly lower than in earlier images.In routine practice we can reduce the scanning time to 10 minutes with the period from 20 to 30 minutes after injection being preferable because TBRmax during this period is comparable to that from 20 to 40 minutes. ***Conclusion:*** Thus, reducing scanning time will allow us to:1. make the examination more comfortable for patients and reduce the risk of movement artifacts taking into account that the severity of the patient's condition does not allow them to maintain a stationary position for a long time;2. reduce the time of anesthesia and the dose of medication when scanning children which will increase the safety of the study for them;3. increase the cost-effectiveness of the PET-CT procedure due to the ability to scan a larger number of patients in a shorter time with less radiopharmaceutical consumption.

EP-0112

Direct Reconstruction of Parametric [18F]FET Images on a Long-Axial Field-of-View PET Scanner in Patients with Suspected Glioma Recurrence

T. Pyka[1], *C. Mingels[1,2], J. Penner[1], D. Pigg[3], K. Krieger[1], P. Cumming[1,4], A. Rominger[1], H. Sari[1,5];*
[1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND, [2]Department of Radiology, University of California Davis, Sacramento, CA, UNITED STATES OF AMERICA, [3]Siemens Medical Solutions, Knoxville, TN, UNITED STATES OF AMERICA, [4]School of Psychology and Counseling, Queensland University of Technology, Brisbane, AUSTRALIA, [5]Siemens Healthineers International AG, Zurich, SWITZERLAND.

Aim/Introduction: Static and dynamic [18F]fluoroethyltyrosine ([18F]FET) PET has proven itself useful in glioma classification, grading, and response assessment. Dynamic FET imaging in a clinical setting generally entails visual evaluation of time activity curves (TACs), since pharmacokinetic analysis is technically demanding and can necessitate blood sampling for the arterial input function. The advent of long-axial-field-of-view (LAFOV) PET scanners enables the extraction of an image-derived input function (IDIF) from vasculature structures. Herein, we evaluate the feasibility of [18F]FET parametric imaging using direct Patlak modelling with IDIFs derived from the aorta in glioma patients. ***Materials and Methods:*** This retrospective analysis involved 30 patients with suspected glioma recurrence undergoing 40 min dynamic [18F]FET PET on a LAFOV scanner. We extracted IDIFs from the descending aorta using a deep learning-based method [1], and generated tracer net influx (Ki) and distribution volume (DV) parametric images using direct Patlak reconstruction [2]. An experienced nuclear medicine physician segmented 53 lesions for computation of mean Ki and DV values, the corresponding tumour-to-background (TBR) values, and TBR in late static images. Finally, we studied the predictive value of Ki, DV and static TBR for tumour recurrence using ROC analysis, and performed logistic regression against visual TAC assessment. ***Results:*** The mean (SD) magnitude of Ki (mL/cm3/min) was 0.0082 (0.0041) in the lesions confirmed as tumour recurrence, 0.0066 (0.0030) in the benign lesions, and 0.0045 (0.0009) in background. DV (mL/cm3) was 0.74 (0.26) in tumour, 0.26 (0.22) in benign lesions and 0.20 (0.09) in background. TBR was 1.88 (0.84) in the Ki, 3.07 (1.95) in DV, and 2.34 (1.07) in static images. Interestingly, DV performed best in the ROC analysis for the prediction of recurrence (AUC DV: 0.95, Ki: 0.68; static TBR 0.92). There was a significant correlation between DV and visual TAC analysis ($p<0.001$), while Ki showed no such relationship. ***Conclusion:*** Direct parametric reconstruction of dynamic [18F]FET PET using an IDIF from deep-learning based segmentation of the aorta proved feasible for generating high quality parametric Ki and DV maps, with a TBR comparable to static [18F]FET images. DV, but not Ki, in suspected lesions showed significant correlation to negative TAC slope in visual analysis, and DV performed best for the prediction of tumour recurrence. These results indicate that [18F]FET uptake in reversible binding compartments serves for the differentiation of glioma recurrence. ***References:*** 1. Pigg D., JNM 2022;63(suppl. 2) 2. Sari H., EJNMMI 2022;49(6).

EP-0113

Diagnostic utility of ^{68}Ga-Prostate-Specific Membrane Antigen-11 PET/CT in glioma recurrence - a prospective analysis

A. Meena, *K. Subramanian, R. Kumar, H. Singh, B. MITTAL;*
Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: Prostate-specific membrane antigen (PSMA), being highly expressed on prostate cancer epithelial cells, is also found in the tumour vasculature of non- prostatic carcinomas. Magnetic resonance imaging (MRI) is the recommended technique for treatment, response evaluation and follow-up of gliomas. However, in patients previously treated with radiotherapy, MRI might be inconclusive as recurrent disease and treatment-related changes often appear similar. The study aimed to assess the diagnostic potential of 68Ga-PSMA PET/CT in patients with histologically confirmed brain tumours and suspected of recurrent disease on MRI. ***Materials and Methods:*** A prospective study was conducted from 2022 to 2024, enrolling patients of histopathologically diagnosed glioma after primary treatment including surgery, chemotherapy and radiotherapy with clinical and MRI suspicion of recurrent disease on follow up. All patients underwent 68Ga-PSMA PET/CT within two weeks of MRI. The PSMA PET/CT images were evaluated by two experienced nuclear medicine physicians. Abnormal PSMA uptake more than the contralateral brain parenchyma with corresponding CT changes were considered as positive study. Visual evaluation based on the intensity of uptake was scored as, no uptake, score 1; mild to moderate uptake ≤ parotid, score 2; and intense uptake ≥ equal to parotid, score 3. Semiquantitative parameters, i.e, SUVmax and tumor to background ratio (TBRmax) of the lesions were also calculated. ***Results:*** 15 patients were enrolled in the study. Median age (IQR) of patients was 36 years (15-58 years). Eight patients had oligodendroglioma, four had astrocytoma, two had glioblastoma, and one had ependymoma, according to the initial histopathological confirmation. Eleven patients had recurrence for the first time and four patients had re-recurrence. Visual interpretation showed increased accumulation of 68Ga-PSMA-11 in the recurrent lesions detected on MRI in all the patients. Interobserver concordance for abnormal sites of accumulation was 100 % for visual assessment and for visual scoring. The mean SUVmax and TBRmax of the recurrent lesions were 12.49 ± 6.97 and 11.9 ± 5.9, respectively. After diagnosis of recurrence, three patients underwent repeat surgery (histopathology confirmed high-grade recurrence in all 3), three received bevacizumab,

five were re-challenged with temozolomide and four patients are planned for redo surgery. ***Conclusion:*** The extremely low background uptake in normal brain tissue and consequently high TBR make 68Ga-PSMA-11 PET/CT highly promising for diagnosis of recurrent disease in brain tumour patients and its potential for theranostics would encourage its use in the treatment of these patients.

EP-0114

[68Ga]Ga-NOTA-anti-HER2-VHH1PET/CT Imaging of brain metastasis: first clinical results in patients with HER2-positive and HER2-negative breast cancer

L. De Mey[1,2], *O. Gondry[1,2], S. Bourgeois[2], A. Bracke[2], H. Everaert[1,2], L. Goethals[1,2], L. Raes[2,1], V. Caveliers[1,2], S. Van den Block[1,2], L. Decoster[1,2], C. Fontaine[1,2], N. Devoogdt[1], H. Dierick[1,2], J. Cousaert[2], M. Keyaerts[1], T. Lahoutte[1,2];*
[1]VUB, Brussels, BELGIUM, [2]UZ Brussel, Brussels, BELGIUM.

Aim/Introduction: The human epidermal growth factor receptor type 2 (HER2) is highly expressed on the cell membrane of several cancer types. HER2-overexpression is associated with tumour aggressiveness and an increased probability for recurrent disease. Targeted therapies for HER2-overexpressing tumours are currently available. At present, HER2-expression is assessed using tissue biopsies, but this is an issue in brain metastasis. [68Ga]Ga-NOTA-anti-HER2-VHH1 PET/CT of the brain has the potential of selecting patients that could benefit from HER2-targeted therapy. ***Materials and Methods:*** This single-centre, open-label, nonrandomized, phase II study evaluates the clinical potential of [68Ga]Ga-NOTA-anti-HER2-VHH1, a radiolabelled single domain antibody fragment for PET/CT imaging of HER2 in patients with HER2-positive (n=5) and HER2-negative (n=2) breast cancer disease with brain metastases. PET/CT imaging with dedicated imaging of the brain was performed at 90 minutes after intravenous administration of 140.63 +/- 30.7 MBq. Per patient, up to three intracranial metastatic lesions of minimal 8mm (assessed via MRI) were assessed. [68Ga]Ga-NOTA-anti-HER2-VHH1 uptake was measured on PET as SUVmax. ***Results:*** Intense focal uptake of [68Ga]Ga-NOTA-anti-HER2-VHH1 was measured in all brain lesions (n=9) of patients with HER2-positive disease: with an average SUVmax of 7.5 ranging between 5.3 and 12.6. One of the HER2-positive patients had no HER2-accumulation (SUVmax< 1) at the level of the lesion suspected for brain metastasis. Histological examination showed radionecrosis instead of tumour invasion. The patients with HER2-negative disease showed low to no uptake of [68Ga]Ga-NOTA-anti-HER2-VHH1 (SUVmax< 1 for all lesions) in the known metastatic lesions. ***Conclusion:*** The first clinical data of [68Ga]Ga-NOTA-anti-HER2-VHH1 PET/CT imaging in brain metastasis indicate specific and intense focal binding of the [68Ga]Ga-NOTA-anti-HER2-VHH1 in lesions of patients with HER2-positive breast cancer. Based on these initial results we have amended the clinical trial to include patients with other potentially HER2-positive cancer types that present with brain metastasis.

EP-0115

[18F]FDOPA PET/MRI hybrid technique in patients with brain tumors and suspicion of tumor recurrence versus radionecrosis

B. Hervás-Sanz[1], *M. Suárez-Piñera[1], L. Rodríguez-Bel[1], M. Pudis[1], A. Pons-Escoda[2], A. M. Lucas-Calduch[3], M. Alemany-Martí[4], A. Fernández-Coello[5], C. Mesià-Barroso[6], G. Reynés-Llompart[7], C. Majos-Torro[2], J. Bruna-Escuer[4], M. Cortés-Romera[1];*
[1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [2]Radiodiagnosis Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [3]Radiotherapeutic Oncology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [4]Neurology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [5]Neurosurgery Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [6]Medical Oncology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [7]Medical Physics Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: PET/MRI is an imaging technique that provides valuable metabolic, functional and morphological information needed in neuro-oncological diseases, in a single study. At present, data on its performance in clinical practice are still limited. The aim of this work is to analyse the diagnostic validity of [18F]FDOPA PET/MRI in patients with brain tumors (BT) and suspected tumor recurrence (TR) versus radionecrosis (RNC). ***Materials and Methods:*** Retrospective study of 29 PET/MRI FDOPA performed in 24 patients (12 female, mean age 57 (40-76)) and 33 lesions evaluated: 6 primary tumors and 27 brain metastases.All BT have been treated previously with (surgery+ hypofractionated stereotactic radiation therapy or radiosurgery) and some patients had received quimotherapy and/or immunotherapy also. All PET/MRI examinations were carried out on a 3 tesla PET/MRI (GE SIGNATM) at least 6 months after the radiotherapy.Images were analysed visually and quantitatively, obtaining ratios: SUVmaxlesion/SUVmaxstriatum (L/S), SUVmaxlesion/SUVmaxcortex (L/C). Sensitivity (S), Specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) were calculated. Mann Whitney test was used to compare difference between groups. Optimal FDOPA PET parameter cut-off were obtained by ROC analysis. Perfusion-weighted imaging (PWI)were visually and quantitative analysed. Results were compared with clinical-radiological follow-up (at least 9 months) and/or histopathology.A multidisciplinary brain tumor board made the final decision based on all available information. ***Results:*** 10/33 lesions (30%) were considered TR and 23 (70%) RNC. FDOPA PET/MRI showed higher ratios in TR (L/S 1.15±0.25, L/C 2.29±0.69) than RC (L/S 0.85±0.26, L/C1.5±0.69) p>0.05. These ratios were assessed together with the visual analysis. S, Sp, PPV, NPV of FDOPA were 100%, 83%, 69% and 100% respectively. 4 false positive and 0 false negative. The best cut-off points were L/C 1.73 and L/S 0.91. S, Sp, PPV, NPV of PWI were 56%, 73%, 45% and 80% respectively, in 2 cases PWI was no valuable. The results of FDOPA and PWI were concordant in 23/31 (74%). ***Conclusion:*** PET/MRI 18F-FDOPA showed high accuracy in differentiating TR from RNC. The information provided by PWI and FDOPA was not always concordant, and the role of both techniques is likely to be complementary. The availability of hybrid PET/MRI equipment allows this information to be obtained in a single scan. In addition, hybrid PET/MRI reduces discomfort in neuro-oncology patients, who are usually in a fragile state.

EP-0116

Proposal of a short acquisition protocol for 18F-DOPA imaging in brain tumors:preliminary results

N. Orrego[1], *B. Martinez-Sanchis[1], C. Guerrero-Calatayud[1], M. Gandia-Ferrero[2], P. Sopena-Novales[1], P. Bello-Arques[1];*
[1]Hospital Universitario y Politécnico La Fe, Valencia, SPAIN, [2]GIBI230-Health Research Institute La Fe, Valencia, SPAIN.

Aim/Introduction: Imaging with radio labelled amino acids like

18F-DOPA has emerged in the last years as a very useful tool for brain tumours. In 2019, the "Joint EANM/EANO/RANO practice guidelines/SNMMI procedure standards for imaging of gliomas using PET with radiolabelled amino acids and [18F]FDG: version 1.0" was published. A specific acquisition protocol for 18F-DOPA imaging is described in the guidelines. In our department, we perform a dynamic acquisition in list mode that allows us to follow the protocol in the guidelines, but also generate different static and dynamic reconstructions. In this study we compare performance of the protocol imaging for 18F-DOPA published in the guidelines with a shorter protocol designed after visually analysing time-activity curves from dynamic images. ***Materials and Methods:*** Patients that were referred to our nuclear medicine department for ^{18}F-DOPA brain imaging to distinguish tumour recurrence from radionecrosis were consecutively included (20 patients, 31 lesions). Images were reconstructed using two protocols: - Protocol A (EANM guidelines protocol): static acquisition of 20 minutes of duration, scan initiated 10 minutes after i.v. injection of ^{18}F-DOPA. - Protocol B (proposal): static acquisition of 10 minutes of duration, scan initiated 5 minutes after i.v. injection of ^{18}F-DOPA. We compared lesions' visual scores (0=no uptake, 1= uptake lower than striatum, 2=uptake similar to striatum, 3=uptake higher than striatum) for both protocols and calculated concordance. We analysed Sensitivity, Specificity, NPV and PPV of each protocol (visual scores of 0 and 1 for radionecrosis, and visual scores of 2 and 3 for tumor). Gold standard was histologic results in 11 lesions (35%) and follow up in 20 lesions (65%). ***Results:*** In our sample, there were 16 primary CNS tumors (52%) and 15 metastases (48%). Size of the lesions ranged from 6 mm to 62 mm (mean: 21 mm). Accuracy, Sensitivity, Specificity, NPV and PPV were 0,77, 0,86, 0,70, 0,67, and 0,81 for protocol A; and 0,74, 1.00, 0,20, 1,00 and 0,72 for protocol B. Concordance between both protocols was fair for all visual score values (kappa index = 0,27) and for radionecrosis (values 0-1) versus tumor (visual score 2-3) (kappa index = 0,29) ***Conclusion:*** The proposed short protocol for brain tumor imaging with 18F-DOPA performed similar to protocol recommended by EANM guidelines, analysing visual score. ***References:*** Joint EANM/EANO/RANO practice guidelines/SNMMI procedure standards for imaging of gliomas using PET with radiolabelled amino acids and [18F]FDG: version 1.0. Eur J Nucl Med Mol Imaging. 2019 Mar;46(3):540-557.

Somatostatin Receptor-Directed Theranostics in Esthesioneuroblastoma

S. Serfling[1], *Y. Zhi[2], M. Augustin[3], A. K. Buck[1], T. Higuchi[1], S. Hackenberg[4], A. Weich[5], R. A. Werner[6];*
[1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Department of Otorhinolaryngology, Plastic, Aesthetic and Reconstructive Head and Neck Surgery, University Hospital Würzburg, Würzburg, GERMANY, [3]Department of Internal Medicine 5, Paracelsus Medical School, Nuernberg General Hospital, Nuernberg, Nuernberg, GERMANY, [4]Department of Otorhinolaryngology, Plastic, Aesthetic and Reconstructive Head and Neck Surgery, Würzburg, GERMANY, [5]Department of Internal Medicine II, University Hospital Würzburg, Würzburg, GERMANY, [6]Goethe University Frankfurt, University Hospital, Department of Nuclear Medicine, Clinic for Radiology and Nuclear Medicine, Frankfurt, GERMANY.

Aim/Introduction: We aimed to report on somatostatin receptor (SSTR)-targeted molecular imaging and therapy in patients affected with advanced esthesioneuroblastoma (ENB). ***Materials and Methods:*** 3 patients with ENB (Kadish stage B in 1/3 [33.3%], Kadish stage C in 2/3 [66.7%]; Hyams Grade 2 in 2/3 [66.7%] and Grad C in 1/3 [33.3%]) underwent SSTR-directed PET/CT using [68Ga]DOTATOC to determine disease extent. We also quantified SSTR-avid tumor volume (TV), maximum SUV (SUVmax) and target-to-background ratios (TBR), thereby providing information on image contrast. In patients scheduled for peptide receptor radionuclide therapy (PRRT), we recorded nephro- and hematotoxicity, including eGFR, haemoglobin, leukocytes, and thrombocytes at baseline and after the last treatment cycle. We classified adverse events following Common Terminology Criteria for Adverse Events (CTCAE) v5.0. Response using RECIST 1.0 and progression-free survival (PFS) was also determined. ***Results:*** All patients (100%) were rated positive on SSTR-PET/CT. On a lesion-based level, we identified 24 SSTR-avid tumor sites with a median TV of 16.25±1.7, and SUVmax of 28.41±4.2. TBR was 21.85±4.2, thereby suggesting excellent image contrast. All subjects were also scheduled for PRRT using a median cumulative activity of 31.4 GBq per patient (median number of cycles, 4 [range, 2-6]). We observed no CTCAE grade III/IV toxicity for eukocytes and thrombocytes and also no CTCAE for renal function. Stable disease after two cycles were recorded in 2/3 (66.7%; progressive disease in 1/3 [33.3%]). Median PFS was 14 weeks. ***Conclusion:*** SSTR-directed molecular imaging provides high image contrast in ENB, thereby suggesting good read-out capabilities in this tumor type. PRRT is also feasible, along with an acceptable safety profile, thereby rendering SSTR-targeted theranostics as a potential treatment option in advanced disease.

EP-0118

Risk Assessment of Xerostomia Using F^{18} FDG PET/CT Metabolic Parameters After Radiotherapy in Head And Neck Cancers

B. Bozdemir[1], *G. Mutevelizade[1], N. Aydin[1], A. F. Suner[2], O. Karakoyun Celik[3], E. Kocabasoglu[4], M. Kahya[4], G. Bakicierler[4], G. Gumuser[1], E. Sayit Bilgin[1];*
[1]Celal Bayar University Department of Nuclear Medicine, Manisa, TÜRKIYE, [2]Dokuz Eylül University School of Medicine Department of Public Health, Izmir, TÜRKIYE, [3]Celal Bayar University Department of Radiation Oncology, Manisa, TÜRKIYE, [4]Celal Bayar University Hospital Department of Radiation Oncology, Manisa, TÜRKIYE.

Aim/Introduction: Xerostomia and radiation-induced salivary gland dysfunction remain common side effects that impair the quality of life for patients undergoing head and neck radiotherapy (RT). This study aimed to investigate using F^{18} FDG PET/CT parameters as a useful tool to predict metabolic changes in the salivary glands, radiation doses received, and severity of xerostomia in patients undergoing RT for head and neck cancers. ***Materials and Methods:*** Our study included 107 non-operated patients who had undergone PET/CT for the staging and treatment response following curative RT. SUVmax and SUVmean of bilateral parotid and submandibular glands were measured on PET/CT performed at staging and 3-6 months after completion of RT. Patients were assessed for xerostomia-related complaints and categorized into three groups after RT: asymptomatic, mild, and severe symptoms. Mean parotid and submandibular gland doses

were determined through analysis of dose-volume histograms. Upon establishing threshold levels of 30 Gy for the parotid gland and 50 Gy for the submandibular gland; symptom severity, ΔSUVmax, and ΔSUVmean were compared. ***Results:*** Nine (8.4%) patients had no symptoms, 30 (28%) had mild, and 68 (63.6%) had severe dry mouth. A significant relationship was found between the mean RT doses of salivary glands and the severity of symptoms. Significant correlations were observed between the mean doses and dose-dependent volumetric ratios of the salivary glands, and ΔSUVmax values, especially in the left parotid gland. A statistically significant relationship was found only between ΔSUVmax and ΔSUVmean of the left parotid gland and symptom presence and severity. In our patient group, left-sided tumors have more nodal involvement than right-sided ones. ***Conclusion:*** We found that despite lower mean RT doses to the parotid glands compared to the submandibular glands, ΔSUVmax and ΔSUVmean of the left parotid gland were significantly related to symptom severity. This result may be attributed to the fact that the nodal involvement was predominantly on the left, with a wider RT field and due to the higher sensitivity of serous acini to RT. As a result, the metabolic changes of the parotid gland due to RT are related to the RT doses and xerostomia, the severity of xerostomia can be predicted by PET/CT parameters.

EP-0119

Tumor Volume Auto-delineation and Survival Prediction for Head and Neck Cancer Patients Using Deep Learning on PET/CT Images

S. Chan[1], *M. Liu[2], C. Wang[2], P. Wu[2];*
[1]Department of Nuclear Medicine, Hualien Tzu Chi Hospital, Hualien, TAIWAN, [2]Artificial Intelligence Medical Innovation and Development Center, Hualien Tzu Chi Hospital, Hualien, TAIWAN.

Aim/Introduction: Identification and delineation of the tumor and malignant nodal volume in medical images are important in treatment planning. In this study, we assessed the applicability of deep learning using ^{18}F-FDG PET/CT images for auto-delineation of tumor volume and survival prediction in patients with head and neck cancer (HNC). ***Materials and Methods:*** 188 patients with HNC who received pretreatment ^{18}F-FDG PET/CT were included. They were divided into training 150 patients, and testing 38 patients sets. In deep learning analyses, three planes of axial, coronal, and sagittal ^{18}F-FDG PET/CT images were assessed by the SegResNet model. The Dice score, f1 score, and precision were used for auto-delineation model evaluation. The performance of the deep learning-based model or clinical stage for survival prediction was assessed by the Concordance index (c-index). ***Results:*** The SegResNet model achieved a Dice score, f1 score, and precision of 74%, 77.2%, and 72.8%, respectively, for automatically delineating tumors in ^{18}F-FDG PET images. The accuracy of the model based on deep learning in predicting the recurrence of cancer patients was 73.6%. The c-index of the DenseNet model was 0.738 for predicting overall survival, which was higher than that of the clinical stage (c-index=0.562). ***Conclusion:*** Using the SegResNet model to analyze ^{18}F-FDG PET/CT images could be a reliable tool for automated delineation in head and neck cancer patients. The deep learning approach appears to more effectively distinguish between patients with favorable and unfavorable survival outcomes compared to traditional clinical staging methods.

EP-0120

Brain metastases in head and neck cancer patients: imaging insights

P. Strouhal;
Alliance Medical Ltd, Warwick, UNITED KINGDOM.

Aim/Introduction: This study investigates the incidence of intracranial metastasis in head and neck cancer patients undergoing follow-up ^{18}F-FDG-PETCT (PETCT) scans, to illustrate the lack of need to include 'whole brain' protocol imaging. Drawing upon existing literature establishes a baseline incidence of brain metastases in head and neck squamous cell carcinoma (HNSCC) patients. ***Materials and Methods:*** Retrospective 6-month review of cohort of 2800 HNSCC patients' scans who underwent PETCT scan, on variety of analogue and digital scanners, across Alliance Medical scanning facilities. Scanners were GE710 (12), GE MI DR (3); Siemens Biograph mCT (3); and GE Discovery MI (digital (3)). Scans reviewed were performed post primary treatment (surgery/chemoradiotherapy), on follow-up with suspected recurrence, or Baseline information taken from data from previous studies/reviews reporting brain metastases incidence of up to 2% in HNSCC patients. ***Results:*** Initial retrospective review of 500 cases reveals no instances (0%) of brain metastases among HNSCC patients undergoing follow-up PETCT scans, suggesting eyes-to-thighs protocol would be all that is required in these HNSCC patients. Further analysis ongoing of remaining cases to be completed soon. ***Conclusion:*** Potentially eliminating CT coverage of the top of the brain, potential radiation dose and scan time savings could be achieved, and perhaps even minimal energy use savings, contributing to the optimisation of imaging protocols in HNSCC patients. This study underscores the importance of surveillance protocols and the potential impact of imaging techniques on the detection of metastatic disease in these patients. ***References:*** (1). EP-0121

The Potential rule of Ga68-Trivehexin in Head and Neck Squamous Cell Carcinoma; Single Institution Experience

A. Baqer[1], *A. Sadeq[1], K. Alyousefi[1], A. Bushehri[2], M. Alfeeli[1], F. Marafi[1];*
[1]Jaber Al Ahmad Nuclear Medicine and Molecular Imaging Center, Kuwait City, KUWAIT, [2]Kuwait Cancer Control Center, Kuwait City, KUWAIT.

Aim/Introduction: Integrin αvβ6 transmembrane cell adhesion receptor overexpression occurs in certain malignancies including head and neck squamous cell carcinoma (H&NSCCs). Up-regulation of Integrin αvβ6 is associated aggressive tumor behavior and poor outcome. Trivehexin labelled with Ga68 is a newly developed nanopeptide that selectively targets Integrin αvβ6. ***Materials and Methods:*** Twenty patients of mean age 56 years were recruited diagnosed with H&NSCC (17 males and 3 females) underwent Ga68-trivehexin for staging and restaging (16 vs 4, respectively). Four patients were diagnosed with oral cancer, six nasopharyngeal, three oropharyngeal, six laryngeal, and one cancer of unknown primary. Patients were injected with Ga68-trivehexin with a mean dose of 172.42 MBq (118.4-259 MBq). Two minutes per bed acquisition was obtained using digital PET/CT camera, after a mean uptake time of 65.5 minutes (56-82 minutes).

Within a period of one month, a FDG PET/CT study was carried out as a reference, with a mean dose of 188.7 MBq (111-351 MBq) and mean uptake period of 64 minutes (57-79 minutes). Studies were evaluated visually and semi-quantitatively. ***Results:*** All four individuals diagnosed with oral cancer exhibit αvβ6 expression in the primary tumor. One of these patients did not exhibit αvβ6 expression in the cervical lymph node when compared to FDG. All patients with nasopharyngeal carcinoma exhibit αvβ6 expression in the primary tumor. Nevertheless, αvβ6 expression was absent in cervical lymph nodes and distant metastatic locations for two patients. Regarding oropharyngeal cancer, all three patients exhibited αvβ6 expression in both the primary tumor and cervical lymph nodes. However, one patient had a lower detection rate of αvβ6 expression in the cervical lymph nodes compared to FDG. In relation to laryngeal cancer, all five patients included in the staging process exhibit αvβ6 expression in the primary tumor. Two of these patients had faint αvβ6 expression or negative results at the cervical lymph nodes and distant metastatic locations. A single patient was selected for restaging and yielded negative results on both examinations. The patient diagnosed with cancer of unknown primary exhibited αvβ6 expression in the cervical lymph node and lacked αvβ6 expression in the metastatic mediastinal lymph node compared to FDG. ***Conclusion:*** αvβ6 expression was detected in all sites of primary disease in H&NSCCs. The fact that seven out of twenty patients exhibited decreased αvβ6 expression in cervical lymph nodes and distant metastases in comparison to FDG, supports the heterogeneity of local and distant metastatic involvement.

EP-0122

Prognostic value of plasma Epstein-Barr virus DNA load and pretreatment and recurrent ^{18}F-FDG PET/CT volumetric parameters in patients with nasopharyngeal carcinoma

M. Romera, *F. Mínguez, A. Basanta, V. Betech, J. Rosales, L. García-Belaustegui, J. López-Picazo, S. Rubio, M. Rúa, N. Muñoz-Rodríguez, A. Fernández-González, M. García-Velloso;*
Clínica Universidad de Navarra, Navarra, SPAIN.

Aim/Introduction: To determine the combined value of plasma EBV DNA title (EBV-t) and semiquantitative 18F-FDG PET-derived parameters in predictive models in patients with nasopharyngeal carcinoma (NPC). To serve as a basis for the development of a population model that relates diagnostic techniques and clinical variables to identify patients at earlier risk and adjust individually therapeutic interventions. ***Materials and Methods:*** A total of 15 studies corresponding to 8 different patients were evaluated. EBV-t was recorded at the time of 18F-FDG PET/CT. To define the contouring margins, an SUV of 2.5 based on the experience of previous investigators was used. SUVmax, MTV, and TLG were calculated for whole body (WB), primary tumour (PT), lymph node (LN) and distant metastasis (DM). EBV-t was expressed as number of copies/mL and its logarithm (log10). The primary dependent variable was progression-free survival (PFS). Overall survival was not analyzed due to the insufficient number of deceased patients. The survival analyses were performed using the Kaplan-Meier method. The cut-off value associated with the lowest p value was taken as the optimal cut-off point. The Cox-Mantel log-rank test was then used to calculate the P values for the intergroup differences in survival rates. Multivariate Cox proportional hazards models were used to identify the independent predictors of survival. Pearson's correlation coefficients were used to analyze the correlations between pairs of continuous variables. The statistical significance was set at $p< 0.05$. ***Results:*** The univariate analysis showed that EBV-t > 10000 copies/mL, WB-TLG > 250, WB-MTV > 60, LN-TLG>210, LN-MTV>60, DM-TLG >0 and DM-MTV > 40 predicted PFS ($p<0.05$). In multivariate analysis only EBV-t>10000 copies/mL independently predicted PFS. The 2-year PFS rate of the patients with WB-TLG<250 and WB-MTV<60 was 33.3% and 30.2%, respectively, compared with 0%, for those with WB-TLG>250 and WB-MTV>60. The DM-MTV > 40 was the most significant prognostic factor in this series (hazard ration, HR, 16.4, $p<0.001$). There was a positive moderate correlation between the EBV-t and the WB-TLG, WB-MTV, LN-TLG, LN-MTV, DM-TLG and DM-MTV. Strong correlation was found between the EBV-t and WB-MTV ($r = 0.703$, $p<0.01$) and between WB-TLG and WB-MTV ($r=0.830$, $p<0.01$). ***Conclusion:*** ^{18}F-FDG PET/CT volumetric parameters and EBV-t predict PFS. In pre-treatment and recurrent NPC patients, EBV-t appears to be an independent risk factor.

EP-0123

Head-to-head Comparison of $^{[18F]}$FDG PET/CT and MRI for the Detection of Recurrence or Residual Tumor in Patients with Nasopharyngeal Carcinoma: a Meta-analysis

N. Quartuccio, *S. Ialuna, S. Pulizzi, S. Nicolosi, D. D'Oppido, A. M. Moreci;*
Nuclear Medicine Unit, Ospedali Riuniti Villa Sofia-Cervello, Palermo, ITALY.

Aim/Introduction: The study aimed to compare the diagnostic performance of $^{[18F]}$FDG PET/CT and MRI in detecting recurrence or residual tumors at the primary site in patients with nasopharyngeal carcinoma (NPC). ***Materials and Methods:*** A comprehensive literature search was conducted through April 2024 in the PubMed/MEDLINE and CENTRAL databases to find studies meeting the following criteria: 1) at least 20 patients with NPC undergoing both $^{[18F]}$FDG PET/CT and MRI for detecting recurrence or assessing residual disease at the primary site, 2) a maximum interval of 2 months between PET/CT and MRI, and 3) at least 2 months after therapy completion in case of PET/CT for response assessment and detection of residual tumors. The pooled sensitivity and specificity of PET/CT and MRI were calculated with 95% confidence intervals (CIs) and compared. A significant difference in performance was determined if the 95% CIs of sensitivity or specificity did not overlap between the modalities. The summary receiver operating characteristic (SROC) curve and area under the curve (AUC) were generated using the SROC model. The AUCs were compared using the method of Hanley & McNeil. The I^2 statistic measured heterogeneity, with values of 25%, 50%, and 75% indicating low, moderate, and high heterogeneity, respectively. Heterogeneity was assessed at a significance level of $p=0.05$, and a random-effects model was used for statistical pooling. ***Results:*** Four studies with 1,841 patients (five patient groups) were included in the analysis. PET/CT had higher sensitivity [93.1% (95% CI: 91.1-94.8%); I2=47.4 %] compared to MRI [80.6% (95% CI: 77.7-83.3%); I2=66.5%], but the specificity was similar for both modalities: 93.9% (95% CI: 92.2-95.2%; I2=9.5%) for PET/CT and 93.9% (95% CI: 92.3-95.3%; I2=60.8%) for MRI. The AUCs for PET/CT and MRI were 0.969 and 0.960, respectively, without significant difference ($p=0.59$). For $^{[18F]}$FDG PET/CT and MRI, the results of the Spearman correlation coefficient demonstrated no threshold effect heterogeneity (Spearman correlation coefficient =0.39, $p=0.67$ for PET/CT; Spearman correlation coefficient =0.39, $p=0.62$ for MRI). ***Conclusion:*** This meta-analysis suggests both

imaging modalities are useful for detecting recurrence or residual tumors in patients with NPC. Although the overall diagnostic performance of PET/CT and MRI did not significantly differ, PET/CT showed higher sensitivity than MRI.

EP-0124

Furin-triggered intracellular ^{68}Ga nanofibers formation enhances micro-PET tumor imaging

H. Wu, *Y. Liu, H. Wang, J. Wu, P. Zou;*
NHC Key Laboratory of Nuclear Medicine, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, Wuxi, China, Wuxi, CHINA.

Aim/Introduction: This research is dedicated to the design of a novel positron emission tomography (PET) probe through the incorporation of furin-triggered self-assembly nanofibers to enhance PET imaging of tumors. We utilized micro-PET imaging to evaluate the biodistribution of the designed probe, [68Ga]Furin-NOTA, in MDA-MB-468 model mice and analyzed the differential accumulation of the probe in tumor tissues versus non-target tissues. ***Materials and Methods:*** Furin was co-incubated with the probe precursor at 37°C to verify the specificity of the probe for tumor-associated enzymes and to observe the structural features of the probe after the enzyme digestion reaction. When tumors in MDA-MB-468 model mice reached 5-10 mm in diameter, the probe [68Ga]Furin-NOTA was injected intravenously and static PET scans were performed at 0.5, 1.0, 1.5, 2.0, 2.5, and 3.0 h post-injection, respectively. Using ASIPro VM software, PET images were analyzed by outlining regions of interest (ROI) of the tumor versus non-targeted regions, and the uptake rates were calculated to assess the targeting performance and distribution characteristics of the probe. ***Results:*** PET imaging results demonstrated that the uptake of the probe in the tumor significantly increased from 2.81 ± 0.63 %ID/g at 0.5 h to 4.88 ± 0.47 %ID/g at 3 h, indicating an effective internal accumulation of the probe. In contrast, PET signals at non-target sites such as the liver and muscle exhibited a continuous decreasing trend, indicating that the probe was rapidly metabolized and cleared from these non-target tissues. In the enzyme digestion experiments, the probe precursor was subjected to rapid enzymatic digestion by furin to form supramolecular hydrogels, which are semi-solid materials with high biocompatibility produced by aggregation of monomer molecules. We speculate that this property of the probe leads to varying aggregation effects in regions with high furin expression (tumor) compared to those with low expression (e.g., liver and muscle), ultimately resulting in selective PET signal accumulation in different tissues. ***Conclusion:*** By integrating furin-triggered self-assembly nanofibers, we developed a novel PET probe, [68Ga]Furin-NOTA, which demonstrated the potential for selective accumulation in tumors. This approach may offer a valuable new strategy for enhancing the imaging contrast of PET technology in tumor diagnosis.

EP-0125

Clinical impact of $^{[18F]}$FDG PET/CT for initial staging in breast cancer patients prior to neoadjuvant chemotherapy

J. Duch Renom, *P. Stefaneli, M. Calls, V. Camacho, G. Guzmán, M. Andrés, A. Fernandez León, C. Soldevila, M. Velasco, S. Castejón, A. Flotats;*
Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN.

Aim/Introduction: Accurate baseline staging is crucial for planning optimal breast cancer (BC) management.$^{[18F]}$FDG-PET/CT has high sensitivity for extra axillary lymph nodes and distant metastasis and its use is agreed for clinical stage ≥IIB. This is a single-institution retrospective study assessing the clinical impact of $^{[18F]}$FDG-PET/CT in patients with BC prior to neoadjuvant chemotherapy (NC), including a subgroup of early stage patients (stage ≤IIA). ***Materials and Methods:*** We included BC patients who underwent $^{[18F]}$FDG-PET/CT before NC. Patients clinical stage was I to IIIB (83 patients at an early stage), including luminal like, HER2+ and triple negative (TN) phenotypes. Initial stage was determined from conventional mammography, breast ultrasound and breast MRI. The clinical impact of $^{[18F]}$FDG-PET/CT findings was studied taking into account changes in the treatment strategy, considering that upstage to IIB or IIIC stages does not represent a change in treatment modality (intra-modality i.e., radiotherapy fields) whereas upstage to IV represents a change in treatment modality (inter-modality i.e., palliative). In addition, the relationship of $^{[18F]}$FDG-PET/CT findings with histology (ductal vs lobular), Bloom-Richardson grade (I-III), proliferative index (Ki67) and tumor phenotype (luminal-like, HER2+ and TN) was studied. Differences in the distribution of categorical variables were assessed using Chi Square test. Biopsy and follow-up were used as a reference standard for the analysis. ***Results:*** From January 2021 to December 2023, 210 patients were included. $^{[18F]}$FDG-PET/CT findings had clinical impact (upstage) in 49 patients (23%). Of these patients, 41% experienced an intra-modality treatment change and 59% experienced an inter-modality treatment change (p=0.19). Upstage was found in 7 patients (8,4%) with early stage disease, and 42 patients (33%) with locally advanced disease. $^{[18F]}$FDG-PET/CT did not significantly change patient management based on tumor phenotype (upstage in 24% of patients luminal-like, 24% of patients HER2+ and 20% of patients TN, p=0.90), tumor histology (upstage in 23% of patients with ductal carcinoma, and 23% of patients with lobular carcinoma, p=0.98), proliferative index (upstage in 22% of patients with low Ki67, and 23% of patients with high Ki67, p=0.89), or tumor grade (upstage in 15% of G1 patients, 25% of G2 patients and 22% of G3 patients; p=0.59). ***Conclusion:*** $^{[18F]}$FDG-PET/CT is useful for staging patients with BC prior to NC. Upstage findings did not relate to histology, Bloom-Richardson grade, proliferative index or tumor phenotype, either in locally advanced or early stage patients.

EP-0126

^{18}F-FDG PET-CT as a Tool for Predicting the Immunohistochemical Profile of Breast Cancer

R. Wakankar, *J. Bal, P. Dougall;*
Max Super Speciality Hospital, New Delhi, INDIA.

Aim/Introduction: The aim of this retrospective study was to demonstrate the value of ^{18}F-FDG PET-CT in predicting the immunohistochemical profile of breast cancer and promote its role as a non-invasive tool to help plan treatment. ***Materials and Methods:*** 48 women with 50 histopathologically and

immunohistochemically characterized breast cancer lesions were included in this study. Data regarding parameters pertaining to their breast mass, like SUVmax, ER, PR, Her2Neu status, ER, PR, Her2Neu & MBR scores was extracted from the electronic health records at our hospital. Descriptive statistics along with correlation coefficients and regression analysis were performed on the data. ***Results:*** Our study cohort had a mean age of 56.4±11.4 yrs, SUVmax: 6.2±4.7, ER score: 5.3±3.6, PR score: 4.4±3.4, Her2neu score: 1.1±1.0, MBR score: 7.2±1.2. 70% of the lesions were ER positive, 60% were PR positive & 32% were Her2Neu positive. 92% were infiltrating ductal carcinomas & 8% were infiltrating lobular carcinomas. Spearman's correlation coefficients were calculated for the variables mentioned above, which demonstrated a significant correlation between tumor SUVmax & ER score (ρ=-0.389, p=0.006), SUVmax & PR score (ρ=-0.432, p=0.002) and SUVmax & MBR score (ρ=0.545, p<0.001). Linear regression analysis of the relation between SUVmax & ER score gave us a regression equation of: ER score=-0.293(SUVmax)+7.133 (R2=0.153, p=0.007). Similar analysis between SUVmax & PR score and SUVmax & MBR score gave us the regression equations: PR score=-0.316(SUVmax)+6.436 (R2=0.199, p=0.002) and MBR score=0.12(SUVmax)+6.392 (R2=0.246, p<0.001). Following this, we performed a logistic regression analysis to ascertain the effect of SUVmax on the ER and PR status of the tumors. The logistic regression model was statistically significant (p=0.029) and explained 18.6% of the variance in the tumor ER status. Tumors with a higher SUVmax were 0.82 times more likely to be ER positive. Similarly, the logistic regression model was also significant (p=0.003) and explained 31.4% of the variance in the tumor PR status. Tumors with higher SUVmax were 0.74 times more likely to be PR positive on immunohistochemical analysis. ***Conclusion:*** This retrospective study was therefore able to demonstrate that breast cancer lesions with a higher SUVmax tend to have lower ER, PR expression and higher MBR scores. We were also able to generate regression models that helped predict the ER, PR & MBR scores along with the probability of ER, PR positivity using the ubiquitous semiquantitative parameter of SUVmax. However, no significant relation could be established between SUVmax & Her2 expression.

EP-0127

The value of ^{18}F-FDG PET/MR in bone lesions of breast cancer patients

Y. Xu;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: Purpose The aim of this study was to evaluate the role of Fluorodeoxyglucose (^{18}F) positron emission tomography/magnetic resonance imaging (^{18}F-FDG PET/MR) for detecting bone metastasis in breast cancer. ***Materials and Methods:*** Between May 2017 and May 2023, 135 histologically proven breast cancer patients who underwent both ^{18}F-FDG PET/MR and 99mTc-MDP planar bone scintigraphy (PBS) for tumor staging were included. With the exception of the head, the skeletal system was classified into four groups: the spine, the pelvis, the thorax and the appendix. ***Results:*** 38 (28.1 %) of 135 patients were confirmed to have bone metastasis. There was no statistical difference between PET/MR and PBS in patient-based analysis (P = 0.125). 2 patient with a super scan was confirmed to have extensive and diffuse bone metastases and excluded for lesion-based analysis. Of the 36 patients, all the 185 ture metastatic lesions were positive in PET/MR while only 105 ture metastatic lesions were positive in PBS. PET/MRI was observed to be more sensitive than PBS in lesion-based analysis (sensitivity 100.0% versus 56.8 %; P < 0.001). ***Conclusion:*** Compared with PBS for tumor staging of breast cancer, PET/MR was observed to be more sensitive in lesion-based analysis of bone metastasis.

EP-0128

The clinical value and cost-effectiveness of Using ^{18}F-FDG PET/MR as an staging procedure for breast cancer patients

Y. Xu;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: The purpose of this study was to determine the clinical value and cost-effectiveness of PET/MR as an staging procedure for breast cancer compared with the PET/CT. ***Materials and Methods:*** From May 2017 to December 2022, 425 breast cancer patients confirmed by pathology in our center were included in this study. Among them, 165 patients underwent PET/MR before treatment and 260 underwent PET/CT. Charges were used as issued in 2021 by the Medical Insurance Administration Bureau of Zhejiang, China. Each patient should be followed up for at least 1 year, with the final clinical staging as the gold standard. Incremental costeffectiveness ratio (ICER) measured cost of using PET/MR per percent of patients who avoid missed or misdiagnosis. ***Results:*** A total of 45 patients with missed or misdiagnosis results were observed. More patients with missed or misdiagnosis results were observed in the PET/CT group (14.2% vs. 4.8%, p<0.001). Small lung metastases (3 cases) and false positive lymph nodes (5 cases) resulted in missed diagnosis and misdiagnosis in the PET/MR group. However, the missed lesions in the PET/CT group mainly appeared in the liver (10 cases), bones (7 cases),brest(5 cases), and brain (2 cases), with false positive (7 cases) and false negative (6 cases) lymph nodes simultaneously.The mean interval from pathological diagnosis to initiation of treatment was 12.5 days in the PET/CT group versus 7.4 days in the PET/MR group (p< 0.001). Mean cost per patient was $739 for PET/CT and $1381 for PET/MR. The ICER was $68 for each percent of patients who avoided a missed or misdiagnosis results. ***Conclusion:*** Compared with PET/CT, PET/MR reduced missed or misdiagnosed cases risk and decreased workup of incidental findings, allowing for earlier treatment start. Meanwhile, PET/MR can significantly reduce radiation exposure in patients during examination. It may be cost-effective in initial staging procedure for breast cancer patients.

EP-0129

Impact of ^{18}FDG PET/CT on clinical management, cost effectiveness and radiation exposure in newly diagnosed breast cancer patients

M. Zaman[1], *N. Fatima[1], U. Zaman[2], A. Zaman[3], A. Ahmed[1], S. Zaman[4], K. Khan[1];*
[1]Dept of Radiology, AKUH, Karachi, PAKISTAN, [2]Dept of Hemoncology, Oklahoma University, OH, Oklahoma, OK, UNITED STATES OF AMERICA, [3]Dept of Medicine, Sunny Downstate Hospital, New York, NY, UNITED STATES OF AMERICA, [4]Dept of Medicine, Oklahoma University, Oklahoma, OK, UNITED STATES OF AMERICA.

Aim/Introduction: For initial staging of breast cancer (BC), 18FDG PET/CT is recommended by professional guidelines in stage III (except T3N1) and inflammatory BC (T4d) and optional when conventional imaging is equivocal or suspicious. However, growing evidence also supports its role in staging of intermediate

risk group (IIA, IIB, T3N1 of IIIA). Aim of this study was to compare impact of 18FDG PET/CT with conventional imaging (CT-chest+abdomen+pelvis and bone scan; CT-CAP+BS) in staging, cost effectiveness and radiation exposure in initial staging of BC. ***Materials and Methods:*** A retrospective study (April 2020-Feb 2024) included 115 biopsy proven BC patients who had CT-CAP+BS and 18FDG PET/CT for initial staging. Data were analyzed to see impact of 18FDG PET/CT on change in staging, cost effectiveness and radiation exposure compared to CA-CAP+BS. ***Results:*** Out of 115 patients (113 female and 02 male), 110 had unilateral and 5 had bilateral BC (Invasive Ductal Ca. 107; Non-IDC: 08) with non-significant laterality. Overall upstaging rate for regional nodal and/or distant metastases was 36% (24/66; excluded 49 with stage-IV). Overall upstaging rate due to unsuspected higher nodal metastases was 20% (predominantly stage IIA, IIB). Upstaging rate to stage-IV was seen in 17% (11/66; predominantly in IIIA-C). The overall concordance (no change in staging) was seen in 64% (42/66) while no downstaging was found in any patient. In patients with stage-IV disease (n = 49), 18FDG PET/CT identified higher number of hypermetabolic lesions in 18 (37%), lesser in 07 (14%) and similar in 24 (49%) cases. Estimated cost in Pak rupees for CT-CAP+BS and PET/CT was 139000 and 106000 respectively. Mean effective dose imparted by ^{18}FDG PET/CT was 8.85 mSv compared to reported 26.6 mSv by CT-CAP+BS. ***Conclusion:*** We conclude that in initial staging of BC, ^{18}FDG PET/CT compared with CT-CAP+BS has a significant impact upon decision making by upstaging the disease in stage-II and III and detects more metastatic lesions in stage-IV disease. Furthermore, ^{18}FDG PET/CT is more cost effective and imparts significantly lower radiation exposure as compared with CT+CAP+BS. These findings support the inclusion of ^{18}FDG PET/CT in initial staging of stage II-IV BC. ***References:*** [1]. Shoukat Z, Shah AJ. Breast Cancer Awareness and Associated Factors among Women in Pakistan: A Cross-Sectional Descriptive Study. Asian Pac J Cancer Prev. 2023 May 1;24(5):1561-70. doi: 10.31557/APJCP.2023.24.5.1561. Assessment of new lesions in [18F]FDG-PET/CT scans of metastatic breast cancer patients: A proposal for metastatic breast cancer imaging reporting and data systems (mBI-RADS)

S. P. Hein[1], *N. M. Jakobsen[2], M. Naghavi-Behzad[2], W. A. Weber[1], W. Vach[3], M. Grubbe Hildebrandt[2,4], M. Vogsen[4,5];*
[1]Department of Nuclear Medicine, Technical University of Munich, Munich, GERMANY, [2]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [3]Basel Academy for Quality and Research in Medicine, Basel, SWITZERLAND, [4]Department of Clinical Research, University of Southern Denmark, Odense, DENMARK, [5]Department of Oncology, Odense University Hospital, Odense, DENMARK.

Aim/Introduction: Metastatic breast cancer (MBC) diagnosis often relies on CE-CT, but the use of [18F]FDG-PET/CT is expanding for staging and response monitoring because of its higher sensitivity. Studies indicate that [18F]FDG-PET/CT detects MBC progression six months earlier than CE-CT1, enhancing 5-year overall survival for the patients2 due to possible earlier adaption of therapy. Such results are based on the application of the PERCIST criteria, following the one-lesion methodology. The experience from these studies suggests, however, that PERCIST may generate false positive decisions, in particular due to misinterpretations of new lesions as signs of progression. Our objective was to explore the feasibility of mitigating this problem by implementing a classification system for new lesions. ***Materials and Methods:*** We developed the metastatic breast cancer imaging reporting and data systems (mBI-RADS) for assessing new lesions in [18F] FDG-PET/CT scans of MBC patients. This was accomplished by abstracting clinical experience and through reevaluation of all new lesions detected in the above mentioned study1 involving 87 patients. Particular features of interest were FDG-avidity (non-avid/equivocal/avid), CT findings (benign/equivocal/malignant/no finding), and lesion localisation (typical/atypical of MBC). We studied to which degree a combination of these features together with additional information from biopsy, anamnesis, or previous imaging might be useful to distinguish between false-positive and true-positive new lesions. ***Results:*** The new classification mBI-RADS categorises new lesions into five main groups (1-5) with subcategories, classifying them as clearly benign (1), likely benign (2), equivocal (3), likely malignant (4), or clearly malignant (5). For equivocal lesions, a follow-up scan with an evaluation according to the confirmatory mBI-RADS is recommended, allowing for reclassification of the initially evaluated lesion based on its development and appearance of new equivocal lesions. Using this two-step approach, 6 out of 7 false positive decisions due to new lesion could be avoided without substantially delaying or removing true positive decisions. ***Conclusion:*** The mBI-RADS is a promising contribution to the assessment of [18F]FDG-PET/CT for monitoring response of MBC patients. It may prevent mischaracterization of false positive lesions, a problem that can arise using the existing PERCIST criteria. The possibility of extending its use to MBC staging is also under consideration. ***References:*** 1. Vogsen et al. EP-0131

Advancing Care: ^{18}F-FDG fdPET/CT input for treatment response monitoring in metastatic breast cancer (MBC) - focus on combined cyclin-dependent inhibitors (CDK4/6i)/endocrine therapy (ET) for better disease prognosis

M. Mihaylova[1], *E. Piperkova[1], L. Chavdarova[1], A. Konsoulova[2], S. Tuncheva[2], K. Zhelev[3];*
[1]University Hospital For Active Treatment In Oncology, "Prof. Ivan Chernozemski", Department of Nuclear Medicine, Sofia, BULGARIA, [2]University Hospital For Active Treatment In Oncology, "Prof. Ivan Chernozemski", Department of Medical Oncology, Sofia, BULGARIA, [3]MHAT Heart and Brain, Radiotherapy and Radiosurgery, Pleven, BULGARIA.

Aim/Introduction: Metastatic breast cancer poses significant clinical challenges, necessitating effective treatment strategies. Monitoring the effect of the combined therapy with CDK4/6i/ET would be of great value for the further establishment of this kind of therapy and there is still missing information about standardize PET/CT monitoring. The aim of our retrospective study was to assess the role of ^{18}F-FDG "full-digital" PET/CT for the response evaluation in MBC patients treated with CDK4/6i. ***Materials and Methods:*** The retrospective study included 241 PET/CT studies in 80 patients with de novo (43p.) or recurrent (37p.) MBC who started treatment with CDK4/6i/ET at the

Department of Oncology at USHATO, Sofia, Bulgaria. The data was recruited between December 2021 and December 2023. All patients received a combination of aromatase inhibitor (71,3%) or Fulvestrant (28,7) and a CDK4/6i, 44 of them (59,5%) as first-line treatment. We divided metastatic sites into visceral (n=33) and non-visceral (n=64), with bone only - 53p. We selected up to 4 lesions with highest FDG uptake at PET1 and measured the same lesions on the follow-up scans. Treatment response was evaluated according to EORTC criteria, using qualitative interpretations and quantitative indices classifying patients into 4 response groups: complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD) and progressive metabolic disease (PMD). ***Results:*** All 80pts (median age: 63y.o.) had initial staging (PET1) and a second restaging -PET2, 51 pts (63,7%) from PET2 were restaged with PET3 and 30pts (37,5%) from PET3 had subsequent PET4. Restaging PETs showed SUV-decrease, corresponding with therapy response - (SUV1mean for primary tumor from 8,7 to 3,3; regional lymph node 7,5 to 2,9; visceral metastasis from 6,1 to 4,9 and nonvisceral - 8,4 to 4,1). Most of the patients demonstrated PMR at PET2 (73.8%) and PET3 (16.3%). CMR was achieved in 20.0% and 25.0% of patients at PET2 and PET3, respectively. PET4 revealed SMD in 11,3%, and 22.5% of patients achieved CMR. From all 80pts, 6pts (4,8%) showed PMD (4pts after PET3 and 2pts after PET4), 4 of them were with visceral and 2 - with bone progression - they were referred for next line treatment. Additionally, progression-free survival (PFS) analysis demonstrated a mean PFS of 18.89 months (11-34), indicating favorable treatment efficacy and disease control. ***Conclusion:*** In conclusion, our retrospective study defines PET/CT as a pivotal tool in assessing treatment response among MBC patients undergoing CDK4/6i/ET and shows the promising efficacy of this treatment combination.

EP-0132

[18F]FDG PET-CT in staging, re staging and assessment of breast cancer response in men

L. Cagua Ruiz[1,2], *T. Aroui Luquin[1], D. Rivas Navas[3], A. Piñero Donis[1], R. Sánchez Sánchez[1];*
[1]Hospital Virgen de las nieves, Granada, SPAIN, [2]Servicio Medicina Nuclear Hospital universitario Virgen de las Nieves, Hospital universitario virgen de las Nieves, SPAIN, [3]Hospital Virgen de las nieves, Granada, SPAIN.

Aim/Introduction: To assess the usefulness, in terms of diagnostic validity, and the therapeutic impact of PET-CT in the diagnosis and follow-up of breast cancer in men. ***Materials and Methods:*** Retrospective observational study (January 2009/ September 2023) in men with an anatomopathological diagnosis of breast cancer who underwent a PET-CT study at diagnosis and/ or follow-up. Diagnostic validity parameters were calculated using as reference the anatomopathological results of the lesions, the results of diagnostic reference tests and/or clinical follow-up of at least 6 months. ***Results:*** 96 PET-CT studies were analyzed in 19 men (mean age 72 ± 17.1 years): 7 for initial staging, 5 for re-staging, 11 for suspected recurrence, 46 for follow-up, and 27 to assess response to treatment. The most frequent histological type was infiltrating ductal (18/19), grade 2 (7/19). The tumors showed expression of ER in 18/19p, RP in 15/19p and HER 2(+) in 2/19. Synchronous tumors in 3 patients (choroidal melanoma, Hodgkin lymphoma and mucosis fungoides) PET-CT was positive in 57/96 studies (54 VP, 3 FP) and negative in 39 (37 VN, 2 FN). S:0.96 (95% CI 0.92-1.01), E:0.93 (95% CI 0.84-1.01), PPV:0.95 (95% CI 0.89-1.01), and NPV:0.95 (95% CI 0.88-1.01). Unsuspected injuries were detected in 32/96 studies (33.3%) and the therapeutic management was changed in 24/96 (25%). ***Conclusion:*** [18F]FDG-PET-CT in men with breast cancer showed high sensitivity, detecting lesions not known by conventional imaging tests (33.3%). These injuries changed the therapeutic management in 25% of the cases.

Aim/Introduction: HER2-positive breast cancer is an aggressive breast cancer subtype and is routinely treated with combinations of HER2-directed drugs and chemotherapy as (neo)adjuvant therapy. While excellent long-term outcome has been achieved, concerns regarding treatment-induced toxicity remain. Therefore, identification of patients who may respond to the de-escalated regimens is of critical importance. In this study, we aimed to evaluate the predictive role of baseline [18F]FDG PET/CT quantitative parameters for response to neoadjuvant treatment in HER2-positive breast cancer patients receiving neoadjuant therapy with atezolizumab in combination with dual HER2 blockade plus epirubicin within the ABCSG-52/ATHENE trial. ***Materials and Methods:*** [18F]FDG PET/CT quantitative parameters of a sub-group of HER2-positive invasive unilateral breast adenocarcinoma patients from a randomized open-label, two-arm phase II study were correlated with postsurgical pathological findings. In the setting of randomized clinical trial, patients were assigned to two neoadjuvant treatment arms (atezolizumab, pertuzumab and trastuzumab vs pertuzumab and trastuzumab) followed by four cycles of epirubicin plusatezolizumab, pertuzumab and trastuzumab in both arms and subsequent surgical resection of the tumor. Complete pathologic response (pCR) and residual cancer burden (RCB) class (RCB 0-III) were evaluated. All patients underwent standard pre-treatment and post-treatment [18F] FDG PET/CT scans. Semi-quantitative measurements (SUVmax, SUVmean, SULmax, SULpeak, SULmean, MTV and TLG) were performed in all detected lesions. ***Results:*** A sub-group of 12 patients (mean age: 55.68±9.67 years) were included in this pilot study (11 patients evaluable for pCR/RCB). RCB classes of 0, I and II were reported in 6 (54.5%), 3 (27.2%) and 2 (18.1%)

patients, respectively. Primary tumor SUVmax and SUVmean were significantly higher in pCR group compared to RCB-II (8.22±1.12 vs 4.12±0.91, p=0.018; 4.93±0.83 vs 2.59±0.81, p=0.007). SUVmax, SULmax and SULmean in metastatic lymph nodes of pCR patients were significantly lower than RCB-I group (p<0.05). There was no patient with positive lymph node metastases in RCB II class. Total TLG was significantly higher in pCR compared to RCB-II group. ***Conclusion:*** The results of this study showed that higher metabolic activity of malignant lesions on [18F]FDG PET/CT is significantly associated with pathological response after neoadjuant therapy with atezolizumab in combination with dual HER2 blockade plus epirubicin in HER-2 positive breast cancer patients. Given these initial findings, baseline [18F]FDG PET/CT parameters could potentially be used for approaching de-escalation strategies and identification of patients who will benefit from this treatment regimen. Future studies with larger sample populations are needed to confirm these findings.

EP-0134

Phase I trial of gastrin releasing peptide receptor antagonist [99mTc]Tc-DB8 for SPECT imaging of GRPR expression in breast cancer.

V. Tolmachev[1], *O. Bragina[2], M. Larkina[3], R. Varvashenya[3], T. Maina[4], B. A. Nock[4], P. Kanellopoulos[5], A. Orlova[5], V. Chernov[2]; [1]Department of Immunology, Genetics and Pathology (IGP), Uppsala University, Uppsala, SWEDEN, [2]Department of Nuclear Therapy and Diagnostic, Cancer Research Institute, Tomsk National Research Medical Center, Tomsk, RUSSIAN FEDERATION, [3]Research Centrum for Oncotheranostics, Research School of Chemistry and Applied Biomedical Sciences, Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [4]Molecular Radiopharmacy, INRaSTES, NCSR "Demokritos", Athens, GREECE, [5]Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN.*

Aim/Introduction: An accurate non-invasive staging of luminal breast cancer remains an unmet clinical need. The tumours with a high expression of gastrin-releasing peptide receptors (GRPR) might respond to therapy using radiolabelled bombesin analogues. There is a strong correlation between GRPR and oestrogen receptor (ER) expression. Thus, quantitative visualization of GRPR expression in breast cancer might provide important information enabling personalized treatment of breast cancer. Preclinical studies have demonstrated that antagonistic bombesin analogue [99mTc]Tc-DB8 binds to GRPR with high affinity and specificity. The aim of this study was to evaluate distribution, safety, tolerability and dosimetry of [99mTc]Tc-DB8 after injection in patients with primary breast cancer. ***Materials and Methods:*** This was a prospective, open-label, non-randomized Phase I diagnostic study was performed in patients with primary breast cancer (ClinicalTrials.gov Identifier: NCT05940298). Fifteen patients with primary ER-positive breast cancer (ER6-ER8) were in three cohorts, five patients each. The injected peptide mass was either with 40, 80, or 120 µg. The injected activity was 362±90 MBq [99mTc]Tc-DB8. Planar scintigraphy was performed after 2, 4, 6 and 24 h and SPECT/CT imaging after the planar imaging 2, 4 and 6 h after injection. Vital signs were monitored before, during and after the imaging. The imaging data were used for calculation of dosimetry using OLINDA/EXM 1.1 (female phantom). Additionally, four patients with ER-negative primary tumours were injected with 80 µg [99mTc]Tc-DB8 and SPECT/CT imaging was performed 2 h after injection. ***Results:*** No adverse events were detected after injection of any mass of DB8. The effective dose was 0.019±0.004 mSv/MBq. The normal organs with the highest accumulation (%IA per organ) were breast, kidney, liver, lung and pancreas. The uptake in the pancreas after injection 120 µg was significantly (p<0.005, Mann-Whitney U test) lower compared with 80 µg . The effective dose was 0.009 ± 0.001, 0.011 ± 0.004 and 0.014± 0.003 mSv/MBq for patients injected with 40, 80 and 120 µg respectively. Injection of 80 µg provided significantly (p<0.05, one-way ANOVA) higher uptake in primary ER-positive breast cancer 2 h after injection (SUVmax 5.3±1.4) than injection of 40 µg (SUVmax 2.0±0.3) or 120 µg (SUVmax 3.2±1.4). The uptake in ER-negative tumours (SUVmax 2.0±0.8) was significantly (p<0.05, Mann-Whitney U test) lower than in ER-positive. ***Conclusion:*** Imaging using [99mTc]Tc-DB8 is safe. The injected protein dose of 80 µg provides the highest tumour uptake. The data indicate that discrimination between ER-positive and negative lesions might be possible using [99mTc]Tc-DB8.

EP-0135

Combining [18F]FDG PET/CT with machine learning can predict neoadjuvant therapy failure in breast cancer patients

E. Giovannini[1], *C. Bachi[1], G. Giovacchini[1], A. Milano[2], C. Aschele[2], N. Yosifov[1], A. Ciarmiello[1];*
[1]Nuclear Medicine OU S. Andrea Hospital, La Spezia, ITALY,
[2]Oncology U. S. Andrea Hospital, La Spezia, ITALY.

Aim/Introduction: In the treatment of locally advanced and high-risk breast cancer, neoadjuvant chemotherapy (NACT) plays a crucial role. Predictive models are essential in identifying patients at risk of therapeutic failure for personalized treatment strategies. This study aims to assess and define the predictive capabilities of FDG-PET metabolic, clinical, and pathological data using machine learning techniques in optimizing NACT outcomes for breast cancer patients. ***Materials and Methods:*** Clinical and pathological variables including patient demographics, histological characteristics, hormone receptor status (ER, PGR), MIB-1, and staging information were collected in 84 patients. All patients underwent [18F]FDG-PET/CT at initial staging before preoperative NACT and 74 out of 84 underwent surgery. Ten patients were not included: 8 out did not perform surgery and 2 of them dropped out. The response to NACT was classified into three classes: pathological Complete Response (CR), pathological Partial Response (PR), and No Response (NR). A total of 9 predictors, including 5 clinical features (HER-2, MIB-1, ER, PGR, Histology), 3 metabolic features extracted from the PET/CT studies (SUVmax, MTV, TLG) and age were included in the analysis. The PET/CT metabolic features were obtained by using segmentation algorithms implemented on the same software platform in AW 4.6 (Advantage Workstation, GE Healthcare). Least absolute shrinkage and selection operator (LASSO) was used to identify the optimal variables for predicting the response to NACT. The LASSO regression was performed using R software with the "glmnet" package. Multinomial logistic regression analysis with selected variables was used to predict the response for each outcome class. The predictive performance was assessed with ROC curves and the AUCs. Mantel-Haenszel statistic was used to generate odds ratios and to assess the strength of association between predictors and outcome. ***Results:*** Twenty-eight patients showed a CR, whereas 13 and 33 were classified as NR and PR respectively. AGE, MTV, TLG, MIB-1, HER-2 variables showed highest predictive value at LASSO regression analysis. The best predictive models of treatment failure to NACT using feature selection obtained an area under the curve of 81.46, [CI=58.91, 92.37] with a sensitivity of 46.15

and a specificity of 95.08. The Mantel-Haenszel chi-square was 3.9 p<0.05 with an odd ratios of 2.15 (CI=1.06, 4.35). ***Conclusion:*** These findings suggest that integrating semiquantitative [18F]FDG-PET/CT data with clinical information into a unified predictive model can effectively forecast neoadjuvant treatment failure in breast cancer patients. This insight may facilitate the selection of individualized treatments for those facing an adverse prognosis.

EP-0136

^{68}Ga labeled single domain antibody for non-invasive determination of the HER2 expression

B. Altunay[1], *A. Florea[1,2,3], A. T. J. Vogg[1], A. Morgenroth[1], F. M. Mottaghy[1,2,3];*
[1]University Hospital RWTH Aachen, Aachen, GERMANY, [2]Department of Radiology and Nuclear Medicine, Maastricht University Medical Center, Maastricht, NETHERLANDS, [3]School for Cardiovascular Diseases (CARIM), Maastricht University, Maastricht, NETHERLANDS.

Aim/Introduction: Human epidermal growth factor receptor 2 (HER2) is overexpressed in several cancers. Therefore, HER2 represents a good target for monoclonal antibodies with vehicles for specific drug delivery. Single domain antibodies (sdAb), in particular, were investigated in depth in the last years, since they offer the advantage of a more accurate determination of the HER2 status compared to monoclonal antibodies. Especially the HIS-tag attached to the nanobody can affect its bioavailability and therefore its tumor uptake rate. Here, a 68Ga-labeled anti-HER2 sdAb ([68Ga]Ga-DOTA-GA-NM-02) with and without HIS-tag was examined in terms of its biodistribution and tumor targeting potential in a HER2 xenograft. ***Materials and Methods:*** Rj:ATHYM-Foxn1nu/nu mice were subcutaneously injected with SKOV-3 cells to form a HER2 positive tumor. After the tumor reached a volume of about 200 mm^3, the mice (n=6) were injected with 10 MBq of the 68Ga-labeled nanobody with HIS-tag and scanned in the PET/CT immediately after injection and 3h post injection (p.i.). On the following day, the same mouse was injected with the 68Ga-labeled nanobody without HIS-tag and scanned again 0h and 3h p.i. in the PET/CT. Another group of mice (n=6) was subjected to the same experimental procedure, but additionally injected with an excess of cold nanobody. All mice were injected with gelofusine as renal protection three minutes before the injection of radioactivity. ***Results:*** The [68Ga]Ga-DOTA-GA-NM-02 products were prepared with a high radiochemical purity (99.8 ± 0.5%). Imaging with the nanobody with HIS-tag showed a mean Standardized Uptake Value (SUVmean) of 1.32 ± 0.36 in the kidney and 0.25 ± 0.19 in the liver 3h p.i.. The tumoral uptake showed 3h p.i. a SUVmax of 0.69 ± 0.11 (45 min p.i. SUVmax 1.2 ± 0.2). In comparison, the SUVmean in the mice injected with the nanobody without HIS-tag was 0.98 ± 0.27 in the kidney and 0.12 ± 0.14 in the liver. The SUVmax in the tumor was 0.54 ± 0.07 (45 min p.i. SUVmax 1.1 ± 0.3). By addition of unlabeled nanobody the tracer uptake in the tumor was reduced by 65% for the nanobody with HIS-tag (SUVmax 0.24) and by 33% for the nanobody without HIS-tag (SUVmax 0.36). ***Conclusion:*** We could demonstrate the feasibility of the use of [68Ga]Ga-DOTA-GA-NM-02 with and without a HIS-tag. For both nanobodies, images with a high tumour-to-background ratio can be obtained only 45 minutes p.i.. The blocking experiment underlined the specific uptake in the tumor.

EP-0137

Development of Trop2-targeting Nanobody 68Ga-MY6349 for PET/CT assessment of Trop2 expression in 15 types of cancers

L. Zhao, *Y. Pang, H. Chen;*
The First Affiliated Hospital of Xiamen University, Xiamen, CHINA.

Aim/Introduction: Trophoblast cell surface antigen 2 (Trop2) is overexpressed in many human epithelial cancers. Here, a nanobody targeting Trop2 (MY6349) was developed as a molecular agent for PET imaging. This study primarily aimed to quantify tumor uptake of 68Ga-MY6349 in various malignancies to identify the most promising markers for clinical applications. Additionally, we analyzed the safety, biodistribution patterns, and preliminary dosimetry of this new class of Trop2 radiopharmaceuticals. ***Materials and Methods:*** A tris(hydroxypyridinone) (THP) chelator was chemically linked to the anti-Trop2 nanobody (MY6349) through a site-specific Michael addition conjugation, then subsequently labeled with the radioisotope 68Ga. Preclinical evaluation were performed using different Trop2 expression level tumor-bearing models to evaluate the Trop2-targeting capacity and specificity in vivo. Subsequently, proof of concept was realized by PET imaging with 68Ga-MY6349 in various malignancies. After dosimetry evaluation, the clinical feasibility of 68Ga-MY6349 PET/CT was evaluated in patients with various types of cancer, and the results were compared with conventional PET tracers. ***Results:*** Preclinical studies demonstrated high intratumoral uptake of 68Ga-MY6349 and fast clearance, resulting in high tumor-to-background contrast. The effective dose was 1.46E-02 mSv/MBq. In 83 patients with 15 types of cancer, 68Ga-MY6349 accumulation well above the background level was demonstrated in most identified sites of disease. The highest average SUVmax (>10) was found in PTC, breast cancer (HR+ and TNBC), and prostate cancer. The lowest 68Ga-MY6349 uptake (average SUVmax < 5) was observed in colorectal cancer, pancreatic cancer. The 68Ga-MY6349 uptake in nasopharyngeal carcinoma, urothelium carcinoma, head and neck cancer, and NSCLC was intermediate (SUV 5-10). A comparison with the commonly used radiotracer (18F-FDG, 68Ga-PSMA) revealed that 68Ga-MY6349 was clearly superior, with higher radiotracer uptake and tumor-to-background ratios, particularly in TNBC, PTC, and prostate cancer. In addition, Trop2 expression by IHC is highly correlated with 68Ga-MY6349 uptake in various tumors. Finally, 68Ga-MY6349 PET/CT was performed before and 24h after Trop2 ADC treatment in 3 patients, which revealed a notable reduction in the tumor uptake of 68Ga-MY6349 after treatment. ***Conclusion:*** 68Ga-Trop2-Nanobody (68Ga-MY6349) PET/CT is a safe procedure with a radiation dose comparable to that of other routinely used PET tracers. Tracer accumulation in Trop2-positive metastases was remarkably higher than that of the commonly used radiotracer 18F-FDG, particularly in patients with PTC, prostate cancer, HR+ breast cancer, and TNBC. In addition, PET imaging of Trop2 expression using 68Ga-MY6349 may provide a method for non-invasive evaluation of Trop2 ADC clinical trials of various malignancies.

EP-0138

Focal FDG uptake in the breast of patients with cancers other than breast cancer

K. Hwang, *H. Lee, S. Kim;*
Gachon Medical School, Gil Medical Center, Incheon, KOREA, REPUBLIC OF.

Aim/Introduction: This study aimed to evaluate the occurrence of malignant focal FDG uptake in the breast among patients

diagnosed with cancers unrelated to breast cancer. ***Materials and Methods:*** A retrospective review of 12,403 consecutive FDG PET/CT scans was conducted on patients with various non-breast primary cancers. We identified and examined 32 instances of unexpected focal breast FDG uptake, confirmed histopathologically. These cases comprised patients with malignancy in uterine cervix/endometrium/ovary (n=9), lung (n=4), colon/rectum (n=3), thyroid/parathyroid (n=3), liver/gallbladder (n=3), and others (n=7). SUVmax values were calculated for each focus, then the Student's t-test and a SUVmax-based logistic classification were utilised to differentiate between benign and malignant lesions. Statistical significance was set at $p < 0.05$. ***Results:*** Among the 32 foci with increased FDG uptake, eight were confirmed malignant lesions, while 24 were benign. Malignant lesions exhibited significantly higher SUVmax values compared to benign lesions (4.5 ± 1.1 vs. 2.4 ± 0.9, $p = 0.017$). Using a SUVmax cut-off value of 3.2, sensitivity and specificity for detecting malignant lesions were 0.750 and 0.750, respectively. Application of logistic classification did not yield significant improvement in diagnostic accuracy. ***Conclusion:*** This study underscores the prevalence of malignant focal FDG uptake (25%) in the breast among patients with non-breast cancers. Furthermore, our findings demonstrate the utility of SUV quantification in distinguishing between benign and malignant breast lesions in this population.

EP-0139

Somatostatin Receptor Imaging with ^{68}Ga-DOTATATE PET/CT and its Comparison with ^{18}F-FDG PET/CT in Patients with Estrogen Receptor Positive Metastatic Breast Cancer

K. Chandekar, *S. Satapathy, Y. Dharmashaktu, S. Ballal, P. Ranjan, A. Batra, A. Gogia, S. Mathur, C. Bal;*
All India Institute of Medical Sciences (AIIMS), New Delhi, INDIA.

Aim/Introduction: The present study aimed to investigate whether somatostatin receptor (SSTR) expression in estrogen receptor positive (ER+) metastatic breast cancer (mBC), as identified by pathology and immunohistochemistry studies, represents a clinically meaningful target for PET imaging and potential theranostics. ***Materials and Methods:*** Thirty (29 female:1 male) patients with ER+ mBC were prospectively recruited and underwent PET/CT with 18F-FDG and 68Ga-DOTATATE (within three weeks). Detection rates (per-patient, per-region), number of lesions detected, SUVmax values, adapted Krenning scores, SSTR-FDG visual scores and PET-based staging were compared for both tracers. ***Results:*** The median time gap between the two PET/CT studies was 4.5 days (IQR, 3-10.25). 29/30 (96.7%) patients had positive lesion(s) on both 18F-FDG and 68Ga-DOTATATE PET/CT. 1 patient (3.3%) had 18F-FDG+ and 68Ga-DOTATATE- disease. Per-region and per-lesion analyses showed comparable detection rates with 18F-FDG and 68Ga-DOTATATE for local/breast lesions (number of lesions, 26 vs 26, respectively), regional nodal (79 vs 77), extra-regional nodal (120 vs 119) and skeletal metastasis (181 vs 174). 18F-FDG significantly outperformed 68Ga-DOTATATE for detection of visceral/other metastasis (95.7% vs 56.5% patients, P=0.012; 235 vs 128 lesions, P=0.003). Dominant local/breast lesions (median SUVmax 10.6 vs 4.0, respectively, P=0.01), regional nodal (median SUVmax 8.6 vs 3.8, P=0.01), extra-regional nodal (median SUVmax 9.4 vs 4.2, P=0.04) and visceral/other metastases (median SUVmax 7.8 vs 3.2, P=0.012) had significantly higher 18F-FDG uptake than 68Ga-DOTATATE uptake, while skeletal metastases (mean SUVmax 8.6±3.5 vs 8.0±4.3; P=0.573) had comparable tracer uptake. Most lesions (73.6%-86.9%) had an adapted Krenning score ≤ 2 and an SSTR-FDG visual score of ≥ 4 (52.6%-83.3%). The overall SSTR-FDG visual score was ≤ 2 in 3/30 (10%) patients. There was no significant correlation between the biopsy ER (P=0.669) or progesterone receptor (P=0.208) Allred scores and highest 68Ga-DOTATATE lesional SUVmax. The highest 68Ga-DOTATATE lesional SUVmax showed a trend of being higher in the HER2- sub-group compared to the HER2+ sub-group (median 9.0 vs 3.8, P=0.078). 3/30 (10%) patients had a lower PET-based M-stage with 68Ga-DOTATATE compared to 18F-FDG, while T- and N-stages were concordant in all (weighted kappa (κ) = 1). Both PET modalities showed excellent inter-reader agreement for region-wise lesion detection (κ values, 0.863-1.0) and overall SSTR-FDG visual scoring (intraclass correlation coefficient, 0.895). ***Conclusion:*** 68Ga-DOTATATE PET/CT can visualize malignancy in patients with ER+ mBC. However, poor sensitivity for visceral metastasis, low levels of radiotracer uptake and significant inter-lesion heterogeneity hinder the meaningful clinical translation of SSTR-based theranostics in breast cancer.

EP-0140

Changes in tumor uptake and physiological uptake over time in dual-time-point ^{18}F-FES PET/CT in patients with breast cancer

K. Miyake[1], *Y. Shimizu[1], M. Kawashima[1], S. Yuge[2], Y. Kitano[1], T. Oishi[1], K. Itagaki[1], M. Kataoka[1], Y. Nakamoto[1];*
[1]Kyoto University Graduate School of Medicine, Kyoto, JAPAN, [2]Tenri Hospital, Nara, JAPAN.

Aim/Introduction: 18F-FES PET/CT is a promising imaging modality for estrogen receptor (ER)-positive breast cancers (BC). However, distinguishing tumor uptake from physiological uptake is sometimes challenging due to limited contrast. 18F-FES PET/CT is typically performed as a single static image 1 hour (1h) after radiotracer injection, but the impact of delayed-time-point imaging on uptake has not been well understood. This study aimed to investigate the effect of imaging time-point on tumor uptake and physiological uptake. ***Materials and Methods:*** This prospective study was approved by the Institutional Review Board. Patients with primary BC or known/suspected metastatic BC who underwent 1h and 2h dual-time-point 18F-FES PET/CT without selective estrogen receptor modulator (SERM) or selective estrogen receptor degrader (SERD) treatment were included. SUV (SUVmax or SUVmean) was measured for physiological uptake and FES-avid primary or metastatic BC lesions. Tumor-to-background ratio (TBR) using blood pool or bone marrow as background (TBRblood and TBRbone, respectively), and retention index (RI), defined as (SUVmax2h-SUVmax1h)/SUVmax1h×100 (%), were calculated for each lesion. Differences in SUVs and TBRs between the two static images were assessed using the Wilcoxon signed-rank sum test. ***Results:*** Ten women (age 46-81 years; 8 postmenopausal, 2 unknown menopausal status) were included. Estradiol (E2) levels were <20 pg/mL in all patients. The median dose of 18F-FES was 193.8 MBq (interquartile range [IQR] 173.8-212.5 MBq). SUVmax of the uterus and gall bladder significantly increased from 1h to 2h, whereas SUVmean of the liver and bone marrow significantly decreased. Retained uptake of the injected vein also significantly decreased over time. No significant change was observed in SUVmean of the aorta, breast tissue, and fat. There were 62 FES-avid BC lesions (35 bone, 14 lymph node, 3 breast, 5 pleura, 2 lung, and 3 others), with median SUVmax of 6.15 (IQR 3.6-8.7) at 1h and 7.5 (IQR 4.3-10.4) at 2h, median TBRblood of 5.1 (IQR 2.9-7.7) at 1h and 6.3 (IQR 3.6-10.1) at 2h, and median RI of 13.3 (IQR 2.9-28.9). Both SUVmax and TBRblood significantly increased from 1h to 2h ($p<0.001$ and $p=0.016$, respectively). In respect of bone

metastases, TBRbone significantly increased over time (median 4.7 [IQR 2.6-9.7] at 1h, median 7.8 [IQR 4.5-19.6] at 2h, p<0.001). ***Conclusion:*** Our preliminary study suggests the advantage of delayed-time-point imaging in enhancing FES-avid tumor uptake. Specifically, bone metastases, the most common distant metastases, exhibited improved contrast with delayed imaging.

EP-0141

The predictive role of [18F]FDG PET radiomics in breast cancer patients undergoing neoadjuvant chemotherapy: preliminary results from a prospective cohort

G. Ninatti[1,2], *L. Cavinato[3], R. De Sanctis[4,5], P. Tiberio[5], M. Rodari[5], A. Chiti[6,2], L. Antunovic[2], M. Sollini[6,2];*
[1]University of Milano-Bicocca, Monza, ITALY, [2]IRCCS San Raffaele Hospital, Milan, ITALY, [3]Politecnico di Milano, Milano, ITALY, [4]Humanitas University, Pieve Emanuele, ITALY, [5]IRCCS Istituto Clinico Humanitas, Rozzano, ITALY, [6]Vita-Salute San Raffaele University, Milan, ITALY.

Aim/Introduction: In the last decade, radiomics has emerged as a source of image-derived biomarkers with diagnostic, predictive, and prognostic potential in various diseases, including breast cancer. However, existing data predominantly stem from retrospective analyses. This study aims to assess the role of [18F] FDG PET radiomics in the prediction of pathological complete response in a prospective cohort of breast cancer (BC) patients eligible for neoadjuvant chemotherapy (NAC). ***Materials and Methods:*** We prospectively enrolled stage I-III BC patients eligible for NAC as per standard of care who underwent staging [18F]FDG PET/CT from 2019 to 2022. The present preliminary analysis included patients who had available data regarding pathological treatment response assessed in the breast post-NAC surgical specimen. Accordingly, patients were grouped into two classes: those with pathological complete response (pCR) and those with residual disease (non-pCR). Clinical and histological data were collected. Seventy-one first-order radiomic PET features were extracted from the volume of interest drawn semiautomatically on the primary breast lesion. The ComBat approach was used to harmonize radiomic data. The predictive role of clinical, histological, and radiomic data with respect to pCR was assessed. Univariate and multivariate statistics were used for inference while principal component analysis (PCA) was used for dimensionality reduction. ***Results:*** We enrolled 53 HER2+ and 40 triple-negative (TNBC) BC patients. pCR was obtained in 24/53 (45%) HER2+ and 20/40 (50%) TNBC patients. The clinical stage was I in 4/93 (2/4, 50% pCR), II 76/93 (38/76, 50% pCR), and III in 13/93 (4/13, 31% pCR) cases, respectively. Distribution of age, molecular subtype, ki-67, and stage was not statistically different in the two classes. None of these variables was a significant predictor of pCR at multivariate analysis. At univariate analysis, 10 radiomic features (1 morphology-based, 7 intensity-based, and 2 histogram-based) resulted with a p<0.1. Upon PCA, 3/22 radiomic principal components (PC) among the ones explaining at least 95% of the variability were found to be discriminative for pCR. Using a cross-validation approach, the radiomic PC failed to discriminate pCR vs. non-pCR groups but were able to accurately predict the stage (mean accuracy=0.79±0.08). The addition of clinical variables to radiomics did not improve the cross-validated results of Logit in terms of pCR prediction. ***Conclusion:*** This preliminary analysis demonstrates the potential role of [18F]FDG PET radiomics for the prediction of clinical stage in BC patients undergoing NAC, while its possible role in predicting pCR to NAC needs to be further investigated.

EP-0142

Correlation between tumor uptake on [18F]FES PET imaging and ESR1 mutation status in metastatic HR+/HER2- breast cancer patients after first-line endocrine therapy

R. Seban[1], *F. Bidard[2], A. Bellesoeur[3], C. Callens[4], N. Jehanno[5], V. Huchet[5], I. Buvat[6], A. Cochet[7], L. Champion[1];*
[1]Nuclear Medicine, Institut Curie, Saint-Cloud, FRANCE, [2]Medical Oncology, Institut Curie, Saint-Cloud, FRANCE, [3]Medical Oncology, Institut Curie, Paris, FRANCE, [4]Genetics Laboratory, Department of Diagnostic and Theranostic Medicine, Institut Curie, Paris, FRANCE, [5]Nuclear Medicine, Institut Curie, Paris, FRANCE, [6]Laboratoire d'Imagerie Translationnelle en Oncologie, Inserm U1288, PSL Research University, Institut Curie, Orsay, FRANCE, [7]Nuclear Medicine, Centre George François Leclerc, Dijon, FRANCE.

Aim/Introduction: The estrogen receptor one (ESR1) gene encodes the estrogen receptor alpha (ER) protein, which is pivotal in hormone receptor-positive (HR+)/HER2-negative (HER2-) breast cancer (BC). Prolonged exposure to selective pressure from first-line aromatase inhibitors (AI), which decrease the synthesis of estradiol, is the most likely mechanism driving the acquisition of ESR1 mutations (ESR1m). ESR1m stabilizes ER in an active conformation in the absence of estradiol usually leading to AI resistance. We tested whether the presence of a mutated ER could influence the [18F]Fluoroestradiol (FES) uptake in tumor lesions. ***Materials and Methods:*** We conducted a retrospective bicentric analysis of metastatic HR+/HER2- BC patients who experienced relapse after first-line treatment with AI and CDK4/6 inhibitors (CDK4/6i). All patients underwent both [18F]FDG and [18F] FES PET imaging before starting second-line treatment (endocrine therapy or chemotherapy). ESR1m(+/-) status was assessed using droplet digital polymerase chain reaction on circulating tumor DNA (ctDNA) or through molecular profiling of tumor tissue obtained after progression on AI+CDK4/6i. PET biomarkers, including the maximum standardized uptake values (SUVmax) of FDG and FES, as well as the FDG/FES SUVmax ratio, were analyzed and correlated with ESR1m status. ***Results:*** A total of 38 patients were included: 31 (81%) with invasive carcinoma of no-special type (NST), 6 (16%) with invasive lobular carcinoma (ILC), and 1 (3%) with mixed carcinoma (NST/ILC). ESR1m status was assessed using tumor tissue in 6 pts or ctDNA in 32 pts. Eight patients (21%) were ESR1m+. Using a SUVmax threshold ≥ versus <2, the PET was FES-negative in 9 (30%) ESR1m- patients versus 1 (12.5%) ESR1m+ patient (p-value=0.27). ESR1m+ patients demonstrated higher SUVmax values on [18F]FES PET compared to ESR1m- patients, although this difference was not statistically significant (median: 7.88 versus 3.85, p-value 0.15). No significant differences were observed between SUVmax values on FES and FDG PET/CT scans (8.35 versus 7.87, p-value=0.84), nor between the SUVmax FDG/FES ratio (0.97 versus 1.68, p-value=0.27) among ESR1m+ versus ESR1m- patients. ***Conclusion:*** Our results indicate that [18F]FES PET imaging can still detect ER+ disease regardless of ESR1m status with a sensitivity of 74% with a positivity threshold set to SUVmax ≥2. A trend towards higher FES uptake was observed in ESR1m+ patients compared to ESR1m- patients suggesting a higher binding affinity of FES to the receptor. While reinforcing the existing trend in (pre-)clinical literature, future prospective studies with larger sample sizes are warranted to confirm these findings and explore their clinical usefulness.

EP-0143

Molecular imaging of Avβ6-integrin using Ga68-Trivehexin PET/CT in cases of Triple Negative Breast Cancer; Single Institution preliminary Experience

***A. Sadeq*[1],** *M. Alfeeli*[1], *A. Bager*[1], *K. Alyousefi*[1], *F. Alterkait*[2], *F. Marafi*[1];
[1]*Jaber AlAhmad center for Molecular Imaging, Shuwaikh medical area, KUWAIT,* [2]*kuwait cancer control center, Shuwaikh medical area, KUWAIT.*

Aim/Introduction: αvβ6 is a subtype of integrin which is a class of heterodimeric transmembrane cell adhesive receptors with established evidence that correlates' αvβ6-integrin expression to the severity of various malignancies including breast cancer. Avβ6-integrin is known for its role in facilitating invasion, inhibiting apoptosis, regulating expression of matrix metalloproteases and activating TGF-β; therefore, the expression of αvβ6 is associated with poor prognosis. Ga68-Trivehexin has 85%-88% affinity of this specific integrin. Our objective in this preliminary study was to explore the viability of Ga68-Trivehexin PET/CT in diagnosed cases of triple negative breast cancer. ***Materials and Methods:*** A sample of 6 patients were involved in this preliminary study of whom five are female and one is male patients. All of the cases were biopsy proven cases of triple negative breast cancer whom were referred for staging and restaging. All patients had Ga68-Trivehexin PET/CT scan after signing an informed consent. Ga68-Trivehexin was performed with constant dose of 4 mCi and images were acquired after an average of 65 minutes post-injection with 2 min/bed from vertex to mid-thigh on digital PET/CT camera. The images were then analyzed visually and semi-quantitively in terms of SUVmax and tumor-to-background ratio and the result were compared to either clinical data, recent conventional radiological images or F^{18}-FDG PET/CT scan done within less than a month. ***Results:*** In all of the 6 patients, the Ga68-Trivehexin showed abnromal localization in the known primary and metastatic lesions that were documented by either recent conventional radiological imaging or molecular imaging using F18-FDG PET/CT. In one of the cases with known biopsy proven non-malignant lymphadenopathy, Ga68-Trivehexin showed no abnormal localization in these enlarged lymph nodes; these lesions were showing mild false-positive hypermetabolic activity in a recent F18-FDG PET/CT. However, Ga68-Trivehexin showed abnormal localization in two cases with post-radiation fibrosis. Another patient who had complicated bilateral total mastectomy with wound infection showed diffused localization of the radiotracer at the surgical beds. ***Conclusion:*** Imaging of αvβ6-integrin expression with Ga68-Trivehexine is an excellent prognostic tool with lean potentials for developing theragnostic target that delineat fast-growing malignant cells. One of the main privileges of this radiotracer is its almost negligible background activity which allows better delineation of targeted tumor. This advantage is essential privilege when considering the potential development of a theranostic agent. Correlation with immunohistopathology and follow-up to assess disease prognosis of a larger number of patients are required for further validation of this radiotracer.

EP-0144

Prisma: A single-center, prospective phase II imaging study using ^{68}Ga-PSMA-11 PET/CT to assess the expression of prostate specific membrane antigen (PSMA) in patients with progressive triple-negative breast cancer

M. Manley, *G. Nader Marta, M. Mileva, M. Léger, A. Arçay Öztürk, L. Taraji, P. Aftimos, Z. Wimana, P. Flamen, G. Gebhart;*
Nuclear Medicine, Institute Jules Bordet, Brussels, Belgium, Brussels, BELGIUM.

Aim/Introduction: High rates of prostate-specific-membrane-antigen (PSMA) expression have been reported in triple-negative breast cancer (TNBC)[1]. In this study we assessed PSMA expression in patients with metastatic TNBC (mTNBC) via positron-emission tomography/computed-tomography (PET/CT). ***Materials and Methods:*** PRISMA is a prospective, single-center study enrolling patients with progressive mTNBC. TNBC was defined according to ASCO/CAP guidelines. Patients with measurable disease on 18F-FDG-PET/CT underwent 68Ga-PSMA-11-PET/CT. For quantitative lesion-based analysis, target-lesions (TLs) were defined as ≥1.5 cm in diameter and PERCIST measurable on 18F-FDG PET/CT. TL volumes were propagated to the 68Ga-PSMA-11-PET/CT to measure maximum standard uptake value corrected for lean body mass (SULmax). Mann-Whitney U test assessed differences in SULmax between subgroups of patients based on age (>50yo), PDL1 positivity, Ki-67 index and number of prior treatment lines. A qualitative analysis was performed by three nuclear physicians who classified patients based on the highest PSMA expressing lesion and PSMA expression in the majority of lesions into four groups respectively: 0 (<blood-pool), 1 (>blood-pool), 2 (>liver) and 3 (>parotid-uptake). In case of discordance, the majority determined final visual score. Interreader reliability for the qualitative classification was evaluated by intraclass correlation coefficient (ICC). ***Results:*** Three out of twenty patients were excluded due to lack of measurable TLs on 18F-FDG-PET/CT. Median age at time of diagnosis was 49yo (range 36-68), median number of TL per patient was 7 (range 1-12). SULmax on 68Ga-PSMA-11 PET/CT of all TLs ranged between 1.2 and 18.7, indicating substantial inter-patient and intra-patient heterogeneity. Overall 65.6% (80/122) of TLs had SULmax above Liver-SULmean. SULmax on 68Ga-PSMA-11-PET/CT of TLs was significantly higher in patients younger than 50yo at diagnosis (4.5vs3.1,p=0.02) and in cases of PDL1 positivity (4.4vs2.9,p=0.001). Number of prior treatment lines and Ki-67 index were not associated with SULmax. Visually 70.6%(12/17) and 41.2%(7/17) had a score of 2(>liver) based on highest PSMA expressing lesion and PSMA expression in the majority of lesions. Interreader reliability was excellent with ICC of 0.91 (95% CI 0.79-0.93) and 0.89 (95% CI 0.74-0.96) for both visual approaches, respectively. ***Conclusion:*** PSMA expression in TNBC is heterogenous between patients but also within patients. We observed in the majority of lesions an uptake higher than the liver. Whether this will be sufficient for the success of radioligand therapy targeting PSMA remains to be explored. ***References:*** Tolkach Y et al. PSMA in breast cancer: a comprehensive evaluation of expression and a case report of radionuclide therapy. Breast Cancer Res Treat. 2018.

EP-0145

A Head-To-Head Comparison of ^{68}Ga-FAPI-RGD and ^{18}F-FDG PET/CT for the Detection of Early Breast Cancer

***J. Xiang*[1],** *R. Wang*[1], *J. Wang*[1], *X. Peng*[1], *Z. Zhu*[1], *J. Zhang*[2];
[1]*Peking Union Medical College Hospital, Beijing, CHINA,* [2]*Clinical Imaging Research Centre, National University of Singapore, Singapore, SINGAPORE.*

Aim/Introduction: Early breast cancer is asymptomatic and difficult in preoperative staging. 18F-FDG PET/CT based on glucose metabolism, is paramount for clinical practice. However, the physiological uptake of breast increased the miss rate of small masses and non-mass malignanices. FAP and RGD, which are respectively known to be highly expressed in tumor

stroma, exhibits rapid tracer accumulation in target lesions and low background signal. The aim of this study was to compare diagnostic ablities of 68Ga-FAPI-RGD, a dual fibroblast activation protein (FAP)- and integrin avβ3- (RGD) targeting tracer, to 18F-FDG PET/CT in a single group of patients with early breast cancer. ***Materials and Methods:*** This was a pilot exploratory study of patients with breast malignancies confirmed by biopsy. All 20 patients were recruited by ultrasound and MRI screening. The participants underwent 68Ga-FAPI-RGD and 18F-FDG PET/CT scan within one week before surgery. SUVmax was measured in the primary tumor region, positive regional lymph nodes. Final diagnosis was made based on histopathological analyses or clinical follow-up reports. The expression of fibroblast activation protein and integrin receptor in the primary lesion was analyzed by immunohistochemistry. ***Results:*** All patients had at least one positive lesion on each of the two scans. Twenty patients (100%) and 17 patentis (85%) showed postive lesions on 68Ga-FAPI-RGD and 18F-FDG PET/CT, respectively. For primary lesions, 68Ga-FAPI-RGD had a higher tumor uptake (SUVmax 10.6 ± 6.2 vs. 8.7 ± 5.6, P = 0.003) and higher tumor-to-background ratio than 18F-FDG (SUVmax 7.0 ± 3.9 vs. 6.1 ± 4.1, P = 0.005). Both tracers produced comparable results for detecting primary tumours (8 vs. 9, P = 0.665), lymph node metastases (11 vs. 15, P = 0.365). There was also a significant difference between the size of 68Ga-FAPI-RGD and 18F-FDG in primary lesions (diameter 4.2 ± 1.4 cm vs. 2.7 ± 1.5 cm, P= 0.038). Immunohistochemistry showed that the SUVmax and TBR of 68Ga-FAPI-RGD PET/CT were positively correlated with fibroblast activation protein and integrin expression (P < 0.001 for both). ***Conclusion:*** 68Ga-FAPI-RGD PET/CT gave a higher tracer uptake, improved detection of small size primary lesions and lymph node metastases compared with 18F-FDG PET/CT in early breast cancer. Since the lesions positive on the dual tracer showed greater cellular affinity, which increased tracer retention in the body. The novel dual-target molecular agent could be expected to optimize clinical staging, and 177Lu-based theranostics can be a potential application for those advanced breast cancer patients.

EP-0146

The prognostic role of [18F]FDG PET/CT for suspected recurrence or monitoring systemic treatment in triple-negative breast cancer: preliminary results of the TRINE-PET trial

Maggiore della Carità, Novara, ITALY, [22]AUSL ROMAGNA, Cesena, ITALY, [23]Ao dei Colli Hospital, Naples, ITALY, [24]University Hospital of Modena, Modena, ITALY.

Aim/Introduction: triple-negative breast cancer (TNBC) is an aggressive neoplasm frequently causing metastatic spread. [18F] FDG (FDG) Positron Emission Tomography (PET) is often used in daily clinical practice in case of suspect of recurrency, or for monitoring systemic treatment, although its prognostic relevance still requires further investigation. TRINE-PET is an Italian, multicenter, retrospective study, aiming to investigate the prognostic meaning of FDG PET/CT in different clinical settings of TNBC. ***Materials and Methods:*** data of TNBC patients who performed FDG PET/CT for suspected recurrency or for monitoring systemic treatment were retrospectively collected from 23 Italian centers. A minimum of 2 years of follow-up was required for inclusion. Correlation between FDG PET/CT positivity per district (T, N and M) and survival outcomes (progression and death) was evaluated with long-rank test. In patients imaged for suspected recurrency, Mann-Withney test was used to correlate the value of the onco-marker Ca-15.3 and the evidence of N+ or M+ disease at FDG PET/CT. In patients monitoring systemic treatment, the change of therapeutic management according to FDG PET/CT was collected. ***Results:*** 81 patients performing FDG PET/CT for suspected recurrency were retrieved. The median value of Ca-15.3 was 31 U/mL and lymph node and distant metastases were identified in 35 (43.2%) and 38 (46.9%) patients, respectively. After a median follow-up of 3.4 years, progression and death were reported in 45 (55.6%) and 37 (45.7%) patients. Median values of Ca-15.3 were significantly higher in patients with N+ and/or M+ disease at FDG PET and dead at follow-up (38.1 vs 15.8 U/mL; p=0.01). N recurrence (p=0.018) and M recurrence (p<0.0001) at FDG PET were significantly correlated with progression at follow-up and M recurrence was also associated to death (p<0.0001). Data of 39 patients who performed FDG PET/CT for monitoring systemic treatment were collected, for a total of 93 studies. FDG PET/CT changed the therapeutic management in 51.2% of cases. In a per-study analysis, progression was reported in 65 (69.9%) cases and death in 43 (46.2%). A statistically significant correlation was found between the presence of N+ and M+ disease at FDG PET/CT and both progression and death at follow-up (both p<0.0001). ***Conclusion:*** TNBC patients with high Ca-15.3 values and evidence of N or M recurrence at FDG PET/CT have an increased risk of death. In TNBC patients with suspected recurrency or undergoing systemic therapy the evidence of N+ or M+ disease at FDG PET/CT is a strong negative prognostic factor.

EP-0147

Prediction of Treatment Response in HER-2 Positive Breast Cancer Patients Undergoing Neoadjuvant Treatment Using PET/CT Parameters and Body Composition Indices

M. Karacan, *B. Okudan Tekin, O. Bayrakci;*
University of Health Sciences,Bilkent City Hospital, Department of Nuclear Medicine Clinic, Ankara, TÜRKIYE.

Aim/Introduction: Neoadjuvant treatment (NACT) improves survival in locally advanced HER2+ breast cancer and Sarcopenia is also one of the factors affecting survival in breast cancer. In this study, we aimed to investigate the predictive relationship between PET/CT and CT-derived sarcopenic indices and metabolic parameters with treatment response in HER2+, breast cancer patients who received (NACT). ***Materials and Methods:*** 64 patients who were HER-2 positive in the initial diagnostic biopsy were included in the study. The pathological treatment response, staging PET/CT parameters and tissue section areas

(cm^2) were evaluated. Hounsfield Units (HU) thresholds were determined as -39 to 150 for skeletal muscle (SM), -190 to -30 for subcutaneous adipose tissue (SAT), and -150 to -50 for visceral adipose tissue (VAT). The calculated SM and AT section areas were normalized to patients' body surface areas (m^2) to derive SM index and AT indices (cm^2/m^2). Additionally, SUVmax values of SM and AT sections at the level of L3 vertebra and PET parameters of primary lesions/metastatic lymph nodes were calculated. The relationship between parameters and treatment response rate was investigated using the Mann Whitney U test (SPSS.v26.). ***Results:*** All patients received neoadjuvant chemotherapy regimen. pCR was in 17 (30.9%) patients, near-complete response (TisN0) in 23 (41%) patients. Partial response was obtained in 7 (10%) patients, while chemotherapy response was not obtained in 17 (18.1%) patients. The demographic informations of the patients and the measurements and parameters obtained are given in Table 1. A statistically significant result was found between the primary tumor MTV value and near-complete treatment response among metabolic parameters. Furthermore, in the ROC analysis, the threshold value for primary tumor MTV was determined as 5.93, and it was observed that as MTV decreased, the response rate increased (sensitivity 67%, specificity 65%, p=0.025). ***Conclusion:*** In this study, an inverse relationship was found between the primary tumor MTV derived from PET/CT parameters and near-complete treatment response in HER-2 positive locally/locally advanced breast cancer patients. Additionally, for the prognostic value of sarcopenic indices obtained with CT component, larger series and prognostic studies are needed. ***References:*** Cruz-Jentoft AJ, Bahat G, Bauer J, Boirie Y, Bruyère O, Ceder-holm T et al (2019) Sarcopenia: revised European consensus ondefnition and diagnosis. EP-0148

Noninvasive imaging of breast cancer and tumor metastasis with ^{68}Ga-DOTA-conjugated TROP2 targeting peptide PET/CT

Y. Pei[1,2], *J. Bai[2], H. Zhu[1], Z. Yang[1], C. Wu[3], G. Zhang[4];*
[1]Department of Nuclear Medicine, Peking University Cancer Hospital & Institute, Beijing, CHINA, [2]Fujian Key Laboratory of Precision Diagnosis and Treatment in Breast Cancer, Xiang'an Hospital of Xiamen University, School of Medicine, Xiamen University, Xiamen, CHINA, [3]Xiamen University, Xiamen, CHINA, [4]Kunming Medical University, Kunming, CHINA.

Aim/Introduction: Recently, the role of TROP family members in breast cancer has received much attention. Human trophoblast cell surface antigen 2 (TROP2) is a widely expressed glycoprotein belonging to the TROP family. According to studies, TROP family members are overexpressed in approximately 80% of breast cancer cells, but they are not expressed in normal tissues or are low expressed. This protein is involved in cell self-renewal, proliferation, and invasion, and is linked to breast cancer development and prognosis1. ***Materials and Methods:*** Based on phage libraries, we previously screened TTP (Trop2-targeted peptide), a polycyclic peptide with a high affinity for TROP2, and constructed the nuclide probe 68Ga-DOTA-TTP.Then we constructed stable cell lines with high TROP2 expression using two different breast cancer cell lines, 4T1 and MDA-MB-231. Using these cells, the mouse model of breast cancer lymph node metastasis, breast cancer lung metastasis, and breast cancer in situ was constructed to test the probe's ability to detect tumors in situ and metastatic tumors. In addition, we observed the imaging effect of the probe using a spontaneous breast cancer model. ***Results:*** The probe has high radiochemical purity and stability. Through non-invasive in vivo immune pet /CT imaging, we showed that 68Ga-DOTA-TTP has an excellent ability to specifically detect primary tumors in mouse models. In addition, it can accurately identify lymph nodes with tumor metastasis and tumor lesions in lung metastasis models, with excellent clarity and signal-to-noise ratios that outperformed conventional 2-fluorodeoxyglucose PET/CT imaging. ***Conclusion:*** Results of this study suggest that TROP2-targeted PET imaging could be used as a diagnostic tool in breast cancer and metastasis. ***References:*** 1.Liu X, Deng J, Yuan Y, Chen W, Sun W, Wang Y, Huang H, Liang B, Ming T, Wen J, Huang B, Xing D. Low standardized uptake value of paraspinal muscle at L3 on FDG PET/CT as a Potent Prognostic Biomarker for Disease Progression in Older Women with Invasive Breast Cancer: A Retrospective Study

J. Park[1], *J. Yoon[2], J. Choi[1], Z. Kim[1], C. Lim[3], S. Park[3], C. Lim[1], J. Moon[1], S. Chin[1], J. Choi[4], S. Woo[5], S. Seo[6];*
[1]Soonchunhyang University Hospital Bucheon, Bucheon, KOREA, REPUBLIC OF, [2]Ajou University School of Medicine, Suwon, KOREA, REPUBLIC OF, [3]Soonchunhyang University Hospital Seoul, Seoul, KOREA, REPUBLIC OF, [4]Samsung Medical Center, Seoul, KOREA, REPUBLIC OF, [5]Korea Institutes of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF, [6]PaiChai University, Daejon, KOREA, REPUBLIC OF.

Aim/Introduction: FDG PET/CT provides cancer metabolic status, increased FDG uptake at the tumor associated with a poor prognosis, including tumor proliferation and a high risk of metastasis. Tumor glucose metabolic conditions can be heterogeneous between the Warburg effect of glycolysis and the reverse Warburg effect related to the mitochondrial oxidative pathway. In breast cancer, mitochondrial dysfunction is linked to cancer progression, observed not only in cancerous tissues but also in normal tissues such as the heart and skeletal muscle. This study aimed to investigate whether clinical metabolic and baseline FDG PET/CT muscle parameters could predict disease progression (PD), including recurrence and distant metastasis, in women aged 50 years or older with invasive breast cancer. ***Materials and Methods:*** A total of 97 patients were enrolled, who underwent curative surgery between 2012 and 2020 at our hospital in Korea. Exclusion criteria included chronic medical illnesses. Their pathological stages are distributed as follows: pstage I (47.4%), pstage II (40.2%), and pstage III (12.3%). Cancer types included 58 luminal, 17 HER2, 10 triple-negative, and 12 luminal HER2. Histopathologic factors, clinical or serological factors (neutrophil-to-lymphocyte ratio [NLR], body mass index [BMI]), and FDG PET/CT muscle parameters including skeletal muscular index at L3 (SMI, area/height^2), L3 paraspinal muscle index (PSP MI, area/height^2), and L3 paraspinal muscle metabolism (SUVmean) were semi-automatically measured using the MIM workstation. ***Results:*** While as SUVmean at L3 PSP showed a significantly positive correlation with aging, the SUVmean at L3 PSP of the PD group (N=13) was significantly lower than that of the non-PD group (N=83). Univariate and multivariable logistic

regression analyses were performed to evaluate predictors of PD. Two significant independent predictors for PD were identified: lower SUVmean at L3 PSP (p=0.02, 95% confidence interval [CI] for estimate: -18.1, -1.9) and pathological staging (p=0.03, 95% CI: 0.25, 4.26 for pstage II; p=0.02, 95% CI: 0.42, 4.7 for pstage III). In the present study, the prediction model including SUVmean at L3 PSP and pathological staging showed a higher area under the curve (AUC) of the receiver operating characteristic (ROC) curve for PD compared to staging alone, 0.84 vs. 0.75 (p<0.05). ***Conclusion:*** Low L3 PSP uptake on FDG PET/CT may serve as a potent novel prognostic biomarker for recurrence or distant metastasis in peri- and postmenopausal women with breast cancer. ***References:*** 1. doi: 10.1053/j.seminoncol.2017.10.00422. 2. doi: 10.1038/cr.2017.15533. 3. doi: 10.1152/ajpcell.00264.2020.

EP-0150

Prognostic Value of Sentinel Lymph Node Biopsy after Neoadjuvant Chemotherapy in Advanced Stage Breast Cancer

T. Suta[1], *M. Mutuleanu[1,2], S. Marian[1], M. Gherghe[1,2]; [1]Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Breast Cancer (BC) is considered a severe threat to women's physical and mental health worldwide. Under the premise of favorable results obtained by new therapeutic protocols, the next objective would be to reduce the extent of needed surgical procedures, such as axillary lymph node dissection, while improving patient's quality of life. Sentinel lymph node biopsy (SLNB) is advocated for patients in T1/T2N0 stages. Nevertheless, the role of SLNB after neoadjuvant chemotherapy (NAC) in more advanced initial stages, remains a subject of debate, mainly because of possible alterations of the anatomical conditions in breast and axilla, after treatment. This study aims to evaluate the prognostic value of radioisotopic mapping followed by SLNB in advanced stages of BC patients after NAC. ***Materials and Methods:*** We conducted a retrospective analysis involving 168 breast cancer patients who underwent NAC prior to lymphoscintigraphy mapping from January 2016 to January 2024. Inclusion criteria encompassed histologically confirmed BC, implementation of NAC before SLN mapping, use of 99mTc-albumin nanocolloid for SLN mapping and TNM staging before and after NAC. A total of 131 patients fulfilled these criteria, out of which 64 were cN0, respectively 67 cN1/2. Favorable clinical response to NAC preceded scintigraphic assessment of sentinel lymph nodes to facilitate conservative surgical planning. Each patient received 18-37 MBq of 99mTc-albumin nanocolloid via peritumoral injection guided by ultrasound. For patients achieving complete tumor remission under NAC, colloid injection surrounded the intratumorally placed metallic clip at core biopsy. SLN mapping occurred 18-20 hours preoperatively, employing planar scans 30 minutes to 2 hours after colloid administration; SPECT/CT scan was added in cases of non-axillary or multifocal drainage for precise lymph node localization. ***Results:*** The lymphoscintigraphy performed in our patients with advanced stage BC after the administration of NAC presented an identification rate (IR) of 94.7%. The IR for intraoperative SLNB was 96.2%, with a false-negative rate (FNR) of 6.78%. After a median follow-up of 28.87 months, we obtained a distant disease-free survival rate of 93.1%. Results reported in literature were similar to those of our study, presenting IR in the range 80.8-96.8%, with a generally accepted FNR of 10%. ***Conclusion:*** SLNB is a reliable and effective procedure in advanced breast cancer stages following NAC, providing a low false-negative rate (FNR) and prognostic value comparable to conventional guidelines, with a low recurrence rate within our study cohort.

EP-0151

SUVmax vs SUVpeak - the Race for Quantitative Supremacy of Bone Lesions Evaluation

M. Mutuleanu[1,2], *R. Ancuceanu[1], M. Szasz[1], M. Gherghe[1,2]; [1]Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, Romania, Bucharest, ROMANIA, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Quantitative SPECT-CT has shown a growing importance in recent times in the management of oncological patients. Innovative technology and application development have offered the possibility to measure the same parameters used in PET-CT on SPECT-CT acquisition, thus getting the capabilities of the two methods closer. The most important clinical applications are represented by treatment response evaluation and patient follow-up. The purpose of our study was to compare the diagnostic accuracy of SUVmax and SUVpeak in differentiating metastatic from degenerative lesions in the management of breast cancer patients. ***Materials and Methods:*** The study included 119 female patients presenting metastatic breast cancer that had a bone SPECT-CT acquisition using [99mTc]-HDP from January 2021 to March 2024. The scanning was performed using the following protocol parameters: 60 views, 20 seconds per view, dual energy window with to energy peaks 140± 10 KeV and 120±5 KeV respectively. Several lesions, with a maximum of ten were evaluated (five degenerative and five metastatic lesions) . A total of 487 lesions were assessed and were characterized as degenerative or metastatic bone lesions based on their morphological appearance. Quantitative SPECT-CT parameters SUVmax and SUVpeak based on lean body mass were measured for each of the target lesions. The ROC curve for both SUVmax and SUVpeak were conducted and the AUC index, cut-off value, sensitivity and specificity were determined. ***Results:*** The mean SUVmax and SUVpeak for the metastatic lesions were 24.72±12.93 and 17.97±9.39, respectively. For the degenerative lesions, the mean SUVmax and SUVpeak values were 10.18±4.71 and 8.08±4.03. To assess the diagnostic accuracy capabilities of the quantitative parameters, receiver operating characteristic (ROC) curve analysis were performed resulting in an area under the curve index of 0.896 for SUVmax and 0.857 for SUVpeak. The cut-off value for SUVmax was 12.65 with a sensitivity and specificity of 85.5% and 76.6%, compared to 9.58, 81.7% and 70.2 % for the SUVpeak in discriminating between degenerative and metastatic lesions. ***Conclusion:*** In conclusion, quantitative parameters of the SPECT-CT data can provide additional information of the target lesions thus improving the diagnostic accuracy in discriminating degenerative from metastatic bone lesions. Furthermore, various quantitative parameters that are now available using the SPECT-CT data can have a significant contribution in patient follow up and treatment response evaluation. Extensive studies need to be conducted to assess their impact in clinical practice.

EP-0152

Detection of bone metastases in breast cancer: a systematic review and meta-analysis of diagnostic test accuracy studies on $^{[18F]}$FDG-PET/CT, $^{[18F]}$F-PET/CT, MRI, and contrast-enhanced CT

M. Naghavi-Behzad[1,2], *O. Gerke[1,2], S. T. Nygaard[1,3], V. R.*

Sigaroudi[2], M. Vogsen[2,4], M. G. Hildebrandt[1,2];
[1]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]Department of Clinical Research, University of Southern Denmark, Odense, DENMARK, [3]Department of Nuclear Medicine, Lillebælt Hospital, Vejle, DENMARK, [4]Department of Oncology, Odense University Hospital, Odense, DENMARK.

Aim/Introduction: Bone metastasis is a common feature in breast cancer patients, significantly impacting patient management and prognosis. This systematic review and meta-analysis compared the diagnostic accuracy and bone metastases detection rate of [18F]FDG-PET/CT, [18F]F-PET/CT, MRI, and contrast-enhanced CT. ***Materials and Methods:*** Following PRISMA-DTA guidelines, we systematically reviewed studies assessing these imaging modalities for detecting bone metastases in breast cancer patients. A comprehensive search of MEDLINE/PubMed, Scopus, and Embase databases was conducted until February 2024. Inclusion criteria involved original studies using [18F]FDG-PET/CT, [18F]F-PET/CT, MRI, or contrast-enhanced CT for diagnosing bone metastases in breast cancer patients. Studies focusing on artificial intelligence or machine learning methods, primary breast cancer patients without metastases, mixed cancer types, pre-clinical studies, and lesion-based diagnostic accuracy were excluded. Preference was given to biopsy-confirmed cases or those confirmed through clinical and imaging follow-up. Risk of bias was assessed using the QUADAS-2 tool. Screening, bias assessment, and data extraction were performed independently by two researchers, with discrepancies resolved by a third senior researcher. A meta-analysis was conducted using bivariate random-effects models. ***Results:*** Forty studies were included, with thirty-one contributing to the meta-analysis. High heterogeneity was observed due to diverse study purposes, including initial staging and comparative accuracy assessments. Sensitivity and specificity for [18F]FDG-PET/CT (N=21) were 0.94 (95% CI: 0.89-0.96) and 0.99 (95% CI: 0.96-1.00), respectively, with MRI (N=5) showing similar diagnostic performance (sensitivity: 0.95, 95% CI: 0.88-0.98; specificity: 0.99, 95% CI: 0.90-1.00). While [18F]F-PET/CT (N=8) demonstrated comparable sensitivity (0.93, 95% CI: 0.83-0.97), it was less specific (0.93, 95% CI: 0.87-0.96). Contrast-enhanced CT (N=6) exhibited lower sensitivity (0.71, 95% CI: 0.62-0.77), but maintained high specificity (0.98, 95% CI: 0.96-0.99). Most included studies lacked a definitive reference standard as biopsies were not feasible in all cases; therefore, clinical follow-up and supplementary imaging served as reference standards. ***Conclusion:*** [18F]FDG-PET/CT and MRI demonstrate high and comparable accuracy for diagnosing bone metastases in patients with breast cancer. [18F]F-PET/CT shows similar sensitivity and marginally reduced specificity compared to [18F]FDG-PET/CT and MRI. However, contrast-enhanced CT significantly falls short in sensitivity, making it unsuitable as a standalone modality for ruling out bone metastases in these patients. The considerable heterogeneity observed across the studies included in our analysis underscores the need for further standardization and research in this field. Additionally, the lack of a definite reference standard for true-negative patients, necessitating clinical and imaging follow-up in many cases, further highlights these challenges.

EP-0153

Which subtypes of breast cancer are more likely to have osseous metastases on bone scintigraphy? A Study in a Hospital in Johannesburg

D. Diamond, *F. Kozhimannil;*
University of the Witwatersrand, Parktown, Johannesburg, SOUTH AFRICA.

Aim/Introduction: In South Africa, breast cancer is the most common cancer in females, comprising 23.25% of all cancers diagnosed in 2020 (1). Metastatic disease is closely associated with breast cancer related mortality, with bone being the most frequent site (2). Bone scintigraphy is effective for the identification of osteoblastic metastases in breast cancer. The immunohistochemical expression of hormone receptors are associated with different metastatic patterns. The hormone receptor subtypes include oestrogen receptor (ER) and progesterone receptor (PR). The other subtypes are human epidermal growth factor receptor 2 (HER2), and triple-negative (TNBC) breast cancer, which is characterized by the lack of expression of any of the above receptors. As metastases are rarely present in early-stage breast cancer, extensive imaging is not cost-efficient, especially in resource restraint settings. The ability to identify patients who are at higher risk of bone metastases may help to prioritize these patients. The aim of the study is to assess which histological subtypes breast cancer are more at risk to develop osseous metastases. ***Materials and Methods:*** A retrospective review of all female patients with breast cancer referred for bone scintigraphy over 4 years was performed to assess which histological subtypes of breast cancer are most common in patients with bone metastases. Patient data including age, subtype of breast cancer and bone scintigraphy findings were obtained from departmental records. ***Results:*** 684 bone scans performed from 2019-2023 were reviewed. The mean age of the patients was 53.26 ± 12.17 years. Bone metastases were present in 27% of patients, absent in 61% of patients and 12% of patients had findings requiring further investigations. Luminal B subtype had the highest prevalence of osseous metastases (34%) and 10% had suspicious findings. Conversely, TNBC had the lowest prevalence of bone metastases (12%). ***Conclusion:*** We confirm in this study that in our setting, Luminal B subtype breast cancer is associated with a higher rate of positive findings on bone scan. Such patients, especially when associated with raised tumour markers, ALP and clinical symptoms, should be prioritized for bone scan in resource constrained settings. ***References:*** 1. NICD. EP-0154

Role of [^{99}m Tc] DTPA-bis(Choline) in Evaluation of Breast Cancer: A Prospective Pilot Study.

N. Kumar Gupta[1], *M. Negi[1], H. Puja P.[2], S. Abhilash[1], K. Vidhya[1], F. Huda[1], A. Syed[1], R. Kumari[1], V. K. Dhingra[1];*
[1]AIIMS Rishikesh, Rishikesh, INDIA, [2]INMAS,DRDO, Delhi, INDIA.

Aim/Introduction: In 2020, breast cancer became the leading global cancer, comprising 11.7% of cases, underscoring the need for early detection. Scintimammography (SM), utilizing radionuclides, visualizes breast tumors. Elevated choline kinase (ChoK) expression and phosphocholine (PC) levels in tumors suggest ChoK's role in malignancy. ChoK activity is notably higher in tumor tissues. Hence, we employed [99mTc]DTPA-bis(Choline) imaging on breast lesions to evaluate choline uptake. Leveraging ChoK's involvement in malignant transformation, this

approach holds promise for enhancing breast cancer diagnosis and management, offering potential improvements in prognosis and patient care. ***Materials and Methods:*** 17 female patients (05 premenopausal and 12 postmenopausal) with a mean age of 49.7±8.7 years having mammography showing BIRADS 4C and 5 lesions underwent SM using [99mTc]DTPA-bis(Choline). 20 mCi of the radiotracer was injected intravenously followed by early and delayed imaging. Anterior and lateral spot images of the thorax along with whole-body images were acquired. Target to background ratio (T: B) was calculated by drawing the Region of interest (ROI) on the target lesion and the adjacent normal breast tissue taken as the background on the lateral images. Later the results were compared with the biopsy findings of the lesion taken as the gold standard. ***Results:*** All patients showed significantly increased tracer uptake at the tumour site with an average T:B ratio of 2.94±0.86. One patient had a bilateral breast tumour with the left breast having benign findings (BIRADS-2) showed a T:B ratio of only 1.4 whereas the contralateral right breast having BIRADS-5 lesion showed significant tracer uptake with a T: B ratio of 2.6. Later all the patients followed up with their biopsy reports showing Invasive carcinoma of no special type (NST) in 16 patients and 1 patient had ductal carcinoma in situ further validating our findings of significant tracer uptake in malignant breast tumours. ***Conclusion:*** This is the first time study done using a SPECT choline tracer for the evaluation of choline uptake in malignant breast tumours. In our study, there is a significant choline uptake in the malignant breast lesion. This makes it a promising SPECT tracer for evaluation, localization, and diagnosis of breast carcinoma. ***References:*** Jaswal AP, Hazari PP, Prakash S, Sethi P, Kaushik A, Roy BG, Kathait S, Singh B, Mishra AK. [99mTc] Tc-DTPA-Bis (cholineethylamine) as an oncologic tracer for the detection of choline transporter (ChT) and choline kinase (ChK) expression in cancer. ACS omega. 2022 Apr 8;7(15):12509-23.

EP-0155

Exploring the Potential of [68Ga]Ga-FAP-2286 in Metastatic Cancer Diagnosis and Therapy

A. Abolhosseini Shahrnoy[1], *S. Banihashemian[2], G. Divband[3], R. Nami[1], M. Nasiri[4], M. Akbari[2];*
[1]Pars Isotope Company, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Cancer Research Center, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Khatam PET-CT Center, Khatam Hospital, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Cellular and Molecular Biology, School of Biology, Damghan University, Damghan, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Fibroblast activation protein (FAP) is a promising target for both diagnosis and treatment due to its high expression in the stromal areas of different cancerous growths. FAP-2286, using cyclic peptides with FAP-binding abilities, aims to enhance the retention of imaging agents within tumors, contrasting with small-molecule FAP inhibitors like FAPi-46. The main goal of this study was to measure the uptake of [68Ga]Ga-FAP-2286 in primary solid tumors, adjacent excised tissues, and metastatic sites. ***Materials and Methods:*** In this study, 57 patients with various types of remaining and metastatic cancers were included. Specifically, there were eleven patients with metastatic sarcoma, fifteen with breast cancer, eight with uterine and ovarian cancer, four with colorectal cancer, four with stomach cancer, four with thyroid cancer, two with lung adenocarcinoma, two with adrenal cancer, one with testicular cancer, one with squamous cell carcinoma, and one with urothelial carcinoma. The patients underwent a [68Ga]Ga-FAP-2286 PET/CT scan, followed by visual assessment and semi-quantification of the results. The study calculated the standardized uptake values (SUV)max of [68Ga] Ga-FAP-2286 in tumor lesions and the tumor-to-background ratio (TBR) for each patient. ***Results:*** The patients' vital signs, including heart rate, blood pressure, and temperature, were monitored before, during, and after the diagnostic procedure over the 4-hour follow-up period. All participants underwent [68Ga]Ga-FAP-2286 PET/CT scans without any observed drug-related pharmacological effects. The PET/CT scans showed significant uptake of [68Ga]Ga-FAP-2286 in tumor lesions in all patients, regardless of the tumors' origin (epithelial or mesothelium) or whether they presented with local recurrence, distant recurrence, or metastatic lesions. ***Conclusion:*** In summary, the findings from this study indicate that [68Ga]Ga-FAP-2286 shows promise as a derivative of FAP for the effective diagnosis of metastatic cancer. Furthermore, the compound is being evaluated as a potential therapeutic option for individuals with advanced metastatic cancers. These results highlight the potential of [68Ga]Ga-FAP-2286 in advancing both diagnostic and treatment strategies for patients with metastatic cancer.

Extending baseline ^{18}F-FDG PET/CT clinical relevance in early stage triple negative breast cancer (eTNBC)

A. Daverio[1,2], *F. Giugliano[3,4], J. Dixon-Douglas[5], L. Rached[6], A. Laparra[7], M. Sakkal[6], C. Bousrih[4], A. Viansone[4], S. Morbelli[1], S. Delaloge[4], B. Pistilli[4], D. Deandreis[2], J. M. Ribeiro[4], T. Henry[2];*
[1]University of Turin, AOU Città della Salute e della Scienza di Torino, Nuclear Medicine Unit, Turin, ITALY, [2]Institut Gustave Roussy, Department of Medical Imaging, Villejuif, Paris, FRANCE, [3]Universitiy of Milan, Department of Oncology and Hemato-Oncology, Milan, ITALY, [4]Institut Gustave Roussy, Department of Medical Oncology, Villejuif, Paris, FRANCE, [5]Institut Gustave Roussy, INSERM U981, PRISM Center, Villejuif, Paris, FRANCE, [6]Institut Gustave Roussy - Cancer Campus, Drug Development Department (DITEP), Villejuif, Paris, FRANCE, [7]Institut Gustave Roussy, Interdisciplinary Department of Patient Pathway Organization, Villejuif, Paris, FRANCE.

Aim/Introduction: Immune checkpoint inhibitors (ICI) have improved outcomes in patients with eTNBC. 18F-FDG-PET/CT scan is routinely performed for initial staging before neoadjuvant treatment with immunotherapy and chemotherapy (NACT-IO). However, clinical benefit versus risk of immune-related adverse events (irAEs) is a major concern in clinical practice. This study aimed to evaluate whether 18F-FDG-PET/CT features could predict pathological complete response (pCR) and/or the occurrence of irAE from NACT-IO in eTNBC. ***Materials and Methods:*** We conducted a single-center retrospective study on eTNBC patients treated with NACT and pembrolizumab, between April 2022 and April 2023. Adverse events were graded according to NCI-CTC-AE version 5. Extracted FDG-PET parameters included features related to the primary tumor and the metastatic loco-regional lymph nodes (SUVpeak/max, metabolic tumor volume-MTV, total lesion glycolysis, primary tumor necrosis), and features extracted from organs not involved by metastatic disease (SUVmean of liver, spleen, bone marrow, blood pool-BP, digestive organs, endocrine glands and breasts). Data cut-off date was November 2023. The association between PET features and pCR or irAE was explored using logistic regression. All analysis were performed using R software version 4.1.1. ***Results:*** Of 86 identified patients, 54 had baseline FDG-PET done at our institution and available toxicity data. 65% (35/54) of patients experienced any-grade irAEs, and 24% (13/54) severe irAEs (grade ≥3). SUVmax of primary lesions ranged between 2.7 and 38.0 (median: 14.4).

44% (24/54) of primary lesions had central necrosis. 57% (31/54) patients had FDG-avid locoregional lymph nodes. Among the FDG-PET parameters explored, BP, liver and spleen SUVmean were highly correlated (BP-liver: 0.87; BP-spleen: 0.68; spleen-liver: 0.74). The correlation between primary tumor SUVmax and MTV was negligible at 0.17. Primary tumor SUVmax and metastatic lymph node SUVmax were linearly associated (LN_SUVmax = 1.3 + 0.64 x Primary_SUVmax; p = 9.3e-5). Only the primary lesion SUVmax was associated with an increased risk of severe irAE (OR 1.10 IC95 [1.01-1.21]; per unit of SUV). Neither lymph node related features nor healthy organ basal uptake value were associated with severe toxicity, and none of the above parameters were predictor of pCR. ***Conclusion:*** Our findings suggest that lymph node uptake can be estimated from the primary tumor, and that the primary lesion baseline SUVmax is significantly associated with an increased risk of severe ICIs irAEs. If confirmed, baseline 18F-FDG-PET/CT may help nuclear physicians to discriminate between irrelevant and metastatic lymph nodes and support multidisciplinary work to personalized risk assessment of irAE in eTNBC.

EP-0157

Optimizing the ^{18}F-FESPET/CT SUVmax Threshold for Estrogen Receptor Status Evaluation in Breast Cancer Lesions: A Comprehensive Retrospective Analysis

S. Lin[1,2,3], *C. Liu[1,2,3], S. Song[1,2,3], Z. Yang[1,2,3];*
[1]Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, CHINA, [2]Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, CHINA, [3]Center for Biomedical Imaging, Fudan University, Shanghai, CHINA.

Aim/Introduction: Breast cancer is the most prevalent malignancy among women, representing a significant cause of cancer-related fatalities in this demographic. The evaluation of estrogen receptor (ER) status assumes paramount significance in the clinical management of breast cancer. Presently, there is a burgeoning adoption of 16α-18F-fluoro-17β-estradiol (18F-FES) PET/CT for assessing ER status in breast cancer patients. However, prevailing studies predominantly employ 18F-FES PET SUVmax=1.5 as the positivity threshold, without specific criteria for various lesion sites. ***Materials and Methods:*** This retrospective study included breast cancer patients presenting with first recurrent or metastatic disease and aged ≥18 years. Patients underwent immunohistochemical testing for ER expression in lesions and 18F-FES PET for SUVmax measurement. The optimal SUVmax threshold was determined using receiver operating characteristic (ROC) curves and the Jordon index. Spearman rank correlation coefficient evaluated the relationship between SUVmax and ER percentage in 18F-FES PET. Specificity, sensitivity, positive predictive value (PPV) and negative predictive value (NPV) were used as reference criteria for predicting ER immunohistochemistry status and confidence intervals were calculated using an adopted Wilson method. ***Results:*** The study comprised 152 patients with 156 biopsied lesions, with 24% classified as estrogen receptor-negative and 77% as estrogen receptor-positive. The AUC for all biopsied metastases was 91% (95% CI, 87-95). According to the Jordon index, the optimal SUVmax thresholds were: 2.0 for overall lesions, 2.1 for lymph node metastases, 2.3 for bone metastases, 1.1 for lung metastases, 1.5 for chest wall metastases, and 2.0 for breast metastases. Adjusting SUVmax thresholds to 2 for metastases in breast, lymph nodes, bone, and other sites (79%) yielded sensitivity of 82% (72-89), specificity of 97% (85-100), PPV of 99% (91-100), and NPV of 71% (57-82). Retaining the traditional SUVmax threshold of 1.5 slightly increased sensitivity (88%) but markedly reduced specificity (66%) and PPV (85%). For lung metastases (9%), the threshold was set at 1, with sensitivity of 90% (54-99), specificity of 50% (9-91), PPV of 82% (48-97), and NPV of 67% (13-98); for chest wall metastases (12%), the threshold was set at 1.5, with sensitivity of 94% (69-100), specificity of 100% (20-100), PPV of 100% (76-100), and NPV of 67% (13-98). ***Conclusion:*** This study underscores the accuracy of 18F-FES PET/CT in predicting ER expression in breast cancer lesions when utilizing distinct thresholds for varied lesion sites. Hence, this noninvasive approach presents a viable alternative to lesion biopsy for determining ER status in primary or metastatic breast cancer lesions.

EP-0158

Diagnostic value of ^{18}F-FDG PET-CT in staging of early-stage breast cancer -a retrospective institutional study

S. Mandal, *P. S. Patro, P. Singh, T. Singhal, K. Agrawal;*
AIIMS Bhubhaneswar, Bhubaneswar, INDIA.

Aim/Introduction: Breast cancer is the most common cancer worldwide and leading cause of cancer death among women making screening, diagnosis and staging vital for appropriate management as well as for prognostication. Mammography, ultra-sonography and MRI are commonly used imaging methods which show limited sensitivity for nodal staging as well as for distant metastasis. The WB-F^{18}-FDG-PETCT is a useful imaging modality used for tumour identification, staging, and follow-up. Furthermore, the hybrid PET/CT strategy can potentially alleviate the restricted specificity of PET, which is impacted by the elevated metabolic activity of some benign tumours and inflammatory tissue. In their clinical practice guidelines for breast cancer ASCO, ESMO, and the Royal College of Radiologists (UK) don't recommend routine imaging for the M-staging of asymptomatic patients with early-stage disease. Nonetheless, a number of studies have demonstrated the value of FDG PET-CT in the early stages of illness as well. ***Materials and Methods:*** Retrospective data of 720 patients were included with biopsy proven carcinoma breast, where 154 patients were referred for initial staging and were included in the study. The patients were categorised as T1 to T4 stage based on 8thedition AJCC staging system. The incidence of metastasis in each T stage was evaluated and displayed in percentage. ***Results:*** In this study 10(6.5%) patients had T1 disease, while 40(25.9%) had T2 disease, 4(2.6%) had T3 disease, 85(55.2%) had T4b disease and 15(9.7%) had T4c disease. Metastatic disease involvement was present in 10% T1stage while it was 27.5% in T2 stage of the total 154 patients. The available literature suggests, presence of metastatic disease in < 2% of T1 and T2 stage of breast cancer. However, in the present study, metastatic disease was present in significant higher number of patients. However, no significant correlation was found in the present study (p=0.121). ***Conclusion:*** The study evaluates the effectiveness of ^{18}F-FDG PET/CT in staging breast cancer, specifically in detecting distant metastases in early-stage T1 and T2 disease. Despite recommendations against routine imaging for M-staging in early stages, there's growing evidence supporting PET/CT's utility early on. This modality offers improved sensitivity and specificity, potentially helping identify hidden metastases missed by conventional methods. By evaluating PET/CT's clinical impact, the study aims to align existing guidelines with emerging evidence to enhance patient care through more precise staging and treatment planning.

EP-0159

Optimizing the Role of Thoracic SPECT in Bone Scintigraphy for Breast Cancer

L. Sobral Torres, *R. Albergueiro, P. Dias, P. Soeiro;*
Unidade Local de Saúde São João, Porto, PORTUGAL.

Aim/Introduction: Breast cancer most commonly metastasizes to the bone, playing an important role in prognosis establishment and disease staging. While bone scintigraphy (BS) is a standard imaging modality for breast cancer staging, the utilization of thoracic single-photon emission computed tomography (SPECT) is not standardized. This study aims to evaluate the complementary role of thoracic SPECT in lesion detection during breast cancer staging and restaging with whole-body (WB) planar BS. ***Materials and Methods:*** A retrospective study was conducted, including adult individuals with breast cancer who underwent WB-BS with [99mTc]Tc-HDP and thoracic SPECT for either staging or restaging of the disease between 2018 and 2023. Exclusion criteria comprised other bone-affecting diseases (metabolic, traumatic or other neoplasm). WB and SPECT images were reviewed to identify suspicious lesions, categorized into three groups (0, 1, or ≥2 lesions), and assessed for consistency in lesion count. Statistical analysis included Chi-square and Fisher's exact test, proportion comparison, and univariate binomial and multinomial logistic regressions. ***Results:*** A total of 230 individuals were included (99% women; mean age: 60.5±12.7 years), with 60% undergoing BS for initial staging. Performing thoracic SPECT resulted in a different number of suspicious lesions reported in 27% of cases compared to WB-BS, with significant differences observed (p<2.2e-16). Notably, cases with a single lesion on WB-BS significantly led to benign classification when evaluated with SPECT (p=0.04). The chances of SPECT reporting a different lesion count from WB-BS decreased by 53% during restaging compared to initial staging (OR=0.47; p=0.019). Importantly, when WB-BS is performed for restaging, SPECT did not significantly change the number of reported lesions (p<0.001). ***Conclusion:*** Thoracic SPECT offers valuable insights into lesion characterization during breast cancer staging, particularly when a single lesion is identified on WB-BS. These findings suggest that thoracic SPECT should be considered a crucial component of breast cancer staging protocols while it may not be warranted and could be omitted in restaging disease.

EP-0160

Value of HER2-PET/CT derived quantitative parameters in metastatic HER2+ breast cancer patients treated with T-DM1 (data from the ZEPHIR trial)

M. Ngo Thi Kim Ngoc, *M. Mileva, M. Manley, C. Marin, T. Guiot, M. Paesmans, P. Flamen, G. Gebhart;*
Jules Bordet, Anderlecht, BELGIUM.

Aim/Introduction: Response to Trastuzumab Emtansine (T-DM1) in breast cancer (BC) treatment requires HER2 expression. The ZEPHIR trial proposed HER2 molecular imaging as a non-invasive method to evaluate HER2 status across the total tumour burden which was found to successfully predict response to T-DM1 using a visual classification of HER2 expression. This study aims to assess whether HER2-PET quantitative parameters can also reflect T-DM1 response. ***Materials and Methods:*** The ZEPHIR trial included patients with metastatic HER2-positive BC who underwent a baseline Zirconium-89 Trastuzumab (HER2)-PET/CT and an FDG-PET/CT. Visual classification of HER2 distribution distinguished HER2+ from HER2- patients [1]. Patient-based RECIST1.1 and late metabolic response were assessed after three T-DM1 cycles. An automated workflow was used to segment the metabolic tumour volume (MTV) on baseline FDG-PET/CT, using PERCIST threshold. These volumes were then propagated on the HER2-PET/CT to assess the relation between HER2 quantitative parameters (SUVmax, SUVpeak and SUVmean) derived from the baseline MTV and patient-based response using Mann-Whitney test, and with time to treatment failure (TTF) using Cox proportional hazards regression analysis. Additionally, MTV in all patients and only HER2+ patients was correlated with TTF. P value <0.05 was considered significant. ***Results:*** 80 patients were analysed. All HER2 quantitative parameters were significantly associated with RECIST1.1 response: median SUVmax, SUVpeak and SUVmean of 7.1, 4.6 and 2.3 in non-responding patients compared to 17.9, 10.3 and 5.6 in responding patients, respectively (all having p<0.01). Furthermore, a similar association was found with late metabolic response. HER2 quantitative parameters however were not predictive of TTF. MTV was significantly associated with TTF in all patients (HR=1.30, 95%CI:10.9-1.55, p=0.004), with stronger association in the HER2+ group (HR=1.66, 95%CI:1.28-2.15, p=0.0001). Finally, HER2 quantitative parameters were in line with the previous patient-based HER2 visual classification (p<0.01). ***Conclusion:*** HER2 quantitative parameters can successfully predict response to T-DM1, similar to the previously established patient-based HER2 visual classification. Further investigation is required to examine the clinical utility and added value of quantitative parameters in HER2 positive BC. ***References:*** [1] M. Mileva et al. Molecular imaging predicts lack of T-DM1 response in advanced HER2-positive breast cancer (Final Results of ZEPHIR trial). NPJ Breast Cancer. 2024;10:4.

EP-0162

Dual FES/FDG PET/CT imaging to predict therapy response in patients with estrogen receptor-positive recurrent or metastatic breast cancer: Preliminary Results

E. Dursun[1], *E. Ozkan[1], H. Yasar[2], M. Araz[1], S. Aksoy[3], Y. Urun[2], N. Kucuk[1];*
[1]Ankara University Medical Faculty, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]Ankara University Medical Faculty, Department of Medical Oncology, Ankara, TÜRKIYE, [3]Hacettepe University Medical Faculty, Department of Medical Oncology, Ankara, TÜRKIYE.

Aim/Introduction: ER expression is both prognostic and predictive biomarker that plays a main role in breast cancer oncogenesis. However, ER expression status may differ in primary and metastatic breast cancer lesions and over time. Moreover, ER positivity in tissue sample does not always reflect the functional status of the receptor. FDG, glucose analogue reflects the metabolic activity of tumor cell. Although SUV is a predictive prognostic factor, the success of FDG PET in evaluation of therapy response in hormone positive breast cancer is limited because it can not provide information about the function of ER. Our aim is to predict therapy response by using dual FES/FDG imaging in patients with estrogen receptor-positive metastatic or recurrent breast cancer. ***Materials and Methods:*** Thirty-one (22 invasive ductal, 9 invasive lobuler) ER+ metastatic or recurrent breast cancer patients prospectively underwent both FES and FDG PET imaging. Images were evaluated on 4 category (FES-FDG-, FES-FDG+, FES+FDG-, FES+FDG+) for whole lesions. FES- and FES+ groups were compared for therapy response under hormonotherapy or not. ***Results:*** While 22/31 patients had under hormonotherapy, remaining 9 patients not. In hormonotherapy

group, 16/22 patients had FES+ images and remaning 6 patients had FES- images. In this group, 6/16 (38%) patients with FES positive had progression, 1/6 (16%) patient with FES negative had progression. In hormonotherapy-off group, 7/9 patients had FES+ images and remaining 2 patients had FES- images. In this group, 3/7 (42%) patients with FES positive had progression, ½ (50%) patient with FES negative had progression ***Conclusion:*** FES positivity under hormonotherapy and FES negativity without hormonotherapy can be related with disease progression. Use of dual FES/FDG PET imaging may be guide to predict the therapy response and prognosis in the groups of hormonotherapy-on or off. Although no statistically significant difference could be found due to the limited number of patients, this preliminary results can be significant.

EP-0163

Correlation Between F^{18} FDG PET-CT SUVmax Values and Hormone Receptor Status -Ki67 Index in Breast Cancer Patients: A Single Centre Experience

G. Shankaramurthy, *K. Pramukh, R. Niti, S. C. Pingali, B. Narendra, N. Nagarjun;*
Fortis hospital, Bengaluru, INDIA.

Aim/Introduction: To assess the correlation between F^{18} FDG PET-CT SUVmax values and hormone receptor status - Ki67 index in cancer patients, elucidate potential correlations that could contribute to prognosis and treatment planning. Hormone receptor status (estrogen, progesterone and Her2neu -ER, PR, HER2) and the Ki67 index are crucial determinants of tumor behavior and treatment response. The relationship between SUVmax and these molecular markers remains unclear. Understanding this correlation could offer valuable insights into tumor biology and guide personalized treatment strategies. ***Materials and Methods:*** 101 breast cancer patients (with invasive, lobular, metaplastic and mucinous carcinomas) who underwent staging F^{18} FDG PET-CT study and had available data on hormone receptor status and Ki67 index were retrospectively analysed. PET-CT images were analysed to determine SUVmax values. Hormone receptor status was assessed using immunohistochemistry, while the Ki67 index was calculated as the percentage of positively stained tumor cells. Statistical analysis, including correlation coefficients and regression models, was performed to evaluate the relationship between SUVmax, hormone receptor status, and Ki67 index. ***Results:*** Among the 101 breast cancer patients included in the study, 68.3%, 64% and 35.6% had positive hormone receptor status for ER, PR and Her2-neu respectively. 12% of patients had triple negative tumors. The mean and median SUVmax values in all patients was 8.888 and 6.15 respectively (Range=1.4-25.7). Among patients with triple negative tumors, the mean, median and range of SUVmax was 12.958, 12.45, and 1.7-20.6 respectively. Among patients with hormone positive tumors the mean, median and range of SUVmax was 10.241, 10.6 and 1.4-34 respectively.The median SUVmax was significantly higher in hormone receptor-negative tumors compared to hormone receptor-positive tumors ($p < 0.05$). Additionally, a positive but weak correlation was observed between SUVmax values and the Ki67 index (correlation coefficient [0.259]). ***Conclusion:*** Our analysis revealed a significant correlation between F^{18} FDG PET-CT SUVmax values and hormone receptor status. However, a positive but weak correlation between SUVmax and Ki67 index was noted. Hormone receptor-negative tumors exhibited higher SUVmax values, suggesting increased metabolic activity, while SUVmax values weakly correlated with the Ki67 index, indicating an association between tumor metabolism and proliferative activity. These findings highlight the potential of PET-CT SUVmax as a non-invasive imaging biomarker for prognostication and treatment planning in cancer patients. Further prospective studies are warranted to validate these observations and explore their clinical implications.

The Value of SUV-Based Parameters in a Large-Scale Retrospective Study on Lung Lesions

C. Pini[1,2], *M. Kirienko[3], F. Gelardi[1,4], P. Bossi[5], D. Rahal[5], L. Toschi[6], G. Ninatti[1,2], M. Rodari[7], G. Marulli[8,9], L. Antunovic[1], A. Chiti[1,4], E. Voulaz[8,9], M. Sollini[1,4];*
[1]Nuclear Medicine, IRCCS San Raffaele, Milan, ITALY, [2]School of Medicine and Surgery, University of Milano-Bicocca, Monza, ITALY, [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, ITALY, [4]Vita-Salute San Raffaele University, Milan, ITALY, [5]Pathology, IRCCS Humanitas Research Hospital, Milan, ITALY, [6]Medical Oncology and Haematology, IRCCS Humanitas Research Hospital, Milan, ITALY, [7]Nuclear Medicine, IRCCS Humanitas Research Hospital, Milan, ITALY, [8]Thoracic Surgery, IRCCS Humanitas Research Hospital, Milan, ITALY, [9]Department of Biomedical Sciences, Humanitas University, Milan, ITALY.

Aim/Introduction: Although many well-known factors affect the maximum standardized uptake value (SUVmax), it remains the most requested and used parameter, especially among clinicians, despite other parameters such as the standardized uptake value corrected for lean body mass and the metabolic tumor volume proved to be less sensitive to the same factors, more robust, and eventually more informative. This study intends to provide robust evidence regarding the diagnostic and prognostic value of SUVmax in a large cohort of patients with suspected malignant lung nodules imaged by $^{[18F]}$FDG PET/CT. ***Materials and Methods:*** We performed a retrospective single-centre analysis of patients with suspected or confirmed primary lung tumours undergoing $^{[18F]}$FDG PET/CT within 180 days before surgery. The required sample size was 567 patients. Demographics, imaging data, surgical information, definitive histology, and follow-up data were collected. SUVmax values were analysed according to histology, TNM stage, scanner type, and outcome data. The impact on SUVmax and SUVmean values of different reconstruction protocols (clinical vs EARL) was assessed. All potential predictors of patients' outcome were assessed. The same analyses were also performed for SUVmean. ***Results:*** 91% of cases were histologically confirmed primary lung tumours. Lung benign nodules or metastases accounted for 5% and 4% of cases, respectively. The predominant primary lung tumour histotype was adenocarcinoma (70%) and most patients presented with stage I disease (51%). 144 patients relapsed during post-surgical follow-up, and 55 patients died. SUVmax failed to effectively differentiate benign lesions from primary tumours or metastases. Stage I patients presented lower SUVmax values. SUVmax significantly correlated with patient weight, injected $^{[18F]}$FDG activity, and lesion size. SUV values differed between clinical and EARL reconstructions. The same results were confirmed for SUVmean. Survival analyses revealed no

independent prognostic significance for SUVmax in progression-free after adjusting for other variables. SUVmax correlated with overall survival, alongside disease stage and tumour histotype. ***Conclusion:*** Our study confirms that SUVmax, though widely employed, present relevant limitations in discriminating between benign lesion and lung cancer, in classifying cancer histotypes, and in predicting patient outcomes independently. Known influencing factors such as patient's weight and reconstruction protocols significantly impact SUVmax and SUVmean values. While SUV-derived parameters remain valuable, their interpretation should be cautious, emphasising the need for comprehensive clinical and imaging assessments.

EP-0165

Clinical Impact of [18F]FDG PET-CT in the Staging of Stage III Non-Small-Cell Lung Cancer

N. Alvarez Mena, *F. Sebastian Palacid, R. Zambrano Infantino, B. Jaramillo Lopez, M. Garcia Aragon, R. Ruano Perez;*
Nuclear Medicine Department, Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: Stage III non-small cell lung carcinoma (NSCLC) is associated with low survival rates despite curative treatment with chemoradiotherapy and/or surgery. Our aim is to evaluate the clinical impact of [18F]FDG PET-CT in the staging of stage III non-small cell lung carcinoma (NSCLC) by conventional imaging. ***Materials and Methods:*** Prospective study of 52 patients diagnosed with stage III NSCLC by computed tomography (CT) between January 2023 and January 2024, who underwent [18F]FDG PET-CT in the first 3 weeks after CT. We analysed variables such as sex, age, histology, staging (TNM) by CT and PET-CT, sensitivity and specificity of these two tests by assessing their concordance with pathological anatomy (endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) and/or mediastinoscopy), change of staging and therapy administered. ***Results:*** 80% of the patients were male. Median age was 68 years (50-86 years). Histologically 31 were squamous and 21 adenocarcinomas. Regarding CT staging 15 were IIIA, 29 IIIB and 8 IIIC. After PET-CT, 25 patients had a new staging: 1 IA2 (previous IIIB), 1 IA3 (previous IIIA), 3 IIB (previous IIIB-C), 9 IVA (previous IIIA-C), 11 IVB (previous IIIA-C). In 44% of patients who remained stage III, a different nodal staging (N) was observed on PET-CT (11 confirmed by pathological anatomy). CT had a sensitivity of 66% and a specificity of 74%, while PET-CT had 100% and 92%, respectively. The inclusion of PET-CT modified the disease stage in 48% (25/52), leading to a therapeutic change: 5 patients to a lower stage (2 IA2-3 and 3 IIB, candidates for surgery) and 20 to a higher stage (IVA-B, candidates for immunotherapy +/- chemotherapy). ***Conclusion:*** [18F]FDG PET-CT is not only essential in the staging of patients with potentially curable NSCLC, but also in stage III as it can lead to a major change in the therapeutic approach. Therefore, its inclusion could avoid irradiation toxicity in patients reclassified at a higher stage and increase cure rates by surgery in those reclassified at a lower stage.

EP-0166

Diagnostic Accuracy of Lymph Node Staging in Stage III NSCLC using $^{[18F]}$FDG digital PET-CT and its Correlation with Metabolic Quantification Parameters

N. Alvarez Mena*, F. Sebastian Palacid, R. Zambrano Infantino, B. Jaramillo Lopez, M. Garcia Aragon, R. Ruano Perez;*
Nuclear Medicine Department, Hospital Clínico Universitario de Valladolid, Valladolid, SPAIN.

Aim/Introduction: Our aim is to assess the diagnostic accuracy of [18F]FDG digital PET-CT for nodal staging in stage III non-small cell lung carcinoma (NSCLC) and its correlation with metabolic parameters. ***Materials and Methods:*** Prospective study of 52 patients diagnosed with stage III NSCLC between January 2023 and January 2024, who underwent [18F]FDG digital PET-CT. Variables such as sex, age, lymph node staging on PET and CT and their concordance with pathological anatomy (endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) and/or mediastinoscopy) were analysed to assess sensitivity, specificity and predictive values of both tests. In addition, the results of the pathological anatomy (PA) were correlated with metabolic quantification parameters: SUVmax tumour (T), SUVmax most hypermetabolic lymph node (N), SUVratio N/hepatic and SUVratio N/T. ***Results:*** 80% were men. Median age was 68 years (50-86 years). Of the 43 N+ patients in PET-CT, 39 were confirmed in PA (PPV 91%; S 100%); while of the 47 N+ in CT only 37 were N+ in PA (PPV 79%; S 95%). In PET-CT all patients classified as N0 (9/9) were truly N0 in PA (NPV 100%; S 69%). On CT 2 of the patients considered as N0 had nodal involvement (N+) in PA (NPV 60%; S 23%). Of the 13 N0 patients in PA, 4 were classified as N+ in PET-CT. Analysing the quantitative parameters, 3 had similar nodal uptake to the liver (SUVratio N/hepatic 1.19-1.35) and 1 had double the nodal uptake compared to the primary tumour (SUVratio N/T 1.92; anthracotic nodes). Of the 39 N+ patients in PA (all of them N+ in PET-CT), nodal uptake was higher than hepatic uptake in al lof them (SUVratio N/hepatic 1.42-12.53). Up to 87% (34/39) had nodal uptake lower or similar to tumour (SUVratio N/T 0.26-1.26). ***Conclusion:*** [18F]FDG digital PET-CT has a higher diagnostic accuracy than CT for nodal staging in stage III NSCLC. In patients where nodal staging may be difficult to assess, quantitative assessment of nodal metabolism with respect to tumour or liver uptake could be a helpful complementary tool. Thus, if lymph node uptake is higher than liver uptake and/or similar to the primary tumour uptake, we can accurately consider that the lymph node is pathological (SUVratio N/hepatic >1 and/or SUVratio N/T ≈ 1).

EP-0167

Predictive Value of Heterogeneity Index in Evaluating Treatment Response with F^{18}-FDG PET CT in Locally Advanced and Advanced Lung Cancer

Y. Okar, *M. Urhan;*
Sultan Abdulhamid Han Research and Training Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: We aimed to evaluate the response to treatment(chemoradiotherapy) and progressive or regressive disease course in locally advanced and advanced lung cancer cases(stage 3,stage 4) with the heterogeneity index and show the predictive value of the heterogeneity index. ***Materials and Methods:*** The images of diagnosed lung cancer patients who applied to our clinic for oncological F^{18} FDG PET-CT examination between 2018 and 2023 were retrospectively examined.A total of 44 patients with Stage 3 and Stage 4 small cell and non-small cell lung cancer,whose first PET-CT was performed in our clinic and whose follow-up images were not found missing,were included in the study.The regressive patient group that was responsive to treatment consisted of 19 cases (43.2%),and the progressive patient group that was unresponsive to treatment consisted of 25 cases (56.8%).Heterogeneity index,SUVmax,SUVmean,MTV,TLG calculations were made based on the first PET-CT imaging. Metabolic tumor volumes(MTV) calculated according to the

treshold values(40%,60%,80%) determined by examining the patients' images at the workstation were used to create a curve on the graph in Microsoft Excel.The slope of this curve was calculated with the linear regression method.The heterogeneity index was determined as the negative value of this slope value. The predictive values of the calculated heterogeneity index with SUVmax,SUVmean,MTV,TLG for response to treatment were compared.ROC(Receiver Operating Characteristic) analysis was performed to determine the diagnostic performance and cut-off point of MTV and heterogeneity index parameters in distinguishing the development of progression.Multivariable logistic regression analysis was performed to identify risk factors independently associated with progression in patients.Data analysis was done with IBM SPSS 23.0. P values <0.05 were considered statistically significant. ***Results:*** There was no significant difference in the median values of SUVmax and SUVmean of the two groups(p=0.740 and p=0.981).The median MTV value was calculated as 55.84 in patients with progression and 36.28 in patients with regression. Median MTV value was found to be statistically higher in patients with progression(p=0.047).The heterogeneity index median value was found to be 1.28 in patients with progression and 0.85 in patients with regression.Heterogeneity index values were significantly higher in patients with progression(p=0.040). Although TLG values were higher in the progression group,this difference was not statistically significant(p=0.139).The optimal cut-off point for MTV with Youden index was found to be >22.3(Sensitivity: 92%,Selectivity: 47.37%) and >0.45 for heterogeneity index(Sensitivity:96%,Selectivity:47.37%). ***Conclusion:*** The heterogeneity index has been found to be superior in predicting response to treatment and the progressive or regressive course of the disease.

EP-0168

The value of a joint model based on clinical features and PET/CT radiomics features in predicting the growth trend of pulmonary nodules

J. Liang;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: To construct a joint model based on clinical features and PET/CT radiomics features to predict the growth trend of pulmonary nodules and evaluate its predictive performance. ***Materials and Methods:*** A retrospective study was conducted on chest PET/CT images and clinical data of 300 patients with a one-year follow-up period in our hospital from January 2019 to January 2023. All patients were divided into a progression group of 124 cases and a non progression group of 176 cases. Progressive nodules are defined as nodules whose diameter increases by ≥ 2mm within one year. All patients were divided into a training group of 240 cases and a validation group of 60 cases through 8:2 stratified sampling. Based on the Region of Interest (ROI), radiomics features of lung nodules were obtained, and the optimal radiomics parameters were selected through dimensionality reduction to obtain the radiomics feature parameter score (Rad score). By incorporating clinical data and radiomics feature scores of patients, logistic regression was used to establish clinical models, radiomics feature models, and joint models, respectively, to obtain a column chart of the joint model. Draw ROC curves separately to evaluate the predictive performance of clinical feature models, radiomics feature models, and joint models on lung nodule growth. ***Results:*** There was a statistically significant difference in the history of lung cancer among first-degree relatives. The 8 optimal radiomics characteristic parameters have statistical differences. The AUC values of the clinical feature model, radiomics feature model, and joint model training sets were 0.687 (95% CI: 0.539~0.701), 0.865 (95% CI: 0.774~0.893), and 0.885 (95% CI: 0.798~0.924), respectively. The AUC values of the validation set were 0.698 (95% CI: 0.578~0.798), 0.783 (95% CI: 0.701~0.876), and 0.886 (95% CI: 0.697~0.897). ***Conclusion:*** The joint model based on clinical features and PET/CT radiomics feature scores is superior to the clinical and radiomics feature models, and has good clinical application value in predicting the growth trend of solid pulmonary nodules.

EP-0169

The utility of ^{18}F-FDG PET in discriminating between local recurrence and inflammatory changes following SABR in primary lung cancer patients

M. Fala, *S. Shah, H. Ariyaratne, T. Wagner;*
Royal Free London NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: Stereotactic ablative radiotherapy (SABR) achieves good cancer control and is indicated in patients with early-stage Non- Small Cell Lung Cancer (NSCLC) who are not fit for surgery or who decline surgery1,2. Patients are followed up using Computed Tomography (CT) surveillance scans, although these scans are frequently difficult to interpret due to the radiation-induced inflammatory and fibrotic changes which can be indistinguishable from a recurring mass3. If there is suspicion of recurrence on CT, FDG PET-CT is often used for further investigation. The aim of this study was to investigate the utility of FDG PET in detecting recurrence in patients with suspicious CT findings. ***Materials and Methods:*** 236 patients underwent SABR for a lung lesion at our institution between 2012 and 2023. Patients who underwent FDG PET for suspected recurrence on CT findings were included. Patients who had SABR for oligometastatic disease and patients who had less than 5 months follow-up after PET scan were excluded from this retrospective study. SUVmax, reported impression of nuclear medicine physicians reporting the scan and patient outcome were studied in these patients. ***Results:*** Out of 27 included patients, 4 patients had local recurrence and 23 did not have recurrence. The SUVmax of the lung lesions post-SABR was significantly higher in patients who had recurrent tumour (median 7.1) compared to those who did not (median 3.4) (p=0.0025). There was overlap in SUVmax values between recurrence and post-SABR changes. The PPV and NPV of FDG PET were 75% and 95%, respectively. There was increased uncertainty associated with patients whose primary tumours demonstrated low FDG avidity. ***Conclusion:*** FDG PET is very useful in guiding management of patients with suspected recurrence in patients after SABR, particularly in cases where the primary tumour is FDG avid. However, no absolute threshold can be used to indicate recurrence, as there is overlap between the SUVmax values of recurrent tumours and fibrotic changes. More research is needed to understand the utility of FDG PET in detecting recurrence of low FDG avid tumours. ***References:*** 1.NICE. Lung cancer: diagnosis and management. 2.Matsuo Y, Nakamoto Y, Nagata Y, et al. Characterization of FDG-PET images after stereotactic body radiation therapy for lung cancer. EP-0170

Diagnostic Utility of Metabolic Parameters in Preoperative ^{18}F-FDG PET/CT to Predict Nodal Metastatic Involvement in Patients with Non-Small Cell Lung Cancer.

M. Camacho Falcon, *R. Fernandez López, J. Vélez Medina, P. De la Riva Pérez, A. Triviño Ramírez, M. Calvo Morón;*
Hospital Universitario Virgen Macarena, SEVILLA, SPAIN.

Aim/Introduction: To evaluate the diagnostic utility of metabolic parameters from positron emission tomography-computed tomography with ^{18}F-fluorodeoxyglucose (18F-FDG PET/CT) in predicting regional lymph node(LN) involvement(N1 and N2) in patients with non-small cell lung cancer(NSCLC). ***Materials and Methods:*** Descriptive-retrospective study of 70 patients(mean age:65 years,11 females and 59 males) diagnosed with NSCLC and who underwent surgery between January-December 2016, staged using ^{18}F-FDG PET/CT. Histology:adenocarcinoma 50%;squamous cell carcinoma 36%;other 14%. Pathological lymph node status(pN):N0:76%,N1:13% and N2:13%.We compared clinical-pathological characteristics and metabolic parameters with the gold standard(pN yes/no). The assessment of nodal involvement based on PET/CT uptake was qualitative. We collected: maximum standardized uptake value(SUVmax) of the tumor(T) and lymph nodes(LN), metabolic tumor volume(MTV), and LN to primary tumor ratio of SUVmax(LPR). Differences between groups were compared using the t-Student test. ROC analysis was performed, and the area under the curve(AUC) was calculated to evaluate the diagnostic performance of metabolic parameters to identify nodal involvement, obtaining the optimal cutoff value according to the Youden index. Multivariable logistic regression analysis was performed to identify predictors of nodal involvement. It is important to note that for ROC analysis and logistic regression, each lymph node station(N1 and N2) was considered as a single observation and each patient as a group of observations. ***Results:*** Out of 70 patients,19(27%) had suspected nodal involvement according to PET/CT, histologically confirmed in 9 cases. Sensitivity(S),specificity(E),positive predictive value(PPV) and negative predictive value(NPV) were 50%,80.77%,47.37% and 82.35%, respectively. False positives were mainly due to inflammatory causes, while false negatives were due to subcentimeter metastatic lymph nodes.Metabolic tumor volume(MTV) was significantly higher in patients with nodal involvement, while SUVmax of the primary tumor(T) showed no significant differences. In ROC analysis, the AUC of MTV[AUC, 0.75; 95% CI(0.678-0.822)] was higher than SUVmax T[AUC, 0.656; 95% CI(0.577-0.735)]. The AUC of LPR[AUC, 0.712; 95% CI(0.636-0.782)] was slightly higher, though not significantly, than AUC SUVmax LN[AUC, 0.707; 95% CI(0.632-0.782)], with cutoff values of 0.37 and 3.56, respectively. In multivariate analysis, we found that LPR value≥0.37 to predict N2 was not significant(p=0.07). MTV was an independent predictor for N2 nodal involvement in adenocarcinoma with a cutoff value of 7.6(p<0.05). ***Conclusion:*** The findings suggest that MTV and LPR could enhance the accuracy in identifying N2 nodal involvement in NSCLC, particularly MTV in adenocarcinoma, although limited by the small sample size. Prospective studies are needed to validate the results and evaluate the effect of metabolic parameters on therapeutic strategy.

EP-0171

Predicting Cachexia Status in Lung Cancer Patients Using PET Radiomics

Y. Jiang, *X. Peng;*
Southeast University School of Medicine, Nanjing, CHINA.

Aim/Introduction: Approximately half of lung cancer patients are at risk of developing cachexia (1). Given the poor prognosis associated with advanced cachexia, early recognition of cachexia status is of paramount importance (1, 2). The aim of this study is to investigate the ability of PET radiomics in early prediction of cachexia in lung cancer patients undergoing [18F]fluoro-2-deoxy-D-glucose ([18F]-FDG) positron emission tomography (PET)/computed tomography (CT) scans. ***Materials and Methods:*** Lung cancer patients who underwent [18F]-FDG PET/CT scans from October 2017 to October 2020 were included in the analysis, with detailed weight data available for the six months preceding and following the PET/CT scan. According to the definition of cancer-associated cachexia, it is necessary to ascertain that the weight change in patients six months prior to the PET/CT scan did not reach the severity of cachexia. Radiomic features were extracted, and a model was developed using the FeAture Explorer Pro (FAE, Ver. 0.5.3) software, analyzing PET scans that included regions of interest such as the liver, pancreas, visceral and subcutaneous fat, as well as the psoas and sacrospinal muscles. When constructing the radiomics model, we applied methods such as Pearson correlation analysis, recursive feature elimination, and auto-encoder. The area under the curve (AUC) was utilized to measure the predictive performance of the radiomics model. ***Results:*** Eighty-nine lung cancer patients were included, with 63 in the training cohort and 26 in the testing cohort. Among the training cohort, 36 were cachectic and 27 were non-cachectic, while in the testing cohort, 15 were cachectic and 11 were non-cachectic. The radiomics model included a total of three radiomic features, with two originating from the pancreas and one from subcutaneous fat. The AUC values of the radiomics model for predicting cachexia status in the training and testing cohorts of lung cancer were 0.775 and 0.727, respectively. ***Conclusion:*** The PET radiomics model can effectively aid in early identification of lung cancer patients at higher risk of developing cachexia. ***References:*** (1) Baracos VE, Martin L, Korc M, Guttridge DC, Fearon KCH. Dual time point imaging ^{18}F FDG PET/CT: Is there any clinical impact on enhancing the diagnostic accuracy of SUV in small Solitary Pulmonary Nodules?

N. Kapsoritakis[1], *F. Tsitoura[2], O. Bourogianni[1], A. Tsaroucha[1], M. Stathaki[1], G. Barmparis[2], G. Tsironis[2], S. Koukouraki[1,3];*
[1]Nuclear Medicine Department, University Hospital, Heraklion, Crete, GREECE, [2]Department of Physics University of Crete, Heraklion, GREECE, [3]Nuclear Medicine department, Medical School, University of Crete, Heraklion, GREECE.

Aim/Introduction: The characterization of solitary pulmonary nodules (SPNs) still remains a complex process. The differential diagnosis based on PET/CT is not always feasible due to the ^{18}F FDG overlap uptake in malignant and inflammatory cells. An SUV≥2.5 is used as a criterion of malignancy. Moreover, well differentiated

malignancies exhibit only minimal increased activity and more recent semiquantitative parameters are investigated. The aim of this study was to evaluate the clinical impact of dual time point imaging based on changes of SUV values in the accurate definition of the nature of SPNs. ***Materials and Methods:*** One hundred forty PET/CT scans from 70 patients with small SPNs ≤ 10mm found on previous CT, were included in this prospective analysis between May 2023 and March 2024. Dual point imaging ^{18}F FDG PETCT, early phase image acquisition 1hr (PET1) and delayed phase images after 2hrs p.i (PET2), were performed on a digital PETCT scanner. Regions of interest (ROIs) were drawn around the lesion on both PET images. A semiquantitative analysis was followed by using the parameter Standardized Uptake Value, SUV1 for early and SUV2 for delayed images. Patients were classified in 3 groups: group 1 malignant (primary or metastatic), group 2 benign and group 3 indeterminate (without differences) lesions based on the difference of SUV1 and SUV2 values. The final diagnosis was based on CT or EBUS guided biopsy and on clinical follow up for more than 6 months. The reference standard in characterizing SPNs was SUV≥2.5 value, comparing early and dual time point imaging and the clinical outcome ***Results:*** CT/EBUS guided biopsy results in 57/70 pts showed 40 malignant nodules (29 adenocarcinomas, 8 squamous cell carcinomas and 3 bronchoalveolar) and 17 benign (inflammatory granulomas, infection). In 13 pts biopsy was not diagnostic and the reference standard was the clinical outcome. The sensitivity, specificity, accuracy, PPV and NPV of the SUV1 in characterizing the nature of SPNs were 64%, 41%,54%,60%,45% respectively. Among the malignant nodules with SUV<2.5 at the early phase 9/12 malignant lesions showed higher values at the delayed phase. Dual point images achieved 96%,46%,78%,75%,87%. Moreover in 16 cases there was no SUV difference (indeterminate) ***Conclusion:*** Dual time point imaging ^{18}F FDG PET/CT has higher sensitivity, specificity, accuracy, PPV and NPV and is recommended mostly for SPNs with SUVvalues <2.5.

EP-0173

A prospective comparison of SUV, MTV and TLG volumetric parameters changes between early and delayed FDG PET/CT in the accurate assessmentof small solitary pulmonary nodules.

N. Kapsoritakis[1], *F. Tsitoura[2], G. Barmparis[2], A. Tsaroucha[1], O. Bourogianni[1], M. Stathaki[1], G. Tsironis[2], S. Koukouraki[1,3];*
[1]Nuclear Medicine Department, University Hospital, Heraklion, Crete, GREECE, [2]Department of Physics University of Crete, Heraklion, GREECE, [3]Nuclear Medicine, Medical School, University of Crete, Heraklion, GREECE.

Aim/Introduction: The differentiation of solitary pulmonary nodules (SPNs) into benign and malignant continues to challenge thoracic oncology, given the multitude of potential causes including benign-inflammatory, metastatic lesions, and primary malignant tumors. Positron Emission Computerized Tomography (PET/CT) using the Standardized Uptake Value (SUVmax) parameter has become essential, exploiting the differential glucose metabolism between cancerous and non-cancerous cells. Due to SUV uncertainties and errors, newer parameters, Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG) have been introduced. The aim of this study was to investigate the correlation of changes in these parameters over time in pts with SPNs with the presence of malignancy, aiming to identify which of these parameters is the most accurate. ***Materials and Methods:*** One hundred sixteen PET/CT scans from 58 patients with small SPNs ≤ 10mm (median lesion size 7mm) found on previous CT were included in this prospective analysis, between May 2023 and March 2024. Early 1hr (PET1) and delayed images 2hrs p.i (PET2) were performed on a digital PETCT scanner. Standardized Uptake Value (SUVmax), Metabolic Tumor Volume (MTV) and Total lesion glycolysis (TLG) for PET1 (SUV1, MTV1, TLG1), for PET2 (SUV2, MTV2 and TLG2)and their percentage changes between PET studies (ΔSUVmax,ΔMTV, ΔTLG) were evaluated. Patients were classified in 3 groups: group 1 malignant lesion (primary or metastatic), group 2 benign lesion and group 3 equivalent (without difference) based on the difference of SUV, MTV and TLG of PET1 and PET2 scans. The final diagnosis was based on CT or EBUS guided biopsy. ***Results:*** Histoapthological findings showed: malignancy in 35/58 and benign lesion in 23/58 patients. On PET 1/PET2, the average ΔSUVmax was (1.17-14.18 vs 1.2-22.4), of ΔMTV (1,25-40,53 vs 1,25-28,97) and of ΔTLG (2,3-38 vs 2,1-32). The sensitivity, specificity, accuracy, PPV and NPV were for SUV (91%, 53%, 78%, 72%, 80%), for MTV (55%, 95%,72%,94%,60%) and for TLG (85%,100%,92%,100%,75%) respectively. Multivariate regerssion analysis showed pvalue<0,05 for MTV 0,001 and for TLG 0,000. ***Conclusion:*** This ongoing study suggests that TLG parameter is the driving factor for the best management of pts with SPNs improving the accuracy.

EP-0174

Integrating PET/CT Imaging and Machine Learning to Enhance Early Diagnosis of Solitary Pulmonary Nodules

F. Tsitoura[1], *N. Kapsoritakis[2], G. D. Barmparis[1], S. Koukouraki[2], G. P. Tsironis[1];*
[1]Department of Physics, University of Crete, Heraklion, Crete, GREECE, [2]Department of Nuclear Medicine, University Hospital of Crete, Heraklion, Crete, GREECE.

Aim/Introduction: Differentiating solitary pulmonary nodules (SPNs) as benign or malignant poses a significant challenge in oncology. Traditional ^{18}F FDG PET/CT metrics such as Standardized Uptake Value (SUV), Metabolic Tumor Volume (MTV), and Tumor Lesion Glycolysis (TLG) provide limited diagnostic accuracy and lack a universal diagnostic threshold applicable to all cases. This study aims to enhance the diagnostic precision of SPNs by integrating these metrics with high-level features extracted with advanced machine learning methods directly from the imaging exams, providing critical insights ahead of biopsy results. ***Materials and Methods:*** In addition to the SUV, MTV and TLG metrics, and demographic data our dataset comprises PET/CT images, analyzed using a GE digital PET/CT Discovery MI 4R system. We employ advanced image processing techniques on the images to precisely detect regions of interest and localize nodules within them. Furthermore, we leverage the capabilities of Convolutional Neural Networks (CNNs) through a pre-trained VGG16 model loaded with ImageNet-trained weights and adapted to extract high-level features, ensuring a robust feature set tailored to SPNs. The high-level image-extracted features are then integrated with the measurements of SUV, MTV, and TLG obtained from both initial and delayed imaging sessions (two hours post-radiopharmaceutical administration) to construct a comprehensive dataset that forms the basis for our predictive modeling.An advanced explainable ensemble decision tree framework like the XGBoost model, is employed to analyze and predict the malignancy of SPNs with enhanced accuracy, harnessing both traditional radiological metrics and novel image-derived features. ***Results:*** Our results demonstrate that by integrating high-level image-extracted features with TLG, SUV, and MTV and demographic data into explainable tree-based ensemble models, we significantly increase the predictability of SPNs among the provided data. Specifically, we find accuracy of

the order of 80% through random tree ensemble analysis while the inclusion of direct image information in the data set increases substantially this figure. This study underscores the potential of AI-enhanced radiomics to reduce false diagnostic rates and improve the early accuracy of diagnoses. ***Conclusion:*** Integrating AI with PET/CT imaging presents a promising avenue for advancing diagnostic procedures for SPNs. The utilization of explainable ensemble tree-based models, along with traditional and novel imaging metrics, supports more effective and earlier clinical decision-making. This approach accelerates the preliminary diagnostic timeline, potentially reducing the time to intervention and optimizing treatment planning.

EP-0175

Development, validation and comparison of PET/CT diagnostic model based on radiomics and deep learning in differentiating benign and malignant pulmonary persistent ground-glass nodules

X. Shao, *X. Shao;*
the Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: To develop PET, CT and PET/CT diagnostic models based on radiomics and deep learning, verify and compare their differential diagnostic efficacy in differentiating benign from malignant pulmonary persistent GGNs, elucidate the application value of each model. ***Materials and Methods:*** 173 patients with pulmonary persistent GGNs who underwent ^{18}F-FDG PET/CT, breath-hold chest CT, and surgery at three PET/CT centers were retrospectively analyzed, 184 pulmonary persistent GGNs (43 benign nodules and 141 malignant nodules) were included in the study, Based on conventional image parameters, radiomics, and deep learning algorithms to extract and screen PET, CT, and PET/CT image characteristics, corresponding diagnostic models were developed to verify and compare the performance of each model in differentiating benign from malignant lung GGNs. ***Results:*** In the test set, AUCs were higher in the CT radiomics (AUC = 0.889) and PET radiomics (AUC = 0.903) models than in the reference model (AUC = 0.869); in the external validation set, AUCs were higher in the CT-VGG19 (AUC = 0.851), PET radiomics (AUC = 0.833), and PET-ResNet50 (AUC = 0.884) models than in the reference model (AUC = 0.824).In addition, the CT-ResNet50 model had a slightly better AUC on the test set than the CT-VGG19 model in models built based on deep learning features (AUC = 0.821 vs. 0.793), but the CT-VGG19 model performed better in the external validation set (0.851 vs. 0.551); the AUC of the PET-ResNet50 model was better than that of the PET-VGG19 model in both the test set and the external validation set (AUC = 0.838, 0.884 vs. 0.814, 0.767). To further improve the differential efficacy of benign and malignant lung GGNs, a combined model (PET/CT radiomics and PET-ResNet50/CT-VGG19) was constructed based on dual-modality radiomics or deep learning characteristics. Because the CT omics feature eventually did not enter the PET/CT omics model (equivalent to the streamlined PET radiomics model), it had a better AUC on the test set than the combined deep learning model (AUC = 0.906 vs. 0.810), but the deep learning combined model had a better AUC in the external validation set (AUC = 0.927 vs. 0.849). ***Conclusion:*** The combined PET/CT diagnostic model developed based on deep learning has higher performance in differentiating benign from malignant pulmonary persistent GGNs and better generalization performance and can be used for the precise management of patients with pulmonary persistent GGNs.

EP-0176

Identifying PET/CT-based biomarkers in lung cancer patients using unsupervised machine learning.

R. Vashistha[1], *S. Kumar[2], H. Singh[3], D. Chhabra[4], P. Kundu[2];*
[1]The University of Queensland, Saint Lucia, AUSTRALIA, [2]Rohtak Nuclear Medcare Imaging, Therapy and Research Center, Rohtak, INDIA, [3]Kainos Super Speciality Hospital, Rohtak, INDIA, [4]Maharshi Dayanand University, Rohtak, INDIA.

Aim/Introduction: Lung cancer holds the highest position among cancer types affecting Indian males aged 40-64 and 65+, constituting 10.6% of all cancer cases in this population (1). With progressively worsening risk factors of smoking and air pollution, there is an urgent need for population specific risk assessment to guide targeted treatment approach. Extracting radiomics features from PET/CT can define predictive and prognostic image markers, potentially limiting treatment failures and costs. Machine learning aids pattern recognition, however requiring extensive annotated datasets. Here, we aim to address this by utilising a publicly accessible PET/CT dataset (n = 103 patients) to train our ML model (2), with an independent patient cohort for testing. ***Materials and Methods:*** Radiomics features of first, second, and third-order types were extracted from publicly available PET/CT images utilising the Pyradiomics. An unsupervised Deep Embedded Multi-View Clustering (DEMVC) network was trained using these features. For testing, we used a dataset consisting of initial staging PET-CT scans of 28 lung cancer patients, with their survival outcomes observed over the past three years. The top five features were ranked by an extra tree classifier and identified clustered on the test set. Finally, the robustness and generalisability of the model were assessed through its validation based on overall survival. ***Results:*** Three clusters were identified based on the training data. All top five features are wavelet transformed, where the first two, glszm_GrayLevelVariance and glrlm_RunEntropy, correspond with the HLL filter. The third feature was generated using an HLH filtered glcm_SumSquares. The fourth and fifth features were first order LLH_RootMeanSquared and LLL_RobustMeanAbsoluteDeviation. We found that cluster 2 dominates with alive patients (62.5%), and cluster 3 dominates with dead patients (74%). The feature values in the notched box plot also had a distinct separation for both clusters. ***Conclusion:*** We identified population specific PET/CT radiomics features based on overall survival. Our findings suggest the potential of initial staging PET/CT scan to guide more efficient clinical decision-making processes in future. ***References:*** 1. EP-0177

Which parameters with F^{18} FDG PET/CT are valuable in predicting contralateral lung parenchymal metastasis?

B. Özdemir, *F. Ustun;*
Trakya University, Edirne, TÜRKIYE.

Aim/Introduction: The etiology underlying contralateral lung metastasis in cases of lung cancer and the determinants contributing to the metastatic process, remain yet to be comprehensively elucidated. We aimed to investigate the additional value of FDG PET/CT to determining contralateral

lung parenchyma metastasis (CLM), its causes and predictive factors in lung cancer. ***Materials and Methods:*** Lung cancer patients who underwent PET/CT between 2009 and 2021 were analyzed. Postoperative histopathological data, follow up data and FDG PET/CT findings including primary tumor lobe, segment, size, pleural effusion, pleural involvement, mediastinal invasion/thorax wall involvement and additional metastasis were recorded. Relationships between these factors and PET/CT parameters were statistically analyzed. Survival analyses were performed. ***Results:*** 125 patients with contralateral lung parenchymal metastases and 100 patients with distant metastasis who chosen randomly were compared. Among them, 81 patient had contralateral metastasis in diagnosis and 44 patients developed CLM in follow up. While there was no difference between the two groups between the primary tumors metabolic parameters such as SUVmax, SUVmean and MTV values; presence of satellite nodules and metastatic nodules in other lobes in the same lung were found to be significantly higher in CLM group (p=0,007; p<0,001). Pleural metastasis and effusion were more common in CLM group rather than control group based on PET/CT findings (p=0,003 and p=0,036). In statistical analyses, satellite nodules in the same lobe raise the probability of CLM by fourfold (p = 0,012; R = -0,2752; 95% CI: 0,082-0,767), and the absence of necrosis in the initial tumor raises the probability of metastasis to the contralateral lung by 3,326 times during follow-up (p = 0,015; R = 0,2656; 95% CI: 1,236-8,950). ***Conclusion:*** PET/CT provide a simple yet potent way to investigate and predict characteristics related to contralateral parenchymal metastases in lung cancer such as ipsilateral nodules, pleural effusion and metastasis. It also contributes to the determination of primary tumor characteristics such as the presence of necrotic tissue and their effect on metastasis to the contralateral lung. ***References:*** 1-Onuigbo WI: Anomalous lung cancer cell carriage: a historical review with present prospects. Maximum Standard Uptake Lean Body Mass (SULmax) [18F] FDG PET/CT and Cell-Free DNA to Predict Adjuvant Therapy requirements in Resectable Non-Small Cell Lung Cancer (NSCLC)

H. Portilla Quattrociocchi, *E. Azkona Uribelarrea, J. Aurrekoetxea Oribe, M. Calvo Martinez, R. Nuñez-Muñoz, M. Jimenez-Alonso;*
Hospital Universitario de Cruces - Osakidetza, Bilbao, SPAIN.

Aim/Introduction: The NSCLC represents 80% of newly diagnosed lung cancers. Accurate staging is critical for prognosis. (SUL) is a volumetric parameter more objective for metabolic quantitative analysis and treatment response evaluation of lung cancer. Increased levels of circulating cell-free DNA (cfDNA) are detected in cancer patients due to various mechanisms, including tumor cell necrosis, apoptosis, and macrophage digestion, with subsequent release of tumor DNA fragments into the bloodstream. The purpose of this study was to evaluate the relationship between SUL and cfDNA concentration to predict adjuvant therapy requirements in patients with early-stage, resectable NSCLC. ***Materials and Methods:*** Prospective cohort study including patients with resectable NSCLC and baseline preoperative [18F] FDG PET/CT between 2021 and 2023. Images were acquired using a GE Discovery™ MI PET/CT after the injection 1.5 MBq/kg of [18F] FDG. Prior to surgery, blood was collected in Streck Cell-Free DNA blood collection tubes. DNA was extracted from plasma using the QIAamp Circulating Nucleic Acid Kit and was measured using the Qubit™ dsDNA HS Assay Kit. The relationship between SULmax, cfDNA and clinical variables was evaluated with Wilcoxon test or Dunn test. A Leave-One-Out Cross Validation (LOOCV) multivariate logistic regression was generated. Model performance was evaluated based on accuracy, which was considered statistically significant by a one-sample t-test if it exceeded the percentage of non-adjuvant cases. ***Results:*** Ninety patients (37 females and 53 males), mean age 65.2±6.81 with stage I (56.66%), II (26.66%) and III (16.66%) were included. The histology were adenocarcinoma (50), squamous (22), large cell (14) and others (4). The squamous presented the mayor SULmax with a median of 10.63 (interquartile range, IQR:6.05). 30% of patients received adjuvant chemotherapy after surgery. Analysis of SULmax revealed significant differences (p<0.05) with respect to tobacco consumption, type of surgery, histology, stage and adjuvant therapy. The concentration of cfDNA was significantly associated with the type of surgery, stage and need for postoperative therapy (p<0.05). There was no correlation (Spearman R<0.10) between cfDNA concentration and SULmax. Logistic regression models showed that stage alone could not predict the need for an adjuvant therapy. However, moderate predictive capacity was observed after adding SULmax and cfDNA concentration (accuracy=0.78, p=0.04) ***Conclusion:*** Combining different clinical characteristics could predict which patients will have the greatest benefit from postoperative therapies. Different but simple combinations, such as SULmax with cfDNA and stage, may help to improve adjuvant therapy decision making.

EP-0179

Detectability of lung lesions on ^{18}F-FDG PET/CT obtained from decimated and CNN-based denoised scan: An observer-based study for lung cancer screening

D. Faist[1], *S. Gnesin[1], S. Medici[1], A. Khan[1], M. Nicod-Lalonde[1], N. Schaefer[1], A. Depeursinge[1], M. Conti[2], J. Schaefferkoetter[2], J. Prior[1], M. Jreige[1];*
[1]Lausanne University Hospital (CHUV), Lausanne, SWITZERLAND, [2]Siemens Healthineers, Knoxville, TN, UNITED STATES OF AMERICA.

Aim/Introduction: 18F-FDG is a key imaging in characterization of undetermined lung lesion (LL). We investigated LL detectability in perspective of lung cancer screening conditions by simulating low-dose and denoised 18F-FDG PET/CT. ***Materials and Methods:*** We retrospectively analyzed full statistics and decimated (30%, 10%, 5%, 2%, 1%) 18F-FDG PET/CT simulating different levels of injected activity in 49 patients presenting at least one LL. Full statistics 18F-FDG PET were acquired on digital PET Biograph Vision 600 and retrospectively reconstructed with different decimation levels. Denoising algorithm based on a convolutional neural network (CNN) was trained to reproduce full statistics PET from the decimated reconstruction and was applied on full and reduced statistics. LL detectability was assessed by three readers on a Likert scale varying from score 0 (negative), 1 (probably negative), 2 (probably positive) to 3 (positive) on a total of 12 randomized reconstructions per subject (6 with denoising, 6 without). SUVmax was normalized to the decimation level. Resulting LL detectability score were dichotomized into positive (1 for LL score=2-3) or negative (0 for LL score=0-1) malignancy score. LL detectability score distribution and quantitative measurements were compared between full statistics and the different decimation levels with and without denoising, respectively. The scores were

also analysed according to lung nodule size. ***Results:*** We analyzed 141 LL (diameter 12±12mm, range 4-30mm) across 588 (12×49) reconstructions. SUVmax was 8.3±9.9g/mL without denoising and 4.7±5.9g/mL with denoising. Compared to the full statistics (100%), LL detectability score distribution differed significantly at 2% and 1% decimation without denoising ($p<0.001$) and 5%, 2% and 1% with denoising ($p<0.001$). The dichotomized LL malignancy score was significantly lower on 10%, 5%, 2% and 1% without denoising ($p<0.029$) and on 5%, 2% and 1% decimation with denoising ($p<0.001$). The results were similar across different lung nodule sizes. Comparing LL scores at same decimation levels with or without denoising, they differed significantly at 10%, 2% and 1% decimation ($p<0.019$), the dichotomized score were similar. Overall, the proportion of LL scores with high diagnostic confidence (3 and 0) were significantly increased on denoised PET ($p<0.038$). ***Conclusion:*** Simulating reduced levels of injected activity, we found similar LL detectability supporting the feasibility of low-dose 18F-FDG PET/CT for lung cancer screening. Moreover, CNN-denoising enhanced LL detectability and diagnostic confidence on the very low-statistics datasets (≤10%).

EP-0180

Utility of Ga68 DOTANOC PET/CT in baseline staging of small cell lung cancer in treatment naive patients

V. Trivedi, *R. KUMAR, A. Mohan, P. S. Malik, C. D. Patel, A. K. Pandey, S. Jha, A. K. Mahalik, A. S. Babu, S. Dharvesh, V. Sharma, A. KM, S. Sagar, D. Khan, J. Jaleel, P. Gupta;*
All India Institute of Medical Sciences (AIIMS), New Delhi, New Delhi, INDIA.

Aim/Introduction: Identify utility of Ga68-DOTANOC-PET/CT for initial staging in treatment naïve patients of Small Cell Lung Cancer and to compare its findings with F^{18}-FDG-PET/CT ***Materials and Methods:*** prospective study done at tertiary care apex medical institute in COVID 19 era for 2 years including 22 patients with histopathologically proven small cell lung cancer. Patients with history of prior treatment for lung cancer were excluded. All patients underwent baseline imaging with Ga68-DOTANOC PET/CT & F^{18}-FDG-PET/CT with in interval of 2 weeks before starting first line treatment. Written and informed consent were taken from all the subjects included in the study with approval from the Institute. AJCC 8th TNM staging was utilized to stage the disease. Imaging data was reported & obtained by two separate qualified nuclear medicine physicians trained experienced in reporting PET/CT & analysed by using statistical software SPSS/strata. Association between categorical data was assessed by chi square/fisher exact test. Quantitative data was compared by independent t test/ rank sum as appropriate. P=0.05 is considered as statistically significant. ***Results:*** : Ga68-DOTANOC-PET/CT had detected all primary lesions & loco regional lymph nodes at par with F^{18}-FDG-PET/CT but their uptake values (described in terms of SUV) differ. It also identified maximum metastatic lesions in all patients as par F^{18}-FDG-PET/CT except in two patients. Ga68-DOTANOC-PET/CT detected additional brain metastases in 1 patient compared to F^{18}-FDG-PET/CT. Ga68-DOTANOC-PET/CT has shown similar M stage on scan findings in 20 patients. 2 patients had different M stage on Ga68-DOTANOC-PET/CT compared to ^{18}F-FDG-PET/CT. One patient got down staged (M1c to M1a) while 01 patient got up staged (M1a to M1b).Both sensitivity & specificity of Ga68-DOTANOC-PET/CT were high (>90%) as compare to F^{18}-FDG PET/CT but the p value >0.05 demonstrated no significant difference between F^{18}-FDG PET/CT & 68-Ga-DOTANOC PET/CT in staging. ***Conclusion:*** Ga68-DOTANOC-PET/CT can detect the primary lesion, locoregional lymph nodes & metastases in small cell lung cancer especially in cases of brain metastases which were better visualized on Ga68-DOTANOC-PET/CT due to very less background uptake of radiotracer in brain cells. Ga68-DOTANOC-PET/CT can stage primary lesion, locoregional lymph nodes & majority of metastatic lesions correctly at par with ^{18}F-FDG-PET/CT. Ga68-DOTANOC-PET/CT was superior to F^{18}-FDG PET/CT in 1 patient & inferior to F^{18}-FDG-PET/CT in another patient to detect metastatic lesions. The SUVmax of Ga68-DOTANOC-PET/CT were less than SUVmax of F^{18}-FDG-PET/CT but lesion to background ratio (SUVr) were higher for Ga68-DOTANOC PET/CT, possibly due to less background activity in Ga68-DOTANOC-PET/CT.

EP-0181

Assessment of risk factors for recurrence of primary lung tumors treated with stereotactic body radiotherapy (SBRT).

I. Vinagre Pérez, *G. Portilla Quattrociocchi, A. Peña Fuentes, J. Lavilla, M. Astudillo Sarmiento, Y. Carreres Ortega, R. Núñez Muñoz, D. Tovar Echeverri, I. Fernández Tercero;*
Hospital Universitario de Cruces, Barakaldo, SPAIN.

Aim/Introduction: To determine which factors (T, histology subtype, radiotherapy dose, lung location, SULmax in baseline PET-CT and at 3 months post-radiotherapy PET-CT) are associated with a higher risk of recurrence in primary lung nodules N0M0 treated with SBRT. ***Materials and Methods:*** We perform a retrospective study of 104 patients (11 women and 93 men) with average age of 76 years, between 2013 and 2023. Follow-up was carried out by PET-CT three months after completing radiotherapy treatment and subsequently every 6 months until 2-3 years post-radiotherapy. The mean follow-up was 22 months. We defined recurrence as new-appearing pathological uptakes that were confirmed in successive PET-CT during follow-up. The patients were divided into two groups: with recurrence and without recurrence (control). ***Results:*** 33 patients presented recurrence during follow-up (17 local, 4 regional and 12 distant recurrence), 21 tumors were non-small cell carcinomas (10 squamous cell carcinoma, 10 adenocarcinoma and 1 unspecified carcinoma) and 12 did not present histology subtype. 29 of 33 were staged as T1 and 4 as T2. 24 nodules were located in the upper lobes, 8 in the lower lobes and 1 in the medial lobe. 22 of 33 were treated with 60 Gray of radiotherapy dose and 11 with <60 Gray.The SULmax mean at the baseline PET-CT and at 3-month PET-CT were 5.67 and 2.82, respectively. 71 patients did not have recurrence during follow-up. 30 were adenocarcinomas, 11 squamous cell carcinoma and 30 did not have histology diagnosis. 59 of 71 were staged as T1, 8 as T2, 3 as T3 and 1 as T4. 46 nodules were located in the upper lobes, 21 in the lower lobes and 4 in the medial lobe.54 of 71 were treated with 60 Gray of radiotherapy dose and 16 with <60 Gray. The SULmax mean at the baseline PET-CT and at 3 month PET-CT were 4.91 and 3.31, respectively. We did not observe significant differences ($p>0.05$) between both groups in the variables of T, histology subtype, radiotherapy dose, pulmonary location, SULmax mean at baseline PET-CT and SULmax mean at 3 months PET-CT. ***Conclusion:*** PET-CT is a useful tool in the early detection of recurrence of primary lung neoplasms treated with SBRT.We did not find a statistical correlation of the variables studied with post-radiotherapy tumor recurrence.

EP-0182

The prognostic and diagnostic significance of conventional PET parameters in NSCLC

D. Dezso[1], *B. E. Kálmán[1], A. Bertalanné Dr. Szommer[1], A. Bos-Liedke[2], E. Kaminska[3], M. Matusewicz[2], Z. Ritter[1];*
[1]University of Pécs, Medical School, Department of Diagnostic, Pécs, HUNGARY, [2]Department of Biomedical Physics of Adam Mickiewicz University, Poznan, POLAND, [3]Centre for Innovative Pharmaceutical Technology of Poznan University of Medical Science, Poznan, POLAND.

Aim/Introduction: Lung cancer is the most common cancer globally and has the highest mortality rate among adults. Accurate prognosis prediction is paramount. Recent literature has explored the diagnostic and prognostic value of imaging parameters derived from pretreatment FDG-PET/CT scans in NSCLC, yielding promising results. Our aim was to evaluate the significance of conventional PET parameters extracted from primary lung nodules (pre-surgery) in our NSCLC patient cohort retrospectively. ***Materials and Methods:*** Pre-treatment FDG-PET/CT scans (Mediso) from 79 patients with suspected lung cancer were analyzed. Scans were conducted at the University of Pecs, Department of Medical Imaging. Following surgery, histopathological confirmation was obtained for all cases: squamous cell carcinoma (23 patients) and adenocarcinoma (56 patients). We investigated significant differences in imaging parameters among groups: partial, complete response, and stable disease (25 patients) versus progression (32 patients), based on RECIST; metastases present at the time of diagnosis or within a 2-year follow-up versus no metastases within 2 years; TNM stage IIA or lower (33 patients) versus higher stage than IIA (46 patients); and PD-L1-positive (18 patients) histology versus PD-L1 negativity (13 patients). Suspected primary tumors were delineated, and conventional PET radiomics were extracted (ROVER software). Parameters assessed included standardized uptake values (SUVmax, mean, peak), metabolic tumor volume (MTV), total lesion glycolysis (TLG), tumor-to-liver uptake ratio (TLR), and first-order parameters such as coefficient of variation (COV), kurtosis, skewness, entropy, and maximal tumor diameter. Group comparisons were performed using non-parametric statistical tests (Mann-Whitney U test). ***Results:*** SUVmax (p=0.049), SUVmean (p=0.033), and TLR (p=0.022) exhibited statistically significant differences between adenocarcinoma and squamous cell carcinoma groups. Regarding PD-L1 expression, SUVmean (p=0.04), TLG (p=0.04), ASP (p=0.02), and TLR (p=0.02) displayed significant differences. TLG (p=0.032) and MTV (p=0.029) showed statistically significant differences between progression and response groups. Significant differences were observed between metastasis and non-metastasis groups, and among stage groups in the following parameters (p<0.001): SUVmax, SUVmean, SUVpeak, MTV, TLG, ASP, TLR, Entropy and max diameter. No significant differences were found in COV, kurtosis, and skewness. ***Conclusion:*** Our analysis suggests that conventional FDG-PET/CT parameters hold promise for prognosis prediction and diagnostic estimation. Further analysis and data collection are warranted to strengthen our findings. ***References:*** Project no. TKP2021-EGA-10 has been implemented with the support provided from the National Research, Development and Innovation Fund of Hungary, financed under the TKP2021-EGA funding scheme.

EP-0183

FDG PET/CT Response Evaluation of Multimodality Treatments in NSCLC

G. Biswas, *S. Panchadar, S. M. A. Assad, Z. Abdullah, R. Al Kordi, M. Garashi, E. Al Awadhi;*
Chest Hospital, Kuwait, KUWAIT.

Aim/Introduction: 18F-FDG PET/CT is an important imaging tool to evaluate early treatment response accurately in solid tumors in order to optimize cancer treatment and patient management. Our aim was to evaluate the role of 18F-FDG PET/CT in assessing post-therapy response of patients with Non Small Cell Lung Carcinoma (NSCLC) who underwent treatment with multiple modalities. ***Materials and Methods:*** We performed baseline and post treatment follow up 18F-FDG PET/CT in 36 patients (24 males,12 females),age: 45-84 years with primary Non Small Cell Lung Carcinoma (NSCLC).All of them were referred to our department for initial staging and assessing response following treatment after an interval of 6-18 months.5 patients had surgery,9 patients had chemotherapy,1 patient had radiotherapy,7 patients had targeted molecular therapy,2 patients had immunotherapy,3 patients had surgery and chemotherapy,2 patients had surgery and radiotherapy,3 patients had chemotherapy and immunotherapy,2 patients had surgery, chemotherapy and radiation therapy,1 patient had chemotherapy and immunotherapy and 1 patient had radiotherapy, chemotherapy and immunotherapy. We performed baseline and post treatment 18F-FDG PET/CT from vertex to mid-thigh in all the patients with a 64 slice,16cms axial FOV (field of view) PET/CT camera (GE 710) 60 minutes after injecting a standard dose of 0.06mci/kg of 18F-FDG.The images were reconstructed on an Advantage (GE) work station and analyzed on a Hermes system by four independent PET/CT readers. ***Results:*** Baseline FDG PET/CT showed disease restricted to lung in 15 patients, loco-regional lymph node metastasis in 11 patients, locally invasive disease in 3 patients and distant metastasis in 7 patients. Following treatment FDG PET/CT PERCIST 1 criteria showed CMR (complete metabolic response) in 8 patients (post treatment changes were observed in 2 patients),PMR (partial metabolic response) in 5 patients, SMD (stable metabolic disease) in 8 patients and PMD (progressive metabolic disease) in 15 patients. ***Conclusion:*** Our study shows that 18F-FDG PET/CT can identify responders and non-responders in patients with NSCLC treated with multiple modalities including targeted molecular therapy and immunotherapy. This may help in designing new treatment options and continue existing ones to improve prognostic outlook in these patients. ***References:*** 1. EP-0184

Dual-Tracer PET/CT in Non-Small Cell Lung Cancer: A Case Series Analysis Using $^{[18F]}$FDG and $^{[18F]}$F-PSMA-1007

N. Silveira, *M. Perroud-Junior, H. Nakano Ide, B. Amorim, M. Lima, C. Souza, C. Lima, C. D. Ramos;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) tracer, used for prostate cancer evaluation, has emerged as a marker of neoangiogenesis, exhibiting accumulation in various

neoplasms with potential theranostic capability. Despite the high sensitivity of FDG-PET/CT for non-small cell lung cancer (NSCLC) detection, it remains uncertain whether PSMA-PET/CT can detect additional lesions. This study aims to compare the uptake patterns of [18F]FDG and [18F]F-PSMA-1007 in primary and metastatic lesions of NSCLC. ***Materials and Methods:*** Five patients diagnosed with NSCLC (4 male), 56-71 years-old were studied. FDG-PET/CT and PSMA-PET/CT scans (respectively performed 60 minutes after intravenous administration of 0.1mCi/kg of [18F]FDG or 90 minutes after 0.1mCi/kg of [18F]F-PSMA-1007) were carried out with a time interval of 1-8 days between them. The imaging data were analyzed by two nuclear medicine physicians and one radiologist. The maximum standardized uptake value (SUVmax) of each lesion was measured for both radiotracers in the primary tumor and metastatic sites identified through visual analysis. Lesions were considered positive if their SUVs exceeded those of the cardiac blood pool, with inflammatory sites being excluded. ***Results:*** A total of 105 lesions were detected, 87 identified using [18F]FDG and 96 using [18F]F-PSMA. Nine lesions were exclusively detected by [18F]FDG (6 lung, 2 adrenal, and 1 lymph node metastases), while 14 were only identified by [18F]-PSMA (11 lymph node, 1 brain, 1 bone, and 1 lung metastases). The median SUVmax of lesions detected by [18F]FDG and [18F]F-PSMA images was 5.2 (1.7-25.0) and 3.7 (0.7-12.4), respectively. Brain lesions were more readily identified on [18F]PSMA images, whereas liver lesions were more notable on [18F]FDG images due to the intense physiological uptake of [18F]FDG and [18F]F-PSMA in the brain and liver, respectively. The uptake intensity and intratumoral distribution of the two tracers varied among different lesions. ***Conclusion:*** Both [18F]FDG-PET/CT and [18F]F-PSMA-1007-PET/CT identify most lesions of NSCLC. Due to ethical considerations, biopsies of all lesions were not feasible, precluding the exclusion of false positive results for both tracers. Although [18F]F-PSMA-1007 images detected a greater number of lesions, the uptake intensity generally appears higher with [18F]FDG. These findings suggest that the two radiopharmaceuticals may have complementary roles in NSCLC, independently detecting lesions with either higher glycolytic activity or greater neoangiogenesis. This potential could lead to a more personalized approach in managing these patients. Additionally, the results hint at a possible theranostic approach in selected patients with high PSMA uptake. Further investigations are essential to validate these findings.

EP-0185

Predicting Major Pathological Response to Neoadjuvant Immunochemotherapy in Non-small Cell Lung Cancer Using Multi-organ ^{18}F-FDG PET Metabolic Parameters: A Preliminary Study

Q. Ma[1], *J. Li[1], Y. Tang[1], S. Hu[1,2];*
[1]Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, CHINA, [2]Key Laboratory of Biological, Nanotechnology of National Health Commission, Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: Neoadjuvant immunochemotherapy (NAIC) has shown promise in improving the prognosis of non-small cell lung cancer (NSCLC). However, a significant portion of NSCLC patients fail to achieve major pathological response (MPR) with this treatment, experiencing rapid disease progression or severe immune-related adverse events. Various FDG PET metabolic parameters of organs like bone marrow, skeletal muscle, and colon have been linked to the prognosis of NSCLC. This study aims to investigate the efficacy of multi-organ parameters on 18F-fluorodeoxyglucose (FDG) positron emission tomography (PET) in predicting MPR to neoadjuvant immunochemotherapy in NSCLC patients. ***Materials and Methods:*** We retrospectively reviewed a consecutive cohort of 26 eligible NSCLC patients who underwent baseline ^{18}F-FDG PET/CT followed by neoadjuvant immunochemotherapy. Ten organs (spleen, kidney, pancreas, liver, colon, heart, aorta, lung, spine, and iliopsoas) were automatically delineated from PET/CT images, and five metabolic PET parameters (SUVmax, SUVmean, SUVpeak, metabolic tumor volume [MTV], total lesion glycolysis [TLG]) were measured. Spearman correlation and gradient boosting decision tree (GBDT) algorithms were used to select discriminative parameters. Logistic regression was employed to construct a prediction model, evaluated using metrics such as the area under the receiver operating characteristic curve (AUC), calibration plots, and decision curve analysis (DCA). ***Results:*** In our study cohort, 13 out of 26 patients achieved MPR following NAIC. Baseline clinical characteristics showed no significant difference between the MPR group and non-MPR groups. Spearman correlation and GBDT algorithms identified six key parameters (Spleen_SUVmax, Kidney_SUVmean, Pancreas_SUVmax, Colon_SUVpeak, Iliopsoas_SUVmean, Iliopsoas_SUVmax). Our logistic model, integrating these parameters with the SUVmean of the primary tumor, demonstrated significant stronger performance than SUVmean alone (AUC 0.92 [95% CI 0.81-1.00] vs 0.65 [95% CI 0.42-0.89], $p<0.05$). It displayed good calibration, and provided a notably higher net benefit in DCA. ***Conclusion:*** The predictive model, combining multi-organ ^{18}F-FDG PET parameters and the SUVmean of the primary tumor, delivered impressive results in predicting MPR to neoadjuvant immunochemotherapy in NSCLC patients. This model holds the potential to serve as a valuable biomarker for enhancing patient selection in future NAIC applications. However, larger sample size and multicenter studies are necessary to confirm our results and explore their clinical implications further.

EP-0186

IMSD in the differential diagnois between lung tumors side effects after chest radiotherapy

C. Altini[1], *A. R. Pisani[1], C. Ferrari[1], D. Rubini[2], C. Palumbo[1], A. Sardaro[3], G. Rubini[1];*
[1]Nuclear Medicine Unit, Interdisciplinary Department of Medicine, University "Aldo Moro"- Policlinic of Bari, Bari, ITALY, [2]Precision Medicine Department, University of Campania "Vanvitelli", Naples, Italy, Napoli, ITALY, [3]Section of Radiology and Radiation Oncology, DIM, University "Aldo Moro", Bari, Italy, Bari, ITALY.

Aim/Introduction: After Radiotherapy (RT) phlogosis can persist for 12 weeks and fibrosis even longer, interfering with relapses diagnosis. With this retrospective analysis we aimed to evaluate ^{18}FDG-PET/CT qualitative pattern and semiquantitative parameters, both automatic and proceeded by physicians, in interpreting lung lesions in the RT irradiation field. ***Materials and Methods:*** 94 patients (pts) submitted to RT (3 months before) for lung cancer with Computed Tomography (CT) doubtful lung lesion in the RT field were included (mean age 68 years old, range 49-84). ^{18}FDG uptake pattern was distinguished in: focal/wide, deep/shade, homogeneous/inhomogeneous. Semiquantitative parameters were: global SUVmax (gSUVmax), MTV and Intratumoral-Metabolic-Spatial-Distribution (IMSD= proximalSUVmax/distal SUVmax). ^{18}FDG-PET/CT was related to pts's outcome (biopsy and/or clinical-instrumental follow up): positive for lung relapse, negative if phlogistic. Chi-squared test for qualitative variables and t-Student for semiquantitative values were applied ($p<0.05$ for statistical significant). ***Results:*** In 76/94 (80.8%) pts, ^{18}FDG uptake was higher compared to the background;

in 18/94 (19.2%) no higher ^{18}FDG uptake were detected. Outcome was positive for lung relapse in 49/94 pts and negative in 45/94, with disease prevalence of 52.13% (95%CI=41.57%-62.54%). In the 18/94 pts without higher ^{18}FDG uptake, outcome was negative for lung relapse. In 49/76 pts with higher ^{18}FDG uptake the outcome confirmed the presence of relapse, while in 27/76 the lesion was phlogistic. Results about the Sensitivity, Specificity, Accuracy, Positive and Negative Predictive Values (95%CI) were respectively: 100% (92.75%-100%), 40% (25.7%-55.67%), 71.28% (61.02%-80.14%), 64.47% (58.84%-69.73%) and 100% (81.47%-100%). Chi-square test showed difference statistical significant between the positive and negative outcome for patterns focal/wide (p=0.02) and deep/shade (p<0.00001). 35/49 (71.4%) pts with lung relapse had focal lesion and 15/27 (55.6%) with phlogosis had wide pattern. 34/49 (69.4%) pts with lung relapse had deep pattern and 25/27 (92.6%) with lung phlogosis had the shade one. Significant difference was observed in evaluation the 3 patterns (p=0.00007), with prevalence of "focal/deep/homogeneous" patterns in lung relapse and "wide/shade/inhomogeneous" in phlogosis. gSUVmax, MTV and IMSD were: in the 76 pts, 5.63 (1.4-24.7), 42.49 (4.94-193) and 3.61 (1-5.54); in the 49/76 true positive pts, 6.93 (1.5-24.7), 35.28 (4.94-85.99) and 3.30 (1.05-5.54); in the 27/76 false positive pts, 3.27 (1.4-19.2), 38.37 (4.94-193) and 1.57 (1-2.13). The difference was statistically significant only for IMSD (t=2.779; p=0.0069). ***Conclusion:*** Physician confidence in evaluating ^{18}FDG-PET/CT lung lesions after RT can be improved evaluating qualitative pattern of uptake and IMSD, especially for differential diagnosis between relapse and RT side effects.

EP-0187

Baseline ^{18}FDG PET/CT derived MTV and TLG as predictors of progression free and overall survival in patients with malignant mesothelioma under first line dual immunocheckpoint inhibition

***H. Hautzel*[1],** *M. Metzenmacher[2], S. Bölükbas[3], J. Volmerig[4], G. Nilius[5], D. Kersting[1], D. Moka[6], K. Herrmann[1], D. C. Christoph[7]; [1]University Hospital Essen, Department of Nuclear Medicine, West German Cancer Center, University Duisburg - Essen, Essen, GERMANY, [2]University Hospital Essen, Department of Medical Oncology, West German Cancer Center, University Duisburg - Essen, Essen, GERMANY, [3]Department of Thoracic Surgery, West German Cancer Center, University Medical Center Essen-Ruhrlandklinik, University Duisburg - Essen, Essen, GERMANY, [4]Department of Thoracic Surgery, Evang. Kliniken Essen-Mitte, Essen, GERMANY, [5]Department of Pneumology, Evang. Kliniken Essen-Mitte, Essen, GERMANY, [6]Center of Nuclear Medicine and Molecular Imaging Essen, Essen, GERMANY, [7]Department of Internal Oncology, Evang. Kliniken Essen-Mitte, Essen, GERMANY.*

Aim/Introduction: Recent guidelines recommend dual immunocheckpoint inhibition (dICI) with ipilimumab and nivolumab as preferred first-line therapy in non-resectable malignant mesothelioma (MM). 18FDG PET/CT is the state-of-the-art imaging method for staging and response assessment in MM. Aim of this study is to evaluate metabolic parameters derived from baseline 18FDG PET/CT at initial staging for prediction of progression free survival (PSF) and overall survival (OS) in MM under first-line dICI. ***Materials and Methods:*** Baseline 18FDG PET/CT data of patients suffering from non-resectable MM before initiation of first-line dICI were collected retrospectively. SUVmax, SUVpeak, MTV and TLG were estimated (SUV cutoffs for MTV and TLG were defined in relation to liver uptake according to PERCIST). Additionally, dICI-related PFS and OS were collected. Spearman's Rho correlation coefficients and Kaplan-Meyer curves were calculated to estimate the significance of the metabolic 18FDG parameters in predicting PFS and OS. ***Results:*** Up to now 31 patients (female n=8, male n=23) were included (histology: n=19 epitheloid, n=4 sarcomatoid, n=8 biphasic). Of those, n=26 were of pleural and n=5 of peritoneal origin. Median PFS was 5.6 months while median OS was 10.8 months. SUVmax and SUVpeak do not significantly correlate with the survival parameters. However, MTV and TLG correlate negatively with PFS (MTV Spearman's Rho: -0.44, p=0.016; TLG: Spearman's Rho: -0.44, p=0.018) but failed to correlate with OS (MTV Spearman's Rho: -0.22, p=0.25; TLG: Spearman's Rho: -0.20, p=0.29). Kaplan-Meyer plots indicate significantly prolonged PFS when MTV was less than 47.5 ml (p=0.0029) or TLG under 293.5 SUVmax*ml (p=0.0034). ***Conclusion:*** Baseline 18FDG PET/CT derived MTV and TLG are feasible metrics to predict prolonged PFS under first-line dICI with ipilimumab und nivolumab. However, it appears that these metabolically derived tumor volumes are not suitable to estimate OS without considering additional parameters. Second-/ third-line chemotherapies, re-challenges with immunotherapies and other patient-related factors might also contribute to the variance in individual OS.

EP-0188

Metabolic aberrations in lung cancer patients as detected with a normative whole-body $^{[18F]}$FDG-PET/CT database

***S. Gutschmayer*[1],** *D. Ferrara[1], T. Beyer[1], Z. Chen[2], J. Taki[3], S. Kinuya[2], L. K. Shiyam Sundar[1], S. Takeda[3], H. Aim/Introduction: Normative databases (NormDB) have long been established in neuroimaging, with MRI and PET NormDB serving as references to identify metabolic and structural aberrations in neurological examinations. We apply this concept to study whole-body metabolic, voxel-based aberrations. We aimed to identify metabolic aberrations in lung cancer patients from a Japanese cohort by comparing whole-body $^{[18F]}$FDG-PET/CT image data against that of a healthy cohort. ***Materials and Methods:*** This study included 49 healthy controls (8F/41M, 69±13 kg) and 10 lung cancer (1F/9M, 56±15 kg) patients at different tumor stages. We curated 28/49 healthy controls to build a normative template image for male subjects with a BMI of 20 to 25. This template image was created by aligning the subjects' PET/CT images with an affine transformation to create an initial template. This was followed by an iterative deformable registration that used an updated reference image for each iteration. The PET and CT images from the 9 male (matched to the sex representing the NormDB) cancer patients were then compared by first segmenting [1] and then aligning, constrained by the segmentation, each organ with its counterpart in the normative template image. Once spatially aligned, a voxel-based aberration map was computed for each organ, thereby normalizing each voxel to its deviation from the NormDB, represented as a z-score. The created aberration images were reviewed by trained physicians regarding aberrations that were initially unrelated to a diagnosis by comparing the aberration images to the initial reports. ***Results:*** The aberration images revealed metabolic aberrations from the norm in all clinically reported lesions across the nine male patients. Observed aberrations in these regions reached z-scores up to 26.4. Additional highlighted aberrations included sites not evident when reviewing the SUV PET images exclusively. Notably, increased $^{[18F]}$-FDG uptake was detected at resection sites of lung

lesions, showing z-scores of up to 18. Additional areas suggesting inflammation, such as in joints and sore muscles, were also identified as aberrations. These findings were confirmed by the investigating physicians upon reviewing the initial clinical reports. ***Conclusion:*** The created aberration images successfully highlighted the targeted primary lesions. Additionally, secondary, subtle metabolic abnormalities that were not initially the focus were highlighted. This capability to detect subtle abnormalities could enhance diagnostic precision and reduce overlooked pathologies, marking a promising development in an oncological setting. ***References:*** [1] Sundar LKS, Yu J, Muzik O, et al. EP-0189

The utilization of a normative [18F]FDG-PET/CT database to highlight metabolic aberrations in cachectic lung cancer patients

S. Gutschmayer[1], *A. Frille[2,3], D. Ferrara[1], S. Hesse[2], M. Hacker[4], L. Hofmann[2,3], W. Langsteger[4], I. Rausch[1], M. Rullmann[2], O. Sabri[2], A. Tönjes[5], H. Wirtz[3], J. Yu[1,4], T. Beyer[1], L. K. Shiyam Sundar[1]; [1]QIMP Team, Medical University of Vienna, Vienna, AUSTRIA, [2]Department of Nuclear Medicine, University Hospital Leipzig, Leipzig, GERMANY, [3]Department of Respiratory Medicine, University Hospital Leipzig, Leipzig, GERMANY, [4]Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [5]Department of Endocrinology, University Hospital Leipzig, Leipzig, GERMANY.*

Aim/Introduction: Cachexia as a multi-organ syndrome is often associated with lung cancer patients (LCP). Patients experience rapid weight loss and, eventually, reduced quality of life and poor survival. In contrast to common organ-based analysis, we employ a voxel-wise analysis of whole-body [18F]FDG-PET/CT images to study metabolic differences between cachectic and non-cachectic patients in relation to healthy controls. ***Materials and Methods:*** In this multi-centre study, a cohort of 19 healthy controls (10M/9F) was used to create two (male and female) normative [18F]FDG-PET/CT images: first, all CT images underwent affine registration and averaging, followed by iterative deformable registration using the averaged image as a template, with updates and refining in each iteration. All alignments and averaging steps were applied to the corresponding PET images. This resulted in a normative PET and CT template image pair and a standard deviation (STD) image depicting normal metabolic ranges for each voxel. Three LCPs, each with or without cancer cachexia (2M/1F, in tumor stage I, II, and IV with either adenocarcinoma or squamous cell carcinoma histology, respectively), were compared with the established normative template. Cachexia status was defined by the body mass index adjusted weight loss grading system (WLGS): non-cachectic (WLGS-0/1) and cachectic (WLGS-3/4). Metabolic aberrations in the patient's SUV PET image were measured on a voxel-by-voxel basis as z-scores by computing each voxel's distance to the corresponding normative voxel in the SUV PET template image and normalizing this by their STD. ***Results:*** Aberrations in target lung lesions were 2.31-fold more severe, expressing a higher distance to the norm in the cachectic (z-score of 95) than in non-cachectic LCP (z-score of 41). Subclavicular adipose tissue regions were of particular interest, as they expressed aberrations up to 15-fold higher in cachectic (z-score of 18) than in non-cachectic LCP (z-score of 1.2). More generally, despite homogenous Hounsfield values in the CT images, subtle differences in the patient SUV PET images were highlighted in the aberration images for both cohorts. ***Conclusion:*** Analyzing data by organ may diminish individual voxel impacts, simplifying aberrations into a single value. However, voxel-wise analysis allows for identifying regional metabolic changes potentially associated with higher tumor burden and cachexia. Subclavicular adipose tissue regions expressing higher SUV might be suggestive of activated brown adipose tissue and could be associated with the onset of cachexia in LCP. The presented voxel-wise comparison approach could be utilized for detecting significant metabolic changes in LCP, suspected for cachexia.

EP-0190

Baseline ^{18}F-FDG PET/CT for prediction of early response to immunotherapy plus chemotherapy in patients with extensive-stage small-cell lung cancer: preliminary results from an ongoing prospective observational study

S. Taralli[1], *E. Perrone[2], A. Capotosti[3], R. Moretti[3], G. Cicchetti[4], F. Monaca[5], S. Ricciardi[6], L. Indovina[3], E. Bria[5], M. L. Calcagni[2]; [1]Nuclear Medicine Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY, [2]Nuclear Medicine Unit, Fondazione Policlinico Universitario Agostino Gemelli IRCCS-Nuclear Medicine Institute, Università Cattolica del Sacro Cuore, Rome, ITALY, [3]UOC Fisica per le Scienze della Vita, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY, [4]UOC Radiologia Toracica e Cardiovascolare, Advanced Radiology Center, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY, [5]Medical Oncology, Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, ITALY, [6]Pneumo-Oncology Unit, San Camillo-Forlanini Hospital, Rome, ITALY.*

Aim/Introduction: Small-cell lung cancer (SCLC) is a highly-aggressive tumour. Immunotherapy with PD-L1/PD1 checkpoint-inhibitors, combined with chemotherapy, was recently approved as first-line treatment in extensive-stage SCLC (ES-SCLC) patients, providing an opportunity to improve disease control and survival. However, only a few SCLC patients benefit of chemo-immunotherapy. Predictive biomarkers of treatment efficacy are lacking, with no reports investigating on 18F-FDG PET/CT for treatment response prediction. Thus, we aimed to explore the value of baseline 18F-FDG PET/CT as potential predictor of chemo-immunotherapy response in an ES-SCLC population. ***Materials and Methods:*** We analysed baseline 18F-FDG PET/CT performed in 13 consecutive ES-SCLC patients (8M; 70.7±6.1years) enrolled in an ongoing prospective, observational study and treated with chemo-immunotherapy. From whole-body dynamic 18F-FDG PET/CT (lasting 71 minutes; fully-automated multiparametric PET suite for kinetic analysis), the following PET parameters were evaluated: 1) number of visually PET-positive lesions; 2) activity of primary tumour (T), loco-regional nodal lesions (N; measuring the two most active) and distant metastases (M; measuring up to 5 lesions for patient, the 2 most active for each involved organ) in terms of SUVmax, SUVmean, SUVpeak and influx rate constants (Kimax, Kimean, Kipeak, expressing 18F-FDG consumption rate); 3) intra-lesional metabolic heterogeneity expressed by differences between SUVpeak and SUVmean, and between Kipeak and Kimean values (Delta-SUV, Delta-Ki). PET/CT performance for predicting early treatment response (after 4 chemo-immunotherapy cycles) was assessed by ROC curve analysis (MedCalc Statistical Software; statistical significance: $p<0.05$), using response evaluation by contrast-enhanced CT (RECIST criteria 1.1) as reference standard. ***Results:*** At baseline PET/CT: 13/13 patients presented nodal involvement; 10/13 additional distant metastases. A mean of 6 target lesions was measured for each patient. After 4 chemo-immunotherapy cycles, 10/13 patients were classified as responders (partial response),

3/13 no-responders (stable/progressive disease). At ROC analysis, PET parameters showing better performance for predicting treatment response were: number of PET-positive lesions (cut-off:20; Sensitivity=100%; Specificity=80%; AUC=0.90; p<0.0001), T-SUVmax and T-SUVpeak (cut-offs:13.7 and 12.3; Sensitivity=100%; Specificity=80% and 70%; AUC=0.87; p=0.001), tumour Delta-SUV (cut-off:4.4; Sensitivity=100%; Specificity=90%; AUC=0.93; p<0.0001), nodal Delta-SUV (cut-off:3.11; Sensitivity=100%; Specificity=71%; AUC=0.81; p=0.046). ***Conclusion:*** Baseline 18F-FDG PET/CT parameters may represent potential predictors of treatment efficacy in an ES-SCLC population candidate to chemo-immunotherapy, especially in terms of metabolic tumour burden, primary tumour activity and intra-lesional metabolic heterogeneity. From our preliminary results, kinetic analysis does not seem to provide additional predictive information and further analyses from ongoing prospective study are in progress, also on the role of post-treatment PET/CT for predicting prognosis.

EP-0192

[18F]FDG parametric PET imaging in non-small lung cancer patients with abbreviated dynamic scan protocols in a LAFOV PET/CT scanner: a clinical perspective

E. Calderón Ochoa[1], *W. Lan[1], J. Benecke[1], H. Dittmann[1], F. P. Schmidt[1,2], C. la Fougère[1];*
[1]University Hospital of Tübingen, Department of Nuclear Medicine and Clinical Molecular Imaging, Tübingen, GERMANY, [2]Werner Siemens Imaging Center, Department of Preclinical Imaging and Radiopharmacy, Tübingen, GERMANY.

Aim/Introduction: [18F]FDG PET/CT is essential in the management of lung cancer. Standard semi-quantitative analysis of malignant lesions relies on SUV, representing a composite of metabolic processes. Conversely, dynamic PET acquisitions provide robust radiotracer kinetics but present well-known practical challenges. Abbreviated dynamic scans exploiting the high sensitivity of long axial field-of-view (LAFOV) PET/CT scanners may offer a viable solution. ***Materials and Methods:*** Twenty treatment-naive patients with diagnosed non-small cell lung cancer (NSLC) underwent [18F]FDG PET/CT in a LAFOV PET/CT scanner. After injection of 3.0 MBq/kg/BW [18F]FDG, a 20-min PET scan was performed at 45 min p.i, following a validated abbreviated dynamic scan protocol grounded on a population-based input function (PBIF). Parametric images in terms of net influx rate of Ki [mL/min/100ml]and Distribution Volume (DV) [%] were obtained by integration of Patlak modeling directly into the image reconstruction. Two nuclear medicine physicians evaluated standard static PET (60-65 min p.i), Ki, and DV images. Primary tumors (n=20) and metastatic lesions (n=20) were segmented with a VOI isocountour of 41% of max SUV in static PET images. Reference VOIs were then overlayed in Ki and DV images for comparability, with adjustments made as necessary. Mean, max, and peak values of SUV, Ki, and DV were recorded. Pearson´s correlation coefficient was conducted to evaluate the linear association between quantification parameters, and paired Student's t-tests were employed to assess differences between variables. ***Results:*** There were no missed lesions between static and parametric PET images. The mean SUVmean, Ki mean, and DVmean for primary tumors were 7.0±4.0, 3.3±1.6, and 188±124, respectively. Paired t-tests between primary tumors and metastatic lesions revealed no statistically significant differences in SUVmean (p=0.3020), Kimean(p=0.3119), and DVmean(p=0.6848) values. Strong positive correlations were found between SUVmean/Ki mean ($r = 0.91$, $p < 0.0001$) and SUVmean/DVmean ($r = 0.67$, $p = 0.0056$) in primary tumors, as well as in metastatic lesions ($r = 0.94$, $p = 0.0167$; $r = 0.98$, $p = 0.0002$, respectively). ***Conclusion:*** Parametric quantitative values show a strong positive correlation with the generally used SUV and no statistically significant differences between primary and metastases. Therefore, by potentially finding different correlations in inconclusive findings such as inflammation, parametric analysis could enable better differentiation by PET alone. Additionally, abbreviated dynamic scan protocols using PBIFs facilitate data acquisition and implementation into the daily clinical routine. Concluding analysis with histopathology will provide the correlation to assess the additional utility of parametric data in NSCLC.

The Role of the Nuclear Medicine Specialist in the Multidisciplinary Tumor Board for Lung Cancer Treatment

A. Tabain[1], *S. A. Rogan[1], I. Puljić[1], J. Radić[2], B. Vučetić[3], T. Regović Džombeta[4], M. Gomerčić Palčić[5];*
[1]Department of radiology and nuclear medicine, PET/CT Centre, Polyclinic Medikol, Zagreb, CROATIA, [2]Department of oncology and nuclear medicine, Clinical Hospital Centre „Sisters of mercy", Zagreb, CROATIA, [3]Department of thoracic surgery, Clinical Hospital Centre „Sisters of mercy", Zagreb, CROATIA, [4]Clinical department of pathology and citology „Ljudevit Jurak", Clinical Hospital Centre „Sisters of mercy", Zagreb, CROATIA, [5]Department of internal diseases, Divison of pulmonology, Clinical Hospital Centre „Sisters of mercy", Zagreb, CROATIA.

Aim/Introduction: The interdisciplinary approach to the menagement of oncology patients has became the standard of care in order to achieve the best treatment outcomes. The aim of this study was to assess the impact of nuclear medicine physicians or nuclear medicine procedures, such as fluorine-18 fluorodeoxyglucose positron emission tomography with computed tomography (18F FDG PET/CT), on the menagement of lung cancer patients discussed at multidisciplinary (MDT) meetings for thoracic neoplasms at our institutions. ***Materials and Methods:*** We retrospectively analyzed patients referred for ^{18}F FDG PET/CT scan, after discussion on weekly MDT meetings over the period form January 2023 to January 2024, for assessing the highly suspicious lung nodules, staging of already confirmed malignancy and for monitoring therapy of previously treated disease. Tissue biopsy, endobronchial ultrasound mediastinal lymph node biopsy, thoracic surgery and subsequent PET/CT or CT scans were performed for evidencing or ruling out the malignancy. ***Results:*** Among the 676 patients presented at the MDTs, 135 individuals were selected for ^{18}F FDG PET/CT. Out of those 135 patients, 58 (43%) were referred for the evaluation of lung nodules metabolic activity, 62 (45.9%) for staging of newly diagnosed lung malignancy, and 15 (11.1%) for therapy monitoring or suspected recurrence of previously treated disease. After the ^{18}F FDG PET/CT, in total subset of 135 patients, 47 (34.8%) exhibited an altered treatment plan, while for remaining 88 (65.2%) patients therapy course hadn't changed. Within the group of 47 patients whose treatment course changed after ^{18}F FDG PET/CT, there were 31 patients (66%) who experienced disease stage progression, due to the solitary or combined findings of positive mediastinal lymph nodes, metabolically active lung and suprarenal lesions as well as detection of occult brain or bone metastases. In contrast, 16 patients (34%) have had lower stage of the disease than previously anticipated by ruling out the malignancy in the non-metabolic or inflammatory lung lesions, mediastinal lymph nodes or suspect suprarenal or bone dissemination. ***Conclusion:***

Due to the substantial proportion of patients for whom ^{18}F FDG PET/CT altered the treatment course, we consider that it is essential to involve the nuclear medicine physicians in MDT discussions whenever feasible. Their inclusion is crucial not only for optimizing and organizing patient care, but also for deepening of clinical understanding among nuclear medicine physicians, supporting advancements in nuclear medicine research, as well as improvement of patients outcomes.

Role of 68Ga FAPI PET-CT in the Evaluation of Gastric Cancer (GC): Comparison with ^{18}F-FDG PET-CT

I. Kostadinova, *G. Mateva, N. Novoselska, M. Garcheva, P. Bochev;*
Clinic of nuclear medicine, University Hospital Acibadem City Clinic, Mladost, Sofia, BULGARIA.

Aim/Introduction: ^{18}F-FDG PET-CT is often used for staging and preoperative evaluation of GC but it has been reported to have a low detection rate especially in some histological types, such as signetring cell, mucinous and poorly differentiated adenocarcinoma and moreover specificity is relatively low. Therefore other more sensitive radiopharmaceutical IS needed in the evaluation of GC. Recently radiolabeled inhibitors of fibroblast activation protein, such as 68Ga FAPI were used to visualize FAP-expressing tumors. The role of 68Ga FAPI PET-CT in patients with GC is now under evaluation in few reports. The aim of the study was to evaluate the role of 68Ga FAPI PET-CT in GS for staging and restaging and to compare the results with ^{18}F FDG PET-CT. ***Materials and Methods:*** Twenty eigh patients-Pts (18 men and 10 women, aged 38-71, in the stages between T3-4 N1-3 and M0-1) with histologically proven gastric cancer, were recruited for the investigation within the period 2021-2023. They underwent 68GaFAPI PET-CT (2MBq/kg) for staging- in 9 of them and for restaging in 19 with as a whole 50 investigations. In 16/28 of the patients ^{18}F-FDG PET-CT (2MBq/kg) was also performed with as a whole of 21 investigations. ***Results:*** Normal result, without evidence of metastases was registered in 10 of the patients after surgery/chemotherapy/immunotherapy and in 18 Pts-metastases were found in regional and/ or distant lymph nodes, liver, peritoneum or lung. In 7/18 of the Pts (37.5% of the cases) investigated with both radiopharmaveuticals, more lesions were found with 68GaFAPI PET-CT, mostly in peritoneum and abdominal lymph nodes, as in 5 of them histological type of the tumors was mucinous or signet ring cell. There was a better contrast with 68GaFAPI, with SUVmax of the primary tumor of 13.5 and 7.9 of the metastases, compared with SUVmax of 2.8 of the metastases with ^{18}F-FDG /without focal activity of the primary tumor/. ***Conclusion:*** According to our preliminary data, we consider that 68GaFAPI PET-CT is a very promising tool for evaluation of patients with advance GC, more sensitive than ^{18}F-FDG PET-CT and could be recommended as a method of choice for staging and restaging in order to plan the most appropriate therapy.

EP-0195

Prognostic value of metabolic and volumetric parameters obtained from pre-treatment F^{18} FDG PET/CT images in patients with Pancreatic Ductal Adenocarcinoma

I. Ak Sivrikoz[1], *B. Yildiz[2], M. Ates[1], S. Aslan[1], H. Devici[1];*
[1]ESOGU School of Medicine Department of Nuclear Medicine, Eskişehir, TÜRKIYE, [2]ESOGU School of Medicine Department of Medical Oncology, Eskişehir, TÜRKIYE.

Aim/Introduction: The 5-year survival rate for advanced stage Pancreatic ductal adenocarcinoma (PDAC) is 2% and effective methods are needed to prevent unnecessary surgery and predict prognosis. The aim of this study was to evaluate the prognostic value of metabolic and volumetric parameters measured from F^{18} fluorodeoxyglucose (F^{18} FDG) positron emission tomography (PET)/computed tomography (CT) in patients with PDAC. ***Materials and Methods:*** Between January 2010 and December 2021, patients with PDAC who underwent F^{18} FDG PET/CT only in our department for pre-treatment staging were retrospectively evaluated . SUVmax, SUVmean, Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG) values of the primary pancreatic lesion were calculated. Clinicopathological and demographic data, radiological progression and death dates of the patients were obtained from the hospital information system. The prognostic values of the FDG-PET parameters for recurrence-free survival (RFS) and overall survival (OS) were assessed by Kaplan-Meier and COX regression analysis. Ethics committee was approved. ***Results:*** A total of 44 PDAC patients, 24 men and 20 women, aged between 33 and 79 years (mean 61.5 years) were included in the study. At the time of evaluation, 41 patients had died and 3 patients were still alive. The mean SUVmax measured from the pancreatic tumour was 7.69 ± 3.42 (range 2.57-16.58), the mean SUVmean was 4.93±1.9 (range 2.57-10.43), the MTV value was 20.39 ± 43.02 (range 0.04 - 265.53) and TLG value was 100.16 ± 178.71 (range 0.1- 963.87) was detected. Tumour size was found to be associated with SUVmax (p=0.02), SUVmean (p=0.04), MTV (P=0.001), TLG (p=0.001) and CEA (p=0.04). Median OS was 11.07 (95% CI: 7.99-14.14) months, and there was no relationship between SUVmax (p=0.25), SUVmean (p=0.38), MTV (p=0.62) values. There was also no relationship between OS and tumour size and intra-pancreatic localization of the tumour (head/tail). While the relationship between OS and CEA levels was significant (p=0.017), its relationship with CA19-9 (p=0.155) was not significant. Median PFS was measured as 7.37 (95% CI: 4.68-10.05) months; No significant relationship was found between PFS and SUVmax (p=0.24), SUVmean (p=0.28) and MTV (p=0.39). No relationship was observed between PFS and CA19-9 (p=0.74) and CEA (p=0.27) levels. ***Conclusion:*** In conclusion; pre-treatment CEA values may be a prognostic marker for OS in patients with PDAC. We could not detect a role of SUV-based parameters obtained from F-FDG PET/CT images in predicting PFS and OS in patients with PDAC.

EP-0196

Role of ^{18}F-FDG PET-CT in the Pretreatment Evaluation & Prognostication of Gall Bladder Cancer

R. Wakankar, *J. Bal, P. Dougall;*
Max Super Speciality Hospital, New Delhi, INDIA.

Aim/Introduction: Through this retrospective study we evaluate and establish the role of whole body ^{18}F-FDG PET-CT as a tool for imaging and prognostication of patients of non-metastatic and metastatic gall bladder cancer. ***Materials and Methods:***

41 patients with confirmed adenocarcinoma of gall bladder were included in our analysis. The findings pertaining to the local disease, lymph node status and metastasis along with other parameters such as SUVmax of the primary and metastatic lesions, dimensions of the lesions, level of differentiation of the primary tumor & liver function test results were included. Descriptive statistics along with Spearman correlation coefficients and linear regression analysis were conducted. ***Results:*** The mean age was 58.4±13.1 yrs, primary tumor size: 4.8±2.8 cm, long axis diameter (LAD) of metastatic lymph node: 2.2±0.8 cm, primary tumor SUVmax: 8.7±3.1, distant mets SUVmax: 7.2±3.1, serum albumin: 3.2±0.8 mg/dl, total protein: 6.6±0.9 mg/dl, ALT: 122.5±119.7 IU/L, AST: 69.2±98.4 IU/L, total bilirubin: 3.9±3.6 mg/dl & direct bilirubin: 2.4±2.0 mg/dl. 17% were male, 83% female; 27% had no metastasis, 73% had metastasis; 46% were well-differentiated, 39% moderately- differentiated, 15% poorly differentiated. Spearman's correlation coefficients were calculated for the variables mentioned above, which demonstrated a significant correlation between primary tumor SUVmax & total protein (ρ= -0.324, p=0.042), primary tumor SUVmax & total bilirubin (ρ=0.550, p<0.001), primary tumor SUVmax & direct bilirubin (ρ=0.366, p=0.022), primary tumor SUVmax & distant metastasis SUVmax (ρ=0.431, p=0.017), long axis diameter (LAD) of metastatic lymph node & distant metastasis SUVmax (ρ=0.622, p<0.001), primary tumor size & metastatic lymph node LAD (ρ= -0.537, p=0.002), primary tumor size & distant metastasis SUVmax (ρ= -0.388, p=0.034). Linear regression analysis of the relation between primary SUVmax & total bilirubin gave us a regression equation of: total bilirubin=0.382(SUVmax)+0.644 (R2=0.112, p=0.038). Similar regression equations were generated for various other variable pairs, such as the following: lymph node LAD & distant metastasis SUVmax: distant mets SUVmax =2.438(LN LAD)+2.474 (R2=0.384, p<0.001); primary tumor size & metastatic LN LAD: metastatic LN LAD= -0.202(primary tumor size)+2.99 (R2=0.284, p=0.002) and distant mets SUVmax & primary tumor size: distant mets SUVmax= -0.471(primary tumor size)+9.305 (R2=0.178, p=0.02). ***Conclusion:*** We have demonstrated that FDG PET-CT helps play a prognostic role in predicting the aggressiveness of gall bladder cancer, derangement in liver function and thus help predict patient outcome.

EP-0197

Interim Analysis of a Phase 2 Trial using ^{18}F-PSMA PET/CT Imaging in Patients with Hepatocellular Carcinoma

E. Mena[1], *J. Chung[1], Y. Dorisca[2], A. Rabiee[3], D. Hrones[4], B. Turkbey[1], L. Lindenberg[1], K. E. Salerno[2], M. Kassin[5], B. Wood[5], J. Hernandez[6], D. Kleiner[7], T. Greten[4], P. L. Choyke[1], F. E. Escorcia[1];*
[1]Molecular Imaging Branch. National Cancer Institute. NIH, Bethesda, MD, UNITED STATES OF AMERICA, [2]Radiation Oncology Branch. National Cancer Institute. NIH, Bethesda, MD, UNITED STATES OF AMERICA, [3]Department of Hepatology, Veterans Affairs Medical Center, Washington DC, DC, UNITED STATES OF AMERICA, [4]Thoracic and GI Malignancy Branch. National Cancer Institute. NIH, Bethesda, MD, UNITED STATES OF AMERICA, [5]Interventional Oncology Branch. National Cancer Institute. NIH, Bethesda, MD, UNITED STATES OF AMERICA, [6]Surgical Oncology Branch. National Cancer Institute. NIH, Bethesda, MD, UNITED STATES OF AMERICA, [7]Laboratory of Pathology. National Cancer Institute. NIH, Bethesda, MD, UNITED STATES OF AMERICA.

Aim/Introduction: While prostate specific membrane antigen (PSMA) is overexpressed in prostate cancer cells, it's also expressed in the tumor neo-vasculature of other cancer cell types, including hepatocellular carcinoma (HCC). Currently, functional imaging agents are limited for assessing HCC, which make diagnosis and re-staging following local therapies difficult. This study aimed to evaluate the feasibility of using ^{18}F-PSMA(DCFPyL)-PET/CT to detect sites of HCC before and after treatment in comparison with CT/MRI and FDG-PET/CT. ***Materials and Methods:*** This is a phase 2, multi-site, prospective IRB-approved trial planned to enroll 50 patients. We included a cohort of 6 patients with suspected HCC eligible for standard local/locoregional treatment. Participants underwent ^{18}F-DCFPyL, ^{18}F-FDG and diagnostic CT/MRI at baseline and within 4-8 weeks post-treatment, and histopathologic assessment. Volumes Of Interest (VOIs) were drawn on the PMSA-PET positive lesions (i.e. focal uptake greater than background with CT abnormality). Maximum Standardized Uptake Value (SUVmax) and tumor volume (TV) burden were calculated. ***Results:*** All six patients (males, 71±10.7 years) had at least one lesion deemed to be HCC by an expert radiologist using Liver Imaging Reporting & Data System (LIRADS, LR). Three patients were treated with ablation (LR-5), two with stereotactic body radiotherapy (LR-4 and LR-5), and one underwent surgical resection (LR-5). All patients (6/6) had at least one PSMA positive lesion(s), which were biopsy-confirmed to represent HCC and 2 out of 6 patients exhibited lesions positive on FDG. At the lesion-based level, 13 liver lesions were seen on CT/MRI, 8 of 13 were PMSA positive (61.5%) whereas 3 of 13 showed FDG-avidity (23.1%). One extrahepatic lesion was positive on all modalities. Lesion(s) PSMA SUVmax ranged from 6.7 to 14.3, mean 10.7; average TV of 8.7 ml (range: 0.9-13.6 ml). Five of the 6 patients underwent post-treatment PSMA-PET/CT, and all five demonstrated decreasing uptake values and tumor volumes in the treated lesions compared to baseline. ***Conclusion:*** In this interim analysis, we confirm the feasibility of using ^{18}F-PSMA-PET/CT to detect tumor sites and assess local treatment response in HCC patients. Results from this completed trial may help determine whether PSMA-selective radiopharmaceutical therapies may be beneficial for patients with HCC. Patient accrual is ongoing for this trial and additional results may be available at the time of the presentation. ***References:*** Hirmas N et al. 68Ga-PSMA-11-PET/CT Improves Tumor Detection and Impacts Management in Patients with Hepatocellular Carcinoma. EP-0198

^{68}Ga-FAPI PET/MRI may not be superior to contrast-enhanced CT in the N-staging of gastric cancer: a head-to-head retrospective study comparing with pathology by D2 lymphadenectomy

Y. Fu[1,2], *C. Qin[1,2], Y. Zhang[1,2], R. An[1,2], X. Lan[1,2];*
[1]Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]Hubei Province Key Laboratory of Molecular Imaging, Wuhan, CHINA.

Aim/Introduction: 68Ga-FAPI PET has been proven to perform well in the diagnosis and staging of diverse solid malignant tumors, including gastric cancer. However, the value of 68Ga-FAPI PET for gastric cancer N staging remains uncertain. Contrast-enhanced CT(CECT) is recommended by NCCN guidelines as conventional imaging for gastric cancer staging. This study aimed to evaluate the performance of 68Ga-DOTA-FAPI-04 (68Ga-FAPI) PET/MRI for the diagnosis of regional lymph node metastasis in patients with gastric carcinomas, utilizing histopathology as the reference standard, and to compare with CECT. ***Materials and Methods:*** Patients with gastric cancer who underwent 68Ga-FAPI PET/MRI from June 2020 to June 2023 were retrospectively collected. Inclusion criteria: (1) histologically

proven gastric carcinomas; (2) underwent radical surgery and D2 lymphadenectomy without neoadjuvant therapy; (3) underwent CECT within 1 month; (4) no anti-tumor treatment before 68Ga-FAPI PET/MRI or CECT and between the two modalities. Exclusion criteria: (1) histologically proven non epithelial gastric malignancies including gastric lymphoma, etc.; (2) suffering from other malignancies; (3) lack of clinical data or histopathological examination of lymph nodes. The diagnostic performance of 68Ga-FAPI PET/MRI for regional lymph node metastasis of the patients received D2 lymphadenectomy was assessed and compared with CECT. Histopathology served as the standard for the final diagnosis. The McNemar's test and chi-squared test were applied to compare the detection efficiency of two modalities. ***Results:*** Eighteen patients with histologically proven gastric carcinomas (median age: 58 y; range: 25-77 y) were enrolled, including 14 men and 4 women. Thirteen patients were diagnosed with regional lymph node metastasis. 68Ga-FAPI PET/MRI correctly diagnosed 13 cases and misdiagnosed 5 cases. CECT correctly diagnosed 12 cases and misdiagnosed 6 cases. 68Ga-FAPI PET/MRI correctly staged 7 cases and underestimated 11 cases. CECT correctly staged 6 cases, underestimated 10 cases, and overestimated 2 cases. A total of 532 lymph nodes were removed for pathological examination. The sensitivity, specificity and accuracy of 68Ga-FAPI PET/MRI for regional lymph node metastases were comparable to CECT (28.3% [28/99] vs. 23.2% [23/99], 99.8% [432/433] vs. 99.3% [430/433], 86.5% [460/532] vs. 85.2% [453/532], all P > 0.05). ***Conclusion:*** In patients with gastric carcinomas who received D2 lymphadenectomy, as confirmed by histopathology, 68Ga-FAPI PET exhibited limited sensitivity in detecting regional lymph node metastasis due to false negatives. 68Ga-FAPI PET/MRI had no advantage over CECT in the evaluation of regional lymph nodes. More large sample multi-center prospective head-to-head comparisons are needed for further validation.

EP-0199

The Significance of SUVmax in ^{18}F-FDG PET-CT for Staging Esophageal Cancer: Understanding Metastatic Influence

G. Cuesta Domingo[1], *C. Rodríguez Rey[1], A. Ortega Candil[1], R. Cano Carrizal[2], P. Nespral[1], P. Dauden[1], M. Vaillant[1], P. Bascuñana[1], M. Cabrera Martín[1];*
[1]Department of Nuclear Medicine, Hospital Clínico San Carlos, Madrid, SPAIN, [2]Department of Cardiology, Hospital Infanta Sofía, Madrid, SPAIN.

Aim/Introduction: The prognostic value of SUVmax in esophageal cancer shows discordant results in the literature, generally due to heterogeneity of the samples and the reduced representation of patients with metastatic involvement. We aim to analyse the prognostic value of SUVmax of the esophageal lesion according to the presence of metastases at diagnosis. ***Materials and Methods:*** Retrospective cohort study (2016-2022) of 118 patients with suspected esophageal cancer attending for staging by ^{18}F-FDG/PET-CT. We excluded tumors of the gastro-esophageal junction (32), atypical/not clearly malignant histologies (10) and those without the possibility of measuring SUVmax (13), obtaining a final sample of 63 patients. We collected predictor variables and tumor-caused mortality as an event. In the multivariate analysis (Cox regression) we added an interaction term between SUVmax and the presence of metastases. ***Results:*** The mean age was 69.1±13.1 years; 84.1% were male, with epidermoid being the most frequent subtype (61.9%). Twenty-four patients (38.1%) had metastases at diagnosis. Median follow-up was 12.2 months (IQR 5.6-25.1), with 50 patients (79.4%) dying. SUVmax was related to mortality in univariate analysis (HR 1.03; CI 95%: 1.00-1.07; p=0.028). In multivariate analysis the interaction between SUVmax and the presence of metastases was significant (p=0.017), so that SUVmax was related to mortality in patients without metastases (HR 1.06; CI 95%: 1.02-1.10; p=0.001), but not in those with metastases at diagnosis (HR 0.99; CI 95%: 0.94-1.03; p=0.593). Other variables related to mortality in multivariate analysis were chemotherapy treatment (HR 0.37; CI 95%: 0.17-0.79, p=0.011) and surgical resection (HR 0.26; CI 95%: 0.11-0.61, p=0.002). ***Conclusion:*** SUVmax of the esophageal lesion is related to mortality in patients without metastases at diagnosis. On the other hand, the prognosis of patients with disseminated disease is independent of SUVmax of the primary lesion.

EP-0200

Exploring the Prognostic Value of ^{18}F-FDG PET-CT Metabolic Parameters in Esophagogastric Junction Tumors

G. Cuesta Domingo[1], *P. Nespral[1], A. Ortega Candil[1], C. Rodríguez Rey[1], R. Cano Carrizal[2], P. Dauden[1], M. Vaillant[1], P. Bascuñana[1], M. Cabrera Martín[1];*
[1]Departament of Nuclear Medicine, Hospital Clínico San Carlos, Madrid, SPAIN, [2]Departament of Cardiology, Hospital Clínico San Carlos, Madrid, SPAIN.

Aim/Introduction: Esophagogastric junction (EGJ) tumors present an important limitation as a tumor entity composed of two different natures (esophageal tumors and gastric tumors). We aim to assess the prognostic utility of metabolic parameters in ^{18}F-FDG/PET-CT staging of patients with EGJ tumors. ***Materials and Methods:*** Retrospective cohort study (2016-2022) of 37 patients attending for staging EGJ cancer by ^{18}F-FDG/PET-CT. SUVmax and metabolic tumor volume (MTV) of the primary lesion were measured in all but two patients, obtaining a final sample of 35. A logarithmic transformation of both variables was performed to approximate normality. We collected predictor variables and tumor-caused mortality as an event. Uni/multivariate analysis was performed using Cox regression to search for predictors of events. Survival curves were compared using the Log-Rank test. ***Results:*** The mean age of the patients was 68.9±10.8 years and 85.7% were male. The majority histological subtype was adenocarcinoma (91.4%). Sixteen patients (47.1%) were considered resectable (only one of them had metastatic disease). In univariate analysis, neither logSUVmax (HR 0.95; CI 95%: 0.55-1.64; p=0.862) nor logVMT (HR 0.95; CI 95%: 0.67-1.33; p=0.749) predicted mortality. Univariate predictors of mortality were the presence of metastases (HR 4.32; CI 95%: 1.83-10.22; p=0.001) and tumor resectability (HR 0.12; CI 95%: 0.05-0.32; p<0.001). In multivariate analysis only tumor resectability remained as an independent predictor (HR 0.08; CI 95%: 0.03-0.24; p<0.001). Median survival in operated patients was 58.1 months, compared to 7.4 in those not operated (p<0.001). ***Conclusion:*** Metabolic parameters of ^{18}F-FDG/PET-CT were not able to predict mortality of patients with EGJ cancer in our sample, mortality is primarily determined by tumor unresectability.

EP-0202

Value of SUV based cellularity measuring FDG uptake for predictions of patient prognosis in Preoperative Carbon-ion Radiotherapy for Pancreatic Cancer

K. Tanimoto[1], *T. Maeda[1], M. Shinoto[1], T. Higashi[2], S. Yamada[1], H. Ishikawa[1];*
[1]QST hospital, National Institutes for Quantum Science and Technology, Chiba, JAPAN, [2]Institute for Quantum Medical Science, National Institutes for Quantum Science and Technology, Chiba, JAPAN.

Aim/Introduction: Various parameters are used for measuring tumor glucose metabolic activity with 18F-FDG PET including measuring the single maximum pixel value within the slice with highest radioactivity concentration(SUVmax) or the mean value of 1.0 mL spherical VOI centered on SUVmax(SUVpeak) within a tumor. The SUV(SUVmax and SUVpeak) are commonly used in FDG-PET to predict patient prognosis. We tried to measure not only glucose metabolism but also tumor cell density using FDG-PET. The results of pathological findings can help prediction of patient prognosis with cancer. We compared the pathology results and the 18F-FDG-PET with the SUVs, as a prognostic factor in pancreatic cancer. ***Materials and Methods:*** Seventeen patients(10males, 7females; mean age, 67±7y) with pancreas cancer underwent 18F-FDG PET/CT scan before carbon ion radiotherapy at a total dose of 35.2-36.8GyE followed by surgery for pancreatic cancer. We think the difference between SUVmax and SUVpeak could mean the tumor cellularity in cancer cells. We evaluated the glucose metabolism by SUVmax and SUVpeak, and evaluated the tumor cellularity by SUVcell. SUVcell was calculated by the following equation: SUVcell = [SUVpeak] / [SUVmax] × 100 We compared these results with the pathological findings according to the 7th of Japanese General Rules for the study of pancreatic cancer. 18F-FDG accumulates in tumor cells but does not accumulate so much in the other cells. The high cellularity tumor may be high SUVmax and high SUVpeak, so SUVcell may be high. The low cellularity tumor may be high SUVmax and low SUVpeak, so SUVcell may be low. The overall survival was calculated using the Kaplan-Meier method by evaluating the results of the glucose metabolism and tumor cellularity using a statistical analysis software R. The SUVs were statistically compared with the pathological findings using the Mann-Whitney's U test with the R. ***Results:*** A Kaplan-Meier analysis showed that patients with a median value of SUVcell≤ 88.0 had a much better overall survival(OS) rate than the patients with a median value of SUV>88.0(p<0.05). There were no statistically significant differences between OS rate and SUVmax, and SUVpeak. Statistically-significant difference was observed between SUVmax and and SUVpeak between pN(+) and pN(-) in regional lymph node metastasis each other(p<0.05). Statistically-significant difference was observed between SUVmax and SUVpeak between pRP(+) and pRP(-) in retroperitoneal tissue(p<0.05). ***Conclusion:*** We think SUVcell could estimate the tumor cellularity using FDG-PET/CT, and the tumor cellularity might be useful for predicting prognosis of the patients with pancreatic cancer.

EP-0203

Is incidental focal F^{18} FDG uptake in gallbladder of oncologic patients worrisome? : Preliminary study

K. Hwang, *H. Lee, S. Kim;*
Gachon Medical School, Gil Medical Center, Incheon, KOREA, REPUBLIC OF.

Aim/Introduction: This retrospective study aimed to assess the clinical implications of incidental focal gallbladder F^{18} FDG uptake in non-gallbladder cancer patients. ***Materials and Methods:*** We retrospectively reviewed F^{18} FDG PET/CT reports from March 2017 to August 2023 in non-gallbladder cancer patients. When incidental suspicious focal gallbladder uptakes were identified, then corresponding histopathological reports were retrieved if available. Twenty patients were eligible, encompassing various primary cancers; five lymphoma, three breast, two lung, two gastric, and eight others. Focal gallbladder uptakes were categorised as malignant, benign, or unconfirmed. Maximum standardized uptake value (SUVmax) of each uptake was measured and compared between malignant and benign lesions. Statistical significance was set at $p < 0.05$. ***Results:*** Among the twenty incidental gallbladder FDG uptakes, five were malignant, eight benign, and seven unconfirmed. Malignant lesions accounted for 25.0% of the focal uptakes. SUVmax failed to differentiate between malignant (mean ± SD: 4.6 ± 1.7) and benign (mostly inflammatory, 4.4 ± 2.0) lesions ($p > 0.5$). Unconfirmed lesions exhibited an SUVmax of 4.3 ± 0.4, with no statistical difference observed among the three groups. ***Conclusion:*** In light of the substantial influence of gallbladder cancer metastasis on 5-year relative survival rates, the imperative for early detection cannot be overstated. Notably, approximately one quarter of incidentally observed focal gallbladder FDG uptakes in cancer patients proved to be malignant. We should underscore the importance of closely monitoring unexpected gallbladder FDG uptake, as relying solely on SUVmax may not yield sufficient accuracy in distinguishing malignant from benign lesions. Further studies with larger cohorts and histopathological confirmation are warranted to elucidate the role of SUV in this context.

EP-0204

PSMA-PET/CT can differentiate between CCC and HCC

S. Serfling[1], *F. Reiter[2], J. Serfling[3], A. K. Buck[1], A. Meining[4], T. Higuchi[1], T. A. Bleay[3], R. A. Werner[5], A. Weich[4];*
[1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Departement of Internal Medicine II, University Hospital Würzburg, Würzburg, GERMANY, [3]Department of Radiology, University Hospital Würzburg, Würzburg, GERMANY, [4]Department of Internal Medicine II, University Hospital Würzburg, Würzburg, GERMANY, [5]Department of Nuclear Medicine, Clinic for Radiology and Nuclear Medicine, Goethe University, University Hospital Frankfurt, Frankfurt, GERMANY.

Aim/Introduction: Differentiating hepatocellular carcinoma (HCC) from cholangiocellular carcinoma (CCC) by non-invasive imaging poses a diagnostic challenge. In the present Phase II study, we aimed to separate between those hepatic tumor subtypes based on PSMA-directed PET (NCT). ***Materials and Methods:*** We included 13 patients affected with liver tumor (CCC in 5/13 (38.4%), HCC in 8/13 (61.6%)). All patients were treatment-naïve and underwent a PSMA-directed PET/CT using [^{18F}]PSMA-1007 and liver magnetic resonance imaging (MRI) upon initial staging. We revealed the diagnostic performance of PSMA-PET/CT on a patient- and lesion-based level and conducted quantification of uptake in sites of disease. ***Results:*** All 13 patients (100%) were rated positive for tumor infiltration on MRI. On a lesion-based level, all HCC tumors showed an elevated PSMA uptake whereas the CCC tumors showed no significant uptake on PSMA-directed PET. The SUVmean for HCC was 17.4±6.2 (CCC, 4.3±2.4) and SUVmax was 31.3±12.2 (CCC, 7.1±3.5; P=0.001, respectively). Indicative for improved contrast, tumor-to-background ratios were also elevated for the HCC in comparison to CCC on PSMA-PET (27.0±19.3 vs 4.3±0.9; P=0.02). ***Conclusion:*** HCC tumors show a significantly increased PSMA expression, while CCC revealed no relevant uptake. As such, PSMA-targeted PET/CT may be used to differentiate non-invasively between those tumor subtypes.

EP-0205

^{18}FDG PET/CT Hepatic Superscan caused by colon adenocarcinoma

M. Agolti, *L. Solari;*
Centro de Medicina Nuclear Clinica Modelo, Parana, ARGENTINA.

Aim/Introduction: "Hepatic Superscan" describes a diffuse increased ^{18}FDG hepatic uptake. It is a rare but interesting finding in daily clinical practice using ^{18}FDG PET/CT. This pattern can be seen coupled with strikingly low cerebral and cardiac FDG uptake and it is associated with an extensive and diffuse involvement by a malignant disease such as primary hepatic lymphoma, diffuse angiosarcoma of the liver, secondary lymphomatous or leukemic involvement, HCC or metastases(1), etc. There are less frequent causes of diffuse increase in hepatic FDG uptake described in the literature, mostly infectious. Our aim is to report this pattern in solid tumors that is not easy to find. ***Materials and Methods:*** This is a retrospective observational study, lasting two years. From March 2022 to March 2024. We performed 1173 ^{18}FDG PET/CT studies and found 2 patients with diffuse increased hepatic uptake confirmed by biopsy to be generated by secondary compromise. ***Results:*** The diagnoses were, colon adenocarcinoma in both patients. The increased hepatic uptake was diffuse, with no clear correlation on CT images, in one case it was clearly diagnosed pre surgery; in the other on it was seen during surgery, the SUV max in one patient was 4,82 and in the other 3,99. When reporting oncologist patients, it is important to keep in mind the normal HEPATIC SUVmax according to the body mass index (2,58±0,33)(2). There are some published cases related to breast carcinoma and lymphoma, but no related to Colon Adenocarcinoma, where the most common pattern is multiple focal metastases. There are also some reported cases of diffuse hepatitis seen as diffuse increased uptake. ***Conclusion:*** There is an increasing incidence of typical and atypical forms of diffuse liver involvement. This unusual finding was an indicator of extensive liver involvement caused by colon carcinoma, and gives us an idea of the importance of the finding and how it could change the staging and treatment of the patient. ***References:*** (1) Kaneko, Koichiro et al. "A case of diffuse-type primary hepatic lymphoma mimicking diffuse hepatocellular carcinoma." EP-0206

Role of PET Radiomic features in characterizing Esophageal Carcinoma

P. Rajput, *D. Datta, R. Kumar;*
AIIMS Jodhpur, Jodhpur, INDIA.

Aim/Introduction: Radiomics has recognized itself as a promising tool in classification and detection of malignancy as well as metastases. Esophageal cancer is one of the most common malignancy with significant morbidity. The squamous subtype is most common in Asia, however the adenocarcinoma is associated with worse prognosis. This study aims to evaluate the role of non-invasive radiomic features of PET to predict the histological subtype of this malignancy. ***Materials and Methods:*** This is a retrospective study conducted in patients with histopathologically proven carcinoma esophagus. The study group consisted of Squamous cell carcinoma and Adenocarcinoma. The PET parameters of tumoral SUVmax, Metabolic ratio of tumor to liver (SUR), Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG) were calculated and compared between the two groups using Mann-Whitney U test. ***Results:*** Out of 59 patients (M:F=33:26) included in the study, 19 had Adenocarcinoma and 40 had Squamous subtype. Median age was 57 years (Range: 30-83). The median SUVmax, SUR, MTV and TLG of both the groups were 12.99, 5.34, 11.52 cc and 77 g/ml. The median SUVmax, SUR, MTV and TLG of Adenocarcinoma group were 10.89, 3.86, 9.98 cc and 55.8 g/ml, and of Squamous group were 13.88, 5.6, 13.52 cc and 108.4 g/ml respectively. There was significant difference noted in the tumoral SUVmax (p=0.043), SUR (p= 0.019) and TLG (p= 0.032) between the two groups, with higher metabolic values observed in the Squamous group. MTV (p=0.224) between the two groups was insignificant. ***Conclusion:*** The radiomics analysis using metabolic parameters can serve as a non-invasive tool to differentiate the pathological subtypes, and hence the prognosis of esophageal malignancy.

EP-0207

Role of DOTANOC PET/CT in the Management of Gastrointestinal Stromal Tumors

S. Sagar, *D. Khan, S. K V, N. Kundu, R. Viswanathan, A. Roy, B. Nayak, R. Kumar;*
AIIMS, Delhi, INDIA.

Aim/Introduction: Gastrointestinal stromal tumors (GISTs) represent a subset of mesenchymal neoplasms characterized by their distinctive molecular profile, particularly mutations in the KIT or PDGFRA genes. The management of GISTs poses significant challenges due to their heterogeneity and potential for metastasis. Accurate staging and surveillance are crucial for determining appropriate therapeutic strategies and assessing treatment response. In recent years, positron emission tomography/computed tomography (PET/CT) imaging using radiotracers such as 68Ga-DOTA NOC peptides has emerged as a promising modality for the evaluation of GISTs. ***Materials and Methods:*** 18 cases of GISTs referred to our center for DOTANOC PET/CT were evaluated on the basis of our imaging reports and final biopsy reports. Acquisition of DOTANOC PET/CT was performed on dedicated PET/CT scanners (Biograph mCT, Siemens Inc and Discovery PET/CT, GE) 45-60 minutes after administration of 2-3 mCi of radiotracer intravenously. All the scans were interpreted by two experienced nuclear medicine physicians. ***Results:*** A total of 18 patients with diagnosed GISTs were included in the study. All patients underwent DOTANOC PET/CT imaging at baseline and 3 patients had follow-up after receiving standard treatment regimens. The mean age was 48.3 ± 8.4 years , with a male-to-female ratio of 4:5. Of the 3 patients who had respone assesment scan, 2 patients had stable disease and 1 showed partial response. 7 patients had only primary disease, 8 patients had metastatic disease and for 3 patients DOTANOC PET/CT was not able to detect any lesions. In patients with metastatic diseases the most common site for metastases were lymph nodes followed by liver. ***Conclusion:*** DOTANOC PET/CT represents a valuable imaging tool in the multidisciplinary management of GISTs. Its high sensitivity, specificity, and ability to provide functional information make it a promising adjunct to conventional imaging modalities. Further prospective studies are warranted to validate its role in treatment decision-making, patient monitoring, and prognostic assessment in GISTs. Integration of DOTANOC PET/CT into routine clinical practice has the potential to optimize patient outcomes and enhance personalized medicine approaches in this challenging disease setting.

EP-0208

Head-to-head comparison of ^{11}C-choline and ^{18}F-FDG PET/CT in the differentiation of benign and malignant liver lesions

X. Wang, *H. Fang, W. Hu, Y. Feng, M. Li, X. Zhang, Y. Zhang, R. An, X. Lan;*
Department of Nuclear Medicine, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: The limitations of 18F-FDG in the diagnosis of hepatic focal lesions are due to the low expression of glucose transporter proteins on the cell membranes of hepatocellular carcinoma (HCC), resulting in low uptake in many primary hepatic lesions. This study aimed to compare the efficacy of 11C-choline and 18F-FDG PET/CT in distinguishing between benign and malignant liver lesions. ***Materials and Methods:*** Forty-seven patients with liver lesions were prospectively enrolled. All patients underwent abdominal three-phase 11C-choline PET/CT and whole-body 18F-FDG PET/CT within one week. Histopathological diagnosis or clinical and regular medical imaging at 6-months follow-up served as the gold standard. All lesions showing higher tracer uptake than normal liver were considered positive for HCC. Average SUVmax of the abdominal aorta (B) served as background reference. The SUVmax of the lesion (T) were measured in both scans, with the average SUVmax of normal liver tissue (L) as reference. T/L and T/B ratios were calculated for both methods. ***Results:*** Among 47 enrolled patients, 30 of them were diagnosed with malignant lesions, and 17 of them were benign lesions. 11C-choline exhibited superior sensitivity (86.2% vs. 83.3%) and specificity (94.4% vs. 42%) compared to 18F-FDG PET/CT. For malignant lesions, T/L and T/B in 11C-choline were significantly higher than in 18F-FDG PET/CT (T/L:1.39 ± 0.55 vs. 0.84 ± 0.32, $P < 0.05$;T/B:6.20 ± 3.25 vs. 1.56± 0.66, $P < 0.001$). There was no significant difference in T/L and T/B between 11C-choline and 18F-FDG PET/CT imaging for benign lesions. In addition, malignant lesions in 11C-choline PET/CT showed a 65.2% (21/30) gradual decrease in T/L from early phase to delayed phase, with average T/L of 1.38 ± 0.6 (early phase), 1.18 ± 0.39 (regular phase), and 1.02 ± 0.33 (delayed phase). Benign lesions in 11C-choline PET/CT maintained stable T/L across all phases, with average T/L of 0.61 ± 0.24 (early phase), 0.66 ± 0.35 (regular phase), and 0.68 ± 0.35 (delayed phase). Changes in T/B across the three phases of 11C-choline PET/CT imaging showed no significant differences for benign or malignant lesions. ***Conclusion:*** 11C-choline outperforms 18F-FDG PET/CT in differentiating between benign and malignant liver lesions, particularly demonstrating higher sensitivity for malignancy. Our study revealed that the trend of T/L in three-phase 11C-choline PET/CT imaging may be a superior predictor of hepatic focal benign and malignant lesions. Therefore, 11C-choline PET/CT imaging is more accurate than 18F-FDG PET/CT for the differentiation of benign and malignant liver lesions.

The value of ^{18}F-FDG PET/MR radiomic features in predicting the malignant degree of pancreatic intraductal papillary mucinous tumors(IPMN)

Y. Xu;
Hangzhou Universal Medical Imaging Diagnostic Center, Hangzhou, CHINA.

Aim/Introduction: The malignancy degree of pancreatic IPMN determines its surgical methods and whether to continue other treatments after surgery.The purpose of this study is to explore the value of ^{18}F-FDG PET/MR radiomics features in predicting malignant degree of pancreatic IPMN,thereby providing guidance for clinical treatment. ***Materials and Methods:*** The clinical and PET/MR imaging data of 189 patients with IPMN were collected, including 76 cases of Benign, 55 cases of borderline and 58 cases of malignant. Pathological and clinical diagnosis results serve as the gold standard for diagnosis. We used AK software to extract the most relevant imageomics features for tumor classification, and randomly divided the two groups of images into training set (70%) and test set (30%). The maximum correlation and minimum redundancy (mRMR) and minimum absolute shrinkage and selection operator (LASSO) methods were used to select features from 1800 features extracted from MR and PET, and finally 9 best features were retained. Multivariate logistic regression analysis was performed using the radiomics features and clinical variables to establish the prediction model. The receiver operating characteristic (ROC) analysis is used to evaluate the prediction model. ***Results:*** The established PET/MR imaging features have good prediction efficiency for distinguishing malignant degree of pancreatic IPMN($P<0.05$). The AUC of the training group and the validation group were 0.945 (95% CI: 0.787-0.956), 0.934 (95% CI: 0.776 - 0.945).The calibration curve showed that the nomogram of radiomics had goodness of fit, and DCA proved that the nomogram of radiomics was useful in clinical practice. ***Conclusion:*** The prediction model of PET/MR radiomics features can be used as an auxiliary method to predict the malignant degree of pancreatic IPMN. It can also provide objective basis for clinical diagnosis and individualized treatment, and may has guiding significance for clinical treatment.

EP-0210

^{68}Ga-PSMA PET/CT Imaging in Metastatic Medullary Thyroid Cancer: Preliminary Results of a Prospective Study

K. Sahin, *M. S. Sager, A. Kibar;*
Department of Nuclear Medicine, Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Istanbul, TÜRKIYE.

Aim/Introduction: Expression of the prostate-specific membrane antigen (PSMA) has been demonstrated in various malignancies, including medullary thyroid cancer (MTC), beyond prostate cancer. The detection of metastatic lesion with 68Ga-PSMA could offer an alternative radioligand treatment option for patients diagnosed with metastatic MTC with limited treatment choices. This study aims to investigate the feasibility of 68Ga-PSMA in patients diagnosed with metastatic MTC by comparing 68Ga-DOTATATE with 68Ga-PSMA positron emission tomography/computed tomography (PET/CT) imaging. ***Materials and Methods:*** This single-center prospective study included adult patients with metastatic MTC diagnosed due to pathological uptake (higher than background) in lesions on 68Ga-DOTATATE PET/CT within the last 9 months. Eligible patients underwent 68Ga-PSMA PET/CT imaging. Two radiopharmaceuticals were compared in terms

of the number and uptake patterns of the lesions. ***Results:*** A total of 6 patients, including 3 females with an average age of 56.5 ± 10.21, were included in the study. Eighty lesions, including 49 lymph nodes, 25 bones, 5 lungs, and 1 liver metastasis, were evaluated. Out of 80 lesions, 79 showed DOTATATE uptake (98.7%), while 71 showed PSMA uptake (88.7%). The median SUVmax values for DOTATATE and PSMA were 2.8 (0.73-17.6) and 3.04 (0.97-31.65), respectively. When comparing the two imaging methods, it was observed that the activity uptake of lesions showed a heterogeneous distribution among patients and within the same patient in three cases. In 4 patients, out of 49 detected lymph nodes, 6 (12.2%) showed no PSMA uptake, while 29 (59.2%) showed similar or lower levels compared to DOTATATE, and 14 lymph nodes (28.6%) showed higher levels of PSMA uptake than DOTATATE. Out of 25 bone metastases detected in 68Ga-DOTATATE PET, 3 (12%) showed no PSMA uptake, while 6 (24%) showed similar or lower levels, and 16 lesions (64%) showed higher levels of PSMA uptake than DOTATATE. In a patient with lung metastases, a total of 5 lesions showed similar or lower levels of PSMA uptake compared to DOTATATE. In one patient, a liver lesion that did not show uptake in DOTATATE PET showed intense PSMA uptake. ***Conclusion:*** This study suggests that the concurrent evaluation of 68Ga-DOTATATE and 68Ga-PSMA PET, due to the presence of metastatic lesions showing heterogeneous distribution among and within the same patients, could contribute to the personalized management of metastatic medullary thyroid cancer. Further studies with larger sample sizes are required to validate these results.

EP-0211

^{18}F-NOTATATE PET/CT non-invasive evaluation of SSTR2 expression in pediatric neuroblastoma

Y. Liu, *X. Sun;*
Department of Nuclear Medicine, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan , Shandong, CHINA.

Aim/Introduction: This study clarifies the feasibility of using 18F-NOTATATE positron emission tomography/computed tomography (PET/CT) to assess somatostatin receptors2(SSTR2)expression in patients with neuroblastoma (NB) by analyzing the correlation between 18F-NOTATATE PET/CT imaging parameters and immunohistochemistry(IHC) scores. ***Materials and Methods:*** Retrospective data were collected from patients with initial or treated NB who underwent 18F-NOTATATE PET/CT scans at Shandong Cancer Hospital between June 2021 and March 2023. Imaging and clinical data were collected, and lesions that were pathologically validated and accurately localized on PET/CT images were selected. uptake of the imaging agent in lesions was assessed using the Krenning score, maximum standardized uptake value (SUVmax), and mean standardized uptake value (SUVmean). Tumor tissue expression of SSTR2 was evaluated using the HER2, IRS, H, and Volante scores. Spearman's correlation test was used to analyze the correlation between the imaging parameters and SSTR2 expression. ***Results:*** A total of 71 lesions from 53 patients were analyzed, comprising 51 NB lesions, 9 lesions converted to ganglioneuroblastoma (GNB) after treatment, and 11 ganglioneuroma (GN) lesions. The SSTR2 scores and uptake of 18F-NOTATATE imaging agent were significantly higher in NB lesions compared to GNB and GN lesions. In both the overall cohort and NB subgroup, the Krenning score, SUVmax, and SUVmean were positively correlated with the four IHC scores ($p < 0.05$), with higher correlations observed with the HER2, IRS, and H scores (Rho ranged from 0.451 to 0.703). However, in the GNB and GN subgroups, no correlation was found between 18F-NOTATATE PET/CT imaging parameters and pathological scores ($p > 0.05$). ***Conclusion:*** 18F-NOTATATE PET/CT imaging can assess SSTR2 expression in newly diagnosed NB lesions or those remaining NB after treatment, serving as a valuable substitute for pathological scoring and providing molecular evidence for future follow-up and guidance for NB treatment.

EP-0212

Preliminary study on the related factors of diffuse nonspecific ^{68}Ga-FAPI uptake of pancreas in patients with gastrointestinal tumors

M. Wang, *J. Wang, F. Kang;*
Xijing Hospital, Xi'an, CHINA.

Aim/Introduction: In previous 68Ga-FAPI imaging studies, high heterogeneity of diffuse uptake of FAPI tracer in the pancreas of patients with gastrointestinal tumors was observed. The purpose of this study was to explore the related factors affecting pancreatic diffuse68Ga-FAPI tracer uptake in patients with gastrointestinal tumors. ***Materials and Methods:*** In this retrospective study, 68Ga-FAPI PET/CT images and patient records of 169 patients with gastrointestinal tumors with diffuse uptake pattern of pancreas were investigated for the correlation between the SUVmax, Pancreas-to-Liver ratio (PLR) values of pancreatic 68Ga-FAPI uptake and characteristics and outcome. ***Results:*** We observed that PLR was negatively correlated with body weight (R=-0.159, P=0.027), BMI (R=-0.161, P=0.016) and myocardial uptake (R=-0.21, P=0.003), while SUVmax was positively correlated with serum CA125(R=0.196, P=0.007) and PCT (R=0.328, P=0.002). In addition, the univariate analysis of SUVmax (7.07±4.57 vs.5.67±3.61, P=0.023) and PLR (4.91±3.40 vs.3.93±3.13, P=0.039) by t-test showed that operation was the influencing factor, while Chemotherapy (6.44±4.23vs.7.06±4.53, P= 0.338;4.48±3.23vs.4.86±3.60, P=0.452) and immunotherapy (7.59±4.45vs. 6.97±4.34, P=0.344;5.42±3.59vs.4.99±3.15, P=0.90) were not. Among them, there was a significant difference in the uptake whether it is surgery with impaired pancreatic structure (such as Whipple operation,14.37±6.57 vs.6.56±3.75,P<0.001) or surgery with impaired pancreatic function (radical distal gastrectomy or total gastrectomy,14.37±6.57 vs.6.51±3.8,P= 0.001;8.37±4.28vs.6.54±3.91,P=0.032), but whether proximal gastrectomy and colorectal surgery were performed or not will not cause the difference in uptake. There was a low negative correlation between SUVmax and operation interval (R=-0.15, P=0.043),PLR and the internal time of immunotherapy(R=-0.20,P=0.046). In addition, we found that there were differences in the factors affecting SUVmax and PLR at different cut-off values (4,5,6). ***Conclusion:*** Pancreatic diffuse 68Ga-FAPI uptake in patients with gastrointestinal tumors is negatively correlated with body weight and positively correlated with serum CA125 and PCT levels. The operating mode is an imaging factor that affects pancreatic uptake, especially pancreatic function and structural destruction. This provides a possible explanation for the diffuse nonspecific uptake of 68Ga-FAPI in the pancreas.

EP-0213

Assessing the long-term efficacy of PRRT on metastatic NET: application of a radiomics-based model on DOTA-peptide PET and contrast-enhanced CT

F. Fiz*[1]**, *G. Centurioni[2], L. Cavinato[3], L. Viganò[4], F. Ieva[3], C. la Fougère[2];
[1]Ospedale Galliera, Genova, ITALY, [2]University of Tübingen, Tübingen, GERMANY, [3]Polytechnic University of Milan, Milan, ITALY, [4]Humanitas Gavazzeni, Bergamo, ITALY.

Aim/Introduction: Peptide-receptor radiotherapy (PRRT) can treat liver metastases from differentiated neuroendocrine tumours (NET). Amenability to PRRT is evaluated with [68Ga] Ga-DOTA-peptide positron-emission tomography (DOTA-PET), yet tools to assess the long-term efficacy of PRRT in disease stabilisation are lacking. The characteristics of the tumour (such as the proliferation index Ki67%) and heterogeneity in tracer distribution across the metastatic lesions could influence the PRRT efficacy. We tested the effectiveness of clinical-radiomics models in predicting the time-to-progression (TTP) in a cohort of NET patients. ***Materials and Methods:*** All NET patients with liver metastases treated with PRRT at our institution (2013-2019) with at least 3 years of follow-up were reviewed. Radiomics features were extracted from up to five liver metastases per patient on the DOTA-PET and co-registered portal venous phase enhanced CT (pvCT) images, using LifeX® V. 6.3; to account for the presence of multiple lesions per patient, their standard deviation value was used. Feature reduction was then performed via recursive elimination; sequential models were constructed via a random forest machine learning algorithm using the clinical parameter and then adding the selected PET and CT features (clinical; clinical+PET; clinical+PET+CT). Cox regression was used to evaluate the impact of the features on TTP. The performance of the models was measured by evaluating their area-under-the-curve (AUC); the hazard ratio (HR) and the significance (p) of the single features were also computed. ***Results:*** Forty-nine patients (243 lesions) were included. Median TTP was 38 months (range 5-93). The clinical model had an average performance (AUC=65); its most significant variables were Ki67% (p=0.03) and Chromogranin A (CgA; p=0.007). The clinical+PET model performed better than the clinical one (AUC=71); other than the clinical parameters, GLZLM_SZE (HR: 1.57, p=0.034), SUV_Skewness (HR: 2.52, p=0.022), and GLZLM_LZLGE (HR: 1.54, p=0.052) were associated with TTP. Adding the pvCT features led to a further improvement (AUC=0.77); particularly, HUmax was associated with progression risk reduction (HR:0.42, p=0.003). ***Conclusion:*** Radiomics analysis significantly improves the prediction of disease progression in patients with NET liver metastases. Features from both DOTA-PET and pvCT appear synergic with the clinical indices. Particularly, PET patterns indicating high uptake variability and large areas of lower uptake (as in intratumoral necrosis) were associated with risk increase, while high CT density (such as in increased vascularisation) proved protective. These data suggest that radiomics and machine learning can improve metastatic NET patients' prognostic evaluation.

EP-0214

Assessment of Gastroenteropancreatic Neuroendocrine Tumors Using SSTR-RADS 1.0 Criteria.

***M. Vaillant López**, M. Zapardiel Martínez-Falero, P. Nespral Torres, P. Daudén Oñate, G. Cuesta Domingo, A. Berardinelli Isea, J. Sastre Valera, R. Couto Caro, M. Cabrera-Martín;*
Hospital Clínico San Carlos, Madrid, SPAIN.

Aim/Introduction: To determine the correlation between SSTR-RADS 1.0 criteria for 68Ga-DOTATOC PET-CT and definitive diagnosis in gastroenteropancreatic neuroendocrine tumors (GEP-NET). ***Materials and Methods:*** Retrospective analysis of patients who underwent 68Ga-DOTATOC PET-CT with i.v. iodinated contrast agent by GEP-NET between August/2019 and December/2023. Two nuclear medicine physicians with >15 years of experience determined SSTR-RADS (1-5) and uptake score (1-3) (Werner et al, J Nucl Med 2018;59:1085-91). Categories 4/5 were considered positive for NET, 1/2 negative for NET. Category 3 was the most controversial of the different subcategories and required further individualised analysis. Histopathological examination (HE) or clinical follow-up (CFU) was considered the gold standard. SP, E, PPV and NPV were calculated. A χ^2 test and logistic regression were performed. ***Results:*** 77 patients (45 males), mean age 63.5 (25-87 years), with suspected or diagnosed GEP-NET. The gold standard was HE (n=28) or CFU (n=49; mean 19.16 months). In 11 cases of suspected neoplasia, GEP-NET was not confirmed by imaging or CF. Of the 66 patients with NET, 38 had stage III-IV disease. Most of the NETs were located in the pancreas (n=33) and small intestine (n=31), 4 were MEN-1. Of the 66 GEP-NET: G1 (n=47), G2 (n=17) and G3 (n=2). The most common metastatic sites were regional lymph nodes (28.6%) and liver (29.9%). SP=100%, E=76%, PPV=90%, NPV=100%. An association was found between SSTR-RADS 1.0 classification and NET diagnosis (χ^2=58.625, p-value<0.001). Logistic regression showed a capacity for correct SSTR-RADS classification of 85.7%. In categories 4 and 5, 100% (n=47) showed tumor. In category 3 (n=13) only 38.5% (2/2 labelled as 3A and 3/9 of 3D) showed NET. In 3C, none (n=2) corresponded to NET. In category 1 (n=17) 17.6% had NET. ***Conclusion:*** The SSTR-RADS 1.0 criteria allow the correct diagnosis of NET in a high percentage of patients. Category 3, especially 3D, requires further confirmation. ***References:*** Werner et al, J Nucl Med 2018;59:1085-91

EP-0215

Head to head comparison of [18F]SiTATE versus [18F]DOPA-PET in patients with neuroendocrine tumors

***W. Roll*[1]**, *P. Hadjitheodorou[2], E. Alevroudis[2], K. Kyrou[2], G. Adamou[2], A. Fesas[2], M. R. Pourkhessalian[2], C. Kalogirou[2], I. Tsechelidis[2], M. Schäfers[2], A. Vrachimis[2];*
[1]Department of Nuclear Medicine, University Hospital Münster, Münster, GERMANY, [2]Department of Nuclear Medicine, German Oncology Center, Limassol, CYPRUS.

Aim/Introduction: In neuroendocrine tumors molecular imaging methods play a key role, either targeting the somatostatin receptor (SSTR) or catecholamine pathways. [18F]SiTATE is a novel SSTR-targeting peptide that uses silicon fluoride acceptor (SiFA) radiochemistry, overcoming disadvantages of Gallium-68 labelled DOTA compounds. Here we present the first prospective data of [18F]SiTATE compared to [18F]DOPA-PET in NET patients. ***Materials and Methods:*** 38 patients with suspected NET were prospectively included. All patients underwent both [18F]DOPA-PET and [18F]SiTATE-PET. The diagnostic performances were compared on a per-patient and per-lesion basis. ***Results:*** 22 of 38 patients did not show [18F]DOPA- or [18F]SiTATE-PET positive disease. [18F] DOPA-PET was rated as the more accurate imaging modality in three cases and [18F]SiTATE-PET in four cases. [18F]SiTATE-PET showed a significantly higher sensitivity on a per lesion basis compared to [18F]DOPA-PET (n=143; sensitivity [18F]SiTATE: 86.7%; [18F]DOPA: 73.4%; p = 0.016). Relative quantitative uptake values were not significantly different ([18F]SiTATE median TBRmax: 8.2; [18F]DOPA TBRmax: 6.5; p=0.247) ***Conclusion:*** In this first prospective study,

[18F]SiTATE-PET provides high tumor to background ratios in the majority of NET patients with complementary results to [18F]DOPA-PET. ***References:*** Ilhan H, Lindner S, Todica A, et al. [68Ga]Ga-DOTANOC PET/CT-Derived Functional Parameters to Predict Response to PRRT: Preliminary Results

E. Fortunati[1], *L. Zanoni[1], M. Di Franco[2], N. Bonazzi[2], C. Mosconi[3,4], F. Porta[3], V. Zybin[3], D. Campana[3,5], C. Malizia[1], E. Andrini[5], G. Lamberti[5], V. Allegri[1], E. Lodi Rizzini[6], A. Morganti[6], S. Fanti[1,2], V. Ambrosini[1,2];*
[1]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [2]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [3]DIMEC, Alma Mater Studiorum, University of Bologna, Bologna, ITALY, [4]Radiology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [5]Medical Oncology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [6]Radiation Oncology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: To define predictive parameters of PRRT (Peptide Receptor Radionuclide Therapy) response is a current unmet need. Aim is to study potential predictive [68Ga]Ga-DOTANOC-PET/CT-derived parameters in a monocentric cohort of NET patients who underwent PET/CT before/after a full course of PRRT (4 cycles of [177Lu]Lu-DOTATATE PRRT) according to standard practice. ***Materials and Methods:*** Among the NET patients treated with a full course of PRRT at our Institution (July2019-April2023), we included those studied with [68Ga]Ga-DOTANOC PET/CT within 4 months of the PRRT and clinical follow-up of at least one year. PET parameters measured before/after PRRT included: lesionSUVmax, lesionSUVmean, lesionSUVmax/lesionSUVmean, liverSUVmax, liverSUVmean, lesionSUVmax/liverSUVmean, RTV (receptor tumour volume), TLA (total lesion activity=SUVmean x RTV), pTC-HU (hottest lesion's HU pre-PRRT on non-diagnostic-CT) and percentage variations of pHU, RTV and of TLA. RTV/SUVmean pre-PRRT was also calculated. ROC-curves were used to search for the best PET cut-off values. Log-rank test was applied to compare TTP (timeframe between baseline PET/CT and disease progression) survival curves.In the patients with a diagnostic-CT performed at our center within 4 months of PRRT, disease status was assessed according to RECIST 1.1 and compared to other response criteria (Choi, EORTC). Additionally, since NET lesions are generally better appreciated in the arterial phase, modified-Choi criteria (mChoi, assessed on the arterial phase) were also employed. ***Results:*** 34 patients were included (G1:G2=10:24; primary tumour site=19/34 ileum, 11/34 pancreas, 2/34 rectum, 1/34 duodenum, 1/34 primary of unknown origin). When survival curves (Kaplan-meyer) were created using the best cut-off values as threshold, patients with values lower than the cut-off showed significantly longer TTP: lesionSUVmax/lesionSUVmean pre-PRRT (<1.74; p=0.0098), RTVpost-RTVpre (<6.6cm3; p<0.0001), TLApost-TLApre (<24.8; p<0.0001), percentage variation of pHU (<28%; p=0.018), percentage variation of RTV (<12%; p<0.0001) and of TLA (<7.5%; p=0.00015), RTV/SUVmean pre-PRRT (<5.2; p=0.0028). Univariate analysis showed a significant association between shorter TTP and higher values of lesionSUVmax/lesionSUVmean pre-PRRT (p=0.016), RTV/SUVmean pre-PRRT (p=0.006) and percentage variation of RTV (p=0.025) and of TLA (p=0.0027). Disease status categorised as SD, PR, PD was: according to RECIST 1.1 12/24, 5/24, 7/24; to EORTC 6/24, 15/24, 3/24; to Choi 6/24, 9/24, 9/24; to mChoi 6/22, 8/22, 8/22 (mChoi was not available in 2/24). Concordance rate with standard RECIST 1.1 criteria was 29% (7/24) for EORTC, 67% (16/24) for Choi and 72% (16/22) for mChoi. ***Conclusion:*** Our data show that response evaluation varies significantly using different response criteria. Some [68Ga]Ga-DOTANOC PET/CT-derived parameters can be used to predict patients'TTP.

EP-0217

Comparison of FDOPA PET/CT and MRI for the diagnosis and follow-up of pheochromocytomas and paragangliomas

L. Rodríguez Díaz, *C. Vigil Díaz, S. Naranjo Sancho, A. Álvarez Amigo, A. Laverde Mächler, A. Álvarez Alonso, S. Menéndez Sánchez, M. L. Domínguez Grande, M. B. Fernández Llana, N. Martín Fernández, V. Pascual Pascual, F. M. González García; Hospital Universitario Central de Asturias, Oviedo, SPAIN.*

Aim/Introduction: Pheochromocytomas (PCC) and paragangliomas (PGL) are rare neuroendocrine tumors derived from adrenal or extra-adrenal neural crest chromaffin cells. Nuclear medicine imaging plays an important role in the diagnosis, staging, and follow-up of these patients. Precise imaging follow-up is essential, given the high risk of tumor recurrence in these patients. The aim of this study is to determine whether 6-I-[18F]-fluoro-3,4-dihydroxyphenylalanine PET/CT (FDOPA PET/CT) is an accurate technique for the diagnosis and follow-up of these patients. ***Materials and Methods:*** Retrospective study including 57 patients (18 male, 39 female; age range 18-85 years) (24 with known disease, 33 with no medical history of PCC/PGL), who underwent FDOPA PET/CT study between January/2021-December/2023. MRI and FDOPA PET/CT qualitative and semi-quantitative findings were studied. ***Results:*** 63 FDOPAPET/CT studies were performed, in which pathological findings were seen in 31/63: 5 PCC, 24 PGL and 2 PCC/PGL (18 carotid body, 6 jugulotympanic, 6 tympanic, 5 jugular, 1 bladder wall and 1 pericardial PGL). Mean SUVmax for PCC and PGL was 12.98 and 10.38, respectively. Follow-up FDOPAPET/CT studies were performed (2 patients with SDH gene mutations with no PCC/PGL history, and 21 with PCC/PGL history, out of which 12 had SDH gene mutations). The remaining studies were performed to evaluate extension and multicentricity (14 SDH gene mutation screening, 9 incidentalomas and 17 due to clinical symptoms or high metanephrines/catecholamines). 24 patients underwent MRI study at the time of FDOPA PET/CT evaluation. In our series, MRI and FDOPA PET/CT results were discordant in 5/24 patients, leading to a change in therapeutic management in 2. FDOPA PET/CT study ruled out PCC/PGL in 3 patients with positive MRI findings (2 laterocervical nodes and 1 lesion compatible with vagal PGL surgical remains). 1 PGL (1 post-surgical disease) and 1 PCC were diagnosed in patients with normal MRI. 3 patients presented with progression during FDOPA PET/CT follow-up. ***Conclusion:*** Our results demonstrate that FDOPA PET/CT should be alongside with the MRI, an imaging technique of choice for both diagnosis and

follow-up of these patients. FDOPA PET/CT provides an accurate diagnostic method for whole-body evaluation and metabolic response assessment with high accuracy and changes patient outcome.

EP-0218

Comparing ^{18}F-DOPA and 68Ga-DOTATOC PET/CT imaging performance and its impact on 177 Lu-DOTATATE outcome in midgut neuroendocrine tumors

***A. Coccarelli*[1,2],** *T. Henry[2], M. Longo[2], T. Khamoun[2], S. Morbelli[1], L. Lamartina[3], F. Pani[3], S. Moog[3], J. Hadoux[3], E. Baudin[3], D. Deandreis[2];*
[1]Nuclear Medicin Unit, AOU Città della Salute e della Scienza di Torino, University of Turin, Turin, ITALY, [2]Gustave Roussy, Nuclear Medicine Division, Department of Medical Imaging, F-94805, Villejuif, Paris, FRANCE, [3]Gustave Roussy, Endocrine Oncology Division, F-94805, Villejuif, Paris, FRANCE.

Aim/Introduction: ^{18}F-DOPA PET/CT is a useful diagnostic tool to evaluate tumor burden in midgut neuroendocrine tumor (NET). On the other hand, 68Ga-DOTATOC is the diagnostic counterpart of 177 Lu-DOTATATE (Lutathera) and necessary for patient selection. The aim was to evaluate if ^{18}F-DOPA imaging is associated with 177 Lu-DOTATATE outcome in patients with positive pre-treatment 68Ga-DOTATOC. ***Materials and Methods:*** All patients with midgut NET that performed ^{18} F-DOPA and 68 Ga-DOTATOC PET before 177 Lu-DOTATATE were retrospectively evaluated. Only patients with both imaging performed within one year before treatment were included. The tumor burden from DOPA and DOTATOC PET was visually compared and patients were classified in 2 groups: Group 1 (G1): DOPA ≥ DOTATOC, Group 2 (G2) : DOPA < DOTATOC. The response was defined according to RECIST1.1 after C2 (n=16/18 patients) and after C4 (n=13/18 patients) of 177 Lu-DOTATATE. Follow-up duration was calculated using first treatment as the starting point. Statistics were computed using R version 4.3.2. ***Results:*** Among 35 evaluated patients, 18 patients treated between 2015-2023 fulfilled inclusion criteria and were analyzed. 61.1% of patients were female (n=11) and the median age was 69 (IQR [56, 74]). Median Ki67 of the tumor was 2% (IQR [1-5]). Patients received a median of 4 treatments of 177 Lu-DOTATATE (range: 1-8). In 77.8% of the cases, 18FDOPA was equal or better than 68GaDOTATOC (n=14/18, IC95 [51.9-92.6], p=0.031). In the remaining 4/18 68GaDOTATOC was superior compared to 18F DOPA. In G1, 2/9 (22.2%), 6/9 (66.7%) and 1/9 (11.1%) presented respectively partial response (PR), stable disease (SD) and progressive disease (PD) at C4. In G2, 1/4 (25%), 1/4 (25%) and 2/4 (50%) presented respectively PR, SD and PD. Median SUVmax of the most intense lesion at 68GaDOTATOC was 30.90 [20.47, 35.60]. Median Follow up after treatment was 25 months. At the end of follow up (n = 3 - 16,7%) patients died. No association were found between DOPA findings and survival, nor between DOTATOC SUVmax of the most intense lesion and survival (respectively p=1 and p=0.98). ***Conclusion:*** DOPA was superior to DOTATOC imaging for lesion mapping in most of patients with metastatic midgut NET treated with 177 Lu-DOTATATE and not associated with response or survival outcome. Larger studies are warranted to better evaluate the potential prognostic value of ^{18}F DOPA PET and impact of lesion mismatch in such patients.

EP-0219

Combined Prognostic Value of Tumor Dissemination (Dmax) and Coefficient of Variation Derived from 68Ga-DOTATOC PET/CT in Patients With Neuroendocrine Tumors

***S. Pellegrino*[1],** *R. Fonti[1], M. Panico[1], R. Morra[2], G. Palmieri[2], A. Servetto[2], R. Bianco[2], S. Del Vecchio[1];*
[1]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [2]Department of Clinical Medicine and Surgery, University Federico II, Naples, ITALY.

Aim/Introduction: The aim of the present study was to test whether the largest distance between two 68Ga-DOTATOC avid lesions (Dmax) and other quantitative imaging parameters may predict overall survival in patients with neuroendocrine tumors (NET). ***Materials and Methods:*** Forty-three NET patients (30 men, 13 women) who had undergone 68Ga-DOTATOC PET/CT scan showing at least two positive lesions were included in the study. All lesions were segmented using an automated contouring program. The largest distance between two 68Ga-DOTATOC avid lesions (Dmax) in each patient was measured. Then the targeted lesion with the highest SUVmax value was selected and SUVmean, Coefficient of variation (CoV), Receptor Expressing Tumor Volume (RETV) and Total Lesion Receptor Expression (TLRE) were determined along with total RETV (RETVTOT) and whole-body TLRE (TLREWB) from all malignant lesions. Univariate analysis of clinical and imaging variables was performed using Cox proportional hazards regression whereas Kaplan-Meier method and log-rank tests were used for survival analysis. Patients were subjected to a mean follow-up period of 29 months (range 1-59 months). ***Results:*** A total of 236 lesions were segmented and mean Dmax value was 22.52±21.62 cm. In 43 targeted lesions, average values of SUVmax, SUVmean, CoV, RETV and TLRE were 40.22±30.69, 13.21±10.80, 0.57±0.24, 51.96±65.48 mL and 643.58±868.19 g, respectively, whereas mean values of RETVTOT and TLREWB were 170.07±186.59 ml and 2365±4060.43 g, respectively. Univariate analysis was performed including age, gender, grading, Dmax, RETVTOT, TLREWB and imaging parameters derived from targeted lesions. Overall survival (OS) was predicted by age (p<0.0001), grading (p=0.0064) and Dmax (p=0.0168) as well as by SUVmax (p=0.0011), SUVmean (p=0.0087) and CoV (p=0.0005) of targeted lesions. By Kaplan-Meier analysis, patients with Dmax ≤ 19.4 cm had significantly better OS as compared to patients with Dmax > 19.4 cm (p=0.0137). Moreover, patients with CoV of targeted lesions > 0.57 had a better prognosis compared to those with CoV ≤ 0.57 (p=0.0019). When we combined these two parameters in all possible arrangements, a statistically significant difference was found among the four survival curves (p=0.0022). In particular, patients with Dmax > 19.4 cm and CoV of targeted lesions ≤ 0.57 had the worst prognosis. ***Conclusion:*** Dmax, by reflecting tumor dissemination, and CoV of targeted lesions, by revealing heterogeneity of somatostatin receptor expression, can predict overall survival in NET patients.

Dual-Time-Point ^{18}F-FDG PET/CT Imaging in the Assessment of Advanced Colorectal Neoplasms in Patients with Focal Colorectal ^{18}F-FDG Uptake

Y. Ma, *M. Zhou;*
The Third Affiliated Hospital of Soochow University, Changzhou, CHINA.

Aim/Introduction: This study aims to investigate the diagnostic efficacy of dual-time-point 18F-FDG PET/CT in detecting advanced colorectal neoplasms in patients with focal colorectal 18F-FDG uptake. ***Materials and Methods:*** A retrospective analysis was conducted on patients who underwent dual-time-point 18F-FDG PET/CT scans between January 2019 and December 2023. Patients showing focal colorectal 18F-FDG uptake in both early and delayed scans, and subsequently undergoing colonoscopy within one month, were included in the study. Advanced colorectal neoplasm was defined as an adenomatous polyp larger than 10 mm in diameter and/or with villous histology and/or presenting with high-grade dysplasia or adenocarcinoma. The maximum standardized uptake value (SUVmax) in the early and delayed scans, as well as the retention index, were compared between advanced colorectal neoplasms and non-advanced lesions. Predictive factors for advanced colorectal neoplasms were identified by uni- and multivariable analysis. ***Results:*** A total of 122 patients were enrolled in this study. A total of 141 lesions was studied, 80 (56.7%) of which were diagnosed as advanced colorectal neoplasms. When compared with non-advanced lesions, advanced colorectal neoplasms had higher SUVmax in delayed scan (25.1±14.2 vs 14.5±7.5, P<0.001), and higher retention index (32.9%±25.4% vs 7.8%±28.4%, P<0.001) in dual-time-point PET/CT. SUVmax in delayed scan (odds ratio [OR],1.084; 95% confidence interval [CI]: 1.037, 1.134; P<0.001) and retention index (OR, 20.120; 95% CI: 4.068, 99.516; P<0.001) were identified as independent predictors for advanced colorectal neoplasms by multivariable logistic regression analysis. When combining the SUVmax in the delayed scan with the retention index, the sensitivity and specificity for predicting advanced colorectal neoplasms were found to be 65.0% and 80.3%, respectively. Based on the threshold values of SUVmax in the delayed scan and retention index, we observed prediction rates of 13.9% (5 out of 36), 58.6% (34 out of 58), and 87.2% (41 out of 47) for advanced colorectal neoplasms in the low-, moderate-, and high-risk subgroups, respectively. ***Conclusion:*** Dual-time-point PET/CT aids in distinguishing lesions with focal colorectal 18F-FDG uptake. Higher SUVmax in delayed scan and higher retention index are predictive factors for advanced colorectal neoplasms.

EP-0221

The Role of PET/MRI Parameters of Primary Tumor in Predicting Pathological Response and Recurrent Disease after Neoadjuvant Therapy in Rectal Cancer

E. Tuncay Ibis, *S. Demir, U. Aydos, E. Balcı, L. Atay;*
Gazi University Faculty of Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Neoadjuvant treatment (NAT) in rectal cancer reduces the risk of recurrence and prolongs survival in locally advanced stage patients. PET/MRI is emerging as an important tool in response evaluation with its multiparametric evaluation opportunities. This study aimed to evaluate the role of quantitative parameters and radiomic features of primary tumor obtained from FDG PET/MRI in rectal cancer for predicting pathological response and recurrent disease after surgery. ***Materials and Methods:*** The data of 33 patients with rectal cancer who underwent FDG PET/MRI for primary staging and treatment response evaluation after NAT, and subsequent surgical resection were evaluated retrospectively. SUVmax, SULpeak, MTV, TLG and ADCmin values of primary tumors and the percentage changes between two images were obtained from staging and response evaluation PET/MR images. Radiomics features of primary tumors were also obtained by using LIFEx-7.2.0 software. Logistic regression analyses were performed to determine the predictive factors for histopathological complete or near-complete response (Ryan regression score 0-1) and a decision tree model was created with the significant variables. Cox regression analyses were performed to determine the prognostic factors for the prediction of recurrence after surgery. Survival curves were estimated by the Kaplan-Meier method. Statistical analyses were performed on SPSS version 23.0. ***Results:*** The pathological complete/near-complete response was observed in 12 patients (36.4%). A decision tree model was created for prediction of treatment response after NAT with the significant variables, post-treatment ADCmin_2 (>85.5), ADCmin change (≥ 77%) and post-treatment tumor zone size nonuniformity (GLSZM_ZSNU_2) radiomics feature (≤24.8). The accuracy of the model was 94%. Recurrent/progressive disease was observed in 13 patients (39.4%) after resection. In univariate Cox regression analyses, ADCmin_2, TLG change and GLSZM_ZSNU_2 were significantly associated with progression-free survival (PFS). In multivariate regression analysis, ADCmin_2 and TLG change were found as independent prognostic factors (p=0.013, p=0.03, respectively). The Kaplan-Meier survival analysis showed that lower TLG change (< 85%), lower ADCmin_2 (≤ 85) were significantly associated with lower PFS rates (27.3% vs 77.3%, p=0.018; 41.2% vs 81.3%, p=0.006, respectively). ***Conclusion:*** ADCmin values and tumor heterogeneity parameter, ZSNU of primary tumor had predictive values in early pathological response assessment in patients with rectal cancer. Conversely, persistent high cellularity and insufficient metabolic-volumetric changes after NAT correlated with disease recurrence. Further studies with larger patients are needed to confirm these findings.

EP-0222

^{18}F-FDG PET/CT for treatment response prediction and evaluation in patients with liver metastases from colorectal carcinoma undergoing SBRT

G. Mateva, *P. Bochev, I. Kostadinova, M. Garcheva, N. Velikova, N. Novoselska;*
Acibadem CityClinic Mladost, Sofia, BULGARIA.

Aim/Introduction: The aim of the study was to investigate the role of ^{18}F-FDG PET/CT for treatment planning and response evaluation in patients with colorectal carcinoma undergoing stereotactic body radiation therapy (SBRT) for liver metastasis Additionally, we looked at the importance of certain metabolic parameters as predictive markers for the treatment response. ***Materials and Methods:*** We retrospectively analysed 22 patients with metastatic colorectal cancer who underwent SBRT for a total of 35 liver metastases. Each patient underwent a staging PET/CT scan prior to the procedure, as well as a follow-up PET/CT scan 3 to 6 months later. The local response for the treated lesions and the overall response were evaluated using PERCIST criteria. We measured and correlated pretherapy values for SUVmax, SUVmean, metabolic tumour volume (MTV) and total lesion glycolysis (TLG) with the treatment outcome. ***Results:*** When looking at overall response rates on the follow-up scans on a patient basis, 15 patients (68.2%) had progressive metabolic

disease (PMD), 3 (14,6%) had partial response (PMR) and 4 (18,2) of them had complete metabolic response (CMR). When looking at local treatment response a on lesion basis, there were 10 lesions with (28,6%) PMD, 13 lesions (37.1%) had PMR and 12 lesions (34,3%) with CMR. In all of the cases of CMR there were residual metabolically unactive hypodense lesions on the low-dose CT. In none of the cases there was uncertainty in the interpretation of the treatment response. In our study, the liver lesions that did not respond well to the treatment (PMD) had significantly higher initial values of MTV (MTVmedian=21.85; MTVmean=54.05-) and TLG (TLGmedian=108; TLGmean= 370.163) compared to those with PMR (MTVmedian=15.6; MTVmean= 25.5; TLGmedian=92.1; TLGmean=133.9) and CMR (MTVmedian=11.2; MTVmean= 18.2; TLGmedian=44.4; TLGmean=115.1). The initial values of SUVmax and SUVmean did not demonstrate patterns that could be clearly connected to the treatment outcome. ***Conclusion:*** In conclusion, ^{18}F-FDG PET/CT is a useful tool for treatment response assessment in patients who received SBRT for colorectal cancer liver metastases. Some metabolic parameters, such as MTV and TLG, might have predictive value for treatment response.

PSMA PET Imaging for Detection of Mesorectal Lymph Node Metastases in Prostate Cancer Impact on Patient Management and Treatment Strategies

M. Haidar, *M. Hijazi, A. Armache, N. Saliba, N. El Ghawi, N. Omran, B. El Baba, A. El Hajj, A. Abi ghanem;*
AUB, Beirut, LEBANON.

Aim/Introduction: This study aims to assess the accuracy of 68Ga-PSMA PET/CT in the detection of mesorectal lymph node (LNs) metastases in prostate cancer, as well as the importance of early identification LNs on patient management and treatment strategies. The predicted ability of 68Ga-PSMA PET/CT to alter patient management is achieved through the identification of additional LNs that affect prostate cancer staging. The potential of 68Ga-PSMA PET/CT to impact patient treatment has received little attention in the existing prostate cancer literature. ***Materials and Methods:*** This retrospective study includes 408 patients with prostate cancer who underwent 68Ga-PSMA PET/CT from 2016 to February 08, 2023. The following parameters were assessed: PSA levels at the time of PET/CT, location, number, and size of positive mesorectal LNs, and subsequent therapy. ***Results:*** Out of the 408 patients, 241 (59%) showed multiple radiotracer avid lymph nodes in the pelvic, pre sacral, mesorectal, and retroperitoneal LNs. Within this group, 27 (27/241 = 11%) had increased uptake in the perirectal, mesosigmoid, and retroperitoneal LNs, among these patients, 20 (20/241 = 8%) had multiple radiotracer avid sub centimetric lymph nodes in both mesosigmoid and mesorectal regions only in keeping with metastatic lymph nodes. The nodal involvement in the pelvic region was thoroughly examined, with 895 nodes detected in various locations. The prevalence of nodes in the common iliac, external iliac, and internal iliac regions was found to be 19.9%, 27.2%, and 21.0%, respectively. The paraortic and interaortocaval areas accounted for 2.02% and 1.46% of the total number of LNs. Mesorectal nodes made up 9.52% of LNs, indicating a significant proportion. Furthermore, 6.6% pre-sacral nodes and 5.0% pelvic sidewall nodes were involved. Of the total number of patients, 43.6% had common iliac LNs, 59.9% had external iliac LNs, 46.0% had internal iliac LNs, 20.8% had mesorectal LNs and 14.5% had pre-sacral LNs (figure 1). A detailed breakdown highlights the distribution of nodal involvement in various pelvic regions, providing useful insights for clinical evaluation and treatment considerations. ***Conclusion:*** In conclusion, this retrospective study demonstrated 68Ga-PSMA PET/CT ability to detect sub centimetric metastatic mesorectal LNs and improve prostate cancer staging. Thus, result influences patient management and treatment strategies by distinguishing between operable and non-operable cases of prostate cancer. ***References:*** 1-Hijazi S et al. EP-0224

An Innovative Approach with Ga-68 PSMA PET/CT: The PRIMARY Scoring System

N. Aydin, *G. Mutevelizade, B. C. Bozdemir, E. Sayit Bilgin;*
Celal Bayar University, Manisa, TÜRKIYE.

Aim/Introduction: Multiparametric magnetic resonance imaging is validated to diagnose clinically significant prostate cancer (csPCa). It has been demonstrated that the Ga-68 PSMA PET/CT-based PRIMARY scoring system (PSS) significantly improves sensitivity and negative predictive value in detecting csPCa. This study aims to investigate the relationship between PRIMARY score and histopathological findings in patients diagnosed with csPCa, undergoing staging with Ga-68 PSMA PET/CT imaging, and to evaluate the consistency of this scoring system among readers. ***Materials and Methods:*** Fifty-one patients with histopathologically diagnosed prostate cancer before prostatectomy underwent Ga-68 PSMA PET/CT and were included in the study. Retrospectively, staging Ga-68 PSMA PET/CT images were evaluated by three different nuclear medicine physicians blinded to each other unaware of the clinical, histopathologic, and laboratory findings. PRIMARY score were determined according to intraprostatic involvement patterns (1). PRIMARY score were compared with ISUP Grade Group (GG), serum PSA levels, and histopathological findings. ***Results:*** The mean age of participants was 71.2±7.4 years, with an average PSA level of 80.8±217.4 ng/ml. TUR-P was performed on 32 patients, and Total Prostatectomy on 19, with pathology reports classifying 1 patient as GG1, 10 as GG2, 4 as GG3, and 36 as GG5. According to PRIMARY Score analyses, 17 (33.3%) patients were assigned Score 2, 6 (11.8%) Score 4, and 28 (54.9%) Score 5. A statistically significant relationship was observed between PRIMARY Score, GG, and PSA levels ($p<0.001$, $p=0.046$, respectively). High concordance was found among nuclear medicine physicians' PRIMARY scoring ($p<0.001$). High-risk patterns (PRIMARY Score 4 and 5), were identified in 34 patients (66.7%), with a higher incidence of cribriform pattern ($p=0.036$); and also higher serum PSA levels were detected in this group ($p=0.034$). ***Conclusion:*** Our findings suggest that the PSS could be a potential tool in staging and managing csPCa. Moreover, the study establishes that PSS can be used as an objective and reliable evaluation method with high inter-reader agreement. The significant correlation between cribriform pattern, a marker of poor prognosis, and PRIMARY score is noteworthy. Our research indicates the satisfactory performance of the PSS in the early and effective detection and management of prostate cancer, though further extensive studies are required for validation. ***References:***

EP-0225

The Intra- and Interobserver Variability of PSMA-expression Scores in Patients with Primary Prostate Cancer

M. Donswijk[1], *R. H. Ettema[2], S. van der Gaag[2], M. Wondergem[3], Z. Cheung[1], H. G. van der Poel[1], A. N. Vis[2], D. E. Oprea-Lager[2];*
[1]Antoni van Leeuwenhoek - Netherlands Cancer Institute, Amsterdam, NETHERLANDS, [2]Amsterdam University Medical Centres, Amsterdam, NETHERLANDS, [3]Noordwest Ziekenhuisgroep, Alkmaar, NETHERLANDS.

Aim/Introduction: The 4-point PSMA-expression score of prostate cancer lesions, according to the PROMISE criteria, is widely used for clinical and research purposes. This study aimed at determining the intra- and interobserver variability in the assessment of the PSMA-expression score of the primary prostate tumour in 100 patients staged with PSMA PET/CT. ***Materials and Methods:*** The observer agreement of visually assessed PSMA-expression scores according to PROMISE criteria was determined both before and after consensus training (CTR). This was compared to a quantification-based PSMA-expression score using SUVmax in the primary prostate tumour and reference organs. ***Results:*** The intra-observer agreement of the visually assessed PSMA-expression score of the primary prostate tumour was nearly perfect (κ 0.87), while interobserver agreement was only moderate and significantly lower (κ 0.57). After CTR, visual interobserver agreement improved (κ 0.70). Using quantitative analysis, the interobserver agreement further improved (κ 0.80). The intra-observer agreement of the visually assessed (after CTR) and quantification-based PSMA expression scores was nearly perfect (κ 0.92). Remarkably lower interobserver agreement rates were seen for [18F]PSMA-1007 compared to [18F]DCFPyL and [68Ga]Ga-PSMA-11. ***Conclusion:*** The intra-observer agreement of visually assessed PSMA expression scores was nearly perfect, while interobserver variability was only moderate. Consensus training and application of a quantification-based assessment using SUVmax further improved interobserver agreement rates.

EP-0226

Synthesis and in vitro evaluation of a small molecule [99mTc]Tc-PCBM as potential PD-L1 imaging agent

Y. Xu[1], *X. Xu[2], Y. Mao[2], C. Lu[1], P. Zou[1];*
[1]NHC Key Laboratory of Nuclear Medicine, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, WuXi, CHINA, [2]School of Pharmacy, Nanjing Medical University, Nanjing, CHINA.

Aim/Introduction: The checkpoint blockade immunotherapy of PD-1/PD-L1 has become a potent treatment strategy for cancers. However, the objective response rate of this immunotherapy is below 30%, which is expected to be improved. Expression level of PD-L1 play a key role in the guidance of immunotherapy, which could be quantified by noninvasive imaging with radiotracers. In this study, we develop a 99mTc labeled small molecule compound for PD-L1 imaging. ***Materials and Methods:*** The labeling precursor N - [2 - (3-cyanobenzene-1-methoxy) - 4 - (2- bromo-3-phenylbenzyloxy) - 5-chlorobenzyl] -2-piperidylglycylglycylglycylcysteine (PCBM) was synthesized from 2-bromo-3-iodotoluene in a seven-step reaction sequence. Using SnCl2 as reducing agent, and in the presence of sodium glucoheptonate, a series of studies were performed to optimize labeling efficiency of [99mTc]Tc-PCBM. The radiolabeling yield (RLY) and radiochemical purity (RCP) of [99mTc]Tc-PCBM were determined by high performance liquid chromatography (HPLC). The in vitro stabilities of [99mTc]Tc-PCBM was determined every 1h at room temperature. The partition coefficient of [99mTc]Tc-PCBM was determined in n-octanol and phosphate buffer (PB) (pH 7.4) and the uptake of [99mTc]Tc-PCBM was performed in PD-L1 positive cell (A375-hPD-L1) and PD-L1 negative cell (A375). ***Results:*** The chemical structures of the labeling precursor and its intermediates were verified by IR, 1HNMR and MS. RLY and RCP of [99mTc]Tc-PCBM were over 95% at selected condition. [99mTc]Tc-PCBM was stable up to 6 h in phosphate-buffered solution (PH=7.4) and radiochemical purities was over 90% at selected condition. Partition coefficient (lgP) of [99mTc]Tc-PCBM was 1.5 at pH 7.4 of the phosphate buffer. The uptake of [99mTc]Tc-PCBM in A375-hPD-L1(20.96%) cell is significantly higher than that in A375(4.75%) cell after co-incubated for 4 hours. ***Conclusion:*** [99mTc]Tc-PCBM is probably a potential SPECT PD-L1 imaging agent and further study is needed.

EP-0227

[18F]siPSMA-14 as a highly promising novel radiotracer for primary PET/CT staging of prostate cancer (PCa) patients: initial experience

M. Dyankova[1,2], *T. Stoeva[1], Z. Dancheva[1], S. Chausheva[1], T. Yordanova[1], B. Chaushev[1], A. Klisarova[1];*
[1]St. Marina University Hospital, Department of Nuclear Medicine, Varna, BULGARIA, [2]Medical University Varna "Prof. Dr. Paraskev Stoyanov", Department of Nuclear Medicine, Metabolic Therapy and Radiotherapy, Varna, BULGARIA.

Aim/Introduction: 18F-siPSMA-14 PET/CT showed high detection rates corresponding to the data of other PSMA radiotracers. The aim of this study was to analyze the association between PSA values, clinical T stage, EAU risk groups and ISUP grade in locoregional nodal (N) and distant (M) staging of PCa with 18F-siPSMA-14 PET/CT detection rate and metastatic lesions incidence in patients with intermediate and high risk disease. ***Materials and Methods:*** We performed a retrospective analysis of 55 consecutive patients with diagnosed biopsy-proven intermediate and high risk PCa who underwent staging 18F-siPSMA-14 PET/CT (without furosemide) between November 2023 to February 2024. The mean age of the patients was 69.2 years. The chi-squared test was used for testing association between two categorical variables. ***Results:*** The median PSA level was 14.5 ng/ml and median International Society of Urological Pathology (ISUP) grade was 4 with high-risk disease in 49 (89.1%). There was a significant relationship between the PSA level (p<0.001), ISUP grade (p<0.001), EAU risk (p= 0.016) and the ability of 18F-siPSMA PET/CT to reveal the metastatic involvement. In males with intermediate-risk PC, metastases were identified in 1 (16.7%), compared to 21 (42.9%) with high-risk disease. Oligometastatic disease (≤5 lesions) was detected in 4 (7.3%) of patients, including 2 (3.6%) with a PSA level of <10 ng/ml and ISUP grade 4-5. Regional metastatic lymph nodes incidence was identified in 15 (27.3%) of males, including 10 (18.2%) with a PSA level of >20.0 ng/ml and 12 (21.8%) with ISUP grade 4-5. Distant lymph nodes were most commonly found in patients with a PSA level of >20 ng/mL (p <0.001) and clinical T 3-4 (p= 0.073). Bone metastases were identified in 12 (21.8%) of patients, including 8 (14.5%) with a PSA level of >20 ng/mL and 9 (16.4%) with ISUP grade 4-5. Visceral metastases were detected in 2 (3.6%) of males with a PSA level of >20 ng/mL and ISUP grade 4-5. Distant metastases as a whole were seen most commonly in

patients with high levels of PSA and ISUP grade 4-5. Low bladder activity provided an excellent contrast for visualization of lesions in this region. ***Conclusion:*** The novel [F^{18}]siPSMA14 PET radiotracer demonstrates favorable kinetics, providing excellent detection of metastatic lesions, oligometastatic disease in the initial staging of patients with high-risk PCa. The detection of locoregional nodal and distant metastatic spread of PCa is positively associated with PSA levels, ISUP grade and EAU risk groups.

EP-0228

Application of ^{68}Ga-PSMA PET/CT in Diagnosis and Management of Prostate Cancer Patients

H. Dadgar;
Nuclear Medicine and Molecular imaging research center, RAZAVI Hospital, Mashad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The early and accurate diagnosis of locoregional recurrence or metastasis in prostate cancer (PC) has a significant impact on treatment options. 68Ga-PSMA PET/CT imaging has recently been introduced as a novel procedure in managing PC. The aim of this study was to evaluate the efficacy of PSMA PET/CT in managing PC patients and to compare the detection rate of PET/CT and bone scans (BSs) in detecting bone metastasis. ***Materials and Methods:*** We evaluated 415 patients with PC who underwent 68Ga-PSMA PET/CT between March 2015 and September 2018. The patients were classified into three groups: staging, biomedical recurrence (BCR), and follow-up or monitoring, based on the intent to perform PET/CT. ***Results:*** We evaluated 415 patients aged 41-99 (68.25 ± 9.59). Of these patients, 344 (82.9 %) had at least one localized lesion. The detection rates were 48.3 %, 52.6 %, 74.4 %, 79.6 %, and 93.9 % for a PSA value of < 0.2 ng/ml, ≥ 0.2-< 0.5 ng/ml, ≥ 0.5-< 1 ng/ml, ≥ 1-< 2 ng/ml, and ≥ 2 ng/ml, respectively ($p < 0.05$). The detection rates increased significantly with higher GSs; the rates were 68.3 % (28/41), 74.5 % (73/98), 93.9 % (46/49), and 91 % (61/67) for a GS of < 7, 7, 8, and > 8, respectively ($p < 0.05$). An ideal cut-off value of > 1.16 ng/ml was obtained for PSA value, which equates to specificity of 75 % and sensitivity of 77 %. In comparing BSs and PET/CT, a region-based analysis showed the superiority of PET/CT over BSs for all regions expect the skull ($p < 0.05$). PET/CT detected 258 suspicious regions, 255 of which were metastatic and three of which were equivocal. BSs detected only 223 suspicious regions, 203 of which were metastatic and 20 of which were equivocal. ***Conclusion:*** 68Ga-PSMA PET/CT showed a high detection rate for lesions in PC patients. PSA level, GS, and a PSA doubling time of less than 6 months were shown to be the affective variables. In addition, 68Ga-PSMA PET/CT showed better performance in detecting bone lesions than BSs.

EP-0229

Comparison of Ga-68 PSMA PET/CT scan with Tc-99m MDP bone scan for detecting skeletal metastasis in patients diagnosed with prostate cancer.

R. Kumar, *S. Kumar, J. Chaudhary, A. Pandey;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Prostate cancer ranks as the second most frequent type of cancer in men with approximately 1.41 million new cases each year as per Global Cancer Statistics 2022. Bone metastasis is the second most common site of prostate cancer spread, following lymph nodes. Traditionally, bone scans utilizing 99mTc-labeled methylene diphosphonate (99mTc-MDP) have been the preferred method for detecting bone metastases in prostate cancer patients. However, there is growing recognition of the effectiveness of Ga-68 PSMA PET/CT in assessing the extent of prostate cancer spread. This prospective study is aimed to compare the diagnostic performance of Ga-68 PSMA-11 PET/CT andTc-99m MDP bone scans in detecting skeletal metastases in patients diagnosed with prostate cancer. ***Materials and Methods:*** This study enrolled histopathologically confirmed prostate cancer patients who underwent both PET/CT andbone scan within a time frame of week from each other. Imaging procedures followed standardized protocols of PET/CT and bone scan.Skeletal metastases were identified by experienced Nuclear Medicine physicianbased on the characteristic findings on both scans, for lesions characterization. Concordance and discordance betweentwo modalities were noted and analyzed. The consistencies of number of lesions detected from PET/CT and bone scan were evaluated with Bland-Altman plot. ***Results:*** A total of 100 patients with the mean age 64.2 ± 8.83 years were prospectively included in this study. Of 100 patients, 83 (83%) patients showed concordance, while 17(17%) patients showed discordance in the detection of skeletal metastasis on both PET/CT scan and bone scan. Of 83concordant patients, the skeletal metastasis was seen in only 26 (32%) patients, however the remaining 57 (68.7%) patients hadno skeletal metastasis. All17 (89.4%) discordant patients were found to be positive for skeletal metastasis on PET/CT only. In 26 concordant patients with skeletal metastasis, the number of metastatic lesions assessed in 07 different anatomical regionssuch as skull, cervical spine, thoracic spine, lumbar spine, upper extremities, lower extremities, thorax, and pelvis were found to be 19, 20, 27, 33, 85, 80, and 49 on PET/CT, and 16, 17, 21, 25, 62, 56, and 36 on bone scan.Most (96.1%) of the dots on Bland-Altman Plot were within two 95% consistency limits indicating that there is no+ significant difference between the number of lesions detected by the two modalities. ***Conclusion:*** Though statistically insignificant, the number of lesions detected by Ga-68 PSMA PET/CT is much higher than that by the Tc-99m MDP bone scan for skeletal metastasis in prostate cancer patients.

EP-0230

Comparative evaluation of pelvic multi-parametric MRI and Ga-68 PSMA-11 PET/CT for Lymph Node staging in prostate cancer patients

A. Phulia[1], *S. Kumar[2], J. Chaudhary[2], R. Kumar[2];*
[1]Maulana Azad Medical College, New Delhi, INDIA, [2]All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Pelvic Multi-parametric MRI (mpMRI) has demonstrated promising outcomes in diagnosing, localizing, and staging clinically significant Prostate Carcinoma patients. Prostate-specific Membrane Antigen (PSMA) is highly expressed in prostate tissue and significantly overexpressed in PCa cells. PET/CT utilizing the PSMA inhibitor radiotracer 68Ga-HBED-CC (Ga-68 PSMA-11) holds potential to enhance sensitivity and specificity for preoperative lymph node (LN) staging. However, the comparative value of pelvic mpMRI and Ga-68 PSMA-11 PET/CT for LN staging in PCa remains uncertain. This study aims to evaluate the diagnostic accuracy of Ga-11 PSMA-11 PET/CT and mpMRI for the initial staging of intermediate and high-risk PCa patients. ***Materials and Methods:*** This study enrolled histopathologically confirmed PCa patients who underwent both mpMRI and Ga-68 PSMA-11 PET/CT scan. Experienced radiologists and nuclear medicine physicians visually analysed the obtained radiological (mpMRI) and nuclear images (PET/CT). Risk stratification (intermediate and high risk) of PCa patients was determined based on serum Prostatic specific antigen (PSA) levels and Gleason score in accordance with the

latest guidelines from the European Association of Urology (EAU). Cohen's Kappa statistic was calculated to assess the agreement between Ga-68 PSMA PET/CT and mpMRI in lymph node staging. ***Results:*** There were Ninety-five (95) patientshaving age: 66.6±8.07 years, median serum PSA level: 38.75 ng/ml (from 3.65 to 736.9ng/ml). 49 out of 95 patients (51%) were classified as having intermediate-risk prostate cancer based on their serum PSA level and Gleason score, while the remaining 46 out of 95 patients (48%) were categorized as having high-risk PCa. Among the 95 patients, 66 individuals (69.4%) exhibited concordance, while 29 patients (30.5%) exhibited discordance in detecting lymph node (LN) involvement between mpMRI and Ga-68 PSMA-11 PET/CT. Of the 66 concordant patients, 11 patients (16%) demonstrated LN involvement, and the remaining 55 patients (83%) showed no LN involvement on both mpMRI and PET/CT. Among the 29 discordant patients, 20 individuals (68%) displayed LN involvement on PET/CT, whereas the remaining 9 patients (31%) revealed LN involvement on mpMRI. The agreement between the Ga-68 PSMA-11 PET/CT and mpMRI in lymph node staging was found to be 69.4% (Cohen's k: 0.24) showing fair agreement. ***Conclusion:*** Ga-68 PSMA-11 PET/CT had better sensitivity in the initial assessment of lymph node (N) for patients with intermediate and high-risk prostate cancer (PCa). There was fair agreement (69.4%) between 68Ga-PSMA-11 PET/CT scans and pelvic mpMRI for LN staging.

EP-0232

Metabolic heterogeneity of human prostate cancer based on ^{18F}PSMA-1007 and ^{18F}FDG PET/CT and introducing the Dice Similarity Coefficient as a New Prognostic Parameter

D. Kim[1,2], *K. Oh[2], K. Choo[2], D. Kim[2], S. Lee[2], H. Lim[2], H. Hwang[1], Y. Choi[2], M. Lee[3], N. Cho[2], M. Yun[2];*
[1]Hallym University Sacred Heart Hospital, Anyang-si, KOREA, REPUBLIC OF, [2]Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF, [3]Incheon National University, Incheon, KOREA, REPUBLIC OF.

Aim/Introduction: This study assesses the diagnostic and prognostic capabilities of ^{18F}PSMA-1007 and ^{18F}FDG PET/CT in primary prostate cancer, exploring metabolic heterogeneity and related clinicopathologic features. It also evaluates the potential of Dice Similarity Coefficients (DSC) between PET and MRI as new prognostic markers. ***Materials and Methods:*** We analysed 32 prostate cancer patients using ^{18F}PSMA-1007 and ^{18F}FDG PET/CT for initial tumour staging. Histologic examinations confirmed the cancer presence in detected lesions, and immunohistochemistry (IHC) provided molecular insights. SUVmax values correlated with PSMA and GLUT1 expression levels, enhancing our understanding of tumour behaviour. ADC MRI-defined regions of interest were used to calculate DSC, offering a novel imaging prognostic parameter. ***Results:*** From 32 patients, 68 positive lesions were detected using ^{18F}PSMA-1007 PET/CT, with 47 (69.1%) confirmed as prostate cancer and 12 (17.6%) showing ^{18F}FDG positivity. IHC analysis revealed a significant reciprocal relationship between PSMA and GLUT1 expressions; regions with high GLUT1 typically exhibited low PSMA uptake, a pattern that correlates with the PET findings. Specifically, ^{18F}FDG-positive regions displayed considerably lower ^{18F}PSMA-1007 uptake (6.214 vs. 27.60, p=0.0021), suggesting reciprocal metabolic activities. Further DSC analysis indicated that lower PSMA DSC scores in ^{18F}FDG-positive tumours (0.6565 vs. 0.8015, p=0.0022) are associated with more aggressive disease. ROC curve analyses provided high AUC values (0.917 and 0.918) for differentiating advanced disease stages and identifying post-surgery biochemical failure, respectively. Additionally, a reciprocal correlation between ^{18F}FDG DSC scores and PSA doubling time (r=-0.7874, p=0.0204) highlighted that higher ^{18F}FDG uptake is linked to faster disease progression. ***Conclusion:*** In conclusion, there is a contrasting pattern of high ^{18F}FDG uptake but low ^{18F}PSMA-1007 PET/CT in mainly ductal-dominant PCa. We discovered that tumour hypoxia causes increased glycolysis and decreased ^{18F}PSMA-1007 uptake in PCa. Thus, the combination of ^{18F}PSMA-1007 PET/CT and ^{18F}FDG PET/CT can be a strategy for evaluating tumours with different metabolism. Moreover, the use of DSC has provided further insights into the prognostic potential of imaging biomarkers in PCa. Lower PSMA DSC scores in ^{18F}FDG positive tumours have been linked to advanced disease stages and a more aggressive tumour phenotype, as evidenced by a shorter PSA doubling time. This correlation emphasises the potential of DSC as a quantifiable measure that reflects tumour aggressiveness and could guide treatment strategies.

EP-0233

Role of ^{18F}-PSMA-1007 PET radiomics for seminal vesicle invasion prediction in men with primary prostate cancer

L. Luo, *J. Gao, Y. Li, C. Shen, X. Duan;*
The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, CHINA.

Aim/Introduction: Seminal vesicle invasion (SVI) is a high-risk indicator for metastasis and recurrence of prostate cancer (PCa). This study aims to investigate whether machine learning-based radiomics models derived from ^{18F}-PSMA-1007 PET could predict SVI and progression-free survival (PFS) after radical prostatectomy (RP) in PCa patients. ***Materials and Methods:*** All patients who underwent ^{18F}-PSMA-1007 PET/CT before RP were enrolled. The intraprostatic lesion's volume of interest (VOI) was semi-automatically sketched with a threshold of 40% maximum standardized uptake value (SUVmax), namely 40%SUVmax-VOI. And seminal vesicle glands were manually contoured (SV-VOI). Features were selected using the Relief and select K best method, as well as the least absolute shrinkage and selection operator algorithm. Logistic regression, random forest, and support vector machine were used for model training. The performance of models from different VOIs was assessed using the ROC curve. The prediction performances of radiomics models were compared against the readers' assessment. Kaplan-Meier analysis was used to test the ability of selected radiomics features to determine the PFS probability. ***Results:*** A total of 112 patients were included in the training set, and 28 patients were in the test set. The highest AUC for the PET radiomics model of 40%SUVmax-VOI and the PET radiomics model of SV-VOI were 0.85 and 0.96 in the test set, respectively. The AUC of the PET radiomics model of SV-VOI was significantly higher than that of the readers' assessment ($P < 0.05$). Using the median of the radiomics scores as a cutoff, the Kaplan-Meier analysis showed that PET radiomics features were associated with PFS in patients with PCa. ***Conclusion:*** Radiomics models developed by preoperative ^{18F}-PSMA-1007 PET/CT were proven useful for the prediction of SVI, and PSMA PET radiomics features were correlated with PFS, suggesting that the PSMA PET radiomics might be a non-invasive tool for PCa characterization.

EP-0234

Pelvic Rosetta Classification (PRC) Project: An interdisciplinary proposal for a lymph node map of the pelvis in prostate cancer

D. Koehler[1], *X. Hoderlein[1], F. Barbato[2], D. Beyersdorff[1], L. Budäus[3], I. Burger[4], M. Eiber[5], M. Graefen[3], B. Hadaschik[6], A. Haese[3], K. Herrmann[2], L. Maack[7], I. Maric[2], A. Mattei[8], I. Rauscher[5], G. Salomon[3], M. Sauer[1], L. Schimmöller[9], A. Schlaefer[7], H. Schlemmer[10], L. Umutlu[11], J. Walz[12], C. Würnschimmel[8], G. Ortner[3], T. Maurer[3];*

Aim/Introduction: The Pelvic Rosetta Classification (PRC) Project was initiated to create a landmark-based lymph node map of the pelvis for patients with prostate cancer (PCa) planned for surgical intervention. Aim of this new classification system is to harmonize communication between imaging specialists (nuclear medicine, radiology) and urologists, and to facilitate localization of suspicious extraprostatic lesions during surgery, accordingly. ***Materials and Methods:*** The project lead (DK, XH, GO, TM) defined anatomical margins of eight pelvic (external iliac, obturator fossa cranial/caudal, dorsal internal iliac, vesico-prostatic pedicle, mesorectal/perirectal, presacral, retropubic/preprostatic) and two adjacent extrapelvic (common iliac, intercommon) lymph node areas using anatomical landmarks that are consistently recognizable on morphological imaging (MRI, CT) and intraoperatively. Regions were contoured by 21 experts on five representative axial contrast enhanced CT images of a patient with PCa, depicting all defined areas. Contours were evaluated qualitatively and quantitatively. The mean Sørensen-Dice coefficient and the corresponding standard deviation (SD) were calculated in comparison to a baseline contour that was created by the first (DK) and senior (TM) authors, which was not available to the experts at the time of contouring to analyse the reproducibility of the proposed definitions. ***Results:*** Strong agreement between experts was found for the lymph node regions of the mesorectal and the retropubic spaces. In contrast, largest variations were observed for regions bordering the peritoneum and without a continuously identifiable margin on CT (e.g., obturator fossa). The mean Sørensen-Dice coefficients were lower for the vesico-prostatic pedicle (0.59, SD 0.27), obturator fossa (caudal: 0.54, SD 0.22; cranial: 0.67, SD 0.19), presacral (0.6, SD 0.17), and dorsal internal (0.64, SD 0.17) areas compared to the intercommon (0.71, SD 0.26), external (0.75, SD 0.2), common (0.77, SD 0.15), retropubic/preprostatic (0.83, SD 0.27), and mesorectal/perirectal (0.86, SD 0.24) regions. In the first consensus meeting, the areas "obturator fossa" (cranial and caudal), "internal", and "vesico-prostatic pedicle" were revised, and the inguinal lymph node region was defined. Furthermore, techniques to differentiate the intraperitoneal and extraperitoneal spaces were elaborated (e.g., identifying the course of mesenteric vessels). ***Conclusion:*** The proposed lymph node map of the pelvis for patients with PCa is the first multidisciplinary approach to facilitate communication between imaging specialists and surgeons based on landmarks identifiable on imaging and intraoperatively. Our results demonstrate fair reproducibility. Further development and validations are ongoing to ensure the successful implementation of the proposed classification in clinical practice.

EP-0235

Standardized Uptake Values and patterns of uptake on 68-Ga PSMA PET CT in prostatic lesions.

P. Mangale, *A. Agrawal, S. Choudhury, V. Rangarajan, G. Prakash, A. Joshi, V. Murthy, S. Menon, P. Maitre, M. Pal, A. Arora, S. Ghosh, N. Purandare, S. Shah, A. Puranik, I. Dev, V. Noronha, K. Prabhash; Tata Memorial Hospital, Mumbai, INDIA.*

Aim/Introduction: Assessment of the SUVmax values and the patterns of uptake on 68-Ga PSMA PET CT in benign and malignant prostatic lesions. ***Materials and Methods:*** This is a retrospective observational study done in patients referred for initial staging with 68-Ga PSMA PET CT in prostate cancer cases. SUVmax in the prostatic lesion was correlated with the risk category, ISUP grade groups, PSA and Gleason's score. The patterns of uptake in each malignant risk category and benign cases were studied. ***Results:*** Total of 325 subjects were included in the analysis (14 benign, 311 malignant). Median SUVmax of benign lesions was 8.29. This was close to the median SUVmax of Grade Group 1 lesions (7.67). Median SUVmax of the Grade Group 4 and 5 (26.42 and 26.55 respectively) were significantly higher than other Grade Groups. Positive correlation was noted between SUVmax values and ISUP grade groups (Spearman's correlation coefficient of 0.440, $p < 0.001$). Significant difference between SUVmax of the ISUP low risk, intermediate risk and high risk prostate cancer groups was observed with Kruskal Wallis test. It was observed that SUVmax of the prostatic lesion showed a positive correlation with the Gleason's score. Statistically significant difference was noted in the SUVmax values of benign, intermediate and high risk clinical categories. For the diagnosis of prostate cancer, SUVmax cut-off was evaluated using ROC analysis, which yielded a cut-off of 10.91 with sensitivity and specificity of 80% and 79% respectively, positive predictive value of 98.81 % and a diagnostic accuracy of 80%. Positive correlation was noted in SUVmax values and serum total PSA values ($p < 0.001$). Majority of the cases (benign and malignant) showed diffuse uptake pattern. With higher SUVmax in the prostatic lesion, in high risk cases, higher SUVmax was observed in nodal and skeletal metastases. ***Conclusion:*** Our study demonstrated SUVmax cutoff of 10.91 to differentiate between benign and high risk prostate cancer. SUVmax values can differentiate high risk prostate cancer from low/intermediate risk. There is considerable overlap between SUVmax values of benign and low risk prostate cancer. A strong trend of rising SUVmax value in prostatic lesion is observed with higher grade malignancy. It can emerge as a pre-biopsy non-invasive diagnostic tool, obviating the need of biopsy in case of higher grade malignancy. It aids targeted biopsy and treatment planning. SUVmax of prostatic lesion is a valuable determinant in risk classification and can change the risk group and management.

EP-0236

Management change after ^{68}Ga-PSMA-11 PET /CT in a large Prostate Cancer cohort with intermediate-unfavorable or high-risk at presentation. Results from a monocentric retrospective study.

G. Frusciante[1], *P. Castellucci[2], S. E. Prisco[1], R. Schiavina[3], E. Brunocilla[3], L. Bianchi[3], F. Monastero[1], A. Farolfi[2], S. Fanti[2];*
[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [3]Division of Urology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, Bologna, ITALY.

Aim/Introduction: The aim of this study was to evaluate 68Ga-PSMA-11 PET/CT (PET PSMA) impact on management if performed in a population with intermediate-unfavourable or high-risk of prostate cancer (PCa) at presentation according to D'Amico criteria. ***Materials and Methods:*** From July 2021 to March 2024 we performed 860 consecutive PET PSMA for staging PCa before primary treatment. According to our inclusion criteria, we selected patients with the following characteristics; 1) biopsy proven PCa 2) PSA values 3) Gleason Score 4) classified as intermediate-unfavourable or high risk according to D'Amico criteria. Five-hundred-thrirty-four patients met our criteria: 495 patients (92,7%) were high-risk and 39 (7,3%) were intermediate-unfavourable risk according to D'Amico criteria. PSMA PET was performed according to standard criteria and images were read by three nuclear medicine physicians with more than 5 years experience. Images interpretation followed PROMISE V2 and E-PSMA criteria. To avoid UBU (Unspecific Bone Uptake) only Scores 4 and 5 were classified as PET PSMA positive. ***Results:*** In the high-risk population 53 patients (10,7%) showed pelvic nodes metastasis (miN1/N2) only; 79 (16%) were positive for M criteria: 9 for distant nodes only (miM1a); 46 for bone metastasis only (miM1b 9,3%); 24 showing multiple metastasis: miM1a and/or b, and/or c (4,0%); within this group,one patient was miM1a-b-c, one was miM1a-c and 22 were miM1a-b. In the intermediate-unfavourable risk population (39 patients) one patient was miN2 (2,5%) and one was miM1b positive (2,5%). ***Conclusion:*** As recently confirmed by EAU guidelines (1)PSMA PET has become an essential tool to stage high risk PCa and might replace standard procedures like CT and Bone Scan. In our large series, we observed a major impact on management in 16% of the patients at high-risk (miM1a and miM1b), while a much lower major impact on management was observed in intermediate-unfavourable risk population (2,5%). In conclusion, a systematic use of PSMA PET in high-risk PCa patients might correctly addressed to systemic treatments (1) sparing futile surgery or RT. ***References:*** (1)https://d56bochluxqnz.cloudfront.net/documents/full-guideline/EAU-EANM-ESTRO-ESUR-ISUP-SIOG-Guidelines-on-Prostate-Cancer-2024_2024-04-09-132035_ypmy_2024-04-16-122605_lqpk.pdf.

EP-0237

Diagnostic value of multiphasic ^{68}GaPSMA11 PET/CT imaging in detection of prostate bed recurrence and regional lymph node metastasis in prostate cancer patients

A. Aghaee, *v. roshan ravan, n. norouzbeigi, k. aryana, s. soltani, h. ghorbani;*
nuclear medicine research center,Mashhad university of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: . The aim of this study is to evaluate the clinical utility of early and delayed imaging in prostate cancer (PCa) patients as well as temporal changes in the semi-quantitative parameters. ***Materials and Methods:*** In this single-center retrospective study, 138 PCa patients were referred for 68Ga-PSMA PET/CT scan for various indications . Patients underwent standard 60 min imaging along with the first 4-min post-injection static acquisition, and delayed imaging, 2.5-3 h after injection, both from the pelvic field. Changes in the lesion SUVmax and target-to-background ratios (TBR) were recorded for each phase of the imaging. ***Results:*** The study evaluated 138 PCa patients, with an average age of 67.7 ± 8.7 years, a median PSA level of 7.5, and an interquartile range of (1.1-23.1), as well as Gleason scores ranging from 3+3 (3.6%) to 5+5 (4.2%). The positivity rates for PSMA-avid lesions in the early, whole-body, and delayed images were 71.5% (93/130), 73.9% (77/110), and 70% (77/110), respectively. The early phase, standard, and delayed images demonstrated prostate beds, local extraprostatic, lymph node, and bone lesions in the following order: 76, 29, 96, and 104 foci in the early phase; 80, 32, 117, and 111 lesions in the whole-body phase; and 61, 28, 98, and 52 lesions in the delayed phase, respectively. . The detection rates for local recurrence in the early, whole-body, and delayed phases were 13.8% (18/130), 15.9% (22/138), and 17.3% (19/110), respectively, with no statistically significant change (p=0.5). The detection rates for lymph node metastases were 23.8% (31/130), 29% (40/138), and 28% (30/110), with a significant difference observed between the early and whole-body phases (p=0.016). The detection rates for osseous lesions in the early, whole-body, and delayed images were 28.46% (37/130), 27.53% (38/138), and 21.81% (24/110), respectively, with no statistically significant difference found (p=0.139). ***Conclusion:*** The detection rates of bone lesions were comparable across all three phases. The early phase imaging was more effective for evaluation of local bladder invasion but was less successful in identifying prostate bed lesions, seminal vesicle invasion, and lymph node metastases. The increased SUVmax pattern appeared more prominent in corrected SUVmax (T/BG) than in SUVmax for various lesions. Additionally, the increasing pattern of SUVmean demonstrated a smaller increase in the proportion of patients compared to SUVmax in the transition from early to whole-body and early to delayed phase images.

EP-0238

Assessment of the Reproducibility, Accuracy, and Incremental Value of Delayed Imaging in PRIMARY Scoring: A Comparative Analysis of [^{68}Ga]Ga-PSMA-11 PET/CT Images

K. Akçay[1], *G. Beydagi[1], O. E. Sahin[2], R. Akyel[3], E. Akgun[4], O. Ekmekcioglu[5], N. Alan Selcuk[1], T. Toklu[1], A. I. Dogan Ekici[6], K. Kapran[1], L. Kabasakal[2];*
[1]Department of Nuclear Medicine, Yeditepe University, Istanbul, TÜRKIYE, [2]Department of Nuclear Medicine, Cerrahpasa University, Istanbul, TÜRKIYE, [3]Department of Nuclear Medicine, Yedikule Chest Disease and Research Hospital, Istanbul, TÜRKIYE, [4]Department of Nuclear Medicine, Basaksehir Cam and Sakura City Hospital, Istanbul, TÜRKIYE, [5]Department of Nuclear Medicine, University of Health Sciences, Sisli Hamidiye Etfal Education and Research Hospital, Istanbul, TÜRKIYE, [6]Department of Pathology, Acıbadem University, Istanbul, TÜRKIYE.

Aim/Introduction: The primary aim of the study was to determine the supplemental value of delayed images in the diagnosis of clinical significant prostate cancer by using PRIMARY scoring on standard and delayed images obtained with [68Ga]Ga-PSMA PET/CT. The secondary aim of the study is to evaluate the intra-observer and inter-observer agreement in PRIMARY scoring

in standard and delayed imaging. ***Materials and Methods:*** 140 patients with bISUP (ISUP GG obtained after biopsy) 1-2 prostate cancer who had standard (mean 59±15 min) and delayed images (mean 138±21 min) with [68Ga]Ga-PSMA PET/CT before the radical prostatectomy were included in the retrospective study. Two experienced nuclear medicine physicians evaluated the images blindly, and discordant scoring was resolved by consensus of the third experienced nuclear medicine physician. A statistical analysis of diagnostic parameters was performed by consensus scoring. The images were also evaluated using PRIMARY scoring by four different nuclear medicine specialists, blind to each other and the patient's clinical information. For intraobserver analysis, a one-month interval was taken between two evaluations. ***Results:*** Of the patients, 51 had bISUP 1 and 89 had bISUP 2. In this patient group, 69% of bISUP 1 cases and 20% of bISUP 2 cases showed an increase in grade group after surgery. When comparing the diagnostic parameters, the sensitivity for PRIMARY scoring for the standard images was 71%, the specificity 35%, the positive predictive value 87% and the negative predictive value 17%, while for the delayed images the sensitivity was 92%, the specificity 20%, the positive predictive value 87% and the negative predictive value 29%. According to Cohen's Kappa analysis, intraobserver agreement was 0.536, 0.798, 0.593, and 0.638 for observers 1, 2, 3, and 4, respectively, for standard images and 0.697, 0.839, 0.769, and 0.740 for observers 1, 2, 3, and 4, respectively, for delayed images. The inter-observer agreement determined by Fleiss Kappa was 0.47 and 0.52 for the standard image in rounds 1 and 2, respectively, and 0.61 and 0.72 for the delayed image in rounds 1 and 2, respectively. ***Conclusion:*** Delayed imaging significantly improved the identification of csPCa patients missed on standard images. There was also enhanced reliability in both intraobserver and interobserver assessments with delayed images. Decreased background activity and increased primary tumor uptake led to better identification of lesions, with clearer discrimination between tumor and benign lesions. Consequently, delayed images have potential for identifying candidates suitable for active surveillance in routine clinical practice.

EP-0239

Clinical, pathological and imaging variables associated with prostate cancer detection by PSMA PET/CT and mpMRI

I. Sonni, *A. B. Weiner, S. Doddipalli, M. Deol, D. Ban, H. Kim, T. Grogan, P. Ahuja, N. Barroso, Y. Zong, P. Soin, A. Sisk, J. Czernin, W. Hsu, J. Calais, R. E. Reiter, S. Raman;*
University of California, Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: Multiparametric MRI (mpMRI) and PSMA-PET are complementary imaging modalities used in the pre-surgical staging of prostate cancer (PCa). Disagreements between the two imaging modalities are found in a small percentage of cases, and the reasons behind them are unclear. Aim: To assess differences in sensitivity and positive predictive value between pre-surgical PSMA-PET and mpMRI and characterize tumors detected and not detected by each imaging modality focusing on identifying the clinical, pathological and imaging variables associated with tumors detected by PSMA-PET and mpMRI invisible. ***Materials and Methods:*** This single-center, retrospective analysis included patients who underwent both PSMA-PET and mpMRI prior to radical prostatectomy with centralized imaging and pathology review. Two nuclear medicine physicians and 2 radiologists blindly and independently contoured PCa lesions on PSMA-PET and mpMRI, respectively. We used a majority rule (2:1) with a third reader for each modality in case of disagreement. We fused the PET/CT and MRI and assessed for agreement/disagreement visually, based on the overlapping lesion contours, and matched each lesion with the tumors delineated by a genito-urinary pathologist on whole-mount histopathology. Logistic regression models explored associations between clinico-pathological variables and tumor detection on imaging. ***Results:*** A total of 132 csPCa tumors from 100 patients were identified on surgical pathology. PSMA-PET and mpMRI identified 143 and 122 lesions, respectively. PSMA-PET showed higher sensitivity (87% vs 80%), but lower positive predictive value compared to mpMRI (87% vs 93%). Tumors correctly identified on each imaging modality had significantly higher ISUP GG, larger size, and were more likely to show large cribriform pattern and intraductal carcinoma. Tumors detected by both imaging modalities were significantly larger and had higher ISUP grade groups than those invisible on one or both imaging modalities. On multivariable analysis, smaller tumor size on pathology and older age were associated with PSMA PET/CT not detecting csPCa. Whereas for mpMRI, smaller tumor size on pathology was associated with invisible PCa, while ISUP GG4/5 vs GG2 was associated with lower odds of non-detection. csPCa tumors invisible on mpMRI but detected by PSMA-PET were smaller in size compared to those detected by both modalities. Limitations include selection bias in a surgical cohort. ***Conclusion:*** PSMA-PET tends to detect smaller csPCa not detected by mpMRI. Larger tumors on pathology with higher grade groups are more likely to be correctly detected by both imaging modalities. These findings provide insights for refining pre-surgical evaluation strategies in PCa.

EP-0240

^{68}Ga-PSMA PET/CT Based Multi-modal Deep Learning Model for Accurate Prediction of Pelvic Lymph-node Metastases in Prostate Cancer

Q. Ma[1], *B. Chen[1], R. Zhou[2], W. Li[3], Y. Tang[1], S. Hu[1];*
[1]Department of Nuclear Medicine, Xiangya Hospital, Central South University, Changsha, CHINA, [2]School of Zhang Jian, Nantong University, Nantong, CHINA, [3]College of Mathematics and Statistics, Chongqing Jiaotong University, Chongqing, CHINA.

Aim/Introduction: The clinical nomogram is a crucial tool for assessing the need for extended pelvic lymph node dissection (ePLND) in conjunction with radical prostatectomy. However, its high sensitivity and low specificity have resulted in unnecessary ePLND and associated complications in 75-85% of patients. In addition, both PET and traditional imaging frequently underestimate lymph node metastases in prostate cancer (PCa). We aimed to develop a multi-modal deep learning model based on PSMA PET/CT for precise preoperative prediction of lymph node involvement (LNI) in PCa patients. ***Materials and Methods:*** We retrospectively enrolled a consecutive cohort of PCa patients who underwent 68Ga-PSMA-617 PET/CT before any initiating treatment, radical prostatectomy and ePLND were then carried out following a standard clinical assessment at a single tertiary referral center. Using ePLND postoperative pathology as the gold standard, Med3D deep learning network was developed to extract discriminative features from the volume of interests encompassing the entire prostate gland in PET and CT images. A multimodal deep learning model was then constructed and cross-validated to predict LNI by combining PET/CT features and clinical parameters, including age, prostate-specific antigen, Gleason grade group for biopsy, clinical tumor stage, and maximum normalized exposure to 68Ga-PSMA PET primary tumors. Optimal

risk-threshold was determined during model development and performance was compared with available nomograms and PET/CT visual assessments using area under the receiver operating characteristic curves (AUC), calibration plots, and decision curve analysis (DCA). ***Results:*** A total of 82 PCa patients were included in the study cohort between January 2020 and December 2023 and 24 patients had pathologically-confirmed LNI disease. Our multimodal deep learning approach demonstrated superior discriminative ability in predicting LNI compared to the reported results of PSMA PET/CT, the Memorial Sloan Kettering Cancer Center (MSKCC) nomogram, and the Briganti-2017 nomogram (AUC 0.89 [95% confidence interval [CI] 0.81-0.97] vs 0.82 [95% CI 0.73-0.92] vs 0.75 [95% CI 0.61-0.89] and 0.73 [95% CI 0.61-0.86], respectively; $p < 0.05$). Furthermore, our model exhibited good calibration similar to the common nomograms and significant higher net benefit at DCA with a threshold probability of ≥ 4%. ***Conclusion:*** Our validated multimodal deep learning model, which incorporates both clinical information and PSMA PET/CT features of prostate, outperforms PSMA PET/CT visual evaluation, the MSKCC and Briganti-2017 nomograms. It has the potential to enhance patient selection for ePLND compared to current clinical nomograms.

Aim/Introduction: Accurate detection, localisation, and staging of clinically significant prostate cancer (PCa) are paramount for therapy planning. The aim of this study was to compare the diagnostic performance of 18F-PSMA-1007 PET/CT and whole-body MRI (wbMRI) in the detection and local staging of intraprostatic tumour foci, using histopathology as the reference standard. ***Materials and Methods:*** The current study is part of a prospective single-centre trial (PROSTAGE, NCT03537391), where patients with newly diagnosed high-risk PCa underwent 18F-PSMA-1007 PET/CT, wbMRI with diffusion-weighted imaging (DWI), contrast-enhanced CT, bone scintigraphy and SPECT/CT for primary staging within 2 weeks from enrolment. Given the purpose of assessing the detection and staging of primary tumours, only patients treated with radical prostatectomy were included in study, and only 18F-PSMA-1007 PET/CT and MRI images were evaluated. Two readers for each modality reported the intraprostatic tumours using a 12-segment-based analysis. Seminal vesicle invasion (SVI) and extraprostatic extension (EPE) were also assessed. Histopathological analysis, including hematoxylin-eosin and PSMA immunochemistry, was performed. Imaging-pathology correspondence was assessed on a lesion level. ***Results:*** Nineteen patients were included in the study, with a mean age of 65 y (range 52-69), and a mean PSA of 8.7 ng/ml (range 5.9-13.5). The majority of the patients, 16 (84%), presented with an ISUP grade group of 3 or higher. Pathological stages were pT2 in 9 (47%) patients and pT3 in the remaining 10 (53%). A total of 38 intraprostatic lesions were detected through histopathological analysis. The detection rates of intraprostatic foci for 18F-PSMA-1007 PET/CT readers were 79% and 74%, respectively, and for MRI readers, the rates were 71% and 45%, respectively. The AUC values for SVI were 0.67 and 0.70 for 18F-PSMA-1007 PET/CT readers, and 0.70 and 0.70 for MRI readers, respectively. The corresponding AUC values for EPE were 0.57 and 0.50 for 18F-PSMA-1007 PET/CT readers, and 0.68 and 0.68 for MRI readers, respectively. ***Conclusion:*** 18F-PSMA-1007 PET/CT showed higher detection rates than wbMRI in assessing intraprostatic tumour foci. Comparable performance between the two modalities was observed in the assessment of SVI. Conversely, MRI seems to be more accurate than 18F-PSMA-1007 PET/CT in evaluating EPE.

EP-0242

Role of Semiquantitative Parameters of the Primary Tumor on Ga-68 PSMA PET/CT in Predicting Pelvic Lymph Node Metastasis: A Prospective Single-Center Study

S. Ceylan[1], *G. Uçmak[1], B. B. Demirel[1], E. Öztürk[2], E. Benzer[3];*
[1]Ankara Oncology Training and Research Hospital Nuclear Medicine Clinic, ankara, TÜRKIYE, [2]Ankara Oncology Training and Research Hospital Urology Clinic, ankara, TÜRKIYE, [3]Ankara Oncology Training and Research Hospital Pathology Clinic, ankara, TÜRKIYE.

Aim/Introduction: The aim of our study was to investigate the diagnostic value of semiquantitative parameters of the primary tumor obtained from preoperative staging Ga-68 PSMA (Prostate-specific membrane antigen) PET/CT in predicting postoperatively proven pelvic lymph node (LN) metastasis in intermediate-high risk prostate cancer. ***Materials and Methods:*** In our study, we prospectively evaluated 50 patients with newly diagnosed, biopsy-proven, intermediate-high-risk prostate cancer who underwent radical prostatectomy with pelvic lymph node dissection and Ga-68 PSMA PET/CT for preoperative staging. SUVmax, SUVmean, TL-PSMA (Total lesion) and PSMA-TV (Tumor volume) parameters of the primary tumor were measured and recorded on Ga-68 PSMA PET/CT images. Postoperative pathology results were recorded. Non-parametric tests, chi-square test and ROC analysis were performed to determine the relationship between the parameters obtained from PSMA PET/CT and histopathologic data. ***Results:*** The postoperative histopathologic features of 50 patients (65±0.7 (52-76)) included in our study are shown in Table 1. Staging Ga 68 PSMA PET/CT showed PSMA expression in the LN in 11 patients (78%). In the postoperative histopathologic analysis , 38 (76%) patients had no LN metastasis, while 12 (26%) had LN metastasis. The sensitivity, specificity, NPV, PPV and accuracy of Ga 68 PSMA PET/CT in detecting LN metastasis were 66%, 92%, 89%, 72% and 86%, respectively. Primary tumor SUVmax, SUVmean, TL-PSMA and PSMA-TV were statistically significantly higher in histopathologically proven LN positive patients compared to negative patients (p=0.004, p=0.009, p<0.001, p=0.032, respectively). In ROC analysis, TL-PSMA had the highest diagnostic value in predicting histopathologic LN metastasis (AUC:0.86, 95% CGA:0.75-0.96, p<0.001). This value was respectfully followed by SUVmax (AUC:0.78, 95% CGA:0.64-0.91, p=0.004), SUVmean (AUC:0.75, 95% CGA:0.60-0.90, p=0.009), and PSMA-TV (AUC:0.70, 95% CGA:0.56-0.85, p=0.032). ROC analysis is shown in table 2. Additionally primary tumor SUVmax, SUVmean, TL-PSMA values

were also correlated with postoperative histopathological findings of seminal vesicle invasion (p=0.004, p=0.003, p=0.001, respectively), positive surgical margin (p=0.023, respectively), p=0.043, p=0.003), extraprostatic invasion (p=0.003, p=0.009, p=0.006, respectively), and higher pT stage (p= <0.001, p= <0.001, p= 0.001, p= 0.001, respectively). Although PSMA-TV, seminal vesicle invasion, positive surgical margin, extraprostatic invasion and higher pT stage were found to be higher in patients with PSMA-TV, they were not statistically significant (p=0.246, p=0.177, p=0.51, 0.706, respectively). ***Conclusion:*** We concluded that TL-PSMA, SUVmax and SUVmean parameters of the primary tumor, independent of LN PSMA expression on Ga-68 PSMA PET/CT, do contribute to the prediction of histopathological LN metastasis in patients with intermediate-high risk prostate cancer.

EP-0243

Immunohistochemical assessment of PSMA expression in biopsy samples predicts PSMA PET/CT uptake in prostate cancer: a new tool to choose the best primary staging imaging method?

L. Sofia[1], *F. Ambrosini[2], N. Piol[3], G. Drocchi[2], M. Martiriggiano[2], C. Paola[2], G. Mantica[2], F. D'Amico[1], B. Spina[3], T. Di Raimondo[1], M. Borghesi[2], G. Sambuceti[1], N. Suardi[4], C. Terrone[2], M. Bauckneht[1];*
[1]Nuclear Medicine Unit, Department of Health Sciences (DISSAL), University of Genoa, Genoa, ITALY, [2]Department of Urology, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [3]Department of Pathology, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [4]5.Department of Urology, Spedali Civili di Brescia, Brescia, ITALY.

Aim/Introduction: In recent years, prostate-specific membrane antigen (PSMA) PET imaging has emerged as the most accurate method for staging primary prostate cancer (PCa). It has been shown that 5 to 10% of PCa lesions exhibit low to absent PSMA expression, as determined by immunohistochemistry. Identifying patients with low PSMA expression through verification in biopsy samples could suggest alternative imaging methods for staging purposes. ***Materials and Methods:*** Patients scheduled for robot-assisted radical prostatectomy between June 2021 and December 2022, and staged with Ga68-PSMA-11 PET imaging, were selected. Immunohistochemical analysis was performed on biopsy specimens, correlating with the respective International Society of Urological Pathology (ISUP) grade, and on each index lesion in the final histology. Results were quantified using the immunoreactive score (IRS). Gwet's agreement coefficient (AC1) calculated the concordance between PSMA expression in biopsy specimens and index lesions in final histology. Univariate and multivariate regression models assessed the influence of biopsy and final histology IRS on the maximum standardized uptake value (SUVmax). ***Results:*** Fifty patients were prospectively selected. The median IRS of the biopsy specimens was 6 (Interquartile Range [IQR] 4, 8.8). The concordance rate for immunohistochemical PSMA expression between biopsy specimens and the index lesion in final histology was 80%, with a statistically significant AC1 of 0.72 (confidence interval [CI] 0.5-0.9) (p < 0.001). Univariate linear regression analysis showed that both the average percentage of PSMA-positive cells and the average IRS in biopsy samples significantly affected SUVmax (beta= 1.2, CI 1.04-1.45, p = 0.02; and beta= 2.5, CI 1.2-3.1, p = 0.008, respectively). In multivariate regression models, the percentage of PSMA-positive cells and the IRS of the index lesion were significant predictors of SUVmax, after adjusting for tumor volume (beta= 1.22, CI 1.05-1.4, p = 0.01; and beta= 6.66, CI 2.03-21.8, p = 0.01, respectively). ***Conclusion:*** The immunohistochemical expression of PSMA in adenocarcinoma from prostate biopsy specimens demonstrates high concordance with PSMA expression in adenocarcinomas from radical prostatectomy specimens. PSMA expression level is an independent predictor of PSMA PET SUVmax. Assessing PSMA immunohistochemical expression preoperatively can significantly influence a more accurate, patient-specific diagnostic approach.

EP-0244

Assessing the Supplementary Role of PSMA PET Parameters in Metastatic Hormone-Sensitive Prostate Cancer Patients Initiating First-Line Therapy

R. Zanca[1,2], *M. Aliprandi[1,3], L. Cecchi[1,3], A. Bertocchi[1,3], F. Borea[1,3], N. Cordua[3], M. Perrino[3], F. De Vincenzo[3], M. Rodari[2], J. Jandric[4], L. Muraglia[2], P. Zucali[1,3], L. Evangelista[1,2];*
[1]Department of Biomedical Sciences, Humanitas University, Milan, ITALY, [2]Department of Nuclear Medicine, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY, [3]Department of Oncology, IRCCS Humanitas Research Hospital, Rozzano, Milan, ITALY, [4]Department of Nuclear Medicine, IRCCS Humanitas Research Hospital, , Rozzano, Milan, ITALY.

Aim/Introduction: The current categorization of disease as high or low-volume in metastatic hormone-sensitive prostate cancer relies on conventional imaging techniques outlined by the CHARTEED and LATITUDE criteria, rather than advanced imaging modalities. However, PSMA PET is increasingly being utilized, particularly in patients with high and very high risk of disease. Therefore, there is a critical need to assess the additional value provided by PSMA PET/CT in patients with metastatic hormone-sensitive prostate cancer. This study aimed to evaluate the utility of PSMA PET in this context. ***Materials and Methods:*** This retrospective monocentric study enrolled patients with metastatic hormone-sensitive prostate cancer who underwent PSMA PET/CT prior to initiating any first-line treatment and at the time of their best response. Patients enrolled in other clinical trials or lacking available PET images at any disease phase were excluded. PET images were quantitatively analyzed using whole-body total lesion activity (wb_TLA) and metabolic tumor volume (wb_MTV). Patients were followed clinically, and disease progression was recorded. Statistical analysis was performed using MedCalc software. ***Results:*** A total of 40 patients (median age: 69; range: 55-84 years) were included in the study. Median values of wb_TLA and wb_MTV significantly differed in patients categorized as having high and low disease burden based on the CHARTEED and LATITUDE criteria (all p < 0.005). The correlation between baseline and best-response PSA and wb_TLA were 71% and 81%, respectively, while correlations were lower for PSA and wb_MTV (38% and 41%, respectively). After a median follow-up time of 34 months (range: 5-97), 31 patients remained disease-free, while 8 experienced disease progression. Neither baseline wb_MTV nor wb_TLA were predictors of progression; however, the best response wb_TLA was significantly higher in patients who progressed compared to those who did not (median: 167 vs. 41, p < 0.05), such as PSA levels (0.88 vs. 0.03; p<0.05). ***Conclusion:*** Strong correlations between PSA levels and wb_TLA suggest PSMA PET's utility in monitoring disease response. While baseline wb_MTV and wb_TLA aren't independent predictors of progression, higher best response wb_TLA correlates with disease progression. These findings highlight PSMA PET's clinical relevance for treatment guidance and disease monitoring in this patient group, warranting further research.

EP-0245

The Relationship of Volumetric Parameters in GA-68 PSMA PET/CT with Clinical Data in Prostate Cancer Staging

R. Yükseltürk, *B. Okudan Tekin;*
University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine Clinic, Ankara, TÜRKIYE.

Aim/Introduction: The aim of this study is to evaluate the relationship between volumetric parameters in Ga-68 PSMA PET/CT performed for staging purposes in patients diagnosed with prostate cancer and PSA, Gleason Score, D'Amico Risk Classification and Memorial Sloan Kettering Cancer Center (MSKCC) nomogram. ***Materials and Methods:*** Patients, who underwent robotic radical prostatectomy between January 2020 and December 2022, and who had Ga-68 PSMA PET/CT performed for primary staging in Ankara Bilkent City Hospital, were retrospectively reviewed. PSMA PET/CT images were visually and quantitatively analysed. Regions of interest (VOI) for PSMA retention above the background activity in the prostate gland and lymph nodes were drawn in LIFEx v7.4 (Local Image Feature Using the Extraction) program with the threshold value set to 42%. SUVmax, whole body total lesion PSMA (wbTL-PSMA) and whole body PSMA tumour volumes (wbPSMA-TV) were calculated. In addition, preoperative PSA levels, Gleason scores, D'Amico risk groups, extraprostatic spread (EPE), lymph node involvement (LNI) and seminal vesicle invasion (SVI) probability values, obtained from the MSKCC nomogram, were recorded. The relationship between the calculated volumetric parameters and clinical data was examined with Pearson correlation analysis. ***Results:*** The mean age of 103 patients, who met the inclusion criteria, was 65.85±6.23 years, the mean serum PSA level before surgery was 16.90±16.16 ng/mL, the mean SUVmax was 17.82±20.84, the mean wb-PSMA-TV was 5.55±5.10 cm3 and mean wbTL-PSMA was 64.11±126.96. A significant correlation was detected between PSA levels and wbPSMA-TV, wbTL-PSMA and SUVmax values (r=0.45, r=0.60, r= 0.41, all p<0.01, respectively). While a significant correlation was found between SUVmax and wbTL-PSMA (p<0.01, r=0.55), no significant correlation was found between wbPSMA-TV and SUVmax values (p>0.05). A significant correlation was detected between preoperative Gleason scores and wbPSMA-TV, wbTL-PSMA and SUVmax values (r=0.24, r=0.34, r=0.27, respectively, all p<0.01). The patients included in the study were in the medium and high-risk class in the D'Amico risk category; while a significant correlation was found between D'Amico risk category, wbTL-PSMA and SUVmax values (r=0.26, r=0.26, p<0.01, respectively), there was no significant correlation with wbPSMA-TV (p>0.05). A significant correlation was detected between the EPE, LNI and SVI probability values obtained from the MSKCC nomogram and wbPSMA-TV, wbTL-PSMA and SUVmax values (p<0.01). ***Conclusion:*** Prospective studies in large patient groups are needed to reveal the relationship of clinical data with parameters such as SUVmax, wbTL-PSMA, wbPSMA-TV, obtained from Ga-68 PSMA PET/CT images taken during the primary staging of prostate cancer period.

EP-0246

PSMA PET/CT and Magnetic Resonsance Imaging Features in Patients with Favorable and Unfavorable Intermediate Risk Prostate Cancer

P. Guglielmo[1], *L. Muraglia[2], J. Jandric[2], G. Giacoppo[3], M. Bambaci[3], M. Bonacina[1], R. Zanca[2], G. Lughezzani[4,5], N. Buffi[4,5], V. Fasulo[4,5], L. Setti[1], K. Marzo[2], M. Rodari[2], D. Aricò[3], L. Evangelista[2,5];*
[1]Nuclear Medicine Unit, Humanitas Gavazzeni, Bergamo, ITALY, [2]Nuclear Medicine Unit, IRCCS Humanitas Research Hospital, Rozzano (MI), ITALY, [3]Nuclear Medicine Unit, Humanitas Istituto Clinico Catanese, Misterbianco (CT), ITALY, [4]Urology Unit, IRCCS Humanitas Research Hospital, Rozzano (MI), ITALY, [5]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele (MI), ITALY.

Aim/Introduction: PET/CT using prostate-specific membrane antigen(PSMA)-based tracers is currently recommended in high-risk PCa. However, its potential benefits in intermediate-risk cases are still to be determined. We aimed to assess the receptorial features through PSMA-PET/CT, together with the magnetic resonance imaging (MRI) characteristics, in a cohort of patients with intermediate-risk PCa. ***Materials and Methods:*** We retrospectively recruited patients with intermediate-risk PCa who underwent [68Ga]Ga-PSMA-11 or $^{[18F]}$PSMA-1007 PET/CT at the Nuclear Medicine Units of the Humanitas group (Italy) for the initial staging. We collected clinical data, MRI, and PET/CT data, and informed consent. Both MRI and PSMA PET/CT images were visually inspected, and the PI-RADS v.2 and Primary Score (PS) were determined by two experienced readers. Our data analysis was conducted using MedCalc version 22.014. ***Results:*** A total of 144 patients were included in the study. The median initial PSA level was 7.31 ng/mL (range: 1.9-63 ng/mL). Based on the biopsy Gleason Score-GS, 84 patients (58.3%) were categorized as "favorable risk" (GS: 3+4), while 60 patients (41.7%) had an "unfavorable risk" (GS: 4+3). MRI-PIRADS scores (available in 126 cases) were distributed as follows: a score of 1-3 in 19 (15%), a score of 4 in 72 (57%) and a score of 5 in 35 patients (28%). At MRI, monofocal lesions were detected in 113 patients (78%), capsular invasion was observed in 22 patients (15%), vesicle invasion in 4 cases (3%). Lymph node involvement was identified in 2 patients, whereas bone pelvic lesions only in 1 case. At PSMA PET/CT, PS were: 14 (9.7%) scored 1, 11 (7.6%) scored 2A, 6 (4.2%) scored 2B, 13 (9%) scored 3, 63 (43.7%) scored 4, and 37 (25.7%) scored 5. PSMA PET/CT identified lymph node involvement in 11 and distant metastases in 12 patients (7.8% and 8.3%, respectively). Patients with both favorable and unfavorable disease exhibited a similar prevalence of PIRADS 4/5. However, the PS of 4/5 was more frequent in unfavorable (n=50/60; 83%) than in favorable disease (n=50/84; 60%) (p<0.01). PSMA PET/CT demonstrated a higher rate of lymph node involvement (9% vs. 7%) and distant metastases (12% vs. 6%) in patients with unfavorable than favorable risk, a distinction that MRI was unable to establish. ***Conclusion:*** For patients with intermediate-risk PCa, PSMA PET/CT offers an additional tool to predict unfavorable outcomes. Future prospective studies should delve deeper into this matter, exploring its relevance not just in the staging process but also during diagnosis.

EP-0247

The added value of PSMA PET/CT compared to mpMRI in detecting locoregional lymph nodes during the primary staging of intermediate-risk prostate cancer

G. Celesti[1,2], *F. Lanfranchi[1], G. Fornarini[3], L. Sofia[1], T. Di Raimondo[1], S. Raffa[1], M. I. Donegani[1], R. Laudicella[2], F. Minutoli[2], S. Baldari[2], G. Sambuceti[1,4], M. Bauckneht[1,4];*
[1]Department of Health Sciences (DISSAL), University of Genova, Genova, ITALY, [2]Nuclear Medicine Unit, Department of Biomedical and Dental Sciences and Morpho-Functional Imaging, University of Messina, Messina, ITALY, [3]Medical Oncology, IRCCS Ospedale Policlinico San Martino, Genova, ITALY, [4]Nuclear Medicine, IRCCS Ospedale Policlinico San Martino, Genova, ITALY.

Aim/Introduction: In the 2024 European Association of Urology (EAU) guidelines, prostate-specific membrane antigen positron emission tomography/computed tomography (PSMA PET/CT) is strongly recommended for the primary staging of high-risk prostate cancer (PCa). However, the recommendation for its use in intermediate-risk settings remains "weak". This is primarily because, among the three available phase 3 trials focusing on primary staging, only two included intermediate-risk patients, who constituted a small percentage compared to those at high-risk. Indeed, the pre-test probability of distant metastatic disease in the intermediate-risk group is low. Consequently, the added value of PSMA PET/CT, compared to multiparametric magnetic resonance imaging (mpMRI) for nodal assessment, requires further evaluation. In this single-center retrospective study, we compared the diagnostic accuracy of PSMA PET/CT and mpMRI for locoregional lymphnode (N) staging in patients with high- and intermediate-risk PCa. ***Materials and Methods:*** We retrospectively analyzed PCa patients who underwent primary staging mpMRI and [18F]PSMA-1007 PET/CT at our institution between 01/2020 and 01/2022. Inclusion criteria were: (i) histologically confirmed PCa categorized as (ii) intermediate- or high-risk according to the D'Amico classification, and (iii) treated with radical prostatectomy and extended pelvic lymphnode dissection (ePLND). Positive nodes were defined as nodes > 8 mm at mpMRI and nodes with PSMA-RADS 4-to-5 at PET/CT, following the standardized E-PSMA reporting criteria. The reference standard for the N-stage was histopathology (pN). We calculated sensitivity, specificity, positive and negative predictive value (PPV and NPV), for mpMRI alone and the combination of mpMRI and PSMA PET/CT in both intermediate- and high-risk patients. ***Results:*** Out of 100 PCa patients, 61 were at intermediate-risk and 39 at high-risk, resulting in 5 (8.2%) and 17 (43.6%) cases of pN1, respectively. In the intermediate-risk PCa setting, the combination of mpMRI and PSMA PET/CT significantly enhanced the sensitivity of N detection compared to mpMRI alone (40% vs. 20%, p=0.016), without significantly reducing PPV (11.8% vs. 16.7%, p=0.441) or NPV (93.2% vs. 92.7%, p=0.915). As expected, in the high-risk setting, combining the two imaging modalities increased both sensitivity (94.1% vs. 52.9%, p<0.001) and NPV (92.3% vs. 69.2%, p=0.010) compared to mpMRI alone. ***Conclusion:*** The combination of PSMA PET/CT and mpMRI increased the sensitivity of N-staging in newly diagnosed intermediate-risk PCa patients without compromising the test's PPV and NPV. Given the high NPV in the PCa intermediate-risk scenario, further studies are necessary to assess the role of a multimodal imaging approach in theoretically preventing the need for ePLND.

EP-0248

Spleen versus right parotid gland for PSMA expression scoring in Prostate cancer imaging with ^{18}F-PSMA-1007 PET/CT according to PROMISE : a critical approach

G. Arsos, *D. Katsampoukas, V. Mpalaris, A. Morfesi, A. Kalaitzoglou, E. Moralidis;*
Aristotle University of Thessaloniki, Thessaloniki, GREECE.

Aim/Introduction: PROMISE offers standardized interpretation of Prostate cancer (ProCa) lesions in ^{18}F-PSMA-1007 PET/CT by scoring based to their uptake in comparison to three reference organs : 0 (< blood pool [BP]), 1(= or > BP and < spleen [SPL]), 2 (= or > SPL and < right parotid gland [RPG]) and 3 (=l or > RPG) [1]. For miTNM classification, PSMA scores and CT and/or MRI data are used to characterise lesions as positive/negative/equivocal. We explore the unconvenient situation of SPL uptake higher than RPG. ***Materials and Methods:*** One hundrent thirty-seven men (aged 50-90 years) with ProCa and 18F-PSMA-1007 PET/CT scan were enrolled, one with abdominal splenosis after splenectomy, none with spenomegaly, haematologic disease, RPG excision or radiotherapy. The suspect lesions were scored according to PROMISE. SUVmax of BP, SPL and RPG were measured in all as was SPL radiodensity. The correlation between SPL and RPG SUVmax was estimated by linear regression analysis. According to their RPG/SPL SUVmax ratio the patients were allocated into groups 1 (ratio > 1) and 2 (ratio = or < 1). The demographic, biochemical and metabolic data of the two groups were compared by Mann-Whitney test. Data are shown as mean±SD. ***Results:*** SUVmax of SPL and RPG are not related to each other. Twenty five out of 137 patients (18.2%) were allocated in group 2. Inversely to PROMISE, their lesion scores 2 and 3 were based on RPG and SPL uptake respectively. The RPG/SPL SUVmax ratio was 1.8±0.1 vs 0.7±0.0, for the groups 1 and 2 respectively (p<0.001). SUVmax of MD, RPG and SPL was 1.8±0.5 vs 1.4±0.8, 22.5±6.1 vs 13.7±4.8 9, and 13.1±4.3 vs 19.0±5.3 for groups 1 and 2 respectively (p<0.05 for all paired comparisons). Age, BMI, administered activity, SPL radiodensity and PSA levels did not significantly differ between the groups. ***Conclusion:*** PROMISE is widely used as a tool for uniform interpretation and reporting 18F-PSMA-1007 PET scans, based on an ordered, organ activity-related scoring system. However, for a considerable percentage of patients this scoring escalation (BP, SPL, RPG) is not valid, with both enhancement of PSMA uptake by the SPL and attenuation in the RPG about equally contributing to this deviation. The biologic basis of the finding, may deserve further attention, especially in relation to disease burden. ***References:*** Eiber M et al. Prostate Cancer Molecular Imaging Standardized Evaluation (PROMISE): Proposed miTNM Classification for the Interpretation of PSMA-Ligand PET/CT. J Nucl Med 2018.

EP-0249

Clinical value of a negative ^{18}F-PSMA PET/CT study in patients with PSA recurrence level below 1 ng/mL after radical prostatectomy. Impact on salvage radiotherapy.

M. Cózar Santiago[1], *J. García Garzón[2], J. Pastor Peiro[3], A. Esteban Hurtado[1], J. Aguilar Barrios[1], R. Sanz Llorens[1], A. Escriba Torres[1], M. Soler Lopez[1], J. Ferrer Rebolleda[1];*
[1]ASCIRES-General Hospital Universitary, Valencia, SPAIN, [2]PET/CT Unit CETIR-ASCIRES, Barcelona, SPAIN, [3]ASCIRES-Department of Radiotherapy, Valencia, SPAIN.

Aim/Introduction: To evaluate the value of pelvic salvage radiotherapy (PSRT) in patients with a negative 18F-PSMA-PET/CT study. ***Materials and Methods:*** We prospectively included 138 patients with post-prostatectomy biochemical recurrence of prostate cancer [mean PSA 0.80 ng/mL (range 0.17-1.0 ng/mL)] who were referred for an 18F-PSMA-PET/CT study.The 18F-PSMA-PET/CT scan was negative in 66/138 patients (47.82%). Differences were analysed between those patients who were or were not candidates for pelvic salvage radiotherapy (PSRT) decided upon multidisciplinary committee and patient consent, with a minimum

follow-up time for 1 year. Response to treatment was defined as a 50% reduction in PSA levels. Recurrence was ascertained upon clinical, analytical and imaging follow-up outcomes. ***Results:*** 59.09% (39/66) of the patients with a negative 18F-PSMA-PET/CT underwent PSRT.Of these, 89.74% (35/39) patients demonstrated response to treatment (PSMA false negatives). In the remaining four patients: one increased PSA, one remained unchanged and two showed only no PSA response (not confirmed on the 18F-PSMA-PET/CT follow-up study). 40.90% (27/66) of patients with negative 18F-PSMA-PET/CT did not undergo PSRT.Of these, progressive PSA elevation was observed in 55.55% (15/27) (PSMA false negatives), localising recurrence on the 18F-PSMA-PET/CT follow-up study in 4 patients: one local recurrence, one iliac lymph node recurrence and two bone recurrence cases.Of the remaining 11 patients (40.74%), three showed fluctuating PSA levels and 8 decreasing PSA values. ***Conclusion:*** Our series confirmed 50 (75.75%) 18F-PSMA-PET/CT false negatives cases.Patients with post-prostatectomy biochemical recurrence and a negative 18F-PSMA-PET/CT study are likely to benefit from pelvic salvage radiotherapy, with response seen in 89.74% of our cases.

EP-0250

Optimizing Prostate Cancer Recurrence Diagnosis using PSMA and Choline PET Radiomics

E. Panagiotidis[1], *S. Andreou[1], K. Angeioplasti[1], A. Paschali[1], E. Vlontzou[2], T. Kalathas[1], M. Chatzimarkou[1], A. Pipintakou[1], A. Makridou[1], J. Datseris[2], E. Papanastasiou[3], V. Chatzipavlidou[1];*
[1]Theageneio Cancer Center, Thessaloniki, GREECE, [2]Evangelismos Hospital, Athens, GREECE, [3]Aristotle University of Thessaloniki, Thessaloniki, GREECE.

Aim/Introduction: To evaluate the potential of 18F-PSMA-1007 (PSMA) compared to ^{18}F-Choline PET/CT (FCH) for identifying metastatic lesions in prostate cancer (PCa) patients with biochemical recurrence (BCR) using radiomic features and quantitative biomarkers. ***Materials and Methods:*** This prospective study recruited 106 BCR patients who had undergone primary PCa treatment. All received both PSMA and FCH PET/CT scans within a 10-day window, followed by a minimum 6-month follow-up. Clinical data (pathology, PSA, doubling time, velocity, and prior treatment) was analyzed. Standardized uptake value (SUV) max, mean, PSMA/Choline total volume, and total lesion PSMA/Choline were calculated for all identified lesions using LifeX software. ***Results:*** Of the 286 lesions identified, the majority 140 (49%) were lymph node metastases, 118 (41.2%) were bone metastases and 28 lesions (9.8%) were locoregional recurrences of prostate cancer. The median SUVmax value was significantly higher for ^{18}F-PSMA compared to ^{18}F-Choline for all 286 lesions (8.26 vs. 4.99 respectively, p<0.001). There were statistically significant differences in median SUVmean, PSMA/FCH-TV and TL-PSMA/FCH between the two radiotracers (4.29 vs. 2.92, 1.97 vs. 1.53 and 7.31 vs. 4.37 respectively, p<0.001). The correlation between SUVmean/ SUVmax and PSA level was moderate, both for ^{18}F-PSMA (r=0.44, p<0.001; r=0.44, p<0.001) and ^{18}F-Choline (r=0.35, p<0.001; r=0.41, p<0.001). TL-PSMA/FCH demonstrated statistically significant positive correlations with both PSA level and PSA velocity for both ^{18}F-PSMA (r = 0.56, p < 0.001; r = 0.57, p < 0.001) and ^{18}F-Choline (r = 0.49, p < 0.001; r = 0.51, p < 0.001). While patients who received hormone therapy showed higher median SUVmax values for both radiotracers compared to those who did not, the difference was statistically significant only for ^{18}F-PSMA (p < 0.05) ***Conclusion:*** Our study suggests that ^{18}F-PSMA-1007 outperforms ^{18}F-Choline in detecting metastatic lesions based on radiomic features and quantitative biomarkers in BCR patients. This improved performance may be particularly relevant for patients with lower PSA levels. ***References:*** 1. Panagiotidis E et al. Evaluation of a novel the most promising radiofluorinated PSMA inhibitor ^{18}F-siPSMA-14 in patients with biochemical recurrence of prostate cancer (PCa)- initial experience

M. Dyankova[1,2], *T. Stoeva[1], Z. Dancheva[1], S. Chausheva[1], T. Yordanova[1], B. Chaushev[1], A. Klisarova[1];*
[1]St. Marina University Hospital. Department of Nuclear Medicine., Varna, BULGARIA, [2]Medical University Varna "Prof. Dr. Paraskev Stoyanov". Department of Nuclear Medicine, Metabolic Therapy and Radiotherapy., Varna, BULGARIA.

Aim/Introduction: The encouraging preclinical assessment of $^{[18F]}$siPSMA-14 was confirmed in an promising proof-of-concept study in PCa males. The aim of this study was to analyze the diagnostic value of $^{[18F]}$siPSMA-14 in patients with PC undergoing imaging for biochemical failure after radical therapy and to define the predictive factors of 18F-siPSMA PET/CT positivity in this context. ***Materials and Methods:*** We performed a retrospective analysis of 67 consecutive patients with biochemical recurrence (BCR) after radical treatment for PC (surgery or radiotherapy (RT)) who underwent 18F-siPSMA-14 PET/CT between November 2023 and February 2024. Potential influences of several factors such as age, International Society of Urological Pathology (ISUP) grade, T stage, actual PSA (aPSA) value and androgen deprivation therapy (ADT) were evaluated. Univariate statistical analysis was performed to assess parameters associated with 18F-siPSMA-14 PET/CT positivity. ***Results:*** The mean age (± SD), median iPSA and aPSA of the patients were: 69.7 (8.2) years, 14.0 ng/ml and 2.5 ng/ml, respectively. 18F-siPSMA PET/CT detected recurrent disease in 49 patients (73.1%). In 24 patients (35.8 %) a local recurrence was revealed. Metastatic lymph nodes incidence was 20 (29.9%). Bone metastases were observed in 22 patients (32.8%) and visceral metastases in 3 patients (4.5%). Lymph nodes plus bone metastases were detected in 6 patients (9.0 %). In univariate analysis, the ISUP groups, the T stage and ADT were found to be predictors of positivity. Tumor-detection was positively associated with iPSA and aPSA levels, whereas ISUP grade, T stage and EAU risk groups showed only a positive tendency. The detection rates were 22.2%, 50.0%, 60.0%, 66.7%, 77.8%, 90.0% and 95.5% for aPSA levels (ng/ml) of 0.2- <0.3, 0.3- <0.4, 0.4- <0.5, 0.5- <1.0, 1.0- <2.0, 2.0- <5.0 and ≥ 5.0, respectively. aPSA was significantly higher in PSMA-positive patients than in PSMA-negative patients (p=0.037). PET-positive males presented a faster kinetic (PSAdt), p =0.074. 18F-PSMA-14 PET/CT was positive in 5 of 6 patients (83.3%) with PSA <0.5 ng/mL and PSAdt <6 months, and in 3 of 14 patients (21.4 %) with PSA <0.5 ng/mL and PSAdt≥6 months. ***Conclusion:*** $^{[18F]}$siPSMA-14 shows excellent kinetics for the restaging of Pca and provides high detection rates of recurrent PC after radical treatment even in close proximity to the bladder and at low aPSA levels. The PSA value at the time of the examination appear to be the main predictor of 18F-siPSMA PET/CT positive findings. Tumor detection is positively associated with iPSA and aPSA levels.

EP-0252

Clinical Value of Volumetric Parameters PSMA-TL and PSMA-TV in Patients with Early Biochemical Recurrence of Prostate Cancer

I. Rogic, *A. Golubic, N. Jukic, D. Huic;*
University Hospital Centre Zagreb, Zagreb, CROATIA.

Aim/Introduction: Our study aimed to assess if there are any correlations between quantifiable volumetric parameters PSMA-TV (PSMA tumour volume), PSMA-TL (PSMA total lesion uptake = PSMA-TV * SUVmean) and whole-body tumour burden (1) with already well-established biochemical biomarkers and risk factors of prostate cancer (PC), as well to compare them with treatment response in patients with early onset of biochemical recurrence and low serum PSA values (<2 ng/ml). ***Materials and Methods:*** We performed a retrospective analysis of 55 patients with biochemical recurrence of PC who underwent 68Ga-PSMA PET-CT scan. Lesions with visually higher uptake compared to the surrounding tissue were rated as PSMA-positive, indicating local recurrence or metastases. In total 198 PSMA avid lesions were reported and analysed further. We used volumetric semi-automatic analysis (Syngo.via volumes of interest (VOIs) with isocontours) to calculate SUVmean, PSMA-TV and PSMA-TL. Whole-body PSMA-total volume (wbPSMA-TV) and whole-body PSMA-total lesion (wbPSMA-TL) were calculated by the sum of each lesion. ***Results:*** A high positive correlation was found between serum PSA values and wbPSMA-TL (Pearsons r=0.628; p< 0.001) and between PSA and wbPSMA-TV (Pearsons r=0.533; p< 0.001). wbPSMA-TV and wbPSMA-TL values were significantly higher in the intermediate unfavourable and high-risk group (ISUP 3,4,5) than in the favourable intermediate and low-risk group (ISUP 1,2) (p<0.001). Patients with shorter PSAdt (doubling time) of less than 6 months also had significantly higher values of wbPSMA-TV and wbPSMA-TL. ***Conclusion:*** PSMA-derived volumetric parameters are excellent imaging biomarkers for the whole-body tumour burden of PC. Higher PSA values, unfavourable PSAdt and high ISUP grade groups are all associated with larger tumour volumes. Whole-body PSMA-TL especially showed a superior correlation with PSA values and should be added in scan reports as an adequate semi-quantitative evaluation of disease. Higher wbPSMA-TV and wbPSMA-TL were also associated with a lower percentage of complete or partial biochemical response.

EP-0253

Prediction of biochemical recurrence in patients following radical prostatectomy using preoperative [^{68}Ga]Ga-PSMA PET/CT prostate lesion uptake features

M. Machado, *F. Oliveira, C. S. Constantino, J. Fonseca, D. C. Costa;*
Champalimaud Clinical Centre, Champalimaud Foundation, Av. Brasília, 1400-038 Lisbon, PORTUGAL.

Aim/Introduction: Biochemical recurrence (BCR) after radical prostatectomy (RP) remains a challenge, affecting a substantial proportion of patients. Despite the development of clinical models integrating traditional prognostic indicators such as PSA levels, clinical T staging, and Gleason score, their predictive accuracy for BCR remains suboptimal. [68Ga]Ga-PSMA PET/CT is a fundamental tool for staging and re-staging after RP. However, the prognostic potential of staging [68Ga]Ga-PSMA PET/CT to predict BCR after RP has been rarely investigated. Therefore, this study aims to investigate whether staging [68Ga]Ga-PSMA PET/CT has predictive value for BCR after RP. ***Materials and Methods:*** The dataset was retrospectively collected from patients who underwent a staging [68Ga]Ga-PSMA PET/CT scan followed by RP at our hospital, from 2017 to 2020. From the 80 patients initially found, 18 were later excluded: 5 since [68Ga]Ga-PSMA PET/CT was performed outside of our institute, and their PET data were unavailable; 8 because they required adjuvant radiotherapy post-RP; 3 due to persistence and subsequent biochemical progression within the first three months after RP; and 2 had also other primary tumors. At surgery, the final dataset (62 patients) had a mean age of 64±6.5 years and, a PSA of 8.91±6.61 ng/mL. All prostate lesions were identified and semi-automatically segmented based on a Bayesian classifier algorithm in the [68Ga]Ga-PSMA PET/CT images by an experienced observer. Prostate lesion PSMA-uptake-related SUVmax, SUVpeak, SUVmean, MTV, and TL-PSMA were extracted. Clinicopathological variables were also collected, namely, Gleason score, clinical T staging, N staging and grade group at RP, and time to BCR or follow-up. Cox regression analysis was performed to assess the association between PSMA-uptake-based features and clinicopathological features with the time to BCR. ***Results:*** During follow-up, 26 patients (42%) experienced BCR with a median time of 1904 days (95%CI:1442-2366) post-RP. Cox multivariate analysis conducted on PSMA-uptake-based features revealed that only SUVpeak was a statistically significant predictor (HR=1.10, 95%CI:1.01-1.19), suggesting a 10% increase in the expected hazard of BCR for an increase of 1 in SUVpeak (IBM SPSS software, Backward Stepwise - LR Conditional). Cox multivariate analysis showed that when clinical T staging, Gleason score, and SUVpeak were assessed together, SUVpeak still preserved potential as an independent predictor of BCR, although not statistically significant (HR=1.08, 95%CI:0.99-1.18). ***Conclusion:*** Our results show that SUVpeak might be an independent predictor of BCR after RP, thus emphasizing the value of staging [68Ga]Ga-PSMA PET/CT. Further studies with larger datasets should be performed to confirm this finding.

EP-0254

Prostate Cancer Survival Time Prediction Using Radiomic Features from PET/CT Scans

K. Molin[1], *N. Barry[1,2], S. Gill[1,3], G. M. Hassan[1], R. J. Francis[4], J. S. L. Ong[5], M. A. Ebert[1,3,2], J. Kendrick[1,2];*
[1]School of Physics, Mathematics and Computing, University of Western Australia, Crawley, AUSTRALIA, [2]Centre for Advanced Technologies in Cancer Research (CATCR), Perth, AUSTRALIA, [3]Department of Radiation Oncology, Sir Charles Gairdner Hospital, Nedlands, AUSTRALIA, [4]Medical School, University of Western Australia, Crawley, AUSTRALIA, [5]Department of Nuclear Medicine, Fiona Stanley Hospital, Murdoch, AUSTRALIA.

Aim/Introduction: Prostate cancer poses a significant challenge due to its high prevalence and unfavourable outcomes for patients with metastatic disease. This study aims to develop a model to predict overall survival (OS) for patients with metastatic biochemically recurrent (BCR) prostate cancer. Such advancements could facilitate personalised treatment approaches, potentially extending patient survival durations. ***Materials and Methods:*** A multi-centre cohort of 238 patients diagnosed with BCR metastatic prostate cancer were included in

the study. Each patient underwent a [68Ga]Ga Prostate Specific Membrane Antigen (PSMA)-11 PET/CT scan, with lesions manually segmented by an expert nuclear medicine physician. From these scans, radiomic features, including various quantitative imaging metrics, were extracted from the identified lesions. We conducted a univariate analysis using Kaplan-Meier curves and Cox proportional hazards models to identify radiomic features correlated with OS. Radiomic data was then combined with key clinical parameters, including age, weight, and initial staging, for multivariable analysis. Three models were compared: a clinical-only, radiomics-only, and a combined feature model, using a Cox proportional hazards model. To ensure robustness, we resampled the dataset 1000 times using bootstrapping techniques. This was done to establish 95% confidence intervals (CI) for optimism-corrected concordance indices and to identify highly prognostic features within each model group. Finally, we developed custom predictive models based on these highly prognostic features to improve predictive capabilities. ***Results:*** In our univariate analysis, 68 out of 118 radiomic features correlated significantly with OS, including total lesional volume, maximum 2D diameter of the lesion, and distribution of pixel intensity, among others. The optimism-corrected 95% CI for the concordance indices of the multivariable models were as follows: radiomics-only model 0.671 (95% CI, 0.554-0.742), clinical-only model 0.721 (95% CI, 0.651-0.779), and combination model 0.724 (95% CI, 0.656-0.785). Both the clinical-only and combination models exhibited similar performance; however, further analysis is required to verify these results. Additionally, traditional clinical features like age, staging, and lesion count were consistently correlated with OS. ***Conclusion:*** Preliminary results generated from this study indicate that radiomics features in combination with standard clinical variables have the potential to prognose patient OS. Comparisons between this combined model and individual radiomic and clinical models will be undertaken to determine the additive benefit that radiomics has. Accurate predictions of OS can guide clinicians in tailoring treatments, thereby improving patient outcomes, especially for metastatic prostate cancer.

EP-0255

The utility of the PET/CT with ^{18}F-Piflufolastat in the localization of locoregional and distant recurrence in patients diagnosed with prostate cancer and its relationship with the different ISUP prognostic grades and PSA values.

J. Badell, *P. García-Talavera San Miguel, E. Campaña Díaz, S. Rama Alonso, F. Caltagirone Gutierrez, A. C. Peñaherrera Cepeda, L. Díaz González, E. Casillas Sagrado, F. Gómez-Caminero Lopez, J. G. Villanueva Curto, J. C. Cañadas Salazar, P. Tamayo Alonso;*
Hospital Clinico Universitario de Salamanca, Salamanca, SPAIN.

Aim/Introduction: To determine the detection rates of locoregional and distant recurrences in patients with prostate cancer by PET/CT with 18F-Piflufolastat and its positivity in relation to different ISUP prognostic grades and PSA values. ***Materials and Methods:*** We included 358 patients (68.8 years ± 7.2 years), diagnosed with prostate cancer, who were referred to our department for a PET/CT study with 18F-Piflufolastat, between October/2020 and April/2024, due to biochemical recurrence. The initial curative treatment for the majority was radical prostatectomy (320/358). A PET/CT study, centred on the cranium-pelvis, was acquired 120 minutes after intravenous administration of 333 MBq of 18F-Piflufolastat, after administration of 20 mg of furosemide 60 minutes prior to image acquisition. In the positive studies, the SUVmax value of the target lesion was located and quantified. The rate of positive PET/CT studies was calculated as a function of ISUP grades and PSA value at recurrence, as well as the correlation of SUVmax value with the different prognostic grades. ***Results:*** Patients were classified into three groups according to their prognostic grade at diagnosis (ISUP Grades), ISUP 1: 56/358, ISUP 2-3: 172/358 and ISUP 4-5: 127/358. 2/290 patients had no medical reports. PET/CT localised the recurrence in 58.9% of patients (211/358), with an average SUVmax value of the target lesions of 11.2. The most frequent site of target lesions was: prostate/prostatic bed 30.80% (65/211), pelvic lymphadenopathy 45.02% (95/211), retroperitoneal lymphadenopathy 8.53% (18/211), bone 14.21% (30/211) and other 1.42% (3/211). The proportion of positive scans according to ISUP prognostic groups was: ISUP 1: 48.21% (27/56), ISUP 2-3: 56.97% (98/172) and ISUP 4-5: 66.14% (84/127) and according to PSA values (ng/ml) at recurrence was: between 0.2-0.5: 42.10% (72/171), 0.51-1: 69.42% (84/121), 1.1-2: 80% (28/35) and ≥2: 87.09% (27/31). There was no significant difference between SUVmax values of target lesions according to ISUP grades. ***Conclusion:*** PET/CT with 18F-Piflufolastat is a useful technique for localisation of recurrence in patients with biochemical recurrence of prostate cancer. The pelvic lymph node disease was the most frequent localisation. A significant increase in the proportion of positive scans is observed the higher the PSA levels at recurrence and the ISUP prognostic grade at diagnosis, however, the mean SUVmax value of target lesions does not correlate with ISUP grades.

EP-0256

PSMA-RADS in the assessment of ^{18}F-DCFPyL (PSMA) PET/CT and its correlation with prostate-specific antigen values.

D. Rivas-Navas, *E. Triviño-Ibáñez, R. Sánchez-Sánchez, J. Villa-Palacios, A. Rodríguez-Fernández;*
Hospital Universitario Virgen de las Nieves, Granada, SPAIN.

Aim/Introduction: To evaluate the findings of 18F-DCFPyL PET/CT in biochemical recurrence (BCR) of prostate cancer (PC) treated with curative intent using the PSMA-RADS version 1.0 classification and its correlation with PSA and its kinetics. ***Materials and Methods:*** Observational and prospective study, including patients with BCR of PC, who underwent 18F-DCFPyL imaging between October 2020 and August 2022. Results were categorized as positive and negative, using confirmatory parameters such as pathological anatomy, other imaging tests, and/or clinical follow-up. Lesions were classified according to their prostate-specific membrane antigen (PSMA) expression intensity (IS) (score 0-3) and their probability of malignancy using the PSMA-RADS version 1.0 system. Finally, we analysed the association between IS and PSMA-RADS with PSA values and kinetics. ***Results:*** A total of 101 patients were included (mean age: 63.24±6.37 years). 88 patients had a positive 18F-DCFPyL study (detection rate: 87.1%). 21.8% had recurrence in the prostatic fossa, 29.7% pelvic lymph node involvement, 9% retroperitoneal involvement, and 22.8% distant disease. A total of 199 lesions were detected. Of them, 1.6% had an IS-0, 50.5% IS-1, 25.8% IS-2, and 22% IS-3; with 2.2% classified as PSMA-RADS-1, 4.8% as PSMA-RADS-2, 26.3% as PSMA-RADS-3A, 21% as PSMA-RADS-3B, 0.5% as PSMA-RADS-3D, 36.6% as PSMA-RADS-4, and 8.6% as PSMA-RADS-5. PSA trigger values showed association with PSMA-RADS (p= 0.04) and IS (p= 0.037). Similarly, PSA velocity was associated with PSMA-RADS (p= 0.015). ***Conclusion:*** 18F-DCFPyL PET/CT

demonstrates good performance in detecting BCR of PC. PSMA-RADS classification is feasible in clinical practice and is associated with PSA values.

EP-0257

[68Ga]-Ga PSMA PET/CT in Detecting the Prostate Cancer Recurrence after HIFU and Brachytherapy Treatment: a Retrospective Analysis.

A. Di Giorgio[1], *M. Rapa[1], A. Farolfi[2], S. Fanti[1,2];*
[1]Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: Focal therapy presents an encouraging approach for selectively treating clinically significant localized prostate cancer (PCa), with minimal invasiveness and potentially more cost-effectiveness. Among these therapeutic options, High-Intensity Focused Ultrasound (HIFU) and brachytherapy, remain limited due to the lack of long-term evidence regarding their efficacy in tumor control. It's recommended to conduct patient follow-ups utilizing biopsies and multiparametric MRI (mpMRI). Nevertheless, mpMRI results after intervention frequently yield false negatives. PET/CT with PSMA has shown promising results in identifying recurrence or residual disease following brachytherapy and HIFU therapy, with high sensitivity and specificity in detecting prostate cancer lesions, including those missed by conventional imaging modalities. Therefore, it can be a valuable tool in post-treatment surveillance, aiding in the early detection of recurrence or residual disease, which may prompt timely intervention or further treatment adjustments. ***Materials and Methods:*** We retrospectively analyzed patients with history of PCa who underwent [68Ga]Ga-PSMA PET/CT for biochemical recurrence (BCR) after HIFU or brachytherapy. Patients were screened from 2016 to 2024. ***Results:*** 22 patients were enrolled in the study. The population included 5 (23%) patients with low-risk PCa, 2 (9%) with intermediate risk, 5 (23%) with intermediate unfavorable risk, 3 (14%) with high risk and for 7 (32%) patients the GS was not known. 7/22 (32%) underwent HIFU, while 15/22 (68%) underwent brachytherapy. Among these patients, 1 underwent HIFU after radical prostatectomy (RP), 4 underwent hormonal therapy after focal therapy, while 2 underwent RP after brachytherapy. The median time elapsed from the procedure to the PET scan execution was 77 months (17 - 90). The median PSA value at the time of investigation was 3 ng/ml (1 - 4). The [68Ga]Ga-PSMA PET/CT was able to identify the site of PCa recurrence in 63,6% (14/22) of patients with BCR. 7/14 (50%) out of the positive PSMA PET/CT scans were found to be positive at the prostate with median SUVmax of 13 (6 - 16); 2/14 (14%) were positive at lymph node level with median SUVmax of 4 (3 - 9) while 4/14 (28%) of them were found to have metastatic localization with median SUVmax of 8 (7 - 9). ***Conclusion:*** Focal therapies, such as HIFU and brachytherapy, are minimally invasive and cost-effective, representing a good therapeutic option in the treatment of localized and clinically significant PCa. PSMA PET/CT is an effective diagnostic tool to detect a recurrence of the disease and plan a potential new treatment.

EP-0258

Impact of [18F]PSMA-1007 PET Imaging on Diagnosis and Management of Recurrent Prostate Cancer - A real-world-experience with a bi-centric, retrospective study involving 776 patients

E. Mamlins[1], *S. Sakali[1], E. Novruzov[1], D. Jazmati[2], J. Haussmann[2], C. Antke[1], U. Haberkorn[3], C. Kratochwil[3], G. Antoch[4], G. Niegisch[5], P. Albers[5], J. P. Radtke[5], F. L. Giesel[1];*
[1]Department of Nuclear Medicine, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Duessedorf, GERMANY, [2]Department of Radiation Oncology, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Duessedorf, GERMANY, [3]Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY, [4]Department of Diagnostic and Interventional Radiology, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Duessedorf, GERMANY, [5]Department of Urology, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Duessedorf, GERMANY.

Aim/Introduction: As the first approved 18F labelled PSMA-ligand in Europe, [18F]PSMA-1007 is supposed to draw the attention of uro-oncological community increasingly due to its practicability and superior diagnostic performance in low PSA-window compared with its counterparts. Several studies, to date, have underscored the abovementioned features of this ligand in a series of small to moderately large cohorts. We aimed, however, to demonstrate the diagnostic performance of [18F]PSMA-1007 with a large cohort in a real-world setting in patients with biochemical recurrence (BCR), as this represents probably the leading indication for PSMA-PET. Another endpoint of this study was to determine the impact of the diagnostic performance in terms of therapy management. ***Materials and Methods:*** This bicentric retrospective study included 776 patients with BCR, who have undergone [18F]PSMA-1007 imaging in University Hospital Duesseldorf and University Hospital Heidelberg as part of routine clinical care. We correlated the detection rate of [18F]PSMA-1007 with different PSA cutoff levels across our entire cohort. Additionally, we analyzed the incidence of different types of malignant lesions in the setting of BCR like local recurrence (LR), lymph node (LNM), bone (BM), or distant metastases. Furthermore, we investigated the impact of [18F]PSMA-1007 in terms of the subsequent clinical management strategies. ***Results:*** [18F]PSMA-1007 PET/CT detected lesions in 659 of 776 cases (84,9%). Categorized according to different PSA cutoff levels, the detection rate was found to be 68.6%, 85.6%, 87.5% and 95.8% for PSA levels of 0.2 - <0.5, 0.5 - <1.0, 1.0 - <2.0 and ≥2, respectively. The most frequent PSMA positive lesions were pelvine LNM (38.8%) followed by LR (35.2%) and BM (34.4%). Due to losses from the follow-up, we could evaluate the subsequent clinical management only in 506 cases (30,8% wait and watch, 29,4% PSMA-guided radiotherapy, 20,0% ADT, 8,7% further diagnostics, 4,7% radiotherapy (PSMA-guided) and ADT, 4,2% surgery, 2,2% chemotherapy). Patients with LR (n=173) tended to undergo PSMA-guided radiotherapy more frequently compared to other subgroups (37% PSMA-guided radiotherapy, 27% ADT, 13% wait and watch, 10% further diagnostics, 9% radiotherapy (PSMA-guided) and ADT, 4% surgery). ***Conclusion:*** Obviously, with increasing expertise in PSMA reporting and improved patient pre-selection, we observe the diagnostic performance of [18F]PSMA-1007 imaging even increasing in comparison to the existing literature data. Correspondingly, this impacts the subsequent therapy approach, especially by LR, due to increasing rates of personalized PSMA-guided therapy management. ***References:*** Giesel et al., J Nucl Med 2019; 60:362-368, DOI: 10.2967/jnumed.118.212233.

Optimized detection of local recurrence of prostate cancer using dual-time [18F]PSMA-1007 imaging with combination of TOF and PSF reconstruction

D. Schmitt[1], *K. Mattes-György[1], A. Feisthauer[1], E. Novruzov[1], J. Kuhlmann[1], M. Beu[1], J. Henke[1], D. Jazmati[2], J. Haussmann[2], C. Antke[1], J. Cardinale[1], J. Radtke[3], G. Antoch[4], G. Niegisch[3], L. Schimmöller[4], F. Giesel[1], E. Mamlins[1];*
[1]Department of Nuclear Medicine, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Duesseldorf, GERMANY, [2]Department of Radiation Oncology, University Hospital Dusseldorf, Medical Faculty, Heinrich Heine University of Duesseldorf, Duesseldorf, GERMANY, [3]Department of Urology, University Hospital and Medical Faculty of the Heinrich-Heine-University Duesseldorf, Duesseldorf, GERMANY, [4]Department of Diagnostic and Interventional Radiology, Medical Faculty and University Hospital Duesseldorf, Heinrich-Heine-University Duesseldorf, Duesseldorf, GERMANY.

Aim/Introduction: [18F]PSMA-1007 imaging has significantly improved the diagnostic accuracy in patients with biochemical recurrence (BCR) due to its predominantly hepatobiliary excretion, enabling a better assessment of small lesions in prostate bed. Yet, accurate detection of local recurrence (LR) in early BCR of prostate cancer (PC) represents one of the major challenges due to typically small lesion size resulting in relatively low PSMA uptake. Within this analysis, we sought to assess the impact of dual-time point acquisition protocol and the added value of the reconstruction algorithm with combination of TOF (time of flight) and PSF (point spread function) on the accurate detection of LR in BCR. ***Materials and Methods:*** We retrospectively included 36 consecutive patients with suspect LR in BCR who received a [18F]PSMA-1007 PET/CT scan with late images of the pelvis per standard clinical care. We evaluated tracer uptake and tumour to background ratio (TBR) using semiquantitative PET parameters on baseline and late images based on the reconstruction algorithms of ordered subset expectation maximum (OSEM) and the combination of TOF and PSF. ***Results:*** LR was detected on baseline images with OSEM in 33 cases with a median SUVmax of 5.2 (range 2.4 - 18.2) and a median TBR of 6.4 (range 2.9 - 14.0) and in all 36 cases on baseline images with TOF+PSF reconstruction algorithm with median SUVmax of 9.4 (range 4.1 - 36.4) and a median TBR of 8.0 (range 3.5 - 16.5). An added value of late images was observed on the images with OSEM (median SUVmax of 6.5 (range 2.2 - 21.7)) as two further cases with LR were detected compared with baseline. TOF+PSF led to a significant increase of semiquantitative parameters on late images (median SUVmax of 10.8 (range 4.0 - 40.9)). Late images of pelvis provided a better detectability of lesions located at critical sites such as vesicourethral anastomosis. The subsequent therapy could be followed up in 19 cases: 14 patients received PSMA-guided radiotherapy, 3 active surveillance, 1 ADT and 1 PSMA-guided radiotherapy plus ADT. ***Conclusion:*** This study highlights the substantial added value of TOF+PSF reconstruction algorithm and dual-time point protocol on the detection of small-sized lesions with only faint tracer uptake in prostate bed in BCR. Furthermore, the dual-time imaging would improve the diagnostic certainty for the lesions at critical sites such as vesicourethral anastomosis and ensure individualized therapy management.

Aim/Introduction: Prostate-specific membrane antigen (PSMA)-based molecular imaging is currently the most sensitive method for confirming and localizing tumor recurrence in the biochemical recurrence of prostate cancer after primary definitive therapy. ***Materials and Methods:*** We performed a retrospective analysis of data from 54 patients who presented with biochemical recurrence (total serum prostate-specific antigen [PSA] elevation) after definitive treatment, and underwent 18F-JK-PSMA-7 PET/CT scans between July 2021 and January 2024. PET/CT scans were evaluated for the presence of local recurrence, lymph node and distant metastases. Patients were divided into two subgroups according to pre-test PSA level and PSA doubling time (PSAdt). Detection rates (DR) were calculated for the entire patient group and for the subgroups. In case of PSMA PET-positivity, we examined whether there was correlation between the maximum standardized uptake value (SUVmax) of the most intense lesion and the PSA level or PSAdt. ***Results:*** 43 of 54 patients presented with PSMA-avid lesions consistent with prostate carcinoma, resulting in a per patient DR of 79.6% . Pathological PSMA-avid lesions were most commonly found in the prostate bed (n=19) and pelvic lymph nodes (n=19), and suspected tumour spread was also reported in extrapelvic lymph nodes (n=7), bones (n=16) and other organs (n=4). DRs per subgroups were as follows: PSA≤1 ng/ml: 57.9% vs. PSA>1 ng/ml: 91.4% (p=0.027); and PSAdt≤6 months: 80.8% vs. PSAdt>6 months: 78.6% (p=NS). Patients with PSA≤1 ng/ml and PSAdt>6 months formed a group with especially low DR of 54,5%. In patients with PSMA positivity, the most intense lesion SUVmax was significantly higher in the PSA>1 ng/ml group than in patients with PSA≤1 ng/ml (20.2±31.8 vs. 9.6±7.9; p=0.0374). Similarly, higher SUVmax values were also measured in patients with PSAdt less than 6 months than in patients with more moderate PSAdt (20.8±33 vs. 11±8; p=0.006). ***Conclusion:*** PSMA PET/CT is a sensitive method for the detection and localization of recurrent prostate carcinomas with the highest detection rate for PSA levels above 1 ng/ml and/or short PSAdt, in accordance with literature. On the other hand, detection rate was considerably low in patients with low PSA levels and long PSAdt. The uptake intensity of 18F-JK-PSMA-7 showed correlation with PSA levels and (invertedly) with PSAdt.

EP-0261

Impact of short-term androgen deprivation therapy on PSMA PET/CT in prostate cancer patients suspected biochemical recurrence

S. Kang, *B. Moon, H. Yoon, J. Kim, B. Kim;*
Ewha Womans University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: PSMA PET/CT has now spread worldwide and is clinically useful in staging and determining recurrence of prostate cancer. The correlation between androgen deprivation therapy (ADT) and PSMA ligand uptake in patients has been analyzed by several researchers, which has important implications

for judging metastatic lesions, especially biochemical recurrence. In this study, it was performed to analyze the correlation between PSA and PSMA parameters, and their effect on PSMA PET/CT according to short-term ADT use in patients with suspected biochemical recurrence. ***Materials and Methods:*** Patients who underwent 68Ga-PSMA-11 PET/CT scans between November 2023 and March 2024 (n = 186) were retrospectively evaluated. Clinical information including pathologic result with Gleason score, PSA level, and ADT status were evaluated. The maximal standardized uptake value (maxSUV) of urethral anastomosis site and suspected metastatic lesions on 68Ga-PSMA-11 PET/CT was measured. Descriptive statistics included the mean ± standard deviation for each clinical characteristic. Student t-tests and Mann-Whitney U tests were used for comparing quantitative variables with or without a normal distribution, respectively, between the groups. Correlations between two variable distributions were analyzed with the Pearson correlation coefficient (PCC). ***Results:*** Sixty-four patients who performed 68Ga-PSMA-11 PET/CT for evaluation of biochemical recurrence after radical prostatectomy were finally included in this study: 39/64 (61%) were treated with ADT before PET scan. The clinical parameters between the two groups based on short term ADT use before PET scan were not statistically significant (age, 66.97 ± 6.41 vs 69.04 ± 7.57, p = 0.238; Gleason score, 7.44 ± 0.75 vs 7.74 ± 0.95, p = 0.20; PSA level, 0.57 ± 0.63 vs 0.84 ± 0.93, p = 0.169). The maxSUVs of suspected metastatic lesions on PSMA PET scan were weakly and positively correlated with PSAs at scan time (PCC = 0.25, p = 0.048). In addition, the maxSUVs of the group without ADT use before PET scan were moderately and positively correlated with PSA levels (PCC = 0.51, p < 0.01). On the other hand, the maxSUVs in the group with ADT use were not correlated with PSA levels (PCC = 0.21, p = 0.302), suggesting that ADT probably affected PSMA ligand uptake in the metastatic lesion. ***Conclusion:*** The short-term use of ADT before PSMA PET/CT may significantly affect the visibility of recurrent or metastatic lesions on PSMA PET/CT in patients with suspected recurrence. Therefore, performing PSMA PET/CT first may need to be considered before initiating ADT.

EP-0262

Comparison of ^{18}F-PSMA-1007 and ^{18}F-DCFPyL PET-CT in prostate cancer patients with occult biochemical recurrence with low PSA values.

P. Plaza López, *F. Amorelli, J. Blanco-Cano, R. Valhondo, P. Hinojosa, Á. Martínez, Y. Aguilar, M. Algara, P. Foro;*
Hospital del Mar Barcelona, Barcelona, SPAIN.

Aim/Introduction: Our porpouse was to compare the diagnostic accuracy and equivocal findings of PET-CT ^{18}F-DCFPyL and ^{18}F-PSMA-1007 in occult biochemical recurrence (BCR) of prostate carcinoma (PCa) with low PSA values. ***Materials and Methods:*** Sixty-eight patients underwent a PSMA-ligand PET-CT for BCR of PCa evaluation, ^{18}F-DCFPyL or ^{18}F-PSMA-1007, depending of the availability of the radiopharmaceuticals without other criteria. ^{18}F-DCFPyL was synthesized and delivered by Curium Pharma Spain and ^{18}F-PSMA-1007 by IRAB Spain . Patients received an intravenous injection between 299 to 333MBq. After 90 min, a Whole body PET with a diagnostic CT Scan were performed in a Siemens Biograph, following recomendations of EANM Guidelines. Iodine endovenous contrast was given except contraindications. PET/CT images were reviewed using SyngoVia-20 (Siemens Healthineers) by two experimented nuclear medicine physicians . Imaging standardized evaluation for the interpretation of PSMA-Ligand PET/CT for Prostate Cancer Molecular (PROMISE) were used. ***Results:*** 34 patientes (50%) underwent a PET-CT with ^{18}F-PSMA-1007, and the other 34 with ^{18}F-DCFPyL. Not statistical differences betweeen both groups were found in clinical initial staging (ISUP and PSA values), primary treatments even PSA nadir after primary. PSA BCR values just before PET-CT were similar (PET-1007 group median: 0.5ng/mL; PET-DCFPyL group median: 0.6ng/mL, p:0.419), and was no statistical differences in PSA doubling time (p:0.524). PET positive findings for recurrence of PCa were observed in 20 of 34 (58.8%)in PET-PSMA-1007 group, and 15 of 34 (45.5%) in PET-DCFPyL group, but not statistical differences were found (p:0.332). Locations of the recurrences were similar, p:0.538, (local: 17.6% vs 15.2%; and adenopathy: 32.4% vs 21.2%, respectively). A statistically significant higher number of non-cancer related bone images (intermediate or high PSMA expresión) was observed in the PET-1007 group (29.4% vs 6.7%, p:0.026), mostly in ribs. Just one extra imagen study (bone MRI) was needed to clarify PET equivocal bone finding. ***Conclusion:*** ^{18}F-PSMA-1007 and ^{18}F-DCFPyL PET-CT show very similar results in the assessment of BCR of PCa with low PSA values. A higher number non-PCa related bone images was observed in the PET-1007 group, with non increase of equivocal diagnosis in the final report , done by a nuclear medicine expert.

EP-0263

Study of the added value of late PET/CT with $^{[18F]}$F-DCFPyL in the evaluation of patients with prostate cancer.

S. Abouzian, *M. Moragas, D. López-Mora, M. Lozano Murgas, L. Berna Roqueta, M. Santos Virosta, J. Martin Miramon, A. Rodriguez Revuelto;*
Nuclear Medicine Department. Parc Tauli Hospital Universitari. Institut d'investigació i Innovació Parc Taulí (I3PT-CERCA). Universitat Autònoma de Barcelona, Barcelona, SPAIN.

Aim/Introduction: To evaluate the utility of 120-minute delayed images compared to standard images acquired at 60 minutes with PET/CT $^{[18F]}$ F-DCFPyL in patients with prostate cancer. ***Materials and Methods:*** Retrospective study of 39 patients with prostate cancer (69.5 ± 7.01 years) referred to the service between November 2022 and December 2023. Of these patients, 33 had suspected recurrence (PSA range: 0.22-12 ng/mL), 5 were for initial staging (high risk), and 1 was referred to assess treatment response. All patients underwent a $^{[18F]}$F-DCFPyL PET/CT study from the cranial vertex to the mid-thighs at 60 minutes post-injection (p.i.) and an abdominopelvic PET/CT at 120 minutes p.i. For quantitative analysis, SUVmax was calculated for the parotid glands, liver, vascular pool, and target lesions on the 60-minute images, and SUVmax of the liver, vascular pool, and target lesions at 120 minutes were determined. In addition, the intensity of PSMA expression (PSMA score, 0-3)[1] was determined, and the PROMISE guide was used for molecular staging (miTNM) [2] . ***Results:*** In 11/39 patients, the study was negative (28.2%) at 60 and 120 minutes. In 26/28 patients, there was an increase in SUVmax of $^{[18F]}$F-DCFPyL on the 120-minute images (92.3%). Pathological uptake was only detected in the 120-minute images in 2 patients. In 9/26 patients, the PSMA score increased, while the miTNM was only modified in 4. Of these 4 patients in whom the miTNM was modified, there were changes in patient management

in 2 of them (2/26). ***Conclusion:*** Preliminary findings indicate that although there is an increase in [18F]F-DCFPyL uptake in PET/CT images at 120 minutes p.i., this increase does not appear to be significant enough to justify changes in patient clinical management. ***References:*** 1-Ceci F, Oprea-Lager DE, Emmett L, et al. EP-0264

Intraindividual comparison of Ga-68-AMTG and Ga-68-PSMA PET/CT in patients with mCRPC in a theranostic setting

J. Urena Poch[1], *M. Heuschkel[1], S. Schwarzenboeck[1], T. Günther[2], J. Kurth[1], B. Krause[1];*
[1]Department of Nuclear Medicine, Rostock University Medical Center, Rostock, GERMANY, [2]Molecular Imaging Program at Stanford (MIPS), Department of Radiology, School of Medicine, Stanford University, Stanford, CA, UNITED STATES OF AMERICA.

Aim/Introduction: While 68Ga- / 177Lu - labelled PSMA has shown promising results in theranostics settings for patients with mCRPC, still 10-20% of patients with recurrent prostate cancer have no sufficient PSMA expression or it is lost during the course of treatment. For this reason alternative options targeting other expressed molecular entities, like the GRPr antagonists, are being studied. RM2 showed a potential complementary theranostic role together with PSMA, but in vivo studies showed a low in vivo stability of the peptide. New approaches include substitution of unstable aminoacid endings in the RM2 molecule with more stable aminoacid bonds, resulting in derivate molecules like AMTG. Preclinical comparison with Cu-64 and Ga-68 labelled RM2 and AMTG showed promising results with more favorable pharmacokinetics and increased metabolic stability for diagnostic imaging using the derivate AMTG. Thus is to presume that AMTG would be a suitable option for theranostics in PSMA-negative prostate cancer. ***Materials and Methods:*** 13 mCRPC patients were scanned with [68Ga]Ga-PSMA-11 as well as [68Ga]Ga-AMTG to identify PSMA or AMTG positivity, 3 of the 2 times, resulting in a total of 17 examinations. Visual uptake and semi-quantitative parameters (SUVmax, SUVpeak, Total Tumor Volume (TTV) and Total Lesion Metabolism (TLM) were compared in 112 metastatic reference lesions (38 lymph nodes, 67 bone, 5 liver, 2 others). ***Results:*** In the visual assessment all patients showed a PSMA uptake of any grade, of whom only 4 showed a higher, 12 a lower and 1 no AMTG uptake. In 3/17 examinations showed complementary AMTG-positive / PSMA-negative and AMTG-negative / PSMA-positive lesions. SUVmax and SUVpeak were higher for PSMA than for AMTG subsuming all reference lesions. A separate analysis regarding uptake in different lesions was significantly relevant: lymph node ($p = 0.0015$), bone ($p = 0.0131$) and liver metastases ($p = 0.0625$). ***Conclusion:*** Most of the included advanced mCRPC patients presented with a higher number of PSMA-positive lesions and higher uptake on [68Ga]Ga-PSMA compared to [68Ga]GaAMTG PET/CT. Almost no lesion showed high PSMA and AMTG uptake simultaneously, suggesting a fundamental change in tumor biology. Patients with absent or weak PSMA but high AMTG uptake may benefit from the use of [68Ga]Ga-AMTG in restaging and a theranostic approach with additional [177Lu]Lu-AMTG therapy.

EP-0265

The predictive ability of pre-therapeutic ^{18}F-PSMA-1007 PET/MRI imaging features for biochemical recurrence after primary definitive treatment for prostate cancer

H. Chunyu[1], *Y. Yang[2], J. Dai[3], X. Chen[1], W. Hai[1], Q. Qu[1], H. Meng[1], B. Li[1], J. Zhao[2], J. Hu[1];*
[1]Department of Nuclear Medicine, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA, [2]Department of Nuclear Medicine, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, CHINA, [3]Department of Urology, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, CHINA.

Aim/Introduction: Radical prostatectomy (RP) remains the recommended treatment for patients with localized prostate cancer (PCa). However, nearly 40% of patients experience biochemical recurrence (BCR) after primary definitive treatment. The clinical D'Amico risk-group stratification model has been developed to predict BCR, including preoperative prostate-specific antigen (PSA), clinical T staging, and Gleason scores from histopathology. Clinical studies showed that the D'Amico model's predictive accuracy for 5-year BCR was below than 70%. It has been reported that either MR assessment or PSMA PET imaging has promising predictive ability respectively for BCR of PCa after prostatectomy. In this study, we aim to evaluate the predictive value of pre-therapeutic images obtained by integrated PET/MR with ^{18}F-PSMA-1007 for postoperative BCR in PCa patients, and to establish a predictive model for BCR by using gained multiple-modality parameters. ***Materials and Methods:*** Consecutive patients, who underwent pre-therapeutic ^{18}F-PSMA-1007 PET/MR imaging from double hospitals in shanghai and were followed up for at least two years after RP, were included in this retrospective double-center study. The correlation between PET/MR multiple parameters and the risk of BCR were analyzed by Chi-square test. The COX multivariate regression analysis was utilized to identify significant influencing PET/MR parameters. Their relationship with the outcomes after surgery was tested through Kaplan-Meier analysis. Finally, a predictive model based on ^{18}F-PSMA-1007 PET/MR was developed, and its predictive performance was compared with that of D'Amico, single-factor SUVmax or PI-RADS model. ***Results:*** 71 patients were included, whose ^{18}F-PSMA-1007 PET/MR imaging parameters, including primary prostate cancer SUVmax, PI-RADS score, ADCmin, and distant metastasis with PSMA uptake, were statistically significantly correlated with their clinical outcomes. COX regression verified that primary prostate cancer SUVmax and PI-RADS scores were significant predictors of BCR. Patients with higher uptake of SUVmax (>14.96) or higher PI-RADS (PI-RADS≥4) had more possibility of BCR. Model based on both had the highest predictive value, with its AUC being 0.858, which performed better than that of D'Amico model (AUC=0.789), single-factor SUVmax model (AUC=0.819), and single-factor PI-RADS model (AUC=0.702). ***Conclusion:*** Model based on primary prostate cancer SUVmax and PI-RADS score from integrated PET/MR with ^{18}F-PSMA-1007, had the best predictive ability for BCR of two years post-RP. However, further large-scale prospective studies are needed.

EP-0266

Comparative analysis of ^{68}Ga-PSMA-11 and ^{18}F-PSMA-1007 in prostate cancer restaging PET/CT: differences and similarities

V. Lavelli, *C. Ferrari, A. R. Pisani, C. Battisti, C. Palumbo, N. C. Merenda, G. Rubini;*
Nuclear Medicine Unit, DIM, University "Aldo Moro", Bari, ITALY.

Aim/Introduction: We investigated the diagnostic performance of 68Ga-PSMA-11 and 18F-PSMA-1007 PET/CT in biochemical recurrent PC patients (BCR), according to clinical and histological parameters. ***Materials and Methods:*** In our centre, 3200 PC patients underwent PET/CT with radiolabelled-choline, fluciclovine, or PSMA; we selected BCR patients with 68Ga-PSMA-11 (Ga-group) or 18F-PSMA-1007 (F-group) PET/CT from July 2022 to August 2023. Patients'clinical features - PSA, Gleason Score (GS<8 or ≥8), ISUP (<3 or ≥ 3), EAU BCR risk group (high/low) - and clinical follow-up were registered. Chi-square, Fisher's exact, and Mann-Whitney U tests were used for calculating the correlation between PET detection rate (DR) and patient features in Ga- and in F-group. Moreover, we calculated the optimal PSA cut-off to predict PET response by ROC curve analysis. Defining clinical follow-up as the gold standard, in both radiotracers-group and in PSA cut-off subgroups, we evaluated sensitivity, specificity, accuracy, PPV, NPV. Finally, in both groups we identified the lesion with greater uptake - reference lesion - and related its SUVmax with the clinical features. A p<0.05 was statistically significant. ***Results:*** We evaluated 120 patients, 77/120 (64.16%) in Ga-group and 43/120 (35.83%) in F-group. A positive PET was found in 32/77 (41.55%) Ga-group patients, with a higher DR (20/77, 26%) in lymph nodes, and in 21/43 (48.83%) F-group patients, with a higher DR in prostate bed (12/43, 27.90%). A statistically significant correlation between PET outcome and GS (p= 0.006), ISUP (p= 0.007) and BCR risk class (p= 0.038) was highlighted only in Ga-group; particularly we found a positive PET scan in 75% of GS≥ 8 and ISUP≥ 3 patients and in 90.6% of high BCR patients. The optimal PSA cut-off predicting a positive PET was 0.85 ng/mL (AUC 0.71, 95% CI 0.611-0.804), with a significative correlation with PET outcome in both groups. Sensitivity, specificity, PPV, NPV, and accuracy in Ga- and F-group were: 68.88% vs 70.37%, 95.65% vs 86.66%, 96.87% vs 90.47%, 61.11% vs 61.90% and 77.94% vs 76.19%, respectively. Only in F-group, SUVmax had a statistically significative positive correlation with patient's clinical features, particularly GS (p= 0.031) and PSA cut-off (p=0.046). ***Conclusion:*** Direct comparison data between 68Ga- or 18F-PSMA are still limited, but our analysis highlighted similar reliability and effectiveness in BCR patients evaluation. The higher 18F-PSMA loco-regional DR was probably explained by its lower urinary excretion. In the real world, most Nuclear Medicine Units choose between these two radiopharmaceuticals based on their availability.

EP-0267

Lymph nodal PSMA-PET/CT radiomic dissemination features to predict Prostate Cancer biochemical recurrence

C. Ferrari[1], *V. Lavelli[1], D. Rubini[2], C. Battisti[1], A. Sardaro[3], G. Rubini[1];*
[1]Nuclear Medicine Unit, DIM, University "Aldo Moro", Bari, ITALY, [2]Radiotherapy, Precision Medicine Department, University of Campania "Luigi Vanvitelli", Naples, ITALY, [3]Radiology and Radiation Oncology, DIM, University "Aldo Moro", Bari, ITALY.

Aim/Introduction: We investigated the clinical significance of PSMA-PET/CT metabolic and dissemination radiomic features of lymph nodal disease in improving the recurrence prediction in prostate cancer (PC) patients. ***Materials and Methods:*** We screened 202 68Ga/18F-PSMA PET/CT performed in PC patients for staging/restaging purpose, selecting patients who presented only lymph nodal disease. For each scan, the LN with the highest uptake was identified and SUVmax, SUVmean, MTV and TLA calculated. The distance between the most-avid LN and pubic symphysis (Dmax1) was calculated for each patient, and normalized to the body surface area (SDmax1). In addition, the farthest LN from prostate bed was pointed out and the absolute and normalized distances (Dmax2, SDmax2) were registered. After PET exams, data about the following treatment and the time of PSA recurrence were collected during 1-year follow-up. The relation between LN metabolic (SUVmax, SUVmean, MTV, TLA) and dissemination (Dmax1, Dmax2, SDmax1, SDmax2) features and PSA recurrence was assessed using Mann-Whitney U test. The cut-off points predictive of recurrence for all the features were determined using ROC analysis. The respective prognostic effects were achieved using the Kaplan-Meier and multiple linear stepwise regression analyses. A p<0.05 was statistically significant. ***Results:*** 40 patients were included in our analysis (mean age 72, range 51-85). Median value of SUVmax, SUVmean, MTV, TLA, Dmax1, Dmax2, SDmax1, SDmax2 were: 12.15 (range: 1.5-83.0), 7.61 (range: 0.86-51.4), 1035mm3 (range: 5.87-253000), 6.4 g/mlxcm3 (range: 1.6-360.2), 108.15mm (range: 65.5-473.8), 113.65mm (range: 68-518.3), 55.96mm (range: 32.42-241.3), 58.25mm (range: 34.13-262.83). In 14/40 (35%) patients, LN was outside the pelvis. In 26/36 (72%), Dmax1 and Dmax2 were coincident. At 1-year follow-up, 23/40 (57.5%) patients experienced PSA recurrence. A strong positive correlation between Dmax1 (p=0.016), Dmax2 (p=0.001), SDmax1 (p=0.03) and SDmax2 (p=0.001) and PSA recurrence was observed. At 1-year PSA follow-up, these parameters were significantly higher in patients with relapse than in patients without. Kaplan-Meier analysis estimated a median PFS of 10.0 months (95%CI 7.8-12.0), and showed the prognostic value of TLA (p=0.023), Dmax1 (p=0.043) and Dmax2 (p=0.023), using as optimal cut-off: 11.2 g/mlxcm3, 136.9mm and 175.4mm respectively. Dmax2 was identified as the unique predictor of biochemical recurrence by multiple linear regression (p=0.001). ***Conclusion:*** Our preliminary results showed that PET metabolic (TLA) and dissemination radiomics (Dmax1, Dmax2) features of lymph nodal disease can improve the prediction of recurrence in PC patients. Particularly, the farthest LN from prostate bed appeared the most reliable feature in the prognostic model.

EP-0268

The prediction value of PSMA and FDG heterogeneity phenotype in mCRPC novel endocrine therapy

L. Panli, *L. Bian, S. Song;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: This study used PSMA and FDG to evaluate the inter-lesion heterogeneity of prostate cancer and explored the predictive value of heterogeneity subtyping for novel endocrine therapy (NHT). ***Materials and Methods:*** This study included 205 patients with prostate cancer who underwent 18F-FDG and 68Ga-PSMA imaging, including 23 patients with BCR, 68 patients with mCSPC, and 114 patients with mCRPC, among mCRPC,62 received NHT. The patients were divided based on the lesion heterogeneity of dual PET/CT images. Group 1 defined as the PSMA+FDG- group, which only showed PSMA+FDG- lesions; Group 2 defined as the PSMA+FDG+ group, which showed at least one PSMA+FDG+ lesion but no PSMA-FDG+ lesion, combined or not with PSMA+FDG- lesions; and Group 3 defined as the PSMA-FDG+ group, which showed at least one PSMA-FDG+ lesion, combined or not with PSMA+FDG- and PSMA+FDG+ lesions. The highest FDG uptake lesion was selected as the analysis target lesion, and the SUVratio was defined as the ratio of PSMA-SUVmax to FDG-SUVmax. Survival analysis methods were used to explore the predictive value of the parameter SUVratio for the PFS of patients

receiving NHT. ***Results:*** The proportion of Group1 (PSMA+FDG-) decreases in the three stages of BCR, mCSPC, and mCRPC, while the proportion of Group2 and Group3 containing (FDG+) increases in sequence, with a statistically significant difference (p=0.001). In the BCR stage, the proportions of Group1-3 were (60.9%, 14/23) vs [34.8%, 8/23] vs [4.3%, 1/23], p<0.001), respectively. For mCSPC patient, the proportions of three groups were (27.9%, 19/68) vs [61.8%, 42/68] vs [10.3%, 7/68], p<0.001), respectively. In mCRPC, the proportion of three groups were (15.8%, 18/114) vs [71.9%, 82/114] vs[12.3%, 14/114], p<0.001), respectively. In the NHA treatment cohort, the proportions of three groups were 15.8% vs 71.9% vs 12.3%. The median PFS of Group 3 patients was significantly lower than Group 1 (133-day vs 497-day, p=0.027). The K-M curve of Group 2 partially overlaps with both Group 1 and 3, and cannot be well stratified. Subgroup analysis of Group 2 revealed that patients with high SUV ratio (cutoff value 2.5) had a higher PSA50 response rate (73.7% vs 33.3%, p=0.014), and a longer median PFS (368 vs 147 days, p=0.031). ***Conclusion:*** The use of FDG and PSMA dual tracers can better understand the heterogeneity between lesions in patients, and the SUVratio parameter can assist in early prediction of NHT. However, there is currently a lack of clear biological feature explanations for SUVratio.

EP-0269

Matched-pair analysis of molecular image outcomes in patients with biochemical recurrent prostate cancer: [^{68}Ga]Ga-PSMA-11 or [^{18F}]-PSMA-1007?

B. Zhu, *C. Liu, S. Song;*
Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: To determine which tracer ([68Ga]Ga-PSMA-11 or [^{18F}]PSMA-1007) was suggested to identify underlying lesions in prostate cancer (PCa) patients with biochemical recurrence (BCR) under various clinical conditions. ***Materials and Methods:*** 64 PCa patients with BCR after radical prostatectomy (RP) who underwent [^{18F}]PSMA-1007 PET/CT imaging were included and a series of similar clinical criteria were used to match the same number of patients who underwent [68Ga]Ga-PSMA-11 PET/CT scans. ***Results:*** In total, 531 and 216 PSMA-ligand positive lesions were revealed by [^{18F}]PSMA-1007 and [68Ga]Ga-PSMA-11, respectively. [^{18F}]PSMA-1007 had greater overall detection rate (DR) (81.3% vs. 59.4%, p=0.007) than [68Ga]Ga-PSMA-11. The DR (38.1% vs. 71.4%, p=0.002) of [^{18F}]PSMA-1007 were found to be higher than those of [68Ga]Ga-PSMA-11 in patients with PSA < 1 ng/mL. For PSA 1-3 ng/mL, [68Ga]Ga-PSMA-11 (p=1.000) was more accurate than [^{18F}]PSMA-1007 (p=0.035) in detecting oligometastatic patients. Compared to [68Ga]Ga-PSMA-11, [^{18F}]PSMA-1007 found more local recurrent lesions in the prostatic fossa (16 vs. 8), but 68.8% and 100% of these individuals were oligometastatic (p=0.214), respectively. However, [^{18F}]PSMA-1007 had more unspecific bone uptake (98 vs. 34) and ganglia uptake (128 vs. 46). ***Conclusion:*** The two tracers here suggested are both effective for detecting lesions in PCa patients at BCR. In patients with PSA < 1ng/mL in [^{18F}] PSMA-1007, better recurrence/metastasis detection is achievable. For PSA 1-3 ng/mL, [68Ga]Ga-PSMA-11 was more accurate in detecting oligometastatic patients.

EP-0270

Clinical Association of Deep Learning Enabled Total PSMA Lesion Quotient (TLQ) and Prostate Cancer Molecular Imaging Standardized Evaluation (PROMISE) Criteria with Outcome in Prostate Cancer Patients

J. Ingvar[1], *A. Anand[2], J. Richter[2], K. Sjostrand[2], E. Tragardh[1], D. Minarik[1], A. Bjartell[1];*
[1]Department of Translational Medicine, Lund, SWEDEN, [2]EXINI Diagnostic AB, Lund, SWEDEN.

Aim/Introduction: PSMA PET imaging is playing an important role in the management of prostate cancer patients, including patient eligibility for PSMA-targeted therapies. However, clinical applications of imaging biomarkers are limited by time consuming calculation of whole body PSMA PET parameters. The objective of this study was to evaluate the association of deep learning-enabled total body quantitative PSMA biomarkers, recommended in the PROMISE framework, with clinical outcome. ***Materials and Methods:*** We retrospectively evaluated prostate cancer patients who underwent PSMA PET-CT for biochemical recurrence (BCR) after initial treatment with curative intent. PSMA PET-CT images were analyzed with the CE marked aPROMISE application for automated segmentation and quantification of SUVmean, tumor volume (Vol), PSMAscore and TLQ (Vol:SUVmean quotient). To generate the quantitative PSMA biomarkers, the reader had to agree or disagree with the pre-defined hotspots marked as candidate lesions by the deep-learning network. The quantitative PSMA parameters were correlated with baseline PSA value at time of PSMA PET-CT and with outcome measures - time to subsequent treatment. Non-parametric Spearman correlation was used to evaluate the association between baseline PSA and quantitative PSMA score. Cox Proportional model with scaled parameters was used to evaluate association with outcome. ***Results:*** We evaluated biomarkers in PSMA PET images at BCR and oncologic outcome in prostate cancer patients. All 69 patients were followed for disease progression and subsequent treatments. The median follow-up time was 112 weeks and 20/69 patients (30%) received subsequent systemic therapies. There was significant (p<0.0001) association of all quantitative PSMA biomarkers with baseline PSA. TLQ was significantly associated with outcome (HR= 1.41 p= 0.023), PSMAscore (HR=1.23; p=0.065) and Vol (HR=1.23; p=0.066) were close to significant. SUVmean (HR=1.02; p=0.942) and SUVmax (HR=1.16; p=0.413) were not clinically significant in their association with outcome. ***Conclusion:*** The study demonstrated that deep learning enabled PSMA biomarkers TLQ and PSMAscore are clinically relevant and may play a significant role in management of prostate cancer patients in BCR setting. Incorporating these biomarkers in prospective and controlled studies are required to validate the findings.

EP-0271

Additional value of whole-body MRI compared to PSMA PET in biochemically recurring prostate cancer

A. Nys[1], *N. Ahmadi Bidakhvidi[1], S. Jentjens[1], A. Laenen[2], G. Devos[3], C. M. Deroose[1], W. Everaerts[4], S. Joniau[3], K. Goffin[1];*
[1]Nuclear Medicine, University Hospitals Leuven; Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM, [2]Interuniversity Institute for Biostatistics and Statistical Bioinformatics, Leuven, BELGIUM, [3]Urology, University Hospitals Leuven; Urogenital, Abdominal and Plastic Surgery, Department of Development and Regeneration, KU Leuven, Leuven, BELGIUM, [4]Urology, University Hospitals Leuven; Laboratory of ion channel research, Department of Cellular and Molecular Medicine, KU Leuven, Leuven, BELGIUM.

Aim/Introduction: At present, prostate-specific membrane antigen (PSMA) PET is the standard imaging modality in biochemically recurring (BCR) prostate cancer (PCa). The role of whole-body magnetic resonance imaging (wb-MRI), however, remains unclear in this setting. Our aim is to evaluate the additional value of wb-MRI compared to PSMA PET in patients with BCR PCa. ***Materials and Methods:*** A post-hoc analysis of data of a prospective monocentric study, including patients with BCR PCa who received a hybrid [68Ga]Ga-PSMA-11 or [18F] PSMA-1007 PET/MRI. Patients were included in this analysis if follow-up data including histopathological results, follow-up imaging and PSA levels following targeted salvage radiation or systemic therapy were available for at least 2 years after PSMA PET/MRI. PSMA PET and wb-MRI scans were independently assessed for the presence and number of malignant lesions, on a patient and organ level. Each malignant lesion was correlated with the available follow-up data of the patient to determine its true positive (TP) or false positive (FP) nature. Comparison between PSMA PET and wb-MRI was done using the TP detection rate (TPPET/(union TPPET and TPMRI); TPMRI/(union TPPET and TPMRI)), positive predictive value (PPV, TPPET/(TPPET and FPPET); TPMRI/(FPMRIand TPMRI)) and number of TP malignant lesions. ***Results:*** A total of 76 patients with BCR PCa were included. At patient level, TP detection rate of PET was higher than wb-MRI, (35/35, 100% versus 23/35, 66%, respectively, p=0.0005) and PET observed a higher number of TP lesions compared to MRI (mean 2.2 versus 1.3, respectively, p=0.0021). At organ level, TP detection rate on PET was higher compared to wb-MRI (47/52, 90% versus 31/52, 60%, respectively, p=0.0042). Organ-specific analysis revealed a higher TP detection rate of distant metastases (i.e. extrapelvic lymph nodes, bone lesions and visceral lesions) on PET compared to MRI (19/20, 95% versus 12/20, 60%, respectively, p=0.039). The number of TP lesions in an organ on PET was higher compared to MRI (mean 1.9 versus 0.9, respectively, p=<0.0001). Organ-specific analysis revealed a higher number of TP lesions on PET compared to wb-MRI for pelvic lymph nodes and all lymph nodes (mean 2.0 versus 1.2, p=0.016 and mean 2.9 versus 1.2, p=0.028, respectively). No difference was seen in PPV between PET and wb-MRI on both patient and organ level. ***Conclusion:*** In patients with BCR PCa, wb-MRI (i) does not provide additional value regarding the TP detection rate compared to PSMA PET and (ii) is equivalent to PSMA PET for PPV.

Use of ^{68}Ga-PSMA-HBED-CC (^{68}Ga-PSMA-11) PET/CT At Initial Staging For Intermediate And High-Risk Prostate Cancer

G. dos Santos[1,2], *A. Banchero[3], J. Leiva[3], V. Trindade[3], E. Savio[3], S. Vilche[1], L. Perez[1], J. Gambini[3], P. Duarte[3], O. Alonso[3];*
[1]Hospital de Clinicas "Dr. Manuela Quintela", Montevideo, URUGUAY, [2]Uruguayan Center of Molecular Imaging (CUDIM), Montevideo, Uruguay, URUGUAY, [3]Uruguayan Center of Molecular Imaging (CUDIM), Montevideo, URUGUAY.

Aim/Introduction: 68Ga-PSMA-HBED-CC (68Ga-PSMA-11) PET/CT remains as a clinically relevant and commonly used technique for the detection of regional lymph-node and distant mmetastases in prostate cancer patients at initial staging with its consequent therapeutic behaviors. The aim of this research was to assess the sensitivity and specificity of 68Ga-PSMA-11 PET/CT for the initial staging of intermediate and high-risk prostate cancer. ***Materials and Methods:*** This is a retrospective, descriptive, observational and multicenter study that included 15 centers in Uruguay and 68 consecutive patients in which 68Ga PSMA-11 PET/CT was used as initial staging after diagnosis of intermediate and high-risk prostate cancer, between January 2019 and October 2023. All patients were previously staged with abdominopelvic computed tomography and bone scan.All patients underwent routine 68Ga-PSMA-11 PET/CT scanning with a 64-slice PET/CT scan with TOF correction. Histopathology, correlative imaging, and/or clinical follow-up were considered the gold standard for reference, and follow-up was conducted at least 5 months after PET/CT scanning. Sensitivity, specificity, and predictive values were calculated. ***Results:*** The mean age was 66 years (range 50-84 years) and the mean PSA was 24.9 ng/mL (range: 10-152 ng/mL). 35.8% of patients were intermediate risk CP and 64.2% high risk. The overall detection rate was 82% (56/68) for 68Ga-PSMA-11 PET/CT. 44.8% of patients had positive 68Ga-PSMA-11 PET/CT for nodal and bone metastasis. A total of 145 extra-prostatic lesions were detected in the bone (n = 56), lymph-nodes (n = 88), and lung (n = 1) by the PET tracer. At initial staging sensitivity and specificity for nodal and bone metastasis was 50% and 87%, and 69% and 76%, respectively. ***Conclusion:*** In our series 68Ga-PSMA-11 PET/CT has a higher sensitivity and specificity for diagnosis of nodal and bone metastasis than conventional imaging with computed tomography and bone scan. This is an novel imaging technique for the assessment of primary medium and high-risk prostate cancer with promising potential for the detection of metastatic spread that would impact patient management. ***References:*** Prostate Cancer, Version 2.2019, NCCN Clinical Practice Guidelines in Oncology. Shen, G., et al. Comparison of choline-PET/CT, MRI, SPECT, and bone scintigraphy in the diagnosis of bone metastases in patients with prostate cancer: a meta-analysis. EP-0273

Innovative Approaches in Prostate Cancer Management: The Efficacy of Ga-68 PSMA PET/CT in Detecting Bone Metastases

B. Bozdemir, *G. Mutevelizade, N. Aydin, G. Gumuser, E. Sayit Bilgin;*
Celal Bayar University Department of Nuclear Medicine, Manisa, TÜRKIYE.

Aim/Introduction: Identifying bone metastases in prostate cancer patients poses a considerable challenge, particularly prior to the emergence of morphological changes discernible through conventional diagnostic methodologies. The aim of this study is to compare the performance of Ga-68 PSMA PET/CT with MRI, CT, and Bone Scintigraphy in detecting bone metastases. ***Materials and Methods:*** A retrospective analysis was conducted on 1113 patients diagnosed with prostate adenocarcinoma, with a Gleason Score of 6 or higher, who presented to our clinic between 2016 and 2023. Of these patients, 126 with MRI, CT, or Bone Scintigraphy images within a 30-day period before and after the Ga-68 PSMA PET/CT imaging for staging purposes were included in the study. Patients were divided into three groups based on the nature of bone metastases: "sclerotic," "bone marrow," and "mixed type" for those with both sclerotic and bone marrow metastases,

and the findings were compared. ***Results:*** The average age of the patients included in the study was 70.98 ±10.19 years, and the average serum PSA value was 246.7± 406.34 µgr/L. In addition to Ga-68 PSMA PET/CT imaging, 53 patients had MRI, 61 had CT, and 32 had Bone Scintigraphy. The Ga-68 PSMA PET/CT images were evaluated independently by two nuclear medicine specialists, without reference to findings from other imaging methods. Of the patients, 65 (51.5%) were in the sclerotic group, 12 (9.5%) in the bone marrow group, and 49 (39%) in the mixed group. The median PSA value was 59.78 mg/dl in the sclerotic group, 104.1 mg/dl in the mixed group, and 3.72 mg/dl in the bone marrow group. When compared with Ga-68 PSMA PET/CT, it was observed that CT failed to detect metastatic bone lesions in 52% of the patients. This rate was calculated as 26% for MRI and 8% for Bone Scintigraphy. ***Conclusion:*** Compared with conventional imaging methods (MRI, CT) and Bone Scintigraphy, Ga-68 PSMA PET/CT has been found to be more successful in detecting bone marrow metastases, especially before morphological changes have occurred. CT, MRI, and Bone Scintigraphy can show false negativity in metastatic bone/bone marrow lesions. In situations where Ga-68 PSMA PET/CT cannot be performed, Bone Scintigraphy maintains its superiority over CT and MRI. Especially in patients with medium and high-risk prostate cancer, for staging, assessing response to treatment, in clinically suspected bone metastases, and/or detected biochemical recurrence, Ga-68 PSMA PET/CT should be considered as the primary examination to be referred to.

EP-0274

The first-in-human study of ^{64}Cu-PSMA-3Q for real-time intraoperatively targeted biopsy in patients with suspected prostate cancer

J. Zhang[1], *B. Xu[1], J. Zhang[1], Y. Liu[1], S. Niu[2], X. Zhang[1], X. Xu[1], Y. Pan[1], H. Liu[1];*
[1]Department of Nuclear Medicine, The First Medical Center of Chinese PLA General Hospital, Beijing, CHINA,
[2]Department of Urology, The First Medical Center of Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: At present, the most common biopsy method for prostate cancer(PCa) is transrectal ultrasound-guided biopsy (TRUS-Bx), but there are still some limitations, such as technical leakage and postoperative complications due to the excessive number of cores. Prostate-specific membrane antigen (PSMA)-targeting radiopharmaceuticals are ideal tools for the diagnosis and treatment of prostate cancer. PSMA PET/CT guided targeted biopsy is expected to become a new method to further improve the diagnostic rate of prostate cancer. This study aims to develop a novel PSMA radiotracer, 64Cu-labeled PSMA, with a long half-life and to explore the feasibility of quantitative radioactive uptake in biopsy tissue to guide accurate intraoperative puncture. ***Materials and Methods:*** 64Cu-PSMA-3Q was prepared and its stability, PSMA specificity, and micro-PET imaging were analyzed. A total of four consecutive patients with suspected PCa were enrolled. All patients underwent 64Cu-PSMA-3Q PET/CT scans followed by PET/CT image-guided 24 hours later. The radioactivity of the biopsy tissue was measured as counts per minute (cpm) in a wiper well gamma spectrometer during the operation. Finally, groups were grouped based on pathological results and statistical results were analyzed. ***Results:*** Micro-PET imaging of 64Cu-PSMA-3Q can clearly differentiate 22Rv1 tumor from background with a high SUVmax(2.23±0.49, 2.59±0.18 and 2.84±0.46 at 1h, 6h and 24h, respectively)and a tumor-to-muscle ratio(15.43±4.44, 20.09±0.95 and 18.06±1.59 at 1h, 6h and 24h, respectively). A total of 44 biopsy cores were obtained in 4 patients, of which 14 cores were pathologically positive for prostate cancer. The median cpm was overall significantly higher in needles with PCa (212, 271 cpm) compared to needles without PCa (18, 34 cpm , P<0.0001). ROC analysis yielded an AUC of 0.965, with an optimal cut-off to confirm PCa at 130 cpm (sensitivity: 100%; specificity: 92.9%). Only 1 out of 14 positive biopsy cores had a count of 18, which was much lower than the average of the prostate cancer group. It may be related to the small proportion of tumor tissue taken by biopsy. ***Conclusion:*** The uptake of 64Cu-PSMA-3Q in prostate cancer can be used to accurately confirm the lesion sampling during biopsy. This technology can enhance the confidence of the biopsy provider, reduce the number of puncture needles, and thus reduce the pain of patients and the occurrence of postoperative complications. Therefore, it is expected to become a promising new tool for biopsy in patients with suspected PCa.

EP-0275

Confirmed Extraprostatic Findings Showing Psma Expression On Gallium-68 Psma Pet/CT Imaging

E. Gökdemir, *Ü. Korkmaz, A. Sarıkaya;*
Trakya University, Edirne, TÜRKIYE.

Aim/Introduction: Aim:The aim of this study was to investigate the findings of PSMA receptor expression on Ga68 PSMA PET/CT imaging that are not related to prostate malignancy. ***Materials and Methods:*** Methods:The medical data of 1345 Ga68 patients who underwent PSMA PET/CT imaging between 2018 and 2024 were retrospectively analyzed. Among these patients, 31 patients who showed PSMA receptor affinity and were radiologically, histopathologically or clinically confirmed not to be secondary to prostate malignancy were included in the study. ***Results:*** In 1 patient who underwent Ga68 PSMA PET/CT and was found to have no involvement secondary to prostate malignancy, the brain lesion was radiologically proven to be osseous cavernous hemangioma in 1 patient and secondary to encephalomalacia in 1 patient.The breast involvement seen in 1 patient was correlated with radiology as secondary to gynecomastia.4 Radiologic correlation of the single bone lesion observed in 4 patients revealed fibrous dysplasia in 1, hemangioma in 1, and artifactual involvement in 2.The diffuse bone involvement observed in 3 patients was radiologically and clinically confirmed to be secondary to Paget's disease.The asymmetric rosenmuller fossa involvement in 1 patient was evaluated as inflammation after clinical examination, and the intense transverse colon involvement in 1 patient was evaluated as physiologic after colonoscopy.2 Of the histopathologically confirmed thyroid nodules observed in 2 patients, 1 was found to be PTK and 1 was found to have atypia of uncertain significance.1 patient with suspicious uptake in the prostate lobe was histopathologically confirmed as chronic prostatitis.1 patient with heterogeneous increased uptake in the liver was interpreted as secondary to multiple cystic lesions by USG.15 Histopathologically, lung adenocarcinoma was detected in 1 patient, chronic bronchitis in 1 patient and inflammatory process in 2 patients. The other patients were found to have benign features such as post-radiotherapy changes, tuberculosis sequelae, consolidation areas, sequelae emphysematous changes, interstitial lung disease after radiological and clinical follow-up. ***Conclusion:*** It should be considered that benign lesions, inflammatory processes and other malignant processes may show PSMA expression. It is also recommended that other malignancies with PSMA receptor affinity should be evaluated for suitability for PRRT. ***References:*** ηττπσ://δοι.οργ/10.1053/φ.σεμνυχλμεδ.2021.06.016

EP-0276

Correlation of Lesion-Based SUV Parameters Calculated in Ga-68 PSMA PET/CT and Lu-177 PSMA SPECT/CT in Patients with Metastatic Castration-Resistant Prostate Cancer.

***B. Cagdas*[1],** *H. San*[1], *A. O. Yüksel*[1], *N. Yildirim*[1,2];
[1]*Ankara Bilkent City Hospital Department of Nuclear Medicine, Ankara, TÜRKIYE,* [2]*Ankara Yıldırım Beyazıt University, Ankara, TÜRKIYE.*

Aim/Introduction: This study aims to investigate the correlation between lesion-based SUV parameters obtained from the 24-hour Lutetium-177 Prostate Spesific Membrane Antigen (Lu-177 PSMA) quantitative Single Photon Emission Tomography/Computer Tomography (SPECT/CT) examination and the SUV parameters from pre-treatment Ga-68 PSMA PET/CT imaging in patients with metastatic castration-resistant prostate cancer (mCRPC) undergoing prostate-specific membrane antigen (PSMA) targeted radioligand therapy (RLT). Furthermore, the aim is to determine the relationship between lesion-based treatment response and these parameters. ***Materials and Methods:*** In the scope of the research SUV parameters, locations, and sizes of physiological and metastatic lesions were calculated from the 24th hour Lu-177 PSMA quantitative SPECT/CT imaging of 55 patients who received at least 2 cycles of Lu-177 PSMA treatment between November 2021 and August 2023. SUV parameters from the same regions were also calculated from Ga-68 PSMA PET/CT before Lu-177 PSMA treatment. Patient data, including Gleason score, age and previous treatments before Lu-177 PSMA therapy, were noted. Lesion-based treatment response was examined by comparing post-treatment Ga-68 PSMA PET/CT with pre-treatment Ga-68 PSMA PET/CT after each of the two Lu-177 PSMA treatments. ***Results:*** Our research revealed that SUV parameters obtained from Ga-68 PSMA PET/CT were higher than those obtained from Lu-177 PSMA SPECT/CT and a moderate to high correlation between the two measurements, especially higher in physiological areas ($p<0.05$). In the subgroup analysis of malignant lesions according to their location, it was determined that primary prostate lesions showed the highest correlation level ($R^2=0.72$, $p<0.01$) in the SUVmax parameter. A higher correlation level was observed in malignant lesions with a volume >3 mL ($R^2=0.67$; $R^2=0.74$). SUV parameters from Lu-177 PSMA SPECT/CT were identified as an independent predictor for lesion-based treatment response. ***Conclusion:*** The correlation of lesion-based SUV parameters obtained from the two imagings is high, and our findings demonstrate the predictive value of SPECT/CT imaging after PSMA Radioligand therapy (RLT) for treatment response. ***References:*** 1. Prognostic value of PSMA PET/CT in synchronous metastatic hormone-sensitive prostate cancer: an interim analysis

***F. Kleiburg*[1,2],** *L. Heijmen*[2], *K. van Duuren*[3], *P. L. C. Zuidgeest*[2], *F. Smit*[4], *L. de Geus-Oei*[1,2,3], *T. van der Hulle*[2];
[1]*University of Twente, Enschede, NETHERLANDS,* [2]*Leiden University Medical Center, Leiden, NETHERLANDS,* [3]*Delft University of Technology, Delft, NETHERLANDS,* [4]*Alrijne Hospital, Leiderdorp, NETHERLANDS.*

Aim/Introduction: In synchronous metastatic hormone-sensitive prostate cancer (mHSPC), stratification into low- and high-volume disease according to the CHAARTED criteria [1] is used to guide treatment decisions. However, these criteria were based on conventional imaging and since the introduction of PSMA PET/CT, the definition of low- and high-volume disease has become unclear. This study aims to provide insight into the prognostic value of PSMA PET/CT in combination with clinical parameters, which can serve as a basis for this redefinition. ***Materials and Methods:*** Patients with mHSPC staged with PSMA PET/CT were included in this retrospective study. After delineation with a threshold of SUV=4 [2], the PET parameters SUVmax, total tumour volume (PSMA-TV), total lesion uptake (TL-PSMA), DmaxVox and metastatic sites were extracted. The clinical parameters WHO performance status, iPSA, Gleason score and age were also collected. The primary endpoints of this study were time to PSA progression (PFS, according to the PCWG3 criteria) and time to death (OS) in months. Cox regression analysis, with stratification for received treatment, was used to assess the prognostic value of all parameters. ***Results:*** Of the 200 patients enrolled, 90 have been analysed so far. They either received ADT + radiotherapy to the prostate (n=12), ADT only (n=43) or ADT + docetaxel chemotherapy (n=35). PSA progression was seen in 61 patients, 41 patients had died at the time of analysis. Median follow-up was 48 months. In univariate analysis, Gleason score, PSMA-TV, TL-PSMA, DmaxVox and the presence of visceral metastases were prognostic markers for PFS; WHO performance status and age were prognostic markers for OS (all $p < 0.05$). In multivariate analysis, PSMA-TV (HR=1.25 per 100 mL increase [1.05-1.50]) and the presence of visceral metastases (HR=7.929 [1.23-51.2]) remained prognostic markers for PFS; WHO performance status (HR=1.94, [1.22-3.10]) remained a prognostic marker for OS. iPSA and SUVmax had no prognostic value in this analysis. ***Conclusion:*** Interim analysis revealed that multiple PSMA PET parameters and clinical parameters have prognostic value in synchronous mHSPC patients. Results from the 200 included patients will follow soon. This will increase statistical power and hopefully provide solid new insights into the risk stratification of mHSPC patients and aid treatment decision-making, also for triple therapy patient selection. ***References:*** [1] https://doi.org/10.1056/nejmoa1503747 [2] https://doi.org/10.3389%2Ffonc.2021.663631.

EP-0278

Detection rate and impact on clinical management for ^{68}Ga-PSMA-11 PET/CT at very low serum PSA: a single-center, retrospective analysis

***M. Nakayama*[1],** *A. Seyedroudbari*[1], *W. Armstrong*[1], *J. Czernin*[1], *J. Calais*[1], *A. Gafita*[2];
[1]*UCLA Health, Los Angeles, CA, UNITED STATES OF AMERICA,* [2]*Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: The utility of 68Gallium prostate-specific membrane antigen-11 positron emission tomography/computed tomography (68Ga-PSMA-11 PET/CT) in detecting PSMA-positive lesions at levels considered undetectable (≤ 0.1 ng/ml) is unknown. It is also unknown how scans performed at PSA ≤0.1 ng/ml affect subsequent clinical management. The aims of this study were: (1) to measure the detection rate and characterize lesions identified by 68Ga-PSMA-11 PET/CT performed at PSA levels ≤0.1 ng/ml and (2) to evaluate subsequent changes in clinical management based on these scans. ***Materials and Methods:*** We retrospectively screened 3340 patients in 7 clinical trials of 68Ga-PSMA-11 PET/CT performed at UCLA (October

2016-January 2023). Of these, 3% (n=95) met the inclusion criteria of serum PSA levels ≤0.1 ng/ml within 12 weeks of scan. We collected their clinical data from institutional electronic medical records, and subgroup analyses were performed for serum PSA levels ≤0.1 ng/ml (n=95), ≤0.05 ng/ml (n= 51), and ≤0.01 ng/ml (n=12). A positive 68Ga-PSMA-11 PET/CT scan was defined as having at least one definite/suspicious PSMA positive lesion. ***Results:*** Detection rates were 42% (40/95), 47% (24/51), and 33% (4/12) at PSA ≤0.1 ng/ml, ≤0.05 ng/ml, and ≤0.01 ng/ml, respectively. Of the 40 patients with PSMA-positive findings at PSA ≤0.1 ng/ml, 30% (12/40) of patients had M0 disease and 70% (28/40) of patients had M1 disease. A total of 38 metastatic lesions were identified in patients with M1 disease, of which 63% were osseous lesions (miM1b). 13% were metastatic lesions in solid organs (liver and lung). Follow-up treatment data was missing in 33% (31/95) patients. Among those with treatment data available, 47% (30/64) had PSMA-positive definitive/suspicious lesions. Among these, 67% (20/30) had a change in clinical management. Initiating radiation therapy was the most common change in management seen in 65% (13/20) of patients. ***Conclusion:*** In our study, the detection rates of 68Ga-PSMA-11 PET/CT at PSA of ≤0.1 ng/ml, ≤0.05 ng/ml, and ≤0.01 ng/ml were 42%, 47%, and 33%, respectively. At PSA ≤0.1 ng/ml, positive findings detected on 68Ga-PSMA-11 PET/CT led to a change in management in 67% of patients, with initiation of radiation therapy being the most common change. Overall, our study suggests the potential benefit of performing 68Ga-PSMA-11 PET/CT at the level of PSA that is considered undetectable (≤0.1 ng/ml). It also highlights the fact that important decisions on clinical management are made based on these scans in clinical practice.

Pretreatment PSMA PET/CT scans predict treatment response and survival in metastatic castration-resistant prostate cancer: a patient-level and lesion-level analysis

F. Kleiburg[1,2], *L. de Geus-Oei[1,2,3], R. Spijkerman[1], W. A. Noortman[1,2], F. H. P. van Velden[2], F. Smit[4], F. A. J. Toonen[4], S. A. C. Luelmo[2], T. van der Hulle[2], L. Heijmen[2];*
[1]University of Twente, Enschede, NETHERLANDS, [2]Leiden University Medical Center, Leiden, NETHERLANDS, [3]Delft University of Technology, Delft, NETHERLANDS, [4]Alrijne Hospital, Leiderdorp, NETHERLANDS.

Aim/Introduction: Metastatic castration-resistant prostate cancer (mCRPC) is a heterogeneous disease with varying survival outcomes. This study investigated whether pretreatment PSMA PET/CT can predict treatment response and survival, which can aid treatment decision-making. ***Materials and Methods:*** 57 mCRPC patients underwent [18F]PSMA-1007 PET/CT at baseline and for assessing imaging response to treatment with androgen receptor-targeted agents or chemotherapy. For patient-level analysis, intensity-based, volumetric and dissemination parameters were extracted from pretreatment PSMA PET/CT, and compared to age, Gleason score and laboratory parameters. PSMA PET/CT scans were delineated using a fixed threshold of SUV=4 [1]. Cox regression analysis evaluated their prognostic value for progression-free survival (PFS, time to either PSA progression on imaging-based progression) and overall survival (OS). For lesion-level analysis (N=300), lesion location and morphological, intensity-based and radiomic texture-based GLCM features were analysed. Logistic regression analysis evaluated their ability to predict lesion progression, defined as increase in volume or PSMA-uptake > 30%. All analyses were corrected for line of treatment. ***Results:*** 29 patients received androgen receptor-targeted agents, 28 patients received chemotherapy. Median follow-up was 28.4 months. Total tumour volume (HR=1.38 per doubling [1.14-1.67]), total lesion uptake (HR=1.36 per doubling [1.13-1.63]), DmaxVox (HR=1.04 per cm increase [1.01-1.06]) and metastatic locations were prognostic for OS, all independent of PSA (HR=0.8 per doubling [0.7-1.0]) and haemoglobin level (HR=0.6 per mmol/L increase [0.4-0.8]). For PFS, only total tumour volume and total lesion uptake (for both HR=1.18 per doubling [1.01-1.38]) had prognostic value. On lesion-level, lesion location (HR=0.32 prostate versus bone [0.12-0.84], HR=0.43 lymph node versus bone [0.24-0.78]) and SUVmean (HR=1.53 per doubling [1.04-2.24]) were the best independent prognostic markers of lesion progression on PSMA PET/CT. Volumetric and texture-based radiomics features were no independent prognostic markers. ***Conclusion:*** Pretreatment PSMA PET/CT scans had prognostic value in mCRPC patients receiving androgen receptor-targeted agents or chemotherapy, both on patient-level and lesion-level and independent of line of treatment. Therefore, PSMA PET/CT can aid treatment decision-making. Further research is required to validate these prognostic models in larger patient cohorts. ***References:*** [1] https://doi.org/10.3389%2Ffonc.2021.663631.

EP-0280

Fully automated AI-based quantification of tumour volume on PSMA PET-CT images is significantly associated with overall survival in patients with prostate cancer

E. Tragardh[1,2], *J. Ingvar[1,3], O. Enqvist[4,5], J. Ulén[6], D. Minarik[1,3], L. Edenbrandt[7,8];*
[1]Skåne University Hospital, Malmo, SWEDEN, [2]Lund university, Malmö, SWEDEN, [3]Lund University, Malmö, SWEDEN, [4]Chalmers University of Technology, Göteborg, SWEDEN, [5]Eigenvision AB, Malmö, SWEDEN, [6]Eigenvision AB, Malmo, SWEDEN, [7]Sahlgrenska University Hospital, Göteborg, SWEDEN, [8]Gothenbrg University, Göteborg, SWEDEN.

Aim/Introduction: We have developed a fully automated artificial intelligence (AI)-based method for detection and quantification of prostate cancer related lesions on [18F]PSMA-1007 PET-CT images. The aim was to determine if automatically obtained measurements of total lesion volume (TLV) is associated with overall survival (OS). ***Materials and Methods:*** A total of 277 patients, referred for clinically indicated PSMA PET-CT between September 2019 and July 2021 due to either primary staging of newly diagnosed high-risk prostate cancer or due to secondary staging of biochemical recurrence were included. TLV for the prostate tumour/prostate recurrence, pelvic lymph node metastases, distant lymph node metastases, bone metastases as well as the total TLV were automatically obtained from the AI method. No manual corrections were made. Uni- and bivariate (adjusted for age) cox regression models for TLV (ml) were used for survival analysis. Harrel's concordance index (C-index) was used for model prediction. Patients were followed for a maximum of 4 years. ***Results:*** During the follow-up period, 36 (13%) of the 277 patients died. TLV for the prostate tumour/prostate recurrence, pelvic lymph node metastases, distant lymph node metastases, bone metastases and total TTV were all significantly associated to overall survival, both unadjusted and adjusted for age ($p<0.001$ for all). Hazard ratios varied between 1.0021 (total TLV) an 1.014 (pelvic lymph node metastases). C-indices were 0.58 for the prostate tumour, 0.63 for pelvic lymph node metastases, 0.67 for distant lymph node metastases, 0.66 for bone metastases and 0.70 for total TLV. ***Conclusion:*** Our fully automated AI-based

method for quantification of prostate cancer related lesions on [18F] PSMA-1007 PET-CT was significantly associated with OS. The total TLV had better predictive potential compared to TLV measured individually in the prostate, lymph nodes and bone. ***References:*** Trägårdh E, et al. Freely available, fully automated AI-based analysis of primary tumour and metastases of prostate cancer in whole-body [18F]PSMA-1007 PET-CT. Diagnostics(Basel) 2022;12:2101.

EP-0281

First-in-human study of [68Ga]Ga-AAZTA-093, a novel PSMA-targeting agent, in patients with prostate cancer

G. Wang[1], *W. Jin[2], Y. Luo[2], R. Wang[2], L. Zhu[2], H. Kung[3], W. Miao[1]; [1]the First Affiliated Hospital, Fujian Medical University, Fuzhou, CHINA, [2]Beijing Normal University, Beijing, CHINA, [3]University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is a promising target for the diagnosis and radioligand therapy (RLT) of prostate cancer (PCa). A series of previous studies have confirmed that [68Ga]Ga-P16-093 showed significantly higher tumor uptake and better target-to-background ratio than [68Ga]Ga-PSMA-11 and [68Ga]Ga-PSMA-617 in patients with PCa. Unfortunately, P16-093 used HBED-CC as a chelator, which can't be labeled with 177Lu for radioligand therapy. Therefore, a new agent, [68Ga]Ga-AAZTA-093 using AAZTA as the chelator suitable for labeling of both 68Ga and 177Lu was developed. The purpose of this study is to explore the clinical application of [68Ga]Ga-AAZTA-093, as well as to compare with [68Ga]Ga-PSMA-11 and [68Ga]Ga-PSMA-617 by PET/CT imaging, respectively. ***Materials and Methods:*** We prospectively enrolled 14 PCa patients for comparative purposes. Among them, 11 patients underwent paired [68Ga]Ga-AAZTA-093 and [68Ga]Ga-PSMA-11 PET/CT, and 3 patients underwent paired [68Ga]Ga-AAZTA-093 and [68Ga]Ga-PSMA-617 PET/CT. Four (4) patients underwent serial dynamic PET scans for [68Ga]Ga-AAZTA-093, and the others underwent PET imaging at fixed time points (60 min for standard scan and 150 min for delayed scan). Standardized uptake values (SUV) were measured for semi-quantitative comparison. ***Results:*** [68Ga]Ga-AAZTA-093 PET/CT scans showed measurably higher SUVmax in tumors than [68Ga]Ga-PSMA-11 PET/CT (25.9 ± 17.0 vs. 21.4 ± 12.7, P = 0.032, at 60 min; 30.0 ± 18.6 vs. 26.1 ± 18.6, P = 0.011, at 150 min). It also showed a higher tumor uptake than [68Ga]Ga-PSMA-617 PET/CT (24.4 ± 10.5 vs. 16.2 ± 8.8, P = 0.132, at 60min,; 29.2 ± 11.2 vs. 20.1 ± 9.6, P = 0.101, at 150 min). In this limited study, biodistribution of [68Ga]Ga-AAZTA-093 showed major uptakes in normal organs (salivary glands, blood pool, kidneys, spleen, liver, muscle, and urinary bladder). But results suggested no statistically significant differences in comparison with [68Ga]Ga-PSMA-11 and [68Ga]Ga-PSMA-617. [68Ga]Ga-AAZTA-093 PET/CT scans yielded similar lesion detection rates as compared with [68Ga]Ga-PSMA-11 and [68Ga]Ga-PSMA-617 PET/CT. However, the same AAZTA-093 has been labeled with [177Lu]Lu(III), which might be useful for radionuclide therapy in the future. ***Conclusion:*** [68Ga]Ga-AAZTA-093 showed improved tumor uptake and retention than [68Ga]Ga-PSMA-11 and [68Ga]Ga-PSMA-617. It is likely that [68Ga]Ga/[177Lu]Lu-AAZTA-093 may be useful as a novel PSMA-targeting agents for both diagnosis and radiotherapy of prostate cancer. Further investigations in a larger number of cohorts were warranted.

Comparison of PSMA Immunohistochemistry Scoring Systems to Parametric [18F]PSMA-1007 PET/MRI in Primary Prostate Cancer

N. Ahmadi Bidakhvidi[1], *T. Gevaert[2], M. De Schepper[3], M. Baldewijns[3], E. Havinga[4], W. Deckers[5], A. Laenen[6], G. Devos[7], A. Giesen[7], S. Joniau[7], M. Koole[1], W. Everaerts[8], C. M. Deroose[1], K. Goffin[1];*
[1]Nuclear Medicine, University Hospitals Leuven; Nuclear Medicine and Molecular Imaging, Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM, [2]Urogenital, Abdominal and Plastic Surgery, Department of Development and Regeneration, KU Leuven, Leuven, BELGIUM, [3]Pathology, University Hospitals Leuven, Leuven, BELGIUM, [4]Radiology, University Hospitals Leuven, Leuven, BELGIUM, [5]Nuclear Medicine, University Hospitals Leuven, Leuven, BELGIUM, [6]Interuniversity Institute for Biostatistics and Statistical Bioinformatics, Leuven, BELGIUM, [7]Urology, University Hospitals Leuven; Urogenital, Abdominal and Plastic Surgery, Department of Development and Regeneration, KU Leuven, Leuven, BELGIUM, [8]Urology, University Hospitals Leuven; Laboratory of ion channel research, Department of Cellular and Molecular Medicine, KU Leuven, Leuven, BELGIUM.

Aim/Introduction: Quantification of prostate-specific membrane antigen (PSMA) expression via PSMA positron emission tomography (PET) is well-established, however quantification of PSMA via immunohistochemistry (IHC) is not standardized. Our aim was to determine the most optimal PSMA IHC scoring system to quantify PSMA expression with PSMA PET as reference standard. ***Materials and Methods:*** Primary intermediate- and high-risk prostate cancer patients received an [18F]PSMA-1007 PET/MRI followed by radical prostatectomy as part of a prospective trial. SUVmax, SUVmean and Ki of the prostate tumour was determined. Prostate tumours were stained with anti-PSMA antibodies and scored by 2 readers via 8 intensity-based IHC scoring systems using a combination of intensity and percentage of positively stained tumour cells (i.e. H-score, immunoreactivity scorepredominant intensity (IRSpredominant intensity), IRS classificationpredominant intensity, IRSmean intensity, IRS classificationmean intensity, Allred score, predominant expression pattern and Shannon diversity index (SDI)), and 2 percentage-based IHC scoring systems (i.e. percentage negatively stained cells and total percentage positively stained cells). Spearman's rank correlation coefficients (ρ) were calculated between PET parameters and IHC scoring systems. Inter-reader agreement for the IHC scoring systems was measured by the intraclass correlation coefficient (ICC). ***Results:*** Fifty tumours in 46 patients were analysed. Of the intensity-based scoring systems, H-score had the best correlation with SUVmax (ρ 0.615, p<0.0001) and SUVmean (ρ 0.570, p<0.0001) and the second best correlation with Ki (ρ 0.411, p=0.0030). SDI had the best correlation with Ki (ρ -0.440, p=0.0014) and the second best correlation with SUVmax (ρ -0.516, p=0.0001) and SUVmean (ρ -0.490, p=0.0003). IRS classificationmean intensity had the third best correlation with SUVmax (ρ 0.515, p=0.0001), SUVmean (ρ 0.481, p=0.0004) and Ki (ρ 0.358, p=0.0106). A moderate inter-reader agreement was observed for H-score (ICC 0.663, 95% CI 0.495-0.797), SDI (ICC 0.546, 95% CI 0.354-0.725) and IRS classificationmean intensity (ICC 0.545, 95% CI 0.353-0.725). Compared to the intensity-based scoring systems, the percentage-based scoring systems showed overall lower correlation coefficients between percentage negatively stained cells and total percentage positively stained cells with SUVmax (ρ -0.432 and 0.432, respectively, p=0.0018), SUVmean (ρ -0.382 and 0.382, respectively, p=0.0061) and Ki (ρ -0.401 and 0.401, respectively, p=0.0039). Good inter-reader

agreement was noted for the percentage of negatively stained cells and total percentage of positively stained cells (both ICC 0.832, 95% CI 0.729-0.901). ***Conclusion:*** H-score had the best correlation with PSMA PET quantification and an acceptable inter-reader agreement. Therefore, we deem H-score the most optimal PSMA IHC scoring system.

EP-0283

Imaging and outcome correlates of ctDNA methylation markers in prostate cancer: A comparative, cross-sectional [^{68}Ga]Ga-PSMA-11 PET/CT study

K. Kluge[1], *V. Lotz[2], H. Einspieler[1], D. Haberl[1], C. Spielvogel[1], D. Amereller[1], G. Kramer[3], B. Grubmüller[4], S. Shariat[3], A. Haug[1], M. Hacker[1], L. Kenner[2], G. Egger[2];*
[1]Medical University of Vienna - Nuclear Medicine, Vienna, AUSTRIA, [2]Medical University of Vienna - Pathology, Vienna, AUSTRIA, [3]Medical University of Vienna - Urology, Vienna, AUSTRIA, [4]Medical University Krems - Urology, Krems, AUSTRIA.

Aim/Introduction: We previously identified a panel of prostate cancer (PCa) -specific circulating tumor DNA methylation markers (meth-ctDNA) [1] with potential for PCa diagnosis and prognosis. To validate their clinical utility, we compared these markers against PSA levels and PSMA PET/CT findings to assess their relative predictive value for clinically actionable disease presence and survival outcomes. ***Materials and Methods:*** 122 patients with confirmed PCa (70.9 (± 7.6) years) who underwent [^{68}Ga]Ga-PSMA-11 PET/CT and plasma sampling between 03/2019 and 08/2021 were analysed. cfDNA was extracted, and a panel of PCa-specific meth-ctDNA markers was queried via methylation-sensitive restriction enzyme digestion coupled with quantitative PCR (MSRE-qPCR). PSMA PET scans were qualitative and quantitatively assessed. PSA and meth-ctDNA markers were compared with PSMA-PET findings according to their castration status, and their relative prognostic value for survival outcomes in castration-resistant PCa (CRPC) patients was evaluated. ***Results:*** For the total cohort and for hormone-sensitive (hsPC, N = 58) patients, PSA exhibited the highest discriminative power to distinguish between patients with negative and tumor-indicative PSMA PET scans (AUC 0.77, CI=[0.683; 0.857] and 0.737, CI=[0.609; 0.866], respectively). In CRPC (N = 64), the meth-ctDNA marker KLF8 performed best (AUC 0.824, CI=[0.652; 0.92]). For the differentiation of non- and metastatic PSMA PET scans, the meth-ctDNA marker CHST11 (AUC 0.705, CI=[0.618; 0.793]) performed best overall, while KLF8 discriminated best in the hsPC (AUC - 0.662, CI=[0.519; 0.806]) and CRPC (AUC 0.85, CI=[0.743; 0.957]) groups.Several meth-ctDNA markers correlated low to moderate with the total PSMA-positive tumor volume (PSMA-TV) in the overall cohort (5/8) and CRPC groups (6/8), while PSA levels correlated moderately to strongly with PSMA-TV in all groups (all $p < 0.001$). Survival outcomes in CRPC patients were significantly and independently associated with the meth-ctDNA marker LDAH and PSA ($p = 0.0168$ and $p < 0.001$, respectively). ***Conclusion:*** The studied ctDNA methylation markers are promising for the minimal-invasive detection and prognostication of advanced, castration-resistant disease but do not allow for clinical characterization of hormone-sensitive PCa. This warrants further prospective studies for their applicability for systemic therapy response and outcome prediction in advanced CRPC and their incremental value for disease monitoring in PSA-low advanced PCa. ***References:*** [1] Dillinger, Thomas, et al. "Identification of tumor tissue-derived DNA methylation biomarkers for the detection and therapy response evaluation of metastatic castration resistant prostate cancer in liquid biopsies." Quantitative parameters to discriminate indeterminate bone lesions on [^{18F}]-PSMA-1007 PET/CT in prostate cancer imaging

R. Sciuto[1], *D. Maccora[1], G. Sanguineti[2], A. Faiella[2], S. Rea[1], A. Annovazzi[1];*
[1]Nuclear Medicine Unit - IRCCS - Regina Elena National Cancer Institute, Rome, ITALY, [2]Radiation Oncology Dpt - IRCCS - Regina Elena National Cancer Institute, Rome, ITALY.

Aim/Introduction: ^{18}F-PSMA-1007 for prostate cancer imaging offers the distinct advantage of low urinary excretion, but is burdened by a high rate of false-positive findings due to unspecific focal bone uptake (UBU), as previously described in a few reports. UBUs are significantly more frequent on digital PET scanners than on analogic scanners. Aim of the study was to determine which semi-quantitative parameter allows to better discriminate between unspecific and metastatic ^{18}F-PSMA bone uptake ***Materials and Methods:*** Eighty-three patients with prostate cancer who underwent an ^{18}F-PSMA PET/CT scan using a digital tomograph were retrospectively evaluated. A total of 183 equivocal bone foci with no morphological correlate or atypical bone lesion at the co-registered CT scan were analysed. Bone focal uptake areas have been definitively classified as benign (n = 119) or malignant (n = 64) by follow-up or MRI imaging. ROC curve analysis was used to assess the best threshold for SUVmax, SUVmean, tumor-to-liver SUV ratio (TLR) and tumor-to-blood-pool SUV ratio (TBR). ***Results:*** The median SUVmax was 5.9 for UBU (interquartile range 5,0-7,0) and 14.7 for metastases (interquartile range 9.9-23.7). A similar accuracy to discriminate unspecific from malignant lesions was observed for SUVmax (cut-off 8.7; sensitivity 0.81; specificity 0.9; accuracy 0.87; PPV 0.81; NPV 0.9), SUVmean (cut-off 5.1; sensitivity 0.81; specificity 0.91; accuracy 0.87; PPV 0.83; NPV 0.9), TLR (cut-off 0.6; sensitivity 0.77; specificity 0.92; accuracy 0.86; PPV 0.83; NPV 0.88), and TBR (cut-off 4; sensitivity 0.78; specificity 0.88; accuracy 0.85; PPV 0.78; NPV 0.88). ***Conclusion:*** In conclusion, the semi-quantitative PET parameters analysed could be conveniently used to discriminate between unspecific and metastatic bone uptake in cases of no morphological correlate or atypical bone lesions at CT scan in patients with prostate cancer.

EP-0285

Prediction of Lymph Node Metastasis in Prostate Cancer Patients Using 68 Ga-PSMA PET Radiomics Based Machine Learning Techniques

S. Biyikoglu[1], *S. ASA[1], M. Demirbilek[2], K. Sağlam[1], L. Kabasakal[1], M. Sağer[1], H. Sayman[1];*
[1]Department of Nuclear Medicine (Cerrahpasa Medical Faculty), Istanbul University-Cerrahpasa, ISTANBUL, TÜRKIYE, [2]Department of Urology (Cerrahpasa Medical Faculty), Istanbul University-Cerrahpasa, ISTANBUL, TÜRKIYE.

Aim/Introduction: Extended pelvic lymph node dissection (ePLND) provides staging and prognostic information in prostate cancer (PCa) patients. Sentinel lymph node biopsy (SLNB) can avoid the more invasive ePLND in patients with negative findings. This study aims to evaluate the performance of 68 Ga-PSMA PET radiomics based using a machine learning approach for predicting lymph node metastasis in PCa patients. ***Materials and Methods:*** In this retrospective study, 68 Ga-PSMA PET scans of 28 PCa patients were examined, with 12 positive and 16 negative

lymph node pathologies. Texture analysis was performed using LIFEX version 7.6.3. When insufficient data was filtered out in the LIFEX program, the remaining 86 different parameters were evaluated using the WEKA platform for machine learning analysis. Predictability values were tested following assessments with several decision tree algorithms, such as RandomForest. Machine learning prediction accuracy was evaluated using metrics such as Accuracy, F-Measure, Precision, Recall, and PRC Area. ***Results:*** Accuracy values were found to be 90%, 60%, 70%, 50%, and 60% for RandomForest, RandomTree, HoeffdingTree, J48, and OneR algorithms, respectively. Additionally, F-Measure, Precision, Recall, and PRC Area values were calculated. (Table-1) (Weka software). ***Conclusion:*** The analysis of data obtained from LIFEX image analysis using WEKA-based machine learning algorithms determined that some tissue parameters in 68 Ga-PSMA PET imaging are significantly associated with pathology results verified through intraoperative lymph node sampling. Positive outcomes were achieved on the effectiveness of machine learning applications in predicting data in the pool, with accuracy values reaching up to 90%. The main limitation of the study is its retrospective nature, which lacks a standardized single protocol for creating texture data. This situation affects data distribution, and it is thought that accuracy values predicted by the machine would be more successful with data obtained from a standard protocol and the inclusion of larger patient groups in the study. ***References:*** 1. Effect of furosemide on the bladder quantitative parameters in patients undergoing Gallium-68[68Ga] Ga-PSMA-11 PET/CT for diagnosis of prostate cancer

D. Valenzuela[1,2], *M. Tormo-Ratera[3], N. Papa[1,4], R. Eapen[5,6], L. Emmett[4], D. Moon[5,6], D. Murphy[5,6], N. Ayati[4], M. Hofman[1,6], J. Buteau[1,6];*
[1]Prostate Cancer Theranostics and Imaging Centre of Excellence (ProsTIC), Molecular Imaging and Therapeutic Nuclear Medicine, Cancer Imaging, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [2]Hospital Dr Sotero del Río, Santiago, CHILE, [3]Department of Nuclear Medicine, Hospital Clínic, Barcelona, SPAIN, [4]Department of Theranostics and Nuclear Medicine, St Vincent's Hospital; Faculty of Medicine, UNSW Sydney, Sydney, AUSTRALIA, [5]Division of Cancer Surgery, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [6]Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, AUSTRALIA.

Aim/Introduction: PRIMARY2 (NCT05154162) is investigating [68Ga]Ga-PSMA-11 PET/CT for prostate cancer diagnosis. Sites of intraprostatic PSMA uptake may be masked by intense bladder activity. One prospective analysis investigated furosemide in patients with prostate cancer in the setting of staging and biochemical recurrence[1]. We aim to investigate the effects of furosemide on quantitative parameters in the bladder in patients undergoing [68Ga]Ga-PSMA-11 PET/CT in the diagnostic setting. ***Materials and Methods:*** Patients with suspected prostate cancer, PI-RADS 2 or 3 on mpMRI, and who had a pelvic-only [68Ga]Ga-PSMA-11 PET/CT were included. The non-furosemide group (PRIMARY trial) was compared with the furosemide group (PRIMARY2 trial) who received furosemide 20 mg IV at time of radiotracer injection. A pelvic-only PET/CT was acquired between 60-70 minutes, without intravenous contrast. Ordered subset expectation maximisation (OSEM) algorithm was used for tomographic reconstruction. Quantitative parameters of the bladder (SUVmax and volume) were measured by two experienced nuclear medicine physicians using an edge-detection tool. 95% confidence intervals were calculated using t-distributions. Association between furosemide and SUVmax was examined with linear regression, adjusting for bladder volume. ***Results:*** Between August 30th 2019 and March 31st 2024, 95 patients were eligible with 53 in the furosemide group (F+) and 42 in the non-furosemide group (F-). Baseline characteristics were similar (F+ vs F-) with median (IQR) age 63 (59-66) vs 64 (58-68) years, PSA 5.3 (4.5-7.2) vs 5.4 (4.3-7.0) ng/mL, and 38/53 (72%) vs 28/42 (67%) had PI-RADS 2 on mpMRI. Technical parameters were similar between groups, with 152 (138-182) MBq vs 152 (106-181) MBq injected [68Ga]Ga-PSMA-11 and uptake time of 61 (60-64) min vs 63 (60-65) min. The median (IQR) SUVmax in the bladder (F+ vs F-) was 11.1 (7.5-14.6) vs 34.8 (18.0-64.2), with a mean difference of 30.9 (95%CI 22.0-39.8). The bladder's volume also considerably differed between groups with 213 (156-303) mL vs 85 (49-148) mL, and a mean difference of 126 mL (95%CI 88-164 mL). After adjusting for bladder volume, the F+ group had a SUVmax 23.0 lower than the F- group (95%CI 12.5-33.5). ***Conclusion:*** Furosemide substantially decreases bladder uptake in patients undergoing [68Ga]Ga-PSMA-11 PET/CT for prostate cancer diagnosis. ***References:*** 1.Fennesy N, Lee J, HoB, Ali SA, Paschkewitz R, et al. Frusemide aids diagnostic interpretation of 68Ga-PSMA positron emission tomography/CT in men with prostate cancer. J Med Imaging Radiat Oncol. 2017;61:739-44.

EP-0287

Combine uptake patterns and MRI findings to evaluate incidentalomas of the prostate detected by ^{18}F-FDG PET/CT

L. Kang[1], *Y. Qiu[1], Y. Peng[1], Z. Sun[2], Z. Chen[1], Q. Yang[1], L. Song[1], W. Huang[1];*
[1]Dept. of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA, [2]Dept. of Radiology, Peking University First Hospital, Beijing, CHINA.

Aim/Introduction: Patients with no history of prostate cancer who undergo 18F-FDG PET/CT scans discover abnormal uptake in the prostate, referred to as prostate incidentalomas. The aim of this study was to investigate the relationship between different uptake patterns of prostate incidentalomas in 18F-FDG PET/CT and possibility of malignancy. We also evaluated whether the consistency of the extent of incidentalomas between 18F-FDG PET/CT and MRI was helpful in the diagnosis of malignant lesions. ***Materials and Methods:*** All patients without history of prostate cancer found prostatic incidentalomas in 18F-FDG PET/CT were retrospectively evaluated. The uptake patterns of incidentalomas were divided into three categories: focal lesions (Pattern 1), focal lesions in a diffuse background (Pattern 2) or diffuse (Pattern 3). The patients' MRI images were further evaluated to determine whether the lesion was consistent with 18F-FDG PET/CT. The probability of malignancy was compared between different groups. ***Results:*** In total, 70 patients were included, and the prevalence of malignancy was 34.3% (24/70). SUVmax, TBR, SUVmax/ADC and TBR/ADC of prostate incidentalomas exhibited statistical differences between the benign and malignant groups. The proportion of the three uptake patterns were respectively 22.9% (16/70), 15.7% (11/70) and 61.4% (43/70). Malignancy is more common in focal lesions (Pattern 1+2) than diffuse lesions (Pattern 3) (51.9% vs 23.3%), and focal lesions in diffuse backgrounds (Pattern 2) are more likely to

suggest malignancy (73.0% vs 37.5% and 23.3%). For focal lesions, when 18F-FDG PET/CT findings were consistent with MRI, the prostate incidentalomas are more likely to be malignant (71.4% vs 11.1%, 100.0% vs 0.0%). ***Conclusion:*** 18F-FDG PET/CT uptake patterns of prostate incidentalomas can help to identify potentially malignant lesions. Malignancy is more common in focal lesions than diffuse lesions. Focal lesions in diffuse backgrounds and lesions consistent with MRI are more likely to suggest malignancy.

EP-0288

The Relation of ^{68}Ga PSMA PET/CT Radiomics Features with Treatment Response and Overall Survival in Metastatic Castration-Resistant Prostate Cancer Patients Undergoing ^{177}Lu PSMA Radioligand Therapy

***M. Atalay*[1],** *N. Coşkun[1,2], B. Okudan Tekin[1];*
[1]University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine Clinic, Ankara, TÜRKIYE,
[2]Ankara Yıldırım Beyazıt University, Ankara, TÜRKIYE.

Aim/Introduction: The study aims to investigate the relation of radiomics features obtained from 68Ga PSMA PET/CT with treatment response and overall survival in patients with mCRPC and received 177Lu-PSMA therapy. ***Materials and Methods:*** Between November 2021 and September 2023, a total of 61 mCRPC patients who had received at least 2 cycles of 177Lu-PSMA therapy in our clinic with pre-treatment 68Ga PSMA PET/CT imaging were included in this retrospective study. For each scan, PSMA involvement above the background activity in prostate gland, bones, lymph nodes and other distant metastases were plotted semiautomatical with 40% threshold by an experienced nuclear medicine physician. Radiomic features and SUV-based volumetric parameters were extracted from PET images for a total of 1129 lesions. Patients were classified into two groups according to the "Prostate Cancer Working Group-3" (PCWG-3) criteria; the biochemical response was defined as a 50% or more reduction in the PSA level compared to the baseline. Otherwise, the patient was considered as no response. ***Results:*** Biochemical response was observed in 24 cases (39,3%), and 38 cases (71%) died during follow-up. According to the logistic regression model made with variables with high AUC values that are associated with the biochemical response to treatment, it was determined that GLRLM-LRE was an independent predictive parameter in showing the biochemical response to treatment. GLRLM-LRE value was negatively correlated with the biochemical response (OR=0,396 p=0,012). According to the median follow-up data of 12 months (2-27 months) on 53 patients for whom survival data were available; the average overall survival of the patients was found to be 11.82 ± 1.32 months. In the logistic regression model made with variables with high AUC values that were associated with mortality in patients; PSMA-TV was an independent predictive parameter predicting the risk of mortality in patients. It was determined that as the PSMA-TV value increased, the risk of mortality increased in patients (OR=1.014 p=0.038<0.05). ***Conclusion:*** In our study, GLRLM-LRE was found to be an independent predictive parameter in showing biochemical response; and PSMA-TV was found to be an independant predictive parameter in determining the risk of mortality in patients. We think that this study is one of the first steps towards identifying noninvasive prognostic biomarkers. For the data obtained using texture analysis methods to be used in daily nuclear medicine practice; there is a need for prospective and multicenter studies with a high number of patients in the field of radiomics.

EP-0289

^{68}Ga-PSMA-617 and ^{68}Ga-RM26 PET/MRI in Disease Localization and Eligibility Assessment for Potential Focal Therapy Candidates with Biopsy-proven Low-/Intermediate-Risk Prostate Cancer: a Whole-Mount Pathology-based Study

Y. Li, *Y. Tang, S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: Focal therapy (FT) is a promising and minimally invasive strategy to selectively ablate localized prostate cancer (PCa). However, conventional diagnostic techniques inadequately identify appropriate candidates, and under-sampling/sampling biases persist in biopsy pathology-based prospective FT trials. In the current study, we aim to evaluate the potential value of 68Ga-PSMA-617 and 68Ga-RM26 PET (individually and combined with mpMRI) in preoperative assessments for FT. ***Materials and Methods:*** Patients with biopsy-proven low-/intermediate-risk prostate cancer (PCa), who underwent mpMRI, 68Ga-PSMA-617 and 68Ga-RM26 PET were included from a prospective database. mpMRI was interpreted using PI-RADS v2.1, while PET was interpreted considering any positive focal lesion uptake (PETFL). Whole-mount pathology from prostatectomy specimen served as the reference standard. Detection rates for csPCa (lesion-level) and diagnostic performances for extent delineation (segment-level) were assessed and compared using the McNemar test, areas-under-curves (AUCs) and the Delong test. Identification of FT-ineligible men (index lesion ISUP>3 or contralateral csPCa) for each modality were documented. Finally, a second analysis for diagnostic performance was performed in truly FT-eligible men. ***Results:*** Thirty-eight men, with overall 73 csPCa lesions, were included. The csPCa detection rate (lesion-level) was 72.6%, 78.1%, 76.7%, 87.7% and 94.5% for mpMRI, 68Ga-PSMA-617, 68Ga-RM26 PET, mpMRI + 68Ga-PSMA-617 PET and mpMRI + 68Ga-RM26 PET, respectively. AUC for localization delineation (segment-level) for corresponding modalities above was 0.81 (0.77-0.84), 0.85 (0.81-0.88), 0.84 (0.80-0.87), 0.87 (0.84-0.90) and 0.90 (0.87-0.93), respectively. 20 of 38 (53%) men with index lesion ISUP>3 or contralateral csPCa were confirmed ineligible for FT. mpMRI, mpMRI + biopsy, mpMRI + 68Ga-PSMA-617 PET and mpMRI + 68Ga-RM26 PET identified 12 (60%), 15 (75%), 20 (100%) and 17 (85%) of all 20 FT-ineligible men, respectively. Finally, mpMRI, 68Ga-PSMA-617, 68Ga-RM26 PET, mpMRI + 68Ga-PSMA-617 PET and mpMRI + 68Ga-RM26 PET identified 76.9%, 69.2%, 76.9%, 88.5% and 100% csPCa lesions in all FT-eligible men. ***Conclusion:*** 68Ga-PSMA-617 PET demonstrated excellent sensitivity in detecting index lesions and contralateral csPCa, identifying 100% FT-ineligible men when combining with mpMRI. mpMRI + 68Ga-RM26 PET detected 100% csPCa lesions in FT-eligible men. PSMA- and GRPR-PET/MRI are potentially robust tools to minimize selection failure and out-of-field disease in men with low-/intermediate-risk PCa considered for FT.

EP-0290

Can ML-based Ga-68 PSMA PET/CT radiomics predict biochemical response in patients receiving Lu-177 PSMA treatment?

***M. Atalay*[1],** *T. A. Serel[2], B. Okudan Tekin[1];*
[1]University of Health Sciences, Ankara Bilkent City Hospital, Department of Nuclear Medicine Clinic, Ankara, TÜRKIYE, [2]Süleyman Demirel University, Department of Urology, Ankara, TÜRKIYE.

Aim/Introduction: Prostate cancer is the second most common

malignancy in men after lung cancer and the fifth most common cause of cancer-related deaths. Lu-177 PSMA treatment is an internal radiotherapy method that targets metastatic tumor foci and has less effect on the healthy tissue. It has a cell irradiating effect by binding to its receptor on the cell membrane of metastatic foci expressing PSMA. Radiomics is a rapidly developing branch of research that refers to the acquisition and analysis of quantitative data according to the gray level intensities of voxels in the image and the distribution of these intensities. The aim of machine learning is to first select the information that is important for the problem at hand and create a model that will allow predicting results from new data with this information. In this study, we aimed to evaluate the prediction performance of Ga-68 PSMA PET/CT based machine learning radiomixes performed before treatment in patients receiving Lu-177. ***Materials and Methods:*** Lesions showing increased Ga-68 PSMA uptake from the pre-treatment Ga-68 PSMA PET images of 61 patients who received Lu-177 PSMA treatment in our clinic were segmented using the Local Image Features Extraction (LIFEx) program, accepting 40% of the SUVmax value as a threshold value. For each lesion, first- and second-order radiomic texture features and SUV-based conventional PET measurements were obtained. The obtained tissue properties were compared with the patient's biochemical response parameters. ML algorithms were implemented using Python 2.3, Pycaret library to identify significant patterns. In the study, the prediction performances of 15 ML algorithms were compared. The best model was then evaluated on the test set and combined with the voting classifier. ***Results:*** The average age of 61 patients who met the inclusion criteria was 71.2 ± 7.2 years. Patients with a 50% or more decrease in PSA after two cycles of Lu-177 PSMA treatment were considered to be responsive to treatment, and cases other than this were considered to be non-response to treatment. Biochemical response was observed in 24 patients (39%). The best model among ML algorithms was determined as decision tree classifier. In the algorithm; Accuracy score (accuracy): 0.97, precision score (specificity): 0.95, F1 score (Precision and recall harmonic average): 0.96. ***Conclusion:*** ML-based PSMA PET/CT radiomixes can predict biochemical response with high accuracy in patients with prostate carcinoma receiving Lu-177 PSMA treatment. Further studies with a larger patient group are needed on this subject.

EP-0291

PSMA PET/CT imaging outperforms PSA-based treatment response evaluation for predicting overall survival in metastatic castration-resistant prostate cancer patients

F. Kleiburg[1,2], *L. de Geus-Oei[1], S. A. C. Luelmo[2], R. Spijkerman[1], J. J. Goeman[2], F. A. J. Toonen[3], F. Smit[3], T. van der Hulle[2], L. Heijmen[2];*
[1]University of Twente, Enschede, NETHERLANDS, [2]Leiden University Medical Center, Leiden, NETHERLANDS, [3]Alrijne Hospital, Leiderdorp, NETHERLANDS.

Aim/Introduction: In metastatic castration-resistant prostate cancer (mCRPC), assessing response to treatment is important for disease management. However, monitoring serum prostate-specific antigen (PSA) levels is not always accurate. This study aimed to assess the efficacy of PSMA PET/CT in treatment response evaluation and survival prediction in mCRPC patients, compared to PSA. ***Materials and Methods:*** 57 mCRPC patients underwent [18F]PSMA-1007 PET/CT at baseline and for treatment response evaluation of either androgen receptor-targeted agents (after 3 months) or chemotherapy (after completion). Visual assessment categorised overall response and response of the worst responding lesion as partial response (PR), stable disease (SD), or progressive disease (PD). Changes in SUVmax, total tumour volume and total lesion uptake were calculated. PSA response was defined according to the PCWG3 criteria. Cox regression analysis identified predictors of overall survival. ***Results:*** PSMA PET/CT and PSA response were discordant in 46% of patients, and PSMA PET/CT response was worse in 92% of these cases. Overall response on PSMA PET/CT independently predicted overall survival (iPD versus non-iPD: HR=6.83, p<0.001), outperforming PSA response and other PSMA PET/CT parameters. Among patients with a PSA decline of >50%, 30% showed PD on PSMA PET/CT (iPD), correlating with higher mortality risk (iPD versus non-iPD: HR=8.72, p=0.002). No flare was observed on PSMA PET/CT. ***Conclusion:*** The use of PSMA PET/CT to assess treatment response at predefined time points showed a higher prognostic value than PSA-based response in mCRPC patients treated with androgen receptor-targeted agents and chemotherapy. Further results on the cost-effectiveness and potential impact on patient outcomes will follow.

EP-0292

Composite prediction score to interpret bone focal uptakes in hormone-sensitive prostate cancer patients imaged with [18F]PSMA-1007 PET/CT

F. D'Amico[1], *M. Ponzano[2], D. Albano[3], M. Balma[4], C. Cabrini[5], F. Dondi[3], T. Di Raimondo[1], V. Liberini[4], L. Sofia[1], S. Peano[4], F. Lanfranchi[1], M. Riondato[6], G. Fornarini[7], R. Laudicella[8], C. Marini[9], F. Bertagna[3], A. Papaleo[4], S. Morbelli[10], G. Sambuceti[1], A. Signori[2], M. Bauckneht[1];*
[1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, 16132 Genoa, Italy, GENOVA, ITALY, [2]Department of Health Sciences, University of Genoa, GENOVA, ITALY, [3]Nuclear Medicine, University of Brescia and ASST Spedali Civili Brescia, Brescia, ITALY, [4]Department of Nuclear Medicine, Santa Croce e Carle General Hospital, Cuneo 12100, Cuneo, ITALY, [5]University of Genoa, 16132 Genoa, Italy, GENOVA, ITALY, [6]Nuclear Medicine Unit, IRCCS, Ospedale Policlinico San Martino, Genoa, GENOVA, ITALY, [7]IRCCS Ospedale Policlinico San Martino, Genoa, Italy, GENOVA, ITALY, [8]University of Messina, Italy, Messina, ITALY, [9]Nuclear Medicine Unit, IRCCS, Ospedale Policlinico San Martino, GENOVA, ITALY, [10]Department of Medical Sciences, University of Turin, Italy, Torino, ITALY.

Aim/Introduction: [18F]PSMA-1007 has significantly advanced PET imaging for prostate cancer (PCa), yet its propensity for non-specific bone uptakes (UBUs) poses a clinical challenge. Our study aimed to investigate whether a combination of clinical, laboratory, and imaging parameters could predict true skeletal metastases in patients exhibiting [18F]PSMA-1007 bone focal uptakes, potentially guiding the interpretation of imaging results. ***Materials and Methods:*** We retrospectively analyzed [18F]PSMA-1007 PET/CT scans performed in 534 patients with hormone-sensitive PCa at three tertiary-level cancer centers. Three expert nuclear medicine physicians visually checked for the presence of focal bone tracer uptakes. For each, a volume of interest (VOI) was manually drawn using a threshold method (40%) to extract SUVmax, SUVmean, PSMA-tumor volume (PSMA-TV), and total lesion PSMA (PSMA-TL). The same VOI was applied to CT images to calculate mean and maximum Hounsfield Units (HU). Clinical and laboratory data were collected from electronic medical records. A composite reference standard, including follow-up i) histopathology, ii) biochemistry, and iii) imaging data, was used to distinguish between PCa bone metastases and UBUs. ***Results:*** 448 bone [18F] PSMA-1007 focal uptakes were identified from 267/534 (50%) PCa patients. According to the reference standard, 188/448 (41.9%)

corresponded to PCa metastases. At the univariate per-lesion analysis, PET/CT indication (staging vs. restaging, p=0.01), PSA at the time of PCa diagnosis (p=0.001) and at PET/CT (p=0.02), the initial ISUP grade group (p=0.009), the ongoing androgen-deprivation therapy (ADT) at the time of PET/CT (p<0.001), the site of bone tracer uptake (p<0.001), SUVmax (p<0.001), TL-PSMA (p=0.01), HUmean (p=0.001), and HUmax (p=0.001) were associated with the presence of PCa metastases. In the multivariate analysis, after setting the center as an offset variable, the ongoing ADT at PET/CT (p<0.001), SUVmax (p<0.001), and HUmean (p<0.001) resulted in independent predictors of bone metastases. The composite prediction model which combined these parameters achieved an AUC of 0.87 and was validated through 10-fold internal cross-validation. A decision curve analysis was performed. Except for a small range of low threshold probabilities, intervening on patients based on the score leads to higher net benefit compared to intervening for all or for none. ***Conclusion:*** This novel composite prediction model demonstrated high accuracy in distinguishing UBUs from bone metastases in PCa patients showing [18F]PSMA-1007 focal bone uptakes. Its application may aid clinicians in accurately interpreting imaging results, thereby potentially reducing the risk of patients' over-staging.

EP-0293

Insights into Renal Split Function Assessment via PSMA-ligand PET/CT

M. Gammel[1], *C. Olufs[1], J. Brosch-Lenz[1], M. Heck[2], M. Eiber[1], I. Rauscher[1];*
[1]Department of Nuclear Medicine, Klinikum rechts der Isar, Technical University Munich School of Medicine and Health, Munich, GERMANY, [2]Department of Urology, Klinikum rechts der Isar, Technical University Munich School of Medicine and Health, Munich, GERMANY.

Aim/Introduction: Tc99m-mercapto-acetyltriglycine (MAG3)-scintigraphy in addition to prostate-specific membrane antigen (PSMA) PET is used as pre-therapeutic work-up prior to Lu177-PSMA radioligand therapy (RLT). PSMA expression in proximal kidney tubule cells leads to significant PSMA-PET tracer uptake, offering potentially valuable insights into renal function. We hypothesize that parameters of renal function may be extracted from PSMA-PET with the potential to replace MAG3-scintigraphy, e.g. for external beam radiation therapy (EBRT) planning. ***Materials and Methods:*** We evaluated 302 metastatic, castration-resistant prostate cancer patients with PSMA-PET/CT (^{18}F-rhPSMA-7.3 [^{18}F-flotufolastat] n=221, 68Ga-PSMA-11 n=81), MAG3-scintigraphy and serum creatinine prior to 177Lu-PSMA I&T RLT. PSMA PET-derived Split Renal Function (PSMA-SRF) was calculated as follows: SRFright=(volumeRight×SUVmeanRight)/(volumeRight×SUVmeanRight+volumeLeft×SUVmeanLeft). MAG3-based SRF was determined using the standard integral method during renal secretion phase. To assess global renal function, we examined the correlation between Total Renal Uptake (TRU=volumeLeft×SUVmeanLeft+volumeRight×SUVmeanRight), Tubular Excretion Rate (TER) of MAG3, and serum creatinine levels. Those were compared to MAG3-SFR using Pearson correlation and Bland-Altman analyses. ***Results:*** PSMA-SRF and MAG3-SRF showed a strong and highly significant correlation (P<0.0001; r= 0.82; CI 95% 0.78-0.85). Bland-Altman analysis verified measurement alignment. High correlations were also observed in the subgroup analyses of patients with ^{18}F--rhPSMA-7.3, and 68Ga-PSMA-11 (r=0.84; CI95% 0.79-0.87, P < 0.0001 and r=0.78; CI 95% 0.68-0.85, P < 0.0001 respectively). TER demonstrated a moderate correlation with TRU (r=0.36; CI95% 0.26-0.45, P<0.0001). ***Conclusion:*** PSMA-PET-derived SRF is highly concordant with the standard technique MAG3-scintigraphy. Prospective studies are warranted to confirm these findings to potentially neglect MAG3-scintigraphy prior to PSMA-PET targeted EBRT of retroperitoneal lesions.

EP-0294

The predictive power of total tumor and bone tumor volumes and prostate-specific antigen levels before prostate-specific membrane antigen-targeted radioligand therapy to predict overall survival.

S. Raad[1,2], *R. Apolle[2], R. Winzer[1,2], C. Brogsitter[1], M. Pretze[1], J. Kotzerke[1], M. Miederer[2,1], S. Hoberück[1];*
[1]Universitätsklinikum Dresden, Dresden, GERMANY, [2]NCT Dresden, Dresden, GERMANY.

Aim/Introduction: Metastatic castration-resistant prostate cancer (mCRPC) presents significant treatment challenges, necessitating innovative therapeutic approaches like PSMA-targeted radioligand therapy (PRLT). Assessing tumor burden through PSMA-PET/CT scans offers a new biomarker suitable for therapy management and ability to predict patient outcomes. This study investigates the predictive capabilities of Total Tumor Volume (TV), Bone Tumor Volume (BV), and Prostate-Specific Antigen levels (PSA) obtained prior to PRLT on overall survival (OS) in mCRPC patients. The objective is to identify the strongest predictor among these parameters, potentially better guiding more personalized treatment strategies. ***Materials and Methods:*** A retrospective analysis was conducted on 104 mCRPC patients scheduled to PRLT. Prior to therapy, each patient was assessed with a baseline PSMA-PET/CT scan (PSMA-11 n=92 / PSMA-1007 n=12). The PET/CT images were semi-automatically segmented according to the PERCIST-LIVER criteria. Metastases were automatically detected and categorized as 'Skeleton' OR 'other'. Using the ROC method, optimal cutoffs for TV, BV, and PSA were determined and patients were stratified into two distinct groups (low and high values) for each parameter based on OS. ***Results:*** Kaplan-Meier curves indicated significantly lower survival rates in the high-value groups (p<0.001) (17.6 vs 7.4mo. for TV, 17.27 vs 6.62mo. for BV and 22.7 vs 9.7mo. for PSA). Univariate Cox regression analysis identified TV, BV, and PSA as significant predictors of OS, with hazard ratios (HR) as follows: TV (HR: 2.97, p<0.001), BV (HR: 3.39, p<0.001), and PSA (HR: 3.90, p<0.001). The Mann-Whitney U test confirmed a significant difference between the alive and deceased patients among for TV, BV, and PSA (p<0.001), and TV showed the highest absolute Z-value (-4.851), followed by PSA1 (-4.001) and BV (-3.381). ***Conclusion:*** This study confirms that a TV >151,96 ml, BV > 116,51 ml, and PSA levels > 72,9 ng/ml have a significant negative impact on OS in patients with mCRPC treated with PRLT. Among these factors, TV emerged as the strongest predictor, highlighting its potential as a marker for guiding therapeutic strategies and optimizing treatment outcomes.

Robot-assisted [^{99m}Tc]Tc-PSMA-SPECT: Are we going to the next level with 'drop-in' radioguidance?

S. Azargoshasb[1,2], *A. Berrens[1,2], L. J. Slof[1,2], L. Zuur[2], H. G. van der Poel[2,3], P. J. van Leeuwen[2], M. N. van Oosterom[1,2], F. W. B. van Leeuwen[1,2];*
[1]Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS, [2]Department of Urology, Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Amsterdam, the Netherlands, Amsterdam, NETHERLANDS, [3]Department

of Urology, Amsterdam University Medical Centers, Amsterdam, The Netherlands, Amsterdam, NETHERLANDS.

Aim/Introduction: Following the clinical success of prostate-specific membrane antigen (PSMA) receptor-targeted PET in the diagnosis of prostate cancer, there is a huge push towards PSMA-targeted therapy, including PSMA-targeted surgery (1). The 'drop-in' gamma probe technology has made 99mTc-PSMA-targeted resections compatible with robotic surgery. In this setting the 'drop-in' probe provides an intraoperative acoustical and numerical readout with respect to tracer avid lymph nodes (2,3). Using a new technology entitled robot-assisted [99mTc]Tc-PSMA-SPECT, we are now trying to improve upon the target identification accuracy for this application. This includes using dedicated tracking and reconstruction methods to generate a gantry-free tomographic scan within the surgical field. ***Materials and Methods:*** Three recurrent prostate cancer patients underwent robot-assisted 99mTc-PSMA-targeted salvage surgery. Patients received a [68Ga]Ga-PSMA-11 or [18F]DCFPyl 3D PSMA PET/CT within 60 days before salvage surgery according to the local protocol. This image was used to select patients with local disease that remained confined to <3 soft-tissue lesions. Selected patients received an intravenous injection of [99mTc]Tc-PSMA I&S (≈550MBq) 21-26 hours prior to surgery. Before surgery, preoperative SPECT/CT was performed. During surgery, 99mTc-PSMA-avid nodes were traced using a 'drop-in' gamma probe functionalized with three sterile PEEK-ring markers. Using the markers, the position of the probe was established via custom computer-vision segmentation and tracking software. Maximum-likelihood expectation-maximization (MLEM) reconstruction algorithm that combined the counts/s, probe positioning and look-up table facilitated gantry-free robot-assisted [99mTc]Tc-PSMA-SPECT reconstructions. These tomographic images were overlayed on the endoscopic view. All excised nodal specimens were analyzed at pathology. ***Results:*** Preoperative [99mTc]Tc-PSMA I&S SPECT/CT imaging revealed a total of three lymph nodes located at the left obturator (2 lymph nodes) and left common iliac, and one local recurrence at seminal vesicle. Intraoperatively, three lesions were pursued and successfully traced using the tracked 'drop-in' probe (median 32 counts/s). Robotic-SPECT scans provided volumetric information on the tracer distribution in all lesions within a volume of approximately 100x100x100 mm, thereby "visualizing" the PSMA-expressing lesions. Ex vivo and (histo)pathological examinations confirmed the target-removal. Median lesion diameter was 15 mm. ***Conclusion:*** Robot-assisted [99mTc]Tc-PSMA-SPECT for PSMA-targeted surgery is feasible. By offering 3D tomographic imaging it helps improve the surgeon's appreciation of the tracer distribution within the surgical field. A critical next step in facilitating high-precision surgical decision-making. ***References:*** [1] Berrens, Anne-Claire, et al. European Urology Open Science 54 (2023): 43-55. EP-0296

Initial clinical experience with ^{99m}Tc-MIP-1404 SPECT/CT for assessment of disease extent and eligibility for ^{177}Lu-PSMA RLT

T. Derlin, *T. L. Ross, F. M. Bengel; Hannover Medical School, Hannover, GERMANY.*

Aim/Introduction: Recently, there has been increased interest in development of 99mTc-labelled radiotracers targeting the prostate-specific membrane antigen (PSMA) to broaden access to PSMA imaging. We report our initial clinical experience with 99mTc MIP-1404, a novel PSMA-targeted ligand for SPECT, in patients with advanced metastatic castration-resistant prostate cancer (mCRPC) undergoing baseline staging and assessment of eligibility for PSMA-targeted radioligand therapy (RLT). ***Materials and Methods:*** Data of 36 mCRPC patients referred for evaluation of PSMA-targeted RLT who underwent baseline 99mTc-MIP-1404 planar scintigraphy and single-photon emission computed tomography/computed tomography (SPECT/CT) for staging and assessment of RLT eligibility were retrospectively analyzed. Administration-related adverse events were recorded. Images were visually analyzed for presence and anatomic localization of lesions with pathological uptake, and compared with results of 177Lu-PSMA scans following administration of PSMA-targeted RLT. Uptake in tumor lesions was visually scored using a three-point scale, and overall image quality was rated. Finally, the usefulness of uptake intensity in 99mTc-MIP-1404 scans to predict early biochemical response according to Prostate Cancer Working Group criteria was determined following 2 cycles of RLT. ***Results:*** No adverse effects were noted after administration of 99mTc MIP-1404 . 99mTc-MIP-1404 identified metastatic PSMA-expression in all patients. 98.6% of tumor localizations were concordantly classified by both 99mTc MIP-1404 and 177Lu-PSMA SPECT/CT (rs=0.9682 (95% CI: 0.9583-0.9758), P<0.0001). 3 of 216 tumor localizations in 3/36 (8.1%) patients were better depicted using 177Lu-PSMA (1 hepatic, one adrenal and one lymph node metastasis). Uptake intensity in metastatic lesions was higher with 177Lu-PSMA (higher than liver in 32 vs 16 patients, P<0.0001; higher than salivary gland uptake in 25 vs 7 patients; P<0.0001). Tumor uptake higher than salivary gland uptake in 99mTc MIP-1404 scans was associated with early treatment response (OR 11.56 (95% CI, 1.799-91.61; P=0.0123), and demonstrated prognostic significance for PFS (median PFS of 133 vs 65 days in patients with tumor uptake higher vs lower or equal to salivary gland uptake; P=0.0485). ***Conclusion:*** Mapping of disease extent using 99mTc-MIP-1404 SPECT/CT demonstrates high concordance with post-therapeutic 177Lu-PSMA RLT scans in terms of accurate classification of organ involvement. Uptake intensity above salivary gland uptake shows promise for early prediction or treatment response to targeted RLT, and may have prognostic significance for PFS.

EP-0297

Bone Scan Index and Quantitative Bone SPECT/CT - a Comparative Analysis in the Follow-up of Metastatic Prostate Cancer Patients

N. Chelaru[1], *B. Stoica[1], M. Mutuleanu[1,2], M. Gherghe[1,2]; [1]Institute of Oncology "Professor Doctor Alexandru Trestioreanu", Bucharest, ROMANIA, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: The most common site of dissemination in patients with prostate cancer (PCa) is represented by bones. Early detection of malignant lesions is essential to facilitate favorable prognosis as metastases severely compromise patient quality of life, thus the role of imaging has become decisive in initial detection and treatment response evaluation. The Bone Scan Index (BSI) serves as an imaging biomarker of disease progression, by estimating the volume of malignant bone lesions on planar images as percentage value. Automated BSI (aBSI) is independently associated with the prediction of overall survival rates in prostate cancer patients with bone metastasis. ***Materials and Methods:*** Our retrospective study included 32 patients diagnosed with metastatic prostate cancer, who underwent at least two consecutive bone scans and SPECT/CT using 99mTc-

hydroxydiphosphonate within a 6-12-month interval. aBSI values were calculated using EXINI aBSI 3.4 software, with manual correction in case of benign foci initially classified as malignant. We assessed a maximum of five lesions with the highest maximum standardized uptake values (SUVmax) in patients with multiple metastases both on the baseline (T0) and follow-up (T1) examinations; in patients with less than five foci, all lesions were analyzed. A total of 221 metastases were assessed and the values of summed SUVmax between the two studies were compared to determine disease status. Changes in BSI results (ΔBSI) were correlated with differences of summed SUVmax (ΔsumSUVmax) using Spearman's rank coefficient. ***Results:*** The median and interquartile range (IQR) SUVmax for T0 were 28.75 (17.62-47.02) and for T1 25.50 (13.90-41.45), while the median and IQR BSI were 0.45 (0.10-1.47), respectively 0.35 (0.10-1.87). The correlation between ΔBSI and ΔsumSUVmax presented a strong positive result ($r=0.797$, $p<0.01$). We appraised 4 patients presenting less than 5 lesions and BSI values equal to 0.0 on both studies; in these patients, SUVmax ranged from 8.82 to 47.90, due to the localization of the metastases in the vicinity of organs with high physiological radiotracer uptake. Manual adjustments were necessary for hotspots such as urinary catheters, degenerative lesions, and known traumatic injuries that were initially classified as bone metastases. ***Conclusion:*** This preliminary study highlights a strong correlation between the two examinations, suggesting that BSI could serve as a surrogate marker in monitoring treatment effectiveness and disease status. BSI exhibits limitations in accurately detecting hotspots that represent malignant lesions, while SPECT/CT offers improvements in minimizing false positives. More extended studies are required to confirm the clinical utility.

EP-0298

Robotic PSMA-targeted surgery - a preliminary evaluation of 60 patients wherein the DROP-IN gamma probe was used

M. van Oosterom[1], *L. Zuur[2], H. de Barros[3], A. Berrens[3], H. G. van der Poel[3], P. J. van Leeuwen[3], F. W. B. van Leeuwen[1];*
[1]Leiden University Medical Center, Leiden, NETHERLANDS, [2]Netherlands Cancer Institute - Antoni van Leeuwenhoek hospital, Amsterdam, NETHERLANDS, [3]Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.

Aim/Introduction: The adoption of PSMA-PET as a staging tool has been paradigm changing for prostate cancer (PCa) management. Not only does PSMA-PET offer highly accurate staging, it also allows urologists to personalize the therapy plan. For example, patients that express local disease with limited nodal spread can benefit from PSMA-targeted surgery [1]. A surgical strategy that, following the clinical introduction of the DROP-IN gamma probe technology, has been made compatible with robotic treatment strategies. Earlier studies report on relatively small patient cohorts that focus on either de novo or salvage surgery [2,3]. Here we report an interim analysis of a mixed study that has included 60 patients thus far. ***Materials and Methods:*** Patient with primary diagnosed PCa and patients with recurrent disease after previous curative-intent therapy were included with up to three PSMA PET avid pelvic PCa lesions (nodal or local recurrences). Robot-assisted PSMA-radioguided surgery using the CE-marked re-sterilizable DROP-IN gamma probe was carried out 19-23 h after intravenous injection of 99m-technetium PSMA-Investigation & Surgery (99mTc-PSMA-I&S). To confirm successful intraoperative removal of the lesion, ex vivo gamma probe measurements were used as control. Following surgery, the nodal specimens were analysed at pathology and the patients were monitored for complications. ***Results:*** 60 patients were included, 7 (11.7%) men underwent a 99mTc-PSMA guided lymph node dissection for primary diagnosed PCa and 53 (88.3%) men underwent 99mTc-PSMA guided resection of pelvic PCa recurrences (nodal or local). The DROP-IN probe helped in realizing robot-assisted PSMA-RGS, providing autonomy for the surgeon and facilitating great manoeuvrability during lesion localization. In general, with respect to preoperative PSMA-PET, using the DROP-IN probe, 71/74 (95,9%) PSMA-avid lesions could be resected robotically. Interestingly, a learning curve was observed in both patient selection, as well as intraoperative DROP-IN probe use, where the detection rate raised to 100% after 25 patients. This underlined the best parameters for successful robotic radioguided PSMA-targeted surgery. One patient suffered from a Clavien-Dindo grade >III complication. ***Conclusion:*** Extending earlier reports on its use during sentinel lymph node procedures, recent findings indicate the DROP-IN gamma probe technology also provides a reliable tool for 99mTc-PSMA-targeted robotic PCa surgery. The optimizations in this field pave the way for the exploration of other receptor-targeted DROP-IN applications. ***References:*** [1] Anne-Claire Berrens et al., Eur J Nucl Med Molecular Imaging, 2023[2] Hilda de Barros et al., Eur Urol, 2022[3] Giorgio Gandaglia et al., Eur Urol, 2022.

EP-0299

PRIMARY SCORE of Ga^{68} PSMA-11 PET/CT in evaluation of suspected Carcinoma Prostate - A retrospective study

V. Nathamedu Chinnaraju, *I. M, S. Simon;*
Apollo Hospitals, Chennai, INDIA.

Aim/Introduction: Ga68 PSMA-11 PET/CT is the imaging modality of choice in staging and recurrence evaluation of patients with primary prostatic malignancy. A novel approach regarding the utilization of a five point scoring system named PRIMARY scoring system based on intraprostatic pattern was established and evaluated by Emmett et.al, (2022). In the present study, we aim to evaluate the diagnostic accuracy of the PRIMARY scoring system in a cohort of suspected prostatic malignancy and association between PRIMARY score and Risk group among the patients with biopsy proven prostatic malignancy. ***Materials and Methods:*** A total of 56 patients who underwent Ga68 PSMA -11 PET CT between October 2023 and April 2024 were collected retrospectively. Ga68 PSMA 11 uptake in prostate scored from 1 - 5 based on PRIMARY scoring system. A PRIMARY score of 1 and 2 were considered negative for malignancy and a PRIMARY score of 3,4,5 were considered positive for malignancy. Diagnostic accuracy parameters (sensitivity, specificity, positive predictive value, negative predictive value) were calculated with biopsy as gold standard. Association between PRIMARY score and Damico risk classification was evaluated in patients with biopsy proven malignancy. ***Results:*** Among 56 patients, PRIMARY score was 1 in 3 (5.3%), 2 in 11 (19.7%), 3 in 6 (10.7%), 4 in 11 (19.7%), 5 in 25 (44.6%) patients. Histopathologically, 40 (71.6%) patients had Castration sensitive Prostate carcinoma (CS PCa) and 16 (28.6%) were negative for CS PCa. The sensitivity, specificity, Postive Predictive value, Negative predicitive Value were 87.5%, 68.75%, 87.5%, 68.75% respectively. In the cohort of biopsy proven malignancy, 17/24 (70.8%) patients with PRIMARY score 5 were of high risk, 1/24 (6.2%) and 6/24 (25%) patients with PRIMARY score 5 were of low and intermediate risk respectively. ***Conclusion:*** PRIMARY scoring system can be considered in interpretation of Ga68 PSMA uptake in prostate with a sensitivity and positive predictive value

of 87.5% each. Among the cohort of biopsy proven prostatic malignancy, a higher PRIMARY score was associated with high risk group. ***References:*** Emmett L, Buteau J, Papa N, Moon D, Thompson J, Roberts MJ, Rasiah K, Pattison DA, Yaxley J, Thomas P, Hutton AC. The additive diagnostic value of prostate-specific membrane antigen positron emission tomography computed tomography to multiparametric magnetic resonance imaging triage in the diagnosis of prostate cancer (PRIMARY): a prospective multicentre study. Mondor, AP-HP, F-94010, Créteil, France, Creteil, FRANCE, [13]Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, University of California Los Angeles, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: To assess [18F]F-FDG (FDG) and [18F]-Fcholine (Fcholine) performance for discordant lesion detection with [68Ga]-Ga-PSMA-11 (PSMA) PET/CT for [177Lu]-PSMA (LuPSMA) radioligand therapy eligibility in metastatic castration-resistant prostate (mCRPC). ***Materials and Methods:*** This multicenter retrospective study included adults who performed FDG, FCholine and PSMA PET/CT before LuPSMA (I&T or 617) radioligand therapy in mCRPC. PSMA and FDG PET/CT were performed within 30 days and FDG and FCholine within 45 days. During this time, the French regulatory agency required the use of Fcholine prior to performing a PSMA PET/CT. Imaging analysis on a lesion-based level was performed by two groups of readers with different imaging reading order (Group 1: PSMA, FDG and Fcholine. / Group 2 : PSMA, Fcholine and FDG). The primary outcome was the percentage rate of patients with discordant findings between PSMA- and FDG-PET (PSMA-FDG) and between PSMA- and Fcholine-PET (PSMA-Fcholine). The secondary outcome was the concordance and discordance rate between FDG and Fcholine PET. ***Results:*** A total of 60 patients (median age, 74 years [IQR, 68-79 years]) were included between May 2021 and June 2022. 57/60 (95%), 35/60 (57%), 20/60 (33%) patients had bone, lymph node, and visceral disease on PSMA PET/CT. PSMA-FDG discordance was found in 16/60 (26%) patients and discordant lesions were detected in viscera, lymph nodes and bone in 5/16 (31%), 8/16 (50%), 9/16 (56%) patients, respectively. PSMA-Fcholine discordance was found in 18/60 (30%) patients. None of the patients had discrepant visceral lesions (0/18), while 8/18 (44%), 13/18 (72%) patients presented discordant findings for lymph nodes and bone metastases on Fcholine. Among patients with PSMA-FDG discordance, 8/16 (50%) also showed discordance in PSMA-Fcholine analysis. PSMA-Fcholine discordance not detected by PSMA-FDG analysis was observed only in bone in 8/18 (44%) patients and in lymph nodes in 2/18 (11%) patients. ***Conclusion:*** Compared to FDG , Fcholine PET/CT did not detect discordant visceral lesions in patients with mCRPC being considered for LuPSMA radioligand therapy. Prognostic significance of bone-only lesions detected by Fcholine PET/CT requires further evaluation.

EP-0301

Can [18F]DCFPyL PET/CT replace [18F]Fluorocholine PET/CT in all the diagnostic settings of prostate cancer

S. Guzmán Ortiz[1], *M. Meneses Navas[1], M. Cruz Montijano[1], L. Garcia Zoghby[1], J. Bonilla Plaza[1], V. Poblete Garcia[2], A. Garcia Vicente[1];*
[1]Nuclear Medicine Department, University Hospital of Toledo, Toledo, SPAIN, [2]Nuclear Medicine Department, General University Hospital of Ciudad Real, Ciudad Real, SPAIN.

Aim/Introduction: PSMA ligands PET/CT have shown higher diagnostic accuracy in several clinical scenarios for prostate cancer (pCa) patients than choline analogues PET/CT. However, whether PSMA ligands should completely replace choline analogues has yet to be determined. The aim is to assess the need for [18F]DCFPyL PET/CT after a previous [18F]Fluorocholine PET/CT and to evaluate the diagnostic and therapeutic impact of [18F]DCFPyL PET/CT compared with [18F]Fluorocholine PET/CT. ***Materials and Methods:*** A retrospective review of all [18F]Fluorocholine PET/CT performed on patients diagnosed with pCa in half of 2022. [18F]Fluorocholine PET/CT (first step) served various purposes: initial staging, detection of biochemical recurrence post-radical prostate treatment, non-metastatic castration-resistant prostate cancer (CRPC-M0), and metastatic (CRPC-M1), in some cases, as a previous step for a requested [18F]DCFPyL PET/CT (second step). [18F]DCFPyL PET/CT under compassionate use, authorized by the SAMHP, approved by a multidisciplinary committee, and with informed, signed consent from patients. The criteria for administering [18F]DCFPyL PET/CT included: (i) previous [18F]Fluorocholine PET/CT that was negative, doubtful for extraprostatic disease, or indicative of oligometastatic disease; and (ii) the patient's clinical eligibility for various alternative treatments based on [18F]DCFPyL PET/CT results. Oligometastatic disease was defined as having ≤3 lesions, potentially involving lymph nodes in the pelvis and/or retroperitoneum, with one lesion possibly in the bone. Data from [18F]DCFPyL PET/CT was gathered from a consecutive and prospective dataset started in August 2021 for biochemical recurrence, January 2021 for CRPC, and March 2021 for staging purposes. ***Results:*** Out of 243 patients, those referred for [18F]DCFPyL PET/CT following [18F]Fluorocholine PET/CT included: 1/3 from the biopsy guide group, 39/79 from initial staging, 2/2 from PSA persistence after prostate resection, 48/65

from biochemical recurrence, 8/36 from CRPC-M0, and 1/58 from CRPC-M1. The therapeutic impact of [18F]DCFPyL PET/CT relative to the findings from [18F]Fluorocholine PET/CT was notable in the first four diagnostic groups: 1 case in biopsy guide, 7 in initial staging (5 treatment up-escalations and 2 down-escalations), 1 up-escalation in PSA persistence, and 19 in biochemical recurrence (18 up-escalations). No treatment modifications were observed in the CRPC-M0 and CRPC-M1 groups. ***Conclusion:*** [18F]Fluorocholine PET/CT appears effective in evaluating disease in patients with CRPC, both M0 and M1 stages, reducing the necessity for [18F] DCFPyL PET/CT in these cases.This allows the latter to be reserved for scenarios where it has a greater diagnostic and therapeutic impact, such as in cases of biochemical recurrence and staging, which show therapeutic impacts of 40% and 18%, respectively.

EP-0302

A Translational Pilot Study of FAP and PSMA Expression by Immunohistochemistry and PET in Castration-resistant Prostate Cancer

A. Holzgreve*[1]*, *R. Huang[2], C. Zuo[2,3], C. E. Mona[1], C. Morrissey[4], P. S. Nelson[5], L. Brady[5], L. True[6], A. E. Sisk Jr.[2], J. Czernin[1], J. Calais[1], H. Ye[2,7];*
[1]Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [2]Department of Pathology and Laboratory Medicine, David Geffen School of Medicine, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [3]Department of Pathology, Rocky Mountain Regional VA Medical Center, Aurora, CO, UNITED STATES OF AMERICA, [4]Department of Urology, University of Washington, Seattle, WA, UNITED STATES OF AMERICA, [5]Divisions of Human Biology and Clinical Research, Fred Hutchinson Cancer Center, Seattle, WA, UNITED STATES OF AMERICA, [6]Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA, UNITED STATES OF AMERICA, [7]Department of Pathology and Laboratory Medicine, Cedars-Sinai Medical Center, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: PSMA-targeted PET imaging and radionuclide therapy are a mainstay in the management of advanced prostate cancer. Yet, metastatic castration-resistant prostate cancer (CRPC) may lose PSMA expression following exposition to systemic treatments. Cancer-associated fibroblasts of various cancer types express fibroblast activation protein (FAP). The aim of this study was to assess if FAP can be a viable theranostic target for CRPC, particularly for PSMA-negative CRPC. ***Materials and Methods:*** We evaluated FAP expression in CRPC, using PSMA as a comparison. In a total of 116 CRPC tumors (78 adenocarcinoma, 11 small cell carcinoma (SmCC), and 27 "anaplastic carcinoma"), FAP expression was assessed using immunohistochemistry (IHC). Tissue microarray cores of n=62 CRPC (including n=9 locally advanced CRPC, and n=53 metastatic CRPC) served for paired FAP and PSMA IHC analysis. Expression positivity was arbitrarily defined by IHC score ≥10. A preliminary analysis of 4 patients included in the trial NCT0445723 was performed to explore the correlation of PSMA/FAP PET imaging and IHC. ***Results:*** Overall, FAP expression in CRPC was significantly lower compared to PSMA expression (median immunoscores 14 vs 72, p<0.001). The level of PSMA expression distinctly varied across different histological subtypes of CRPC, while all subtypes consistently showed low FAP expression. Among the 19 PSMA-negative tumors, 11 (58%) exhibited FAP positivity. FAP expression leves in nodal metastases were significantly lower than in non-nodal metastases (p=0.021), whereas FAP expression levels in hepatic metastases were significantly higher compared to extra-hepatic metastases (p=0.016). In 4 patients with CRPC, uptake intensity on FAPi PET was lower compared to PSMA PET (median SUVmax 9.6 vs. 14.5), consistent with the lower FAP expression than PSMA expression in the corresponding biopsied tumors (median immunoscores 30 vs 160). ***Conclusion:*** The utility of FAPi PET imaging may be limited due to overall lower levels of FAP expression in CRPC. FAPi PET imaging should be tested for its ability to detect PSMA-negative tumors, such as small cell carcinoma of prostatic origin, as they express variable levels of FAP expression.

EP-0303

[64Cu]Cu-PSMA-Q PET/CT in late stage Prostate Cancer: a Diagnostic and Dosimetric Study

S. Li[1], ***H. Zhang[1],*** *F. Chen[1], Z. Li[2];*
[1]Department of Nuclear Medicine, Affiliated Hospital of North Sichuan Medical College, Nanchong, CHINA, [2]C-Ray Pharmaceuticals (Chengdu) Co. Ltd., Chengdu, CHINA.

Aim/Introduction: [64Cu]Cu-PSMA-Q is a novel radiopharmaceutical targeting prostate-specific membrane antigen (PSMA), which has been proven to exhibit a high specific uptake in prostate cancer(PCa) lesions and an excellent tumor-to-background ratio [1]. In this study, we first aimed to compare the diagnostic performance of [64Cu]Cu-PSMA-Q and [18F]F-FDG in the same group of PCa patients. The secondary aim was to perform dosimetry analysis. ***Materials and Methods:*** With institutional review board approval and informed consent, a total of 29 histopathological confirmed PCa patients were enrolled. All of the 29 patients underwent paired [64Cu]Cu-PSMA-Q and [18F] F-FDG PET/CT. The activity of tracer accumulation in lesions was assessed by maximum standardized uptake value (SUVmax) and tumor-to-background (TBR). The imaging data were used for calculation of dosimetry using OLINDA/EXM 2.1 (male phantom). ***Results:*** To date (Dec 26th, 2023), 29 patients were included. The median age was 72.0 years (range, 58-87), their median baseline prostate-specific antigen was 265.0 ng/mL (range, 4.0-2747.0). The radiotracer uptake of primary and metastatic lesions in [64Cu]Cu-PSMA-Q was significantly higher than those in 18F-FDG (Median SUVmax: primary tumors, 18.4 vs. 4.9, P<0.001; regional lymph nodes, 7.4 vs. 3.7, P=0.007; distant metastases, 11.0 vs. 6.3, P=0.081. Median TBR: primary tumors, 8.3 vs. 2.3, P=0.002; regional lymph nodes, 4.9 vs. 1.7, P=0.001; distant metastases, 5.5 vs. 3.1, P=0.135). [64Cu]Cu-PSMA-Q had a higher detection rate for primary and lymph node lesions. In 21 patients with primary lesions, [64Cu] Cu-PSMA-Q detected primary tumor in 95.2% (20/21), while [18F] F-FDG detected primary tumor in 66.7% (14/21). In 16 patients with peripheral lymph node metastases, 50% (8/16) showed more peripheral lymph node lesions on [64Cu]Cu-PSMA-Q than on [18F] F-FDG, 12.5% (2/16) showed the opposite, and the remaining 37.5% (6/16) showed identical results. In 11 patients with distant lymph node metastases, 72.7% (8/11) detected more lymph node lesions on [64Cu]Cu-PSMA-Q, whereas 27.3% (3/11) showed comparable results with both tracers. In 20 patients with bone metastases, no significant difference of trunk and limb bone metastases were observed between [64Cu]Cu-PSMA-Q and [18F] F-FDG PET/CT. However, [64Cu]Cu-PSMA-Q detected more cranial bone metastases. Nine patients were included for dosimetric studies. The median total body effective dose of [64Cu]Cu-PSMA-Q was 0.0284 mSv/MBq. No IMP related adverse events were observed. ***Conclusion:*** [64Cu]Cu-PSMA-Q is a promising new diagnostic PET tracer for detection and characterization of PCa, it may aid physicians in patient management decision making. ***References:*** [1] Wu Y et al. Eur J Nucl Med Mol Imaging. 2022 Jul;49(8):2774-2785.

EP-0304

Optimising the use of 18F-Fluorodeoxyglucose Positron Emission Tomography (FDG PET) imaging in patients with metastatic castration-resistant prostate cancer (mCRPC) in the era of Radioligand Therapy (RLT)

L. Sofia[1], *F. D'Amico[1], T. Di Raimondo[1], F. Lanfranchi[1], S. Raffa[2], S. Chiola[2], M. I. Donegani[2], G. Celesti[3], G. Sambuceti[1], G. Fornarini[4], M. Bauckneht[1];*
[1]Nuclear Medicine Unit, Department of Health Sciences (DISSAL), University of Genoa, Genoa, ITALY, [2]Nuclear medicine unit, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY, [3]Nuclear Medicine Unit, University of Messina, Messina, ITALY, [4]Department of Oncology, IRCCS Ospedale Policlinico San Martino, Genoa, ITALY.

Aim/Introduction: In the era of RLT, understanding how to select mCRPC patients eligible for this treatment is crucial. The combination of FDG and prostate-specific membrane antigen (PSMA) PET imaging has been proposed to enhance patient selection, even within clinical trials. However, using both tracers entails higher costs for public healthcare systems and potential issues related to the availability and allocation of resources. Given these considerations, we aimed to evaluate the presence of clinical or imaging parameters that could predict the occurrence of FDG-positive/PSMA-negative mismatch in a single-centre retrospective cohort of mCRPC patients. ***Materials and Methods:*** We retrospectively identified mCRPC patients who underwent FDG and PSMA PET/CT within 30 days without treatment changes between 2021 and 2024. Univariate and multivariate logistic regressions for FDG+/PSMA- mismatches were performed, considering various clinical (primary treatment, ISUP grade group, previous lines and types of treatments for mCRPC), biochemical (prostate specific antigen [PSA], alkaline phosphatse [ALP], lactate dehydrogenase [LDH]), and PSMA PET/CT-derived parameters (standardized uptake value [SUV]max, PSMA tumour volume [PSMA-TV], and total lesion PSMA [PSMA-TL]). Eligibility for RLT according to the imaging selection criteria of the VISION phase III trial was also assessed. ***Results:*** Among the 46 patients (median age was 72.3 years, range: 55-87), 67% had previously undergone more than two lines of therapy for mCRPC. Univariate analysis revealed that previous treatment with enzalutamide (OR 0.25, 95%CI 0.06-1.1, p=0.05), eligibility for RLT as per the VISION trial criteria (OR 0.14, 95%CI 0.02-0.76, p<0.05), and a PSMA-TL above 2282 (OR 0.07, 95%CI 0.008-0.62, p<0.05) were significant predictors of the absence of FDG-positive/PSMA-negative mismatched lesions. Notably, in the multivariate analysis, both PSMA-TL and previous treatment with enzalutamide remained significant predictors (p<0.05 for both). ***Conclusion:*** Previous treatment with enzalutamide and high PSMA-TL emerged as significant and independent predictors of the absence of FDG-positive/PSMA-negative mismatched lesions. The ability of enzalutamide to upregulate PSMA expression, combined with the lower PSMA expression observed in patients with undifferentiated FDG-avid mCRPC, may explain these results. If these findings are confirmed by further studies, they could help identify patients who are more likely to benefit from dual-tracer PET/CT imaging, thereby guiding treatment decisions more effectively.

EP-0305

Is there any added value of radiomics analysis in the interpretation of focal bone uptakes in prostate cancer patients imaged with [18F]PSMA-1007 PET/CT?

T. Di Raimondo[1], *G. Pasini[2], G. Russo[3], M. Donegani[1], S. Raffa[1], D. Dubois[1], L. Peñuela[1], F. D'Amico[1], L. Sofia[1], C. Cabrini[1], G. Sambuceti[1], A. Stefano[1], M. Bauckneht[1];*
[1]Nuclear Medicine Unit, Department of Health Sciences (DISSAL), University of Genoa, Genoa, ITALY, [2]Sapienza University of Rome, Rome, Italy, Rome, ITALY, [3]IBFM, National Research Council, Cefalù, Italy, Cefalù, ITALY.

Aim/Introduction: Recent advancements in logistics and availability of [18F]PSMA-1007 have significantly increased its use in PET imaging for prostate cancer (PCa). However, its propensity for non-specific bone uptakes (UBUs) presents a notable clinical challenge. Our study aimed to investigate whether radiomic features could enhance the interpretation of bone focal uptakes and assess their potential additive value to the visual interpretation by PET readers with varying levels of prior expertise. ***Materials and Methods:*** We retrospectively analysed [18F]PSMA-1007 PET/CT scans from 102 patients with histology-proven hormone-sensitive PCa performed at IRCCS Ospedale Policlinico San Martino, exhibiting at least one focal bone tracer uptake, as jointly determined by two nuclear medicine physicians. To differentiate between PCa bone metastases and UBUs, we employed a composite reference standard that included follow-up histopathology, biochemistry, and imaging data. Using matRadiomics, 1781 radiomic features were extracted from PET and CT images of each bone uptake. Features were elaborated through a machine-learning pipeline (30 repetitions), incorporating an 80%/20% split for training/testing, Least Absolute Shrinkage and Selection Operator (LASSO) feature selection, and model building using six classifiers (Discriminant Analysis, DA), Support Vector Machines (SVM), K-Nearest Neighbors (KNN), Neural Networks (NN), Random Forests (RF), AdaBoost (Boost). Iterations included 5-fold cross-validation and models testing, the results were averaged over the 30 repetitions. Moreover, ensemble versions of each classifier were built, computing their performance. In parallel, PET readers with low experience (n=2, < 30 previous PSMA PET readings) and high experience (n=2, > 300 previous PSMA PET readings), and blinded to the clinical history of PCa patients, rated each bone uptake as either UBU or bone metastasis. ***Results:*** Out of the 178 bone [18F]PSMA-1007 focal uptakes, 74 (41.5%) were identified as PCa metastases according to the reference standard. Two radiomics features, "log_sigma_4_5_mm_3D_glszm_SmallAreaEmphasis" and "wavelet_HLH_ngtdm_Contrast1" showed robustness to training/testing splitting greater than 70%. Overall, the highest accuracies were reached by the ensemble classifiers, ranging from 78.65% to 82.58%. However, the accuracy of radiomics did not surpass that of expert PET readers, as both achieved a diagnostic accuracy of 92.1%. In contrast, the diagnostic accuracy for low-experienced readers was lower, at 83.7% (p=ns compared to experts and radiomics) and significantly lower at 54.4% (p<0.05 compared to experts and radiomics). ***Conclusion:*** While the performance of radiomics in interpreting bone [18F]PSMA-1007 focal uptakes did not surpass the visual assessment by expert PET readers, it potentially improves the interpretative accuracy of readers with less experience.

EP-0306

[68Ga]GaPSMA617 PET-based radiomics model to identify candidates for active surveillance amongst patients with Gleason GradeGroup 1-2 prostate cancer at biopsy

J. Yang, *Y. Tang, Y. Li, S. Hu;*
Xiangya hospital, Changsha, CHINA.

Aim/Introduction: Current inclusion criteria for active surveillance (AS) may results in some patients carrying with adverse pathology

(AP) at final pathology receiving an AS regimen. By enrolling these patients in AS, they may miss the opportunity for curative treatment due to disease progression. Additionally, the flexibility of inclusion criteria may limit the number of patients with pathologically indolent PCa who are eligible for AS, increasing the risk of overtreatment. Several models based on the clinical and MRI features have been developed to overcome these limitations but aren't ideal. Our study aims to develop a [68Ga]Ga-PSMA PET-based radiomics model to predict postoperative AP in patiens with biopsy Gleason Grade Group (GGG) 1-2 PCa, aiding in the selecting patients for AS. ***Materials and Methods:*** Seventy-five men with biopsy GGG 1-2 PCa who underwent radical prostatectomy (RP) were enrolled. The presence of AP at RP, defined as non-organ confined disease and/or lymph node invasion and/or GGG ≥ 3, represented the study's outcome, which means that the patient wasn't suitable for AS. All patients were divided into training group (70%) and testing group (30%) randomly. Radiomics features were extracted from [68Ga]Ga-PSMA PET scans and selected by the minimum redundancy maximum relevance algorithm and the least absolute shrinkage and selection operator regression model. The clinical model based on the clinical features and conventional [68Ga]Ga-PSMA PET/CT features, radiomics model based on the radiomics features, and combined model based on all above features were developed using logistic regression analyses. ROC curve was used to assess the diagnostic value of those models. ***Results:*** Thirty of seventy-five patients had AP confirmed by RP. The clinical model showed an AUC of 0.821 in the training set and 0.795 in the testing set. The radiomics model achieved AUC values of 0.830 and 0.829 in the training and testing set. The combined model, which incorporated the Radiomics score and FPSA/TPSA, demonstrated higher diagnostic efficacy than both the clinical and radiomics models, with AUC values of 0.875 and 872 in the training and testing set. decision curve analysis showed that the net benefits of the combined model and radiomics model exceeded the clinical model. ***Conclusion:*** The combined model shows potential in stratifying men with biopsy GGG 1-2 PCa based on the presence of AP at RP and outperforms models based solely on clinical or radiomics features. It may be expected to aid urologists in better selecting suitable patients for AS.

A new SPECT agent for PSMA visualization, [^{99m}Tc]Tc-BQ0413: preclinical evaluation and preliminary results of Phase I clinical study

A. Orlova[1], *E. Bezverkhniaia[1], P. Kanellopoulos[1], A. Medvedeva[2], M. Larkina[3], R. Varvashenya[3], A. Abouzayed[1], A. Rybina[2], M. Oroujeni[1], A. Vorobyeva[1], U. Rosenström[1], V. Tolmachev[1], V. Chernov[3];*
[1]Uppsala University, Uppsala, SWEDEN, [2]Tomsk National Research Medical Center, Tomsk, RUSSIAN FEDERATION, [3]Siberian State Medical University, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Radionuclide imaging using radiolabelled inhibitors of PSMA can be used for staging of prostate cancer (PCa). We have designed a molecule BQ0413, which contains Glu-urea-Lys binding moiety, optimized linker structure including 2-napththyl-L-alanine and L-tyrosine [1], and mercaptoacetyl-triglutamate chelator for labelling with Tc-99m. The purpose of this study was to evaluate the imaging properties of [99mTc]Tc-BQ0413. ***Materials and Methods:*** Synthetically produced pseudo-peptide was labeled with technetium-99m. [99mTc]Tc-BQ0413 was studied on target specificity, affinity and in vivo biodistribution. A whole body planar scintigraphy and SPECT/CT imaging were performed 2, 4, and 6 h after injection of 50, 100, or 150 µg (680±140 MBq) of [99mTc]Tc-BQ0413 in five PCa patients for each dose (NCT05839990). ***Results:*** [99mTc]Tc-BQ0413 bound specifically to PSMA-expressing cells with affinity 33±15 pM. In tumor-bearing mice, the tumor uptake of [99mTc]Tc-BQ0413 (38±6 %IA/g in PC3-pip 3 h after injection of 40 pmol) was dependent on PSMA expression (0.9±0.3 %IA/g in PSMA-negative tumors). The co-injection of 5 nmol of unlabeled BQ0413 blocked [99mTc]Tc-BQ0413 uptake in normal PSMA-expressing tissues without blocking the uptake in tumors that resulted in an appreciable increase in the tumor-to-organ ratios. In patients, all injections of [99mTc]Tc-BQ0413 were well tolerated, no adverse events were registered. The elimination of [99mTc]Tc-BQ0413 was predominantly renal. The stable physiological uptake of [99mTc]Tc-BQ0413 was observed in the lacrimal and salivary glands, liver, spleen, and kidneys for all tested peptide doses. Activity uptake in clinicaly relevant organs (bones and muscles) was low and decreased with time (SUVmean<1). An average effective doses were 0.007 ± 0.001, 0.0049±0.0003, and 0.0062±0.0008 mSv/MBq for 50, 100, and 150 µg/injection. With the given activity, the radionuclide-associated dose burden per patient was 4-7 mSv/study. Uptake of [99mTc]Tc-BQ0413 in primary tumors was identified in all patients (SUVmean increased from 3.4±1.4 [1.15-4.82] for 50 µg/dose to 5.1±1.2 [3.86-7.01] for 150 µg/dose). Uptake in LN and BM was the highest at 100 µg/dose (SUVmean 29.6±28.9 [12.34-62.99] and 20.0±12.3 [6.41-30.29]). Physiological uptake and uptake in cancer lesions did not changed significantly with time or with injected peptide dose. ***Conclusion:*** [99mTc]Tc-BQ0413 demonstrated specific binding to PSMA with binding affinity in low picomolar range. The results of the Phase I study show that injections of [99mTc]Tc-BQ0413 are well-tolerated, safe and associated with low absorbed doses. Imaging using [99mTc]Tc-BQ0413 enables visualization of primary prostate cancer lesions, as well as metastases in lymph nodes and bones. ***References:*** 1. Lundmark et al. Pharmaceutics 2022, 14, 1098.

EP-0308

Effect of post-injection acquisition time on the qualitative evaluation of whole-body [^{68}Ga]Ga-PSMA PET/CT scans

J. Castanheira, *R. Teixeira, C. Constantino, F. Oliveira, D. C. Costa; Champalimaud Foundation, Lisbon, PORTUGAL.*

Aim/Introduction: Post-injection (p.i.) acquisition time may originate different interpretations of whole-body [68Ga]Ga-PSMA PET/CT scans due to radiopharmaceutical kinetics in tumor lesions and/or radiopharmaceutical decay. This work aims to compare visual interpretation in the same patients on whole-body [68Ga]Ga-PSMA PET/CT scans acquired in three consecutive p.i. times. ***Materials and Methods:*** Eighty-two patients with prostate cancer were included. 18% were referred for disease staging and the remaining for re-staging or assessment of therapy response. Patients were injected once with approximately 2.0±0.25 MBq/kg of [68Ga]Ga-PSMA. Each patient underwent three consecutive PET scans in the same equipment (Philips Gemini TF16): approximately 56±10min, 89±9min, and 124±11min p.i. (T1, T2, T3, respectively). Each scan duration was approximately 65±9, 75±6, and 86±8 seconds/AFOV, respectively. All scans (246 in total) were evaluated independently and anonymously by two experienced nuclear medicine physicians, unaware of any patient clinical information. Scans were randomly shuffled and anonymized. The evaluation was based on overall image quality (1: low; 5: excellent); and the presence of suspected malignant lesions (yes/no), namely in the prostate or prostate site, bones, and lymph nodes (supra and/or infradiaphragmatic). ***Results:*** Inter-

reader image quality was rated as 3.3±0.5, 3.3±0.5, and 3.2±0.5 for the T1, T2, and T3 scans, respectively. Regarding the detection of suspected malignant lesions, reader 1 identified 36-32-34 scans with prostate lesions, 19-18-18 scans with bone lesions, 9-13-11 scans with supradiaphragmatic lymph node lesions, and 27-27-26 scans with infradiaphragmatic lymph node lesions for times T1-T2-T2, respectively. Reader 2 identified 45-40-41, 26-22-23, 11-12-14, and 33-32-31, respectively. Intra-reader agreement varied between 85% (T1 vs T2, for the detection of prostate lesions) to 100% (T2 vs T3, for the detection of bone lesions), for reader 1; and between 82% (T1 vs T2 and T2 vs T3, for the detection of prostate lesions) to 96% (T2 vs T3, for the detection supradiaphragmatic lymph node lesions) for reader 2. There were no statistically significant differences among the detection of lesions for the three acquisition times. Now, regarding the inter-reader agreement, it varied between 77% (T1 vs T1, for the detection of prostate lesions) to 99% (T2 vs T2, for the detection of supradiaphragmatic lymph node lesions). There was no statistically significant difference among the three acquisition times. ***Conclusion:*** Overall, this study did not demonstrate a significant effect of the post-injection time (from 1 to 2 hours p.i.) in the detection of suspected malignant lesions with [68Ga]Ga-PSMA PET/CT.

EP-0309

PSMA-PET: is there something we can do to facilitate the interpretation of the image?

V. Betech-Antar[1], *E. Guillén[2], J. Rosales[1], F. Minguez[1], M. Romera[1], Á. Bronte[3], F. Pareja del Río[1], J. Pérez-Gracia[1], R. Martínez-Monge[1], B. Miñana[1], M. Rodríguez-Fraile[1];*
[1]Clínica Universidad de Navarra, Pamplona, SPAIN, [2]Clínica Universidad de Navarra, Madrid, SPAIN, [3]Hospital Universitario Son Espases, Palma de Mallorca, SPAIN.

Aim/Introduction: Some modifications to standard (SD) 68Ga-PSMA-11-PET protocol seems to facilitate image interpretation: 1) iv contrast at the excretory phase (50 ml of Omnipaque® 10-15 minutes before PET acquisition) to define the ureteral anatomy 2)Dynamic pelvic acquisition (0-8 minutes post-injection) to visualize the prostate bed before bladder excretion of 68Ga-PSMA, in patients with radical prostatectomy (RP) 3)Late images (100-180 minutes post-injection) to further increase detectability of low-uptake-lesions at SD. Nevertheless, as their use can increase both the costs and complexity of the study, we tried to define if these modifications have a real impact on PSMA-PET interpretation. ***Materials and Methods:*** PSMA-PET performed for both recurrence detection and initial staging were prospectively analysed. For each patient we evaluated the improvement of these modifications respect to the SD (at 60-100 minutes without contrast). Moreover, their potential increase in the 5-point-scale reader confidence when using EANM standardized report e-PSMA (ePSMACR)1 in comparison with just the use of SD. ***Results:*** Thirty-six patients were included (70 years [53-82], PSA at PET=0.84 ng/ml [0.1-125]; 33/36 for recurrence detection (23/33 after RP; 7/33 under antiandrogen deprivation). -Dynamic acquisition was performed in 23 patients. It helped to detect local recurrence not seen on SD in 2/23(8%), switching from 2 to 4 in ePSMACR; in 3/23(13%) to define that the uptake was not due to local recurrence but rather to anatomical changes post-RP (switching from 3 to 1-2 in ePSMACR). -In 32 patients iv contrast was used. In 5/32 (15%) it avoided the potential pitfall of uretral diverticulum post-RP (from 5 to 1-2 in ePSMACR) and in 4/32 (12.5%) it discriminated between positive lymph nodes and ureteral excretion (2 without change in ePSMACR; 1 patient from 3 to 4 and another from 4 to 1). -In 32 patients late images (159 minutes±40) were obtained. In 2/32(6%) it better define focal uptake in seminal vesicles indeterminate at SD (switching from 3 to 5 in ePSMACR) and in 11/32(34%) it helped to discriminate between malignant (increase in uptake) and physiological/benign lymph nodes (switching from 3-4 to 5 in 7 patients and from 2-4 to 1 in 4 patients) ***Conclusion:*** Modifications to SD protocol have been shown to have a real impact on 68Ga-PSMA-11-PET interpretation and ePSMACR reader confidence. When used, dynamic acquisition modified final diagnosis in 21% of patients, iv contrast in 27.5% and late images in 40%. ***References:*** 1. Ceci F et al. Eur J Nucl Med Mol Imaging. 2021.

EP-0310

Preoperative Volumetric PSMA-PET Parameters for Risk Assessment and Predicting Biochemical Recurrence in Prostate Cancer Patients.

J. Rosales, *V. Betech, F. Minguez, M. Romera, A. Basanta, F. Guillén, J. Pérez Gracia, M. Rodríguez;*
Clínica Universidad de Navarra, Pamplona, SPAIN.

Aim/Introduction: The aim of this study is to describe the distribution of volumetric parameters of PET-PSMA in patients with intermediate and high-risk prostate cancer, along with the histopathological characteristics of the tumor after radical prostatectomy, as well as the differences in patients who developed biochemical recurrence during follow-up. ***Materials and Methods:*** One hundred and thirteen patients referred for PSMA-PET/CT for initial staging and scheduled for radical prostatectomy (RP) were included. PET parameters, including tumor SUVmax, tumor SUVmean, Prostate Molecular Tumor Volume (pMTV), Prostate Volume (pV), Prostate Total Lesion Activity (pTLA), and Prostate Disease Burden % (pDB), were recorded. pV was obtained by automated segmentation of the prostate gland on CT images. pDB was calculated using the formula (pMTV x 100 / pV). The Mann-Whitney U test was used for comparing groups. A p-value <0.05 was considered statistically significant. ***Results:*** Fifty-four intermediate-risk (IR) and fifty-nine high-risk (HR) PCa patients were included in the study. The median SUVmax was 9.89 (range: 6.23-13.13) in the IR group and 10.10 (range: 6.70-18.66) in the HR group. Volumetric parameters were significantly higher in the HR group compared to the IR group. Specifically, the median values for pMTV, pTLA, and pDB in the HR group were 4.6 cc, 29.5%, and 9.3%, respectively, whereas the median values in the IR group were 3.6 cc, 19.1%, and 6.8%, respectively. Furthermore, significantly higher values of pMTV, pTLA, and pDB were observed in patients with positive margins after surgery, those with seminal vesicle infiltration, and patients with Gleason Scores ≥ 8. In the context of biochemical recurrence (BCR), volumetric parameters of PSMA-PET were found to be statistically higher in patients who developed BCR compared to those who maintained undetectable PSA levels ($p < 0.05$), as indicated in Table 1. However, no significant differences were found in terms of SUVmax or SUVmean between risk groups or among histopathological or biochemical recurrence status. ***Conclusion:*** The inclusion of volumetric PSMA-PET parameters such as pMTV, pTLA, and pDB could enhance preoperative risk assessment and provide valuable insights into tumor aggressiveness based on PET imaging data. These parameters offer additional information that aids in better understanding the tumor's behavior before surgery. In terms of predicting biochemical recurrence (BCR), PSMA-PET parameters emerge as promising tools for stratifying patients at higher risk. However, further studies are necessary to validate these findings and elucidate the precise role of PSMA-PET parameters in predicting BCR.

EP-0311

Optimal PSMA-metrics for clinically significant prostate cancer detection in patients with previously negative biopsy.

***E. Lopci*[1],** *A. Saita[1], L. Disconzi[1], P. Colombo[1], V. Fasulo[1], R. Peschechera[1], E. Scapaticci[2], E. Vuono[1], R. Hurle[1], R. Zanca[1], J. Jandric[1], L. Muraglia[1], F. Mrakic[1], P. Casale[1], M. Rodari[1], G. Guazzoni[1], L. Balzarini[1], N. Buffi[1], M. Lazzeri[1], G. Lughezzani[1];*
[1]IRCCS - Humanitas Research Hospital, Rozzano MI, ITALY, [2]CDI, Milano, ITALY.

Aim/Introduction: The detection of clinically significant prostate cancer (csPCa) can represent an imaging challenge in patients with previously negative biopsy. In the current study we aimed to define the optimal PSMA-metrics for the detection of csPCa derived from two prospective trials. ***Materials and Methods:*** Overall, we enrolled 127 patients complying with the inclusion criteria and derived from two prospective trials. Inclusion criteria were: [68Ga]PSMA PET/CT, target fusion biopsy, PSA>4.0ng/ml, free-to-total PSA ratio <20%, progressive rise of PSA levels in two consecutive samples, at least one previous negative biopsy, negative digital rectal examination. Target lesions were defined by computing Primary score, SUVmax and SUVratio to contralateral prostatic background, and statistically correlated to pathology findings. ***Results:*** Median age was 63 years (range 50-82), median PSA 9.7 ng/ml (range 4.3-35), median PHI 46 (range 34-59) and median prostatic volume 73cc (range 17-190). Most patients (96; 76%) had one previous negative biopsy, while the remaining >1. According to re-biopsy results, 23 patients presented with csPCa (18%), 14 with GS 3+3, while the majority had a negative biopsy (90; 71%). Primary scores were: 103 score 1-3 (81%), and 24 score 3-5. Median SUVmax and SUVratio were 4.1 and 1.6, respectively. Optimal cut-off points for the detection of csPCa were: SUVmax >6.12 (AUC 0.792; 95%CI 0.711-0.859) and SUVratio >2.4 (AUC 0.773; 95%CI 0.690-0.842), while the best correlation was set for Primary score >3 (AUC 0.796; 95%CI 0.716-0.863). Sensitivity and specificity for the detection of csPCa resulted as follows: SUVmax cut-off 70% and 87%, SUVratio cut-off 70% and 91%, while Primary score 65% and 91%, respectively. On logistic regression, all above mentioned PET-metrics were significantly correlated to biopsy results (p<0.0001), with SUVratio cut-off >2.4 resulting an independent predictor (p=0.0197) of csPCa detection. ***Conclusion:*** [68Ga]PSMA PET/CT metrics predict the detection of csPCa in patients candidate to rebiopsy, with the SUVratio cut-off granting the best correlation to pathology results. ***References:*** The study was financially supported by the Ministry of Health (Ministero della Salute) with the Grant GR-2018-12366240.

EP-0312

Comparison of [^{68}Ga]PSMA PET/CT vs. mpMRI in patients with suspicion of prostate cancer and previous negative biopsy.

E. Lopci, *L. Disconzi, A. Saita, P. Colombo, V. Fasulo, R. Peschechera, E. Scapaticci, E. Vuono, R. Hurle, R. Zanca, J. Jandric, L. Muraglia, F. Mrakic, P. Casale, M. Rodari, G. Guazzoni, L. Balzarini, N. Buffi, M. Lazzeri, G. Lughezzani;*
IRCCS - Humanitas Research Hospital, Rozzano MI, ITALY.

Aim/Introduction: Primary trial has proven the added role of [68Ga]PSMA PET/CT compared to mpMRI for the detection of prostate cancer (PCa) in biopsy-naïf patients. Herein, we present the results of our study, designed to compare [68Ga]PSMA PET/CT with mpMRI in men with a high suspicion of PCa after at least one previous negative biopsy. ***Materials and Methods:*** Overall, we enrolled 109 patients complying with the inclusion criteria and derived from two prospective trials. Inclusion criteria were: [68Ga]PSMA PET/CT, mpMRI, target fusion biopsy, PSA>4.0ng/ml, free-to-total PSA ratio <20%, progressive rise of PSA levels in two consecutive samples, at least one previous negative biopsy, negative digital rectal examination. Target lesions were defined based on PI-RADS v2.1 for mpMRI and Primary Score, SUVmax and SUVratio to contralateral prostatic background for [68Ga]PSMA PET/CT, then correlated to pathology findings. ***Results:*** Median age was 65 years (range 50-82), median PSA 10 ng/ml (range 4.3-35), median PHI 46 (range 34-59) and median prostatic volume 73cc (range 17-197). Most patients (83; 65%) had one previous negative biopsy, while the remaining >1. According to re-biopsy results, 21 patients (19%) presented with clinically significant PCa (csPCa), 12 with GS 3+3, while the majority had a negative biopsy (76; 70%). mpMRI results were: 63 patients with PI-RADS 1-2 (58%), 12 with PI-RADS 3 (11%), 26 with PI-RADS 4 (24%), and 8 with PI-RADS 5 (7%). Primary scores were: 90 score 1-3 (83%), and 17 score 3-5. PI-RADS and Primary scores were significantly correlated to each other (p=0.0001), with optimal cut-offs for csPCa set in both cases for scores >3. Median SUVmax and SUVratio were 4 and 1.5, with optimal cut-off values set at 6.12 and 2.4, respectively. Sensitivity and specificity resulted as follows: PI-RADS 71% and 78%, Primary score 65% and 91%, SUVmax cut-off 70% and 87%, SUVratio cut-off 70% and 91%, respectively. All imaging parameters were significantly correlated to csPCa detection on biopsy, with PI-RADS resulting an independent predictor (p=0.0058). When combining [68Ga]PSMA PET/CT with mpMRI, the specificity reached 98% for csPCa, leading to a potential change in patient management in 18% of the cases. ***Conclusion:*** [68Ga]PSMA PET/CT parameters predict biopsy results in patients candidate to re-biopsy, with a complementary role compared to mpMRI; the combination of both modalities can spare most unnecessary re-biopsies, by potentially changing management in 18% of the cases. ***References:*** The study was supported by the Ministry of Health (Ministero della Salute) with the Grant GR-2018-12366240.

EP-0313

Preliminary Pharmacokinetic Results of ^{18}F-PSMA-1007 in Prostatic Oncological Lesions Using the SRTM Compartmental Model

J. Muñoz Romero, *E. A. Marino, G. A. Peña;*
Fundación Escuela Medicina Nuclear, Mendoza, ARGENTINA.

Aim/Introduction: The Simplified Reference Tissue Model (SRTM) offers a promising and less invasive alternative for the study of prostatic oncological lesions with 18F-PSMA-1007, as it does not require arterial input curves, unlike traditionally used models. Although it is not the conventional approach for this type of analysis, the goal is to evaluate the SRTM and analyze the behavior of its pharmacokinetic constants. ***Materials and Methods:*** In a preliminary study, six patients with Ca. Prostate were injected with dose mean of 4.53 mCi of 18F-PSMA-1007. Imaging was performed using PET-CT and PET-MR scanners with dynamic 45-minute protocols. Volumes of interest (VOIs) were delineated in areas of bone metastases, lymph node metastases, local recurrence, and normal prostatic tissue, using gluteal tissue as a reference for the SRTM model. Temporal activity curves were analyzed, and Monte Carlo modeling was applied to reduce noise-related errors, using a compartmental model to derive the pharmacokinetic constants: ligand uptake (R1), specific receptor density (BPnd), ligand clearance rate to plasma (k2), ligand clearance rate to reference tissue (k2'), and undifferentiated ligand clearance rate (k2a). ***Results:*** R1 values were significantly higher in lymph node metastases (average of 3.30) compared to normal

prostatic tissue (average of 1.59). BPnd also showed elevated values in lymph node and bone metastases (averages of 14.16 and 12.83, respectively). In contrast, the k2 constant was lower in bone metastases, with a value (average of 0.3). It was also observed that ligand uptake (R1) was 80.9% higher and the clearance rate (k2) was 38.6% lower in patients with confirmed recurrence compared to those with undifferentiated pathology, indicating greater ligand retention and a significantly higher receptor density (BPnd increased by 156.1%). Additionally, the elimination rates of the ligand from the reference tissue (k2′) and undifferentiated ligand (k2a) decreased by 62.9% and 60.2%, respectively. ***Conclusion:*** According to the SRTM model, lymph node and bone metastases show significantly higher metabolic activity and receptor availability than normal prostatic tissue. Moreover, in patients with confirmed recurrence, there is an observed increased retention of the ligand and a higher receptor density, accompanied by a significant decrease in the ligand elimination rates, which reflects changes in the pharmacokinetic dynamics associated with advanced prostatic pathology.

Strong correlation between intuitive and standardized evaluation of radioiodine therapy whole-body scintigraphy in thyroid cancer

F. Eilsberger[1], *H. Wolfram[1], W. Bowl[1], K. R. Pfestroff[1], J. Taprogge[2], M. Luster[1], A. Pfestroff[1];*
[1]University Hospital Marburg, Marburg, GERMANY, [2]Joint Department of Physics, Royal Marsden NHSFT, Sutton, United Kingdom and Institute of Cancer Research London, United Kingdom, London, UNITED KINGDOM.

Aim/Introduction: In patients with differentiated thyroid carcinoma, whole-body scans (WBS) are usually assessed 48 h after radioiodine administration. Aim of this study is to correlate the intuitive assessability after different time points with a standardized diagnostic algorithm. ***Materials and Methods:*** Data were available from 35 consecutive, prospectively treated (97% exogenous TSH stimulation) patients in whom WBS were acquired at up to 6 time points (6, 24, 48, 72, 98 and 168 h). Blinded reading of WBS was done by to three experienced observers regarding diagnostic quality. After one year of latency, the whole-body scintigraphies were re-evaluated using a standardized Likert scale (Van Nostrand criteria). The qualitative ranking was determined intuitively, the standardized quality was determined using a predefined scale (1 to 5 points) for 10 parameters (max. 50 points). ***Results:*** The intuitive ranking of the three observers was consistent in terms of the best scan after 24 h (average rank 1.76), followed by 48 h (rank 2.27), 6 h (rank 2.77) and 72 h (rank 3.48). Using the standardized evaluation criteria, all observers had the same ranking, only one observer rated 4 and 48 h scans on average as equivalent (31.66 vs. 31.32 points). The standardized score and the intuitively perceived score correlate strongly with each other according to Spearman (rS=-0.69, P<0.001, n=504). The time of admission "24h" achieves a significantly (P<0.001) better score compared to all other scans. The time points 6 and 48h are not significantly different from each other. ***Conclusion:*** There was a high concordance in the intuitive versus standardized assessment of the diagnostic value of the whole-body scans and between the investigators. The diagnostic performance of the scans after 24 h (rank 1; 39.52 points) is comparable to that after 48 h (rank 2; 34.73 points); for radiation protection reasons, a preference for the 48 h scan is advisable.

EP-0315

Diagnostic accuracy of ^{18}F-FDG-PET/CT for incomplete biochemical response with possible refractoriness differentiated thyroid cancer, exploring the same patient with and without thyrotropin stimulation

J. Nogueiras Alonso[1], *V. Pubul Núñez[2], M. Fernandez Cervera Fernandez Herrerin[1], I. Garcia Jover[1], R. Guitian Iglesias[1];*
[1]Hospital do Meixoeiro, Vigo, SPAIN, [2]Santiago Universitary Hospital, Santiago, SPAIN.

Aim/Introduction: Up to 15-20% of differentiated thyroid cancer patients(p) with incomplete biochemical response have negative 131INa(RAI) WBS. Different causes explain it and can lead to iodine refractoriness(R-RAI). With stimulated Tg≤10ng/ml, ^{18}FDG-PET/TC has low sensitivity (<10%-30%), then guidelines recommend ^{18}FFDG-PET/CT with stimulated Tg≥10ng/ml. Our objective is to evaluate ^{18}-FDG-PET-CT localizing disease in R-RAI patients, comparing the results by patients without(NO-rhTSH) and with(YES-rhTSH), valuing profitability of the test. ***Materials and Methods:*** Recruited 74p in a prospective study (2020-2022) with progressive increase in serum Tg levels (suppressed >2ng/ml) and negative131INa-WBS(with TSH>30mIU/L). Sixteen (16/74) patients were explored by ^{18}F-FDG-PET/CT suppressed (NO-rhTSH) and YES-rhTSH, separated by 3-14days. The mean follow-up duration was 22±4 months. No patient belonging to double examination group (NO-rhTSH/YES-rhTSH) was anti-Tg antibodies positive (15p/74p). ***Results:*** Disease was detected in 5p/16p NO-rhTSH ^{18}F-FDG-PET/TC and 15p/16p NO-rhTSH/YES-rhTSH. In YES-rhTSH group PET was positive in 15p/16p and 1p/16p negative, 60 focus were pathologically confirmed, sensitivity:98%(0.93 -1.02 95%CI) and specificity: 50% (0.27-0.73 95%CI), PPV: 82%; NPV: 90%. In NO-rhTSH group, positive PET on 5/16 and negative 11/16, S:33.33%, Sp:100%, PPV:100% and NPV:9.09%. Localization of YES-rhTSH-^{18}F-FDG-PET/CT: 21 cervical lymphadenopathies, 1 thyroid bed, 5 skeletal and 5 lung nodules, showing coincidence the lesions found in 5 positive NO-rhTSH-PETp. Positive-PET in 5 NO-rhTSH had meanSUV:2.65g/ml, and meanSUV:9.25 g/ml in YES-rhTSH. Exploration performed on NO-rhTSH-PET had mean Tg-value:7.6 ng/ml (1.2-23ng/ml). Global cut-off of serum Tg:15ng/ml achieved S:58%; Sp:76%; PPV:75%; NPV:59%, accuracy: 66%, with Tg:20ng/ml: S:52%; Sp:88%; PPV:84%; VPN:59%, accuracy:68%. With significantly greater sensitivity (p<0.05) in YES-rhTSH. ***Conclusion:*** Although a small group was explored without rhTSH, the sensitivity decreased to 33.33%, patients with FN results who were tested without rhTSH, had an average serumTg: 7.6ng/ml, which is relatively low, less than current guidelines. Although the sample size is small and further research is needed, the use of rhTSH may have been crucial in increasing the test's diagnostic yield. Specifically, in patients with low Tg values, the use of rhTSH appears to improve the sensitivity, particularly for those with serum Tg levels below (<10ng/ml), incomplete biochemical response, and possible R-RAI. ***References:*** 1.Qichang W,et al. EP-0316

THE IMPORTANCE OF GA68 DOTA-TATE PET/CT IMAGING IN MEDULLARY THYROID CANCER AND ITS CONTRIBUTION TO THE CLINICAL DECISION

O. Ekmekcioglu[1], *E. Arslan[2], S. Halil[3], H. Ozvar[4], E. Cil Sen[5];*
[1]University of Health Sciences Sisli Etfal Education and Research Hospital, Istanbul, TÜRKIYE, [2]University of Health Sciences, Nuclear Medicine Department, Samatya Education and Research Hospital, Istanbul, TÜRKIYE, [3]University of Health Sciences, Medical Oncology Department, Sisli Etfal Education and Research Hospital, Istanbul, TÜRKIYE, [4]University of Health Sciences, Radiation Oncology Department, Sisli Etfal Education and Research Hospital, Istanbul, TÜRKIYE, [5]University of Health Sciences, Endocrinology Department, Sisli Etfal Education and Research Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: Ga68 DOTA-TATE PET/CT, a somatostatin receptor imaging method in the clinical management of medullary thyroid cancer, a parafollicular cell-derived neuroendocrine tumor, is a proven method for both recurrence metastasis research and radionuclide treatment options that may contribute to the next stage. ***Materials and Methods:*** Images of a total of 32 patients, 18 women and 14 men, with an average age of 57 years (range 22-84) diagnosed with medullary thyroid cancer, were retrospectively examined. After Ga68 DOTA-TATE was administered at an appropriate dose according to weight, PET/CT images of the skull base and mid-thigh were obtained 50-60 minutes later. Pathological lesion areas on CT sections with increased DOTA-TATE activity, which was detected to be different from the physiological activity distribution, were evaluated. The cases were evaluated together with the available clinical and radiological findings. ***Results:*** From the images of the total patients participating in our study, findings of lesions with activity involvement at a level that could be evaluated in favor of local recurrence in 7 patients, lymph node metastasis in 17 patients, skeletal system in 5 patients and visceral metastasis in 5 patients, and pathologically evaluated on CT sections were detected. No pathological activity involvement was detected in the images of eight patients. DOTA-TATE negative lesions evaluated as metastasis were detected in the liver parenchyma in two patients. In addition, lesions that were clinically proven to be pheochromocytoma were observed in 2 other patients. Additional evaluation could not be made in cases with missing data in terms of laboratory findings. ***Conclusion:*** Somatostatin receptor imaging methods provide great benefit in the clinical management of patients with medullary thyroid cancer. While it determines the chance of surgery in cases of local recurrence, areas of activity involvement with distant metastasis are an important step in determining the prognosis. In addition, the physiological high activity involvement in the liver parenchyma and the need to be careful in metastatic lesions were evaluated as important data in terms of our clinical experience. It was also observed that it made an additional contribution to the detection and management of multiple endocrine neoplasia cases.

EP-0317

Imaging after ^{131}I treatment combined with preoperative CECT to assess imaging features and implications of massive remnants after total thyroidectomy for DTC

Y. Sun[1,2], *X. Sun[1], Z. Lu[2], X. Wang[1], P. Li[1], C. Bian[1];*
[1]Department of Nuclear Medicine, Shandong Cancer Hospital and Institute, Shandong First Medical University and Shandong Academy of Medical Sciences, Jinan, CHINA, [2]Department of Graduate, Shandong First Medical University, Jinan, CHINA.

Aim/Introduction: Using 131I-NaI Rx-SPECT/CT as the gold standard, to clarify the relationship between the extent of remnants after total thyroidectomy for DTC and 131I treatment outcome, and to investigate the preoperative CECT imaging characteristics of massive residual sites. ***Materials and Methods:*** Retrospective collection of patients with intermediate or high risks DTC who were postoperatively treated with 131I and underwent preoperative CECT at our institution from 2023.1.30 to 2023.9.30. Patients with significant photon scattering in the neck were defined as the massive residual group based on Rx-WBS. The chi-square test was used to evaluate the difference in initial efficacy response between the two groups of massive and trace residues. To assess the presence and extent of remnants on either side of the thyroid cartilage (region I), cricoid cattilage (region II), tracheal cartilage (region III) and adjacent to the anterior median line (region IV) using 131I-NaI Rx-SPECT/CT. Then analyzing the imaging characteristics of massive residual sites on preoperative CECT and their impact on assessing 131I uptake in adjacent lymph nodes. ***Results:*** A total of 82 DTC patients were enrolled. The mean 131I dose administered was 119.8 ± 26.3 mCi. 131I-NaI Rx-SPECT/CT showed that the good sites for residues were in the order of regions IV, III, I and II. Regions II (71%) and IV (43%) were prone to massive remnants, the former corresponding to preoperative CECT with parathyroid or supraglottic/recurrent laryngeal nerve > pyramidal lobe > capsule, the latter to pyramidal lobe > thyroglossal duct remnants. 33 (40%) patients had massive thyroid reside, and the initial efficacy response assessment after 131I treatment was not statistically different with trace residual group. 53% of massive remnants interfered with 131I uptake assessment in adjacent lymph nodes, of which 21% were pyramidal lobe or thyroglossal duct remnants, and 71% were in parathyroid or nerve regions. ***Conclusion:*** Massive remnants tend to occur on either side of the cricoid cartilage or in the anterior median line after total thyroidectomy for DTC, and preoperative CECT may suggest pyramidal lobe or thyroglossal duct remnants that are easily missed during surgery.

EP-0318

^{99m}Tc scintigraphy predicts a successful of thyroïd remnant radioiodine ablation in patients with differentiated thyroid carcinoma

T. Zehnati[1], *M. Benrabah[1], A. Bouzidi[2], A. Lakehal[2], T. Ouyed[3], R. Hamlat[1], L. Redhouane[4];*
[1]University Hospital of Oran, Oran, ALGERIA, [2]University Hospital of Constantine, Constantine, ALGERIA, [3]Cancer Center of Tizi Ouzou, Tizi Ouzou, ALGERIA, [4]university hospital of Oran, Oran, ALGERIA.

Aim/Introduction: 99mTc scintigraphy indicates absence or small volume of thyroid remnant. The aime of this study is to evaluate the diagnostic value of post surgical 99mTc scintigraphy to predict radioiodine ablation success of thyroid remnant in patients with thyroid carcinoma. ***Materials and Methods:*** Prospective study including patients with differentiated thyroid carcinoma at low or

intermediate risk of recurrence and eligible for radioiodine therapy with 1,1 GBq of iodine 131. 99mTc scan with determination of cervical uptake and stimulating thyroglobulin level (sTg) were performed before treatment. The ablation success was evaluated nine months later by cervical ultrasound and sTg. In the absence of visualisation of thyroid remnant, the software attributes an uptake value of 0,01% and the scan was considered negative. ***Results:*** Ninety-six patients were included and evaluated, 95% were females and the average age was 47,78 years. The mean uptake rate was 0,07% (ranging from 0,01% to 0,48%). The 99mTc scan was positive in 63%. The uptake rate was strongly correlated with the sTg before ablation, therefore with the remnant volume (r= 0,943 , p<0,001). We found also a significant and negative correlation between the uptake rate and the ablation success rate (r = - 0,258 , p=0,01%). The uptake threshold which predict ablation success was 0,065%. Giovanella et al found that a visually negative 99mTc scintigraphy confers a strong prediction value for ablation success (p=0,008). A visually positive scan with uptake rate less than 0,09% also predict ablation success (p=0,01). ***Conclusion:*** 99mTc scintigraphy is aa simple and reliable method allowing thyroid remnant evaluation. Post surgical scintigraphy is more effective to predict ablation success. Visually negative scan as well as positive scan with uptake rate less than 0,065% correctly predict the successful of thyroid remnant ablation with low activities of iodine 131 in patients with differentiated thyroid carcinoma at low or intermediate risk of recurrence. ***References:*** Giovanella L, Usuriano S, Ricci R, Cerini L, Verburg F.A. EP-0319

131I-SPECT/CT may provide prognostic information regarding the time to complete response and progression-free survival in patients with differentiated thyroid cancer and known lymph node metastases

M. Heinrich[1], *E. Blickle[1], P. E. Hartrampf[1], A. Kosmala[1], A. Kerscher[2], A. K. Buck[1], K. Michalski[1];*
[1]Department of Nuclear Medicine, University Hospital Wuerzburg, Wuerzburg, GERMANY, [2]Comprehensive Cancer Center Mainfranken, University Hospital Wuerzburg, Wuerzburg, GERMANY.

Aim/Introduction: To investigate whether the detection of persistent lymph node metastases (LNM) on cervical posttherapeutic 131I-SPECT/CT in patients with differentiated thyroid cancer (DTC) has a prognostic impact on time until complete response (CR) and progression-free survival (PFS). ***Materials and Methods:*** This retrospective, monocentric study included 194 patients with DTC and histological proven LNM who underwent adjuvant radioiodine (RAI) therapy. On posttherapeutic cervical 131I-SPECT/CT, four groups were defined: CT0/S0 (anatomical normal LN and no visual 131I-uptake), CT0/S1 (anatomical normal LN and increased 131I-uptake), CT1/S0 (enlarged LN (≥1cm in short axis diameter) without 131I-uptake), and CT1/S1 (enlarged LN with increased 131I-uptake). The chance of achieving CR in the different groups was analyzed at 9, 18 and 36 months after RAI therapy using the exact Fischer test. PFS was evaluated using Kaplan-Meier curves and log-rank comparisons. CR was defined as undetectable TSH-stimulated thyroglobulin (Tg) and the absence of clinical and ultrasonographic evidence of residual disease, alongside with the absence of 131I-uptake on a diagnostic whole-body scan during TSH-stimulation. Progression was defined as either a 2-fold increase in Tg levels in the period before CR or any new Tg rise following CR, as well as the identification of new lesions on diagnostic imaging or fine needle aspiration. ***Results:*** Patients classified CT0/S0 (n=140) showed a significant higher chance to reach CR 9 months after ablative RAI therapy (chance 2.16, 95% CI 1.24 - 3.97; p<0.01) than patients with persistent LNM (CT0/S1, CT1/S0 and CT1/S1, n=60). No significant differences were observed at either 18 months (p=0.42) or 36 months (p=0.19). A comparison between CT0/S0 (n=140) and CT0/S1 (n=31) revealed no significant difference at 9 months (chance 1.38, 95% CI: 0.82 - 2.56; p=0.31). A significant reduction in the risk of disease progression was observed in patients classified CT0/S0 compared to patients classified CT1/S1 (median PFS not reached in both groups; HR 0.27, 95% CI 0.06 - 1.16, p=0.0027). No significant difference in PFS was observed between patients classified CT0/S0 and patients classified CT0/S1 (median PFS not reached in both groups; HR 2.2, 95% CI 0.73-6.651, p=0.2743). ***Conclusion:*** In patients with DTC and histological proven LNM, the detection of small but RAI-positive LNM on posttherapeutic 131I-SPECT/CT does not provide prognostic information regarding an early complete response or a longer PFS. In contrast, patients with posttherapeutic enlarged RAI-positive LNM are at a higher risk for disease progression.

EP-0320

Predictive value of quantitative indexes of FDG PET in the evaluation of thyroid nodules

H. Kim, *Y. Kim, S. Kim;*
Korea University Anam Hospital, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: With increasing use of 18F-fluorodeoxyglucose positron emission tomography (FDG PET) in the clinical field, thyroid nodules are one of the common incidental findings. It is reported that about one third of these nodules are proven to be malignant nodule. In this study, efficacy of quantitative PET indexes in predicting the cytopathology of thyroid nodules was evaluated. ***Materials and Methods:*** A total of 338 patients with thyroid nodules detected on FDG PET from 2019 to 2024 were retrospectively enrolled. The nodules were further examined with fine needle aspiration (FNA). Quantitative PET indexes such as maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), total lesion glycolysis (TLG), were measured in the thyroid nodule. Their efficacies in predicting the cytopathologic nature of the nodule by FNA were evaluated along with other clinical variables such as age, gender, size, thyroid function test values. ***Results:*** SUVmax and TLG of thyroid nodule were statistically significant in predicting cytopathology based on Bethesda scoring system (p value of 0.001 and 0.005, respectively). SUVmax and TLG tended to increase as the category escalated, with highest value in the malignant category (Bethesda VI). SUVmax was able to discriminate the group with higher risk of malignancy (Bethesda IV, V, VI) from lower risk group (Bethesda II, III) with optimal cutoff value set as 4.8 (sensitivity 70.5, specificity 64.2, AUC 0.718). Other variables were not statistically significant in predicting malignant groups. ***Conclusion:*** Quantitative indexes of FDG PET are well associated with Bethesda scoring system in thyroid nodules. Measuring SUVmax of thyroid nodule on FDG

PET can aid in predicting the cytopathology and thus guiding the optimal treatment for the patient.

EP-0321

Clinical importance of thyroid involvement in ^{18}F-FDG PET/CT imaging: correlation with USG and pathology

M. Kaya, *S. Karaçavuş, F. Demir;*
Kayseri City Hospital, Kayseri, TÜRKIYE.

Aim/Introduction: This study aimed to reveal the importance of focal or diffuse increased FDG uptake seen in the thyroid gland in patients who underwent FDG PET/CT imaging for any reason, by correlating it with ultrasonography imaging and pathological results, and to determine a cut-off value for the SUVmax value in malignant lesions. ***Materials and Methods:*** 900 patients who underwent F^{18} FDG PET/CT imaging at Kayseri City Hospital Nuclear Medicine clinic between June 2018 and February 2023 and were found to have focal or diffuse increased FDG uptake in the thyroid gland were included in the study. F^{18} FDG PET/CT studies, USG reports and histopathological results of the patients were evaluated retrospectively. ***Results:*** Focal increased FDG uptake was detected in 731 (81.2%) of 900 patients, and diffusely increased FDG uptake was detected in 169 (18.8%). The number of patients who underwent histopathological examination was 86, and all of these patients had focal FDG uptake. In lesions showing FDG uptake in the thyroid gland, the SUVmax value was between 1.0 and 48.4, and the average value was found to be 5.2 ± 4.6. Malignant lesions were included in the n1 group, and benign lesions were included in the n2 group. The difference in SUVmax between the two groups was evaluated with the Mann Whitney U test, and the SUVmax value of the malignant lesions was found to be statistically higher (n1: 13; n2: 24; p: 0.001, p<0). .05). ROC analysis was performed to determine the cut-off value for SUVmax and the cut-off value was determined as 6.1 . The specificity of this value was calculated as 71.4% and the sensitivity was calculated as 66.7% . Of the 207 patients who underwent USG, 37 patients had diffuse FDG uptake and 170 patients had nodular FDG uptake. Groupings were made taking into account the echogenicity and nodule internal structure defined for the nodules on USG. The difference between the groups in terms of benign/malignant cytopathology was evaluated with the Pearson Chi-square test and no statistically significant difference was found (p=0.277; p>0.05). ***Conclusion:*** Although it has been statistically demonstrated that the SUVmax value is higher in malignant lesions in the evaluation of incidental thyroid lesions detected on PET imaging, there is no common opinion for the cut-off value. It was concluded that more multicenter and well-designed studies are needed to obtain a cut-off value with higher sensitivity and specificity values.

EP-0322

F^{18} FDG PET/CT Results Before I-131 Ablation Treatment in Patients with Post-Operated Thyroid Cancer with Lymph Node or Suspicious Distant Metastasis

H. Isci, *F. Demir;*
Kayseri Şehir Hastanesi, Kayseri, TÜRKIYE.

Aim/Introduction: Thyroid cancers are the most common endocrine cancers. Radioactive iodine (RAI) treatment can be given after surgery. Residual disease extent, the presence of local or distant metastases are some of the factors determining RAI dosage. Our aim in this study is to present the F^{18} PET/CT results we performed before RAI ablation treatment and their relationships with other parameters. ***Materials and Methods:*** Patients with post-operative thyroid cancer with and underwent F^{18} FDG PET/CT between 2018 and 2023 were included in our study. The patients' demographic data, pathology reports, postoperative PET/CT images and post-ablative whole body iodine scan (TVT) image evaluations were analyzed in the SPSS program. Chi-Square and Fisher's exact test were used for categorical data, and Student T test and Mann Withney U test were used for numerical data. ***Results:*** Of the 106 patients included in the study, 72 (67.9%) were women and 34 (32.1%) were men. While 47 (44.3%) of the patients had no lymph node metastasis, 59 had metastatic lymph nodes. Post-operative PET/CT imaging results of the patients are summarized in Table 1. In the post-ablative screening of 75 patients, 29 (38.7%) had metastatic lymph nodes, while 46 (61.3%) did not. The relationship between other parameters in patients with/without distant metastasis detected on PET/CT is summarized in Table 2. There was no significant difference between the patient groups with and without distant metastasis detected on PET/CT in terms of gender, tumor location, and presence of metastatic lymph nodes in post-op pathology (p=0.280;0.411;0.676). In the patient group with distant metastasis detected on PET/CT; Age, tumor size, and Tg values were significantly higher than the undetected patient group (p<0.001;0.021;0.003). As expected in the post-ablative TVT results, the number of patients with metastasis was significantly higher in the patient group with metastasis detected on PET/CT (p<0.001). ***Conclusion:*** The results show that FDG PET/CT provides meaningful information in the determination of distant metastasis in patients with suspected metastasis, especially with unexplained high Tg levels. However, the information it provides in terms of lymph node metastasis is more limited, and pathological confirmation may be preferred, keeping in mind that there may be false positivity. ***References:***

Role of ^{18}F-FDG PET/CT in differentiated thyroid carcinoma

D. Craciun[1], *M. Alexa[1], C. Mazilu[1], A. Mazilu[2], M. Oancea[1], A. Goldstein[3], G. Voicu[3], D. Neagu[3], I. Chiriac[3], R. Mititelu[1,4];*
[1]Clinic of Nuclear Medicine, Central Universitary Emergency Military Hospital Bucharest, Bucharest, ROMANIA, [2]Clinic of Endocrinology, Central Universitary Emergency Military Hospital Bucharest, Bucharest, ROMANIA, [3]Institute of Endocrinology CI Parhon, Bucharest, ROMANIA, [4]Department of Nuclear Medicine, University of Medicine and Pharmacy Carol Davila Bucharest, Bucharest, ROMANIA.

Aim/Introduction: Treatment with iodine-131 (I-131) is a well documented and efficient therapy in differentiated thyroid carcinoma. Following surgery and radioiodine therapy, residual disease can persist in certain patients. This study focuses on patients with negative I-131 post-therapy "whole body" scintigraphy (WBS) and clinical or biochemical persistence of the disease. In these patients ^{18}F-fluorodeoxyglucose ($^{[18F]}$FDG) PET-CT can be a useful tool for the purpose of identifying local recurrences and distal metastases. ***Materials and Methods:*** We performed a retrospective analysis of 29 consecutive patients that underwent $^{[18F]}$FDG PET-CT scan with an established diagnosis of differentiated thyroid carcinoma. All

patients performed [18F]FDG PET-CT after surgery and at least one cycle of I-131 therapy and all patients had clinical or biochemical persistence of the disease: palpable enlarged lymph node and/or high level of thyroglobuline (Tg) or anti-thyroglobulin antibodies (ATG). Images were evaluated visually and semi-quantitatively using the maximum value of the radiotracer uptake, corrected for body mass without adipose tissue and injected activity (SULmax). ***Results:*** Of the 29 patients, 23 were women and 6 were men, with a median age of 60 years; the average dose of I-131 previously administered to the patients was 340 mCi. The histopathological types were 83% papillary thyroid carcinoma (n=24) and 17% follicular thyroid carcinoma (n=5). [18F]FDG PET-CT detected glucose avid lesions suggestive of local disease recurrence and/or lymph node metastases or other organs metastases in 69% of cases (n=20): 15 lymph node metastases and/or local recurrences, 5 pulmonary metastases and 2 bone metastases. In some cases, patients with elevated SULmax values also exhibited higher levels of thyroglobulin, exceeding the reference range by more than double. This observation is consistent with findings from other studies, although this correlation lacks specificity [1]. ***Conclusion:*** The findings of this study align with the literature, showing the value of PET-CT with [18F]FDG in monitoring patients with recurrent thyroid carcinoma with clinical or biochemical markers indicative of recurrence and negative scintigraphy with I-131. ***References:*** Larg M. 18F-FDG PET/CT in Differentiated Thyroid Carcinoma. Acta Endocrinologica (Bucharest). 2019;15(2):203-8.

EP-0324

Effectiveness of 131I iodine under rhTSH stimulation in treatment of advanced, non-operable thyroid cancer

A. Ledwon, *E. Paliczka - Cieślik, A. Kropińska, A. Blewąska, T. Olczyk, A. Kluczewska-Gałka, D. Handkiewicz-Junak; M. Sklodowska-Curie National Research Institute of Oncology, Gliwice branch, Gliwice, POLAND.*

Aim/Introduction: Differentiated thyroid cancer (DTC) is the most common malignancy of the endocrine glands. Treatment with radioactive iodine (131I) for advanced thyroid cancer is a therapy that significantly improves time to progression and overall survival. The prerequisite for 131I treatment is adequate stimulation with endogenous TSH. However, data on treatment with exogenous stimulation (rhTSH; Thyrogen) are scarce and rhTSH stimulation is not wieldy used in this settings. Retrospective evaluation of rhTSH stimulated 131I treatment of metastatic DTC in patients with at least 5 years of follow-up from last 131I treatment. ***Materials and Methods:*** The analysis includes 189 patients treated with 131I after total thyroidectomy in the rhTSH-stimulated setting between 2008 and 2011. In 81 (42%) (rhTSH group) all cycles of 131I treatment were after rhTSH stimulation (rhTSH-group, in remaining 108 at least one therapy was after TSH withdrawal (mix-group). Patients in mixt were younger, had longer follow-up and had less macrometastases that in the rhTSH-group. The majority (64%) of the treated patients were women, with a median age of 58 (41-86) years. Patients were treated with 3.7-5.5 MBq 131I activity every 3-6 months. Follicular thyroid cancer was diagnosed in 61 (32%) patients, while papillary carcinoma was diagnosed in 99 (52%), and low-differentiated carcinoma in 29 (15%). All patients had distant metastases, including 94 (50%) to the lungs, 35 (19%) to the bones, the remaining patients had at least two locations of metastatic lesions. Radiological evaluation of response to treatment was performed every 6-12 months (RECIST 1.1 criteria). All patients received adequate TSH stimulation before 131I administration. This is the preliminary analysis of radiological response and progression ***Results:*** Complete or partial remission was found in 77 (41%) and stable disease in 93 (49%) patients. During follow-up, radiological progression of disease occurred in 96 (51%) patients. The median time to progression was 29 (16-50), months and the median time to death was 52 (33-78). In multivariate analysis only type of metastases (micro vs. macro) and best radiological response and has significant impact on progression free survival. Treatment with 131I during rhTSH stimulation was well tolerated, and none of the patients showed signs of hyperthyroidism. ***Conclusion:*** Compared with a historical group of patients with advanced RHT, rhTSH stimulation appears to be as effective as endogenous TSH stimulation in preparation for 131I treatment and is well tolerated.

EP-0325

The value of functional [18F]F-DOPA PET/CT parameters in patients with medullary thyroid cancer

S. Li, *Z. Zhang, J. Yu, P. Riss, M. Hacker; Medical University of Vienna, Vienna, AUSTRIA.*

Aim/Introduction: The purpose of this study was to evaluate the diagnostic and prognostic value of functional [18F]F-DOPA PET/CT parameters in patients with medullary thyroid cancer (MTC). ***Materials and Methods:*** MTC patients who underwent [18F]F-DOPA PET/CT from June 2008 to November 2023 were investigated. Clinical characteristics, follow-up data, and the following [18F]F-DOPA PET/CT parameters were recorded: maximum standardized uptake value (SUVmax), mean standardized uptake value (SUVmean), metabolic tumour volume (MTV), and SUVmean of multi-organs. Receiver operating characteristic (ROC), Kaplan-Meier and Cox regression analyses were performed. ***Results:*** 109 patients (50 women, 59 men; average age, 55 ± 14 y) were included in the analysis. Significant positive correlations were found between basal calcitonin (bCt), stimulated calcitonin (sCt) and CEA with SUVmax, SUVmean and MTV of [18F]F-DOPA PET/CT ($P<0.001$). [18F]F-DOPA PET/CT results and MTV may be useful for evaluation of prognosis of patients with recurrent MTC, while MTV and age were independent prognostic factors in patients with primary MTC. For all patients, SUVmean of the left kidney, liver, aorta, and pancreas might be used to independently predict overall survival (OS). ***Conclusion:*** Functional [18F]F-DOPA PET/CT parameters may be important for diagnostic and prognostic assessment in patients with MTC. The DOPA PET/CT parameter SUVmean and MTV showed significant association to OS.

EP-0326

MIBI SPECT is a powerful tool to exclude malignancy in hypofuntioning thyroid nodules - long-term study > 1500 patients

M. Baehr[1,2], *K. Liepe[1]; [1]Department of Nuclear Medicine, General Hospital Frankfurt (Oder), Frankfurt (Oder), GERMANY, [2]Department of Radiology, Neuroradiology and Nuclear Medicine, Johannes Wesling University Hospital, Ruhr University Bochum, Minden, GERMANY.*

Aim/Introduction: The value of thyroid SPECT using 99mTc-sestamibi (MIBI) in risk assessment of hypofunctioning thyroid nodules is discussed controversially. In current guidelines it is not integrated in routine assessment. We propose that MIBI SPECT is a powerful tool to non-invasively exclude malignancy. ***Materials and Methods:*** In a single center study, 1527 patients with hypofunctioning thyroid nodules were examined within 9 years and 4 months using 398 MBq ± 42 MBq MIBI by local scintigraphy 10 min and 120 min p.i. and SPECT 130 min p.i. Fine-needle biopsy

was performed in high-risk nodules (EU-TIRADS 5), in patients with symptomatic nodules and in asymptomatic patients with MIBI SPECT positive nodules. Long-term follow-up ranged from 12 to 112 months with a mean of 35.4 months. ***Results:*** MIBI SPECT was positive in 107 cases. In 13 % of these patients, the suspected nodule was MIBI negative but another small nodule, an isthmus nodule or a primarily inconspicuous part of a multinodous goiter was MIBI positive. Surgery was performed in 125 patients with negative MIBI SPCET because of severe local symptoms or high-volume multinodous goiter. Retrospectively histological diagnosis was concordant with positive MIBI SPECT and FNP in 67 % of cases, whereas in 32 % MIBI was superior and in 3 % FNB was superior.In long-term follow up MIBI negative patients revealed malignancy in 0,6 %. Histological diagnosis were papillary microcarcinoma or medullary carcinoma with low Ki-67 < 5%. %. Statistical analysis for MIBI SPECT showed an overall sensitivity of 73%, specificity of 95%, negative-predictive value of 99% and positive predictive value of 24%. MIBI SPECTs were positive benign neoplasia like hürthle cell adenoma, follicular adenoma and parathyroid adenoma. In follicular adenoma and hürthle cell adenoma, invasive growth only can be excluded by surgery. Parathyroid adenoma require surgery, too. Assessing these patients as true-positive, the adapted predictive values were 80%, 98%, 76% and 99%. ***Conclusion:*** MIBI SPECT is a powerful tool in the assessment of hypofunctioning thyroid nodlues with low to intermediate risk of malignancy. Given a negative predictive value of 99% after up to 112 months of follow-up, MIBI SPECT has proven an excellent non-invasive screening tool. Surgical resection of only MIBI positive and FNB positive hypofunctioning nodules may reduce the frequency of thyroidectomies significantly.

EP-0327

Comparison of the diagnostic performance of [18F] F-DOPA PET/CT and [18F]F-choline PET/CT in patients with recurrent medullary thyroid cancer

L. Lezaic*[1]*, *E. Macek Lezaic*[2]*, S. Rep*[1]*, K. Zaletel*[1]*, M. Hocevar*[3]*, J. Jamsek*[1]*;*
[1]University Medical Centre Ljubljana, Department for Nuclear Medicine, Ljubljana, SLOVENIA, [2]Rozna Dolina, C. VI/8, Ljubljana, SLOVENIA, [3]Department of Surgical Oncology, Institute of Oncology Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: Curative approach for medullary thyroid cancer (MTC) is surgery involving central and optionally lateral cervical compartment(s). Recurrence after initial surgery is common, typically detected biochemically by increase in calcitonin as a tumour marker, as is progressive disease. Molecular imaging using [18F]F-DOPA PET/CT improves detection of recurrent/progressive disease over conventional imaging (CT, US), but its availability is limited. The use of [18F]F-choline PET/CT was recently introduced for molecular imaging of MTC. The aim of the work was to compare the diagnostic performance of [18F]F-DOPA PET/CT and [18F]F-choline PET/CT in patients with recurrent/progressive MTC. ***Materials and Methods:*** Medical records of patients with MTC recurrence were retrospectively reviewed and patients with both imaging modalities performed were identified; time interval between both studies was noted. PET/CT imaging with both modalities was compared for the number, distribution and visual impression of detected lesions; [18F]F-DOPA PET/CT was used as a reference imaging method. Clinical data (calcitonin, CEA, genetic status) was noted at [18F]F-choline PET/CT and correlated with imaging findings. ***Results:*** Seven patients (two male) with both imaging modalities performed were found. The average time interval between imaging studies was 35 (1-72) months. Average calcitonin level was 1404 (33-8739) ng/L and CEA level 23 (4-120) ug/L; two patients had MEN2. The number of detected lesions ranged from 0 to 15 for [18F]F-DOPA and 0 to 7 for [18F]F-choline PET/CT. In patient-based comparison, the number of detected lesions was comparable between both tracers, with overall higher lesion-to-background ratio favouring [18F]F-DOPA; in one patient with multiple liver metastases, a significantly higher number of lesions was detected with [18F]F-DOPA (15 vs 3) due to the high physiological uptake of [18F]F-choline PET/CT. Higher number of lesions were found on [18F]F-choline PET/CT in 3 patients (additional head/neck lymph node). ***Conclusion:*** [18F]F-choline appears to offer comparable diagnostic performance to [18F]F-DOPA in patients with MTC recurrence/progression with the exception of liver lesions due to the high physiological uptake of [18F]F-choline in the parenchyma. Direct comparison of the tracers and further validation of the method is warranted.

EP-0328

Accuracy of ^{18}F DOPA PET-CT in the assessment of medullary thyroid cancer recurrence

M. Santisteban*[1,2]*, *M. Cortés Romera*[1]*, J. Vercher Conejero*[1]*, B. Hervás Sanz*[1]*, J. Diaz Moreno*[1]*, M. Zamorano*[1]*;*
[1]Hospital Universitari Bellvitge, L'Hospitalet (Barcelona), SPAIN, [2]Hospital Universitario Puerta del Mar, Cadiz, SPAIN.

Aim/Introduction: PET/CT with ^{18}F-DOPA is considered first-line in the diagnosis of midgut G1-NET. It is also indicated in medullary thyroid cancer (MTC) with suspected cervical relapse with calcitonin levels >150 pg/mL and/or doubling time of less than two years. Although false positives have been described, its ratio is lower than other radiopharmaceuticals such as ^{18}F-FDG.AIMTo evaluate the diagnostic performance of ^{18}F-dihydroxyphenylalanine (FDOPA) positron emission tomography/computed tomography (PET/CT) in the detection of suspicious clinical recurrence in patients already diagnosed with medullary thyroid carcinoma (MTC). ***Materials and Methods:*** The patients who had undergone ^{18}F-FDOPA PET/CT imaging for increasing/elevated calcitonin levels after primary surgery of MTC were included in the study. All the patients have at least one follow-up ^{18}F-FDOPA PET/CT, and the results were compared with histopathological findings and/or follow-up in a retrospective study. The sensitivity and diagnostic performance of ^{18}F-DOPA PET/CT were analyzed.Calcitonin levels were registered, and other nuclear medicine imaging techniques are included. ***Results:*** A total of 17 patients (8F and 9M) were included in the analysis. 3 patients had MEN IIA syndrome, 3 had RET + mutation and 11 patients had a diagnosis of sporadic MTC. Median calcitonin levels of the patients were calculated as 1913.19 (min-max: 22-10476) pg/mL. ^{18}F-FDOPA PET/CT was positive in 11 out of 17 patients. All patients had a calcitonin level higher than 150 pg/ml but one. Five underwent surgery that confirmed the positivity. Four were clinically followed up and 2 received medical treatment (Vandetanib.) In 6 cases ^{18}F-FDOPA PET/CT was negative (calcitonin levels were between 22-978 pg/ml, and only in 2 cases those levels were higher than 150 pg/ml). All of them were clinically followed upThe sensitivity of ^{18}F-FDOPA PET/CT in the detection of recurrent disease was calculated as 76%, due to 13 of 17 accurate results, yet positive or negative. ***Conclusion:*** The ^{18}F-FDOPA PET/CT prove the accuracy of the results in three quarters of the patients who were tested. In addition, the superior availability of ^{18}F-FDOPA PET/CT results in a suitable candidate to role out a suspicious clinical recurrence.

EP-0329

A novel nanocarrier system for precise delivery of ^{68}Ga to tumors

P. Zou, *H. Wu, Y. Liu, H. Wang, J. Wu;*
NHC Key Laboratory of Nuclear Medicine, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Aim/Introduction: The construction of PET nanoprobes by labeling positron nuclides on the surface of nanocarriers is a common strategy to enhance the internalization and retention of positron nuclides in tumors. However, traditional nanocarriers are limited by their lack of active targeting, low tumor penetration, poor biocompatibility, and reproducibility. Therefore, there is a critical need to develop nanocarrier systems that are both efficient and safe for the precise delivery of positron nuclides to tumors. This study describes a novel enzyme- instructed self-assembled nanofiber drug delivery system and evaluates its application in delivering 68Ga to tumors, aiming to facilitate the clinical translation of PET nanoprobes. ***Materials and Methods:*** The probe precursor NAYp-DOTA was synthesized in a one step by solid-phase peptide synthesis. The self-assembly performance of the probe was evaluated using alkaline phosphatase, and the microstructure of the self-assembled product was analyzed using transmission electron microscopy, as well as its rheological properties were evaluated using a rotational rheometer. In the micro-PET imaging experiments, HeLa tumor-bearing nude mice were divided into two groups: the experimental group, which received [68Ga]NAYp-DOTA intravenously, and the blocking group, which was pretreated with an L-phenylalanine inhibitor before injection. Finally, the toxicity of the probe in cells and tissues was evaluated using CCK-8 assays and hematoxylin-eosin staining. ***Results:*** Under the catalysis of ALP, the probe was rapidly digested and self-assembled into nanofibers with an average diameter of 24.33 ± 2.81 nm. Micro-PET imaging results revealed that the signals in the experimental group were clearly visible and gradually increased from 3.54 ± 0.41 %ID/g at 0.5 h to 4.72 ± 0.27 %ID/g at 3 h. In contrast, the signal in the blockade group remained below 0.72 %ID/g throughout the process. Cytotoxicity testing demonstrated that HeLa cell viability remained above 98% after 24 h of incubation with samples at a concentration of 500 μM. Additionally, hematoxylin-eosin staining indicated that the morphology of major organs (heart, liver, spleen, lungs, and kidneys) and tumor tissues remained normal and unaffected by the probe. ***Conclusion:*** In this study, we developed an enzyme-instructed self-assembled nanofiber drug delivery system that achieved rapid delivery of 68Ga to tumors. Through its unique in situ self-assembly mechanism, the retention of 68Ga was significantly prolonged, resulting in a sustained elevation of tumor signals. Meanwhile, this system demonstrated good adaptability and low toxicity to the biological environment, providing an important guarantee for long-term application and clinical translation.

EP-0330

PET imaging of [^{68}Ga]PATTYp: a novel peptide probe targeting tumor-associated enzymes

W. Hongyong, *H. Wu, Y. Liu, J. Wu, P. Zou;*
NHC Key Laboratory of Nuclear Medicine, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Aim/Introduction: A novel PET probe [68Ga]PATTYp targeting tumor-associated enzymes was designed based on an enzymatic peptide self-assembly strategy. After verifying the stability and safety of the probe, the PET imaging of the probe in HeLa tumor-bearing nude mice was systematically studied. ***Materials and Methods:*** The PET probe was injected into the blood through the tail vein, and after reaching the tumor site, it was dephosphorylated by alkaline phosphatase secreted by tumor cells to form hydrophobic peptides. These hydrophobic peptides could self-assemble into nanofibers through non-covalent forces such as hydrogen bonding. Naturally, the probe molecules were enriched at the tumor for enhanced PET imaging. The probe precursor PATTYp was first synthesized using solid-phase peptide synthesis. MTT assay was employed to evaluate the cytotoxicity of the probe on Hela cells. After fully analyzing the in vitro properties of the probe, the probe was injected into the tail vein of HeLa tumor-bearing nude mice, and micro-PET imaging was performed for 10 min at 1 and 2 h after injection, respectively. The tumor and muscle in micro-PET imaging were delineated for five consecutive layers, and the tumor uptake and in vivo distribution performance of the probe were studied by calculating the percentage injection dose rate (%ID/g) per gram of tissue. ***Results:*** Radioactive HPLC of 68Ga labeled reaction solution showed that the radiochemical purity of the probe more than 98%, which meets the requirements of subsequent in vivo experiments without purification. The stability test results show that the radiochemical purity of the probes is unchanged within 3 h. MTT assay indicated that the cell survival rate was 98 % at the concentration of 500 μM probe precursor. The tumor is clearly visible in micro-PET imaging. The tumor uptake values at 1 h and 2 h were 2.32 ± 0.31 %ID/g and 3.45 ± 0.23 %ID/g, respectively. ***Conclusion:*** The probe precursor has the advantages of simple preparation process, mild reaction conditions, and low raw material cost. The probe has good stability and safety performance, meeting the requirements of animal experiments. Micro-PET imaging results showed that the probe imaged well in HeLa tumor-bearing nude mice after 2 h with a high tumor/muscle ratio. The use of different enzyme-targeting molecules to replace the phosphate group in the probe holds promise for the development of a variety of tumor-specific PET probes.

EP-0331

A preliminary report: [^{68}Ga]Ga-Prostate-specific membrane antigen PET/CT in endometrial cancer.

K. Pelka[1,2], *J. Kunikowska[1], M. Bizoń[3], M. Olszewski[3];*
[1]Nuclear Medicine Department, Medical University of Warsaw, Warsaw, POLAND, [2]Laboratory of Center for Preclinical Research, Department of Methodology, Medical University of Warsaw, Warsaw, POLAND, [3]LUXMED Oncology Hospital, Warsaw, POLAND.

Aim/Introduction: Endometrial cancer is the most common cancer of the female reproductive system. Prostate-specific membrane antigen (PSMA) is expressed in prostate cancer cells but can be found in other cancers, including endometrial cancer, during angiogenesis. The aim of this pilot study was to

evaluate the feasibility of using [68Ga]Ga-PSMA-11 PET/CT in endometrial cancer patients before surgical treatment. ***Materials and Methods:*** We have included in the study seven women with a mean age of 58±7.9 years. All patients underwent standard imaging studies involving transvaginal ultrasound, ceCT scans of the chest, abdomen and pelvis, and magnetic resonance imaging (MRI) as qualified for surgery. Additionally, PET/CT was performed on a Siemens Biograph scanner 60 min after the injection of 2 MBq/kg [68Ga]Ga-PSMA-11. ***Results:*** Positive [68Ga]Ga-PSMA-11 PET/CT images had six of seven patients, and histopathology confirmed endometrial cancer. One patient also exhibited uptake in the left ovary, and final histopathology revealed a hemorrhagic cyst. One patient with lymph node involvement was also visible in [68Ga]Ga-PSMA-11 after fusion with ceCT. The consensus of histopathological staging of endometrial cancer and ceCT, MRI and [68Ga]Ga-PSMA-11 PET/CT was 4/7, 6/7, and 5/7, respectively. All methods were consistent in terms of staging in 3/7 patients. ***Conclusion:*** The initial experience showed the possibility of using [68Ga]Ga-PSMA-11 in endometrial cancer patients. However, prospective large studies are needed to explore the real diagnostic role of radiolabelled PSMA in this field.

EP-0332

Role of ^{18}F-FDG PET-CT in the Detection & Disease Extent Evaluation in Ovarian Carcinoma

R. Wakankar, *J. Bal, P. Dougall;*
Max Super Speciality Hospital, New Delhi, INDIA.

Aim/Introduction: The aim of this retrospective study was to highlight the utility of ^{18}F-FDG PET-CT in the workup of patients of ovarian carcinoma of various histological variants who presented to our institute for staging work-up. ***Materials and Methods:*** The data from a total of 15 patients was collected and analyzed retrospectively for the purpose of this study. Descriptive statistics were generated based on the data that was collected. ***Results:*** Of the 15 patients, 73% had serous adenocarcinoma, 13% had mucinous adenocarcinoma and the remaining 14% had been diagnosed with endometrioid adenocarcinoma of the ovary. Recurrent disease was detected on PET-CT in 20% of the patients with the remaining 80% being evaluated for staging purposes of a treatment naïve ovarian malignancy. Of the patients who had recurrent disease, 33% had serous ovarian carcinoma, 33% had mucinous ovarian carcinoma and 33% had endometrioid ovarian carcinoma. Only 13% of the patients had metastatic disease with all the metastatic lesions being located in the liver. Approximately 47% patients that had ovarian cancer, had peritoneal disease as well. 40% patients had lymph nodal disease, with 100% of the patients have infra-diaphragmatic lymph nodal metastasis and approximately 17% of them having supra-diaphragmatic lymph nodal metastasis. The mean CA-125: 364.5±426.3 IU/ L (95% CI: 148.8 - 580.3), SUV max of all the infra-diaphragmatic metastatic lymph nodes: 11.9±1.2 (95% CI: 10.9 - 12.9), SUV max of the peritoneal deposits: 9.2±2.9 (95% CI: 6.9 - 11.3), SUV max of distant metastatic lesions: 16.2±6.4 (95% CI: 7.2 - 25.1) and SUV max of the recurrent disease: 14.2±7.1 (95% CI: 6.2 - 22.2). The sensitivity (Sn), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV) and accuracy of ^{18}F-FDG PET-CT were 92.8%, 100%, 100%, 50% and 93.3%, respectively. ***Conclusion:*** ^{18}F-FDG PET-CT is an excellent imaging modality for detecting and staging of ovarian adenocarcinoma.

EP-0333

Lymphatic Mapping: Cervical vs. Myometrial in Endometrial Cancer

K. Quintero Martinez, *A. Glickman, J. Ribera, M. Munmany, B. Diaz-Feijoo, I. Romero, A. Niñerola, F. Campos, A. Torné, M. Tormo, E. Garcia, J. Carrasco, N. Agustí, N. Carrera, S. Vidal-Sicart, P. Paredes;*
Hospital Clinic Barcelona, Barcelona, SPAIN.

Aim/Introduction: European guidelines recommend cervical injection of tracers for sentinel lymph node (SLN) detection in endometrial cancer (EC); however, intramyometrial injection better reflects the natural drainage of the myometrium. The aim was to compare lymphatic drainage according to the tracer injection route, cervical vs. myometrial. ***Materials and Methods:*** Patients with intermediate to high-risk EC were included in the randomized clinical trial with two-arms, HYBRID ENDONODE. All patients underwent injection of radiotracer ([99mTc]Tc-albumin nanocolloid) or hybrid tracer ([99mTc]Tc-albumin nanocolloid-ICG) via cervical and transvaginal ultrasound-guided myometrial (TUMIR) routes the day before surgery, with no more than a 14-day difference between them. After each injection, early and late planar images and abdominopelvic SPECT/CT were acquired. ***Results:*** Fifty-seven patients were included with a median age of 65 years, 30 in the radiotracer group and 27 in the hybrid tracer group. For the cervical injection, drainage was observed in 89.5% of patients (51/57). Of these, drainage was bilateral in 36/51 (71%) and para-aortic in 6/51 (12%). For the TUMIR injection, drainage was observed in 70% of cases (40/57), which was bilateral in 23/40 (57.5%) and para-aortic in 12/40 (30%). Exclusive para-aortic drainage was not observed in any case. No differences were observed according to tracer. The mean detection of sentinel lymph nodes by lymphoscintigraphy was 3.27 ± 2.27 after cervical injection and slightly lower, although not significantly, for myometrial injection: 2.69 ± 2.55. ***Conclusion:*** The lymphoscintigraphic drainage rate in endometrial cancer after cervical tracer injection is higher than that of the myometrial route, although it shows a lower rate of para-aortic drainage.

EP-0334

Validation of a Short Dynamic [18F]FDG PET/CT Acquisition Protocol for Parametric Imaging in Endometrial Cancer

J. Sæterstøl[1,2], *B. Næss[3], I. S. Haldorsen[1,2], K. E. Fasmer[1];*
[1]Mohn Medical Imaging and Visualization Centre, Department of Radiology, Haukeland University Hospital, Bergen, NORWAY, [2]Department of Clinical Medicine, University of Bergen, Bergen, NORWAY, [3]Centre for Nuclear Medicine/PET, Department of Radiology, Haukeland University Hospital, Bergen, NORWAY.

Aim/Introduction: Dynamic positron emission/computed tomography (PET/CT) with Patlak compartment modelling, has the potential to improve quantitative cancer imaging, but is prone to elongated scanning times. The aims of this study were 1) to validate a published population-based arterial input function (PIF)1 in an endometrial cancer cohort undergoing dynamic [18F]fluoro-deoxy-glucose (FDG) PET/CT, and 2) to compare quantitative tissue values in parametric FDG metabolic rate (MRFDG) images with corresponding values in conventional standardized uptake value (SUV) images. ***Materials and Methods:*** Preoperative FDG PET/CT was performed in 24 consenting patients with histologically confirmed endometrial carcinoma. Nine (9/24) patients (subcohort A) underwent dynamic 80-minute scans from the time of FDG injection. Fifteen (15/24) patients (subcohort B)

underwent shorter dynamic 20-minute scans, starting 50 minutes post-injection. In A), MRFDG images were reconstructed using both a patient-specific image-derived input function (MRFDG,IDIF) and the individually scaled PIF (MRFDG,PIF). Percentage differences in area under PIF and IDIF (AUC) were derived and compared with differences in quantitative tissue values measured in the resulting MRFDG,IDIF and MRFDG,PIF images. In B), MRFDG images were only reconstructed using the individually scaled PIF (MRFDG,PIF). For all patients (A and B) conventional SUV images were reconstructed. From volumes of interest placed in the primary tumour, liver, and spleen, mean SUV and MRFDG,PIF values were measured and compared using Spearman's rank correlation coefficients (ρ). ***Results:*** In A) the mean (standard deviation (sd)) AUC was 4 (3)% higher for PIF than for IDIF. The differences were similar (with opposite sign as expected from the Patlak equation) when comparing quantitative MRFDG,PIF and MRFDG,IDIF values. The mean (sd) differences were -4 (3)% for tumour, -2 (2)% for liver and -2 (2)% for spleen. For all patients, mean tumour SUV was strongly correlated with mean tumour MRFDG,PIF values (ρ=0.93, p<0.001). No significant correlations were seen between mean SUV and mean MRFDG,PIF values in the liver and spleen (ρ≤0.33, p≥0.11 for both). ***Conclusion:*** A shortened 20-minute dynamic FDG PET/CT protocol utilizing a PIF, seems feasible and yields only a small (4%) difference in AUC and a corresponding small (-2 to -4%) difference in mean MRFDG values compared with using an IDIF and the 80-minute acquisition protocol. SUV and MRFDG values are strongly correlated in endometrial tumour tissue, but not significantly correlated in liver and spleen. ***References:*** [1] Dias, et al: 'Clinical validation of a population-based input function for 20-min dynamic whole-body ^{18}F-FDG multiparametric PET imaging', EJNMMI Phys(2022) doi: 10.1186/s40658-022-00490-y.

EP-0335

Prognostic value of pretreatment ^{18}F-FDG PET metabolic distribution pattern in advanced high grade serous ovarian cancer

D. Travaglio Morales[1,2], *M. Coronado Poggio[1], I. Losantos García[3], A. Heinzel[2], L. Dominguez Gadea[1];*
[1]La Paz University Hospital. Department of nuclear medicine, Madrid, SPAIN, [2]Halle University Hospital. Department of nuclear medicine, Halle (Saale), GERMANY, [3]La Paz University Hospital. Department of biostatistics, Madrid, SPAIN.

Aim/Introduction: To evaluate the prognostic value of pretreatment 18F-FDG PET metabolic distribution pattern in patients with advanced high-grade serous ovarian cancer. ***Materials and Methods:*** A review of 50 patients(p) diagnosed of advanced high grade serous ovarian cancer between January 2012 and September 2020 was made, evaluating the following pretreatment 18F-FDG-PET abdominal metastatic metabolic pattern: Single mass (SM), multiple peritoneal bulky masses (MBM), miliary/disperse peritoneal carcinomatosis, retroperitoneal lymph nodes without peritoneal carcinomatosis or retroperitoneal lymph nodes with peritoneal carcinomatosis. The images were visually assessed. Clinical data of relapse/progression and final status (exitus/alive) was collected. Disease-free survival (DFS) and overall survival (OS) were calculated. Correlation between the metabolic distribution pattern and DFS/OS was calculated using univariate Cox regression analysis. ***Results:*** Mean DFS was 22.7 months (17.9-27.5) and OS 55.1 months (43.5-66.7). From the 50p, 15p have a single abdominal mass, 22p multiple peritoneal bulky metastases, 9p have miliary/disperse peritoneal carcinomatosis pattern, 3 patients have retroperitoneal lymph nodes without peritoneal carcinomatosis and only 1p have retroperitoneal lymph nodes with peritoneal carcinomatosis. Subgroup analysis with SM+MBM vs the rest of patterns was made because of the small sample (tendence of better survival in SM and MBM patients in a preliminary analysis). A statistically significant association was found between SM+MBM pattern with OS. Patients with SM or MBM pattern have a better survival than the rest of patterns (p=0.002) with OS of 64.7 months (±6.7) vs 27.8 months (±4.2). The risk of dead (1-HR) was reduced by 75.4% (HR=0.246 p=0.003 IC05%=0.096,0.627). None correlation was found with DFS. ***Conclusion:*** In patients with high-grade advanced serous ovarian cancer, abdominal metabolic distribution pattern in pretreatment 18F-FDG PET has prognostic value: patients with single mass or multiple peritoneal bulky masses have better prognosis, with a higher overall survival.

EP-0336

Endometrial cancer: predictive value of ^{18}F-FDG Digital PET/CT in post-operative restaging and response to adjuvant chemotherapy assessment

P. Alongi, *C. Longo, V. Vultaggio, A. Mirabile, G. Arnone;*
Nuclear Medicine Unit, A.R.N.A.S Ospedale Civico, Palermo, ITALY.

Aim/Introduction: To assess the value of 8F-FDG Digital PET/CT in the post-operative restaging and response to adjuvant therapy of endometrial cancer patients. ***Materials and Methods:*** 50 consecutive patients with histological diagnosis of primary high-risk endometrial cancer, who underwent PET/CT with [18F]FDG at least 2 months after surgery and 2 weeks after adjuvant chemotherapy, were retrospectively evaluated. After therapy [18F]FDG PET/CT findings were correlated with other imaging, clinical oncological notes and 6 months follow-up as standard reference. The diagnostic accuracy of [18F]FDG PET/CT for local relapse, lymph nodal involvement and distant metastases was assessed. Changes in functional and molecular imaging parameters after chemotherapy were compared between responders and non-responders with the Mann-Whitney U test. The significance threshold was set at a P value of less than 0.05. The impact on clinical management was also evaluated. ***Results:*** [18F]FDG PET/CT was negative in 12/50 patients but could correctly detect primary residual disease in 8/50 patients, nodal disease in 21/50 and distant mestastasis in 9/50. The overall [18F]FDG PET/CT patient-based sensitivity, specificity, positive predictive value, negative predictive value and accuracy were 91.6, 88, 88, 92, and 94%, respectively, for revealing lymph nodal neoplastic involvement, and 88.8, 97,4, 88.8, 92.6, 92%, respectively, for detecting distant metastases. Responders showed a significantly greater reduction in metabolic tumor volume (P = 0.02) and total lesion glycolysis (P = 0.04) after chemotherapy than non-responders. PET findings, compared to conventional imaging, changed the therapy management in 32% of patients. ***Conclusion:*** 18F]FDG PET/CT confirms its ability to accurately detect nodal disease and distant metastases in the restaging of endometrial cancer. Our preliminary data indicate that the [18F]FDG PET/CT-derived metabolic tumour volume and total lesion glycolysis, acquired after adjuvant chemotherapy, are predictive biomarkers for response to therapy. A potential role is intrinsic in PET imaging as a therapy management driver in the clinical setting.

EP-0337

Exploring the utility of ^{18}F-FDG PET/CT in detecting ovarian cancer recurrence with elevated CA-125 levels

S. Shamim, *N. Kumar, S. Yadav, G. Arora, R. Pramanik, S. Singhal;*
AIIMS New Delhi, Delhi, INDIA.

Aim/Introduction: Worldwide, ovarian cancer is the fourth leading cause of cancer death in women, often diagnosed in advanced stages, leading to a poor prognosis. Despite certain effective treatments, recurrence occurs in 50-80% patients, that underscores the importance of early detection of disease. CA-125, a glycoprotein expressed on epithelial cells, is the reference method for detecting ovarian carcinoma recurrence with a high positive predictive values, however it is not specific and sensitive for small-volume disease. 18F-FDG PET/CT stands out as a non-invasive imaging method, highly accurate in staging and follow-up for numerous cancers, including ovarian cancer. With a high sensitivity rate, it proves invaluable in detecting recurrence in ovarian cancer cases. Thus, the present study aimed to investigate the role of ^{18}F-FDG PET/CT in detection of recurrence in ovarian cancer patients with increased CA-125 levels. ***Materials and Methods:*** Thirty one (31) patients, mean age 50.77±12.52 years, underwent 18F-FDG PET/CT for restaging due to high CA-125 levels (Normal range: 0-35 U/mL) were retrospectively evaluated. All patients had undergone surgery and chemotherapy or radiotherapy prior to PET/CT imaging. Further, 18F-FDG PET/CT findings were compared with histopathological, radiological and clinical follow-up findings. All 18F-FDG PET/CT imaging were evaluated visually and semi-quantitatively by two nuclear medicine physicians. For semi-quantitative evaluation, maximum standardized uptake values (SUVmax) were calculated for all pathological lesions. The lesions with a SUVmax greater than background liver uptake at the site of pathologic changes on CT imaging were accepted as malignant lesions. ***Results:*** CA-125 levels ranged between 45-1301 U/mL (N: 0-35 U/mL). Recurrent disease was detected in all 31 patients on PET/CT imaging. Two (2) of 31 patients showed normal values of CA-125 level (<35 U/mL), however, PET/CT showed recurrent disease with metastasis to lungs, liver and deposits in serosa and omentum, that were consistent with radiological findings. In addition to abdominal and pelvic lesions, 13 patients showed distant metastatic lesions (breast, lung, liver and bone metastasis) identified correctly on PET/CT imaging. The sensitivity and positive predictive value of 18F-FDG were calculated as 93.5%, and 100%, respectively. ***Conclusion:*** 18F-FDG PET/CT proves to be a valuable imaging asset in identifying ovarian cancer recurrence among individuals with elevated CA-125 levels. As a whole body scan, it enables the detection of distant metastases in addition to abdominal and pelvic lesions, thus assisting in patient care.

Aim/Introduction: The amount of tissue affected by cervical neoplasms affects its therapeutic management and prognosis. Metabolic Tumour Volume (MTV) and Total Lesion Glycolysis (TLG) on an [18F]FDG PET-CT have been identified as good baseline prognostic factors, but standardization of the methodology to evaluate both is crucial. The aim of this study has been to assess inter-observer variability in metabolic parameters, as well as MTV and TLG measurements, in patients with cervical uterine neoplasms in an initial staging [18F]FDG PET-CT. ***Materials and Methods:*** We retrospectively reviewed data from 18 patients with cervical neoplasms who underwent initial staging [18F]FDG PET-CT. Two independent observers reviewed the images and processed them using PETVCAR software (GE Healthcare). The metabolic parameters evaluated included MTV and TLG, SUVmax, SUVmean and SUVpeak, for cervical lesions, lymphadenopathies and metastatic lesions. Total MTV and TLG were calculated. Statistically significant differences in the parameters studied between observers were assessed using a Wilcoxon paired test. Finally, we used the Intraclass Correlation Coefficient (ICC) and Bland-Altman Plot analysis with R studio 2023.09.0 to calculate the statistical significance of the inter-observer differences. ***Results:*** Eighteen patients with cervical neoplasms and initial staging [18F] FDG PET-CT were included. There were no statistically significant differences between observers in any of the parameters studied. There was low concordance for the lymphadenopathies' MTV (0.457), good for cervical MTV, lymphadenopathies' TLG and total MTV, and excellent for the rest of the parameters. The Bland-Altman Plot reported a bias in lymphadenopathies' MTV of -1.39. Although there were no significant differences, we identified some gaps in the results of local lesions due to the difficulties that the software presents in some patients in separating urinary activity in the bladder from the lesion, which forced us to solve it manually. Also, urinary activity can explain our biggest differences in the evaluation of lymphadenopathies, which can be mistaken for the ureters. ***Conclusion:*** There were no statistically significant differences between observers in any of the parameters of interest, with mostly good to excellent concordance. However, potential interferences like urinary activity (both in the primary lesion and in the evaluation of lymphadenopathies) need to be considered to avoid inaccurate measurements.

Selective sentinel lymph node biopsy after cryoablation in patients with early breast cancer

Y. Abadi Sedraoui, *C. Escabias Del Pozo, P. Portilla Merino, D. Monachello Araujo, J. Otero Gonzalez, M. Coronado Poggio, C. Lancha Hernandez, J. Cordero Garcia, S. Rodado Marina, S. Rizkallal Monzon, L. Giraldo Gonzalez, L. Gadea Dominguez; Hospital Universitario La Paz, Madrid, SPAIN.*

Aim/Introduction: To examine the reliability of selective sentinel lymph node biopsy (SSLNB) and assess potential factors impacting its detection in cryoablated patients. ***Materials and Methods:*** Retrospective analysis of 45 cryo-ablated patients between 02/2021 and 01/2023, previously evaluated by a Multidisciplinary Committee and meeting inclusion criteria for cryoablation, initially with small tumors and negative axilla. Subsequent consent was obtained. The variables collected included: age, affected breast, tumor location, time between cryoablation and lymphoscintigraphy, pre-cryoablation tumor size measured by ultrasound or MRI, size of tumor resection and cryoablation area, presence and location of residual tumor, margin enlargement, histological grade (G), presence of Her2, progesterone and estrogen receptors (RP and RE), ki67%, prior hormone therapy and treatment duration until surgery. Lymphoscintigraphy data encompassed drainage presence, location, number of sentinel nodes, and post-surgery histology. Analysis was performed using absolute frequencies and percentages. ***Results:*** Mean age: 63 years (range 50-78). Five patients received prior hormone therapy, administered on average 61 days preoperatively. Tumor size before

cryoablation averaged 9.75 mm, assessed by ultrasound (32) and MRI (13). Breast cancer was predominantly located in the left breast in 47% of cases. Tumor distribution included 15 superolateral-quadrants, 2 superomedial-quadrants, 3 inferomedial-quadrants, 6 junctions of outer-quadrants, 8 junctions of inner-quadrants, and 11 junctions of upper-quadrants. Histological findings revealed 41 infiltrating ductal carcinomas (IDC), 2 lobular carcinomas, and 2 tubular carcinomas, with 22 G1, 22 G2, and 1 G3. Mean PR: 23%, ER: 79%, and Ki67%: 9.3. Mean cryoablation area, determined by histological analysis: 16 mm. Mean size of surgical specimens: 44 mm. Residual tumor was observed in 20% of patients, predominantly IDC nests (G2-G3) adjacent to the cryoablated area, with margin enlargement performed in three cases. Mean interval from cryoablation to lymphoscintigraphy: 16 days (range 6-77). 69 sentinel nodes were identified (mean 1.33 nodes/patient). Two nodes tested positive for metastasis in two patients. Axillary lymphadenectomy was not performed in either case, with patients receiving chemotherapy, radiotherapy, and subsequent hormonotherapy. Additionally, 4/45 patients showed drainage to the ipsilateral internal mammary region without specific surgical intervention, and 4/45 had intramammary drainage (removed intraoperatively). All cryoablated patients exhibited visualized sentinel nodes, achieving a surgical detection rate of 100%. ***Conclusion:*** In our series, SSLNB after cryoablation in early breast cancer presents a high detection rate. Cryoablation does not appear to influence radiotracer migration. Larger samples and longer follow-ups are needed to detect potential limitations and determine extrapolation to the general population.

Role of PET-CT in the Staging of Squamous Cell Carcinoma of the Cervix (A Study of 100 Cases)

O. Zakaria, *A. Sara, B. Hakim, B. Halima, B. Hafsa, A. Hind, G. Amal;*
Nuclear Medicine Department, Ibn Rochd University Hospital of Casablanca, Hassan II University, Casablanca, MOROCCO.

Aim/Introduction: Worldwide, in 2018, approximately 570,000 cases of cervical cancer and 311,000 deaths were reported. In Morocco, it ranks as the third most common cancer in women after breast and thyroid cancer. The aim of this work is to highlight the usefulness of the ^{18}FDG PET/CT in cervical cancer in Moroccan patients. ***Materials and Methods:*** This is a retrospective study of a series of one hundred patients with cervix squamous cell carcinoma, collected over 15 months from January 2023 to April 2024, at the Nuclear Medicine Department of Ibn Rochd University Hospital in Casablanca. After fasting for at least 6 hours and ensuring blood glucose levels were <1.1g/L, patients received an injection of 2.5 to 4 MBq/kg of FDG. After a resting period of 45 to 60 minutes, patients underwent a PET-CT scan from mid-skull to mid-thigh, along with a CT scan for anatomical localization and attenuation correction. ***Results:*** The average age was 53 years [37 to 71 years]. The PET-CT scan was positive in 87% of cases with the highest SUV max being 14. The PET-CT was negative in 6% of cases, and equivocal in 7%. Regarding staging, PET-CT scan with ^{18}FDG revealed localized disease in the cervix in 25% of cases, locally extended disease in 25% of cases, pelvic lymph node involvement in 13% of cases, lombo-aortic lymph node involvement in 27% of cases,and hepatic metastasis in 4% of cases For therapeutic response evaluation, the examination showed hypermetabolic foci limited to the cervix in 25% of cases, extended to adjacent anatomical structures in 38% of cases, inguinal lymph node involvement in 25% of cases, iliac lymph node involvement in 23% of cases, lombo-aortic lymph node involvement in 20% of cases, and hepatic involvement in 16% of cases. For therapeutic response evaluation during treatment, PET-CT favored persistent disease in 60% of cases and progressive disease in 40% of cases. For therapeutic response evaluation at the end of treatment, PET-CT favored persistent disease in 55% of cases, progressive disease in 35% of cases, and residual disease in 10% of cases. ***Conclusion:*** PET-CT is recommended for the initial staging of N and M-stage disease, as it also allows for the detection of extension of disease outside of the pelvis. It has prognostic value and aids in defining the target volume in radiotherapy. The PET CT scan may also help to evaluate response to radiotherapy and chemotherapy.

Preliminary study of the diagnostic capacity of dynamic F^{18} fluorodeoxyglucose PET scan in the differential diagnosis of ovarian masses

T. Shinya[1], *A. Shinya[2], T. Matsushita[1], Y. Otomi[1], M. Kubo[1], J. Hiraoka[1], H. Inui[1], K. Yoshida[1], M. Nishimura[1], T. Iwasa[1], M. Harada[1];*
[1]Tokushima University Hospital, Tokushima-city, JAPAN,
[2]Tokushima Red Cross Hospital, Komatsushima-city, JAPAN.

Aim/Introduction: This prospective study assessed the diagnostic capacity of dynamic F^{18} fluorodeoxyglucose (FDG) positron-emission tomography (PET)/computed tomography (CT) comparing with 1-h early scan in the differentiation between benign ovarian lesion and malignant ovarian tumour. ***Materials and Methods:*** Dynamic scans (5-15 min [1st phase], 15-25 min [2nd phase], 25-35 min [3rd phase] postinjection) and consecutive 1-h early scan (60 min postinjection) were undergone in nine patients with nine ovarian masses (4 endometrioid carcinomas; 1 high-grade serous carcinoma; 1 mucinous carcinoma; 1 granulosa cell tumor; 1 mature teratoma; 1 hemorrhagic ovarian cyst). For the calculation of maximum standardized uptake values (SUVmax) of the ovarian lesion, the placement of the region of interest (ROI) was decided by consensus between two nuclear medicine physicians. We statistically compared the diagnostic capacity of SUVmax for each phase in the discrimination between benign ovarian lesion and malignant ovarian tumour using receiver operating characteristic (ROC) curve analysis. ***Results:*** SUVmax gradually decreased or remained similar with minimal fluctuations in two cases of benign ovarian lesions and two cases of malignant ovarian tumours. In contrast, SUVmax had been increasing tendency over time in five cases of malignant ovarian tumours. In ROC analyses, the areas under the curve (AUC) are higher than 0.786 in all analyses and AUC yielded the highest values at 0.929 on dynamic 1st phase and 1-h early phase for differentiating benign ovarian lesion from malignant ovarian tumour. ***Conclusion:*** Dynamic F^{18} FDG PET scans have the potential to be good predictors of discriminating benign ovarian lesion and malignant ovarian tumour in clinical practice.
