manufacturer's method and alternative method by subtracting the percentage due to impurities from 100%. ***Results:*** With NaCl 0,9% as mobile phase, free 99mTcO4- and 99mTc-coligands are displaced to the solvent front. The mean RCP value following the reference method, was 99,5±0,4 % after incubation and 99,4±0.5 % before heating, versus 95,1±2,2 % and 9,2%±1,2 % with the alternative method. The mean 99mTc-coligand value, obtained by subtracting the free 99mTcO4- value of the strip developed with MEK from the peak at Rf=1 of the strip with NaCl 0,9%, was 4,4±2,1 % after incubation and 90,3±2.3 % before heating. ***Conclusion:*** The manufacturer's method is not able to discriminate the 99mTc-coligand from the 99mTc-(EDDA)2/HYNIC-TOC, so it overestimates the RCP value and gives compliant values even before heating, incubation and complex formation. Coligand exchange at high temperature is a critical step for the labelling [2], but the reference method fails to detect if appropiate heating has been applied. The alternative method with NaCl 0,9% provides further information and allows us to obtain the real RCP value. Since it separates both free 99mTcO4- and 99mTc-coligand, TLC with MEK could be omitted unless quantifying each impurity separately is desired. ***References:*** [1] Guggenberg EV et al. (2004) J Pharm Sci. Oct;93(10):2497-506. [2] Von Guggenberg et al. (2003). J Label Compd Radiopharm, 46: 307-318.

EP-1028

Optimization and validation of [18F]fluorocholine radiosynthesis on an automated cassette-based system

T. Koivula[1], *J. Laine[1], T. Lipponen[1], D. Lumen[1], K. Kiviluoto[2], J. Lehto[1];*
[1]HUS Diagnostic Center, University of Helsinki and Helsinki University Hospital, Helsinki, FINLAND, [2]HUS Pharmacy, University of Helsinki and Helsinki University Hospital, Helsinki, FINLAND.

Aim/Introduction: HUS Diagnostic Center performs approximately 3800 PET/CT imaging studies annually. In 2022-2023, the clinical use of [18F]fluorocholine ([18F]fluoromethyl-dimethyl-2-hydroxyethylammonium, [18F]FCH) was increased significantly and raised interest towards in-house production of this radiotracer at the Cyclotron Unit. In this work, the radiosynthesis of [18F]FCH and its quality control methods were set up, optimized and validated. ***Materials and Methods:*** [18F]Fluoride was obtained from the cyclotron. The radiosynthesis was performed on a fully automated system using two identical synthesis modules. Reagent set and applicable GMP compliant synthesis cassettes were purchased from a commercial supplier, but the overall synthesis script had to be created and optimized. The radiosynthesis of [18F]FCH was based on published methods on labelling of dimethylethanolamine (DMEA) with [18F]fluorobromomethane. The 18F-fluoromethylation reagent was produced in the first module from where it was distilled to the second module containing 0.5 ml of DMEA on a reversed-phase HLB cartridge. [18F]FCH was purified by cation exchange (CM cartridge). The final product was eluted with 3.5 ml of 0.9% NaCl and diluted into final volume in a dispensing unit. Special attention was paid to prevention of radioactive exhausts: modules liquid waste vial was vented to a gas collection bag and gases from the hot cell were collected to the air compression station for 20 h. ***Results:*** [18F]FCH was produced repeatably with excellent radiochemical purity, ≥ 99% (by radioTLC and -HPLC). In first studies, the amount of DMEA in the final product exceeded the limit set in European Pharmacopoeia, but it was able to be minimized (≤0.1 mg/ml) by modification of the cartridge purification. All the other tests for chemical purity (Kryptofix, dibromomethane) and residual solvents (ACN, EtOH), as well as pH, radionuclidic purity, sterility and endotoxin content met the acceptance criteria. Stability of the product was confirmed until 6 h. By the optimized method the decay-corrected radiochemical yield of [18F]FCH was 24.5±1.2% (process validations, n=5) of the estimated [18F]F- activity available from the cyclotron. However, the radiochemical yield was increased markedly, >33% when a fresh reagent set was used. The overall synthesis time was 60 min. The radiosynthesis was validated up to 100±5 GBq starting activity which provides [18F]FCH for 8-10 consecutive imaging studies for a one PET scanner. ***Conclusion:*** A reliable radiosynthesis method of [18F]FCH by combination of two cassette-based modules was validated and production for clinical studies was started in January 2024. This radiotracer is now produced routinely for parathyroid imaging.

Aim/Introduction: Cardiovascular diseases, including fatal myocardial infarctions from atheromatous plaques, are the primary global mortality cause. Detecting stenotic atheromatous plaques is possible through coronary angiography, but vulnerable plaques with eccentric remodeling are undetectable with current diagnostic methods. Addressing this challenge, our group developed a radiopharmaceutical drug targeting vascular cell adhesion molecule 1, radiolabeled with technetium-99m. Given the absence of a monograph in the European Pharmacopoeia, analytical methods had to be validated. The aim of this work is to validate the analytical method for determining the radiochemical purity (RCP) of the radiolabeled 99mTc-cAbVCAM1-5 by high performance liquid chromatography (HPLC) and thin layer chromatography (TLC). ***Materials and Methods:*** The validation of the analytical method for the determination of 99mTc-cAbVCAM1-5 RCP was carried out according to the EANM Guidelines, the ICH Q2 guidelines and the guide for the elaboration of monographs on radiopharmaceutical preparations. The method validation ensuring conformity with specificity, accuracy, repeatability and intermediate precision, linearity, robustness, quantification limit (LoQ), and range criteria. ***Results:*** Regarding the results of specificity, both HPLC and TLC methods demonstrated excellent separation of 99mTc-cAbVCAM1-5 from impurities, with a high resolution factor greater than two. Accuracy results indicated recovery percentages within the range of 99.52 to 101.40 % for the HPLC and 99.51 to 101.97 % for TLC, ensuring reliable measurements for each concentration of 99mTcO4-. Precision of the methods was validated by assessing repeatability and intermediate precision, with coefficients of variation of less than 2 %. Linearity was determined over the usual concentrations range and the correlation coefficient (R2) was greater than 0.99 for both methods. To assess the robustness of HPLC and TLC methods, we changed different parameters as chromatographic column, composition of the mobile phase. For

each conditions, the RCP of 99mTc-cAbVCAM1-5 assessment was not affected. The LoQ was measured by diluting the 99mTcO4- in order to obtain a signal-to-noise ratio around 10:1. Under these conditions, we obtained an LoQ of 2.1 MBq/mL for HPLC and 2 Mbq/mL for TLC. The validated analysis range was between the value found for the LoQ and the high value of the linearity test (202.0 MBq/mL for both methods). This range was selected to meet the validation guidelines by EDQM and our synthesis specification. ***Conclusion:*** In conclusion, the analytical methods developed in this study comply with EANM recommendations. This therefore allows us to correctly assess the RCP of 99mTc-cAbVCAM1-5, a new radiotracer targeting inflammation in vulnerable plaques.

EP-1030

Improved production ^{68}Ga-MAA: the LASER-assisted radiolabelling.

L. Canziani, *G. Pepe, G. De Matteis, T. Padellini, L. Lodola;*
Fondazione IRCCS Policlinico San Matteo, Pavia, ITALY.

Aim/Introduction: 68Ga radiolabeling of commercially Macro-Aggregate of Albumin (MAA) kits has recently gained interest, due to the availability of 68Ge/68Ga generators and the enhanced spatial resolution offered by PET imaging. There are numerous clinical investigations focusing on the evaluation of [68Ga]Ga-MAA, but setting up a standardized and effective production procedure remains crucial. Conventionally, a heating procedure up to 90°C is employed. This method is associated with temperature-induced partial disintegration of MAA particles, leading to the need for an additional step of purification. In this study, we present the outcomes of a novel radiolabelling LASER-assisted method for [68Ga]Ga-MAA preparation. ***Materials and Methods:*** Three vials of MAA (Pulmocis ®) were reconstituted with 4 ml of saline and 200 MBq of buffered 68Ga solution (1.25 mL) each. Vial-1 was kept at room temperature for 15 min, Vial-2 was heated at 75 °C for 15 minutes, Vial-3 underwent irradiation with a blue LASER (Techhodd PWM/TTL Blue laser OEM Module, China) (wavelength 450 nm, power 7 W, frequency 30 Hz) for 15 minutes in a custom-built facility designed to shield irradiation. The temperature of Vial-3 was monitored during irradiation using a thermocouple thermometer. The Labelling Yield was assessed after the labelling procedure using thin-layer chromatography, with ITLC-SG and as mobile phase 0.1 M tribasic citrate solution. Stability tests in serum were also conducted. Particle dimensions were measured using a series of two polycarbonate membrane filters (3 µm and 400 nm pores) and observed in Burker chamber. The particle sizes were then compared to those obtained after standard 99mTc labelling. ***Results:*** Labelling Yield (LY) of [68Ga]Ga-MAA obtained in Vial-1 was very low (38%), while reached 88 % in Vial-2 (heat method) and to > 98% in Vial-3 (LASER method). In Vial-3 only a minimum increase of temperature, up to 38°C, was reported. LY was stable after serum incubation. Moreover, the percentage of particles with size <400 nm was negligible in Vial-1 and Vial-3 (about 1%), similar to the results of routine 99mTc labelling procedure, while it was dramatically higher, up to 68%, in Vial-2 (heat method). ***Conclusion:*** LASER-assisted radiolabelling of [68Ga]Ga-MAA assures a labelling yield higher than the usual heating-method. Also, LASER-assisted method does not affect the MAA size, thus avoiding the need of further purification steps necessary for the heating-method proposed so far. LASER Induced chemical reaction is an interesting approach under development, with no previous applications in the field of radiopharmaceuticals production.

EP-1031

Self-radiolysis rate of small-molecule Lu-177-PSMA verified with external irradiation

V. Reijonen[1], *M. Rautiainen[1], S. Keskimäki[2], K. Kiviluoto[2], V. Ahtiainen[1], M. Tenhunen[1];*
[1]Helsinki University Hospital Cancer Center, Helsinki, FINLAND,
[2]Helsinki University Hospital Pharmacy, Helsinki, FINLAND.

Aim/Introduction: Radiochemical purity (RCP) of radiopharmaceuticals is tested with high-performance liquid chromatography (HPLC). Within small-molecule Lutetium-177-labeled prostate-specific membrane antigen (PSMA) targeting ligand, Lu-177 forms a bond with the PSMA peptide via a chelate. Various factors can compromise RCP over time. In this work, we tested the hypothesis that self-radiolysis predominantly drives this decline. ***Materials and Methods:*** We irradiated a vial of in-house synthesized small-molecule Lu-177-PSMA ("Vial 1") with a clinical linear accelerator on three occasions on the day following the production: each irradiation with 6 MV photons delivered a dose of 500 Gy at the rate of 12 Gy/min. HPLC analyses were carried out after the synthetization, in the beginning of the next day, and after each irradiation. Activity was measured with a radionuclide calibrator and weight with a precision scale to determine the self-absorbed radiation dose during each time interval. This self-dose was calculated assuming local-energy deposition of all beta radiation. Later, we repeated the test using a commercial version of the Lu-177-PSMA product ("Vial 2"): in this case, however, the irradiations and analyses were performed on the second day after the production. ***Results:*** Initially, Vial 1 contained 5.65 GBq in 6.94 g. The product was tested with HPLC right after its synthetization: RCP was 96.23%. After 25 hours, RCP was decreased to 94.16%, while the self-dose was 1653 Gy. After the first round of external irradiation (500 Gy+self-dose 51 Gy), RCP was 93.32%; after the second round (500 Gy+97 Gy), 92.27%; and after the third round (500 Gy+63 Gy), 91.82%. Vial 2 contained 3.77 GBq in 7.35 g, with RCP 93.48% (22 h post-production). The next sample was analyzed 21 hours after this, resulting in RCP 92.30%, while the self-dose during the time interval was 872 Gy. Then followed the three rounds of irradiation: RCP 91.58% (500 Gy-11 Gy; negative value due to delay in the previous HPLC analysis); 90.86% (500 Gy+39 Gy); and 90.19% (500 Gy+42 Gy). For both Vial 1 and 2, the reduction in RCP was linearly related to the accumulated dose ($p<0.001$): for Vial 1 RCP reduction was -1.35% per kGy of absorbed dose ($R2=0.994$), and for Vial 2 -1.36% per kGy ($R2=0.999$), respectively. ***Conclusion:*** Our experiments using external irradiation indicate that radiolysis is the main cause of decrease in radiochemical purity of small-molecule Lu-177-PSMA. The rate of RCP reduction appears to be approximately -1.3% to -1.4% per 1000 Gy absorbed dose.

EP-1032

Evaluation of an automated synthesis method for $^{[18F]}$ fluoromisonidazole using an automated synthesis module in a South African hospital radiopharmacy using off-site produced fluoride-18.

J. le Roux, *J. Oliver, S. Rubow;*
Stellenbosch University, Stellenbosch, SOUTH AFRICA.

Aim/Introduction: $^{[18F]}$FMISO is the only PET hypoxia-imaging radiopharmaceutical with a dedicated monograph in the European Pharmacopoeia (Ph. Eur.) [1]. The synthesis of $^{[18F]}$FMISO has previously been reported on both manual and automated synthesis platforms [2,3]. This report details the synthesis and quality control of $^{[18F]}$FMISO using a cassette-based automated synthesis module following a validated method but using commercially

supplied [18F]fluoride from a distant cyclotron. The method using this model of synthesis module has not been published yet. ***Materials and Methods:*** Cassettes, reagent sets, precursor vials and other consumables for the automated synthesis of [18F]FMISO were procured from an approved supplier.The [18F]fluoride solution was purchased from a local commercial PET radionuclide supplier and delivered to our hospital radiopharmacy. A validated synthesis method which was specifically developed for a synthesis module similar to our institution's automated module was provided by the manufacturer of the reagent set. Briefly, the [18F]fluoride solution was trapped on a QMA cartridge and then eluted using a solution of tetrabutylammonium hydrogen carbonate. The [18F]fluoride/ TBAHCO3 solution was dried in anhydrous acetonitrile at 95°C. The precursor was allowed to react with the dried [18F]fluoride solution for 10 min at 110°C.The crude product was evaporated at 95°C for 3 minutes whereafter the solution was purified through a series of SPE cartridges and filtered into a sterile vials. The pH of the final product was adjusted with a citrate buffer. Quality control was performed according to the Ph. Eur. Monograph 2459. Shelf-life was determined over a time period of 8 hours. ***Results:*** Five batches were evaluated for the purpose of this study. The average decay-corrected radiochemical yield was 27.4% ± 3.6%. The average [18F]FMISO activity at the end of synthesis was 1.7 ± 0.5 GBq. The radiochemical purity of the product was 99.4 ± 0.5%. The product met all release criteria. Problems included logistical constraints related to the amount of [18F]fluoride activity available from the supplier. This limited yield and number of patients doses that could be reliably provided. ***Conclusion:*** Using the automated module available to us, a validated method, disposable cassettes, and commercially acquired [18F]fluoride, we successfully synthesised [18F]FMISO with high chemical and radiochemical purity, meeting all the Ph. Eur. quality requirements. This study confirms that the module can be used to produce [18F]FMISO for small-scale in-house applications. The major challenges in our study were problems due to the commercial supply of [18F]fluoride.

EP-1033

Stability of different radiopharmaceuticals used in gastric emptying scintigraphy test

L. Garcia Lama, *C. Jimenez Pena, C. G. Franco Monterroso, B. Santos Montero, L. Rey Sanchez, M. A. Hernandez Fructuoso; Hospital Universitario Vall d´Hebron, Barcelona, SPAIN.*

Aim/Introduction: In gastric emptying scintigraphy tests, the radiopharmaceutical is incorporated into egg and an omelette is cooked and eaten by the patient. The aim of this study was to evaluate the stability of diethylenetriamine pentaacetate ([99mTc] Tc-DTPA) and albumin nanocolloids ([99mTc]Tc-nanocolloid) during this procedure. Both radiopharmaceuticals were exposed to acid pH, egg, or heat. ***Materials and Methods:*** For each radiopharmaceutical, three types of samples were prepared: radiopharmaceutical at room temperature, radiopharmaceutical mixed with egg (1:1) and radiopharmaceutical heated at 100°C for 5 minutes ([99mTc] Tc-DTPA n=18 and [99mTc]Tc-Nanocolloid n=18). All samples were incubated 2 hours with 1 ml of hydrochloric acid (HCl) at increasing concentrations (0.001M, 0.01M, 0.08M, 0.2M). From each radiopharmaceutical labelling a control sample was obtained that was not incubated with HCl. The radiochemical purity (RCP) of the samples and control samples (2h post-labelling) was determined by chromatography. For [99mTc] Tc-DTPA we used strips of Whatman 3 paper with 0.9% NaCl and methyl ethyl ketone and ITLC-SG with methanol: H2O (85:15) for [99mTc]Tc-Nanocolloid. The strips were counted in a MiniGITA TLC-scanner. ***Results:*** The average RCP of the [99mTc] Tc-DTPA and [99mTc]Tc-Nanocolloid control samples was 99.5% and 99.8%, respectively. The average RCP results of the [99mTc]Tc-Nanocolloid samples with increasing HCl concentrations (0.001M, 0.01M, 0.08M, 0.2M) in all samples (at room temperature, mixed with egg and heated 100°C for 5 minutes) were always above 95%. RCP of [99mTc]Tc-DTPA samples was always higher than 95%, except radiopharmaceutical with 0.2M HCl and heated with 0.2M HCl, where RCP was 63.80% and 61.68%, respectively. No significant differences were observed between the RCP results of room temperature and heated samples between the two radiopharmaceuticals, except for the 0.2M HCl samples ($p<0.05$). Significant differences were also observed in the egg samples ($p<0.05$) with higher average RCP of [99mTc] Tc-Nanocolloid. ***Conclusion:*** [99mTc]Tc-Nanocolloid has a higher RCP than [99mTc]Tc-DTPA in all samples and is more stable against heat, acid pH and egg. The RCP of [99mTc]Tc-DTPA is affected at lowest pH. The addition of egg seems to neutralise the acidity and stabilise [99mTc]Tc-DTPA. Therefore, both radiopharmaceuticals can be used in this test.

EP-1034

Fully Automatic Quality Control Tests for Radiopharmaceuticals - the FDG Case

Y. Zandona[1], *J. Morelle[1], J. Adam[2], A. Popova[2], V. Geay[1], S. Leloux[1], S. Rouelle[1], F. Baplue[1], L. Hercot[1], L. Quirynen[1], M. Tasset[1], N. Verbrugge[1], N. Godeau[1], P. Dumont[1], F. Marenne[1], X. Franci[1]; [1]Trasis SA, Ans, BELGIUM, [2]ÚJV Řež, a. s., Brno, CZECH REPUBLIC.*

Aim/Introduction: With the increasing number of different PET radiotracers that commercial radiopharmacies are required to deliver nearly simultaneously and on daily basis, quality control (QC) of the radioactive drugs is becoming a limiting factor. Moreover, QC operations are a main source of radiation exposure to the staff. Trasis has developed a compact device, called QC1, enabling at this stage 10 different tests to be carried out automatically from a single sample. Applied to FDG as a first tracer, the analytical performance of the QC1 with its ready-to-use consumables is compared with the results obtained in parallel from separate conventional analytical instruments on more than 30 batches at commercial activity levels. ***Materials and Methods:*** The following QC tests and measurements are addressed : appearance - color and clarity, radioactivity concentration, pH, K222 or TBAOH spot tests, radiochemical purity by TLC, radionuclide identity, half-life, and purity, as well as residual solvents by GC, within 30 minutes from a single 300µL sample. ***Results:*** The results obtained on the first QC1 commercial units are in line with measurements from conventional instruments. Extension of the equipment beyond the FDG example is also addressed, such as residual solvent methods for up to 6 different solvents (acetone, THF, methanol, 2-butanone, ethanol and acetonitrile), and also methods for 11C tracers. All the data collected are compiled into a comprehensive report next to acceptance criteria and complete traceability informations on the analytical process from equipment, consumable, reference standards and software stand point are provided. They meet the criteria of the European and American pharmacopoeias. ***Conclusion:*** In radiopharmacy, the automation of quality control is a crucial axis of development (e.g., ALARA principle, budget constraints, shortages & dependence on specialized skills).This highlights the increasing integration of automation technologies not only in production but also in quality control, further enhancing its qualitative added value (e.g., standardization, traceability).We demonstrate that with an automated process, QC1 analyzes the quality of a drug based on a single sample (300µL) with improved reliability over conventional

quality control, notably by reducing human errors (e.g. handling, visual interpretation).The integration of instruments (e.g., GC, SG, TLC Reader, Spectrometric Readings), and the upcoming arrival of an HPLC module directly integrated into the QC1, makes it versatile and paves the way for a wide variety of future developments.

EP-1035

Synthesis and quality control of [^{68}Ga]Ga-DOTATOC cold kits produced with two simultaneous elutions from different models of GMP generators

S. Benkhoris[1], *J. Vanney[2], D. Alizé[1], L. Barthelemi[1], L. Rubira[2], P. Kotzki[1], C. fersing[2];*
[1]Centre hospitalier universitaire de Nimes, Nimes, FRANCE, [2]ICM Montpellier, Montpellier, FRANCE.

Aim/Introduction: Over the past 20 years, gallium-68 PET imaging has raised increasing interest. Obtained from 68Ge/68Ga radioelement generator, some of which being available in GMP-grade quality, 68Ga allows in-house preparation of single vial cold kits (e.g. [68Ga]Ga-DOTATOC, SOMAKIT®). However, activity levels involved in the preparations of such radiopharmaceuticals decrease over time as the 68Ge/68Ga generator decays, limiting the number of examinations per preparation. Thus, generators can be resupplied before expiry date and used for a few months in combination with a new one. Besides, different suppliers may be selected in case of a new call for tenders, raising the question of production using two different generators. To validate a method for preparing [68Ga]Ga-DOTATOC cold kits using two generators concomitantly, either identical or from different suppliers. ***Materials and Methods:*** A total of five [68Ga]Ga-DOTATOC syntheses were carried out : three with double GALLIAD® (IRE) generators elutions in manual mode and two with elutions from a GALLIAD ® (IRE) generator coupled with a GALLIAPHARM®(Curium) generator, in automated mode using a GAIA® module (Elysia-Raytest). At the end of synthesis (EoS), activites were measured and quality controls were performed: organoleptic characteristics, pH, sterility tests, bacterial endotoxin tests and radiochemical purity, by both TLC and HPLC, immediately after EoS (H0) and every hour for 4 hours (H1 to H4). ***Results:*** Mean activity measured at EoS when using two GALLIAD® generators was 1590 ± 57 MBq. PRC at H0 by TLC and HPLC was > 95% and >90%. The pH was 3.6. For the two syntheses made with a GALLIAD® plus a GALLIAPHARM®, activities at EoS were 1334 ± 206 MBq. PRC at H0 was > 98.24% in TLC and > 98.81% in HPLC. The pH was 3.2. All the preparations were stable between H0 and H4. Endotoxin and sterility tests were negative for all preparations. With such radiolabeling conditions, more than 10 PET examinations can be performed per synthesis, compared with 7 with a single generator at start of use. ***Conclusion:*** Automated production of [68Ga]Ga-DOTATOC with two generators was successful for all the syntheses performed. The combination of identical and dissimilar generators, as well as use of manual and automated method allowed adaptation to different radiolabeling setups. This dual-generator synthesis is an option for optimizing kits and prolonging generators and reducing costs. In addition, it would be interesting to investigate the use of two GALLIAPHARM® generators, in order to suit all possible configurations.

EP-1036

First Fully Automatized In-house Synthesis of[^{177}Lu]Lu-DOTA-TOC in Bosnia and Herzegovina

A. Stankovic, *Z. Rajkovaca;*
University clinical centre of the Republic of Srpska, Banja Luka, BOSNIA AND HERZEGOVINA.

Aim/Introduction: [177Lu]Lu-DOTA-TOC is a beta particle-emitting radioactive agent indicated for the peptide receptor radiotherapy (PRRT) of advanced neuroendocrine tumours (NET). The substance is characterized by affinity to somatostatine receptors, which are overexpressed in NET patients. Since 2022, the Department of Nuclear Medicine in Banja Luka has opened a laboratory where the synthesis of radiopharmaceuticals for theranostic is possible. The aim was to develop and automate the in-house synthesis of [177Lu]Lu-DOTA-TOC to improve NET patient management in our clinical centre. ***Materials and Methods:*** Using a fully automated cassette-based theranostics synthesizer, a radiolabelling process was developed. The complexation reaction was performed in ascorbate buffer at pH 4-5 and with thermal heating (90°C for 33 min) of 115 µg DOTA-TOC and 8,0-8,4 GBq of 177Lu. At the end of the complexation, elution of the drug substance through a sterile filter into the product vial was performed. Then, saline was added to dilute the solution and the final volume of the product was 20mL. Regarding quality control, the radiochemical purity (RCP) of [177Lu]Lu-DOTA-TOC was determined by radio-HPLC and TLC. Two mobile phases were used for TLC based on ITLC-SG strips as a solid phase. The first mobile phase was 0,1 M citrate buffer pH 5,5 and the second mobile phase was ammonium acetate 1 M /methanol 1:1. Confirmation of the identity of [177Lu]Lu-DOTA-TOC was done by UV HPLC using a non-radioactive standard. Following European Pharmacopoeia, sterility and endotoxin tests were performed. An automated filter integrity test was performed on the final sterile filter. ***Results:*** The three validation batches of [177Lu]Lu -DOTA-TOC were synthesized with an activity of 7,55 ± 0,15 GBq and production yield of 92,32 ± 0,08. The application volume was from 19 mL to 20 mL. The RCP determined by HPLC was 99,6 ± 0,5% and with TLC was 99,2 ± 0,5%. The [177Lu]Lu-chloride and [177Lu] Lu -colloid determined by TLC were quantified and the results obtained were 0,7, 0,14, and 0,31% for [177Lu]Lu-chloride and 0,4, 0,2, and 0,4% for [177Lu]Lu-colloid respectively. The retention time comparison between the standard and [177Lu]Lu-DOTA-TOC was inferior to 12s. The bubble point test passed for each batch. The drug products were sterile and endotoxin-free. ***Conclusion:*** The automatized synthesis of [177Lu]Lu-DOTA-TOC was successfully implemented in our department. The reproducibility and the cost of this in-house synthesis give an opportunity to increase the access of the patient with NET to this innovative therapeutic radiopharmaceutical for this region.

EP-1037

Development of Kit-Composition for the Preparation of [^{99m}Tc]Tc-PSMA-GCK01 / RHN001-DX

J. Cardinale[1], *C. Kratochwil[2], H. Ndlovu[3], E. Mamlins[1], E. Novruzov[1], M. Sathekge[3], U. Haberkorn[2], F. Giesel[1];*
[1]University Hopital Duesseldorf, Department of Nuclear Medicine, Duesseldorf, GERMANY, [2]University Hopital Heidelberg, Department of Nuclear Medicine, Heidelberg, GERMANY, [3]Steve Biko Academic Hospital, University of Pretoria, Pretoria, SOUTH AFRICA.

Aim/Introduction: Albeit known for a long time, the theranostic pair 99mTc / 188Re has found few applications. With our recently published PSMA ligand PSMA-GCK01 [1] we try to apply this promising pair for the disclosure of PSMA-theranostics to low-income countries. An important cornerstone is the availability of reliable kit-technology. Here we report on our results developing a kit for 99mTc-labelling of PSMA-GCK01 (RHN001-DX). ***Materials and Methods:*** Kit composition was adapted from [2]. All chemicals used for the kit development were of pharmaceutical

grade. The precursor was provided by a commercial supplier in >95 % purity. Test reactions were conducted under without extensive precautions such as exclusion of atmospheric oxygen in 2 ml Eppendorf vessels. The test kits were heated at different temperatures for approx. 10 minutes. The product was analyzed by iTLC for free pertechnetate and radiocolloids. Important results were confirmed by radio-HPLC. First goal is a reliable RCY/RCP > 90%, while our "break-even" was defined as RCY/RCP > 95%. ***Results:*** First successful kits were composed using SnCl2 as reducing agent. Sodium citrate, Mannitol and ascorbic acid were used as buffer and/or auxiliary reagents. The necessary purity was met at 80 °C & 100 °C for 10 minutes with values of free pertechnetate and radio colloids of approx. 2-5 %, each. Currently we are fine-tuning the reagent composition aiming at RCP > 97.5 % and planning robustness testing using different generators (Curium, Rotop and Monrol). ***Conclusion:*** We have successfully adapted a reagent composition for the kit based production of [99mTc]Tc-PSMA-GCK01. Temperature and heating conditions were chosen "conservatively", so that the final kit will provide the product in a broad temperature range of 90 ± 10 °C and reaction times of approx. 15 minutes. The choice of broad reaction conditions without protection against oxygen will secure a high level of robustness for the final kit applying GMP grade materials. ***References:*** [1] J. Cardinale et al., J Nucl Med 2023, 64, 1069-1075. [2] L. L. Fuscaldi et al., Front. Chem. 2023, Online Publication, DOI10.3389/fchem.2023.1271176.

^{18}F-FDG PET/CT in a case of SMARCA4-deficient poorly differentiated non-small cell lung cancer

Y. Ma, *Y. LI, X. LI;*
Department of Nuclear Medicine, The First Hospital of China Medical University, Shenyang, CHINA.

Aim/Introduction: SMARCA4-deficient in poorly differentiated non-small cell lung cancer is a newly discovered pathological type in recent years. This is a rare tumor with poor differentiation, high malignancy and poor prognosis. We report a case of poorly differentiated non-small cell lung cancer with SMARCA4-deficient 18F-FDG PET/CT showing focal FDG uptake. This case suggests that 18F-FDG PET/CT may be useful in the diagnosis of SMARCA4-deficient poorly differentiated non-small cell lung cancer. ***Materials and Methods:*** A 70-year-old male patient with sputum and dyspnea was admitted to hospital for six months. The patient underwent CT and enhanced CT imaging. 18F-FDG PET/CT was used to further identify the cause. ***Results:*** Early diagnosis and staging of SMRCA4-deficient lung cancer is helpful to improve the prognosis of patients. Studies have shown that the primary lesions and metastases of SMRCA4-deficient lung cancer show a strong affinity for 18F-FDG, suggesting that 18F-FDG PET/CT has potential clinical value in the diagnosis and staging of SMRCA4-deficient lung cancer, which still needs to be further explored. ***Conclusion:*** In this case, 18F-FDG PET/CT showed a case of SMARCA4-deficient poorly differentiated non-small cell lung cancer with lymph node metastasis, which provided a strong molecular imaging basis for clinical diagnosis and staging.

EP-1039

Case report: ^{18}F-FDG PET/CT revealing unexpected life-threatening massive neoplastic thrombosis and incidental new primary breast cancer in a patient monitored for recurrent metastatic hepatocellular carcinoma

S. Proto[1], *L. Zanoni[2], A. Palloni[3], G. Brandi[3,4], M. Barakat[5], S. Fanti[2,1];*
[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [3]Medical Oncology, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, ITALY, [5]Pediatric and Adult CardioThoracic and Vascular, Oncohematologic and Emergency Radiology Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: A 75-year-old woman affected by recurrent metastatic hepatocellular carcinoma underwent a ^{18}F-FDG PET/CT scan for comprehensive restaging; although asymptomatic, her medical history included multiple liver resections and a recent (2 months prior) adrenal gland resection, pathologically confirmed as metastasis. ***Materials and Methods:*** The patient was addressed by the referring Oncologists to the Nuclear Medicine Unit to perform a ^{18}F-FDG PET/CT as part of standard clinical practice for routine follow-up and restaging. Subsequent ^{18}F-FDG scans, approximately 3 and 9 months later, were also performed and reported. The patient signed written informed consent for data treatment and imaging publication. ***Results:*** The initial FDG PET/CT scan revealed intense uptake consistent with neoplastic pulmonary thromboembolism (SUVmax= 8.4) and thrombosis in subdiaphragmatic vessels, including the inferior vena cava (IVC) (SUVmax= 15.9), left renal vein and left gonadal vein. Additionally, diffuse, heterogeneous intense uptake was depicted along the stomach wall (SUVmax= 9.4), suggesting tumour invasion, and focal moderate uptake was noted in the left breast (SUVmax= 5.8).The patient was addressed to the Emergency Department to perform an urgent AngioTC, which confirmed the presence of massive thrombosis, leading to initiation of appropriate medical treatments, including anticoagulation therapy for thrombosis and immunotherapy for progressive metastatic hepatocellular carcinoma. Histological confirmation subsequently identified the breast lesion as a primary invasive mucinous carcinoma, prompting initiation of hormonal therapy. Due to the high risk of bleeding, determination of stomach wall invasion was deferred.Three months later, an interim FDG PET/CT showed pulmonary progression (SUVmax= 12.3) along with persistent venous thrombosis (SUVmax in the IVC = 10.5), confirmed to be of neoplastic origin: no increase in anticoagulant therapy was deemed necessary. The focal FDG uptake, corresponding to the breast carcinoma, was fully normalized, suggesting response to hormonal therapy.The final scan at 9 months showed progressive disease with lumbar canal invasion, prompting initiation of second-line immunotherapy. ***Conclusion:*** Although it is already reported that thrombosis might show significant ^{18}F-FDG uptake when neoplastic, this case highlights the crucial role of FDG PET/CT in uncovering unexpected, rare and life-threatening complications of metastatic hepatocellular carcinoma, represented by neoplastic pulmonary and subdiaphragmatic vessel thrombosis. In addition, the simultaneous, incidental detection of a new primary breast cancer further emphasizes the diagnostic sensitivity and clinical impact of PET/CT. This case can be encountered within "actionable PET imaging findings" requiring prompt report communication for timely receipt of the information and related clinical interventions.

EP-1040

^{18}F-FDG PET/CT and 68Ga-DOTA-NOC PET/CT in large cell neuroendocrine carcinoma of the lung with myocardial metastasis mimicking primary heart tumor

***S. Stanzel*[1],** *L. Brcic*[2], *B. Pernthaler*[1], *J. Schmid*[3], *E. Plhak*[1], *R. M. Aigner*[1];
[1]*Medical University of Graz, Department of Radiology, Division of Nuclear Medicine, Graz, AUSTRIA,* [2]*Medical University of Graz, Diagnostic & Research Institute of Pathology, Graz, AUSTRIA,* [3]*Medical University of Graz, Department of Radiology, Division of General Radiology, Graz, AUSTRIA.*

Aim/Introduction: Large cell neuroendocrine carcinoma (LCNEC) of the lung is a rare high-grade NET with a prevalence of approximately 3% of resected lung carcinomas. At diagnosis, the tumor often presents with local invasion, thoracic lymph node metastases, and distant spread, resulting in poor prognosis. Myocardial metastases of neuroendocrine tumors (NET) are extremely rare, occurring in 0.7% to 2.4% of NET patients. The most common tumors affecting the heart are metastases from primary lung cancer, followed by breast cancer and hematological malignancies such as lymphoma. We herein present a case of a 76-year-old male presenting with myocardial metastasis of LCNEC in cardiac MRI and 18F-FDG PET/CT and identification of primary tumor in 68Ga-DOTA-NOC PET/CT. ***Materials and Methods:*** 18F-FDG PET/CT was performed on a Discovery ST PET/CT system (GE Healthcare) 65 minutes after injection of 346.7 MBq of 18F-FDG. 68Ga-DOTA-NOC PET/CT was performed on a Biograph mCT 40 PET/CT system (Siemens) 60 minutes after injecting 162 MBq 68Ga-DOTA-NOC. ***Results:*** A 76-year-old male presented with a 5.5 cm right ventricular tumor with significant tracer uptake and a faint lesion centrally in the left lower lobe of the lung in 18F-FDG PET/CT. After resection, the right ventricular tumor was diagnosed as an atypical carcinoid G3, which was regarded as a myocardial metastasis from a neuroendocrine tumor (NET) of another organ. A subsequent postoperative 68Ga-DOTA-NOC PET/CT revealed a significant somatostatin receptor (SSR)-positive lesion centrally in the lower lobe of the left lung with a 1.2 cm size, which was afterward resected. Histopathology revealed an LCNEC, which favors the lung as the primary tumor, showing faint tracer uptake in 18F-FDG and significant uptake in 68Ga-DOTA-NOC PET/CT. Due to multiple SSR-positive mediastinal lymph node metastases and one soft tissue metastasis in 68Ga-DOTA-NOC PET/CT, the patient received 4 cycles of 177Lu-DOTA-TATE peptide receptor radionuclide therapy (PRRT), resulting in partial response with disappearance or regression of the metastases. ***Conclusion:*** This case report shows the existence of LCNECs with predominant 68Ga-DOTA-NOC uptake reflecting preserved somatostatin-receptor expression even in high-grade NET. In conclusion, in myocardial metastasis of LCNEC, both 68Ga-DOTA-NOC and 18F-FDG PET/CT are necessary for therapy planning and staging. However, 68Ga-DOTA-NOC PET/CT can help identify the primary tumor and thus be more sensitive than 18F-FDG PET/CT. In addition, 68Ga-DOTA-NOC PET/CT alone offers a tailored therapeutic approach with PRRT.

EP-1041

A Case of Metabolic Response byFDG PET/CT in Evaluation of Therapy Response for Blastic Plasmacytoid Dendritic Cell Neoplasm

S. Wang, *Y. Li, X. Li;*
The First Hospital of China Medical University, Shenyang, CHINA.

Aim/Introduction: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare and aggressive hematological malignancy of plasmacytoid dendritic cells. ***Materials and Methods:*** A 48-year-old woman with a biopsy-proven BPDCN underwent FDG PET/CT twice for therapy response evaluation. ***Results:*** After treatment in our hospital with venetoclax, FDG PET/CT revealed relatively high activity in the cutaneous nodule in the right forearm. After adjusting the chemotherapy management decision, metabolic response by FDG PET/CT revealed that the activity of the primary lesion was significantly reduced, accompanied by the shrinkage of the cutaneous nodule. ***Conclusion:*** FDG PET/CT is a suitable strategy to assess therapy response in clinical oncology.10 The activity changes before and after treatment can indicate the therapy response, and can also timely indicate the recurrence and metastasis of the disease. FDG PET/CT is crucial in evaluating of therapy response and adjusting chemotherapy management decision of BPDCN. ***References:*** 1. Pemmaraju N, Wilson NR, Khoury JD, et al. ^{18}F-FDG PET/CT in the Diagnosis of a Collision Tumor of Endometrial Adenocarcinoma and Mantle Cell Lymphoma: A Case Report

A. Leiva Montejo, *A. De Agrela Serrao, C. Ruiz Corbalan, G. Martinez Gomez, A. Hernandez Martinez, M. Castellon Sanchez, L. Frutos Esteban, J. Navarro Fernandez, T. Rodriguez Locarno, T. Moreno Monsalve, M. Ibañez Ibañez, N. Sanchez Izquierdo, L. Mohamed Salem, J. Contreras Gutierrez;*
Hospital Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: The appearance of primary neoplasms in the same individual has been described in the literature and is relatively common. These neoplasms can be of the same or different histological types and can appear simultaneously or separated in time. The appearance of two histologically different neoplasms affecting the same tissue or organ is called a "collision tumor". ***Materials and Methods:*** A 73-year-old woman patient who was diagnosed 7 years ago with clear cell adenocarcinoma of the endometrium (CCAE) underwent extensive surgery. After that, a ^{18}F-FDG PET/CT control showed retroperitoneal and pelvic adenopathies up to 1.6 cm (SUVmax 9.0) so her treating doctors decided to give her chemotherapy and radiotherapy at the

same time and follow-up every 6 months, achieving complete response. 5 years after the diagnosis, a computed tomography (CT) showed a new retroperitoneal paraaortic lesion, so it was recommended to perform an ^{18}F-FDG PET/CT to determine the origin. ***Results:*** The ^{18}F-FDG PET/CT was performed, showing supra/infradiaphragmatic adenopathies with malignant metabolic characteristics, the most significant were left laterocervical and supraclavicular adenopathies up to 0.9 cm (SUVmax 8.3). Excision of the left supraclavicular adenopathy was performed, and the biopsy showed a mantle cell lymphoma (classic) in the lymph node with metastasis of high-grade gynecological adenocarcinoma Ki67 <30%. It was decided to start first-line treatment for the lymphoma until completing 6 cycles. Currently, the patient is in minimal morphometabolic progression of the infradiaphragmatic adenopathies. Given these results, since the lesions are not biopsiable and after the normalization of tumor markers (CA 125), it was decided to follow up closely. ***Conclusion:*** The coexistence of a carcinoma and a lymphoma affecting the same lymph node is rare. A review of the literature shows that the primary neoplasm in these cases is usually a low-grade lymphoma, which has generally been diagnosed years before the appearence of the epithelial neoplasm. High-grade lymphomas have been described less frequently. Probably the relatively indolent course of low-grade lymphomas allows enough time for a second epithelial neoplasm to develop. However, in our case, the CCAE was diagnosed first and, years later, the diagnose of the mantle cell lymphoma was done, which is a high-grade lynphoma. To sum up, the possibility of a collision tumor is infrequent but should be considered due to its therapeutic implications. The identification of a second neoplasm may require a therapeutic strategy modification and it also has a negative impact on patient survival.

EP-1043

A Case Report: Primary Renal Lymphoma Presenting with a Pathological Femur Fracture

N. Aydin, *G. Mutevelizade, B. C. Bozdemir, E. Sayit Bilgin;*
Celal Bayar University, Manisa, TÜRKIYE.

Aim/Introduction: The absence of lymphatic tissue in the kidney makes primary renal lymphoma (PRL) a rare occurrence. While PRL is generally unilateral in adults, it can be bilateral in pediatric patients. PRL lacks definitive clinical symptoms and can be confused with renal cell carcinoma, renal abscess, and other metastases. Patients with PRL may present with hematuria, acute/chronic renal failure, flank pain, or weight loss. ***Materials and Methods:*** A 57-year-old female patient presented with a right femur diaphysis pathological fracture. Direct radiography revealed reduced bone density along the femur diaphysis, cortical irregularities, and periosteal reaction, prompting an F^{18} FDG PET/CT scan for primary malignancy investigation. The F^{18} FDG PET/CT scan identified an exophytic, malignant-appearing mass approximately 27x53 mm in size in the right kidney's mid-section anteriorly, along with conglomerate metastatic lymph nodes in the abdomen and pelvis. A soft tissue component causing destruction in the right femur cortex was also observed. A tru-cut biopsy of the mass in the right kidney was performed under ultrasound guidance. The biopsy was reported as compatible with Diffuse Large B-Cell Lymphoma originating from the germinal center, exhibiting CD20(+), BCL-2(+), CD10(+), BCL-6(+) immunophenotype. At diagnosis, the patient had no B symptoms (weight loss, night sweats, fever), and her hemogram parameters, kidney, and liver function tests were within normal limits. ***Results:*** The patient was planned to undergo 4 cycles of R-CHOP chemotherapy (cyclophosphamide, doxorubicin, vincristine, prednisone, rituximab) and 5 cycles of palliative radiotherapy to the femur. An interim F^{18} FDG PET/CT scan post-chemotherapy showed significant regression of the renal mass and lymph nodes, evaluated as score 2 according to Deauville response criteria. ***Conclusion:*** Primary renal lymphoma is a rare and controversial type of lymphoma due to the normal kidney structure's lack of lymphoid tissue. The whole-body scanning capability of F^{18} FDG PET-CT is critically important for detecting the disease's primary focus, identifying extranodal lesions, and monitoring the treatment process. In the presented case, in addition to conventional imaging methods, F^{18} FDG PET-CT detected not only the renal mass but also lymph node involvement in abdominal and pelvic areas. Despite receiving a diagnosis of diffuse large B-cell lymphoma through tru-cut biopsy, the detection of extrarenal involvement opened discussions regarding the diagnosis of primary renal lymphoma. In differential diagnosis of renal masses, primary renal lymphoma should be considered as a rare but possible option.

EP-1044

Unmasking an Incidental Tenosynovial Giant Cell Tumor on FDG PET/CT in a Melanoma Patient

A. Sadija, *S. Ceric, T. Ceric;*
Clinical Center of University in Sarajevo,
Sarajevo, BOSNIA AND HERZEGOVINA.

Aim/Introduction: Tenosynovial giant cell tumor (TSGCT) is a benign, yet metabolically active tumor affecting the synovium, bursa, or tendon sheath. ***Materials and Methods:*** Case report: We present a 48-year-old male with malignant melanoma undergoing FDG PET/CT surveillance. ***Results:*** A highly FDG-avid mass in the right foot raised concern for melanoma metastasis. However, biopsy revealed an unexpected diagnosis of TSGCT. ***Conclusion:*** This case highlights the importance of FDG PET/CT in diagnosis of extraosseous lesions, particularly in cancer patients. In such scenarios, considering alternative diagnosis and pathohistological diagnosis confirmation becomes crucial to avoid misdiagnosis of metastases.

EP-1045

^{18}F-FDG-PET/CT Findings and Surgical Outcome in a Case of Nodular Pulmonary Amyloidosis

A. Leiva Montejo, *C. Ruiz Corbalan, A. De Agrela Serrao, G. Martinez Gomez, T. Moreno Monsalve, M. Castellon Sanchez, A. Hernandez Martinez, T. Rodriguez Locarno, J. Navarro Fernandez, L. Frutos Esteban, N. Sanchez Izquierdo, M. Ibañez Ibañez, L. Mohamed Salem, J. Contreras Gutierrez;*
Hospital Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: Primary nodular pulmonary amyloidosis(PNPA) deposits as a solitary amyloid mass in the lungs without evidence of systemic amyloidosis(SA). It is extremely rare and can mimic primary bronchogenic carcinoma. It is usually an incidental finding and its diagnosis is difficult because initial symptoms, laboratory tests and imaging are more related to common diseases. While the gold standard for diagnosis is green birefringence of Congo red staining on biopsy, this procedure could be invasive and risky in the respiratory tract. ***Materials and Methods:*** A 72-year-old male patient was being studied for an hematoma in the left lumbar and costal region. A computed tomography was performed, which showed necrotizing fasciitis of the left hemithorax and hemiabdomen wall and, as an incidental finding, a 1.6 cm irregular nodule was observed in the parahilium of the right middle lobe(ML). Therefore, an ^{18}F-FDG-PET/CT

and bronchoscopy were recommended for further evaluation. ***Results:*** The PET/CT showed a 1.8 cm peribronchial nodule in the ML with increased glucose metabolism (SUVmax 2.7), lesion that cannot exclude low grade malignancy. A core needle biopsy(CNB) of the nodule was performed without finding a neoplasia. However, given its morphological characteristics and fast growth, the multidisciplinary committee decided to perform a medial lobar lung lobectomy with an anatomopathological result of tumor cells of lambda light chain amyloidoma, which is usually related to local amyloidosis. The following studies were performed for diagnosis: probability of monoclonal gammopathy: no M component, serum immunofixation: IgG Kappa paraprotein in very low concentration, urine immunofixation: negative, bone marrow aspirate: normohypercellular without plasma cell infiltration, abdominal fat pad CBN: amyloid negative and blood smear and normal hemogram. So SA was excluded. Follow-up was performed with PET/CT that showed post-surgical changes without evidence of new suspicious lesions. Currently, the patient is in complete remission after first-line treatment (ML lobectomy). ***Conclusion:*** The diagnosis PNPA is extremely rare, due to the unusual nature of the condition, but also because patients are often asymptomatic and the mass growth is usually slow. Its early detection with PET/CT might be difficult at first because it could not differentiate PNPA from other more frequent diseases such as infections and/or neoplasms but it is important in order to know its metabolic behavior (high FDG uptake), the extension and to prevent the destruction of adjacent tissues. Therefore, the resection of the amyloidoma is recommended as a treatment to reduce its destructive impact and improve respiratory function.

EP-1046

Distinguishing Ovarian Metastases from Primary Ovarian Tumors: The Value of ^{18}F-FDG PET/CT in a Patient with Pancreatic Adenocarcinoma

A. Leiva Montejo, *G. Martinez Gomez, A. De Agrela Serrao, C. Ruiz Corbalan, T. Moreno Monsalve, A. Hernandez Martinez, J. Contreras Gutierrez, M. Ibañez Ibañez, N. Sanchez Izquierdo, L. Frutos Esteban, J. Navarro Fernandez, L. Mohamed Salem, M. Castellon Sanchez;*
Hospital Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: Between 5-22% of ovarian metastases (OM) are originated from non-gynecological cancers, mainly of the digestive tract (80%), of which the pancreas represents only 5-12%. Therefore, OM from the pancreas in women are very rare in clinical practice, difficult to early diagnose and generally miss the surgical treatment,which gives them an unfavorable prognosis ***Materials and Methods:*** A 66-year-old woman under oncological follow-up for treated lung adenocarcinoma and a second neoplasm, pancreatic adenocarcinoma, which was surgically intervened (corporocaudal pancreatectomy). The patient was asymptomatic. CA 19.9 levels were slightly elevated and CA 125 was within normal limits. ***Results:*** A ^{18}F- FDG PET/CT control showed a slight hilar thickening of the right lung, with a slight metabolic increase SUVmax 2.9 (previously 2.4), without signs of recurrence. Additionally, a nodular lesion was observed in the pancreatic bed measuring 0.8 cm with a focal FDG uptake SUVmax 4.1 (previously 4.8), slightly lower than the previous study, which could be related to persistence of viable tumor tissue. New-onset peritoneal implants were also seen, one in the mesogastrium immediately posterior to the right rectus abdominis muscle measuring 1.6x1.7 cm with SUVmax 10.2 (accessible for biopsy) and another measuring 1.2 x 2.0 cm adjacent to the descending colon segment with SUVmax 10.4. Finally, newly appearing solid-cystic lesions in the bilateral ovaries were described, on the right measuring 3.5x2.7 cm with SUVmax 14.5 and on the left measuring 3.8x 3.5 cm with SUVmax 14.0, both suggestive of malignancy. Subsequently, biopsies of the peritoneal nodule and right ovary were performed, revealing cylinders of desmoplastic stroma occupied by pancreatic adenocarcinoma. ***Conclusion:*** Generally, pancreatic metastases affect both ovaries and appear simultaneously. It could be difficult to distinguish OM from pancreas and primary mucinous ovarian tumors by imaging techniques and histopathological examination. Although these last confirm the diagnosis, PET/CT can help to differentiate them, since it detects pathological uptake in the rest of the body and can find the primary tumor and its metastatic behavior. Finally, surgical resection remains the treatment of choice in this cases combining pancreatectomy and salpingo-oophorectomy.

EP-1047

The Role of 99mTc-Labeled Heat-Denatured Red Blood Cell Scintigraphy in Differentiating Intrapancreatic Accessory Spleen from Neuroendocrine Tumor

A. Leiva Montejo, *A. De Agrela Serrao, C. Ruiz Corbalan, G. Martinez Gomez, T. Rodriguez Locarno, T. Moreno Monsalve, A. Hernandez Martinez, N. Sanchez Izquierdo, M. Ibañez Ibañez, M. Castellon Sanchez, L. Frutos Esteban, J. Navarro Fernandez, L. Mohamed Salem, J. Contreras Gutierrez;*
Hospital Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: Ectopic splenic tissue presence in the abdominal cavity has been reported in the general population at a rate of 10 to 15%. There are two categories to describe this entity: splenosis secondary to trauma or splenectomy, and accessory spleen, considered a congenital duplication. Its intrapancreatic presence is observed in 1 to 2% of cases. Generally, these anomalies remain asymptomatic, so they are mostly discovered as incidental findings. The importance of these cases lies in their potential to be misdiagnosed as pancreatic neoplasms, leading to unnecessary laparotomies. ***Materials and Methods:*** A 41-year-old woman was initially referred from primary care due to a weight loss of about 10 kg over 4 months without any diet restriction. She was evaluated by a gynecologist who did not find any related disease. A computed tomography(CT) revealed a 2 cm solid nodule in the pancreatic tail with homogeneous enhancement, that was suspicious of a neuroendocrine tumor. Days later, a magnetic resonance imaging(MRI) described a nodular lesion adjacent to the pancreatic tail suggestive of anaccessory spleen. Finally, after consulting with nuclear medicine a 99mTechnetium(TC) labeled heat-denatured red blood cell scintigraphy was done. ***Results:*** A sequential scintigraphic study was performed following intravenous administration of 537 Megabecquerels of 99mTC labeled heat-denatured redblood cells, obtaining static abdomen images at 30 and 120 minutes that did not show any pathological uptake of the radiopharmaceutical at theoretical locations of clinical interest. In addition, an abdominopelvic SPECT-CT was performed, that showed a focal uptake coinciding with a 1.6 cm nodular lesion in the pancreatic tail, suggestive of a peripancreatic accessory spleen. ***Conclusion:*** Imaging studies are important diagnostic techniques that are useful in the study of intrapancreatic accessory spleen, as they determine the morpho-metabolic characteristics of the lesions. MRI shows a similar intensity between the accessory spleen and the normal spleen. CT is not useful for differentiating this entity from a neuroendocrine neoplasm, hence the recommendation of a 99mTC labeled heat-denatured red blood cell scintigraphy, that shows an increased uptake in the intrapancreatic accessory spleen but not in the

neuroendocrine neoplasm. Furthermore, when it is combined with SPECT-CT, it offers great sensitivity and specificity, avoiding unnecessary surgeries.

EP-1048

Penile Metastasis of Prostate Cancer Imitating Peyronie's Disease Detected on [^{68}Ga]Ga-PSMA-11 PET/CT

I. Rogic, *M. Rubic, D. Huic;*
University Hospital Centre Zagreb, Zagreb, CROATIA.

Aim/Introduction: [68Ga]Ga-PSMA-11 PET/CT (Gallium prostate-specific membrane antigen positron emission tomography/computed tomography) is an established molecular imaging technique for identifying the spread of prostate cancer in patients with biochemical recurrence (BCR) and in initial staging. Penile metastases of prostate cancer are very rare and can be easily misdiagnosed as noncancerous nodules as part of Peyronie's disease. Most cases of penile metastases are in patients where the disease is already disseminated and usually diagnosed in the late stages. ***Materials and Methods:*** In our case, a 74-year-old patient with prostate cancer had a successful prostatectomy, ADT and radiation of prostate bed with PSAnadir of 0.01 ng/ml. Three and half years after surgery, biochemical recurrence occurred, and the patient was referred to our clinic for a [68Ga]Ga-PSMA-11 PET/CT scan. Before this scan, the patient had sought an evaluation from a urologist for a palpable lump under the skin of his penis, clinically consistent with an early stage of Peyronie's disease. ***Results:*** PET/CT showed pathological PSMA expression in a proximal part of the penile root, later confirmed with pathohistological analysis as prostate cancer metastasis. Our patient, with a PSA value of only 0.38 ng/ml has one of the lowest values of serum PSA and penile metastasis described in the available literature.Penile tissue metastases are exceedingly rare, despite the rich and intricate vascularization of the corpus cavernosum. The earliest case of penile metastasis was reported by Eberth in 1870 (1).In a retrospective study done by Tatkovic et al out of 4860 [68Ga]Ga-PSMA-11 PET/CT studies reported, the incidence of PC penile metastases was 0,1%. (2). Most literature describes these cases as occurring in patients with late-stage disseminated PC and being linked to poor prognosis. ***Conclusion:*** Our case affirms the importance of [68Ga]Ga-PSMA-11 PET/CT in the evaluation of patients with prostate cancer as it enables the detection of rare and unusual metastases. In patients with biochemical recurrence irrespective of PSA levels or in patients with a risk of undiagnosed cancer if clinical suspicion arises for Peyronie's disease, it is crucial to consider the differential diagnosis of penile metastasis. ***References:*** 1.Eberth C.J. Krebsmetastasen des corpus cavernosum penis. (Cancer metastases of the corpus cavernosum of penis) Virchows Arch. 1870;51:145.2.Tatkovic, A., McBean, R., Schoeman, J. and Wong, D. (2020), Prostate penile metastasis: Incidence and imaging pattern on 68Ga-PSMA PET/CT. J Med Imaging Radiat Oncol, 64: 499-504. https://doi.org/10.1111/1754-9485.13052.

EP-1049

^{18}F-FDG PET-CT Findings in an Unusual Case Of Paravertebral Giant Cell Tumor

R. Wakankar, *Y. Dharmashaktu, S. A. Shamim, S. Rastogi;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: A giant cell tumor is a benign tumor of bone. However, at times it may behave aggressively locally and can also metastasize. The stromal cell overly expresses RANKL expression, leading to increased osteoclastic activity. The typical age of occurrence is between 20 and 40 years, with a slight female predominance. More than 50% of GCT occurs around the knee joint. The frequency of GCT decreases in the following order, the distal end of the femur, proximal end of the tibia, distal radius, and sacrum. It rarely occurs at other sites. ***Materials and Methods:*** This case involved a 35-year-old woman who was initially worked-up for complaints of lower backache with associated neurological features which involved paraesthesia and motor weakness in the bilateral lower limbs at a local healthcare facility. She had undergone a magnetic resonance imaging (MRI) of her spine to look for evidence of intervertebral disc prolapse and nerve impingement. However, during the MRI she was incidentally found to have a right sided paravertebral mass that was eroding into the adjacent L2 vertebra and extending into the adjoining spinal canal. The mass was also seen to extend into the right upper quadrant up to the level of the right subhepatic region. Based on these clinical and radiological findings, she was diagnosed to have spinal tuberculosis (TB) and was started on anti-tubercular therapy (ATT). However, even after completing the appropriate course of ATT her clinical presentation continued to worsen. She was then transferred to our facility for further evaluation, where she underwent an F^{18}-labelled fluorodeoxyglucose (^{18}F-FDG) PET/CT to evaluate the metabolic activity of the paravertebral mass and to look for a suitable site for a biopsy. The PET/CT revealed a metabolically active mass in the right paravertebral region which was eroding into the adjacent L2 vertebra with intraspinal extension. ***Results:*** She underwent a surgical tumor biopsy, and to our surprise, the histopathology findings were indicative of a giant cell tumor (GCT). ***Conclusion:*** GCTs have a good prognosis when diagnosed and managed promptly. Local excision of tumor is curative in most patients. In case of unresectable tumors, neoadjuvant therapy with denosumab helps in decreasing the tumor size so that it becomes resectable. When GCTs occur at unusual sites, as seen in this case, diagnosis can get delayed. Therefore, this case serves as a teaching point for physicians who may be dealing with a similar conundrum.

EP-1050

Dual Ectopic Thyroid in an Adult Filipino Female as seen on Technetium-99m Pertechnetate Scintigraphy with SPECT/CT

L. Mariano, *E. Lim;*
The Medical City, Pasig City, PHILIPPINES.

Aim/Introduction: Dual ectopic thyroid is an extremely rare form of thyroid dysgenesis, with only a very few cases reported globally. This study aims to present the importance of thyroid scintigraphy in the diagnosis and management of an adult Filipino female with hypothyroidism suspectedly caused by ectopic thyroid tissue. ***Materials and Methods:*** This is a case of a 32 year-old Filipino female with hypothyroidism and ultrasound findings of an absent thyroid fossae with a midline focus superoanterior to the trachea. She was referred for thyroid scintigraphy to confirm the absence of normally-located thyroid and to investigate the presence of thyroid ectopia. ***Results:*** Planar imaging using Technetium-99m (Tc-99m) pertechnetate showed two foci of radiotracer uptake in the supra- and infrahyoid neck regions. Additional SPECT/CT images allowed localization of these two foci to the base of the tongue and left thyroid cartilage lamina, confirming the presence of two functioning thyroid tissues in these areas. ***Conclusion:*** This study further establishes that thyroid scintigraphy, using either radioiodine-131 or Tc-99m pertechnetate, remains the gold

standard for the diagnosis of ectopia. Moreover, the addition of SPECT/CT provides accurate localization of these ectopic sites. ***References:*** [1] Noussios G, Anagnostis P, Goulis DG, Lappas D, Natsis K. Axillary schwannoma mimicking lymphadenopathy in a patient with follicular lymphoma on ^{18}F-FDG PET/CT

Y. Cui, *X. Li, Y. Li;*
The First Hospital of China Medical University, Shenyang, CHINA.

Aim/Introduction: This case report presented a patient diagnosed as follicular lymphoma accompanied with axillary schwannoma on 18F-FDG PET/CT, which is rare and difficult to distinguish from primary malignancy. ***Materials and Methods:*** A 44-year-old man complained of pain in shoulder with cervical lymphadenopathy. Left cervical lymph node was excised and confirmed as follicular lymphoma. 18F-FDG PET/CT was performed for staging. ***Results:*** The MIP image (A) revealed intense FDG uptake in multiple organs. The soft-tissue lesion in left axilla presented with elevated FDG uptake (34mm; SUVmax, 2.2) was also considered as lymphadenopathy involved by lymphoma (B-D), compared to retroperitoneal involved lymph node(E-G).The patient started on chemotherapy for 3 cycles and underwent post-therapy PET/CT. Compared to the baseline imaging, metabolic activity and extent of disease were significantly reduced (H, MIP) with remaining hypermetabolic lesions at left axilla (34mm; SUVmax, 3.2; I-K) and retroperitoneum (14mm; SUVmax,3.8; L-N) , indicating a 4-point Deauville score. Biopsy of lesions in left axilla indicated schwannoma(O) compared to left cervical lymphoma(P). ***Conclusion:*** 18F-FDG PET/CT play an important role in staging and therapeutic evaluation in follicular lymphoma[1]. Schwannoma is a neoplasm arises from schwann cells of the peripheral nerve sheath, occuring in any organ, among which axillary schwannomas are rare[2]. Schwannomas may be intense and heterogeneous FDG avidity with average SUVmax 5.4 ± 2.7[3],making a dilemma for differential diagnose from malignancy. Several cases have indicated schwannoma mimicking lymph node metastasis in different malignancy[4,5]. In this case, PET/CT failed to distinguish schwannoma from lymphadenopathy, for the imaging manifestation of schwannoma was quite similar to lymphoma. In conclusion, schwannoma should be considered as a differential diagnosis of axillary masses when concurrent with lymphoma. ***References:*** 1. Ricard F, Cheson B, Barrington S, et al. EP-1052

^{68}Ga-PSMA-11 and ^{18}F-siPSMA-14 positive synchronous differentiated thyroid carcinoma in routine staging and restaging PET/CT scans of a patient with prostate cancer

M. Dyankova[1,2], *T. Stoeva[1], Z. Dancheva[1], S. Chausheva[1], T. Yordanova[1], B. Chaushev[1], A. Klisarova[1];*
[1]St. Marina University Hospital, Department of Nuclear Medicine, Varna, BULGARIA, [2]Medical University Varna "Prof. Dr. Paraskev Stoyanov", Department of Nuclear Medicine, Metabolic Therapy and Radiotherapy, Varna, BULGARIA.

Aim/Introduction: Thyroid cancer is the main endocrine neoplasia worldwide. Given the increased expression of carboxypeptidase type II in the vascular endothelium in the neovasculature of many solid tumors, increased 68Ga- prostate specific membrane antigen (PSMA) PET/CT uptake has been demonstrated in several non-prostate malignancies, including thyroid cancer. The increased expression of PSMA in the detected lesions - incidentalomas of the thyroid gland with 68Ga - PSMA are due to a malignant process up to 23.0% (1). ***Materials and Methods:*** A 67 old male diagnosed with prostate cancer undewent staging 68Ga PSMA PET/CT study and revealed tumor with increased PSMA expression, presented as bilateral malignant involvement of the peripheral zones of both lobes of the prostate, seminal vesicles and malignant infiltration of the urinary bladder (confirmed by MRI); as well as metastatic pelvic lymph nodes, without evidence of distant metastatic lesions. As an additional finding, an incidentaloma- nodular lesion in the left lobe of the thyroid gland with increased PSMA-expression was found. The patient underwent hormone therapy, and 4 months later, a reduction in PSA levels was reported at 5.73 ng/m. ***Results:*** A restaging PET/CT was performed with the newly synthesized radiopharmaceutical 18F-siPSMA-14, which revealed PSMA-active changes associated with PC (defining a partial response from the performed therapy). Increased PSMA expression was also demonstrated in a hypodense nodule involving the left thyroid lobe, persisting without significant dynamics compared to the previous scan (regarding size and activity). Ultrasonographic clarification of the finding and fine-needle aspiration biopsy were recommended. Subsequently, differentiated thyroid carcinoma, papillary type, was histologically verified ***Conclusion:*** The hybrid method using PSMA radiopharmaceuticals (18F-PSMA-14 and/or 68Ga-PSMA) in the presented clinical case, aided the diagnosis of differentiated thyroid carcinoma, which raised the question of their possible future application in thyroid cancer patients. The PSMA uptake mechanism is independent of the I-Na symporter and does not require levothyroxine suppression, moreover, the hybrid method can prematurely identify lesions with more aggressive potential that may undergo radioiodine refractoriness. Future prospective studies are needed to investigate the diagnostic value and possible advantages of the

hybrid method with PSMA radiopharmaceuticals (18F-PSMA-14 and/or 68Ga-PSMA), with a view to the possible expansion or supplementation of therapeutic options and the potential application of the principles of theranostics-PSMA -targeted radionuclide therapy for patients with limited therapeutic options. ***References:*** 1. Bertagna F, Albano D, Giovanella L, Bonacina M, Durmo R, Giubbini R, et al. 68Ga-PSMA PET Thyroid Incidentalomas. Hormones (Athens) (2019) 18(2):145-9.

EP-1053

Increased PSMA expression in synchronous neoplastic processes in patient with prostate cancer on PET/CT staging imaging with the newly synthesized radiopharmaceutical, a highly promising novel radiotracer ^{18}F-siPSMA-14

M. Dyankova[1,2], *T. Stoeva[1], Z. Dancheva[1], S. Chausheva[1], P. Ilieva-Gabarska[2], T. Yordanova[1], B. Chaushev[1], A. Klisarova[1]; [1]St. Marina University Hospital. Department of Nuclear Medicine., Varna, BULGARIA, [2]Medical University Varna "Prof. Dr. Paraskev Stoyanov", Department of Nuclear Medicine, Metabolic Therapy and Radiotherapy, Varna, BULGARIA.*

Aim/Introduction: Preliminary findings suggest that [18F]siPSMA-14 exhibits favorable kinetics for prostate cancer (PC) staging. Despite the rarity of synchronous 68Ga-labeled prostate-specific membrane antigen (PSMA)-avid malignancies in PC patients (0.7%), data on the utility of 18F-siPSMA-14 radiopharmaceutical remain sparse in the literature. ***Materials and Methods:*** A 69-year-old patient with histologically confirmed PC, Gleason score 5+4=9, and ISUP group 5, presented with an initial PSA level of 126.0 ng/ml. After initiation of endocrine therapy, a decline in PSA levels to 1.45 ng/ml was noted. ^{18}F-siPSMA-14 PET/CT staging imaging revealed, alongside changes related to the primary PC, two synchronous tumors exhibiting increased PSMA expression, subsequently confirmed histologically as rectal cancer and lung carcinoma. ***Results:*** PET/CT images demonstrated diffuse and heterogeneous increased PSMA expression throughout both prostate lobes, accentuated in the peripheral zones at the mid/apex level, indicative of primary PC. Additionally, two focal areas exhibiting heightened PSMA activity were identified: in the body of the right iliac bone and the body of Th8 vertebra, consistent with bone marrow metastatic lesions. Further synchronous tumors with increased PSMA expression were observed. The first, involving the rectum, appeared/manifested as irregular thickening of the intestinal wall, later confirmed as rectal adenocarcinoma via flexible colonoscopy and biopsy. The second synchronous tumor, characterized by parenchymal involvement with spiculated margins, was located peripherally in the upper lobe of the right lung. It displayed heterogeneous PSMA expression increase and pleural involvement, subsequently confirmed histologically as synchronous lung adenocarcinoma. A small subpleural nodular lesion ipsilateral to the lung adenocarcinoma was identified, warranting further characterization through contrast-enhanced CT and staging ^{18}F-FDG PET/CT examination. Additionally, bilateral cervical and mediastinal lymphadenopathy with increased PSMA expression were noted, likely related to synchronous lung cancer in the right lung. ***Conclusion:*** It is crucial to histologically confirm lesions exhibiting heightened ^{18}F-siPSMA-14 expression, even if they appear atypical for prostate cancer involvement. A thorough evaluation, taking into account the clinical background, morphological characteristics of the lesions, and additional imaging results, is vital to ascertain their relevance. The utilization of ^{18}F-siPSMA-14 holds considerable promise in broadening the scope of PSMA-targeted theranostics beyond prostate cancer.

Keywords: ^{18}F-siPSMA-14 PET/CT, synchronous primary lung cancer, synchronous primary rectal cancer. ***References:*** Medhat M. Osman, Amir Iravani, Rodney J. Hicks and Michael S. Hofman. EP-1054

^{99m}Tc-PSMA and ^{99m}Tc-FAPI-46 uptake in pulmonary lymphangitic carcinomatosis as a rare form of metastasis in a patient with prostate cancer: case report

N. Raeisiestabragh, *a. aghaee, K. Aryana; Nuclear medicine research center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: We presented a 70-year-old patient with the history of significant weight loss and lower urinary tract symptoms including hematuria, nocturia, hesitancy and incontinency since 4 months and cough since from 1 month before the referrence who refused to have any history of previous lung disease and bone pain. Regarding the high serum prostate-specific antigen level (PSA>100 ng/ml), the patient with the primary diagnosis of prostate cancer was referred for further molecular imagings to clarify the distant metastases and 3 month after initiation of treatment with ADT and taxane-based chemotherapy. ***Materials and Methods:*** We administered 20 mci of 99m Tc-PSMA and the same dose of 99m Tc- FAPI 46 in two separate days, followed by delayed whole body imaging as well as SPECT/CT images performed for precise localization of the detected lesions. ***Results:*** In our study we noted diffuse 99m Tc- PSMA and 99m Tc- FAPI 46 uptake throughout both lungs of a metastatic patient which was considered to be compatible with lymphangitic carcinomatosis pattern. The findings on the hybrid imaging included nodular and irregular interlobular septal thickening, sub pleural nodules and mediastinal nodal enlargement on the dedicated CT slices. In interim 99mTc-PSMA scintigraphy, decreased PSMA uptake in both lungs and skeletal metastases as well as decreased in interlobular thickening and sub pleural nodules along with decreased in clinical respiratory symptoms were noted. ***Conclusion:*** Our study illustrated lymphangitic carcinomatosis as an unusual form of metastasis in prostate cancer as a first presentation that showed diffuse lung uptake on both 99m Tc-PSMA and 99m Tc-FAPI 46 scintigraphies.

EP-1055

The Significance of Total Body ^{18}F-FDG PET/CT in Multiple Myeloma: A Clinical Case

T. Stoeva, *Z. Dancheva, T. Yordanova, B. Chaushev, S. Chausheva, A. Klisarova, M. Dyankova; UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.*

Aim/Introduction: Multiple myeloma (MM) manifests with long bone involvement in approximately 25% of patients. This report aims to present a clinical case of a MM patient with established metabolically active lesions affecting the long bones of the lower limbs, as revealed by ^{18}F-FDG PET/CT imaging. ***Materials and Methods:*** We describe the case of a female patient diagnosed with MM IgG-kappa. Initial staging imaging with computed tomography of the thorax identified a solitary osteolytic lesion with a soft tissue component in the sternum, categorizing the stage as Ia (Durie-Salmon PLUS). Subsequently, the patient

underwent ^{18}F-FDG PET/CT evaluation after completing 6 courses of chemotherapy due to persistent lower extremity pain, requiring crutches for ambulation. Because of this complaints, it was decided to perform a total body PET/CT- from the vertex to the toes. ***Results:*** The ^{18}F-FDG PET/CT scan revealed multiple metabolically active osteolytic lesions in the thoracic vertebrae, both femurs, and tibias, prompting a re-evaluation of the patient's disease stage and treatment strategy. Following an intensified chemotherapy regimen, a follow-up total body ^{18}F-FDG PET/CT showed a significant expansion of osteolytic involvement and elevated glucose metabolism within the long bones of the lower limbs. Additionally, a new metabolically active lesion was identified in the right tibia, indicative of disease progression. ***Conclusion:*** Long bone lesions and fractures significantly diminish quality of life in MM patients. Limited literature exists regarding long bone involvement in multiple myeloma. Standardizing the extent of the scan field remains unresolved. We recommend extending the scan field from the vertex to the distal third of the tibia in MM patients presenting with lower extremity pain or signs of diffuse bone involvement. This approach facilitates early detection of osteolytic lesions, which are prone to fractures and associated with impaired quality of life, thereby enhancing diagnosis, monitoring, and treatment strategies.

EP-1056

Challenges in Interpretation of ^{18}F-FDG PET/CT in Multiple Myeloma: Potential Diagnostic Pitfalls and Mitigation Strategies - Illustrated by Two Clinical Cases

T. Stoeva, *M. Dyankova, Z. Dancheva, T. Yordanova, S. Chausheva, B. Chaushev, A. Klisarova;*
UMHAT "Sveta Marina" EAD- Varna, Varna, BULGARIA.

Aim/Introduction: ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (^{18}F-FDG PET/CT) is a pivotal imaging modality in the assessment of multiple myeloma (MM). However, its nuanced interpretation poses challenges, particularly in distinguishing diffuse bone marrow infiltration characteristic of MM from other conditions such as anemic syndrome. This study presents two clinical cases to elucidate a potential diagnostic pitfall in 18F-FDG PET/CT imaging in MM patients and explores strategies to mitigate misinterpretation. ***Materials and Methods:*** Two cases are described: First patient, who presented with debilitating general fatigue, bone pain, and elevated total protein, underwent 18F-FDG PET/CT for staging the disease. Second patient had MM (light chain Lambda, International Staging System [ISS] III) and concomitant anemia after chemotherapy. Both patients underwent either staging or post-therapeutic 18F-FDG PET/CT scans as part of their diagnostic workup. ***Results:*** In the first patient, the 18F-FDG PET/CT exhibited diffusely increased bone marrow activity without distinct osteolytic lesions, yet a noticeable diffuse reduction in bone density, particularly observed in pelvic bones and sacrum. This imaging pattern may be attributed to the diffuse patchy bone marrow infiltration characteristic of MM. Later, those findings was histologically proven for myelomatous infiltration. In contrast, second patient, despite presenting with stable disease and anemia, demonstrated above-background increased metabolic activity in the bone marrow without evident osteolytic lesions on the post-therapeutic ^{18}F-FDG PET/CT. The patient's hemoglobin level was 76g/L. After biopsy, no myeloma cells were found in the bone marrow. ***Conclusion:*** These clinical cases serve to highlight a potential diagnostic pitfall in ^{18}F-FDG PET/CT interpretation in MM patients, where the overlapping metabolic patterns between diffuse bone marrow involvement from MM and anemic syndrome can lead to challenges in differentiation. This emphasizes the critical need for meticulous correlation between ^{18}F-FDG PET/CT findings and laboratory results in the management of MM. Heightened awareness of this diagnostic challenge is essential to prevent false positive interpretations and guide precise clinical decision-making in MM patients undergoing ^{18}F-FDG PET/CT imaging.

EP-1057

Misleading Focal [99mTc]Tc-MDP Uptake in the Whole-body Scintigraphy of a Patient with History of a Recent high energy Trauma

A. Saber Tanha, *N. Raeisi, A. Aghaee;*
Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: This case report discusses the use of bone scintigraphy in diagnosing suspected occult fractures, emphasizing the importance of hybrid imaging for confirming the whole-body plannar findings. ***Materials and Methods:*** A 54-year-old man presented with thoracic pain following car accident. Despite negative radiographs and CT scans, a three-phase bone study with technetium-99m MDP was conducted, followed by pelvic SPECT/CT imaging to investigate focal uptake in the left pubis ramus. ***Results:*** Bone scintigraphy revealed increased uptake in the right 9th rib, indicating an occult fracture, while uptake in the pubis ramus was initially misinterpreted as a traumatic lesion. Pelvic SPECT/CT identified urine contamination on the glans of the penis as the cause of the misleading uptake. ***Conclusion:*** This report underscores the significance of SPECT/CT imaging as an integral component of bone scintigraphy, particularly when dealing with abnormal findings on whole-body planar images.

EP-1058

False-Positive Radioactive Iodine Uptake in A Huge Uterine Fibroid: A Case Report

A. Saber Tanha, *N. Raeisi, E. Askari, F. Rabbani Banou;*
Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Differentiated thyroid carcinoma (DTC) patients often undergo post-treatment whole-body iodine scans (WBIS) to assess treatment efficacy. However, interpreting incidental findings on these scans can be challenging, particularly when distinguishing between physiological and pathological uptake. We present a case highlighting a notable pitfall in WBIS interpretation. ***Materials and Methods:*** A 37-year-old woman with DTC, pT3aN1b, underwent adjuvant radioactive iodine therapy. Post-treatment WBIS revealed unexpected iodine uptake in a large uterine fibroid. Clinical and radiological correlations were assessed to elucidate the nature of this uptake. ***Results:*** The patient's WBIS showed iodine uptake in the mid-abdomen, above the bladder. Physical examination and SPECT/CT correlation confined the uptake to a uterine mass. Review of gynecologic history and imaging studies revealed a known uterine fibroid, stable in size, which had trapped the radioiodine. ***Conclusion:*** This case underscores the importance of recognizing potential pitfalls in WBIS interpretation, particularly in women of reproductive age with thyroid carcinoma. Differentiating between physiological and pathological iodine uptake is crucial to avoid unnecessary interventions. Hybrid imaging modalities, such as SPECT/CT, can aid in localizing and characterizing unexpected iodine avidities, improving clinical decision-making and reducing the risk of overtreatment in thyroid cancer patients.

EP-1059

Focal Radiotracer Uptake in the Falciform Ligament; A Rare lymphoscintigraphic Pattern in Breast Cancer

A. Saber Tanha, *F. Jafari Zarrin Ghabaei, P. Sahafi, R. Sadeghi, M. Ahmadi;*
Mashhad University of Medical Sciences,
Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Breast cancer lymphatic drainage involves pathways towards axillary and extra-axillary regions. A rare challenging case in this understanding is the identification of lymphatic drainage via the falciform ligament, presenting a unique pattern in breast cancer lymphoscintigraphy. ***Materials and Methods:*** A 67-year-old woman with invasive ductal carcinoma underwent lymphoscintigraphy using technetium-99m Phytate. Planar imaging and subsequent SPECT/CT were conducted to localize tracer uptake. ***Results:*** Planar imaging revealed two distinct focal uptake in the left axilla as well as another focus in the falciform ligament amidst diffuse hepatic activity which is a rare finding. SPECT/CT precisely identified this uptake within the ligament without any underlying distinct lymph node, suggesting a rare lymphatic drainage pathway. Histopathologic evaluation of axillary sentinel nodes showed no metastatic involvement. ***Conclusion:*** The identification of lymphatic drainage via the falciform ligament challenges conventional understanding, indicating potential implications for breast cancer metastasis. Factors such as lymphatic obstruction and impaired contractility may contribute to this phenomenon. Further cases evaluations are warranted to elucidate the complexity of breast cancer lymphatic pathways and their role in metastasis.

EP-1060

Iodine Contamination Mimicking a Common Pattern in Whole Body Iodine Scan Unveiled by SPECT/CT: A Case Study

A. Saber Tanha, *N. Raeisi, S. Zakavi;*
Mashhad University of Medical Sciences,
Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: The whole-body iodine scan (WBIS) is essential for assessing metastasis in thyroid cancer patients, particularly where SPECT/CT is unavailable. However, interpretation challenges can lead to misdiagnosis, emphasizing the need for hybrid imaging modalities. ***Materials and Methods:*** A 61-year-old man with poorly differentiated thyroid carcinoma underwent total thyroidectomy and adjuvant radioactive iodine (RAI) therapy. Post-treatment WBIS initially showed misleading patterns, later clarified by SPECT/CT. ***Results:*** The WBIS revealed misleading iodine uptake patterns, including a zone of contamination misinterpreted as thyroid bed uptake. SPECT/CT confirmed the misinterpretation, highlighting the importance of hybrid imaging techniques. ***Conclusion:*** This case underscores the critical role of integrating SPECT/CT with WBIS to prevent misdiagnosis and ensure accurate treatment planning in thyroid cancer patients. Complementary imaging modalities enhance diagnostic accuracy and improve patient outcomes.

EP-1061

Sentinel node mapping and biopsy in a rare case of ectopic breast cancer

N. Raeisiestabragh, *A. Saber Tanha, R. Sadeghi;*
Mashhad University of Medical sciences,
Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Primary breast cancer arising within accessory breast tissue is a rare occurrence. Accurate diagnosis and management of ectopic breast cancer pose significant challenges due to its unusual presentation and localization. We present a case of invasive ductal carcinoma originating in accessory breast tissue located in the left axillary region, emphasizing the importance of precise diagnostic techniques and optimal treatment strategies. ***Materials and Methods:*** A postmenopausal 62-year-old woman presented with a palpable mass in the accessory breast within the left axillary region. Core needle biopsy confirmed invasive ductal carcinoma. Lymphoscintigraphy was performed by injecting 30MBq of technetium-99m Phytate intradermally in the periareolar region of the eutopic breast. Plannar and single-photon emission tomography/computed tomography (SPECT/CT) images were obtained to visualize lymphatic drainage and identify sentinel lymph nodes. ***Results:*** Lymphoscintigraphy revealed a solitary sentinel lymph node in the ipsilateral axilla, corresponding to the accessory breast malignancy. Surgical resection of the accessory breast and sentinel lymph node biopsy were performed. Pathological examination of the sentinel node showed no evidence of metastasis. The patient underwent adjuvant radiotherapy, chemotherapy, and anti-hormonal therapy. ***Conclusion:*** Our case highlights the diagnostic and therapeutic challenges associated with primary breast cancer in accessory breast tissue. Lymphoscintigraphy with periareolar injection of radiotracer proved effective in identifying sentinel lymph nodes, guiding surgical decision-making, and minimizing unnecessary mastectomies. Accurate diagnosis and appropriate management are crucial for improving outcomes in patients with ectopic breast cancer.

EP-1062

Application of Tc-99m FAPI-46 Imaging in a Patient with Medullary Thyroid Carcinoma: Navigating the Landscape of Novel Radiotracers

N. Raeisiestabragh, *A. Saber Tanha, K. Aryana;*
Mashhad University of Medical sciences,
Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Metastatic medullary thyroid carcinoma (MTC) poses significant therapeutic challenges, often refractory to conventional treatments. We present the case of a 58-year-old male with metastatic MTC unresponsive to peptide receptor radionuclide therapy (PRRT) and lutetium-177 Dotatate therapy, highlighting the need for alternative approaches in managing this aggressive malignancy. ***Materials and Methods:*** The patient underwent multiple interventions, including total thyroidectomy and cervical lymph node dissections, followed by PRRT and lutetium-177 Dotatate therapy. Despite these treatments, serum calcitonin levels continued to rise, indicating disease progression. Subsequent evaluation with technetium-99m FAPI-46 scintigraphy was performed to assess the potential of FAPI-labeled radioisotopes in detecting and targeting metastatic lesions. ***Results:*** Technetium-99m FAPI-46 scintigraphy revealed remarkable uptake in metastatic lesions, including parapharyngeal mass, lung metastasis, lymph nodes, and bone metastasis. This finding suggests a potential role for FAPI-targeted radiotracers in the management of metastatic MTC, especially in cases refractory to conventional therapies. ***Conclusion:*** Our case highlights the emerging utility of technetium-99m FAPI-46 scintigraphy in identifying and characterizing metastatic lesions in MTC patients resistant to standard treatments. FAPI-targeted radiotracers hold promise as a novel approach in oncologic nuclear medicine, warranting further investigation to explore their therapeutic potential in metastatic MTC and other malignancies.

EP-1063

Newly Formed Hepatic Inflammatory Myofibroblastic Tumor Mimicking Neuroblatoma Metastasis: ^{18}F-FDG and ^{68}Ga-DOTANOC PET/MRI Imaging

Y. Zhao, *G. Shao;*
Department of Nuclear Medicine, Nanjing First Hospital, Nanjing Medical University, Nanjing, CHINA.

Aim/Introduction: A 4-year-old boy with history of stage IV neuroblastoma (NB) underwent surgery resection, chemotherapy and radiotherapy. One enhancing hepatic lesion with intense 18F-FDG uptake (SUVmax of 6.8) on the right lobe was newly found on latest PET/MRI which is negative on prior PET. Hepatic metastasis from NB was highly suspected at first but was ruled out due to its absence of 68Ga-DOTA-NOC uptake, a somatostatin receptor targeted radiotracer. An extremely rare inflammatory myofibroblastic tumor (IMT) in liver was confirmed based on post-operation histopathologic examination. ***Results:*** NB is the most common extracranial solid tumor in childhood with unknown etiology, highly variable biologic behavior and clinical presentation. Recurrence and metastasis after therapy are the major obstacle to improve the prognosis of NB patients. Liver is one of the most common sites of metastases from NB. To detected metastatic lesions, routine imaging methods including CT, MRI and ultrasonography may be complemented by functional imaging methods such as PET/CT or PET/MRI. Various PET tracers have been used in NB patients. Somatostatin receptor 2 (SSTR2) is expressed by the majority of NB tumors. Therefore, SSTR enabling PET imaging agents, for example, 68Ga-DOTA-TATE, 68Ga-DOTA-TOC and 68Ga-DOTA-NOC, show high sensitivity in detecting NB lesions. 18F-FDG is usually considered to be a second-line imaging agent because of its less specific for NB. Actually, FDG is useful for those NB lesions do not uptake meta-iodobenzylguanidine (MIBG) However, IMT is an extremely rare tumor with no known unique clinical, laboratory, or radiological features for identification, especially it is usually FDG-avid. On this occasion, the hepatic lesion may be misdiagnosed as a metastasis from NB. According to our knowledge, this is the first reported case of solitary liver IMT in a NB patient. It is suggested that surgical resection should be recommended for solitary lesions if not prohibited by anatomic location or morbidity. Targeted imaging methods and pathologic studies are crucial in these atypical cases. ***Conclusion:*** Somatostatin receptor imaging can be critical in the differential diagnosis of NB metastasis and multimodality PET/MRI imaging may provide more information about the lesion.

EP-1065

Hyper parathyroid scan case report

R. Abushawareb;
Ministry of Health / Al Amiri Hospital, Kuwait, KUWAIT.

Aim/Introduction: Hyperparathyroidism is a state of increased synthesis and release of PTH from single or multiple parathyroid glands. The parathyroid scan is intended to localise the active parathyroid tissue for unilateral minimally invasive surgery intent. Intraoperative 50% reduction of serum PTH level post gland removal indicates a successful procedure. ***Materials and Methods:*** A 60-year-old female with a known case of recurrent urinary stones and thyroid MNG had persistent PTH levels and midline non-painful neck swelling with generalised muscle pain. Thyroid U/S showed multiple bilateral thyroid nodules, confirming the diagnosis of MNG. FNAC was done for the suspected left thyroid nodule, which was benign. MIBI scan was done as well to locate the source of hyperfunctioning parathyroid tissue before surgery. ***Results:*** MIBI scan showed evidence of multiple hyperactive parathyroid tissues that could be hyperplasia, though no renal impairment was present for histopathological follow-up post-surgery. ***Conclusion:*** Multiple adenomas are rare in 5% of cases of hyperparathyroidism. Secondary hyperparathyroidism to renal insufficiency is usually associated with parathyroid hyperplasia(seen in 20% of hyperparathyroidism cases), and an MIBI scan, in this case, has lower sensitivity (around 60%). ***References:*** SNMMI procedure standard for parathyroid scintigraphy 4.0, 20122009, EANM parathyroid guidelines Seminars in Nuclear medicine Volume 45, Issue 5, Sep 2015, Pitfalls and limitations of Radionuclides Imaging in EndocrinologyScintigraphic parathyroid imaging Concepts and new developments, 22 June 2015, 2015:5-9-18.

^{18}F-FDG PET/CT Findings in a Rare Case of Renal Synovial Sarcoma with SYT-SSX1 Translocation

R. Wakankar, *S. A. Shamim, S. Rastogi;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: We present the case of a 65-year-old man with presenting complaints of recurrent hematuria whose initial abdominal CECT demonstrated a hyperenhancing mass arising from the right kidney, following which he underwent a staging ^{18}F-FDG PET/CT to look for locoregional spread and distant metastasis. ***Materials and Methods:*** The ^{18}F-FDG PET/CT revealed a hypermetabolic right renal mass along with the presence of a hypermetabolic metastatic nodule in the left lung. He underwent a radical right sided nephrectomy. ***Results:*** The post-operative histopathology of the specimen revealed the mass to be a synovial sarcoma with rhabdoid and sarcomatoid changes and accompanying perinephric fat & lymphovascular invasion. Real time PCR of the specimen revealed the presence of SYT-SSX1 translocation. ***Conclusion:*** He received multiple lines of therapy including cabozantinib, nivolumab, lenvatinib & brigatinib before finally being initiated on Doxorubicin based chemotherapy. This case demonstrates the PET/CT findings of metastatic renal synovial sarcoma.

EP-1067

A typical case of follicular cell sarcoma of the duodenum on ^{18}F-FDG PET

Z. Zheng, *P. Hu, H. Shi;*
Zhongshan hospital, fudan university, Shanghai, CHINA.

Aim/Introduction: Follicular dendritic cell sarcoma (FDCS) is a rare malignant neoplasm. This article presents a case of typical FDCS located in the pancreatic-duodenal region, with findings from enhanced CT and 18F-FDG PET/CT. This case exhibits typical features of FDCS, emphasizing the importance of considering FDCS in the differential diagnosis of characteristic gastrointestinal hypermetabolic lesions. ***Materials and Methods:*** We report the case of a 69-year-old woman who presented with a pancreatic mass found during a routine physical examination. Blood tests revealed CA125 at 26.1 U/ml, and NSE at 20.1 ng/ml. The primary lesion manifested as a large cystic-solid mass, showing significant enhancement on enhanced CT. The patient underwent 18F-FDG PET/CT to further evaluate the potential malignant tumor. The primary lesion showed notable uptake in the solid portion on 18F-FDG PET/CT . ***Results:*** The tumor was surgically resected. Histopathological and immunohistochemical analysis confirmed it to be a follicular dendritic cell sarcoma located on the serosal aspect of the duodenum adjacent to the pancreatic capsule. ***Conclusion:***

Follicular dendritic cell sarcoma is a rare malignant tumor derived from follicular dendritic cells, typically involving lymph nodes, with occasional extranodal occurrences [1]. It often presents as a slow-growing, painless mass with few systemic symptoms [1]. CT often depicts well-defined, round, or oval-shaped masses, which may appear lobulated when the lesion is larger, with the presence of cystic changes, necrosis, and calcifications [2]. Enhanced CT scans reveal progressive, uneven, and intense enhancement of the mass [2].18F-FDG PET/CT has been proven to be an important imaging modality for differentiating extranodal follicular dendritic cell sarcoma [3]. Currently, there are limited reports on the 18F-FDG PET/CT findings of gastrointestinal follicular dendritic cell sarcoma [4]. This case presents a typical follicular dendritic cell sarcoma of the duodenum, emphasizing the need to consider the possibility of follicular dendritic cell sarcoma in the differential diagnosis of gastrointestinal tumors. ***References:*** 1. EP-1068

Utility of FDG PET/CT in a Case of Primary Retroperitoneal Extraosseous Ewing's Sarcoma of Atypical Age

Z. Zheng, *P. Hu, H. Shi;*
Zhongshan hospital, fudan university, Shanghai, CHINA.

Aim/Introduction: We report a case of a 57-year-old female with a rare and rapidly progressive extraosseous Ewing's sarcoma (EES) located in the retroperitoneum. ***Materials and Methods:*** The patient presented with a large retroperitoneal mass discovered during a medical examination for herpes zoster-related pain. Histopathological and immunohistochemical staining showed positive staining for CD99, Fli-1, and Vim. The Ki67 proliferation index was 40%. FISH testing revealed EWSR1 positivity, indicating the diagnosis of extraosseous Ewing's sarcoma. Subsequently, 18F-FDG PET/CT was performed for staging. The maximum intensity projection image displayed a large abdominal mass. It showed an indistinct border with the diaphragm, exerting compression on the thoracic and abdominal organs and wrapping around the aorta and its major branches. The patient did not fit the typical age characteristics of extraosseous Ewing's sarcoma and had a significant tumor burden. She underwent combined chemotherapy and radiation therapy, and on follow-up chest CT, multiple lung metastases were detected. Subsequently, targeted therapy was initiated. One year later, a PET scan showed a reduction in the size of the retroperitoneal mass compared to previous imaging. There was a slight decrease in glucose metabolism, and the mass displayed heterogeneous density with a multi-cystic appearance. The boundary between the mass and the surrounding tissues remains indistinct, as observed during the previous examination. There were new findings of widespread metastases, including lymph node, lung, liver, pancreatic, bone, and pathological fracture of the fourth lumbar vertebra. ***Results:*** EES is a rare malignant tumor that typically affects young individuals, presenting with subtle clinical manifestations but exhibiting high malignant potential and invasiveness [1]. It commonly metastasizes to lungs, lymph nodes, and bones, resulting in a poor prognosis [2]. Imaging studies typically reveal poorly defined borders of soft tissue masses, but a definitive diagnosis requires histopathological confirmation [1]. 18F-FDG PET/CT demonstrates high sensitivity in detecting both primary lesions and distant metastases [2]. ***Conclusion:*** The atypical age of onset in our case suggests that the possibility of EES should be considered when a large retroperitoneal mass is discovered in elderly individuals. Furthermore, our case emphasizes the significant role of 18F-FDG PET/CT in assessing the disease burden of EES, thereby guiding diagnosis and treatment. ***References:*** 1. EP-1069

^{18}F-FDG PET Images in a Patient with Nephritis Mimicking Renal metastasis from Primary Hepatocellular Carcinoma on MR: a case report

Z. Zheng, *P. Hu, H. Shi;*
Zhongshan hospital, fudan university, Shanghai, CHINA.

Aim/Introduction: We report the 18F-FDG PET/CT findings of postoperative newly inflamed renal nodules that were mistaken for renal metastases on MR in a 58-year-old patient with hepatocellular carcinoma(HCC). ***Materials and Methods:*** A 58-year-old man underwent a partial hepatectomy for HCC and was followed up for monitoring 1 month after surgery. The tumor marker levels were normal. The patient underwent contrast-enhanced MR of the chest, abdomen, and pelvis. MR showed two new nodules with hypointense on DWI in the upper pole of the left kidney. Nodules were suspected to be metastatic. To further clarify the nature of the nodules, 18F-FDG PET/CT was performed subsequently. Two nodules of increased metabolic activity were shown in the upper pole of the left kidney. Delayed imaging was performed at 3h after the injection of 18F-FDG to exclude the effects of renal urine. For subsequent treatment arrangements, the identification of benign versus malignant renal nodules is crucial. The findings on 18F-FDG PET suggested that nodules were inflammatory. Subsequent pathological examination did not reveal any definite tumor tissue. In combination with the imaging findings and laboratory parameters, the renal nodules were clinically considered to be inflammatory nodules. ***Results:*** HCC can cause intra- and extrahepatic metastases. 1/3 of patients with HCC develop extrahepatic metastases and are associated with a poor prognosis [1]. The most common sites of extrahepatic metastases are lung, adrenal glands, bone, and regional lymph nodes, with renal metastases rarely occurring [2]. Care should be taken to consider nephritis in the differential diagnosis when renal metastases are suspected in patients with HCC [2]. Determining whether HCC has extrahepatic metastases is crucial for accurate staging and treatment planning. [1]. In this case, MRI showed an abnormal signal in the kidney, which was considered to be metastasis. Combining conventional and delayed imaging in PET/CT, these abnormal signal lesions were considered inflammatory, which was consistent with the pathological diagnosis. ***Conclusion:*** Renal metastases rarely occur in hepatocellular carcinoma. When nodules show a malignant sign, it may lead to misdiagnosis in MR. FDG-PET/CT may provide additional information for staging and monitoring the efficacy of hepatocellular carcinoma. ***References:*** 1 Uchino K, Tateishi R, Shiina S, et al. ^{18}F-FDG PET/CT findigs of primary Ewing sarcoma of the Prostate

***A. Namazova*[1],** *O. E. Şahın*[2], *H. B. Sayman*[2];
[1]*Istanbul University-Cerrahpasa, Lütfen Seçiniz, TÜRKIYE,*
[2]*Istanbul University-Cerrahpasa, ISTANBUL, TÜRKIYE.*

Aim/Introduction: Ewing sarcoma/PNET are the second-most common primary malignant bone tumor in children and adolescents, but the extraosseous sarcomas rarely manifest in the prostate. In this article, we present 18F-FDG PET/CT findings of a patient who presented with dysuria and was diagnosed with extraskeletal Ewing sarcoma of the prostate. ***Materials and Methods:*** The patient was administered 0.15 mCi/kg FDG intravenously PET/CT imaging was obtained from whole body at 60th minute after the injection. ***Results:*** A 22-year-old male was admitted to hospital for dysuria that had persisted for more than 2 months. In the pelvic CT imaging of the patient, a heterogeneous cystic mass lesion with axial dimensions of 80x70 mm was detected in the left anterolateral aspect of the prostate gland. Thereafter, he underwent prostate biopsy. Histopathological examination revealed small round tumor cells and immunohistochemistry showed that the tumor cells were positive for vimentin, CD59, and CD99, but negative for myogenin, MyoD1, SMA, S100, desmin, SALL4, PANCK, NSE, WT1, and CD34, suggesting extraskeletal Ewing sarcoma. 18F-FDG PET/CT was then performed for primary tumor diagnosis and staging. On the MIP image (Figure 1), abnormal uptake was observed in the pelvic region. The corresponding axial CT and fusion PET /CT images showed (Figure 2): The gross mass lesion completely occupying the prostate with the widest extent of 103 x 74 x 118 mm that shows heterogeneous, intensely elevated FDG metabolism, also containing focal hypometabolic necrotic areas (SUVmax=17.71); a second gross mass lesion weas detected in the left lateral neighborhood of the mass, having intense FDG metabolism in bilateral iliac lymphatic basin (SUVmax,13.45). ***Conclusion:*** Extraskeletal Ewing sarcoma of prostate is an extremely rare condition1-2. The other rare locations in this respect include the retroperitoneum, omentum, orbit, skin, chest wall, and viscera3-5. ***References:*** 1.Guo, Yue-Hong MD; Yang, Min-Fu MD. ^{18}F-FDG PET/CT of Primary Extraskeletal Ewing Sarcoma of the Prostate. EP-1071

Carcinosarcoma Originating From The Inferior Vena Cava Detected on 18F-FDG PET-CT

R. Wakankar, *J. Bal, K. Sharma, P. Dougall;*
Max Super Speciality Hospital, New Delhi, INDIA.

Aim/Introduction: Primary carcinosarcoma originating in the inferior vena cava (IVC) is a very rare, malignant neoplasm which is composed of both carcinomatous and sarcomatous elements. To the best of our knowledge, there are no cases in literature describing a primary IVC carcinosarcoma. We present the case of a biopsy-proven primary carcinosarcoma of the IVC in a 63-year-old man whose ^{18}F-FDG PET/CT demonstrated a large hypermetabolic lesion in the IVC along with hypermetabolic pulmonary tumor emboli. ***Materials and Methods:*** We report the case of a 63-year-old man who initially presented to us with complaints of swelling in his feet, dyspnoea & non-productive cough with the non-specific radiological findings of deep vein thrombosis (DVT) of the bilateral lower limbs along with an IVC thrombus and had been started on enoxaparin for the same. However, despite being given appropriate medical treatment, his condition slowly continued to deteriorate over the course of a few months. A whole body ^{18}F-FDG PET/CT was performed in view of the patients deteriorating medical condition to help identify a potential cause for the same. ***Results:*** The PET/CT revealed a dilated IVC with a large hypermetabolic non-enhancing hypodense intraluminal lesion in the intrahepatic IVC with extension into the right hepatic vein, extending into the suprahepatic IVC up to the right atrium & the infrahepatic IVC up to the right renal vein & associated with ascites. The PET/CT also helped identify few hypermetabolic filling defects in segment branches of the bilateral pulmonary arteries in the lungs which were deemed to be metastatic tumor emboli originating from the lesion in the IVC along with bilateral pleural effusion. A CT-guided biopsy was performed for securing a tissue-based diagnosis, which ultimately revealed the IVC lesion to be a carcinosarcoma. Unfortunately for him, the lesion was not amenable to surgery. He underwent stenting of the right hepatic vein & was put on palliative care. His condition continued to deteriorate over the next few weeks at which point he developed septic shock & coagulopathy & had to be put on vasopressor support. He eventually succumbed to his disease. ***Conclusion:*** The role of ^{18}F-FDG PET/CT was pivotal in this case for two reasons; first, it helped to differentiate a tumor thrombus from a bland thrombus; and second, it also allowed us to upstage the disease from being locally advanced to being metastatic, by identifying pulmonary tumor emboli.

EP-1072

Adrenocortical Carcinoma with Sarcomatoid Differentiation Detected on ^{18}F-FDG PET-CT

R. Wakankar, *J. Bal, K. Sharma, P. Dougall;*
Max Super Speciality Hospital, New Delhi, INDIA.

Aim/Introduction: We present the case of a 52-year-old woman who presented to the out patient department of our hospital with chief complaints of left flank pain and vague lower backache. She was suspected to be suffering from renal stone disease and was asked to undergo a non-contrast CT (NCCT) of the abdomen to look for evidence of renal calculi. However, upon undergoing the NCCT, it was revealed that she in fact did not have any renal calculi, but was instead found to have a mass originating from her left adrenal gland. ***Materials and Methods:*** Based on these findings, it was suspected that the adrenal mass may be neoplastic in origin. It was decided to perform a whole body ^{18}F-FDG PET-CT of the patient to look for any evidence of suspicious metabolic activity in the mass and also to look for evidence of any metastatic lesions. Upon performing the PET-CT, it was revealed that she had a large, enhancing and hypermetabolic mass (SUVmax: 10.4) with areas of internal necrosis situated in her left adrenal gland, measuring

approximately 6.9x6.2 cm. The mass was involving the left adrenal so extensively that the gland could not be visualized separately at all. There was no evidence of infiltration of any adjacent blood vessels. Additionally, the PET-CT also revealed to us, the presence of another, smaller, hypermetabolic (SUVmax: 9.7) nodular lesion arising from her right adrenal gland, measuring approximately 1.7x1.4 cm. She also had developed a hypermetabolic (SUVmax: 12.8) lytic lesion in her D8 vertebra which had an accompanying soft tissue component as well. Apart from all these ominous findings, her PET-CT also revealed the presence of diffuse hypermetabolism in the walls of her ascending aorta, aortic arch, descending aorta, upper abdominal aorta all the way till the level of the superior mesenteric artery- this was considered to be due to some form of active vasculitis. ***Results:*** She underwent a left adrenalectomy and retroperitoneal lymph node dissection. The histopathology of the left adrenal mass revealed the presence of cells that were positive for CDK4 and negative for CD45, CK8, CK18, CK HMW, CD31, CD34, HMB45, Melan A, SOX-10, Calretinin, Inhibin, Chromogranin, GATA3 and EMA. However, the retroperitoneal lymph node turned out to be benign. ***Conclusion:*** Based on the radiological findings, the morphology and immunohistochemistry findings of the mass, it was suggested to be a poorly differentiated adrenocortical carcinoma with sarcomatoid differentiation and skeletal metastasis.

EP-1073

Poorly Differentiated Gastric Carcinoma Incidentally Detected on ^{18}F-FDG PET-CT in a Known Case of Bladder Cancer

R. Wakankar, *J. Bal, K. Sharma, P. Dougall;*
Max Super Speciality Hospital, New Delhi, INDIA.

Aim/Introduction: We present the case of a 43-year-old woman who had just recently been diagnosed with a high grade of muscle invasive urothelial carcinoma of the urinary bladder and who had just undergone a transurethral resection of the urinary bladder tumor (TURBT). Her past history was significant for having undergone a renal transplant a decade ago. CT urography had revealed only an eccentric thickening of the urinary bladder wall. It was decided to perform a whole body ^{18}F-FDG PET-CT to look for any evidence of locoregional or distant metastasis of the disease. ***Materials and Methods:*** Upon performing the PET-CT, it was revealed that she had no evidence of any metabolically active soft tissue thickening in the urinary bladder-post TURBT, to suggest any form of residual disease. Her renal graft was also visualized as being located in the right iliac fossa. However, an incidental finding of a hypermetabolic (SUVmax: 7.7) eccentric and minimal soft tissue thickening along the pylorus and the 1st part of the duodenum was made, it is important to note that this thickening was not, in any way, causing an obstruction of the gastric outlet. This pyloro-duodenal soft tissue thickening was observed to extend upto the right lobe of the liver. There was no evidence of any metastatic lesions anywhere else in the body. The patient herself, did not complain of any symptoms at all that could corroborate these findings. Therefore, based on these findings and given her recent diagnosis of a high-grade muscle invasive urothelial bladder carcinoma, it was suspected that this hypermetabolic lesion was, in fact, a metastasis from the urinary bladder malignancy. After discussion with the oncologist and surgeons, it was decided to perform a distal gastrectomy with regional lymph node sampling of the pyloro-duodenal lesion. ***Results:*** After she underwent the distal gastrectomy and regional lymph node sampling, the tissue samples were sent to the pathologist for characterization. The lesion showed features of a poorly differentiated adenocarcinoma with involvement of the muscularis mucosa and no infiltration into the adjacent esophagus or duodenum and no lymphovascular or perineural invasion. ***Conclusion:*** The tumor stained positively for CK7 and CDX2 and negatively for Synaptophysin, CK20, P63, HMWCK and GATA3. Since it was negative for GATA3, P63 and HMWCK, the possibility of a urothelial primary was ruled out by us. Thereby making this a second primary malignancy of the gastric pylorus which was incidentally detected on PET-CT.

EP-1074

^{18}F-FDG PET-CT Findings in Pancreatic Adenocarcinoma with Ovarian Metastasis

R. Wakankar, *J. Bal, K. Sharma, P. Dougall;*
Max Super Speciality Hospital, New Delhi, INDIA.

Aim/Introduction: Ovarian metastasis in pancreatic adenocarcinoma is very rare and is seen in only 4-6% of patients with this malignancy. It is even less likely to present has a recurrence in patients who have already been treated for pancreatic cancer. Herein, we present the case of such a patient and describe the findings of her whole body ^{18}F-FDG PET-CT scan. ***Materials and Methods:*** This case is of a 62-year-old woman who had been diagnosed with adenocarcinoma of the head of the pancreas 2 years prior to the events of this case report. At that time, she had undergone a Whipple's surgery as her disease was amenable to resection and had received all the appropriate adjuvant treatment. She was completely symptom free when she presented to the oncology clinic with complaints of post-menopausal bleeding. A USG of her abdomen and pelvis revealed a large abdomino-pelvic mass which appeared to arise from the left adnexa. Her serum CA 125 and CA 19.9 were both elevated. This prompted us to perform a whole body ^{18}F-FDG PET-CT for the patient to evaluate the abdomino-pelvic mass for possibility of a primary ovarian malignancy. ***Results:*** The PET-CT revealed no evidence of any residual/ recurrent disease in the post-operative bed of the Whipple's surgery. However, it did reveal a large hypermetabolic (SUVmax: 4.5), abdomino-pelvic mass with areas of internal necrosis arising from the left adnexa, measuring approximately 8.4x9.0x9.7 (cc) in volume and was seen to abut the uterus & compress the anterior wall of the urinary bladder along with multiple hypermetabolic bilateral axillary lymph nodes and multiple subcentimeter sized omental and peritoneal deposits in the abdomen and pelvis. There was also evidence of mildly metabolically active (SUVmax: 2.9) soft tissue thickening in the aortocaval region, which was encasing the aorta, inferior vena cava and extended upto the origin of the superior mesenteric artery. ***Conclusion:*** In the end, she underwent a biopsy of the abdomino-pelvic mass and the axillary lymph nodes. The mass revealed a mucinous adenocarcinoma with few patchy signet ring cells that stained positively for CK7, CK19, CA 19.9, MUC2, CDX2 and CK20 while staining negatively for ER and PAX8. However, the axillary lymph nodes turned out to have reactive lymphoid hyperplasia. Based on the presence of an elevated CA 19.9, previous history of pancreatic adenocarcinoma and a pancreatico-biliary phenotype, the final diagnosis of primary pancreatic carcinoma with ovarian metastasis was finally made.

EP-1075

Hydatic cyst infection of the tibia mimicking chondrosarcoma on FDG PET-CT scan

F. Avci[1], *B. Kocabeyoglu[1], I. Tamsel[2], H. Kaya[3], B. Doganavsargil[4], Z. Ozcan[1];*

[1]Ege University, Nuclear Medicine, Izmir, TÜRKIYE, [2]Ege University, Radiology, Izmir, TÜRKIYE, [3]Ege University, Orthopedy, Izmir, TÜRKIYE, [4]Ege University, Pathology, Izmir, TÜRKIYE.

Aim/Introduction: Hydatid cyst is a zoonotic infection caused by Echinococcus granulosus, with the liver and lungs being the most commonly affected organs. Although rare, hydatid cyst disease can also involve bone due to the hard structure of the bone trabeculae, which prevents the formation of adventitia. The spine is affected in almost half of patients. While FDG PET findings in hepatic and pulmonary hydatid cysts are well described, FDG PET/CT scans in hydatid bone disease have not been reported in the literature. ***Materials and Methods:*** We report a 54-year-old male patient who presented with pain and swelling in the left knee region for several years. Physical examination revealed mild local tenderness. Anteroposterior knee radiographs showed diffuse lytic destructive changes in the tibia. MRI showed a large bone lesion at the epiphyso-metaphyseal level of the tibia with cystic necrotic features without signal enhancement on T1 and T2 calcified areas. This finding strongly suggested the possibility of chondrosarcoma, a fairly common primary bone malignancy in this age group. ***Results:*** FDG-PET/CT was requested to determine the systemic extent of the disease and to plan therapeutic management. The scan clearly showed cortical irregularities at the distal end of the femur, at the level of the lateral condyle, with intense increased FDG uptake. This was followed by a distinct mass lesion in the posterior tibiofemoral joint extending distally along the tibia with obvious destructive changes and continuity in the soft tissue component containing ossified/chondroid calcific densities. Mild hypermetabolic lymph nodes were also seen in the left groin. No other pathological uptake was detected. After discussion with the institutional musculoskeletal tumour service, a tru-cut biopsy was scheduled. Pathology confirmed a solitary hydatid cyst in the tibia, which is a rare site. Abdominal CT and HRCT were performed for further evaluation of the disease, but no findings compatible with hydatid cysts elsewhere in the body were noted. The patient was started on antihelminthic albendazole and total surgical excision was achieved. ***Conclusion:*** To our knowledge, this case appears to be the first report of a patient with osseous hydatid disease evaluated by F^{18} FDG PET/CT scan. This unusual case shows that nuclear medicine physicians should be aware of the potential pitfalls of hydatid disease mimicking malignancy, especially in patients living in rural areas. It also illustrates the complexity of making a correct diagnosis in patients with rare bone diseases, even with the use multimodality imaging.

EP-1076

Differentiating Brown Tumors from Malignancy: A Combined Approach with ^{18}F-FDG PET/CT and ^{99m}Tc-sestaMIBI Scan

M. Zekri, *M. Bel Lakhdar, D. Alami, I. Zahfir, M. Aboussabr, D. Nakro, C. Bensaid, A. Mouaden, I. Ghfir, H. Guerrouj; Department of Nuclear Medicine, Ibn Sina teaching hospital, Faculty of Medicine and Pharmacy, Mohammed V University, Rabat, MOROCCO.*

Aim/Introduction: Brown tumors are non-malignant and lytic bone lesions characterized by rapid osteoclastic activity, typically stemming from hyperparathyroidism. These lesions can present a significant diagnostic challenge due to their deceptively malignant appearance on various imaging modalities. We present a case of multiple brown tumors mimicking malignancy on 18F-FDG PET/CT. ***Materials and Methods:*** The patient was a 35-year-old male, with a chronic history of generalized bone pain, fatigue and weight loss. Physical examination did not reveal any notable abnormalities. A plain radiography of the left shoulder revealed an osteolytic lesion along the humeral shaft. To further investigate the possibility of a primary malignant tumor, a PET/CT scan was performed following the administration of 222 MBq of ^{18}F-FDG. ***Results:*** The 18F-FDG PET/CT scan demonstrated widespread, multiple and relatively symmetrical foci of increased FDG uptake in the skeleton. Additionally, a mass with a lower FDG uptake was discovered in the anterosuperior mediastinum. Laboratory tests later revealed hypercalcemia associated with unexpectedly high PTH levels of 600 pg/ml. A whole-body 99mTc-sestaMIBI scan showed a mediastinal round lesion with increased uptake, with good spatial correlation to the one previously detected on PET/CT, associated with a mild diffuse uptake throughout the skeleton. Further investigation confirmed the diagnosis of brown tumors secondary to parathyroid adenoma. ***Conclusion:*** Given their remarkably malignant-like glucose uptake and aggressive nature, brown tumors represent a rare pitfall in interpreting18F-FDG PET/CT scans when screening for bone malignancy. This case illustrates how molecular imaging with 18F-FDG PET/CT, combined with a 99mTc-sestaMIBI scan proved valuable in differentiating brown tumors from true bone metastases within the context of hyperparathyroidism.

EP-1077

Bone Scintigraphy in Recurrent Assessment of Chondroblastoma - a Case Report

M. Satyr[1], *I. Noverko[1], T. Pantus[1], O. Karpova[2], O. Tykhonenko[2]; [1]State Institution "Ukrainian Health Ministry Heart Institute", Kyiv, UKRAINE, [2]Clinical Hospital Feofaniya, Kyiv, UKRAINE.*

Aim/Introduction: Chondroblastoma is one of the most frequently encountered benign epiphyseal neoplasms in immature skeleton. According to WHO diagnostic criteria chondroblastomas are characterized by following features: 1) lesions are predominantly osteolytic, 2) lesions contain network of pericellular calcifications and 3) chondroblastomas might be complicated by local recurrence (from 6 month up to 8 years). Bone scintigraphy (BS) usually demonstrates increased 99mTc-labelled bisphosphonates uptake in uninvolved bone tissues adjacent to chondroblastoma (e. g. stroma, inflammatory and vascular cells), as well as in intratumoral calcification network. Due to faint indistinct structure, the small recurrent lesions are difficult to recognize by plain radiograph, CT or MRI. On the contrary, BS is sensitive not to structural, but also to metabolic changes and thus may help to detect the bone neoplasm recurrence at early stage. ***Materials and Methods:*** We report a case of a 19-year-old woman with chondroblastoma lateral condyle of the right tibia (diagnostic criteria according to the WHO classification of soft tissue and bone tumors), diagnosed in 2013. The patient underwent surgical removement of lesion with autograft replacement on 04.12.2013. The disease was considered as cured for almost 7 years. Due to new clinical symptoms, which appeared in 2020 (fever, pain and swelling at the right knee joint) the patient was referred for the clinical investigation. ***Results:*** MRI (25.01.2020) revealed imparity and small surface defects with areas of heterogeneity at articular cartilage in lateral condyle of the right tibia, and slight perifocal swelling of the bone marrow, which were interpreted as postoperative osteochondral changes with stress reaction. Clinical data and MRI evaluation did not find new bone neither soft tissue injury; thus, patient underwent anti-inflammatory therapy. The control MRI (01.12.2020) revealed only enhancement of perifocal edema at postoperative area with clinical symptoms remained. Thus, it was decided to make a 3-phase BS for evaluation

metabolic activity. At 3-phase BS and SPECT (21.12.2020) the large area of intensive 99mTc-methylenediphosphonate fixation (30 x25 mm) in the lateral condyle of the right tibia was visualized, that corresponded osteochondral changes at MRI. Due to these findings, the patient was directed to the next surgical intervention that was performed on 10.03.2021. As the result of intervention, the chondroblastoma's recurrence was confirmed. ***Conclusion:*** The results suggest that 3-phase BS and SPECT was sufficient method to reveal and evaluate metabolic status and localization of small recurrent lesions which are undetectable by other methods.

EP-1078

Patient Case Study - HER2+ Breast Cancer Patient with Brain Metastasis, Treated in a Phase 1/2 Study with the HER2-Directed Radiopharmaceutical, CAM-H2

J. Gayton[1], *D. Roberge[2], D. Juneau[3], A. Marton[4], H. Elgammal[5];*
[1]Precirix, London, UNITED KINGDOM, [2]CHUM, University de Montreal, Montreal, QC, CANADA, [3]Universite de Montreal, Montreal, QC, CANADA, [4]McGill University, Montreal, QC, CANADA, [5]Precirix, Brussels, BELGIUM.

Aim/Introduction: This case study reports the journey of patient 001-001, a 45-year old female diagnosed with metastatic HER2+ breast carcinoma with brain metastasis in a phase 1, open-label trial of the HER2-directed radiopharmaceutical, CAM-H2 ***Materials and Methods:*** This patient was diagnosed with HER2+ breast cancer in 2016. She underwent a mastectomy and received systemic anti-cancer treatments including Tucatinib, Emtanzine-Trastuzumab, Trastuzumab, and Capectabine. She had undergone loco-regional radiation in 2016, scapular and pelvic palliative radiotherapy in 2019 and multiples courses of brain irradiation (multiples sites of radiosurgery and 2 courses of fractionated posterior fossa radiation) in 2019, 2020 and 2021. Patient 001-001 entered this phase I trial, and received 2 doses of CAM-H2. 50 mCi doses were administered on Sept 28, 2021, and Oct 26, 2021. ***Results:*** SPECT/CT imaging revealed significant uptake of CAM-H2 in brain lesions, suggesting a potential for intracranial therapeutic effect. Three intracranial tumors showed absorbed dose (Gy) of 3.1, 2.5 and 3.9 after the 1st administration of CAM-H2 and 5.4, 5.6 and 5.8 after the 2nd administration of CAM-H2. After the 1st administration of CAM-H2, absorbed dose (Gy) to the kidney was 1.8, 0.4 to the liver and 0.1 to the bone marrow. Absorbed dose (Gy) of CAM-H2 after the 2nd administration was 1.5 to the kidney, 0.3 to the liver and 0.1 to the bone marrow. Overall safety was acceptable with no grade 3 AEs reported. Despite promising imaging findings, the patient's disease progressed as based on CT/MRI performed 8 weeks after the first dose of treatment. This led to the discontinuation of CAM-H2. ***Conclusion:*** Patient 001-001's case demonstrates the challenges associated with advanced HER2+ breast cancer with brain metastasis. CAM-H2 therapy showed encouraging imaging results without obvious clinical benefit. This was the first patient treated in the dose escalation part of the study and the patient received a total of 100mCi of the investigational product. This dose was expected to be below the therapeutic dose level and doses were increased in subsequent study cohorts. Early progression did not allow for a higher total dose to be reached.

EP-1079

Pancreatic lesions dilemma

A. Mahmood[1], *S. Yusuf[1], T. Gurung[2], A. Omar[2], B. Drake[1];*
[1]Royal Marsden Hospital, London, UNITED KINGDOM, [2]Derriferd Hospital, Plymouth, UNITED KINGDOM.

Aim/Introduction: Accessory spleen/splenunculus/splenosis is common variant of normal splenic anatomy and is present in 10-12% of cases. It can present incidentally in locations that can mimic other pathology. Multimodality imaging is investigation of choice for these patients as differential includes pancreatic neuroendocrine tumours, malignant and benign pancreatic processes including metastases and inflammatory processes as well as peritoneal lesions. ***Materials and Methods:*** We present a series of complex cases that highlight the central use of Tc-99m nanocolloid and Tc-99m labelled heat-denatured RBC studies from 2 tertiary centres in conjunction with other imaging modalities in identifying splenic variants/splenosis from other pathological processes. ***Results:*** None. ***Conclusion:*** Tc- 99m nanocolloid "liver spleen" study is an under-used but low cost, safe and readily available study to differentiate splenic tissue from other pathological processes.Other radionuclide studies including Tc-99m labelled heat-denatured RBC, FDG and DOTATATE PET/CT, contrast enhanced CT and MRI scans as well as endoscopic ultrasound can all be helpful in these cases of diagnostic difficulty. ***References:*** 1.Bulushi NA, Sawafi FA (2023) Local Experience: The Role of Tc-99m Nano-Colloid Scintigraphy in the Diagnosis of Post-Traumatic Shattered Spleen. EP-1080

An Unusual Vertebral Body Collapse

L. Bonniaud[1], *J. Alberini[1,2,3], R. Ahond-Vionnet[1];*
[1]Department of Nuclear Medicine, Hôpital Pierre Beregovoy, Nevers, FRANCE, [2]Department of Nuclear Medicine, Centre Georges-François Leclerc, Dijon, FRANCE, [3]ICMUB Laboratory, UMR CNRS 6302, University of Burgundy, Dijon, FRANCE.

Aim/Introduction: Kummell's disease is a rare condition initially described by Dr. Hermann Kummell in 1891, and is defined as a delayed post-traumatic secondary osteonecrosis of a vertebral body, predominantly affecting elderly subjects mostly females. Clinically, it manifests as recurrent dorso-lumbar pain several months after an often minor or unnoticed initial trauma. Osteoporosis is the main risk factor, but other risk factors have been identified such as corticosteroid therapy, diabetes, or inflammatory diseases like vasculitis or granulomatosis. ***Materials and Methods:*** A 73-year-old female patient experienced an initial painful episode at the dorso-lumbar junction which resolved spontaneously after a few weeks. At this time, a CT scan did not show any recent vertebral compression but only old compression of L1 and L4. Six months later, she consulted for progressively intensifying dorso-lumbar pain associated kyphosis. ***Results:*** A spine CT scan revealed a recent T12 collapse with a 50% loss of height, a relatively dense appearance when compared to others and an intravertebral vacuum cleft. No significant regression of the posterior wall and no infiltration of the peripheral soft tissues were shown. Bone scintigraphy 99mTc-SPECT/CT showed a faint uptake of T12 on both early and late acquisition. A biopsy of T12 revealed a macrophagic resorptive and siderophagic inflammatory reaction with signs of steatonecrosis, consistent with osteonecrosis without suspicious malignant features. A cimentoplastie was then perfomed. This set of arguments enabled us to diagnose Kummell's disease. The diagnosis is mainly based

on the clinical history of the disease with five stages: 1) initial injury, may vary in severity and mechanism; X-rays are negative, 2) post-traumatic stage, with localized symptoms and no physical activity limitation, 3) latent interval, which is asymptomatic and lasts from a few weeks to one year, 4) the recrudescent stage, relapse of pain that gradually increases and 5) terminal stage, a permanent kyphosis occurs, added to pain. One radiological sign that can help in the diagnosis of Kummell's disease is an intravertebral vacuum cleft (IVC). IVCs represent important disruption of cortical and cancellous vertebral bone, vary in their radiographic appearance depending on patient's body posture, and trend to disappear over time. ***Conclusion:*** Kummell disease is probably underdiagnosed and its incidence is likely to increase in an ageing population. Diagnosis is mainly based on the disease history, clinical presentation, and imaging. Treatment relies either on nonoperative treatment as analgesic drugs and bed rest or on surgery and interventional radiologic techniques.

EP-1081

Skeletal metastasis detection in an asymptomatic patient with elevated serum alkaline phosphate level

E. Gharepapagh, *S. Rezaei;*
Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, Tabriz, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Detection of possible malignant involvement by radionuclide scan according to a patient's clinical symptoms, laboratory biomarkers, or occasionally even without them ***Materials and Methods:*** A 77-year-old man with a history of multinodular goiter operated (total thyroidectomy) one year ago. The pathology report was benign goiter, but when he was referred to the endocrinologist for periodic management of the disease, his physician accidently noticed an increase in the serum alkaline phosphatase level (ALP=536, normal range =44-147 IU/L). The patient's other tests were as follows (Ur = 49, Cr = 2.3, Ph = 3.8, Ca = 8.9). It is important to note that the patient did not mention any obvious bone pain. Whole body bone scan was requested by the attending physician for further evaluation of the patient. After an intravenous injection of 630 MBq of 99mTc-MDP, the whole body scan was performed three hours later in poster, anterior, and some spot views. ***Results:*** Several osteoblastic lesions were observed and reported at the regions of the Post. skull, Rt. lateral upper ribs, and Lt. ischium, suggesting metastatic involvement. Then the spiral chest CT was requested and showed a suspicious lesion in the superior segment of the right lung. During the evaluation by an interventional radiologist, a CT-guided biopsy was performed, and pulmonary carcinoma was diagnosed by the pathologist. Chemotherapy was prescribed for the patient in accordance with his condition. ***Conclusion:*** It is possible for bone metastasis to cause an increase in the serum alkaline phosphatase (ALP) titer or other biomarkers without even skeletal pain. Consequently, in such cases, it is recommended to perform whole body functional imaging, specifically bone scintigraphy.

EP-1082

A case report of fibrous dysplasia detected by Tc-99m MDP bone scintigraphy

E. Gharepapagh, *S. Rezaei;*
Department of Nuclear Medicine, Medical School, Tabriz University of Medical Sciences, Tabriz, IRAN, Tabriz, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Bone cells make an abnormal type of fibrous bone when they are affected by fibrous dysplasia caused by a gene mutation. Despite beginning to form before birth, abnormal bones are often not diagnosed until childhood, adolescence, or adulthood. As a result, this study aims to demonstrate the value of a whole-body bone scan when dealing with multiple skeletal involvement such as Paget's disease and fibrous dysplasia. ***Materials and Methods:*** A 22-year-old man presented for whole-body bone scintigraphy to assess skeletal pain and bone lesions with a history of left radius bone fractures 4 years ago and left femoral shaft fractures 2 years ago. In radiologic examination, osteolytic lesions were noted in the left femur of the patient who has been experiencing pain and numbness in his lower limbs since age 11. As a result of a biopsy performed in 2013, ABC (Aneurysmal Bone Cyst) was reported in the left lower limb. The patient complains of general body pain, especially in the ribs and pelvis, as well as movement limitation. Moreover, due to the pathological fracture of the left femur, a prosthesis has been placed there. Whole body bone scintigraphy was performed 3 hours after intravenous administration of 20 mCi 99mTc-MDP using a Siemens dual-headed gamma camera with LEHR collimators. ***Results:*** As a result of the scan, a nuclear medicine specialist reported both irregular and diffuse osteoblastic lesions in the skeletal system including the right maxilla and mandible, both sides ribs, the left hand and shoulder (with deformity), the left hemipelvis, the left lower limb (with mild deformity and proximal expansion) with high probability of fibrous dysplasia. Following the bone scan result and sites of involvements, another bone biopsy was performed on the left femur and tibia, confirming fibrous dysplasia. ***Conclusion:*** Therefore, the results indicate that a whole-body bone scan can be very useful in guiding and diagnosing rare and genetic bone conditions like fibrous dysplasia that have multiple involvements, and it may delay the diagnosis process if it is not used.

EP-1083

Gastric Metastasis from Breast Cancer Detected on ^{18}F-FDG PET-CT A Rare Finding

J. Bal, *R. Wakankar;*
Max Super Specialty Hospital, Delhi, INDIA.

Aim/Introduction: Gastric metastasis from breast cancer is a very rare occurrence with an incidence rate of only 0.04%, with most of the cases being reported postmortem during autopsy. Herein, we present the case of one such patient and describe the findings of her whole body ^{18}F-FDG PET-CT. ***Materials and Methods:*** This is the case of a 63-year-old woman who had been diagnosed with breast cancer involving the right breast which was immunoreactive for ER, PR and Her2Neu antibodies. Her previous ^{18}F-FDG PET-CT scan had revealed the presence of multiple hypermetabolic metastatic lesions in the liver and her axial & appendicular skeleton. She had received systemic therapy in the form of palbocicilib and letrozole followed buy alpelisib and fulvestrant. On her next follow-up whole body PET-CT scan, her breast primary along with her hepatic and skeletal metastasis had shown evidence of a partial response to the treatment. However, we had also detected some metabolically active and diffuse thickening of the gastric wall, which at the time seemed rather suspicious, given the patients complains on gastric fullness. It was decided to perform an upper GI endoscopy and biopsy to further evaluate these findings. ***Results:*** Her upper GI endoscopy revealed the presence of gastric mucosal edema and congestion, wrinkling and redness involving all parts of the stomach. Multiple biopsy samples were taken for histopathological

and immunohistochemical correlation. The final results from the gastric biopsy revealed the presence of metastatic breast carcinoma in the stomach. Her treatment plan was modified and she was started on capecitabine and trastuzumab deruxtecan therapy. Following this, she underwent another PET-CT for assessing the response to her new therapy. This scan revealed that the gastric wall thickening had now become metabolically inactive and the remaining skeletal lesions had also shown some response to treatment, indicating and overall partial response to therapy. ***Conclusion:*** In conclusion, ^{18}F-FDG PET-CT proved to play a pivotal role in this patients treatment as it not only helped us to stage and evaluate the disease and its response to chemotherapy, respectively, but also allowed for us to detect an unusual and often overlooked site of metastasis. This can lead to misdiagnosis of metastatic disease and insufficient treatment of the patient, which can later lead to disease progression or recurrence. Therefore, any abnormal metabolically active thickening in the stomach must be evaluated thoroughly even though it might appear innocuous.

EP-1084

Malignant Phyllodes Tumor with Sarcomatoid Lung Metastasis Detected on ^{18}F-FDG PET-CT

J. Bal, *R. Wakankar;*
Max Super Specialty Hospital, Delhi, INDIA.

Aim/Introduction: We present the case of a 40-year-old woman who had been diagnosed with a malignant form of phyllodes tumor and was on follow-up at our facility when she was incidentally detected to have lung nodules. ***Materials and Methods:*** The 40-year-old woman had been diagnosed with a malignant phyllodes tumor in the lower inner quadrant of the right breast, for which she had undergone a lumpectomy followed by adjuvant radiation therapy to the chest wall. There was no evidence of metastatic disease at the time of her lumpectomy. Following the lumpectomy from the lower inner quadrant of her right breast along with the adjuvant radiation therapy, she had followed up regularly with no new clinical symptoms.However, on her most recent visit to the oncology clinic, she was advised to undergo a routine chest CT scan, which revealed the presence of parenchymal nodules in both her lungs which had features suspicious of a neoplastic process. Based on these radiological findings and given the malignantnature of her phyllodes tumor, it was decided to perform a whole body ^{18}F-FDG PET-CT for her, to look for hypermetabolism in the lung nodules and to also look for evidence of metastasis in the rest of the body. ***Results:*** The ^{18}F-FDG PET-CT revealed the presence of hypermetabolic nodular soft tissue thickening in the post-operative bed of the right breast lower inner quadrant along with few right level I-II axillary lymph nodes. The nodules detected on the chest CT were also showing hypermetabolism and werelocated in the upper lobes of both the lungs. Apart from these, there was no evidence of any metastatic lesions in the rest of her body. A bronchoscopy guided biopsy of the lung nodules revealed the presence of atypical spindled cells arranged in a haphazard pattern within a fibrocollagenous stromawith osseous and chondroid differentiation at places. All these features were indicative of a spindle cell sarcomatoid neoplasm with chondro-osseous differentiation. ***Conclusion:*** This case is meant to highlight the utility of ^{18}F-FDG PET-CT in helping to choose which lung nodules are likely to be neoplastic and also in helping to identify which lesions are the best to biopsy based on the amount of metabolic activity and viable tumor tissue in them.

EP-1085

Case Report of a ^{18}F-FDG PET/CT after Pegfilgrastim Administration

D. Šnajder Mujkic*, I. Mihaljević;*
Clinical Institute of Nuclear Medicine and Radiation Protection, Osijek, CROATIA.

Aim/Introduction: It is known that pegylated G-CSF (pegfilgrastim) enhances bone marrow and spleen FDG uptake after administration following chemotherapy. ***Materials and Methods:*** In our case, a 48-year-old female was diagnosed with invasive ductal carcinoma of the left breast with cytologically proven metastases in the axillary lymph nodes. She had not received any prior therapy, including surgical resection of the primary tumor. The patient was undergoing preoperative doxorubicin hydrochloride and cyclophosphamide chemotherapy, and because of neutropenia as a side effect, was given pegfilgastrim on day 2 after each cycle of chemotherapy. 18F-FDG PET/CT was performed one week after 4 cycles of chemotherapy to assess early metabolic imaging for predicting tumor response. A weight-based dose of 18F-FDG was injected intravenously in the arm contralateral to the primary breast carcinoma and after a 60-min uptake phase, a combined PET/CT from mid-skull to mid-femur level was obtained. ***Results:*** We observed a rise in bone marrow FDG uptake in all bones after pegfilgrastim administration (SUVmax=6,3). ***Conclusion:*** Pegfilgastrim increased bone marrow uptake of 18F-FDG because of pegfilgrastim-induced stimulation of neutrophil progenitor cells, and therefore a change in 18F-FDG biodistribution must be considered before quantitative assessment of PET scans.

EP-1086

Patterns of [^{68}Ga]Ga-PSMA-11 Uptake in Synchronous Prostate Cancer and Diffuse Large B Cell Lymphoma

I. Próspero, *G. Ferreira, N. Vasconcelos, D. Silva, D. Barbosa, J. P. Teixeira, I. Lucena Sampaio;*
Instituto Português de Oncologia do Porto, Porto, PORTUGAL.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) overexpression in prostate cancer (PCa) correlates with PSMA-targeted radiopharmaceuticals uptake in positron emission tomography/computed tomography (PET/CT) studies. However, PSMA is known to be expressed in several other tissues/conditions, including other malignant processes, potentially leading to false-positive findings. Few reports describe PSMA uptake in lymphomas, with follicular lymphoma being the most commonly described subtype. ***Materials and Methods:*** We report a case of a 79-year-old man diagnosed in 2015 with a PCa (initial PSA level 7,56 ng/mL; Gleason 7 (4+3) and no evidence of metastases), treated solely with hormonal therapy and surveillance, due to the simultaneous diagnosis of a stage IV-B Diffuse Large B Cell Lymphoma (DLBCL) involving cervical, retroperitoneal, iliac and inguinal lymph nodes (LNs) and the bone marrow (BM). The patient underwent chemotherapy in 2015 and in 2018 (due to lymphoma recurrence), with a favourable response according to imaging and clinical criteria. In 2020, a thoraco-abdominopelvic CT performed due to rising PSA values under testosterone castrate levels, showed several abdominopelvic adenopathies and two metastatic bone lesions. A [68Ga]Ga-PSMA-11 PET/CT was requested for restaging (acquisition protocol: dynamic pelvic acquisition for ten minutes; whole-body study from the thighs to the skull base 60 minutes after injection). ***Results:*** The [68Ga]Ga-PSMA-11 PET/CT, performed in July/2020, revealed intense focal uptake in the prostate gland (SUVmax= 24,8) and in two bone

lesions (right ischiopubic ramus, SUVmax= 17,8; and T7 vertebral body, SUVmax= 18,2), attributed to local tumour and bone metastases, respectively. Additionally, the study unveiled findings atypical for PCa: diffuse and homogeneous uptake in the pelvic BM on early dynamic acquisition, not evident in the whole-body study at 60 minutes post-injection; splenomegaly with diffuse uptake moderately higher than liver. Mild PSMA uptake was also observed in abdominopelvic (SUVmax= 3,6) and retrocrural LNs, with no uptake in a supraclavicular adenopathy. The PET/CT report raised the hypothesis of DLBCL recurrence, which was later confirmed by BM biopsy. ***Conclusion:*** This case study presents potential key findings of PSMA uptake in DLBCL, specifically the splenic and BM uptake. Interpretation of PSMA uptake in the lymph nodes was challenging and equivocal, given the initial lymphoma involvement in the abdominopelvic region. The described patterns can be useful in the interpretation of similar findings in patients with no known previous or synchronous haematological disease, suggesting referral for additional studies, namely biopsy.

EP-1087

A case of osteopœcilia detected on bone scintigraphy coupled with SPECT CT

E. Kpekpeou, *A. Muhoza, S. Chkikar, M. Otmane, A. Seddouki, N. Ismaili Alaoui;*
Service de Médecine Nucléaire CHU Hassan II, Fès, MOROCCO.

Aim/Introduction: Osteopœcilia is a rare benign sclerosing bone dysplasia of autosomal dominant inheritance, first described by Alberg-Schönberg on radiographic findings. We report a case of osteopœcilia discovered incidentally on bone scintigraphy coupled with SPECT-CT in a patient undergoing treatment for infiltrating metastatic breast carcinoma to the sternal level ***Materials and Methods:*** A 41-year-old female patient with left breast cancer underwent baseline TAP CT and bone scintigraphy, which were consistent with secondary sternal bone localization. A follow-up bone scan performed three years later showed clear regression of the secondary sternal bone localization. Complementary SPECT-CT revealed a globally symmetrical distribution of multiple nodular osteocondensing lesions without scintigraphic translation opposite the proximal ends of the humeri and femurs, the right clavicle, osteoarticular structures of the pelvis and hands of benign appearance ***Results:*** Osteopcecilia is diagnosed radiographically. The radiological lesions described take the form of numerous rounded, ovoid areas of sclerosis present in the periarticular bone regions. Their distribution is fairly symmetrical, with a predilection for the epiphyses and metaphyses of long bones. Bone scans are generally normal, except when osteopœcilia is associated with other pathologies, notably tumours. SPECT-CT can improve its specificity in order to mask the radiological lesions of osteopecilia. In the case of this patient, the aim was to rule out other secondary bone localizations. The regression of the secondary sternal bone location on bone scintigraphy without the identification of other bone fixation abnormalities, combined with the scannographic discovery of multiple nodular osteocondensing lesions, symmetrically distributed, epiphyseal and metaphyseal location in the humeri and femurs, and in the osteoarticular structures of the pelvis and hands, led to the diagnosis of osteopœcilia. ***Conclusion:*** This observation highlights the diagnostic difficulty of osteopocilia when it is associated with tumour pathology metastatic to the bone, as in our patient's case, and the usual problem-solver role of bone scintigraphy coupled with SPECT-CT, which proved useful in making the diagnosis of osteopœcilia ***References:*** 1-Resnick D, Niwayama G. Neuro-Behçet's disease - a rare disease diagnosed with the help of FDG PET-MRI

J. Stulik, *T. Macek;*
FN Brno, Brno, CZECH REPUBLIC.

Aim/Introduction: Behçet's syndrome is a rare, chronic, multisystem inflammatory disease that has a heterogeneous spectrum of clinical manifestations including mucocutaneous, joint, ocular, vascular, neurological, and gastrointestinal manifestations. The differential diagnosis is very broad due to the non-specific clinical and paraclinical presentation. The aim of this case report is to demonstrate the role of PET/MRI in patients treated for chronic non-specific inflammatory problems, as a comprehensive modality capable of guiding the referring physician to the correct final diagnosis. ***Materials and Methods:*** A 26-year-old man was referred for FDG PET-MRI with chronic inflammatory findings in the cerebrospinal fluid, the etiology of which was unknown. Clinically, he had six months of cephalea, facial and upper extremity paresthesias, drooping eyelids, and migratory radiculopathy. In the last three months the patient's difficulties have worsened into progressive central left-sided hemiparesis, oropharyngeal dysphagia of mild degree and newly evident oral aphthae. The examination was performed using a standard protocol for the differential diagnosis of inflammation, ranging from the pelvic floor to the vertex. Thus, PET with ^{18}F-Deoxyglucose (^{18}F-FDG), MRI contrast transversal T1 and T2 weighted sequences with water and fat signal separation using the Dixon. ***Results:*** PET/MRI scan showed increased metabolic activity in several spinal nerves, with a variable correlate of signal changes on MRI; in addition, MRI showed an intracranial focus of pathological signal in the basal ganglia and capsula interna on the right side. This finding led to a targeted MRI brain scan, which showed a cascade sign (also known as a waterfall sign) in the mesodiencephalic junction on the right side, that is described in patients with neuro-Behçet disease. In combination with other abnormalities, the patient fulfilled International Criteria for Behçet's Disease - 2014. ***Conclusion:*** This case demonstrates that PET/MRI is a robust imaging modality in the differential diagnosis of inflammation of unclear etiology, even in very rare diseases such as Behcet's disease. ***References:*** Davatchi, F., et al. "International Team for the Revision of the International Criteria for Behçet's Disease (ITR-ICBD). EP-1089

Tc-99m Labeled Erythrocyte Scintigraphy Reveals Giant Mediastinal Cavernous Hemangioma Mimicking Malignancy on FDG PET/CT

B. Arca, *D. Has Simsek, Y. Sanli, S. Kuyumcu;*
Istanbul University, Istanbul Faculty of Medicine, Nuclear Medicine Department, Istanbul, TÜRKIYE.

Aim/Introduction: Hemangiomas are benign tumors that develop from the proliferation of normal or abnormal vascular structures. While these lesions grow slowly and remain asymptomatic, they can lead to symptoms or complications depending on their location and their effects on surrounding structures. When other modalities fail to provide a diagnosis, Tc-99m labeled erythrocyte scintigraphy is a reliable imaging tool for the differential diagnosis. In this case presentation, we aimed to contribute to the literature by highlighting the role of Tc-99m labeled erythrocyte scintigraphy in the diagnosis of a mediastinal hemangioma mimicking low FDG-avid malignancy on FDG PET/CT. ***Materials and Methods:*** A 43-year-old female patient was referred to the surgical clinic after the detection of a malignant nodule in the right lobe of the thyroid gland. Contrast-enhanced CT images revealed an incidentally detected heterogeneous contrast-enhancing mass lesion with microcalcifications, extending to the left supraglottic region and surrounding the vascular structures and the esophagus down to the infracarinal level in the mediastinum. Further evaluation for malignancy investigation with FDG PET/CT revealed mild heterogeneous FDG uptake in the described mass lesion, equivalent to the mediastinal blood pool. Considering the findings, differential diagnosis included both low FDG-avid malignancies and hemangiomas, given the contrast uptake identified on preoperative CT and the equivalence of FDG uptake with the mediastinal blood pool. Due to the risk of bleeding, histopathological confirmation could not be obtained from the mediastinal mass. Therefore, Tc-99m labeled erythrocyte scintigraphy was planned for diagnostic purposes. ***Results:*** In the Tc-99m labeled erythrocyte scintigraphy, increased uptake of labeled erythrocytes was observed, and the described lesion was evaluated in favor of mediastinal cavernous hemangioma. ***Conclusion:*** Mediastinal cavernous hemangioma is a rare, benign tumor originating from vascular endothelial cells. Imaging characteristics manifest as oval-shaped masses with well-defined borders. However, invasion of adjacent organs may lead to their classification as malignant lesions. Morphological findings from CT and MRI may not always definitively rule out malignancy. Tc-99m labeled erythrocyte scintigraphy is a reliable imaging tool for the differential diagnosis. Cases of mediastinal cavernous hemangioma evaluated with Tc-99m labeled erythrocyte scintigraphy are limited in the literature, and thus, this case constitutes an important example in this context. ***References:*** 1) Cohen AJ, Sbaschnig RJ, Hochholzer L, et al. Mediastinal hemangiomas. Ann Thorac Surg 1987;43(6):656-9. 2) Dobritoiu F, Moldovan H, Oncica R, et al. Giant cavernous hemangioma of the right atrium: a rare case and literature review. EP-1090

The conundrum of radioactive iodine therapy in malignant struma ovarii: A case of extensive disease managed with radioactive iodine therapy.

A. Nimmagadda, *A. Zakir Ali, B. Prathyusha, P. Thapa;*
Basavatarakam IndoAmerican Cancer Hospital and Research Institute, Hyderabad, INDIA.

Aim/Introduction: Struma ovarii is a type of monodermal teratoma that consists of thyroid tissue. It usually presents as a vague abdominal mass with non specific complaints. Suspicion or diagnosis of struma ovarii clinically is challenging. Most of the time, it is a histopathological diagnosis, post surgery of a ovarian lesion. Sometimes, it can be presented as a metastatic disease. Total thyroidectomy is performed either to identify the primary or facilitate the management. Radioactive iodine therapy is the standard of care in management of thyroid cancer post surgery. Review of literature shows few case reports and studies related to malignant struma ovarii. And a handful of these cases were treated with radioactive therapy. Due to the paucity of data, no clear guidelines exist regarding the risk stratification and use of radioactive iodine therapy in cases of malignant struma ovarii. ***Materials and Methods:*** Here, we present a case of 37 year old patient who presented with an ovarian mass. She underwent unilateral salpingooophorectomy and based on post operative histopathology, diagnosed as struma ovarii, with follicular variant papillary carcinoma thyroid . The patient also had multiple abdominal deposits at the time of presentation. ***Results:*** The patient has underwent multiple surgeries, including total thyroidectomy, and high dose radioactive iodine therapy (7 times, cumulative dose of 1300mCi) over a period of 20 years, as part of management with good clinical, anatomical and biochemical response. Currently the patient is asymptomatic with decreasing trend of Thyroglobulin levels. ***Conclusion:*** Malignant struma ovarii is a rare tumor and can often be misdaignosed. Because of the disease rarity, the management protocol is a dilemma. Surgery of the lesions is essential of a better outcome, but not always possible in extensive disease. Radioactive iodine therapy in such conditions will help in good disease control. Malignant struma ovarii should be treated and observed in similar lines of a metastatic thyroid carcinoma as our case suggests.

EP-1091

"No More Tears (Enough Is Enough)"- A Case Highlighting the Importance of Dacryoscintigraphy

J. Duarte, *J. Carvalho, A. Marques, F. Abreu, S. Pintão;*
Unidade Local de Saúde de Lisboa Ocidental, Carnaxide, PORTUGAL.

Aim/Introduction: Dacryoscintigraphy is a simple, minimally invasive and widely available imaging technique for the assessment of epiphora and the evaluation of nasolacrimal duct patency. Despite its utility, this procedure is not commonly conducted, since its radiological counterpart, dacryocystography, tends to be more frequently requested by clinicians, provided its higher level of anatomical detail. The latter has, however, the disadvantage of being a more invasive procedure and subjecting the patient to higher radiation exposure. ***Materials and Methods:*** We present a case of a 61-year-old woman with a history of sarcoidosis, which was referred to the otolaryngology department due to an episode of exuberant acute dacryocystitis with resolution after medical treatment. Due to persistence of complaints of bilateral epiphora, worse in the left eye, the patient was referred to our department to perform a dacryoscintigraphy.After the direct instillation of a 10µL drop of 3,7 MBq of [99mTc]TcO4- in the lateral cantus of each eye, a dynamic study was acquired for 15 minutes. The dynamic acquisition was repeated after the instillation of 3 drops of saline solution. Finally, the patient was requested to blow her nose, and a final static image was acquired. ***Results:*** The study demonstrated a normal drainage of the radiopharmaceutical to the medial cantus of the left eye and lacrimal sac, with accumulation at this level after the first dynamic study. After instillation of saline solution and blowing the nose, the retention persisted at the same level, supporting the diagnosis of functional impedance at a pre-ductal level. The right eye demonstrated a normal drainage to the nasolacrimal duct and nasal cavity within the first dynamic study.These findings were consistent with the results of a dacryocystography performed shortly after. The patient was then referred for a dacryocystorhinostomy in the left nasolacrimal duct, re-establishing the communication between the lacrimal

ducts and the nasal cavity. ***Conclusion:*** This case highlights the fact that dacryoscintigraphy remains a sensitive and easy exam, studying the lacrimal drainage in a physiological and non-invasive way, and obtaining fast and reliable results, obviating the need of dacryocystography in most cases. While it has the limitation of a lower anatomical resolution, valuable in some circumstances, it has the major advantage of a much lower exposure to radiation. ***References:*** 1 - DOI: 10.1097/MNM.0b013e32834f6cf7; 2 - DOI: 10.4103/ijnm.IJNM_18_18.

EP-1092

[18F]PSMA-1007 PET/CT findings in patient with the third oligometastatic brain recurrence of prostate cancer

A. Khalimon, *T. Antonevskaya, L. Atakishieva, M. Khodzhibekova, A. Leontyev;*
P. Hertsen Moscow Oncology Research Institute – branch of the National Medical Research Radiological Centre of the Ministry of Health of the Russian Federation, Moscow, RUSSIAN FEDERATION.

Aim/Introduction: Prostate cancer (PCa) is characterized by certain metastatic patterns, with bones being the predominant localization of distant metastases. The presence of visceral metastases is usually associated with rapid progression, generalization and death. Solitary visceral metastatic lesions, especially in a brain, without further generalization, are extremely rare for PCa [1]. ***Materials and Methods:*** Whole body [18F]PSMA-1007 PET/CT was performed on patient with biochemical recurrence (BCR) of PCa. Further histological examination was conducted on the identified pathological brain lesion. ***Results:*** A 79-year-old man with PCa (T2cN0M0, initial PSA level 5.4 ng/mL, Gleason score 10 (5+5)) underwent radiotherapy combined with hormone therapy in 2009, PSA level decreased to 0.07 ng/ml. In 2011, the patient complained about constant headaches, PSA level increased to 2.8 ng/ml. Brain MRI revealed the pathological signal focus in the right frontal lobe. Microsurgical removal followed by morphological study was performed. Immunohistochemical staining showed negativity for vimentin, CD45, CK7, CK5/14, synaptophysin, chromogranin A, CDx2K, TTF1 and also for GFAP, S-100, CDx2 (excluding glial tumor), positivity for PSA, AMACR, CK18 and AR. No other metastatic foci were identified. Oligometastatic recurrence of PCa as a solitary brain lesion was confirmed. From 2011 to 2017, the patient irregularly received androgen deprivation therapy, maintaining a stable PSA level (0.4 ng/ml). In 2017, patient again noted headaches without PSA level growth. Brain MRI revealed the pathological signal focus in the right frontal lobe similar to the previously removed one. No other metastatic foci were identified. The second oligometastatic recurrence was verified after microsurgical removal followed by histological examination. In 2022, during an annual follow-up, MRI revealed the pathological signal focus in the left hemisphere of the cerebellum, interpreted as metastatic. Whole body [18F]PSMA-1007 PET/CT was performed to assess the extent of the tumor process. Solitary focal pathological uptake with SUVmax 3.3 was identified in the left cerebellar hemisphere, corresponding to the pathological signal focus on MRI. Considering the patient's history and PSMA hyperexpression on PET/CT, the third oligometastatic recurrence was confirmed. Follow up brain MRI in 2023 after stereotactic radiosurgery of metastatic cerebellum lesion showed decrease of its size. The patient remains under follow up with no signs of relapse to date. ***Conclusion:*** The presented clinical case illustrates an exceptionally rare course of prostate cancer, characterized by a series of oligometastatic brain recurrences without progression and generalization. ***References:*** 1.Barakat T., et al. Solitary brain metastasis from prostate cancer: a case report. AnnPalliatMed2016;5(3):227-232. DOI:10.21037/apm.2016.04.02.

EP-1093

Unilateral Graves' Disease

A. Muhoza, *E. Kpekpeou, S. Chkikar, M. Otmane, N. Ismaili Alaoui;*
CHU Hassan II, Fès, MOROCCO.

Aim/Introduction: Graves' disease is the most frequent and expressive cause of hyperthyroidism, and is more common in women. Found at all ages, peak incidence is between 40 and 60. Unilateral involvement is rare. In this paper, we report on a case of unilateral Graves' disease and highlight the contribution of thyroid scintigraphy. ***Materials and Methods:*** Patient 52 years old, Caucasian, multiple comorbidities, body mass index of 56.8 kg/m2, with subclinical hyperthyroidism and normal thyroid gland size, elastic palpation and regular surface without cervical adenopathy. Biological tests revealed a Thyroid Stimulating Hormon (TSH) suppressed to 0.001 IU/mL, Free-thyroxine (FT4) and Free triiodothyronine (FT3) levels 1.3 and 1.5 times normal respectively, and antibodies to TSH-receptor positive at 12.94 U/L (>1.5). The patient was started on Carbimazole 5 mg per day.Cervical ultrasound revealed a diffuse anodular hypervascular thyroid in favor of thyroiditis. T99m thyroid scintigraphy revealed a thyroid with regular contours and intense, inhomogeneous fixation in the left lobe, contrasting with normal fixation in the right lobe. ***Results:*** Graves' disease is an autoimmune hyperthyroidism characterized by T and B lymphocytic infiltration [1]. Unilateral involvement not due to hemiagenesis is very rare. Few cases have been reported with preferential right lobar involvement [2]. In our case, the involvement concerned the left lobe.Clinical features resemble classic Graves' disease, but can mimic a toxic adenoma in cases of selective lobe hypertrophy. Antibody positivity, anodular heterogeneous ultrasonography and unilateral diffuse thyroid hyperfixation make the positive and differential diagnosis with other pathologies presenting unilateral involvement on thyroid scintigraphy (thyroid hemiagenesis, Hashimoto's thyroiditis, toxic adenoma, toxic multinodular goiter, subacute thyroiditis) [2].Treatment strategies are those of classic Graves' disease [2]. ***Conclusion:*** Knowing the pathophysiology of unilateral involvement would offer personalized therapies. Clinical, biological, morphological and functional imaging results must be collected to confirm the diagnosis and make a differential diagnosis. Practitioners need to be aware of this entity in order to improve management. ***References:*** [1] Y. Tomer, "Mechanisms of autoimmune thyroid diseases: From genetics to epigenetics," Annu. Rev. Pathol. Mech. Dis., vol. 9, pp. 147-156, 2014, doi: 10.1146/annurev-pathol-012513-104713. [2]S. Elamari, F. Z. Rhmari Tlemcani, I. Motaib, S. Laidi, and A. Chadli, "Grave's disease affecting one thyroid lobe: About 2 cases," Med. Nucl., vol. 46, no. 3, pp. 164-167, 2022, doi: 10.1016/j.mednuc.2022.03.001.

In-transit Sentinel Lymph Nodes in Melanoma - Hybrid Specifics and Clinical Significance: case reports

L. Chavdarova[1], *V. Georgiev[2], I. Gavrilova[3], E. Piperkova[1];*
[1]Clinic of Nuclear Medicine, University Specialized Hospital for Active Treatment in Oncology, Sofia, BULGARIA, [2]Clinic of Surgery, University Specialized Hospital for Active Treatment in Oncology, Sofia, BULGARIA, [3]Clinic of Oncodermatology, University Specialized Hospital for Active Treatment in Oncology, Sofia, BULGARIA.

Aim/Introduction: Although the incidence of in-transit sentinel lymph nodes (intSLN) in malignant melanoma (MM) is reported to be relatively low, the presence of metastatic cells in them reaches a significant percentage, with corresponding upstaging and adjuvant treatment initiation for stages IIB/C-III. Harvesting intSLNs could be a challenge for the surgeon due to "unconventional" location and small size. Hybrid SPECT/CT-detection during routine lymphoscintigraphy is of significant help, providing exact anatomy and morphology. PET/CT in the follow-up of intSLN-histologically positive patients undergoing adjuvant therapy could be of further value for early relapse detection. Our aim is to present the role of SPECT/CT for intSLN-detection in MM patients with consequent PET/CT follow-up for micrometastasis-positive (+) SLN cases. ***Materials and Methods:*** We present 4 cases of superficial-spreading MM patients with primaries on the skin of the trunk (3 - back, 1 - abdominal wall) with SPECT/CT-mapped intSLN, successful surgical gamma-probe removal and consequent PET/CT-follow-up where applicable. ***Results:*** One patient had a 4mm, pigmented, (+) intSLN in subcutaneous lumbar region and a second, negative axillary (-) SLN. Target-therapy was initiated with 3 consequtive PET/CT-studies, showing stable disease. The second patient had a 3mm, (+) intSLN in scapular region along with a (-) axillary SLN - tailored to adjuvant immune therapy with 1 follow-up PET/CT so far with no evidence of disease. Patient 3 had a (-) intSLN in dorso-lumbar region with no other „expected" drainage and was appointed for clinical observation. Patient 4 had a 4mm (-) intSLN on the front abdominal wall, FDG-non-avid on preoperative PET/CT, also for further clinical follow-up. ***Conclusion:*** The detection of in-transit SLN in MM is crucial for accurate staging, since "expected" SLN-basins could give false-negative staging. SPECT/CT is of great importance for surgical harvesting of in-transit SLN and PET/CT follow-up should be integrated in histologically positive patients for further adjuvant-treatment effect stratification.

Comparison of PET/CT images with ^{18}F-FDG and ^{18}F-PSMA-1007 in musculoskeletal tumors to evaluate the potential of theranostics approach

E. Etchebehere, *M. Silva, N. Tobar, A. O. Santos, G. O. Barbosa, M. C. L. Lima, J. B. Carvalheira, M. Etchebehere;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: Diagnosis and management of metastatic musculoskeletal tumors are challenging. MRI and FDG PET/CT play a crucial role in assessing the extent of these tumors. PSMA-1007 PET/CT may be an interesting diagnostic marker due to the potential Theranostics implications. This study aimed to compare the performance of FDG and PSMA PET/CT images in patients with advanced-stage unresectable recurrent and metastatic musculoskeletal tumors. ***Materials and Methods:*** Eight patients underwent FDG PET/CT and PSMA PET/CT imaging with a 24-hour interval between studies. ***Results:*** In 5/8 patients, PSMA uptake was higher than FDG uptake. A giant cell recurrent sacral tumor in a 27-year-old male exhibited the highest PSMA uptake (PSMA SUV=100; FDG SUV=16). PSMA uptake was also higher than FDG in the following tumors: osteolytic renal cell carcinoma metastasis in the scapula of a 58-year-old male (PSMA SUV=40; FDG SUV=11); a recurrent spindle-cell neural tumor in the upper limb of a 69-year-old male (PSMA SUV=27; FDG SUV=8); myxofibrosarcoma mass in the distal leg of a 61-year-old female (PSMA SUV=18; FDG SUV=10). Interestingly, chordomas had heterogeneous PSMA and FDG uptake. The PSMA PET/CT of A 65-year-old male with multiple chordoma metastases with soft tissue invasion showed PSMA uptake higher than FDG in all lesions (PSMA SUV=32; FDG SUV=19). PSMA-avid additional sites of metastases were noted in mediastinal lymph nodes and the right hepatic lobe; FDG uptake was minimal in these metastases. In contrast, FDG uptake was higher than PSMA in a 54-year-old male with a large recurrent chordoma (30x24 cm mass) extending from L4 to the proximal left thigh (PSMA SUV=9; FDG SUV=31). FDG uptake of two males with desmoid tumors in the upper limb was higher than PSMA (PSMA SUV=4; FDG SUV=7). ***Conclusion:*** The study results show the potential advantage of using PSMA PET/CT with FDG PET/CT to provide additional information for monitoring patients and combining therapies. PSMA PET/CT demonstrated more extensive disease and has the advantage of the possibility of a Theranostic approach. ***References:*** Kleiburg F et al. PSMA as potential target for molecular imaging and treatment in bone and soft tissue sarcomas. Br J Radiol. 2023;96:20220886. EP-1096

Comparison of PET/CT images with ^{18}F-FDG and ^{18}F-PSMA-1007 in metastatic acral melanoma: a case report.

E. Etchebehere, *D. M. Mendanha, N. Tobar, L. T. Macedo, A. O. Santos, M. C. L. Lima, C. S. P. Lima;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: Acral melanoma (AM) is a rare form of cutaneous melanoma and affects acral areas such as the palms, soles, and nails. AM is associated with a worse prognosis compared to other subtypes of cutaneous melanoma. Despite advances in surgery, radiotherapy, and molecular targeted/immunotherapy, new treatment modalities for AM is highly desirable to improve survival. Staging and restaging AM with FDG PET/CT is essential to detect nodal and distant metastasis. However, FDG cannot be used as a Theranostic radiopharmaceutical. The possibility of investing in a Theranostic approach to these patients is desirable and radiolabeled PSMA may be a potential Theranostic tool. Here, we present a patient with AM, which progressed with brain and lung metastases, and highlight the importance of PET/CT images with FDG and PSMA-1007 for the identification of metastases and potential Theranostic approach for this challenging disease. ***Materials and Methods:*** D.R.M., a 50-year-old male, rural worker, developed AM in the 3rd left toe in January 2023. In September 2023, the patient underwent amputation of the 3rd and 4th toes and left ilioinguinal lymphadenectomy. Histopathology confirmed melanoma with vertical growth and deep invasion into the dermis as well as lymph node metastases. In January 2024, he presented a reduction in the level of consciousness and intense headaches. Cranial MRI revealed multiple brain metastases with sizes ranging from 0.6 to 4.6 cm, significant swelling, edema, and midline shift. The patient underwent restaging FDG PET/CT and PSMA PET/CT, with a 24-hour interval between studies. ***Results:*** FDG PET/CT identified mild metabolism in the brain metastases and no extracranial metastases. PSMA PET/CT impressively identified all brain metastases detected by MRI (SUVs ranging from 8 to 11) with uptake higher and more extensive than FDG uptake and no extracranial metastases. Neurological symptom control was initiated with dexamethasone, and significant improvement was observed. The patient will initiate antineoplastic therapy. ***Conclusion:*** This case highlights the importance of comparing

FDG and PSMA PET/CT in assessing patients with AM. PSMA PET/CT emerges as a promising diagnostic imaging modality for detecting distant metastasis in AM, especially brain metastases since PSMA is not normally taken up by the central nervous system and is extremely avid for AM metastases. PSMA may be a potential Theranostic tool in specific cases. ***References:*** The study was supported by Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) and Fundação de Apoio ao Ensino e à Pesquisa do Estado de São Paulo (CEPID FAPESP #2021/10265-8).

EP-1097

Comparison of PET/CT images with ^{18}F-FDG and ^{18}F-PSMA-1007 in relapsed adenoid cystic carcinoma

E. Etchebehere, *H. S. V. Sousa, N. Tobar, L. T. Macedo, S. Kuba, A. O. Santos, B. J. Amorim, C. S. P. Lima;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: Adenoid cystic carcinoma (ACC) is a tumor of the salivary glands, characterized by insidious growth, recurrences, and distant metastases.This study aimed to describe the findings of PET/CT images performed with ^{18}F-FDG (FDG PET/CT) and ^{18}F-PSMA-1007 (PSMA PET/CT) in patients with relapsed ACC to verify whether any of these studies are more suitable for identifying local recurrence and distant metastases. ***Materials and Methods:*** Patients were submitted to restaging PET/CT studies with FDG and PSMA-1007 with a 24-hour interval between exams before treatment. ***Results:*** Patient 1: A 29-year-old female was diagnosed with ACC of the parotid in 2016. She underwent total parotidectomy and radiotherapy. In 2021, a chest CT identified lung nodules, and the patient underwent resection of the largest lesions. In 2024, a restaging FDG PET/CT was negative for metastases while PSMA PET/CT identified mild PSMA uptake in two pulmonary nodules (0.8 cm, SUV=2.2; 0.9 cm, SUV=3.4) suspicious for ACC metastases. The patient remains asymptomatic. Patient 2: A 49-year-old male with newly diagnosed ACC in the salivary gland, underwent tumor resection and radiotherapy in 2010. In 2022 the patient recurred in the lungs, skull, and L5 and was submitted to lung nodule resections and radiotherapy to skull and L5. In 2023, FDG PET/CT revealed hypermetabolic metastases in multiple lung nodules (highest SUV=13.4) and L5 vertebrae (SUV=8.5). PSMA PET/CT showed only mild uptake in the pulmonary nodules (highest SUV=4.7) and similar uptake in L5 vertebrae (SUV=8.7). The patient is currently asymptomatic. Patient 3: A 46-year-old male with ACC in the parapharyngeal space underwent surgical resection and radiotherapy in 2008. In 2022, chest CT identified lung nodule metastases (>3.8 cm). In 2023 FDG PET/CT demonstrated hypermetabolic lung nodule metastases (>SUV=12.3) and multiple liver nodules (>2.7 cm) without FDG uptake. A PSMA PET/CT showed uptake in the same lung nodules although with lower uptake (SUV=8.8). The patient currently reports dyspnea. ***Conclusion:*** There is heterogeneity in FDG PET/CT and PSMA PET/CT uptake in relapsed ACC. Combining both PET/CT radiotracers can provide additional information for monitoring patients. PSMA PET/CT has the advantage of the possibility of a theranostic approach. ***References:*** Tan BF et al. PSMA PET Imaging and Therapy in Adenoid Cystic Carcinoma and Other Salivary Gland Cancers: A Systematic Review. Cancers 2022:14;3585. The study was supported by Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) and Fundação de Apoio ao Ensino e à Pesquisa do Estado de São Paulo (CEPID FAPESP #2021/10265-8).

EP-1098

[^{68}Ga]FAPI Cardiac Uptake in Takotsubo Cardiomyopathy - Occasional Findings in PET/CT Imaging

R. Calabretta, *K. Hamzaraj, A. Lazarević, A. Kammerlander, L. Zisser, T. Nakuz, P. Binder, S. Graf, M. Hacker;*
Medical University of Vienna, Vienna, AUSTRIA.

Aim/Introduction: Takotsubo cardiomyopathy (TC) is expressed as acute left ventricular (LV) systolic dysfunction as response to emotional or physical stress and is associated with high mortality. Its diagnosis requires exclusion of concurrent underlying conditions and is facilitated by multimodality cardiac imaging. Due to a limited understanding of its pathogenesis, dedicated diagnostic methods are absent. ***Materials and Methods:*** We report a case of occasional findings of LV apical and periapical [68Ga]FAPI-overexpression on PET/CT imaging in a patient with hypokinetic and ballooning LV apex and higher T1-times in CMR, as suggestive pattern of TC. ***Results:*** Static whole-body [68Ga] FAPI PET/CT was performed 60 min. post tracer injection (p.i.). Further static cardiac PET/CT images were acquired 70 min. and 120 min. p.i.. On PET/CT imaging, a dilated, balloon-shaped, hypertrophic LV apex with a diffuse [68Ga]FAPI-overexpression in the apical and periapical segments (SUVmax:13,9;SUVmean:11) was observed. Elevated [68Ga]FAPI-uptake was observed also at basal LV (SUVmax:11,8;SUVmean:7,5). Also 70 and 120 minutes p.i., a elevated [68Ga]FAPI-overexpression was recorded in the apical, periapical and in the basal LV, only slightly reduced compared to the initial scan. The patient underwent also native, late gadolinium enhancement (LGE) (0.15 mmol/kg Gadovist®), and advanced tissue characterization CMR images (1.5 Tesla) revealed a viable LV myocardium with no LGE. The CMR images depicted a ballooning LV apex with reduced apex contractility and longitudinal strain. Volumetric measurements generated a LV end-diastolic dimension of 41mm, end-diastolic volume of 99ml and ejection fraction of 59%. Furthermore, extracellular volumes (ECV) of 28% and high native T1-times of 1031ms, with an apical peak of 1200-1400ms were suggestive of a TC. ***Conclusion:*** Our incidental findings of LV apical and periapical [68Ga]FAPI-overexpression might suggest a potential diagnostic role of this emerging tracer as well as might provide insights that enhance the ability to assess myocardial functional alterations, disease progression and clinical outcomes in patients with TC.

EP-1099

^{18}F-FDG PET/CT in ulcerative colitis

B. Pernthaler, *T. Nazerani-Zemann;*
Medizinische Universität Graz, Universitätsklinik für Radiologie, Klinische Abteilung für Nuklearmed, Graz, AUSTRIA.

Aim/Introduction: Ulcerative colitis (UC) and Crohn's disease (CD) are chronic inflammatory bowel diseases affecting the gastrointestinal tract. Accurate assessment of disease activity is crucial for treatment selection. Endoscopy is the preferred method, but CT and MRI are also used. Nowadays, ^{18}F-FDG PET/CT has emerged as a valuable non-invasive molecular imaging tool for evaluating inflammatory bowel disease. ***Materials and Methods:*** A 34-year-old man with a history of UC underwent ^{18}F-FDG PET/CT prior to colectomy, as colonoscopy was not feasible due to high mucosal vulnerability and increased perforation risk. The CT revealed inflammatory wall thickening of the rectum, sigmoid colon, and descending colon without abscesses or perforations. The PET/CT showed a mural increased tracer uptake in these bowel segments, indicating active inflammation. UC and CD

are chronic inflammatory bowel diseases, with UC limited to the colon's mucosa and submucosa. Disease extent varies, classified as proctitis, left-sided colitis, or pancolitis. ***Results:*** Our patient presented with proctitis and left-sided colitis sparing the transverse colon, a discontinuous inflammatory pattern atypical for UC, as UC typically spreads continuously from the rectum to the rest of the colon. Diagnosis is based on a medical history, physical examination, laboratory tests, imaging, endoscopy and histology. ^{18}F-FDG PET/CT offers high sensitivity and specificity in detecting inflammation, especially in patients at increased risk of perforation, strictures or inadequate bowel cleansing. ***Conclusion:*** This case highlights the utility of ^{18}F-FDG PET/CT in UC, providing important molecular insights into the extent and activity of the disease. ^{18}F-FDG PET/CT is a promising non-invasive imaging technique in the evaluation of chronic inflammatory bowel disease in treatment selection and response assessment, especially when endoscopy is challenging or not feasible.

EP-1100

Breast lymphoma as Richter Syndrome in an elderly man 12 years after diagnosis of chronic lymphocytic leukemia.

S. Martin Aguilar, *M. Sanchez Torrente, P. Guardia Jimena, A. Santos Bueno, M. Ureña Lara;*
Complejo Hospitalario de Jaén, Jaén, SPAIN.

Aim/Introduction: Chronic lymphoblastic leukemia (CLL), the most common leukemia in elderly patients, is generally an indolent and low-grade disease, however in about 2-9% of patients may develop another more aggressive lymphoid malignancy (most commonly diffuse large B-cell lymphoma (DLBCL)), what is known as Richter's Syndrome (RS). Positron emission tomography with 18-fluorodeoxyglucose (^{18}F-FDG PET/CT) has been widely used as a noninvasive molecular imaging technique in managmento of hematologic malignancies and can be extremely beneficial in CLL patients when RS is suspected. Primary breast lymphoma (PBL) is a rare presentation of non-Hodgkin's lymphoma (NHL) (less than 1-2% of all NHL and less than 0.5% of all malignant breast neoplasms) that almost occurs in females among 60-65 years. ***Materials and Methods:*** We present the case of an 89-year-old asymptomatic man diagnosed in 2012 with CLL, clinical stage A of Binet RAI 0, with no data on tumor activity until August 2023, at which time he presented with a poorly delimited, stony, ulcerated right breast tumor adhered to the costal wall. Clinically in good general condition, afebrile, asymptomatic. An initial study was performed with breast ultrasound, computed tomography (CT) and biopsy. ***Results:*** Biopsy of the lesion showed a pathological result of DLBCL, CD10, Bcl-6 and MUM1 positive phenotype (activated phenotype). Proliferative index measured with Ki67: 90% cells. A baseline study with CT was performed, which only showed the known breast tumor. He began first-line treatment with the R-miniCHOP regimen on November 14, 2023 (punctual hypotensive reaction to rituximab that recovered with the administration of serum). The interim FDG PET-CT study after 3 treatment cycles showed a hypermetabolic mass in the right breast (3.5x9x8cm, with SUVmax 30.03) and residual lymphadenopathy in the right axilla and right retropectoral region. ***Conclusion:*** We are faced with a doubly rare case; a PBL in a man that also presents as a late-onset RS. In the literature, cases of breast involvement due to lymphoma are rare, so this patient is interesting as an illustrative case of its presentation and the usefulness of ^{18}F-FDG PET/CT in its management.

EP-1101

Exploring the diagnostic utility of Octreoscan scintigraphy in neuroendocrine tumors : a case study

H. Bennani, *S. Amellouk, N. Abaouz, H. Batani, Z. Ouassafrar, A. Guensi;*
CHU IBN ROCHD, Casablanca, MOROCCO.

Aim/Introduction: Neuroendocrine tumors (NETs) pose a diagnostic challenge due to their diverse clinical presentations and potential for metastasis. This study aims to illustrate the diagnostic significance of Octreoscan scintigraphy in localizing primary lesions and assessing metastatic disease in NETs. ***Materials and Methods:*** Patient Selection: A 31-year-old male with a history of epigastric pain underwent a thorough diagnostic workup. Imaging Protocol: Octreoscan scintigraphy, in conjunction with CT, was performed post-administration of Tc99m Tektrotyd. Imaging scans were conducted at 1 hour and 4 hours post-injection, followed by SPECT-CT imaging. Data Analysis: Scintigraphic findings were assessed based on intensity of tracer uptake and anatomical localization. ***Results:*** Initial Presentation: The patient's chief complaint was epigastric pain persisting over two months, without apparent jaundice or other associated symptoms. Imaging Findings: Octreoscan revealed intense tracer uptake in the liver, supraclavicular region, and epigastric area, indicative of possible primary and metastatic lesions. SPECT-CT Imaging: Detailed imaging demonstrated multifocal hepatic uptake, lymph node involvement, and focal uptake in the gastric region, further characterizing the extent of disease involvement. ***Conclusion:*** Octreoscan scintigraphy emerges as a valuable adjunct in the diagnostic algorithm for NETs, offering insights into both primary tumor localization and metastatic spread. While Octreoscan provides valuable information, its limitations in identifying small primary lesions underscore the importance of complementary imaging modalities. Integrating Octreoscan with advanced techniques like PET may enhance diagnostic accuracy and facilitate optimal management strategies for patients with NETs. ***References:*** [Tenenbaum F. EP-1102

New-onset pancreatic involvement on a follow-up ^{18}FDG PET-CT in a patient with non-Hodgkin's lymphoma.

S. Martin Aguilar, *M. Sanchez Torrente, P. Guardia Jimena, A.*

Santos Bueno, M. Ureña Lara;
Complejo Hospitalario de Jaén, Jaén, SPAIN.

Aim/Introduction: 18F-fluorodeoxyglucose-positron emission tomography/ computed tomography (18F-FDG-PET/CT) is powerful for cancer staging and detection, but this leads to a significant number of foci of doubtful interpretation; Studies have examined incidental FDG uptake in the thyroid, the breasts, the colon, and the prostate with different rates of detection (0.82-3.8% of FDG uptake, of which about 12.7-63.6% resulted in malignancy). However, almost no study has examined the frequency of new pancreatic FDG uptake and its proportion of malignance. Non-hodgkin's lymphoma (NHL) is often determined with enlarged lymph nodes and may commonly affect extranodal organs, but the involvement of pancreas is rare (approximately 5% of all pancreatic masses and 1% of all extranodal lymphomas). ***Materials and Methods:*** We present the case of an 83-year-old male patient diagnosed in April 2023 with large cell follicular B NHL with MYC and BCL2 rearrangements, proliferative index of 70%, constitutional syndrome (anorexia and loss of more than 20 kg) and lesions at the dorsal and lumbar with spinal cord involvement in cervical injuries. The initial study showed supra- and infradiaphragmatic lymph nodes, heterogeneous splenomegaly, and an intraperitoneal tumor in the right upper quadrant (probable adenopathic conglomerate); IVSB stage. Receives 1st line treatment according to the R-miniCHOP scheme for 6 cycles between April and July 2023. In 18FDG PET-CT at the end of treatment in September 2023, no significant hypermetabolic lesions were observed. We take as reference the study by Iwasa et all from February 2021, in which they analyzed the appearance of FDG uptake in the pancreatic area in patients under follow-up for cancer other than pancreatic, finding 0.3% of pancreatic foci, of which 85% were malignant. ***Results:*** In control 18FDG PET-CT in December 2023, a newly appearing hypermetabolic nodule was detected that seems to depend on the tail of the pancreas (size 2.1x2.4cm and SUVmax 22.35), highly suggestive of malignancy. An ultrasound endoscopy was performed that identified homogeneous hypoechogenic lesions with well-defined edges in the tail of the pancreas-splenic hilum; The biopsy of the lesion confirmed relapse of diffuse large B cell lymphoma, deciding treatment with Polatuzumab-R-Benda with good tolerance to date. ***Conclusion:*** The pancreatic hypermetabolic focis found in control 18FDG PET-CT in cancer patients, although rare, seem to have a high rate of malignancy, so their directed study is essential to characterize them, although the research carried out for this purpose until the date is scarce.

EP-1103

Isolated Tonsillar Kaposi Sarcoma: A Rare Case

B. Bozca[1], *A. Cinar[1], S. Demirtas Senlik[1], D. Cayir[1,2], E. Tatci[1,2];*
[1]Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]University of Health Sciences, Ankara, TÜRKIYE.

Aim/Introduction: Kaposi sarcoma is an angioproliferative neoplasm generally seen in immunosuppressed patients caused by kaposi sarcoma-associated herpes virus (HHV-8). There are four types of Kaposi sarcoma: classic, endemic, epidemic (HIV-related), and iatrogenic (corticosteroid-related). It typically manifests as multiple, pigmented, non-blanching lesions on the skin or at the same level, often painless but may also involve bone and organ infiltration. ***Materials and Methods:*** Here, we present a rare case diagnosed with tonsillar Kaposi's sarcoma using F^{18} FDG PET/CT imaging. ***Results:*** A 69-year-old female with a history of smoking presented to the ENT department with throat pain. She did not have B symptoms such as fever, weight loss, or night sweats. Examination revealed an ulcerovegetative mass starting from the right tonsil and extending to the base of the tongue, measuring approximately 30x20 mm. Other ENT examination findings were normal. Laboratory tests showed CRP: 13.61 (N: 0-5) and WBC: 13.14 (N: 4.5-10), with other values within normal ranges. MRI revealed a mass lesion measuring approximately 26x30 mm in the lingual tonsil on the right side, with hypertrophy of the right palatine tonsil compared to the left. F^{18} FDG PET/CT imaging showed increased metabolic activity in the soft tissue density extending from the anterior wall of the right nasopharynx to the base of the tongue, narrowing the air passage (SUVmax: 8.94). Additionally, asymmetric hypertrophy and increased metabolic activity were observed in the right tonsil (SUVmax: 7.18). Low-level metabolic activity increase was observed in multiple cervical lymph nodes bilaterally. Biopsy from the right tonsillar fossa revealed clusters of spindle cells with nuclear atypia, diffusely positive for CD34 and showing HHV-8 nuclear expression, confirming the diagnosis of Kaposi sarcoma. The patient was referred to the Radiation Oncology Clinic for radiotherapy planning. ***Conclusion:*** The treatment of Kaposi sarcoma varies depending on the type, severity, extent, and organ involvement of the disease. Currently, staging is done using CT, MRI, endoscopy, or bronchoscopy. However, the invasiveness and time-consuming nature of some of these procedures highlight the importance of PET/CT, which allows whole-body scanning. F^{18} FDG PET/CT imaging can detect increased metabolic activity due to inflammatory changes in the bilateral tonsillar region. In cases where intense metabolic activity accompanies asymmetric tonsillar hypertrophy and soft tissue thickening, Kaposi's sarcoma should be considered in the differential diagnosis, especially when investigating for primary malignancies.

EP-1104

Unexpected discovery : ectopic thyroid focus in a patient with painless subcutaneous nodular formation prior thyroidectomy

H. Bennani, *S. Amellouk, N. Abaouz, H. Bensimimou, Z. Ouassafrar, A. Guensi;*
CHU IBN ROCHD, Casablanca, MOROCCO.

Aim/Introduction: This case presents the unexpected detection of an ectopic thyroid focus in a 57-year-old female with metastatic invasive ductal carcinoma of the right breast. Despite a prior thyroidectomy in 2015, imaging revealed an ectopic thyroid, emphasizing scintigraphy's role. ***Materials and Methods:*** A 57-year-old Caucasian female with metastatic invasive ductal carcinoma of the right breast, undergoing post-Patey procedure chemotherapy and hormone therapy, and receiving levothyroxine following a 2015 thyroidectomy, was enrolled. Evaluation followed the discovery of a painless subcutaneous nodular formation near the thyroid cartilage. Tc-99m scintigraphy, known for distinguishing ectopic thyroid from other neck masses, was employed.Imaging Protocol:The protocol included a thyroid scan using 3mCi of Tc-99m pertechnetate, followed by low-dose SPECT-CT to characterize abnormal radiotracer uptake. ***Results:*** The thyroid gland was absent due to the previous thyroidectomy. An ectopic thyroid focus measuring 4.4 x 5.1 mm was identified anterior to the thyroid cartilage. Significant hyperfixation adjacent to the thyroidectomy site, corresponding to residual thyroid residue, was noted. ***Conclusion:*** This case emphasizes scintigraphy's significance in identifying ectopic thyroid tissue. Regular monitoring is advised for asymptomatic cases,

while levothyroxine therapy may mitigate mass enlargement. Scintigraphy's sensitivity and specificity underscore its importance in tailored patient management. A multidisciplinary approach is crucial for accurate diagnosis and personalized care in ectopic thyroid nodules. ***References:*** ersaneti, J. A., Silva, R. D. P., Ramos, R. R. N., de Matsushita, M. EP-1105

A pitfall finding showing FDG accumulation in postoperative mass formation: Pseudomeningocele

A. Alakbarli, *M. Guven;*
Ege üniversitesi, Bornova, TÜRKIYE.

Aim/Introduction: Pseudomeningocele commonly occurs as a result of the accumulation of cerebrospinal fluid (CSF) outside the dura mater due to a defect formed after surgery or trauma. Despite the lack of a clear theory explaining its pathophysiology, it is thought to occur due to incomplete closure of the dura and protrusion of the arachnoid membrane through the defect. The diagnosis is made using CT or MRI imaging. In this case presentation, since there is no literature information on imaging pseudomeningocele with FDG PET/CT, we aim to share our experience incidentally detecting this significant clinical entity. it is emphasized that in cases with a history of craniotomy, pseudomeningocele should be considered in the differential diagnosis of mass-like lesions showing FDG uptake in the operative site. ***Materials and Methods:*** A 60-year-old male patient, diagnosed with lung cancer and operated on for brain metastasis, presented to the emergency department on the 10th day post-metastasectomy with complaints of headache, dizziness, nausea, and vomiting. A non-contrast brain CT scan revealed a lesion in the left occipital region consistent with pseudomeningocele. In the FDG PET/CT imaging performed to evaluate possible new systemic involvement foci after symptomatic medical treatment, a primary lesion located in the posterior segment of the right upper lobe of the lung and a mass lesion with hypermetabolic periphery and hypometabolic central area, presenting a cystic appearance, were observed in the left occipital region. The patient received cranial radiotherapy, and on the FDG PET/CT imaging performed 4 months after radiotherapy, it was observed that the hypermetabolic lesion identified in the left occipital region had regressed significantly. ***Results:*** Pseudomeningocele develops as a complication after craniotomy in approximately 4-23% of cases. In most instances, pseudomeningocele appears within days or weeks after surgery and rapidly resolves spontaneously within 1-2 days. However, in some cases, it can lead to life-threatening clinical outcomes such as rupture of the sac. While there is no standardized guideline for the treatment of pseudomeningocele, the optimal management strategy varies from conservative approaches to surgical intervention. Diagnosis typically involves the use of CT and MRI imaging, and to our knowledge, no cases demonstrating FDG uptake on PET/CT imaging have been reported in the literature. Awareness of this rare clinical entity in the interpretation of FDG PET/CT imaging, especially in individuals with a history of cerebral and medullary spinal interventions or trauma, would be beneficial and should be considered in reporting.

EP-1106

Role of HIDA scan in follow up of patients post APOLT procedure

N. Al Balushi[1], *Z. Al Bimani[2];*
[1]Oman Medical Specialty Board, Muscat, OMAN, [2]Royal Hospital (Nuclear Medicine Department), Muscat, OMAN.

Aim/Introduction: Acute liver failure in children is a fatal disorder characterized by multiorgan involvement and is associated with high mortality. Liver transplant is the accepted form of treatment that has led to these patients survival. APOLT is a technique of liver transplant where a partial liver graft is implanted in an orthotropic position after leaving behind a part of the native liver for the potential advantage of immunosuppression withdrawal. Here we describe a case of partial orthotopic liver transplant in a 2-year-old child who presented to us with acute liver failure and encephalopathy. Surgery was performed where the native left liver lobe was resected and replaced with left lateral segment of the donor, and the patient was then started on immunosuppression. ***Materials and Methods:*** A 2-year-old female child presented with history of vomiting and lethargy. Labs showed a significant derangement in liver functions and coagulation. Initial ultrasound showed hepatomegaly, with reduced parenchymal echogenicity, along with moderate ascites, that supports the diagnosis of acute liver failure. After meeting the criteria for liver transplant, the patient underwent "living donor APOLT with Roux EN Y procedure and was started on immunosuppression treatment. Follow-up imaging and biopsies were performed to assess for regeneration. HIDA scan was performed to evaluate the extent of regeneration and assess the relative function of the two hemi livers. ***Results:*** The intial HIDA scan showed relatively good function of both native and grafted liver (Native: 48% Transplanted: 52%). The following scan showed slightly less uptake in the transplanted liver in comparison to the previous scan (Native: 54% Transplanted:46%). The last scan showed an interval increase in the relative uptake of the native liver. Follow-up biopsy results showed normal morphology of the native kidney and mild T-cell mediated rejection of the liver allograft. The child was gradually weaned off immunosuppression (tacrolimus). The final laboratory results after stopping immunosuppression were within normal. The patient remained well, asymptomatic and with no concerns. ***Conclusion:*** The role of HIDA scan in patients who underwent APOLT, has shown to be of notable utility in the assessment of regeneration of native liver and has helped guide pediatricians to wean the patients of immunosuppressants. ***References:*** Shrivastav M, Rammohan A, Reddy MS, Rela M. Auxiliary partial orthotopic liver transplantation for acute liver failure. Ann R Coll Surg Engl. 2019

EP-1107

A Case of Extensive Systemic Sarcoidosis on ^{18}F-FDG PET/CT Study

C. Marsh, *Z. Saad;*
University Hospital Southampton NHS Foundation Trust, Southampton, UNITED KINGDOM.

Aim/Introduction: Sarcoidosis is a multi-systemic non-caseating granulomatous disease. Intrathoracic involvement is most common and occurs in 90% of patients. Extrapulmonary manifestations include cutaneous involvement, uveitis, liver or splenic lesions, peripheral and abdominal lymphadenopathy, and peripheral arthritis.1 This case report explores a rare presentation of extensive systemic sarcoidosis on ^{18}F-FDG PET/CT study. ***Materials and Methods:*** Information for the case report was gathered from the electronic patient record and Radiology Information System. ***Results:*** The case involved a 62 year old man, who first presented with erythema nodosum and was diagnosed with sarcoidosis via cutaneous biopsy in 2013. The patient also subsequently developed bilateral anterior uveitis, intrathoracic involvement (lymphadenopathy and pulmonary nodules), and basal cerebral artery low-grade vasculitis with associated previous old infarcts. Most recently in 2022 and 2023, the patient suffered from bilateral, sequential phrenic nerve palsies requiring intensive care admission, though the cause of this has not been confirmed. An FDG PET/CT study performed in February 2024 demonstrated widespread FDG avid disease on both sides of the diaphragm, involving lymph nodes (cervical, thoracic, abdominopelvic and inguinal), liver, spleen and multiple bones. Multiple pulmonary parenchymal lesions showed variable intensities with some of these considered significant, however it is challenging to differentiate between sarcoidosis and inflammatory/infective aetiology on the study. Given the pattern of involvement on the PET/CT study and background of systemic sarcoidosis, these findings are suspicious of malignancy. In particular, lymphoma should be considered due to known sarcoidosis-lymphoma syndrome and the similarity in presentation. Histological confirmation was advised and the right inguinal nodes were deemed most accessible. The histology confirmed granulomatous inflammation suggestive of sarcoidosis. Culture results did not show any organism growth, and stains for acid-fast bacilli and fungi were negative. ***Conclusion:*** Sarcoidosis patients are at increased risk of malignancy, particularly lymphoma (known as sarcoidosis-lymphoma syndrome). Sarcoidosis and lymphoma can have similar presentations. In addition, sarcoidosis can obscure the presence of other malignancies.2 There needs to be increased suspicion for malignancy in patients with sarcoidosis, particularly those with atypical/extensive presentations or treatment resistant disease. ***References:*** 1. Sève P et al. Sarcoidosis: A Clinical Overview from Symptoms to Diagnosis. Cells. 2021 Mar 31;10(4):766. doi: 10.3390/cells10040766. PMID: 33807303; PMCID: PMC8066110. 2. El Jammal T et al. Sarcoidosis and Cancer: A Complex Relationship. Front Med (Lausanne). 2020 Nov 24;7:594118. doi: 10.3389/fmed.2020.594118. PMID: 33330555; PMCID: PMC7732692.

EP-1108

[^{99m}Tc]Tc-MIBI SPECT/CT and [^{11}C]Choline PET/CT in the perioperative parathyromatosis study - a case report

I. Casimiro[1], *R. Silva[1,2], T. Saraiva[1], G. Costa[1,3];*
[1]Unidade Local de Saúde de Coimbra, Coimbra, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL, [3]Faculdade de Medicina da Universidade de Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Recurrence of disease after parathyroidectomy and following normalization of calcium and parathyroid hormone (PTH) serum levels, could be observed in a minority of patients with primary sporadic hyperparathyroidism (pHPT). Parathyromatosis is a rare cause of recurrence of pHPT, being often described as incidental seeding of parathyroid tissue, in the neck soft tissue, after surgical procedures. It is difficult to diagnose and the adequate treatment is a challenging task, once several surgeries may be required to achieve complete remission. We present a case of recurrent pHPT in which preoperative [99mTc]Tc-MIBI SPECT/CT helped to localize parathyromatosis foci and the postoperative [^{11}C]Choline PET/CT highlighted the persistence of hyperfunctioning parathyroid tissue. ***Materials and Methods:*** Six years ago, a 26-year-old woman underwent right inferior parathyroid adenomectomy (histologically confirmed). After the apparently successful surgery, the patient remains under clinical active surveillance. Three years later, the blood test showed increased calcium (11mg/dL; normal range: 8.8-10.6) and PTH (187pg/mL; normal range: 9-72) serum levels. Ultrasound revealed the presence of multiple solid hypoechoic pericentimetric nodules, below the thyroid gland. Those nodules presented increased uptake of [99mTc]Tc-MIBI on early phase of the parathyroid scintigraphy, with slower washout on delayed phase and without uptake of [99mTc]NaTcO4. These findings were consistent with ectopic hyperfunctioning parathyroid tissue, located anterior to the trachea and below the thyroid isthmus, evaluated by cross section images of early phase SPECT/CT. In October 2023, the patient was submitted to a second surgery, guided by these findings. ***Results:*** Intraoperative PTH level decreased from 1636 pg/ml to 948 pg/mL and all removed nodules were reported on the histological study as hyperplastic parathyroid tissue, suggestive of parathyromatosis. Even though the patient has presented important reduction of post-surgery PTH levels, serum calcium and PTH were still elevated (373pg/mL and 11.2mg/dL, respectively) at time of discharge, justifying complementary investigation. Two months later, a [^{11}C]Choline PET/CT showed intense focal uptake of the tracer, located below the right lobe of the thyroid close to suture material, as well as several foci with less intense uptake than the thyroid parenchyma. At the moment, our patient hasn't been submitted to a third surgery yet, guided by the late findings of [^{11}C]Choline PET/CT that might justify the persistence of hypercalcemic hyperparathyroidism. ***Conclusion:*** Our case illustrates the well-known challenging therapeutic task of parathyromatosis and highlight the importance of hybrid functional imaging in the anatomical localization of the hyperfunctioning parathyroid tissue, helping surgery to be more effective.

EP-1109

Technitium-99m MDP Uptake in Adult-Type Granulosa cell Tumor of the Ovary: A Case Report

A. Saber Tanha, *E. Askari;*
Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: A 47-year-old perimenopausal female presented with a right breast mass diagnosed as invasive carcinoma of no special type in core needle biopsy. Post neo-adjuvant chemotherapy, metastasis workup with technetium-99m MDP Scintigraphy revealed focal uptakes in the lower ribs

and pelvis. ***Materials and Methods:*** The patient underwent SPECT/CT for further evaluation of pelvic uptakes which one of them subsequently localized to right ovary. Review of literature suggested potential tumoral etiology for MDP uptake in ovary. Consequently, excision of the right ovary was recommended concurrent with partial mastectomy ***Results:*** Pathological examination of the right ovary revealed an adult-type granulosa cell tumor. Subsequent completion surgery, including left salpingo-oophorectomy, omentectomy, and peritoneal resection, showed no evidence of tumor. ***Conclusion:*** Adult-type granulosa cell tumors of the ovary may manifest Technetium-99m MDP uptake and should be included in the differential diagnosis when encountering ovarian MDP uptake.

EP-1110

Unveiling Pitfalls: Axillary Siliconomas Mimicking Malignancy in Breast Cancer Evaluation Using ^{18}F-FDG PET

A. De Agrela Serrao, *A. M. Leiva Montejo, C. Ruiz Corbalan, G. Martínez Gómez, J. L. Navarro Fernandez, A. C. Hernández Martínez, T. E. Rodriguez Locarno, M. J. Ibañez Ibañez, T. Moreno Monsalve, L. Frutos Esteban, N. Sanchez Izquierdo, L. Mohamed Salem, M. I. Castellón Sanchez, J. F. Contreras Gutierrez; Hospital Clinico Universitario Virgen de Arrixaca, Murcia, SPAIN.*

Aim/Introduction: In recent decades, ^{18}F-fluorodeoxyglucose (FDG) positron emission tomography (PET) has been established as a powerful and useful tool in the management of breast cancer, especially during staging, detection of recurrence and evaluation of treatment response. In this case review, we aim to address one of the pitfalls of this technique. ***Materials and Methods:*** A 51-year-old woman with a personal history of bilateral breast prostheses replaced 9 years ago, who has currently been diagnosed with infiltrating ductal carcinoma in the left breast T4bN2M0 G3, estrogen receptors <5%, negative progesterone receptors and negative Her2 Ki67 40-50% whom underwent neoadjuvant treatment. ***Results:*** In the initial staging PET performed after the start of neoadjuvant therapy, high uptake was identified in left axillary and retropectoral lymphadenopathy (SUVmax 15.2) (Figure 1 red arrow) and high uptake lesion in the left breast adjacent to the breast implant (Figure 1 green arrow). The follow-up PET scan identified a decrease in the size and metabolism of the left axillary and retropectoral lymphnodes (figure 2 red arrow) and a residual lesion without significant metabolism in likelihood to a complete metabolic response; However, growth of right axillary and retroperitoneal lymph nodes of up to 2 cm with high uptake (SUVmax 19.4) was identified, from a metabolic point of view, they do not rule out malignancy (Figure 2 blue arrow). Given that the patient's initial lesions presented a good response, the possibility arises that the right lymphadenopathy has a different etiology than the tumour. Subsequently, complementary evaluation was performed using ultrasound, which confirmed that they were axillary siliconomas (figure 3 white arrows), and although the evaluation of the breast prostheses did not show rupture of the capsule, there are mechanisms where due to an increase in permeability of the capsule (called gel bleeding) thar leads to the presence of silicone in the armpit or outside the prosthesis associated with inflammatory changes. ***Conclusion:*** While ^{18}F-FDG PET is invaluable in distinguishing malignant from benign lesions in augmented breasts, our case underscores the potential for false positives. Inflammation due to silicone deposition in axillary lymph nodes can lead to high FDG uptake, mimicking malignancy. Thus, comprehensive evaluation within the clinical context and judicious use of complementary tests are essential.

EP-1111

Incidental Cold Thyroid Nodule with a False Positive Semi-Quantitative Study on Dual-Tracer Sestamibi Scan

M. Bel lakhdar, *O. Boumaaza, M. Zekri, D. Alami, I. Zahfir, M. Aboussabr, A. Mouaden, I. Ghfir, H. Guerrouj; University Mohamed V, FMPR, Rabat, MOROCCO.*

Aim/Introduction: 99mTc-sestamibi scan is a well-established imaging technique for hyperparathyroidism. Additionally, many studies have demonstrated its usefulness in predicting malignancy of hypofunctioning thyroid nodules. Cancer cells are characterized by a higher electrical gradient of the mitochondrial membrane, leading to increased accumulation of sestamibi compared to normal cells. We report the case of an incidental cold thyroid nodule exhibiting isointense sestamibi uptake and a positive Washout index, which was confirmed to be a follicular adenoma. ***Materials and Methods:*** The patient was a 59-year-old female with a history of chronic kidney failure requiring hemodialysis, presenting with polyarthralgia. Corrected plasma calcium was 11,1 mg/dL, phosphorus level was 5.0 mg/dL, TSH level was 0.7 µIU/mL, and PTH level was 3172 pg/ml, suggesting a tertiary hyperparathyroidism. Dual tracer 99mTc pertechnetate / 99mTc-sestamibi planar scintigraphy was conducted for a pre-surgical assessment. ***Results:*** Pertechnetate scintigraphy demonstrated a cold nodule in the right thyroid lobe. Sestamibi scan showed increased uptake with foci of tracer retention in the upper and lower poles of the left lobe and isointense uptake in the right thyroid nodule with an elevated Washout index of 61%, which corresponded to an Eu-TIRADS 4 right thyroid nodule on US. Fine-needle aspiration was non-diagnostic. Given the high suspicion of malignancy, the patient underwent total thyroidectomy and 7/8 parathyroidectomy. Subsequent pathological examination concluded to a follicular adenoma and a parathyroid hyperplasia, ruling out malignancy. ***Conclusion:*** Semi-quantitative sestamibi study is known to be superior over both visual assessment and molecular testing for pre-surgically characterizing thyroid nodules. However, some follicular adenomas may present a high cellular activity and exhibit increased sestamibi uptake, and thus inducing false-positive results and potentially triggering unnecessary surgical procedures. ***References:*** [1] Giovanella L, Campenni A, Treglia G et al. EP-1112

Duodenal Diverticulum Mimicking Hepato-Biliary Malignancy on ^{18}F-FDG PET/CT

D. Alami, *M. Zekri, M. Bel lakhdar, D. Nakro, I. Zahfir, M. Aboussabr, A. Mouaden, I. Ghfir, H. Guerrouj; Department of Nuclear Medicine, Ibn Sina teaching hospital, Faculty of Medicine and Pharmacy, Mohammed V University, Rabat, MOROCCO.*

Aim/Introduction: Duodenal diverticula are protrusions that form in the wall of the duodenum. They are common and typically asymptomatic. When discovered by different imaging modalities, they may mimic malignancy in the retroperitoneum or in the pancreas, therefore potentially prompting unnecessary medical procedures. Here, we present a case where a duodenal diverticulum, trapped between the gallbladder and the liver, displayed notably heightened 18F-FDG activity in a PET/CT scan. ***Materials and Methods:*** The patient was a 78-year-old male with a history of type 2 diabetes and a prior surgically-treated anal fistula, who presented to the internal medicine department due to recurrent thigh abscesses and polyarthralgia. Laboratory tests revealed elevated CRP(C-reactive protein) levels at 130 mg/l. Additionally, serum protein electrophoresis (SPE) revealed increased alpha 1 and alpha 2 levels along with hypergammaglobulinemia. Infectious investigations as well as immunological markers were negative. Given the unexplained inflammatory syndrome, a PET/CT scan was conducted following the injection of 205 MBq of 18F-FDG. ***Results:*** The PET/CT scan showed focal uptake in a hypodense structure located between the gallbladder and the liver, with a high SUVMAX of 8.1, initially raising suspicion of a hepato-biliary neoplasm, with no other pathological uptake of interest found elsewhere. An abdominal contrast-enhanced HRCT later revealed a duodenal diverticulum forming in the D2 portion of the duodenum, containing digestive material, interposed between the hepatic segment 4b and the gallbladder, linked to the duodenum with a fine pedicle. A consensus among radiologists and nuclear medicine physicians confirmed that the anomality observed in PET/CT was correlated to the uncomplicated duodenal diverticulum described in the abdominal HRCT. No further investigation was required. ***Conclusion:*** As observed in this case, 18F-FDG PET/CT can yield false-positive results in the presence of a duodenal diverticulum. This abnormal finding can be accounted by the elevated rate of glucose utilization by inflammatory cells within the diverticulum. To date, there have been very few reports of 18F-FDG uptake within a duodenal diverticulum. However, considering their potential risk of inducing false positive results, physicians should be aware of their presence and careful analysis of morphological slices and comparison to other imaging modalities, if necessary, can help rule out malignancy.

EP-1113

Tuberculosis Mimicking Lung Cancer on ^{18}F-FDG PET/CT in a Patient with Suspected Paraneoplastic Dermatomyositis

M. Bel lakhdar, *M. Zekri, D. Alami, I. Zahfir, M. Aboussabr, A. Mouaden, I. Ghfir, H. Guerrouj;*
University Mohamed V, FMPR, Rabat, MOROCCO.

Aim/Introduction: ^{18}F-FDG PET/CT is an established procedure for the evaluation of malignancy. However, FDG is not specific to cancer. Some benign conditions, such as infection or inflammation, have been reported to cause FDG uptake. Differentiating between benign and malignant lesions is challenging. Therefore, it is important to acknowledge the conditions that may mimic malignancy to reduce misinterpretation. Here we present a patient with dermatomyositis who underwent an FDG-PET scan because of suspected paraneoplastic syndrome. The FDG-avid lesion in the lung was later proved by tissue biopsy to be secondary to tuberculosis infection. ***Materials and Methods:*** A 44-year-old woman with no significant medical history, discovered painless purplish subcutaneous nodules which worsened over time. The nodules became painful, deep, and pruriginous, with erythema on the face along with muscle pain in the scapular and pelvic regions, fatigue, dysphagia, and dyspnea, prompting hospitalization. Her Creatine Kinase level was elevated at 244 UI/L (normal range: 29-168). Anti-nuclear matrix protein 2 antibodies (anti-NXP 2) were positive, while anti-transcription intermediary factor 1 gamma antibodies (anti-TIF-1 gamma) were negative. Skin biopsy confirmed the diagnosis of dermatomyositis and the patient was started on steroids and methotrexate therapy. Investigations for a paraneoplastic origin were systematically conducted, including FDG PET/CT. ***Results:*** ^{18}F-FDG PET/CT showed a lung nodule with increased FDG uptake in the superior right lobe, with no other suspected focal metabolic uptake. Bronchoscopy and analysis of the bronchoalveolar lavage with Genexpert were negative. CT-guided biopsy ruled out malignancy and revealed tuberculosis. ***Conclusion:*** While FDG-PET/CT is a valuable tool in oncologic evaluation, it is not specific for cancer, and benign conditions such as infection or inflammation can lead to false-positive results. For clinicians, it is crucial to consider alternative diagnoses, especially in patients with systemic inflammatory conditions like dermatomyositis, where paraneoplastic syndromes are a concern.

EP-1114

A Case of Incidental Brain Metastasis of Papillary Thyroid Carcinoma Showing I-131 Uptake

L. Hashimoto[1], *S. Watanabe[1,2,3], K. Hirata[1,2,3], J. Takenaka[1,2], R. Kimura[2,4], H. Ishii[1,2], K. Kudo[2,3,4];*
[1]Department of Nuclear Medicine, Hokkaido University Hospital, Sapporo, JAPAN, [2]Department of Diagnostic Imaging, Graduate School of Medicine, Hokkaido University, Sapporo, JAPAN, [3]Global Center for Biomedical Science and Engineering, Faculty of Medicine, Hokkaido University, Sapporo, JAPAN, [4]Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, JAPAN.

Aim/Introduction: Papillary thyroid carcinoma (PTC) makes up about 80% of all thyroid cancer cases. The most common site of thyroid cancer metastasis is the lymph nodes of the neck, followed by the lung and the bones, while brain metastasis (BM) is much less common. Although PTC is generally a cancer with a good prognosis, once BM is developed, the mortality rate significantly increases up to 74%. BM is usually treated by surgical resection or external radiotherapy, whereas radioactive iodine therapy (RAIT) using I-131 is not recommended because BM often shows poor uptake of I-131. In addition, even in case I-131 accumulates in the BM, RAIT could cause adverse effects such as brain hemorrhage and cerebral edema. We present a case of BM of PTC that was detected with I-131 scintigraphy following I-131 therapy. ***Materials and Methods:*** A 43-year-old woman presenting with multiple incidental lung nodules was diagnosed with PTC after undergoing right lung middle lobectomy. She reported no significant neurological symptoms. She received total thyroidectomy to be referred to our department for RAIT against remaining lung metastases. Pre-treatment FDG PET/CT showed multiple lung metastases, but no abnormal increase or decrease of FDG accumulation in the brain. As a first course of treatment, 5.5GBq of I-131 was administered and I-131 scintigraphy was performed three days later. ***Results:*** I-131 uptakes were observed not only in the thyroid bed and lung metastases, but also in her left cranial area on planar image. This uptake was localized to her left frontal lobe on SPECT/CT, rather than the skull, indicating BM. Brain MRI with gadolinium showed enhancement in the same site identified by I-131 scintigraphy. She underwent

external radiotherapy for BM two months after her first I-131 administration, and then she took a second course of RAIT six months after the first course to treat the residual metastases. FDG PET/CT before the 2nd RAIT showed marked shrinkage and reduced uptake of lung metastases with no significant finding in the left frontal lobe. I-131 scintigraphy after the 2nd RAIT not only showed decreased uptake in the lung lesions, but also confirmed the extinction of the uptake in the brain. Blood thyroglobulin level also decreased from 249.00ng/mL to 0.42ng/mL, indicating successful treatment. ***Conclusion:*** BM of thyroid cancer itself is quite rare, and furthermore infrequently exhibits I-131 uptake. We unexpectedly observed BM on I-131 scintigraphy after RAIT. SPECT/CT was useful to distinguish BM from bone metastasis.

EP-1115

Atypical Vertebral Haemangiomas: A Diagnostic Nuclear Medicine Challenge

A. Al Mujaini[1], *Z. Al Bimani[2];*
[1]Oman Medical Specialty Board, Muscat, OMAN,
[2]The Royal Hospital, Muscat, OMAN.

Aim/Introduction: Vertebral haemangiomas are the most common benign tumors of the spine, typically found incidentally on imaging studies. Although generally asymptomatic, they can occasionally present with neurological deficits or back pain due to compression fractures or aggressive features. The majority of vertebral haemangiomas exhibit typical characteristic imaging features on computed tomography (CT) and magnetic resonance imaging (MRI), aiding in their diagnosis and differentiation from other spinal lesions. However, a subset of vertebral haemangiomas manifests atypical imaging characteristics, posing a diagnostic dilemma and potentially leading to misinterpretation or delayed diagnosis. We hereby report the pathology, etiology and imaging characteristics of atypical vertebral haemangiomas. ***Materials and Methods:*** A previously healthy young adult who presented with lower back pain, bilateral lower limb radiculopathy, claudication on the right side and spinal extension underwent a complete radiological assessment, lumbar spine MRI followed by a CT-guided biopsy and a bone scan. The patient then underwent a 99m-Tc-RBC labelled liver scintigraphy to further characterize the lesion. ***Results:*** In his initial workup, Lumbar spine MRI was done which revealed an L3 vertebral body lesion with diffuse bone marrow edema, destruction of the superior endplate and an underlying cystic focus. The patient underwent a CT-guided biopsy due to the aggressive appearance of the lesion, and although the results were inconclusive, the CT and MRI findings were still in favor of an aggressive haemangioma.To further characterize the lesion and rule out the possibility of metastasis, the patient also underwent a bone scan. The study revealed moderate to severe focal uptake in the underlying L3 vertebral body lesion. These findings were not typical for benign vertebral haemangiomas, however aggressive haemangiomas and other aggressive bone tumors can show a similar uptake pattern. RBC labelled liver scintigraphy showed abnormal prompt focal increased blood flow and soft tissue hyperemia in the L3 vertebral lesion, and mild uptake on the delayed images. ***Conclusion:*** Atypical presentations of vertebral haemagiomas may mimic malignant lesions such as metastases or primary bone tumors, necessitating a thorough understanding of their varied imaging appearances and clinical manifestations. Nuclear medicine plays a limited but potentially valuable role in the diagnosis of atypical vertebral haemangiomas. While conventional imaging modalities such as CT and MRI remain the mainstay for evaluating vertebral lesions, nuclear medicine techniques can provide complementary information, particularly in cases where the diagnosis is uncertain or when there is a need for functional characterization of the lesion.

EP-1116

Significant Improvement of Quality of Life after first dose of Peptide Receptor Radionuclide Therapy (PRRT) in a Malignant Refractory Insulinoma: a Case Report Study.

A. Georgakopoulos[1], *M. Tsoli[2], A. Koumarianou[3], N. Papadopoulou[2], M. Panagaki[2], G. Kaltsas[2], S. Chatziioannou[1];*
[1]Department of Nuclear Medicine and Molecular Imaging, National and Kapodistrian University of Athens, "Attikon", University General Hospital, Athens, GREECE, [2]EKPA-LAIKO ENETS CoE, Laiko Hospital, National and Kapodistrian University of Athens, Athens, GREECE, [3]Hematology-Oncology Unit, 4th Department of Internal Medicine, Attikon Hospital, National and Kapodistrian University of Athens, Athens, GREECE.

Aim/Introduction: Malignant insulinomas are rare functional neuroendocrine tumors of the pancreas. Glycemic and tumor volume control are the two therapeutic objectives. The control of the hypoglycemic syndrome is difficult and often refractory to symptomatic treatment. Peptide receptor radionuclide therapy (PRRT) appears to be a very promising treatment for progressive metastatic insulinomas. Self-reported health-related quality of life (HRQoL) is an important outcome for the effect of a therapy in patients with neuroendocrine tumors. We present the case of a patient with malignant insulinoma and refractory hypoglycemia treated with PRRT considering the change in level of HRQoL. ***Materials and Methods:*** A 62-year-old with diagnosis of metastatic malignant mixed insulinoma-gastrinoma (Ki-67 25%) and refractory hypoglycemia despite having received several lines of treatment (somatostatin analogues, everolimus, chemotherapy, liver metastasectomy and radioembolization, as well as, cyber knife for a brain metastasis). He has been hospitalized several times with hypoglycemic coma. A 68Ga-DOTA-Somatostatin Analog Positron Emission Tomography/Computed Tomography was performed which revealed liver, nodal and bone metastases, as also, a brain metastasis with high somatostatin receptors (SSTRs) expression. He was proposed for PRRT with 177Lu-DOTATATE and he received the first cycle in December 2023. Before receiving the first and second dose of therapy he completed the quality of life questionnaire (QLQ) core module (C30) and the disease-specific QLQ-GINET21 which include QoL issues important to patients with NETs. ***Results:*** Within three days following the first cycle of PRRT, the patient experienced significant clinical improvement without any episode of hypoglycemia. Blood glucose levels were normalized. A more than 30% improvement was observed in the global health status (GHS) /QoL and physical functioning (PF) scale score between the two cycles. Also, clinically significant changes (25%-90%) were observed in the symptom scales (fatigue, diarrhea and dyspnea). Moreover, in the disease-specific QLQ-GINET21 improvement was noted in disease related worries (33%), social function scale (33%) and sexual function (25%). ***Conclusion:*** This case supports the rapid and significant improvement of PRRT in the control of hypoglycemia and quality of life in patients with malignant refractory insulinoma. ***References:*** 1. EP-1117

Case report: Secondary syphilis multiorgan involvement in ^{18}F-FDG PET/CT mimicking lymphoproliferative syndome

M. Tagliatori Nogueira, *M. De la Rubia Marcos, M. Alvarez Moreno, D. Rodriguez Oviedo, C. Galindo Fernandez, K. Guichay Duran, L. Castillejos Rodriguez, A. Herrero Muñoz, C. Paniagua Correa, A. Ortega Valle, P. Garcia Alonso;*
Hospital Universitario de Getafe, MADRID, SPAIN.

Aim/Introduction: Syphilis is a sexually transmitted infection caused by the bacteria Treponema pallidum. Over the last years there has been an increase of the incidence of this disease due to the growing infection by the human immunodeficiency virus (HIV) and the immunosuppression. It is a chronic systemic infection that has a wide variety of manifestations with a very disparate clinical course, known as "the great imitator". In this case, we expose the findings visualized in a ^{18}F-FDG PET/CT performed on a patient in the context of a secondary syphilis. ***Materials and Methods:*** An ^{18}F-FDG PET/CT study was performed due to suspicion of lymphoproliferative syndrome in a 37-year-old patient who presented skin lesions, polyarthritis, night sweats and polyadenopathy. The protocol is carried out from the skull to the proximal third of the thighs, 60 minutes after the intravenous administration of 293 MBq of ^{18}F-FDG. PET, CT and fusion images are analyzed in the axial, sagittal and coronal axis. The findings are correlated with the patient's clinical and analytical findings. ***Results:*** The PET/CT revealed increased metabolism in the lymphoid tissue of Waldeyer's ring, numerous but small bilateral laterocervical, mediastinal, axillary, retroperitoneal, iliac and inguinal lymphadenopathy, reactive metabolism in the spleen, pleural thickening, as well as lytic lesions in the right scapula and 10th left posterior costal arch. Findings of an indeterminate nature but that require confirmation through complementary study. A complete analytical study was performed, obtaining syphilis IgG+IgM antibodies: positive and Treponema pallidum particle agglutination (TP-PA): positive 1/32, so the patient began treatment with Doxycycline 100 mg every 12 hours for 2 weeks and noticed a significant improvement in symptoms and a reduction in lymphadenopathy. ***Conclusion:*** Diagnosing syphilis can be very difficult due to the wide variety of manifestations that the disease can mimic. The treatment is simple and very effective, especially when it is performed early, determining the patients' prognosis. The importance of the case lies in the fact that in a patient with indeterminate symptoms, especially in patients without clear risk factors for malignant tumor pathology, the finding of reactivity in lymphoid tissue (spleen, lymph nodes, Waldeyer's ring, etc.), as well as areas of osteitis, should make us consider syphilis in our differential diagnosis.

EP-1118

^{18}F-FAPI PET/CT imaging for Cranium Fibrous Dysplasia

D. Biao;
Department of Nuclear Medicine, the First Affiliated Hospital of Zhengzhou University, Zhengzhou, CHINA.

Aim/Introduction: 18F-labeled fibroblast activation protein inhibitor (18F-FAPI) is a prospective malignant tumor imaging agent, however it also shows positive results in some benign lesions. ***Materials and Methods:*** We reported a case of cranium fibrous dysplasia (FD) about a 65-year-old female patient, who undertook 18F-FDG PET/CT, 18F-FAPI PET/CT and whole-body bone image. ***Results:*** We found 18F-FAPI PET/CT can diagnose more cranial FD lesions than 18F-FDG PET/CT. This was due to the less FAPI uptake of brain, which resulted in a higher tumor-to-background ratio, thus improving diagnostic accuracy. ***Conclusion:*** This case indicates that 18F-FAPI PET/CT may be an alternative method of evaluating cranium fibrous dysplasia. ***References:*** 1. EP-1119

Limitation of [^{67}Ga]Gallium citrate scintigraphy in the evaluation of Pott's Disease: a case report

J. Carvalho, *J. Duarte, A. Marques, F. Abreu, S. Pintão;*
Unidade Local de Saúde de Lisboa Ocidental, E.P.E., Carnaxide, PORTUGAL.

Aim/Introduction: Pott's disease is an uncommon extrapulmonary form of tuberculosis, involving one or more components of the spine. [67Ga]Gallium citrate scintigraphy has been used to detect active inflammatory lesion and tumours, although its clinical use is now restricted to centres without PET equipment. When the diagnosis of tuberculosis is known, it can be useful in defining the degree of disease activity, monitoring treatment response and evaluating the extent of the disease by detecting the presence of other foci of infection. ***Materials and Methods:*** We report a case of a 29-year-old man with suspected multisegmental spondylodiscitis in the context of extrapulmonary tuberculosis after radiological findings of destructive lytic lesions involving the spine (C4-D1 and D11-L1), as well as liquid paravertebral collections suspected of being abscesses in the cervical region. The patient underwent [67Ga]Gallium citrate scintigraphy in order to assess the presence of another foci of infection. Planar and SPECT/CT images were acquired 24 and 48 hours after radiopharmaceutical administration. ***Results:*** [67Ga] Gallium citrate scintigraphy demonstrated markedly increased tracer uptake in the cervical-dorsal spine (C4-D1), suggesting the presence of active infection in this region. There were no other abnormal foci of significantly increased tracer uptake at other locations, namely in the lumbar spine, where a lytic destructive lesion involving the vertebrae between D11-L1 was seen on the additional low-dose CT scan. Transpedicular percutaneous biopsies of D11 and L1 were performed, with a RT-PCR test positive for Mycobacterium tuberculosis complex, confirming lumbar involvement. ***Conclusion:*** Although commonly described as being a useful tool in the evaluation of extrapulmonary tuberculosis, [67Ga]Gallium citrate scintigraphy has the potential of missing active foci of infection, namely when involving the spine. This pitfall, in addition to its unfavourable physical characteristics, demonstrates [67Ga]Gallium citrate's limitations and further confirms the preferred usage of other tracers for tuberculosis evaluation, such as 2-$^{[18F]}$FDG.

EP-1120

[18F]PSMA-1007 PET/CT:Does the "P" stands for Paget? A case report of newly diagnosed Prostate Cancer with concurrent Paget's disease of bone.

L. Airò Farulla[1,2], *V. Longari[2], L. Florimonte[2], A. F. Scarale[3], S. Pacella[2], E. Gay[3], C. Rossetti[3], M. Castellani[2];*
[1]Department of Oncology and Hemato-Oncology, University of Milan, Milan, ITALY, [2]Nuclear Medicine Unit, Fondazione IRCCS Ca'Granda Ospedale Maggiore Policlinico, Milan, ITALY, [3]Nuclear Medicine Unit, ASST Grande Ospedale Metropolitano Niguarda, Milan, ITALY.

Aim/Introduction: Positron emission tomography/computed tomography (PET/CT) with [18F]-labeled prostate-specific membrane antigen (PSMA) ligands is emerging as a promising tool in the staging of high-grade prostate cancer (PC). In spite of its high sensitivity and specificity for detecting metastatic bone involvement, false-positive results in benign conditions such as Paget disease of the bone (PD) may occur. PD is the second most common bone disorder, and it is characterized by an increase of osteoclast cell activity, causing an excessive bone remodeling. The well-known up-regulation of PSMA on endothelial cells observed in various solid tumors suggests that the radioligand bone uptake in PD may happen during the hyperperfusion phase (osteolytic) of PD. ***Materials and Methods:*** We report a case of an 86-year-old man medically treated with abiraterone acetate after recent diagnosis of prostate cancer. In spite of normal CT scan images of the neck, chest, and abdomen-pelvis, abnormal [99mTc] HDP accumulation in the right knee, distal femur, and proximal tibia was observed at staging bone scintigraphy. The uncertain metastatic scenario led to perform [18F]PSMA PET/CT. ***Results:*** [18F] PSMA PET/CT exhibited a focal radiopharmaceutical uptake in the prostate gland (Primary Score 3). A diffuse and intense radiotracer uptake was observed on the right knee, distal femur and proximal tibia, sites of osteotropic tracer uptake. In the mid-tract of the right femur and in the distal tibia, PSMA ligand uptake mainly occurred in the bone cortex. Areas of focal uptake were also observed in the proximal right femur, in the heel and in the third right toe, resembling the typical "mosaic" pattern seen in early osteolytic-stage of PD. Correlation with co-registrated CT images showed diffuse sclerosis, coarsened trabeculae, thickened cortex, and initial bone expansion. The alkaline phosphatase and bone-specific alkaline phosphatase values were 204 U/L (46-116 U/L) and 57.8 ug/L (5.5-22.9 ug/L), respectively. ***Conclusion:*** Despite its high accuracy, rare instances of false-negative and false-positive findings have been reported in [18F]PSMA PET/CT. PSMA expression in neo-vasculature, shared in cases of metastasis as in PD, emphasizes the need for cautious PET images interpretation. This case highlights the importance of recognizing PD as a potential mimic of bone metastases of PC on PSMA PET/CT, also suggesting the need for a multimodalities diagnostic approach to ensure comprehensive clinical evaluation and targeted treatment. The observed "mosaic" uptake pattern appears to reflect the distribution of neovascularization in PD across its various stages, contributing to a more in-depth understanding of the pathology.

EP-1121

Unveiling a Rarity: Primary Pulmonary Plasmacytoma Presenting as Multiple Lung Nodules

A. De Agrela Serrao, *C. Ruiz Corbalan, A. M. Leiva Montejo, G. Martínez Gómez, T. E. Rodriguez Locarno, T. Moreno Monsalve, A. C. Hernández Martínez, M. I. Castellón Sanchez, M. J. Ibañez Ibañez, N. Sanchez Izquierdo, J. L. Navarro Fernandez, L. Frutos Esteban, L. Mohamed Salem, J. F. Contreras Gutierrez;*
Hospital Clinico Universitario Virgen de Arrixaca, Murcia, SPAIN.

Aim/Introduction: Extramedullary plasmacytoma (EMP) represents a rare form of plasma cell neoplasm, characterised by localised proliferation within soft tissues, devoid of bone marrow involvement or the systemic features typical of multiple myeloma. While EMP predominantly occurs in the head and neck region, particularly in the upper aerodigestive tract, primary pulmonary plasmacytoma (PPP) constitutes an exceptionally rare subset of extramedullary plasmacytomas. In this abstract, we present a rare case of PPP presenting as multiple lung nodules, emphasizing the diagnostic intricacies and therapeutic considerations associated with this atypical manifestation. ***Materials and Methods:*** An 88-year-old woman, who has been experiencing mild asthenia and persistent dry cough for the past few months, without any other associated symptoms, was referred by her primary care physician for a chest CT scan. The scan revealed multiple bilateral lung consolidations, which persisted after antibiotic treatment. Consequently, she was referred to pulmonology, where bronchoscopy with biopsy of the lesions was performed, a 18F-fluorodeoxyglucose (18F-FDG) PET-CT along with blood tests showing normocytic iron-deficiency anaemia, hypergammaglobulinaemia, hypoalbuminaemia, elevated B2 microglobulin, and Bence-Jones proteinuria. ***Results:*** The initial diagnostic suspicion was primary lung neoplasia. To complete the staging a ^{18}F-FDG PET-CT scan was performed, revealing multiple bilateral masses and consolidations in the lungs, with heterogeneous metabolic uptake reaching a SUVmax of 6.1, suggesting a malignant origin. No hypermetabolic bone lesions or nodal disease were identified. Pathological examination revealed a plasma cell neoplasm, with positive immunohistochemical staining for CD138, CD38, and CD45, and heterogeneous positivity for Kappa and Lambda. These findings were consistent with primary pulmonary plasmacytomas. Although surgical treatment followed by radiotherapy is the mainstay for this condition, the number and extent of plasmacytomas, along with the patient's comorbidities, rendered surgery unfeasible, hence, chemotherapy was recommended. ***Conclusion:*** our case highlights the diagnostic challenges and therapeutic complexities associated with primary pulmonary plasmacytoma (PPP) presenting as multiple lung nodules. Despite its rarity, PPP should be considered in the differential diagnosis of pulmonary masses, especially in elderly patients. Comprehensive imaging studies, including PET-CT, coupled with histopathological examination, play a pivotal role in establishing an accurate diagnosis. While surgical excision followed by radiotherapy remains the cornerstone of treatment, individualized management strategies, considering the extent of disease and patient's overall health status, are imperative. In our case, chemotherapy emerged as a viable therapeutic option, underscoring the importance of a multidisciplinary approach in managing this atypical manifestation of plasma cell neoplasms.

EP-1122

Autosomal dominant polycystic kidney disease: how to locate the source of infection?

G. Martínez Gómez, *T. Rodríguez Locarno, A. De Agrela Serrao, C. Ruiz Corbalán, Á. Leiva Montejo, M. Castellon Sánchez, T. Moreno Monsalve, N. Sánchez Izquierdo, M. Ibáñez Ibáñez, A. Hernández Martínez, J. Navarro Fernández, L. Frutos Esteban, L. Mohamed Salem, J. Contreras Gutiérrez;*
Hospital Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: The infection of cysts is a common complication in polycystic kidney disease. For the diagnosis

and localization of the infection in vitro labeled leukocyte scintigraphy (LLS) with Technetium-99m can be used. ***Materials and Methods:*** A 78-year-old woman with autosomal dominant polycystic kidney disease (ADPKD), renal transplant, and multiple comorbidities, was admitted with poor general condition. Blood cultures detected Klebsiella pneumoniae and Candida albicans. According to the antibiogram result antibiotic intravenous treatment with meropenem was initiated obtaining a good clinical response. Abdominal ultrasound revealed multiple bilobar hepatic and renal cysts. The presumptive origin of the bacteremia was a cortical renal cyst in the right kidney with echogenic content suggestive of hemorrhagic or infectious complication. The nuclear medicine department proposed to realize a LLS to assess the localization of the complicated cyst, with the aim of considering nephrectomy of the transplanted kidney. ***Results:*** The leukocyte scintigraphy with 370 MBq of autologous leukocytes labeled in vitro with 99mTc-HMPAO was performed, obtaining whole-body images at 30 minutes and 2 hours post-injection (Figure I), and an abdomino-pelvic SPECT obtained at 2 hours (Figure II) and at 24 hours (Figure III). The LLS with 99mTc-HMPAO showed increased uptake at the level of a hepatic cyst located in segment IVb. Based on this finding, it was decided to continue treatment with carbapenems for 6 weeks and they decided to disregard the kidney removal. ADPKD is the most common inherited kidney disease. Computed tomography (CT) and magnetic resonance imaging (MRI) have limitations for localizing and differentiating infected cysts, especially for small cysts. LLS with 99mTc-HMPAO is the most useful technique for identifying focal inflammatory or infectious processes detecting leukocyte diapedesis and chemotactic processes in immunocompetent patients. Antibiotic treatment should be discontinued whenever possible prior to the performance off LLS. The advantages of the LLS are diagnosing cyst infection with higher sensitivity, differentiating an hemorrhagic cyst from an infected cyst and avoiding iatrogenic effects to contrast used in CT and MRI. ***Conclusion:*** Hepatic cysts in ADPKD are the most frequent extrarenal complication. Early diagnosis avoids complications from infection and reduces antibiotic treatment, thereby reducing the possibility of developing multi-resistant bacteria. Techniques such as LLS with 99mTc-HMPAO are highly useful for detecting cyst infections with better sensitivity. This technique is the preferred complementary imaging when conventional tests fail to detect the infection's origin and as an initial diagnostic tool in patients not candidates for intravenous contrast.

EP-1123

Bilateral breast metastasis of small cell lung cancer: A rare case

A. Inanir, *B. Bozca, A. Erdem, A. Çinar, D. Çayir;*
Etlik City Hospital, Ankara, TÜRKIYE.

Aim/Introduction: Small cell lung cancer accounts for 10-15% of lung cancers. It isthought to develop from submucosal located neuroendocrine (Kulchitsky) cells.It is the fastest growing and most rapidly spreading type of lung cancer. The most common sites for distant metastasis are the brain, bone and liver. Here, we present a rare case of small cell lung cancer with bilateral breast metastasis in a 63 years old female patient observed by F^{18} FDG PET/CT. ***Materials and Methods:*** We used mammography, MRI, F^{18} FDG PET/CT and biopsy data ***Results:*** In the biopsy of the right breast performed on the patient whose mammography showed suspicion of malignancy in both breasts, aninvasive carcinoma, thought to be small cell carcinoma, was detected. Breast MRI showed many masses suspicious for malignancy in both breasts. In the F^{18} PET/CT examination performed in our clinic; in both breasts, left lung,anterior-lateral abdominal wall, transverse colon, cervical-mediastinal-axillarylymph nodes that FDG uptakes suspicious for malignancy were observed. Theleft breast biopsy was found to be compatible with small cell carcinoma. Thepatient was evaluated as metastatic small cell lung cancer. Cisplatin-etoposideregimen was started. The pathology of the left lung biopsy was not diagnostic.Cranial MRI showed many nodular lesions thought to be metastatic. The patientwas diagnosed with metastatic small cell lung cancer without requiring a repeatlung biopsy. In the F18-FDG PET/CT examination performed in our clinic afterthe 4th cycle of cisplatin-etoposide treatment, an appearance and metabolicactivity involvement (SUVmax: 2.65) that may be compatible with a residue inthe nodular area with pleural extension in the lower lobe bronchus periphery ofthe left lung were observed. Other findings observed in the F-18 PET/CTexamination before chemotherapy were not observed in the examinationperformed for interim evaluation. In addition, no involvement in the brain wasdetected in the cranial MRI examination performed at the same time. Later, thepatient's cisplatin-etoposide regimen was completed for 6 cycles, and thefindings in the F^{18} PET/CT examination performed in our clinic for treatmentresponse evaluation were similar to the previous PET/CT examination. Thepatient is still under follow-up of the oncology clinic. ***Conclusion:*** Small cell lung cancer is a type of cancer that has a poor prognosisand frequently metastasizes. In our scan, the number of cases with bilateralbreast metastases in the literature is below 5. Breast tissue should not be ignoredin F^{18} FDG PET/CT, especially in female patients diagnosed with small celllung cancer.

EP-1124

Three Different Etiologies in Three Similar Looking Intrathyroid Nodules: Role of Tc-99m Sestamibi Scintigraphy & SPECT-CT in a Patient with Primary Hyperparathyroidism (PHPT)

R. Wakankar, *N. Damle, Y. Dharmashaktu, D. Kandasamy, S. Chumber, G. Puri, P. Ranjan, S. Agarwal, R. Sahu, Y. Gupta, P. Dhakal;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Hyperoxaluria occurs due to an inborn error of metabolism or due to a small bowel bypass. It mimics primary hyperparathyroidism as patients develop recurrent renal calculi made of calcium oxalate or chronic kidney disease. We discuss a rare case of concomitant hyperoxaluria and primary hyperparathyroidism. ***Materials and Methods:*** A 46-year-old woman, presented with recurrent episodes of pancreatitis, renal calculi, bone pain and arrhythmia. Biochemical evaluation revealed severe hypercalcemia 15.6 mg/dl (normal range: 8.4-10.2 mg/dl), elevated intact parathyroid hormone (iPTH) level of 394 pg/ml (normal range: 15-68.3 pg/ml) and a 25(OH) vitamin D level of 13.1 ng/ml (normal range: 25-80 ng/ml). A working diagnosis of PHPT was considered and localization was attempted. ***Results:*** An ultrasound of the neck was inconclusive for parathyroid adenoma, however, showed few thyroid nodules. A 4D-CT showed an early arterial enhancing lesion at the location of the left inferior parathyroid. Tc-99m sestamibi scintigraphy, however, revealed an abnormal focal area of radiotracer uptake on the early and delayed phase static images, in the right lobe with complete washout of the radiotracer from rest of the thyroid gland on delayed phase images. On the SPECT-CT image, three

well defined tracer avid lesions were detected; largest measuring 6.0x4.5 mm, in the lower half of the right lobe of the thyroid gland, with visible thyroid parenchyma surrounding it. The other two lesions measured 5.0x2.0 mm (left superior parathyroid) & 3.0x1.0 mm (intrathyroidal). Apart from this, no other suspicious lesions were noticed. One of these was thought to be an intrathyroidal parathyroid adenoma. The patient was planned for right hemithyroidectomy and excision of left inferior parathyroid adenoma. The histopathology was rather surprising in this case as the left superior and right inferior lesions were parathyroid adenomas, the 3 intrathyroidal lesions included NIFTP, multifocal micropapillary PTC (tall cell variant) and intrathyroidal parathyroid adenoma. The left inferior parathyroid lesion, as described on 4D-CT turned out to be thyroid follicular nodular disease. ***Conclusion:*** The learning point in this case is the importance of Tc-99m sestamibi scintigraphy with SPECT-CT in the accurate anatomical localization and detection of other equally important thyroid findings. This case also highlights the limitation of 4D-CT case plus the fact that all these three different etiologies may have the same morphological and radiotracer uptake characteristics.

EP-1125

Thyroid Nodule or Intrathyroidal Parathyroid Adenoma ?: The Role of Tc-99m Sestamibi Scintigraphy & SPECT-CT, 4D-CT and Needle FNA PTH

R. Wakankar[1], *N. Damle[1], Y. Dharmashaktu[1], D. Kandasamy[1], S. Chumber[1], G. Puri[1], P. Ranjan[1], S. Agarwal[1], Y. Gupta[1], D. Khandelwal[2], R. Reddy Kaipa[1];*
[1]All India Institute of Medical Sciences, New Delhi, INDIA, [2]Khandelwal Diabetes, Thyroid & Endocrinology Clinic, Delhi, INDIA.

Aim/Introduction: An intrathyroidal parathyroid adenoma is an important cause of surgical failure and recurrent/ persistent primary hyperparathyroidism (PHPT). An intrathyroidal parathyroid adenoma is a parathyroid gland, located entirely within the thyroid parenchyma which may or may not have a capsule of its own. This entity should be differentiated from subcapsular/ intracapsular parathyroid glands as the kind of surgery required may differ. Here-in, we highlight that this entity is an important pitfall of Tc-99m sestamibi scan and requires careful interpretation of a 4D-CT scan. ***Materials and Methods:*** A 36-year-old man with a history of recurrent bilateral renal calculi was found to have primary hyperparathyroidism (PHPT) with a serum calcium of 11.8 mg/dl (normal range: 8.4-10.2 mg/dl), an intact parathyroid hormone (iPTH) level of 124 pg/ml (normal range: 15-68.3 pg/ml) and a 25(OH) vitamin D level of 13.1 ng/ml (normal range: 25-80 ng/ml). ***Results:*** An ultrasound of his neck did not localize the adenoma. A Tc-99m sestamibi scan was done but there was no evidence of any abnormal focal uptake on the early and delayed phase static images. However, the SPECT-CT image revealed that there was an intra-thyroidal nodule in the right lobe of the thyroid gland, measuring 5.1x3.5 mm, however the uptake was indiscernible. Given the unequivocal biochemical diagnosis, the possibility of an intrathyroidal parathyroid adenoma was considered. A 4D-CT was performed to visualize the contrast dynamics, however, that was initially reported as normal. A thorough review of the imaging revealed an arterially enhancing nodule in the right lobe of the thyroid with early washout. A decision to perform a needle FNA aspirate and send it for PTH analysis was taken. The PTH from the aspirate came out to be >5000 pg/ml, clinching the diagnosis. The patient underwent a right hemithyroidectomy and the lesion was identified on cutting open the specimen. Histopathology confirmed the lesion as an adenoma and the serum calcium and iPTH normalized postoperatively. ***Conclusion:*** The learning point in this case is the pitfall on Tc-99m sestamibi imaging even with SPECT-CT, the careful interpretation of 4D-CT by an experienced radiologist, the role of needle FNA PTH as a problem solver in such tricky cases with unequivocal biochemical diagnosis.

EP-1126

Celiac Disease and Pernicious Anemia: A Rare Association revealed by Metabolic Super Bone Scan

I. Zahfir, *M. Zekri, M. Bel Lakhdar, M. Aboussabr, D. Alami, A. Mouaden, I. Ghfir, H. Guerrouj;*
Department of Nuclear Medecine, Ibn Sina Teaching Hospital, Mohammed V University, Rabat, MOROCCO.

Aim/Introduction: Celiac disease is an autoimmune disorder affecting multiple organs, often manifesting with gastrointestinal symptoms and malabsorption. Diagnosing it in adults can be challenging due to its varied presentation and is often incidentally discovered due to complications related to malabsorption syndrome. The association with pernicious anemia is rare, with only occasional reports of the two conditions occurring together. We report the case of a patient with pernicious anemia in whom a bone scan helped guide the diagnosis of associated celiac disease. ***Materials and Methods:*** We present the case of a 52-year-old patient with a history of pernicious anemia since childhood, managed with Vitamin B12 supplementation, who presented with fatigue, anorexia, and a general deterioration in health, associated with diffuse bone pain. An initial thoracic and abdominal CT scan revealed multiple lytic bone lesions throughout the skeleton. A whole-body bone scan was performed 2 hours following the administration of 740MBq of 99m Tc-hydroxymethyldiphosphonate in order to assess the findings of the CT and orient a potential biopsy site. ***Results:*** The bone scan revealed diffuse increased and homogeneous uptake throughout the axial and peripheral skeleton, contrasting with the absence of uptake in the kidneys and soft tissue, describing the classical aspect of a "Metabolic Super Bone scan". Bone densitometry showed osteoporosis. A full blood panel revealed hypoalbuminemia, hypocalcemia, hypophosphatemia, and elevated PTH levels, indicating the diagnosis of malabsorption syndrome. Serology and intestinal biopsy confirmed the diagnosis of celiac disease, and the patient was put on a gluten-free diet with a good response. ***Conclusion:*** Celiac disease can lead to numerous bone complications such as osteoporosis, osteomalacia, and secondary hyperparathyroidism. These complications can be prominent, making the diagnosis challenging. Bone scan can help assess the diagnosis and orient further investigation by revealing osteoblastic activity at the cellular level. In our patient, the metabolic superbone scan revealed a secondary hyperparathyroidism to a malabsorption syndrome, findings that led to the correct diagnosis.

EP-1127

The use of FLT PET/MRI in differentiating recurrent rectal cancer from post-therapeutic changes.

J. Foukal, *T. Kopřivová;*
Fakultni nemocnice Brno, Brno, CZECH REPUBLIC.

Aim/Introduction: Evaluation of recurrent rectal cancer may represent a diagnostic challenge. Mass lesions in the presacral space occur in up to half of patients after treatment. FDG PET can be used to exclude recurrent tumour from fibrosis, because fibrosis has low metabolic activity. However some benign processes such as sinus tract may also show high metabolic activity.

Fluorothymidine (FLT) is a radiopharmaceutical used mainly in brain tumours, but its use has been tested in other tumours. It has been found to be able to detect colorectal cancer. Furthermore, inflammation has been shown to have no significant effect on FLT uptake in gynecological cancers. ***Materials and Methods:*** A 67-year-old man with rectal cancer was referred for a follow-up FDG PET/MRI after neoadjuvant chemoradiotherapy and total mesorectal excision with coloanal anastomosis. There was a mass lesion in presacral space in the level of anastomosis with very high metabolic activity (SUVmax 17,6). We weren't able to differentiate between recurrent tumour and early postoperative changes. Follow up FDG PET/MRI showed persistent metabolic activity. For ruling out recurrent tumour FLT PET/MRI was suggested. ***Results:*** On FLT PET, the activity in the region of the mass was mild (SUVmax 3,6), only slightly above surrounding tissues. This finding was favourable for inflammatory changes and not a recurrent tumour. The patient received no treatment. Benign etiology was confirmed by follow-up. After 3 years FDG PET/MR showed no progression of metabolic activity or lesion size on MRI. Thus, this lesion was evaluated as inflammatory changes around the anastomosis with a possible small fistula without abscess formation. ***Conclusion:*** This case report demonstrates the potential of FLT PET in deciding between tumour recurrence and inflammatory changes in patients after treatment for rectal cancer. ***References:*** 1). EP-1128

A rare case of leptomeningeal involvement in variant ATTR amyloidosys: the utility of Tc99m-DPD bone scintigraphy

S. E. Prisco[1], *M. Rapa[1], S. Longhi[2], M. Sguazzotti[2,3], G. Saturi[2,4], E. Biagini[2,3], N. Galiè[2,3], S. Fanti[1,5], R. Bonfiglioli[5];*
[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Cardiology Unit, Cardiac Thoracic and Vascular Department, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [3]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, ITALY, [4]Bologna, Bologna, ITALY, [5]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: Amyloidosis is a multi-organ systemic disease caused by tissue deposition of misfolded protein aggregates of amyloid fibrils. The two most common forms of systemic amyloidosis with cardiac involvement are: Light Chain Amyloidosis (AL) caused by the deposition of immunoglobulin light chain and Transthyretin Amyloidosis (ATTR). ATTR is classified in two variants: wild type ATTR (wtATTR) caused by age-associated deposition of misfolded non-mutated transthyretin fibrils and variant ATTR (vATTR) due to mutation of the transthyretin gene. It is weel knew that bone-avid tracers (Tc99m-PYP/DPD/HMDP) are capable of visualizing amyloid deposits in tissues, particularly in the heart. ***Materials and Methods:*** A 45-year-old woman makes an initial admission to the emergency department for paresthesia, bilateral low back pain, stenotic deficit in the hemiface and left limbs and autonomic dysfunction symptoms (xerostomia, dysgeusia and dysuria). CT-angiography and Magnetic-Resonance angiography shown multiple subarachnoid hemorrhages of the convexity. Brain infections were escluded after Cerebrospinal fluid and blood analysis. Biopsy of the Dura Mater and right frontal lobe shows diffuse immune-reactivity of moderate intensity for transthyretin (ATTR-TIE), and no evidence of immunoreactivity for immunoglobulin light chains. A subsequent genetic analysis highlights c.259G>C variant (p.Gly87Arg) in heterozygosity of the TTR gene. Small-caliber fiber involment is reported at the Sudoscan. To evaluate the presence of cardiac involvente, echocardiography and ECG (both negative) and bone scintigraphy were performed according to standard procedures (740 MBq of Tc99m-DPD ev). ***Results:*** 99mTc-DPD bone scintigraphy showed no clear uptake at the cardiac site on planar investigation, Perugini Score 0, confirmed by complementary SPECT/CT of the chest. Intense and diffuse osteotropic radiopharmaceuticals uptake to all body soft tissues (axial and appendicular) with poor/absent visualization of the skeleton is reported, compatible with tissue amyloidotic deposition/altered wash out. ***Conclusion:*** Bone scintigraphy is useful in all cases of vATTR amyloidosis with or without signs of amyloidotic cardiomyopathy. The absence of cardiac involment, together with a diffuse soft tissue uptake, influences therapeutic options. In fact, the indications of new target drugs also differ according to the various organs involvement (heart vs peripheral nervous system).

EP-1129

Tuberculosis Lymphadenitis Mimicking Malignancy

C. Güneren, *L. Uslu Beşli, H. B. Sayman;*
Istanbul University-Cerrahpasa Cerrahpasa Medical Faculty Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: Tuberculosis (TB) remains a major health issue in developing countries, however its diagnosis can be challenging and can be confused with malignancy or other granulomatous diseases. ***Materials and Methods:*** We will present a 62-year-old female with sarcoidosis who presented with new-onset headaches, fatigue, night sweats, and weight loss. ***Results:*** Cranial MRI revealed space-occupying lesions, initially suggesting metastasis and prompting surgical consideration. However, lesion regression post-steroid therapy led to a provisional diagnosis of neurosarcoidosis. FDG PET/CT identified hypermetabolic lesions in lymph nodes, lungs, liver, spleen, and colon. A lymph node biopsy confirmed tuberculous lymphadenitis, and colonoscopy showed granulomatous changes, suggesting TB. Liver biopsies were negative for malignancy, and the patient commenced quadruple anti-TB therapy. ***Conclusion:*** Although pulmonary TB is the most common form of the disease, TB can spread to any tissue or organ hematogenously, lymphatically, or through contiguous spread. Hepatobiliary TB is a rare extrapulmonary form, and can mimic malignancies, causing diagnostic delays due to its vague symptoms. In cases of multiple hypermetabolic liver lesions, especially in the immunocompromised, TB should be considered (1,2). FDG PET/CT is invaluable for detecting tuberculous lymphadenitis and is a complementary tool in the diagnosis of extrapulmonary tuberculosis. It can identify lesions missed on morphological imaging, allows for the selection of biopsy site and can differentiate between active and inactive lesions by detecting early treatment response. However, FDG PET/CT cannot

reliably differentiate tuberculosis lymphadenitis from lymphoma, sarcoidosis, or metastatic lymph nodes. Particularly in countries where tuberculosis is prevalent, considering tuberculous lymphadenitis as a differential diagnosis in patients with enlarged lymph nodes and the role of lymph node biopsy in the diagnosis in the light of FDG PET/CT findings is crucial (3,4). ***References:*** 1) Wang X, Shi X, Yi C, et al. EP-1130

Head&Neck Paraganglioma in 68Ga-PSMA PET/CT - A Case Report

N. Vasconcelos, *L. Violante, J. Teixeira, H. Duarte, I. Próspero, D. Barbosa, D. Silva, I. Lucena Sampaio;*
Instituto Português de Oncologia do Porto, Porto, PORTUGAL.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) is a transmembrane glycoprotein overexpressed in prostate carcinoma. Gallium-68 (68Ga)-PSMA-directed positron emission tomography/computed tomography (PSMA PET/CT) is a non-invasive imaging modality mostly used in biochemical recurrence and staging in intermediate or high-risk prostate cancer due to its high sensitivity and specificity when compared to other non-specific radiotracers. However, despite its name, PSMA is not specific to prostate tissue, and PSMA uptake in other nonprostatic malignancies and benign conditions have been reported. ***Materials and Methods:*** We present a case of a 65-year-old male patient diagnosed with prostatic adenocarcinoma Gleason 7 (4+3), treated with radical prostatectomy that presented with biochemical recurrence. ***Results:*** PSMA PET/CT revealed a suspicious tracer-avid right laterocervical mass (SUVmax=31.6). Further characterization with magnetic resonance imaging raised suspicion of a cervical paraganglioma, a rare neuroendocrine tumour, characterized by cellular over-expression of somatostatin receptors that was confirmed after biopsy. The patient presented slightly raised chromogranin A, normal urine metanephrines and no apparent clinical or functional symptoms. 68Ga-DOTATOC PET/CT showed intense focal tracer uptake adjacent to the right carotid artery bifurcation (SUVmax=68.8), compatible with paraganglioma. Surgical removal of the tumour was proposed. ***Conclusion:*** Recently published prostate cancer guidelines recommended PSMA PET/CT as the front-line imaging modality for initial staging of unfavourable intermediate or high-risk prostate cancer, evaluation of biochemically recurrent or progressive disease, and eligibility for PSMA radioligand therapy. This clinical case illustrates a rare case of a paraganglioma detected in 68Ga-PSMA-PET/CT, a possible pitfall, since PSMA is expressed in a range of different structures and lesions, both physiologic and pathologic. Therefore, a familiarity of the common patterns of prostate cancer progression, in addition to knowledge of common pearls and pitfalls may increase confidence in interpreting PSMA PET/CT and suggesting further investigation in these cases.

EP-1131

Possible Pitfall on PET/CT with ^{18}F-FDG 10 Years After Surgical Correction of Bilateral Vesicouretral Reflux

N. Vasconcelos, *H. Duarte, L. Violante, J. Teixeira, J. Ferro, I. Próspero, D. Barbosa, D. Silva, I. Lucena Sampaio;*
Instituto Português de Oncologia do Porto, Porto, PORTUGAL.

Aim/Introduction: Positron emission tomography with computed tomography (PET/CT) with 2-deoxy-2$^{[18F]}$-fluoro-D-glucose (^{18}F-FDG) is an important tool in staging and evaluating response of various oncological pathologies. However, its specificity is limited since many physiological and benign processes have high avidity for ^{18}F-FDG. The main causes of glycolytic hypermetabolism that is not associated with malignant pathologies are physiological processes or lesions of an inflammatory/infectious nature, benign tumours, hematomas/seromas and fractures, and their distinction is often challenging. ***Materials and Methods:*** We present a case of a 12-year-old female child, with a history of bilateral vesicourethral reflux (VUR) with surgical correction at the age of 3, referred to our centre after right adnexectomy for an immature teratoma of the right ovary. ***Results:*** She underwent chest CT without changes suspicious of secondary involvement. The ^{18}F-FDG PET/CT study revealed tenuous radiopharmaceutical uptake in endometrial topography, of probable physiological nature (catamenium) and two retrovesical/parauterine areas of ^{18}F-FDG hypermetabolism, more evident in complementary images acquired after 2 hours (SUVmax initial = 9.3 -> late SUVmax = 12.1), correlated with changes resulting from endoscopic VUR correction surgery. ***Conclusion:*** This clinical case illustrates an unusual pattern of high ^{18}F-FDG uptake, resulting from a surgical intervention which occurred several years previously, that can present as a challenge in interpreting the PET/CT study and constitutes a pitfall if secondary involvement is mistakenly considered to be suspected in a patient with recently diagnosed malignancy. We therefore seek to raise awareness for the necessity to maintain a high suspicion index for the existence of potential false positives, namely through the collection of a detailed clinical history, integration with other imaging tests, knowledge of biodistribution patterns and secondary involvement, as well as imaging and functional characteristics of the lesions.

EP-1132

Vascular Lymphomatous Involvement on ^{18}F-FDG PET/CT: An Unusual Pattern

N. Vasconcelos, *H. Duarte, L. Violante, J. Teixeira, I. Próspero, D. Silva, D. Silva, I. Lucena Sampaio;*
Instituto Português de Oncologia do Porto, Porto, PORTUGAL.

Aim/Introduction: Less than 1/3 of lymphomas present as extra-nodal involvement, with the gastrointestinal tract and skin being the most common sites of presentation. Primary testicular lymphoma (PTL) represents only 1% of all non-Hodgkin's lymphomas (NHL), despite being the most common testicular neoplasm in the elderly. Its evolution is usually aggressive with a poor prognosis and involvement of the central nervous system (CNS). The most common clinical presentation is increased testicular volume and local pain. Diagnosis is generally based on scrotal ultrasound followed by biopsy with anatomopathological and immunohistochemical analysis. The recommended treatment is orchidectomy and systemic chemotherapy, along with intrathecal chemotherapy (to reduce CNS recurrence), followed by radiotherapy to the contralateral testicle. ***Materials and Methods:*** We present a case of an 87-year-old man, with a history of prostate carcinoma who underwent radiotherapy, without

constitutional symptoms, who, due to an increase in left testicular volume, underwent a scrotal ultrasound which revealed a 27mm testicular nodule, reason why he underwent radical orchidectomy. ***Results:*** The anatomopathological examination was compatible with the diagnosis of diffuse large B-cell non-Hodgkin's lymphoma (NHL-DLBCL). A bone marrow biopsy was performed without signs of neoplastic involvement. A whole-body positron emission tomography/computed tomography (PET/CT) study was also performed with 2-deoxy-2[18F]-fluoro-D-glucose (^{18}F-FDG) for staging. Intense uptake of the radiopharmaceutical was identified along the course of the left testicular vein and the ipsilateral lumboaortic chain, which begins at the level of the axial plane of D12/L1 and extends to the distal portion of the left inguinal canal, suggestive of lymphoproliferative involvement. The patient was initially proposed for systemic chemotherapy. ***Conclusion:*** Primary testicular lymphoma is a rare entity. ^{18}F-FDG PET/CT has limited value in the differential diagnosis and characterization of testicular masses, however, as in other subtypes of NHL, it is the imaging method of choice for staging PTL, due to high avidity for ^{18}F-FDG. This case illustrates an unusual pattern of lymphomatous involvement along the course of the testicular vein, characteristic of PTL but uncommon in other testicular neoplasms.

EP-1133

A rare case of primitive neuroectodermal tumor on ^{18}F-FDG PET/CT

A. Gültekin[1], *Ü. Aydoğmuş[2], G. Sarıoğlan[2];*
[1]Pamukkale University Medical Faculty Department of Nuclear Medicine, Denizli, TÜRKIYE, [2]Pamukkale University Faculty of Medicine, Department of Thoracic Surgery, Denizli, TÜRKIYE.

Aim/Introduction: Ewing sarcoma/primitive neuroectodermal tumors (ES/PNET) are high-grade malignant neoplasms. Very rarely, it may occur in the thoracopulmonary region and mediastinum. They originate from bone and soft tissue. ES/PNET include Ewing sarcoma, extraskeletal Ewing sarcoma, Askin tumors of the chest wall, and primitive neuroectodermal tumors of bone or soft tissues. On computerized scanning, ES/PNET usually presents as a large, unilateral, heterogeneously growing mass containing cystic necrotic areas. Lymph node metastasis is also rare. Distant metastasis is rare at diagnosis in thoracopulmonary ES/PNET. Surgical excision, chemotherapy and radiotherapy combination are the standard treatment methods. ES/PNET group tumors have a poor prognosis. Askin et al reported median survival after tumor diagnosis as only 8 months. Recent studies demonstrate a significant improvement in 5-year overall survival exceeding 60% to 65% for localized ES/PNET with the combination of surgical excision, intensive chemotherapy, and high-dose radiotherapy. The most important prognostic factors are known as tumor size, presence of distant metastasis at presentation, and surgical resection margin.We present a rare case ES/PNET. ***Materials and Methods:*** After fasting and resting for six hours, the patient received 305 MBq of F^{18} FDG intravenously when their fasting bloodglucose level was <200 mg/dL. The patients were examined using a dedicated PET/CT scanner. ***Results:*** Case report: A 43-year-old male patient applied with the complaint of a mass in the thoracic region. Thoracic computed tomography revealed a mass of 21x15 cm in size, invading the left thorax wall and extending into the thorax cavity. The biopsy result of the patient was reported as Ewing Sarcoma/PNET. In the F^{18}-FDG PET/CT taken for staging purposes, heterogeneous pathological F^{18} FDG uptake (SUV max: 10.48) was observed in a 22x16 cm mass that invaded the right thorax wall and caused destruction in the adjacent ribs. No metastasis was detected. The patient underwent surgical treatment . As a result of pathology, it was confirmed as ES/PNET. Ki67 proliferation index was determined as 90%. The patient died in the second month after surgery due to bleeding and infection complications. ***Conclusion:*** Ewing sarcoma/primitive neuroectodermal tumors (ES/PNET) are high-grade malignant neoplasms. These malignancies can very rarely occur in the thoracopulmonary region and even more rarely in the mediastinum. On 18F FDG PET/CT, it is observed as giant masses with cystic necrotic areas showing heterogeneous ^{18}FDG uptake. Not detecting metastasis on PET/CT is associated with a better prognosis.

EP-1134

Brown tumor: A rare complication of a hyperparathyroidism - A case report

N. Bozhinovska, *A. Jankulovska, T. Makazlieva, B. Stoilovska Rizova, S. Stojanoski, N. Manevska;*
Institute of Pathophysiology and Nuclear Medicine "Isaac Tadzer" -Skopje, North Macedonia, Skopje, NORTH MACEDONIA.

Aim/Introduction: A brown tumor (BT) is a rare, but severe complication of primary or secondary hyperparathyroidism. It is a benign bone lesion, caused by increased osteoclastic activity, due to overproduction of parathyroid hormone (PTH), causing hypercalcemia and hypophosphatemia. BTs may appear in any bone, with higher incidence in ribs, clavicles, extremities and pelvic bones. It is crucial to distinguish them from other bone diseases, especially from bone metastases, when detected by bone scan. ***Materials and Methods:*** We present a case of a 38 years old female patient that was referred to our institution for bone scan because of osteolytic changes in the left hip, previously seen on pelvic X-Ray scan. Bone scan revealed intensive pathological accumulations in the proximal diaphysis of the left femur, as well as in the distal metadiaphysis of the right femur. The histopathological finding was consistent with a giant-cell tumor. Serum levels of both PTH and ionized calcium were elevated (PTH=436pg/mL; ionized calcium=3.4mmol/L). Therefore, a dual-phase 99mTc-MIBI parathyroid scan was indicated and it showed a presence of parathyroid adenoma under the lower pole of the left thyroid lobe. The whole body 99mTc-MIBI scan acquired 2 hours after i.v radiotracer application, besides the pathological accumulation in the neck region, revealed pathological accumulations in the trochanter region of the left femur and the distal metadiaphysis of the right femur. ***Results:*** The distribution of the pathological accumulations on the whole body 99mTc-MIBI scan corresponded to the pathological accumulation pattern found in the previously conducted 99mTc-MDP bone scan. After the surgical intervention and histopathological confirmation of the parathyroid adenoma, serum PTH and calcium levels were in normal ranges, and BTs detected on control 99m Tc-MIBI whole body scan were diminished. ***Conclusion:*** Due to its intense osteoclastic activity BTs can be easily misdiagnosed as bone metastases presenting as 'hot spots' on bone scans, making it difficult to differentiate between them. In this case report we emphasize the utility of 99mTc-MIBI WBS, as a useful diagnostic technique for detecting skeletal lesions in the setting of the metabolic bone disease, as a complication of hyperparathyroidism.

EP-1135

Bilateral Vertebral Artery Vasculitis: Case report and literature review

P. Strouhal[1], *V. Prakash[2];*

[1]Alliance Medical Ltd, Warwick, UNITED KINGDOM, [2]Royal Surrey County Hospital, Guildford, UNITED KINGDOM.

Aim/Introduction: Giant cell arteritis (GCA) is an immune-mediated disease affecting medium and large-sized extracranial arteries. Vertebral artery involvement in GCA is rare with few cases published; women are more commonly affected than men. We report a case of vertebral arteritis confirmed via 2-deoxy-2-^{18}F-fluoro-D-glucose positron emission tomography/computed tomography (FDG PET/CT). ***Materials and Methods:*** Vertebral arteritis is part of the spectrum of Giant Cell Arteritis (GCA); itself often challenging to diagnose and with negative biopsy results. We present a relatively frail 83 year old female presenting with neck pain and stiffness, accompanied by elevated acute phase protein levels. Magnetic resonance imaging (MRI) revealed mild synovial thickening.She underwent scan on GE Discovery MI 5-ring digital PETCT scanner; scanned vertex to thighs 60 min after 194 MBq (3.5 MBq/kg). QClear600 PET recons used for SUVmax analysis. Low dose free breathing CT without IV contrast for AC. Blood Glucose = 5.6 mmol/l.Normal background liver SUV max = 1.8 ***Results:*** FDG PETCT exhibited moderate avidity using EANM/SNMMI criteria in both vertebral arteries extending to the basilar tip, more on the right but bilateral, indicative of inflammatory activity. Notably, some peri-articular uptake was also noted so accompanying inflammatory arthropathy was suspected. Good symptomatic relief seen with treatment (and post treatment scan will be shared if available).Our case underscores the diagnostic utility of FDG PETCT in confirming vertebral arteritis, particularly in cases where temporal artery biopsy would be challenging and, as in this case, likely inconclusive. Furthermore, it highlights the potential of FDG PETCT to visualize ongoing arterial inflammation, guiding therapeutic decisions in this challenging clinical scenario. ***Conclusion:*** Prompt recognition and management are imperative to mitigate the risk of complications such as transient ischemic attacks and irreversible neurological deficits. This case demonstrates the crucial role of hybrid imaging techniques in enhancing our understanding of arteritis pathophysiology and optimising patient care strategies. ***References:*** (1). EP-1136

When All Else Fails: Compassionate Use of Terbium-161 PSMA in the Treatment of Metastatic Prostate Cancer

N. Jacobs[1], *O. Kolade[1,2], K. Hlongwa[1,3], S. More[1];*
[1]University of Cape Town, Cape Town, SOUTH AFRICA, [2]University College Hospital, Ibadan, NIGERIA, [3]Red Cross War Memorial Children's Hospital, Cape Town, SOUTH AFRICA.

Aim/Introduction: Multiple clinical trials and published data have demonstrated the benefit of Lutetium-177 PSMA on PSA levels and survival of patients with metastatic, castrate-resistant prostate cancer (mCRPC). Limited data is available documenting the therapeutic effect of Terbium-161 (Tb-161) PSMA in patients with mCRPC1,2. Ongoing trials are available regarding its utility in dose escalation and efficacy studies. We describe our experience with Tb-161 PSMA in a 66-year-old male with metastatic, castrate-resistant prostate cancer referred for Lutetium-177 PSMA radioligand therapy due to increasing PSA refractory to docetaxel and worsening clinical symptoms. His baseline Eastern Cooperative Oncology Group (ECOG) performance status was 2. ***Materials and Methods:*** His PSA prior to Lutetium-177 PSMA was elevated. Baseline Technetium-99m HYNIC PSMA scintigraphy demonstrated widespread PSMA-avid skeletal metastases more than liver uptake. His baseline bone marrow reserve and renal function were acceptable for treatment. ***Results:*** After four Lutetium-177 PSMA cycles, his PSA had increased and a further three cycles of Lutetium-177 PSMA were administered. After seven cycles, his ECOG status improved to 1, his PSA had nearly halved from baseline, his post-therapy imaging demonstrated stable disease, and his bone marrow reserve remained stable. Multiple logistical issues with Lutetium production and delivery resulted in a delay in receiving his eighth treatment cycle. Owing to the potential negative impact on the patient's clinical progress, he was treated with two cycles of Tb-161 PSMA. Post therapy imaging showed adequate uptake of Tb-161 PSMA in the known areas of disease. The patient's ECOG performance status subsequently regressed to 4 with a PSA doubling time of two months. The patient declined any further treatment and was referred to radiation oncology for palliative management. The patient demised shortly thereafter. ***Conclusion:*** Terbium-161 PSMA radioligand therapy is a potential alternative to Lutetium-177 PSMA in the treatment of mCRPC. Further research into its effect on various outcome parameters and side effect profiles would be beneficial for the future of radioligand therapy in mCRPC management. ***References:*** 1. EP-1137

Role of [^{67}Ga]Ga-citrate scintigraphy in systemic sarcoidosis

A. Marques[1], *J. Carvalho[2], F. Abreu[1];*
[1]Instituto de Medicina Nuclear da Faculdade de Medicina de Lisboa, Lisboa, PORTUGAL, [2]Unidade Local de Saúde de Lisboa Ocidental, Lisboa, PORTUGAL.

Aim/Introduction: Sarcoidosis is a systemic inflammatory disease of unknown aetiology characterized by the development of noncaseating epitheliod granulomas in various organs and tissues.[67Ga]Ga-citrate scintigraphy has proved to be a sensitive technique in the assessment of disease activity and extension, particularly useful in departments where 2-[^{18}F]FDG PET/CT is not available.The authors present a clinical case illustrating the usefulness of of [67Ga]Ga-citrate scintigraphy in the evaluation of sarcoidosis. ***Materials and Methods:*** Description of clinical case. ***Results:*** A 31-year-old woman with a history of weight loss (approximately 10 kg) over the last year, alopecia, skin lesions on the arms and back, and a right cervical mass with progressive growth in the last 3 months was admitted to the Internal Medicine Department. Blood test results demonstrated markedly increased plasma angiotensin converting enzyme levels, thrombocytopenia, leukopenia with neutropenia and lymphopenia, hypergammaglobulinemia and vitamin D deficiency. HIV and EBV were negative. The Interferon Gama Release Assay was negative. Computed tomography (CT) showed multiple adenomegaly in various territories, with pulmonary and hepatic microdularity and nodular splenomegaly. A biopsy of a right inguinal node was

compatible with the diagnosis of sarcoidosis.Given the clinical context, [67Ga]Ga-citrate scintigraphy was performed to assess disease activity and extension. 370 MBq of [67Ga]Ga-citrate were administered and images were obtained at 48 and 72 hours after injection, as well as SPECT/CT of the pelvis and SPECT of the knees at 48 hours. This exam showed multiple hot spots in the soft tissues (nodal involvement), skin (left arm), peripheral skeleton of lower limbs in close proximity to joints; lacrimal and salivary glands (producing the "panda" sign); and irregular distribution of radiopharmaceutical in liver and spleen.These findings confirmed the diagnosis of systemic sarcoidosis and immunosuppressive therapy was instituted. The patient showed significant clinical and analytical improvement. ***Conclusion:*** [67Ga]Ga-citrate scintigraphy is the scintigraphic method of choice in the evaluation of the activity and extension of sarcoidosis, being also helpful in clinical management for starting or altering treatment, especially when PET/CT is not available.

EP-1138

Intrapancreatic accessory spleen mimicking pancreatic tumor: role of [^{99m}Tc]Tc-nanocolloid scintigraphy

A. Marques[1], *J. Carvalho[2], F. Abreu[1];*
[1]Instituto de Medicina Nuclear da Faculdade de Medicina de Lisboa, Lisboa, PORTUGAL, [2]Unidade Local de Saúde de Lisboa Ocidental, Lisboa, PORTUGAL.

Aim/Introduction: Accessory spleen is present in 10% of human population and is usually located in the area of the splenic hilum or near the tail of the pancreas1. [99mTc]Tc-nanocolloid is a radiopharmaceutical that is taken up by reticuloendothelial cells in the liver and spleen, allowing for visualization of these organs. Our aim is to highlight the role of [99mTc]Tc-nanocolloid scintigraphy in the differentiation between an intrapancreatic accessory spleen and a pancreatic tumor, particularly in cases where other imaging modalities may be inconclusive. ***Materials and Methods:*** We report a case of 61-year-old man with prostatic cancer who underwent computed tomography (CT) study to exclude metastatic disease. The abdominal CT showed a solid nodular lesion in the tail of the pancreas with contrast enhancement. Since the radiologist could not differentiate between an accessory spleen and a pancreatic tumor, a [99mTc]Tc-nanocolloid scintigraphy was requested. 185 MBq of the radiopharmaceutical were administered and planar scintigraphy and SPECT/CT images were obtained at 30 minutes after injection. ***Results:*** The planar images showed an area of increased uptake below the spleen. The SPECT/CT study demonstrated that this activity was coming from the suspicious lesion located in the pancreatic tail, so the diagnosis of an intrapancreatic accessory spleen was confirmed. ***Conclusion:*** The [99mTc]Tc-nanocolloid scintigraphy provides an easy and inexpensive method for the definitive diagnosis of an intrapancreatic accessory spleen, preventing patients from undergoing unnecessary major surgery in cases where a pancreatic tumor is suspected. ***References:*** 1-Freeman JL, Jafri SZ, Roberts JL, et al. CT of congenital and acquired abnormalities of the spleen. RadioGraphics.1993;13:579-610.

EP-1139

Tumor Thrombus From Follicular Thyroid Cancer On F^{18}-FDG PET/CT; Case Report

M. Mehesen, *E. Elkholy;*
National Cancer Institute, Cairo university, Egypt., Cairo, EGYPT.

Aim/Introduction: Thyroid carcinoma with major vascular tumor thrombosis is a rare finding. The incidence of tumor thrombus in thyroid carcinoma is between 0.2% and 3.8%. Vascular invasion, or venous tumor thrombus, in thyroid cancer is a risk factor for distant metastases or early relapse. ***Materials and Methods:*** After 60 minutes of administering FDG intravenously, a whole-body PET/CT scan was acquired, extending from the base of the skull to the mid-thigh. ***Results:*** A 68-year-old female patient with follicular thyroid cancer had a total thyroidectomy and a total neck dissection. Pathology revealed a widely invasive tumor, an infiltrating thyroid capsule with focal extension into surrounding soft tissue, and IJV occluded by the tumor.Post-operative FDG PET/CT study revealed linear intense FDG avid metabolically active enhancing tumor thrombosis distended the right brachiocephalic vein as well as SVC reaching to the right atrium and filling its lumen with SUV max~12.1. Numerous bilateral pulmonary nodules are detected with SUV max~3.3. In addition, there are enlarged FDG-avid right para-tracheal and small-sized, low-grade FDG-avid left supra-clavicular nodes. Moreover, bony lesions involving the sternum, both iliac bones, right humeral shaft, and spine of SUV max~11 are also noted. A cardiovascular surgical consultation was done, but the option of surgical intervention was refused due to the critical situation. ***Conclusion:*** F^{18}-FDG PET/CT plays an important role in proper staging as it helps in the detection of tumor thrombus and its extension, as well as the detection of distant metastases.

EP-1140

Shunt malfunction with multilevel CSF leaks on serial imaging: a case report

S. Katal, *K. Taubman;*
Medical imaging department, St. Vincent's Hospital Melbourne, Melbourne, AUSTRALIA.

Aim/Introduction: Radionuclide cerebrospinal fluid (CSF) shunt studies provide a simple, effective, and low-radiation-dose method for evaluating CSF shunt patency and function. However, despite its value, these studies are not commonly performed nowadays, leading to challenges in maintaining proficiency in this skill. Here, we represent a 39-year-old woman with clinical suspicion of lumboperitoneal (LP) shunt malfunction who had multilevel CSF leaks on two sets of radionuclide CSF studies. ***Materials and Methods:*** Following injection of 250MBq Tc-99m diethylenetriaminepentaacetic acid via a lumbar puncture needle into the thecal sac, serial imaging of the head, thorax, and abdominal regions were acquired. SPECT/CT imaging was also performed. ***Results:*** The radionuclide CSF study demonstrated multifocal sites of CSF leaks and large CSF-omas within the lower cervical/thoracic, lumbar, and right posterior flank regions. Careful examination of the SPECT/CT images has also aided in confirming the CSF leakage and collections beyond the shunt tract, as suspected in the planar images. ***Conclusion:*** This case highlights the value of radionuclide CSF imaging for the evaluation of shunt function, particularly in patients with recurrent symptoms or equivocal anatomic imaging findings. It underscores the necessity of maintaining our skills in such traditional radionuclide studies which are not performed frequently nowadays. A thorough examination of SPECT/CT images is also crucial for accurate diagnosis and management of CSF shunt complications.

EP-1141

Multıple Skeletal Muscle Metastases In Neuroblastoma: A Rare Case

A. Erdem[1], *D. Çayır[1,2], A. Çınar[1], N. Altun Yoloğlu[1], S. Demirtaş Şenlik[1];*

[1]Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]University of Health Science, Ankara, TÜRKIYE.

Aim/Introduction: Neuroblastoma, the most common extracranial solid tumor of childhood, originates from neural crest cells and predominantly affects children under the age of 5. Most neuroblastomas are found in the abdomen and adrenal glands, but they can occur anywhere along the sympathetic nervous system. Common sites of metastasis include bone, bone marrow, lymph nodes, and liver. Metaiodobenzylguanidine (MIBG), a noradrenaline analogue, is used for imaging neuroectodermal-origin tumors. Here, we present a case of skeletal muscle metastasis rarely seen in the course of neuroblastoma, detected by MIBG scintigraphy. ***Materials and Methods:*** In January 2023, an 17-month-old female patient diagnosed with neuroblastoma and treated with 8 cycles of chemotherapy was referred to our clinic for I-123 MIBG scintigraphy. No pathological findings were observed on whole abdomen ultrasound, but focal increased MIBG uptake was observed in the left lower abdomen, left side of bladder, and both lower extremities at the level of the proximal shaft of the femur and the proximal level of the right tibia. SPECT/CT images obtained from the pelvis and lower extremities revealed increased MIBG uptake within soft tissue densities measuring 15 mm in diameter between the left gluteal muscle structures, within muscle structures at the lateral section of the proximal right femur and the medial section of the proximal left femur, and within muscle structures posterior to the right tibia measuring 18x11 mm in diameter. The described findings were interpreted as favor of metastasis. The patient is under follow-up at the Pediatric Hematology-Oncology Clinic. ***Results:*** MIBG scintigraphy is often used in determining the primary focus of neural crest originated tumors, staging the tumor, detecting metastases, investigating the effectiveness of treatment, and investigating residual and recurrent disease. Skeletal muscle metastasis of neuroblastoma is very rare and has been reported in a limited number of cases in the literature. ***Conclusion:*** SPECT/CT images play an important role in distinguishing between commonly observed bone metastases and rarely seen skeletal muscle involvement, which can alter the stage of the disease.

EP-1142

Normocalcemic Parahtyroid Carsinoma: A Rare Case

A. Erdem[1], *D. Çayır[1,2], S. Demirtaş Şenlik[1], A. Çınar[1];*
[1]Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]University of Health Science, Ankara, TÜRKIYE.

Aim/Introduction: Parathyroid carcinoma is a quite rare disease that presents with severe hyperparathyroidism.It comprises about 1% of all hyperparathyroidism cases. Typically, carcinomas are >3 cm in size and PTH levels are in the thousands. Serum Ca level greater than 14 mg/dL and accompanying metabolic bone disease support the diagnosis. Pathological findings may be insufficient to differentiate between parathyroid adenoma and carcinoma. Here, a very rare case of parathyroid carcinoma with widespread bodily pain and incidental fracture detected on parathyroid imaging was presented. ***Materials and Methods:*** In the examinations of a 47-year-old female patient who applied with the complaint of difficulty in walking; BMD values were L1-L4=-6.2, femur=-4.9, serum PTH level was 1897 pg/mL (N:15-65). Serum Ca level was 10.06 mg/dL (N:8.6-10.2) and 25-OH Vitamin D level was 8 (< 10, very low). On physical examination, a hard fixed palpable mass was detected in the neck, located in the right lobe of the thyroid. Cervical US reported as; a hypochoic solid lesion with a heterogeneous internal structure, 42x31x21 mm in size, containing cystic/necrotic areas, located intrathyroidally in the right lobe. The findings were primarily evaluated in favor of parathyroid carcinoma. The patient was referred to our clinic and underwent MIBI whole-body scanning in addition to dual-phase parathyroid scintigraphy. The early and late images showed parathyroid pathology with MIBI uptake on the right lobe. MIBI uptake was seen inferior to normal bladder activity in the whole-body scan, prompting pelvic SPECT/CT imaging. It revealed that the observed MIBI uptake was from bladder activity, while findings consistent with a fracture line were noted in the bilateral ischiopubic ramus. The patient underwent parathyroidectomy, right lobectomy and ipsilateral neck dissection. The patient, with normal PTH and calcium levels post-operative, is under follow-up at the Endocrinology Clinic. ***Results:*** Parathyroid carcinoma should be considered in patients with a palpable mass in the neck, PTH value 3-10 times the upper limit, severe hypercalcemia, lesion size >3 cm on cervical US, accompanying bone and kidney findings. Since the disease may progress with local invasion and relapses, surgery is performed more extensively. Normocalcemia in our case was attributed to very low levels of 25-OH vitamin D. Incidental bilateral ischiopubic fracture was detected with SPECT/CT performed after MIBI whole-body scan. ***Conclusion:*** Considering that MIBI is also used as a tumor imaging agent, we think that whole-body scan should be performed in selected patients in addition to routine parathyroid scintigraphy.

EP-1143

Finding Meckel's Diverticulum: a clinical perspective

G. Martínez Gómez, *T. Rodríguez Locarno, A. De Agrela Serrao, Á. Leiva Montejo, C. Ruiz Corbalán, M. Castellon Sánchez, T. Moreno Monsalve, N. Sánchez Izquierdo, M. Ibáñez Ibáñez, A. Hernández Martínez, J. Navarro Fernández, L. Frutos Esteban, L. Mohamed Salem, J. Contreras Gutiérrez;*
Hospital Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Aim/Introduction: Meckel's diverticulum is the most common congenital anomaly of the gastrointestinal tract and is present in 1 to 3% of the general population. It develops due to incomplete obliteration of the omphalomesenteric duct in the embryo and it is the most frequent location of ectopic gastric mucosa. Only 35% of Meckel's diverticulum present clinical symptoms, of which 60% have ectopic gastric mucosa, increasing the percentage to 98% in those who have bleeding complication. ***Materials and Methods:*** A 4-yeard-old child is brought to the emergency department presenting with melena, abdominal pain, weakness, and pale skin. The blood test showed severe normocytic normochromic anemia. After blood transfusion, the patient remains hemodynamically stable with resolution of the melena. The abdominal ultrasound identified an image of intussusception in the ileal region. Given the high suspicion of Meckel's diverticulum a ectopic gastric mucosa scintigraphy was performed. ***Results:*** A dynamic and sequential ectopic gastric mucosa scintigraphy was performed after intravenous administration of a 55.5 MBq dose of 99mTc-pertechnetate under camera, obtaining dynamic images of the abdomen every second for 60 seconds followed by every 30 seconds for 15 minutes and static images at 45 and 60 minutes in which an area of focal hypercaptation of the tracer was observed that appears simultaneously with gastric and duodenal activity, in the right iliac fossa, which is sugestive of ectopic gastric mucosa in that location. We used 99mTc-pertechnetate as the radiopharmaceutical for the scan, which is the choice due to its high affinity for gastric mucosa. The radiopharmaceutical

is absorbed by the mucinous cells of the gastric mucosa and then secreted into the intestinal lumen. After confirming the Meckel's diverticulum, the surgeons performed a laparotomy with intestinal resection and latero-lateral anastomosis. The pathology study described the piece of small intestine with Meckel's diverticulum, in which extensive gastric heterotopia. ***Conclusion:*** Gastric mucosa scintigraphy is the most widely used test for the location of Meckel's diverticulum as a preoperative study, having a sensitivity of 85% and a specificity of 95% (1). Since gastric mucosa is responsible for most complicated diverticula with bleeding or perforation, it is a useful tool for diagnosis and decision-making in the surgical management of these patients. ***References:*** 1. Spottswood SE, Pfluger T, Bartold SP, Brandon D, Burchell N, Delbeke D, et al. SNMMI and EANM Practice Guideline for Meckel Diverticulum Scintigraphy 2.0. EP-1144

Crossing Borders: Ovarian Cancer Metastasizing To The Brain A Case Report

E. Vilceleanu-Merlusca[1], *C. Mazilu[1], D. Craciun[1], C. Calin[2], M. Mititelu[1,3];*
[1]Clinic of Nuclear Medicine, "Dr Carol Davila" Central University Emergency Military Hospital, Bucharest, ROMANIA,
[2]Department of Oncology, "Dr Carol Davila" Central University Emergency Military Hospital, Bucharest, ROMANIA,
[3]Department of Nuclear Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, ROMANIA.

Aim/Introduction: Brain metastases of ovarian cancer seldom occur and are rarely taken into consideration during differential diagnosis. We present the case of a patient with ovarian carcinoma (OC) associating a brain lesion visible on [18F]-Fludeoxyglucose Positron Emission Tomography - Computed Tomography ([18F]-FDG PET-CT). ***Materials and Methods:*** Our patient is a 74-year-old female with a long history of FIGO III high-grade BRCA negative OC, in follow-up for more than 9 years, with multiple local recurrences. She underwent radical hysterectomy and adjuvant chemotherapy. Now she presented with fatigue, vertigo and disorientation. The patient had slightly elevated CA-125 level, raising concerns for disease progression. Therefore, she was scheduled for [18F]-FDG PET-CT. ***Results:*** The PET study showed focal glucose uptake in the left fronto-parietal cortex with a discrete hyperdense lesion and surrounding oedema on the computed tomography (CT) images. There was also an increased glucose uptake in the vaginal stump, compatible with local recurrence of the tumour. Cerebral magnetic resonance imaging (MRI) study revealed a heterogenous gadolinium enhanced lesion with smooth irregular margins, in the left parietal lobe with diffusion restriction and surrounding oedema, highly suggestive for a metastatic lesion. The patient underwent neurosurgery and the specimen tested positive for poorly-differentiated ovarian cancer cells consistent with high-grade serous carcinoma metastasis. Although [18F]-FDG PET-CT has a limited role in brain tumours due to high physiological neuronal glucose uptake[1], it is still advisable to perform scans from the vertex rather than the tentorium. In addition, for some patients with certain risk factors (later diagnosis, recurrences), brain MRI should be considered as part of follow-up. As brain MRI is not routinely performed in patients with OC, true incidence of brain metastases in these patients may be underestimated, with limited evidence in the literature [2]. ***Conclusion:*** Brain imaging is rarely included in OC follow-up protocols, but our practice ensures a thorough examination. For oncologic patients with long courses of disease, a comprehensive [18F]-FDG-PET-CT scan from the vertex may be a better option to assess disease progression. Keywords: [18F]-FDG PET-CT, brain metastasis, ovarian cancer, serous carcinoma, brain imaging ***References:*** 1. Purohit BS, et al. FDG-PET/CT pitfalls in oncological head and neck imaging. Insights Imaging. 2014;5(5):585-602. 2. Pakneshan S, et al Brain metastasis from ovarian cancer: a systematic review. J Neurooncol. 2014;119(1):1-6.

EP-1145

Peculiar Findings at [18F]-FDG PET-CT in a Typical Pulmonary Carcinoid

M. Matei[1], *B. Constantinescu[1], A. Rosca[1], T. Mititelu[2], C. Mazilu[1], R. Mititelu[1,3];*
[1]Clinic of Nuclear Medicine, Central Universitary Emergency Military Hospital, Bucharest, ROMANIA,
[2]Institute of Military Medicine, Bucharest, ROMANIA,
[3]Department of Nuclear Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, ROMANIA.

Aim/Introduction: Pulmonary carcinoids account for less than 30% of all carcinoid tumors and only 1-2% of all pulmonary malignancies. Histologically, they are classified as typical carcinoid, atypical carcinoid, small cell lung carcinoma and large cell neuroendocrine carcinoma. ***Materials and Methods:*** We present a case of a 56-year-old female with a history of a well-differentiated, typical pulmonary carcinoid tumor located in the left superior pulmonary lobe, for which she underwent a lobectomy with lymphadenectomy. After five disease-free years, she presented with a left posterior thoracic wall mass, originating from the ninth left rib. Biopsies taken from the mass indicated an atypical pulmonary carcinoid metastasis, with a proliferation index (ki67) of 10%. A bone "whole-body" scan with 99mTc-HDP revealed multiple osteogenic foci of high uptake located in several vertebrae, the rib cage and in the pelvic bones, suggestive of bone metastases. ***Results:*** The patient underwent a positron emission tomography with computed tomography (PET-CT) scan with [18F]-FDG to further assess the disease extension, which revealed multiple active lesions located in the thyroid, pancreas, liver and bone. The thyroid had multiple heterogeneous, hypodense lesions avid for [18F]-FDG with a SULmax up to 5.83. In the liver there were several hypodense lesions, the biggest and the most active located at the limit of the second and third hepatic segment, with a SULmax of 4.82 and diameter of 23/25 mm. In the pancreas there was an expansive solid mass, located at the conjunction of the istm and pancreatic body with a diameter of 13/12 mm, that showed a moderate glucose uptake (SULmax of 2.0)1. The numerous bone metastases previously described, showed high avidity for [18F]-FDG. Biopsies from the thyroid lesions suggested pulmonary well-differentiated carcinoid metastasis (Ki67 of 2%, Chromogranin A and Synaptophysin positive), while the pancreatic biopsy displayed inflammatory histological features. The patient is undergoing chemotherapy, with the last bone scan showing no new focal lesions. ***Conclusion:*** The findings of our case report emphasizes the importance of [18F]-FDG PET-CT scan in the long-term management of typical pulmonary carcinoid tumors, as it displays heterogeneity of differentiation; [18F]-FDG PET-CT can detect various metastases even those who showcase a low proliferation rate and with an unusual localization, hence modifying the therapeutic strategy. Keywords: pulmonary carcinoid, distant metastases, [18F]-FDG PET-CT.

EP-1146.

Amyloidosis Insights: Right Ventricle and Atrial Radiolabelled Bisphosphonates Uptake in Cardiac Scintigraphy

***B. Constantinescu*[1],** *C. Mazilu[1], S. Stanciu[2,3], R. Mititelu[1,4];*
[1]Clinic of Nuclear Medicine, Central Universitary Emergency Military Hospital, Bucharest, ROMANIA, [2]Central Universitary Emergency Military Hospital, Bucharest, ROMANIA, [3]Department of Internal Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, ROMANIA, [4]Department of Nuclear Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, ROMANIA.

Aim/Introduction: Atrial and right ventricular uptake on cardiac scintigraphy is not yet routinely analyzed when a patient with suspected cardiac amyloidosis (CA) is evaluated. This is a new topic that may shed more light on prognosis of the disease. The aim of this case report is to raise awareness of these issues so that the diagnostic algorithm and the best method of treatment can be determined. ***Materials and Methods:*** We present a case of an 86-year-old male patient whose echocardiography suggested hypertrophic cardiomyopathy: left ventricular thickness with mild ventricular dysfunction - ejection fraction 45%, biatrial and right ventricular dilatation. The patient had a history of paroxysmal atrial fibrillation (AF), but at his last hospitalization ECG showed sinus rhythm with left axis deviation, left bundle branch block and secondary repolarization changes. ***Results:*** "Whole body" scan with subsequent SPECT/CT was performed after intravenous administration of 99m-Technetium-Hydroxydiphosphonate. Planar and "whole-body" scans showed intense extraosseous uptake in the cardiac projection area with a visual Perugini score of 3 and a heart-contralateral lung ratio of 2.3. High diffuse biventricular and mild right atrial uptake of radiotracer were noted on SPECT/CT.Recent research in the field of CA suggests that the extent of right ventricular impairment may be critical in fully assessing the disease and determining the most effective treatment strategy. Patients with biventricular uptake are associated with extensive amyloid accumulation and often have poor overall outcome and reduced life expectancy[1]. Some recent research suggested that atrial bisphosphonates uptake, especially in the left atrium, is linked with atrial fibrillation[2]. In our case, bisphosphonates uptake was only detected in the right atrium wall.This could be interpreted as a consequence of mechanical stress on the heart as well as an indicator of progressive disease, considering that the patient had a history of paroxysmal AF. ***Conclusion:*** Scintigraphy with radiolabelled bisphosphonates is a suitable, non-invasive method for the detection of TTR amyloid deposits in the heart muscle, which allows successful differentiation between various forms of CA. In particular, distribution of bisphosphonate uptake can be of prognostic significance, especially if detected in the right ventricle or the atrial wall. ***References:*** 1. Dorbala, Sharmila. The diagnostic value of Tc99m-human serum albumin scintigraphy in the investigation of Protein Losing Enteropathy

***I. Sevaslidou*[1],** *S. Episkopopoulou[1], M. Papachristou[2], A. Velidaki[1], A. Goules[3], M. Patsouras[3], I. Karavokyros[4], I. Vagios[4], E. Mylonakis[4], E. Dagrakis[1], N. Prosotsianiotis[1], T. Kostou[1], G. Bramis[1], A. Kolindou[1];*
[1]Nuclear Medicine Department, General Hospital " LAIKO", Athens, GREECE, [2]Nuclear Medicine Department, General Hospital "EVANGELISMOS", Athens, GREECE, [3]Department of Pathophysiology, General Hospital " LAIKO", Athens, GREECE, [4]First Department of Surgery, General Hospital " LAIKO", Athens, GREECE.

Aim/Introduction: The Tc 99m-human serum albumin (HSA) scintigraphy is a noninvasive method, with low radiation exposure, low cost, easily accessible and can be used to detect Protein losing enteropathy(PLE) ***Materials and Methods:*** We report a case of a 54-year-old man with PLE, who was hospitalized due to generalized edema, ascites, and several hypoalbuminemia(1,7mg/dl). Cardiac insufficiency, cirrhosis, and nephrotic syndrome have been excluded. The measurements of fecal alpha-1-antitrypsin were increased. As part of the PLE, a series of examinations were performed. Further investigation was requested with HSA-Tc 99m scintigraphy. The radiolabeling of the HSA with 99mTc is not well established and there is no available kit so it was done in vitro labeling. The protocol used contained 0.1mg of HSA, stannous chloride 0.2 mg mixed with 30mCi Na 99mTc04.The labeling efficiency and stability were determined with TLC developed in acetone. The patient was placed in a supine position under the gamma camera. The region of interest was the abdominal region. After intravenously injection of 30mCi HSA -Tc99m dynamic images started immediately. Serial static images were obtained for the first 30 min and at 1,2,4,6 and 24 h. In order to obtain more anatomical information, SPECT imaging was performed at the 1st and 3rd hour and abdomen computer tomography (CT) was performed before and after the administration of gastrografin. ***Results:*** Physiological activity is visible in the liver, spleen, kidneys, bladder and blood vessels. No uptake by stomach and thyroid was noted. In the HSA -Tc 99m scintigraphy, increased uptake of the radiopharmaceutical was observed in intestinal in the left abdominal quadrant. The findings were correlated with those from the CT before and after administration of gastrografin, indicating involvement of the jejunum region. The patient underwent mesenterium laparoscopic biopsy followed by intraoperative full intestine endoscopy and excision of 10 cm length of jejunum. Pathology evaluation revealed lymphoid follicles and polyclonal plasmocytic infiltration in the mesenterium whereas jejunum biopsies revealed non-specific inflammation and moderate lymphatic vessel dilation. The patient was given iv methylprednisolone and showed significant clinical improvement with normalization of a1 antithrypsin levels in the stool. ***Conclusion:*** PLE is characterized by a loss of serum protein into the gastrointestinal tract (GIT)due to different etiologies. Localizing the site of protein loss in the GIT is very important for diagnosis and therapeutic management and in this direction can help the Tc99m-HSA scintigraphy.

EP-1148

Case report: unveiling an infrequent metastatic site in differentiated thyroid cancer with iodine-124 PET/CT

***D. Valenzuela*[1,2],** *K. Jewell[1], A. Cardin[1], R. Alipour[1];*
[1]Prostate Cancer Theranostics and Imaging Centre of Excellence (ProsTIC), Molecular Imaging and Therapeutic Nuclear Medicine, Cancer Imaging, Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [2]Hospital Dr Sotero del Río, Santiago, CHILE.

Aim/Introduction: Differentiated thyroid cancer (DTC) typically has a favourable prognosis1; standard of care treatment may include total thyroidectomy followed by radioactive iodine (RAI) therapy.

Distant metastases can occur in a small percentage of cases, most commonly involving the lungs and skeleton. Renal metastases are rare and tend to occur years after primary tumour resection, most often in female patients aged >45 years, and usually in the setting of multifocal metastatic disease2. Conventional peri-RAI imaging includes iodine-123 or -131 whole-body SPECT/CT, however iodine-124 PET/CT has also emerged as a valuable tool for staging and detecting DTC lesions with higher accuracy2. This advanced technique allows for an individualised treatment approach, and we present here a case highlighting its use in an uncommon metastatic presentation. ***Materials and Methods:*** A 68-year-old female with follicular thyroid carcinoma underwent two-stage thyroidectomy, followed by RAI in 2017 (3.7 GBq/100mCi) and 2019 (5.5 GBq/148.6mCi; cumulative dose 9.2GBq/248.6mCi). In 2020, she presented with a progressive rise in serum thyroglobulin (Tg), and FDG PET/CT revealed a lytic lesion in the left femur which was treated with stereotactic radiotherapy. In 2023, she presented with a new, rising Tg level, increasing >10-fold in under 12-months. ***Results:*** Paired iodine-124 and FDG PET/CTs were performed, revealing iodine-avid osseous metastases in the right mandible, a right-sided rib, and left proximal femur. Additionally, at least three iodine-avid soft tissue lesions were present involving both kidneys, with no definite structural changes visualised on low-dose CT. Only the left femur lesion was minimally FDG-avid. Subsequently, the patient received another 7.3 GBq (197.3mCi) of RAI; the post therapy scan revealed moderate-to-intense uptake at the dominant left upper pole renal lesion (SUVmax 47.8), with mild activity in the remaining right renal lesions (SUVmax 9.6) and osseous metastases. ***Conclusion:*** In our patient, I-124 PET/CT revealed a rare DTC metastatic site involving bilateral kidneys which may otherwise have gone undetected. I-124 PET/CT is a valuable addition for staging of patients with recurrent DTC, in this case outperforming conventional imaging techniques2. In our institution, pre-RAI I-124 PET/CT staging is our standard clinical practice. ***References:*** 1. Song HJ, Xue YL, Xu YH, Qiu ZL, Luo QY. Rare metastases of differentiated thyroid carcinoma: pictorial review. Endocr Relat Cancer. 2011 Aug 30;18(5):R165-74. doi:10.1530/ERC-11-0068. PMID:21632805.2. Zampella E, Klain M, Pace L, Cuocolo A. PET/CT in the management of differentiated thyroid cancer. Diagn Interv Imaging. 2021 Sep;102(9):515-523. doi:10.1016/j.diii.2021.04.004. Epub 2021 Apr 27. EP-1149

Omental Hernia as a Potential Cause of False Positive GI Bleeding on Tc-99m RBC Scintigraphy

F. Karamian, *R. Sadeghi, P. Sahafi, A. Saber Tanha;*
Mashhad university of medical science,
Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Gastrointestinal bleeding scintigraphy is a noninvasive study used to determine the presence of active bleeding, localize the bleeding site, and estimate the bleeding volume for prognostic purposes in patients with suspected gastrointestinal bleeding. However, it is important to note that false positive results can occur due to various reasons. This case highlights the significance of considering anatomical anomalies and non-bleeding pathologies such as an omental hernia when interpreting 99mTc-RBC scintigraphy results for gastrointestinal bleeding. ***Materials and Methods:*** A 45-year-old woman recently diagnosed with obscure gastrointestinal bleeding was referred to our center for 99mTc-RBC scintigraphy for additional assessment. Dynamic images were taken for 60 minutes and the SPECT/CT acquisition was performed at the end of early dynamic images at 60 minutes. Delayed dynamic images was also taken every 3 hours for 20 minutes till 24 hours. ***Results:*** The early dynamic images showed an accumulation of radiotracer in the hypogastric region, which was remained unchanged over time. The zone of 99mTc-RBC uptake was also evident on delayed dynamic images. The CT component of the study revealed that the zone of activity was localized to a fat density mass in the abdominal wall, which was determined to be an omental fat herniation. It is important to note that the patient had a history of hysterectomy for a non-cancerous condition, and the physical examination showed an abdominal bulge in the hypogastric region, which had been previously confirmed as an omental hernia through an ultrasound examination. ***Conclusion:*** Omental hernias are rare conditions that can be difficult to diagnose. They occur when omental fat protrudes through an opening in the abdominal wall or into another part of the abdomen, potentially leading to complications such as bowel obstruction or strangulation. Gastrointestinal bleeding is a common clinical issue that requires prompt and accurate diagnosis. 99mTc-RBC scintigraphy is a valuable tool for localizing the source of bleeding in patients with obscure gastrointestinal hemorrhage. However, false positive results can occur due to various factors, including anatomical anomalies and non-bleeding pathologies. Other potential pitfalls which have been reported include varices, abdominal/gluteal hematomas, aortic aneurysms, and hemangiomas. In this case, the omental hernia caused compression on adjacent blood vessels, resulting in altered blood flow and mimicking gastrointestinal bleeding on 99mTc-RBC scintigraphy. This case emphasizes the importance of considering anatomical anomalies and non-bleeding pathologies when interpreting 99mTc-RBC scintigraphy results for gastrointestinal bleeding.

EP-1150

Non-malignant 68Ga-FAPI-46 uptake in two cases of TENIS syndrome: comparison with ^{18}F-FDG

F. Karamian, *R. Sadeghi, A. Aghaee, E. Askari, H. Roustaei;*
Mashhad university of medical science,
Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: TENIS syndrome, characterized by elevated thyroglobulin levels and negative iodine scintigraphy, poses a diagnostic challenge in thyroid cancer management. While 18F-FDG PET/CT has traditionally been the standard imaging modality for assessing TENIS syndrome, recent studies have shown promising results with 68Ga-FAPI PET/CT. This novel imaging technique targets fibroblast activation protein and has emerged as a potential alternative for these cases. However, it is important to understand the potential pitfalls and limitations of 68Ga-FAPI PET/CT. This case report aims to highlight some of these pitfalls and challenges, comparing the findings with concurrent FDG PET/CT. ***Materials and Methods:*** Two middle-aged women with a history of TENIS syndrome and high serum thyroglobulin levels underwent both 68Ga-FAPI-46 PET/CT and 18F-FDG PET/CT scans to search for possible metastasis sites. ***Results:*** Neither the 68Ga-FAPI PET/CT nor the 18F-FDG PET/CT scans revealed any suspicious tumoral involvement. However, a few non-malignant uptakes were observed on the FAPI study. The atrophic parotid gland exhibited FAPI uptake, which was not consistent with the FDG scan. This finding correlated with chronic parotiditis observed on the CT images. Additionally, increased uptake was observed in the gallbladder on the FAPI scan, while no uptake or pathological findings were seen on the FDG or CT images. Intense uptake in the FAPI scan and moderate FDG uptake were

observed in the degenerative changes of the L5-S1 facet joint, with sclerotic changes visible on the CT images. The uterus demonstrated intense uptake in the FAPI scan, while only mild uptake was seen in the FDG, and no underlying pathology was evident on the CT images. It is important to note that this post-menopausal woman had no history of gynecological disease. ***Conclusion:*** Fibroblast activation protein inhibitor (FAPI)-targeted radiopharmaceuticals are being explored as potential alternatives to FDG for tumor-specific imaging. However, it has been observed that these radiopharmaceuticals can also accumulate in benign diseases and normal tissues. This is due to the expression of fibroblast activation protein (FAP) during various physiological processes such as embryogenesis, wound healing, inflammation, and fibrosis. Therefore, when interpreting a FAPI study, it is crucial to consider non-malignant causes of FAPI uptake.

EP-1151

Silent Right Coronary Hypoplasia in Young Adult. A SPECT MPI Case Report

I. Hrapsa[1], *D. A. Iancu[2], L. E. Mititelu[3], C. V. Mazilu[1], S. M. Stanciu[2,4], R. Mititelu[1,5];*
[1]Clinic of Nuclear Medicine, Central Universitary Emergency Military Hospital, Bucharest, ROMANIA, [2]Department of Cardiology, Central Universitary Emergency Military Hospital, Bucharest, ROMANIA, [3]Faculty of Medicine, University of Medicine and Pharmacy Dr. Carol Davila, Bucharest, ROMANIA, [4]Department of Internal Medicine, University of Medicine and Pharmacy Dr. Carol Davila, Bucharest, ROMANIA, [5]Department of Nuclear Medicine, University of Medicine and Pharmacy Dr. Carol Davila, Bucharest, ROMANIA.

Aim/Introduction: Coronary artery anomalies (CAAs) are congenital malformations with potential for serious consequences. Right coronary artery hypoplasia (RCAh), a specific type, can present with diverse symptoms or remain silent. Tragically, undiagnosed CAAs have been linked to sudden cardiac death in young athletes, highlighting the need for early detection. Noninvasive imaging, like SPECT myocardial perfusion, aids in diagnosis, assessment and risk stratification (1-3). ***Materials and Methods:*** We present a 22-year-old male recently diagnosed with incomplete right bundle branch block (iRBBB) on a routine medical checkup; he was subsequently referred for a thorough cardiovascular investigation. CT Angiography confirmed RCAh with superdominant left coronary artery (LCA). He subsequently underwent Myocardial Perfusion Imaging (MPI) SPECT. We followed a 1-day stress-rest MPI SPECT protocol with 8mCi/20mCi of 99mTc-SESTAMIBI. Image acquisition was EKG gated. Image processing and review was done using a commercial FDA approved software while interpretation was done following the EANM guidelines. Additionally, stress MPI surface volume was fused with the coronary tree from the CT coronary angiography to better visualize the anatomy-perfusion relationship. ***Results:*** Despite no symptoms, MPI stress testing revealed a mild chronic infero-septal hypoperfusion with moderate ischemia (Summed Difference Score = 6) at stress in the RCA territory, in accordance with the anatomical anomaly. The ischemic deficit was 9% of the left ventricle, with 6% attributed to the RCA territory. Gated stress images showed impaired endo-systolic thickening in the same region with slight septal hypokinesis that improved at rest. Stress and rest left ventricle ejection fraction (LVEF) were 58% and 59% respectively with a transient ischemic dilatation (TID) index of 1.02. ***Conclusion:*** Despite his young age and lack of overt symptoms, SPECT MPI identified moderate ischemia in this patient with RCAh. This finding, combined with the anatomical anomaly, underscores the importance of early diagnosis and risk stratification in individuals with CAAs, particularly young athletes or individuals pursuing careers involving physical activity.

EP-1152

Exceptional Finding: Thigh Myxofibrosarcoma Metastasizing to the Breasts

F. Karamian, *A. Aghaee;*
Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Myxofibrosarcoma is a rare type of soft tissue sarcoma that typically arises in the extremities of elderly patients. Metastasis to distant sites is uncommon, with the lungs being the most common site of spread followed by regional lymph nodes, pleura and bone. Here we are reporting what we believe to be the first case of myxofibrosarcoma originating in the thigh and metastasizing to the breast. ***Materials and Methods:*** A 60-year-old woman with a documented history of myxofibrosarcoma originating in the left thigh was referred to our facility. The patient underwent limb amputation, followed by chemoradiotherapy, and has been regularly monitored using conventional imaging modalities. In the most recent CT scan, concerning lesions were identified in the right lung, along with masses in both breasts. To further evaluate these findings and explore potential metastatic sites, a whole-body FDG PET/CT scan was conducted. ***Results:*** The FDG PET/CT scan revealed a hypermetabolic metastatic pulmonary nodule in the upper lobe of the right lung. Additionally, a few breast masses with mild metabolic activity and signs of pectoralis muscle involvement on the left side were observed bilaterally. Given the rarity of distant metastasis in myxofibrosarcoma, particularly to the breast, the patient was referred for a biopsy to investigate the possibility of secondary cancer. Surprisingly, the core needle biopsy of the breast masses and immunohistochemistry findings indicated metastatic myxofibrosarcoma with the primary tumor originating in the thigh. Subsequently, the patient underwent chemotherapy, leading to the observed shrinkage of the masses on the follow-up CT scan. ***Conclusion:*** We report the very first case of myxofibrosarcoma originating in the thigh and metastasizing to the breast. This case highlights the importance of considering unusual sites for metastasis in patients with soft tissue sarcomas. Further research is needed to better understand the mechanisms underlying metastasis in these tumors and to improve treatment outcomes for patients with advanced disease.

EP-1153

Chylous Ascites Flare-Up Revealing Cirrhosis: Role of Lymphoscintigraphy

D. Nakro, *A. Mouaden, M. Zekri, M. Bel Lakhdar, C. Bensaid, D. Alami, I. Zahfir, M. Aboussabr, I. Ghfir, H. Guerrouj;*
Department of Nuclear Medicine, Ibn Sina Teaching Hospital, Faculty of Medecine and Pharmacy, Mohammed V University, Rabat, MOROCCO.

Aim/Introduction: Chylous ascites (CA) is defined as a leakage of triglyceride-rich lymph into the abdominal cavity, with an accumulation of lipid-rich, milk-like peritoneal fluid. The diagnosis of CA is made on the basis of clinical symptoms, and confirmed by an analysis of the fluid obtained by abdominal puncture. CA results from diverse underlying cause such us postoperative complications, cirrhosis, and malignancies. The lymphoscintigraphy stands out due to its ability to visualize the lymphatic system, and offers precise localization of anatomical defects in the lymphatic system associated with chyloperitoneum when combined with SPECT-CT. We present the case of a patient who developed chylous ascites after laparoscopic surgery in which lymphoscintigraphy was used to exclude the diagnosis of chylous ascites. ***Materials and Methods:*** Single-case study was conducted on a 15-year-old boy with abdominal adenopathies of unknown origin. He underwent a biopsy excision of the hepatic hilum adenopathies along with a cholecystectomy due to the discovery of a multilithiasic gallbladder. In the immediate postoperative, he presented an abdominal distension. A liquid puncture was realized showing a milky fluid rich in triglycerides; confirming the suspicion of chyle leak for which he was placed on a low-fat diet. Meanwhile the patient developed cholestasis icterus with progressive liver failure. The diagnosis of cirrhosis was confirmed by a liver biopsy. Lymphoscintigraphy was performed after the injection of 0.2ml of 37MBq 99mTc-Nanocolloids, using a tuberculin syringe, under sterile conditions, at the level of the first interdigital space of both feet. Static acquisitions were performed during 7 hours and repeated after 24h, in order to localize the lymphatic breach. ***Results:*** The lymphoscintigram showed fairly prompt ascent of radio colloid up both lower limbs, with the absence of pathological accumulation of radiotracer in the abdominal cavity excluding the presence of chyloperitoneum. We also noted the absence of physiological visualization of the hepatic area compatible with cirrhosis.Our findings were confirmed by second analyses of the peritoneal liquid that showed a normalization of the triglycerides level. ***Conclusion:*** Lymphoscintigraphy should be considered as a valuable tool in the management of CA thanks to its capability to whole-body assessment of lymphatic vessels in all three spatial planes. This non-invasive technique allows the identification of the site of lymphatic leakage in order to promptly begin the correct therapy, and also to eliminate with certitude a doubtful diagnosis of chylous peritoneum.

EP-1154

Intense Uptake of 68Ga-DOTANOC Unveils High Somatostatin Receptor Expression in a Follicular Lymphoma

D. Silva, *H. Duarte, I. Próspero, D. Barbosa, N. Vasconcelos, J. P. Teixeira, I. L. Sampaio;*
Instituto Português de Oncologia do Porto Francisco Gentil, Porto, PORTUGAL.

Aim/Introduction: Somatostatin receptor (SSTR) imaging with 68Ga-DOTA-conjugated peptides is the gold standard imaging method to detect differentiated neuroendocrine tumors (NETs). SSTR expression by lymphomas has been reported in the literature, although their expression is significantly lower when compared to NETs. ***Materials and Methods:*** We present a case of a 44-year-old female patient, who started to refer left lower back pain with inguinal/hypogastric irradiation, along with drenching night sweats, and sporadic self-limited (2 to 5 minutes) episodes of palpitations associated with thoracic discomfort, nausea and dizziness. Blood pressure was normal and other symptoms were denied, namely headaches. There was no prior relevant clinical background. Regarding family history, the patient had a sister who died from renal carcinoma, and two second cousins diagnosed with pituitary adenoma and glioblastoma. An abdominal/pelvic CT was performed and a 6 cm, well-defined, left para-aortic bulky mass at L1-L2 level suspicious of a paraganglioma was discovered. Analytical parameters were normal, including endocrine tumor markers and urine amine levels. The 68Ga-DOTANOC PET/CT showed intense radiotracer uptake in the retroperitoneal mass (SUVmax 23.8), as well as in a small para-aortic lymph node. ***Results:*** Laparoscopic surgical excision of the bulky lesion was performed, and histological results revealed a grade III-A Non-Hodgkin Follicular Lymphoma. Other studies were performed to complete staging, including an 18F-FDG PET/CT, which revealed high uptake on three para-aortic lymph nodes (SUVmax 9.3). The patient underwent 6 cycles of chemotherapy, and a complete metabolic response was documented on 18F-FDG PET/CT. Until this date, the patient remains disease-free, after a 3-year follow-up time. ***Conclusion:*** This case report demonstrates the importance of keeping differential diagnosis in mind when reporting 68Ga-DOTANOC PET/CT scans, and alerts to the potential risk of misinterpreting other tumors as NETs, if a representative biopsy is unavailable. The expression of SSTRs by lymphomas remains a subject that needs further study, particularly uptake specificity among different lymphoma subtypes. Additional investigation is also required to understand if PRRT could represent a valid treatment option for lymphoma subtypes with higher SSTR expression, namely as a palliative intent.

EP-1155

Mapping the uncharted:FDG PET/CT detection of breast cancer metastases to rare anatomical sites

P. Singh[1], *Y. Khandelwal[2], V. Mishra[1], S. Yadav[1];*
[1]King George Medical University, Lucknow, INDIA, [2]All India Institute Of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Breast cancer is the most common malignant neoplasm in women resulting in high mortality and morbidity. Breast carcinoma comprises a heterogeneous array of diseases characterized by varied tumoral behavior, treatment responsiveness, and prognosis, up to 30% of patients develop metastatic disease during progression or follow-up. Breast cancer can disseminate to various organs, with prevailing metastatic sites encompassing bone, lungs, liver, and skin. The metastasis of breast cancer to atypical anatomical sites can pose a diagnostic conundrum. Discerning the diverse presentations of metastatic breast disease is pivotal in directing patient care and prognostication. Here we report a case of Carcinoma breast with cutaneous and pancreatic metastasis. ***Materials and Methods:*** A 31 year old female with no comorbidities presented with lump in left breast since 6 months.There was no h/o associated pain/nipple discharge/lump in opposite breast.HRSG both breasts was done which revealed large ill defined multicystis multiloculated collection with low level internal echoes and thin sepate within and subcutaneous edema in left breast with enlarged left axillary lymph nodes.Histopathological examination was suggestive of carcinoma left breast.IHC was suggestive of triple negative and Ki67:80%.In view of severe bone pain, Bone scan was done which revealed increased bone turnover suggestive of underlying bone metabolic disease and there was increased focal osteoblastic activity involving inferior angle of left scapula and distal 1/3rd shaft of left femur in anterior cortical/subcortical region without cortical disruption which revealed probability of malignant lesion as low.Patient underwent left MRM followed by 9 cycles of CT and

16# radiotherapy. ***Results:*** FDG PET/CT was done to assess disease status. PET-CT revealed FDG avid well-defined few (2 in number) soft tissue lesions in right breast with cutaneous thickening. Also noted was FDG avid left supraclavicular and left axillary level I and II lymph nodes. There were multiple FDG avid cutaneous deposits in the right anterior and left lateral chest wall with a well-defined hypodense lesion in the tail of the pancreas which on further biochemical and histopathological correlation came out as metastatic disease. ***Conclusion:*** This case endeavors to elucidate the imaging characteristics of uncommon/ infrequent sites of breast metastases through this captivating case, thereby revisiting this rare clinical phenomenon. FDG PET/CT stands as a pivotal asset in the orchestration of breast carcinoma management. Its significance spans across staging, evaluation of treatment response, and post-treatment surveillance, enriching patient care through the provision of vital insights crucial for treatment strategizing and surveillance.

EP-1156

Ga-68 PSMA Brain Parenchyma Uptake in Encephalomalacia Secondary to Ischemia

A. Aslan, *F. Üstün;*
Trakya University, Edirne, TÜRKIYE.

Aim/Introduction: Prostatespecific membrane antigen (PSMA) is a type-II transmembrane glycoprotein that is overexpressed in prostate cancer(PCa). Ga-68 PSMA PET/CT is a modality that is increasingly used in PCa cases. Although initially believed to be specific to the prostate, PSMA radioligand uptake has subsequently been reported in a variety of nonprostatic disorders. We present a rare finding of PSMA radioligand uptake in the brain parenchyma in a 57-year-old male with encephalomalacia secondary to previous ischemia. ***Materials and Methods:*** The patient was diagnosed with PCa (Gleason score 4+5) in 2017. He received radiotherapy and hormonotherapy and was followed up with Ga-68 PSMA PET/CT. In the PET/CT imaging performed in January-2024, no PSMA avid lesion was detected, which would suggest the presence of a malignant focus. However, radiotracer activity was observed in the patient's right parietal cortex. Retrospective examinations showed that the patient had been admitted to the hospital in February-2023 with complaints of loss of strength in the left arm and leg, as well as slurred speech. Radiological imaging performed during this period revealed findings that were secondary to acute ischemia in the right brain hemisphere. In the follow-up imaging, a hypodense area compatible with encephalomalacia secondary to ischemia was observed at the parietal lobe level of the right cerebral hemisphere. ***Results:*** The use of PSMA-labeled radiotracers has revealed that PSMA expression is not specific to PCa and can also occur in other conditions. This can lead to potential complications in the interpretation of PSMA-targeted imaging. Ga-68 PSMA PET/CT is an effective diagnostic tool in the detection of brain metastases and primary brain tumors because normal brain tissue does not show any significant uptake of PSMA tracer due to the intact blood-brain barrier. However, if there is a defect in the blood-brain barrier, it can lead to the accumulation of the tracer at the site of infarction/bleeding, which can mimic brain metastasis. This is because the increased permeability of the tracer and the neovascularization process that occurs in such regions can lead to nonspecific tracer avidity. Therefore, it is essential to note that unexpected PSMA radioligand retention can occur in the brain parenchyma after ischemic events. Hence, it is crucial to take a detailed anamnesis to help interpret unexpected findings, such as this condition. ***Conclusion:*** Nuclear medicine physicians should keep such alternative clinical situations in mind, as misinterpretation of PSMA PET/CT studies may lead to unnecessary further examination and/or treatment.

EP-1157

Dramatic response of multiple skeletal metastases of PTC to a single dose of radioiodine proved by FDG PET/CT and FAPI PET/CT

F. Karamian, *S. Zakavi, A. Aghaee, E. Askari;*
Mashhad university of medical science,
Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Thyroid cancer is a prevalent endocrine malignancy that often leads to bone metastases in advanced stages. Radioactive iodine therapy using I-131 is a well-established treatment for differentiated thyroid cancer, targeting residual thyroid tissue and distant metastases. However, the response to I-131 therapy in patients with bone metastases can vary. This case report aims to document a significant response to I-131 therapy in a patient with thyroid cancer and bone metastases. ***Materials and Methods:*** A middle-aged woman with a history of papillary thyroid carcinoma (PTC) and total thyroidectomy was referred to our center for radioiodine therapy. Based on her high-risk status and stimulated serum thyroglobulin (Tg) levels, she received 150mCi of I-131. The post-treatment scan revealed thyroid remnant in the left thyroid bed and multiple bone metastases. Interestingly, these bone metastases did not show any changes in the corresponding CT slices of SPECT/CT images. The patient's serum Tg levels started to decrease and reached 1.35 ng/dL after a year. Another 200 mCi of I-131 was administered to treat the known metastatic disease. Surprisingly, the post-treatment scan showed tracer accumulation only in the left parotid gland, with no evidence of metastasis elsewhere in the body. ***Results:*** The patient was monitored with ultrasonography and serum Tg levels, which remained stable and normal, respectively. A diagnostic whole-body iodine scan yielded negative results. Additional scans using ^{18}F-FDG PET/CT and 68Ga-FAPI showed no uptake at the previously detected metastatic sites. ***Conclusion:*** This case report highlights the effectiveness of radioiodine therapy in treating metastatic PTC, with potential for cure. The response to treatment can vary depending on factors such as radiosensitivity, disease extension, and patient characteristics. Early detection of distant metastasis is crucial for a better treatment response. The absence of structural lesions at the metastatic sites suggests that they may be located in the marrow, making them more susceptible to I-131. This case underscores the importance of early detection and treatment for a more effective response to therapy. In conclusion, this case demonstrates the successful use of radioiodine therapy in treating metastatic PTC, with potential for cure. It also emphasizes the significance of regular monitoring and early detection of distant metastasis for an improved treatment response. Further research is needed to determine the optimal treatment approach for patients with TENIS syndrome and differentiated thyroid cancer.

EP-1158

F^{18}-FDG PET/CT in primary malignant melanoma of the cervix uteri

B. Pernthaler, *T. Nazerani-Zemann;*
Medizinische Universität Graz, Universitätsklinik für Radiologie, Klinische Abteilung für Nuklearmed, Graz, AUSTRIA.

Aim/Introduction: Primary malignant melanoma of the cervix uteri has only been reported in a few cases in the literature,

especially in those examined using F^{18}-FDG PET/CT. Despite its rarity, F^{18}-FDG PET/CT is deemed crucial in the management of cervical melanoma, serving as a vital imaging modality for primary staging, detecting distant metastases, and ruling out metastasis from a primary melanoma elsewhere in the body. We present a rare case of a woman diagnosed with malignant melanoma of the cervix uteri. ***Materials and Methods:*** A 54-year-old woman presenting with vaginal bleeding and abdominal pain underwent gynecological examination, revealing a large pelvic mass in the cervix uteri. Biopsy was performed, confirming the presence of malignant melanoma supported by immunohistochemical positivity for MelanA and SOX10. A F^{18}-FDG PET/CT scan was conducted for primary staging, revealing metastatic disease with a sizable pelvic tumor mass with pathologically increased uptake along the border and central areas, indicative of a centrally necrotic organ-spanning cervical tumor. Pathological F^{18}-FDG uptake in metastatic sites such as the lung, liver, bone, lymph nodes, and intramedullary regions was observerd. ***Results:*** Malignant melanoma of the cervix uteri is exceedingly rare, with poor prognosis often due to late diagnosis. Diagnosis and treatment remain challenging due to limited clinical studies, but surgery is the preferred option. Prognosis is heavily influenced by the FIGO stage at diagnosis. This abstract emphasizes the importance of imaging modalities like F^{18}-FDG PET/CT in diagnosis, staging, and treatment evaluation, particularly in the context of emerging immunotherapies for advanced or metastatic melanoma. Additionally, F^{18}-FDG PET/CT plays a significant role in assessing melanoma therapy response, particularly in patients receiving advanced or metastatic melanoma treatments like immunotherapies. ***Conclusion:*** This case highlights the utility of ^{18}F-FDG PET/CT in rare cases such as primary malignant melanoma of the cervix uteri, providing important molecular insights into the extent and activity of the disease. This non-invasive imaging technique aids in treatment selection and response assessment.

EP-1159

Rare involvement of Tarsal, Metatarsal and Phalanges in a Case of Erdheim Chester disease.

S. Sagar, *D. Khan, S. K V, M. Y S, A. Gawande, S. A. Shamim, R. Kumar, N. Damle, B. Chandra, M. Tripathi, C. Bal;*
AIIMS, Delhi, INDIA.

Aim/Introduction: Erdheim-Chester disease (ECD) is a rare entity. ^{18}F-FDG avid involvement were seen in most of the long bones as expected with involvement of flat bones below ankle which is extremely rare finding. ***Materials and Methods:*** none ***Results:*** A 46 year male who is a known case of Erdheim-Chester disease (ECD) was referred for PET/CT to look for the extent of disease. On FDG PET/CT (A) the MIP image showed increased FDG uptake in multiple appendicular long bones and right scapula. (B and C) Axial PET/CT showed increased FDG uptake with sclerosis of bilateral calcaneum and talus. (D and E) Axial PET/CT showed increased FDG uptake with sclerosis of left navicular bone. (F and G) Axial PET/CT showed increased FDG uptake with sclerosis of left first phalynx.Erdheim-Chester disease (ECD) is a type of non-Langerhans's cell histiocytosis with multi-system involvement with almost 50% of the patient showing BRAFV600E mutation leading to histiocytosis pathogenesis of inflammation and fibrosis due to activation of mitogen-activated protein kinase pathway. Almost 95% of the patients present with skeletal involvement. Involvement of ECD is commonly noted in long bones with very rare reports of involvement below ankle joint,. Symmetrical sclerosis of the metaphysis and diaphysis of the long bones are considered pathognomonic radiological changes for ECD.We report a case of ECD with rare bilateral involvement of bones below the ankle. ***Conclusion:*** This case highlights the use of ^{18}F FDG PET-CT in rare diseases like Erdheim-Chester disease to evaluate the extent of disease to rare sites like below ankle involvement.

Splenic Angiosarcoma: A Rare Case

A. Erdem[1], *D. Çayır[1,2], N. Altun Yoloğlu[1], E. Tatcı[1], Ö. Özmen[1];*
[1]Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE, [2]University of Health Science, Ankara, TÜRKIYE.

Aim/Introduction: Angiosarcoma accounts for approximately 1% of soft tissue sarcomas, itself being a rare malignancy. They are aggressive tumors originated from lymphatic or vascular endothelial cells. Treatment is challenging, and prognosis is poor; especially in cases with metastasis at the time of diagnosis. Here, we present a rare case of splenic angiosarcoma detected with F^{18} FDG PET/CT. ***Materials and Methods:*** A 54-year-old female presented to an external center with complaints of fatigue and weakness. After detection of pancytopenia, abdominal ultrasound has been performed and it revealed splenomegaly, with the spleen measuring 135x75 mm. Within the splenic parenchyma, iso-hypoechoic lesions with a thin peripheral halo, the largest measuring 47x44 mm, were observed. Bone marrow biopsy revealed a neoplasm composed of spindle cells with eosinophilic cytoplasm, hyperchromatic nuclei lacking distinct nucleoli, staining positive for CD34, CD31, ERG, FLI-1, and CD99, reported as compatible with angiosarcoma. F^{18} FDG PET/CT images obtained at our clinic revealed significantly enlarged spleen with increased metabolic activity within multiple hypodense nodular lesions, predominantly hypometabolic (necrotic?) in the upper mid-section (SUVmax: 8.06). Skeletal involvement included lytic/sclerotic lesions in the sternum, vertebral column, both humeri, pelvic bones, both femurs, and proximal bilateral tibiae, with diffuse intense increased metabolic activity involving bone/bone marrow (SUVmax: 8.73). The patient was diagnosed with metastatic splenic angiosarcoma and received GCSF + 6 cycles of paclitaxel therapy. Response evaluation is planned at the end of treatment. The patient is currently under Oncology Clinic follow-up. ***Results:*** While the etiology of angiosarcoma is not fully understood, risk factors such as chronic lymphedema, history of radiation exposure, environmental carcinogens, and certain familial syndromes have been reported. The most common sites of involvement are the skin, breast, bone, and liver. Splenic involvement has been reported in a limited number of cases in the literature. ***Conclusion:*** When anemia of unknown cause and accompanying splenomegaly are detected, splenic angiosarcoma should not be overlooked in the differential diagnosis when evaluating F^{18} FDG PET/CT images.

EP-1161

Cardiac metastases in Malignant Melanoma Detected on FDG PET/CT

D. Khan, *S. Sagar, S. K V, L. Goriparti, J. Krishna P, A. Gawande, M. Y S, S. A. Shamim, R. Kumar;*
AIIMS Delhi, Delhi, INDIA.

Aim/Introduction: Cardiac metastases is usually found in 6-20 % of autopsies with malignant melanoma leading to 4.4 % of these cardiac metastases and other causes being lymphoma, sarcoma and leukaemia. Malignant Melanoma is the tumor with the highest propensity for hematogenous spread to the heart, with

autopsies in melanoma demonstrating cardiac metastases in up to 65 % of the cases.We present a case of malignant melanoma with cardiac metastases in ^{18}F-fluorodeoxyglucose positron emission tomography PET/CT scan. ***Materials and Methods:*** none ***Results:*** A 59 year old female patient presented with complaints of bleeding, vaginal discharge and pain in perineal region since last 2 years. MRI pelvis showed a mass lesion arising from vulva favoring a neoplastic etiology. Posterior vaginal growth biopsy was suggestive of malignanat melanoma. Patient underwent posterior exenteration surgery and also received IGRT (Image-guided radiation therapy). FDG PET/CT was done for response assessment and revealed residual metastatic disease with metabolically active primary soft tissue density lesion with hypodensity involving ischiorectal fossa abutting posterior wall of rectum and anal canal (B,F) along with lesions in lungs, bilateral breast , liver , spleen (D,H) ,bones and lymph nodes(involving both sides of diaphragm)and brain(E,I) as shown in maximum intensity projection (A) and tranaxial CT and fused PET/CT slices. An interesting finding was observed with FDG avid lesions in the interventricular septum and left ventricular wall of the heart in transaxial CT and fused PET/CT slices(C,G).Imaging has an critical role in clearly defining the location, extension, and hemodynamic consequences of cardiac metastases. Cardiac MRI helps in pathological tissue characterization within the cardiac muscle and pericardium and in most cases shows inhomogenously hyperintense signal in T1 and T2 weighted images based on melanin content. FDG PET/CT can distinguish pathologic areas from normal myocardial tissue combining anatomical and metabolic information and therefore has typically shown high 18F-FDG uptake in malignant cardiac tumors and vice verse. In this case we would like to accentuate the presence of cardiac metastases in a case of malignant melanoma, which is a rare visualization in routine clinical practice and especially at the site of interventricular septum, which are reported only in few cases in literature.However such a finding of 18F-FDG PET/CT is rarely reported. ***Conclusion:*** This is a rare finding in routine practice and can help nuclear medicine physicians to confidently report rare findings like cardiac metastases in cases with high propensity for such metastatic pattern.

EP-1162

A Case Of Multiple Myeloma Presented In The Pathological Fracture In Ulna

A. Erdem, *S. Demirtaş Şenlik, A. İnanır;*
Ankara Etlik City Hospital, Department of Nuclear Medicine, Ankara, TÜRKIYE.

Aim/Introduction: Multiple myeloma is a malignant neoplasm characterized by the clonal proliferation of abnormal plasma cells in the bone marrow. The average age of patients diagnosed with MM is approximately 70 years. It tends to cause lytic lesions on bone especially in axial skeleton. ***Materials and Methods:*** The 81-year-old female patient without a history of trauma presented to our hospital with complaints of pain in the left forearm for the past three months. The patient, who was observed to have a fracture in the proksimal ulna on X-ray, was referred to our clinic for bone scintigraphy to evaluate for pathological fracture. In the three-phase bone scintigraphy performed, increased activity uptake was observed in the proximal ulna in all three phases. Additionaly focal mild increased activity uptakes were observed in the anterior of the left 2nd costa and the posterior of the 10th costa. In the MRI imaging, a lesion measuring approximately 5x2.3 cm with a soft tissue component causing the fracture in the proximal segment of the ulna, showing mild contrast enhancement, was described, and histopathological correlation was suggested. The pathology of the excisional biopsy of the lesion described in the ulna reported neoplastic cells showing diffuse strong positivity with CD138 and MUM-1 exhibited monoclonal staining with both kappa and lambda, predominantly with kappa, consistent with plasma cell dyscrasia. The patient is under the follow-up of the Hematology clinic with a diagnosis of multiple myeloma. FDG PET/BT was requested for the staging of multiple myeloma. In the F^{18} FDG PET/CT images, a lytic lesion and focal increased FDG uptake were observed in the left 10th rib. No lesion was observed since the ulna was excised and no lesion or FDG uptake was observed in the 2nd costa. Except an isolated lesion in the ulna and a solitary lytic lesion in the costa, there were no findings suggestive of myeloma in other areas of the body. The patient diagnosed with multiple myeloma is under the control of the Hematology Clinic for the treatment and follow-up. ***Results:*** In patients with myeloma, pathological fractures are commonly seen as a result of lytic lesions, especially in the axial skeleton. In our patient, atypical localization of a pathological fracture and findings consistent with multiple myeloma were observed. ***Conclusion:*** Differential diagnosis of multiple myeloma should be considered in older patients presenting with pathological fractures without a history of trauma even in atypical localizations.

EP-1163

Value of F^{18} FDG-PET/CT in a Patient with Positive anti-TIF1 Gamma Antibody

S. Tepmongkol, *C. Buakhao;*
Chulalongkorn University, Bangkok, THAILAND.

Aim/Introduction: Dermatomyositis (DM) is a rare systemic disease belonging to the idiopathic inflammatory myopathies. Adult-onset DM with anti-TIF1 gamma antibody is associated with cancers. ***Materials and Methods:*** We present a case of a woman who presented with cutaneous manifestations of adult-onset DM. A fluorodeoxyglucose positron emission tomography/computed tomography (F^{18} FDG PET/CT) was sent to exclude occult malignancy. ***Results:*** F^{18} FDG PET/CT showed abnormal hypermetabolic soft tissue lesions adjacent to the left-sided uterus and along the peritoneal lining, leading to tissue biopsy and a final diagnosis of high-grade serous carcinoma of the ovary. ***Conclusion:*** Our report supported the value of F^{18} FDG PET/CT as a tool for malignancy screening and staging in DM patients with anti-TIF1 gamma antibody.

EP-1164

Intrathymic ectopic parathyroid adenoma in an adolescent patient

G. Figueroa Ardila, *E. R. Marques Aparicio, M. J. Azorín Belda, M. J. Torres Tarraga, C. Sandoval Moreno, P. Gonzalez Cabezas;*
Hospital Universitario del Vinalopo, Elche, SPAIN.

Aim/Introduction: Primary hyperparathyroidism (PHPT) is a relatively rare condition in adolescence, particularly before the age of 14, being adenomas the predominant cause. The clinical presentation varies widely, posing diagnostic challenges. In the case that we present below, we will discuss the clinical presentation, diagnostic evaluation, management strategy, and outcomes of this pathology, aiming to contribute to the understanding and management of PHPT in adolescence ***Materials and Methods:*** A 16-year-old female without significant medical history, with dizziness, was diagnosed of persistent

hipercalcemia and hyperparathyroidism for the last year (Calcium up to 14.9mg/dl and iPTH 732 pg/ml). Cervical and abdominal ultrasound, where normal. Parathyroid scintigraphy showed a hypercaptant lesion in the anterior mediastinum, with differential diagnosis of ectopic parathyroid adenoma, thymoma, teratoma, or lymphoma. Further evaluation was performed, because the patient reported migrainous headaches and vasovagal dizziness of several years, without symptoms of motor plate disease. A PET-CT ^{18}F-FDG was performed revealing a nodular image in the anterior mediastinum with soft tissue density of approximately 3 x 2 cm, without metabolic activity, suggesting thymus. ***Results:*** After discussing the case in a multidisciplinary committee, surgical intervention of the lession was performed without complications. The histopathological findings revealed an intrathymic ectopic parathyroid adenoma with a mitotic index of <1/50 CGA, no necrosis, intact capsule, and a proliferative index (ki67) of <1%, without evidence of malignancy.After surgery calcium and iPTH levels normalized. (calcium 10.2 mg/dl and iPTH 34.1 pg/ml). ***Conclusion:*** we presented a rare case of PHTP in adolescence with an atypical location. We discussed its clinical presentation, diagnostic challenges, and management. Through a multidisciplinary approach involving endocrinology, radiology, nuclear medicine, hematology, and surgery, the patient underwent surgery successfully. Histopathology revealed a benign adenoma. The surgical treatment normalized calcium and iPTH levels. This case underscores the importance of considering unusual causes of hypercalcemia, particularly in young individuals, and highlights the efficacy of a collaborative approach. Further studies and long-term follow-up are warranted to elucidate the optimal management strategies and outcomes in similar presentations ***References:*** 1. Jerushalmi J, Frenkel A, et al. EP-1165

2-$^{[18F]}$FDG PET/CT Imaging in the diagnosis of Pacemaker Infection: a Case Report

I. Ferreira, *O. L. Silva, R. T. Ferreira, A. I. Santos;*
Unidade Local de Saúde Almada-Seixal - Hospital Garcia de Orta, Almada, PORTUGAL.

Aim/Introduction: Infections associated with cardiovascular implantable electronic devices (CIEDs) can pose significant clinical and diagnostic challenges, particularly in patients with complex medical histories and multiple comorbidities. Timely and accurate diagnosis is essential for effective management. PET/CT with 2-$^{[18F]}$FDG (FDG-PET/CT) has emerged as a rapidly evolving diagnostic modality for infectious diseases. Nevertheless, the ideal timing for imaging in CIEDs infection remains uncertain. We aimed to review the role FDG-PET/CT had in identifying a pacemaker infection in a patient with a complex clinical condition. ***Materials and Methods:*** We present the case of a 59-year-old woman with a history of arterial hypertension, dyslipidaemia, type 2 diabetes mellitus, ischemic stroke with residual aphasia and hemiparesis, pacemaker implantation in 2002 (non-functioning) and unexplained complaints of weight loss, evening fever and arthralgia for the previous 6 months. She was admitted into the intensive care unit of our institution with a septic shock of assumed intra-abdominal origin, acute renal injury and haematological dysfunction (severe thrombocytopenia). Initial workup raised suspicion of acute cholecystitis and she was started on empirical antibiotherapy and aminergic support. Blood cultures were positive for multisensitive E.coli and antibiotherapy was switched. However, doubts regarding alternative infection origins remained in clinical assessment, and subacute endocarditis was suspected due to electrocatheter thickening and non-specific mass near the tricuspid valve on transthoracic echocardiography. Due to clinical instability and the risk of iatrogenic complications post-transesophageal echocardiography (TEE), FDG-PET/CT was requested. ***Results:*** FDG-PET/CT demonstrated a pattern strongly suggestive of electrocatheter infection, with hypermetabolism in its intracardiac trajectory, more intense at the tricuspid valve plane, in the region of the left subclavian and up to the pacemaker generator.Tricuspid valve endocarditis originating from an infected pacemaker lead was confirmed through TEE, which revealed an adherent mass to the ventricular electrocatheter compatible with vegetation. Antibiotherapy was adjusted to Ceftriaxone plus Gentamicin and the patient underwent pacemaker excision, which proceeded without complications. The patient remains hospitalised, has currently completed 6 weeks of antibiotherapy and maintains proper rhythm without need for pacemaker re-implantation. ***Conclusion:*** Our case underscores the utility of FDG-PET/CT imaging in diagnosing CIED infections, especially when conventional diagnostic modalities yield inconclusive results or the patient's clinical condition limits more invasive diagnostic methods. By revealing metabolic patterns indicative of infection, FDG-PET/CT was a crucial contribution to effective CIED infection management, underscoring the need for standardised protocols to optimise patient care.

EP-1166

The reason of downstaging in a prostate cancer patient with a superscan like Bone Scan. Over 6 months long post-surgical observation in prostate cancer patient with myelofibrosis.

P. Gadzicki[1], *M. Nowak[2], A. Dyla[2], Z. Adamczewski[1];*
[1]Medical University of Lodz, Nuclear Medicine Departament, Lodz, POLAND, [2]Central Veterans' Hospital, Department of Nuclear Medicine, Lodz, Poland, Lodz, POLAND.

Aim/Introduction: The accurate primary staging of prostate cancer prior to primary therapy is crucial, advanced bone metastatic disease is related to less favorable outcome and a different therapeutical approach. Myelofibrosis is a bone marrow condition in which superscan like Bone Scan can occur. ***Materials and Methods:*** A 69-year-old patient diagnosed with prostate cancer (Gleason (4+4) in prostate biopsy) was referred for bone scintigraphy. Whole-body planar scintigrams and SPECT/CT showed increased bone metabolism similar to that seen in the superscan image. In the questionnaire completed before the study, the patient did not mention conditions that could explain the pattern of radiopharmaceutical accumulation. Disseminated skeletal metastasis would disqualify the patient from radical prostatectomy. Due to the relatively low PSA concentration (7 ng/ml) and superscan like image with increased radiotracer uptake in the epiphyseal area, an additional interview was conducted. The patient revealed that he suffered from myelofibrosis (the first diagnosis of bone marrow disease was made about 6 years earlier, then a significantly enlarged spleen was observed, lowering the left kidney). The pattern of increased bone metabolism was caused by this disease. The patient was qualified for laparoscopic

prostatectomy. Systemic treatment (e.g., chemotherapy) adequate to the disseminated process metastatic disease could worsen patient's condition because of myelofibrosis. ***Results:*** Postoperative histopathological examination confirmed prostate adenocarcinoma, Gleason 7(4+3). 3 months after the surgery the PSA concentration was 0.03ng/ml. Such a large postoperative decrease in PSA concentration would not be in the case of advanced skeletal metastases. The patient remains under oncological, urological, and hematological supervision, 6 months after the surgery the PSA concentration was 0.04ng/ml. ***Conclusion:*** Additional medical interview and precise interpretation of the specific pattern radiopharmaceutical accumulation contributed to qualify the patient for surgical treatment. ***References:*** 1.Oon SF, Singh D, Tan TH, Lee A, Noe G, Burbury K, Paiva J. Primary myelofibrosis: spectrum of imaging features and disease-related complications. Insights Imaging. 2019 Aug 7;10(1):71. doi: 10.1186/s13244-019-0758-y. PMID: 31388788; PMCID: PMC6684717.2.EAU Guidelines. Edn. presented at the EAU Annual Congress Milan 2023. ISBN 978-94-92671-19-6.

EP-1167

Bone scan in evaluating isolated alkaline phosphatase elevation: a case-report

J. Veloso Trevisan, *P. Soeiro, A. Oliveira;*
ULS São João, Porto, PORTUGAL.

Aim/Introduction: Bone scans (BS) are valuable for assessing bone involvement in malignant, metabolic, and traumatic diseases, as well as investigating clinical/laboratory findings suggestive of bone pathology. Alkaline phosphatase (ALP), primarily produced in the bone and liver, typically elevates alongside other cholestasis markers in hepatic disease. Therefore, isolated ALP elevation is usually seen in bone disease. However, there is no established diagnostic approach for isolated elevated ALP. Our aim was to highlight the crucial role of BS in detecting the etiology of isolated ALP elevation, through a case-report. ***Materials and Methods:*** An asymptomatic 24-year-old man with a history of resolved giant cell hepatitis during infancy, presented with persistent and isolated elevation of ALP on laboratory tests. Previous imaging studies were normal, and no family history of bone disease was identified. Suspecting bone pathology, he was referred for a whole-body BS with [99mTc]Tc-HDP. ***Results:*** The BS revealed diffuse hyperactivity throughout the entire skeleton (skull, right scapula, right humerus, ulnas, ribs, right iliac, femurs and tibias). Given the absence of oncologic history, this pattern of generalized osteoblastic activity suggested a metabolic bone disease. We considered some differential diagnoses:Paget's disease could present with this scintigraphic pattern and is often asymptomatic in younger patients. However, it is not very prevalent in this age group and therefore not the most likely diagnosis.Camurati-Engelmann syndrome, characterized by hyperactivity in the diaphysis of long bones, is usually symptomatic and diagnosed during childhood, making it unlikely in this patient. McCune Albright Syndrome, characterized by fibrous dysplasia, café-au-lait spots, and endocrine pathology, was considered. However, the absence of café-au-lait spots made it unlikely.Fibrous dysplasia without genetic alteration, typically presenting with asymmetric and intense hyperactivity in the skull, scapulas, ribs, iliac bones, vertebral column, and long bones, was considered as a potential and likely diagnosis.The patient was referred to endocrinology, where a thorough clinical examination revealed a small café-au-lait spot on the back. Subsequently, genetic and endocrinologic laboratory tests were requested. The final diagnosis of McCune Albright syndrome was made based on the BS pattern, the observation of a café-au-lait spot, and an increase in TSH, T3, and prolactin levels. ***Conclusion:*** The BS, with its high sensitivity and capability to assess the entire skeleton, plays a critical role in assessing isolated cases of elevated ALP. When combined with medical history, laboratory tests, and other imaging studies, the BS significantly contributes to achieving an accurate diagnosis.

EP-1168

Pathological findings in a Nodular Goitre associated to Basedow's disease induced by Radioiodine (RAI) treatment: a case report

B. Criscuoli[1], *G. Follacchio[1], F. Corica[1], C. Manni[1], L. Diamanti[2], L. Riccioni[2], M. Tulli[3], F. Capoccetti[1];*
[1]Nuclear Medicine Unit, Macerata Hospital, AST Macerata, Italy, Macerata, ITALY, [2]Human Pathology Unit, Macerata Hospital, AST Macerata, Italy, Macerata, ITALY, [3]Otorinolaringoiatric Unit, Civitanova Marche hospital,AST Macerata, Civitanova Marche, ITALY.

Aim/Introduction: A 63-years-old male with thyroid nodular goitre and synchronous Basedow's disease without ophthalmopathy on high-dose thyrostatic treatment was referred for RAI after refusing surgery ***Materials and Methods:*** Prior RAI, a large"cold"right nodule(5cm diameter) was investigated with FNAB showing benign cytology: TIR2(according to Italian Thyroid Cytology classification System, 2014).After personalized dosimetry,RAI treatment was performed with 1110MBq of 131I and again six months later, for disease persistence, with 1872MBq of 131I. Stable hypothyroidism was obtained and corrected by oral levothyroxine.One year later, due to tracheal deviation and the onset of compressive symptoms from the right nodule, mini-invasive treatment with Microwave thermoablation was proposed ***Results:*** As ordinary procedure, the nodule was submitted to FNAB which demonstrated: "Colloid-haematic material, some foamy histiocytes and rare aggregates of thyroid follicular cells with marked nuclear asymmetries.The morphological appearance may be attributed to previous radiometabolic treatment. TIR3a(according to SIAPEC-AIT Consensus Cytology 2014)".Due to the peculiar cytology, FNAB was repeated 4months later: "Presence of some small aggregates, microfollicular structures with voluminous atypical cells,markedly hyperchromatic nuclei with irregular profiles. Colloid absent.Cytological finding consistent with Indeterminate high-risk lesion:TIR3b(according to SIAPEC-AIT Consensus Cytology 2014). Comment: The finding appears similar to what was observed in the previous fine needle aspiration, and although it may be related to previous radiometabolic treatment, as previously suggested, it does not definitively exclude a proliferation (adenoma with bizarre nuclei? Hyalinizing trabecular adenoma? Other?)."To further evaluate the nature of the nodule, thyroid scintigraphy with 99mTc-MIBI was performed demonstrating a Wash-out Index of -41%.Due to this complex scenario, the patient eventually decided to undergo total thyroidectomy.Final pathology demonstrated: "Multiple sections of thyroid parenchyma located on the right side of a predominantly cystic nodular area delimited by scleroialinosis,with foci of macrophage necrosis loaded with hemosiderin pigment, giant-cell granulomas of foreign-body type incorporating cholesterol crystals, evident calcific deposits.Within the scleroialinosis area, there is a rim of cells with abundant eosinophilic cytoplasm and atypical, voluminous, often pleomorphic nuclei, which appear interpretable initially as atypia induced by radiometabolic therapy. The remaining parenchyma shows evident scleroialinosis with associated cystic areas and the presence of cellular elements with

eosinophilic cytoplasm and voluminous, sometimes pleomorphic nuclei." ***Conclusion:*** To our knowledge, no current literature provides an insight on pathological abnormalities induced by RAI on thyroid tissue.This case has showed a so peculiar pattern, where different diagnostic and therapeutic options come into play to obtain, in a complex and varied clinical presentation, the best management choice.

EP-1169

The Added Value Of [99mTc]-EDDA/HYNIC-TOC Scintigraphy In The Management Of Bilateral Glomic Tumor

J. Rabah[1], *R. Drobota[1], T. Suta[1], M. Mutuleanu[1,2], M. Gherghe[1,2]; [1]Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Glomus tumors are characterized as mesenchymal neoplasms with a slow growth rate, representing a minority of less than 2% among soft tissue tumors. Head and neck paragangliomas (HNPs) are rare vascular neuroendocrine tumors arising from neuroendocrine cells of the neural crest, affecting both genders equally. The majority of cases are diagnosed between the ages of 40 and 60, with approximately 10% presenting as multiple or bilateral tumors. The aim of this case is to demonstrate the clinical utility of [99mTc]-EDDA/HYNIC-TOC. Other molecular imaging investigations that can be used in the evaluation of paraganglioma include [123I]-MIBG scintigraphy, PET-CT with $^{[18F]}$-flubrobenguane, $^{[18F]}$-DOPA, $^{[18F]}$-FDG, [68Ga]-DOTATOC and [68Ga]-DOTATOC. ***Materials and Methods:*** A 37-year-old patient presented to the ear, nose and throat department in 08.2021 with palpable, painless laterocervical masses for evaluation. Initial assessment included a cervical CT scan, which revealed two iodophilic, non-homogeneous lesions located at the carotid glomus. The lesions were classified as Shamblin class II on the right side and Shamblin class I on the left side. In August 2021, an Angio-MRI examination detected nodular tissue with non-homogeneous T2 hyperintensity without diffusion restriction, and no apparent vascular involvement on time-of-flight (TOF) arterial sequence. In the same month the MRI was followed by a contrast enhanced CT scan of the thorax, abdomen, and pelvis which revealed no abnormal findings. The patient was periodically evaluated presenting stable disease and no treatment was initiated. For more accurate evaluation the patient was referred for somatostatin analog scintigraphy (SRS). ***Results:*** In October 2023 a [99mTc]-EDDA/HYNIC-TOC scintigraphy "whole-body" acquisition and SPECT-CT were performed showing high radiotracer uptake in the nodular lesions located at the bifurcation of the common carotid artery, bilateral, with stable dimensions, 33/21/34 mm in the right side and 24/25/38 mm in the left side compared to the MRI performed in august 2021. No other sites of pathological radiotracer uptake were visualized indicating stable disease. Due to the high expression of somatostatin receptors and the associated surgical risk, treatment with a somatostatin analog (SSA) was initiated. Notably, throughout the investigative process, the patient remained asymptomatic. ***Conclusion:*** Accurate evaluation of neuroendocrine tumors like paragangliomas can present challenges, especially when they are asymptomatic. SRS has shown notable sensitivity in detecting HNPs and has significantly influenced patient management, particularly by enabling the initiation of SSA therapy in individuals with high surgical risk.

EP-1170

Unveiling the Utility of $^{[18F]}$FDG PET/CT for Response Assessment in a Rare Case of Large Vessel Vasculitis

D. Vasile[1], *I. Marcuseanu[1], A. Constantin[2], M. Gherghe[2,3]; [1]National Institute of Infectious Diseases "Prof. Dr. Matei Bals", Bucharest, ROMANIA, [2]Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA, [3]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Takayasu arteritis (TAK) is a rare, chronic, granulomatous large vessel vasculitis (LVV), predominantly affecting young women. Typically, LVV affects the aorta and its major branches, often leading to severe complications, including stroke, myocardial infarction, mesenteric ischemia, and limb claudication, usually contributing to substantial morbidity among affected individuals. Monitoring TAK during treatment presents challenges, as none of the clinical symptoms and laboratory tests is entirely specific for LVV. ***Materials and Methods:*** We present the case of a 51-year-old male patient, who presented in 2022 an onset including fever of unknown origin (FUO), abdominal pain and irritative cough. Initial biochemical tests revealed elevated inflammatory markers and iron-deficiency anemia. The patient underwent a series of viral, bacterial and immune serological tests and transesophageal echocardiography to exclude infectious arteritis and endocarditis. Bone marrow biopsy eliminated the possibility of a myeloproliferative disorder. Corticoid therapy was initiated, but with no clear result. Serial computed tomography (CT) examinations was performed, with no specific morphological findings, but revealing the enlargement of the spleen.Given the complexity of the case and the persistence of the inflammatory syndrome upon discontinuation of corticosteroids, a ^{18}F-Fluorodeoxyglucose $^{[18F]}$FDG PET/CT scan was recommended to establish the diagnosis and further guide the treatment plan. ***Results:*** $^{[18F]}$FDG PET/CT revealed diffuse and increased metabolic activity in the superior wall of aortic arch and the right lateral wall of descending aorta, suggesting inflammatory arteriopathy. Considering that other pathologies were excluded through gastroenterological, hematological, infectious and cardiological investigations, the most plausible etiology remained a subtype of LVV. These imaging findings are consistent with the biochemical changes and symptoms observed prior to PET-CT examination, it was decided to initiate treatment with high- dose immunotherapy and corticotherapy, leading to decrease of inflammatory markers. One year after the initial diagnosis a follow-up $^{[18F]}$FDG PET/CT examination was performed revealing near-complete regression of metabolic activity within affected vessels was noted, which correlated with the clinical improvement. ***Conclusion:*** In summary, our case emphasizes the utility of $^{[18F]}$FDG PET/CT as a valuable imaging tool in the management of TAK, providing essential information for diagnosis, disease activity and treatment response monitoring, through its capacity to identify inflammatory infiltration prior to morphological and vascular structural changes with high sensitivity.

EP-1171

Role of Lung Perfusion Scan in Jeune Syndrome: A Case Report

A. Dewi[1,2], *Y. Tuti[1], R. Hidayatullah[3]; [1]Dharmais Cancer Center - National Cancer Center, Jakarta, INDONESIA, [2]Universitas Padjadjaran, Bandung, INDONESIA, [3]Cipto Mangunkusumo Hospital, Jakarta, INDONESIA.*

Aim/Introduction: Jeune syndrome as knowns as asphyxiating thoracic dystrophy is a rare congenital disorder associated with

multi-organ involvement, including skeletal abnormalities. Radiographic findings are small, bell-shaped, narrow chest, with horizontally oriented ribs, resulting in pulmonary hypoplasia. The condition often cause respiratory distress and recurrent respiratory infections in early childhood. Priority management in this situation is supporting respiratory function. Several articles report surgical approach to correct the thoracic cavity size. We report case of Jeune syndrome scheduled for thoracic wall expansion. ***Materials and Methods:*** A 6-months-old male patient with multiple skeletal abnormalities correspond with Jeune syndrome was several times hospitalized due to recurrent pulmonary infection. No abnormalities were found on renal and hepatic function. The patient was referred for pulmonary function evaluation prior to surgery. An 8-projection lung perfusion scan with Tc- 99m MAA 1.85 MBq showed normal radioactivity distribution on both lung, therefore a ventilation scan would be unnecessary. ***Results:*** Surgical approach were reported beneficial for Jeune syndrome. Chest expansion procedure conducted in patient showing imaging of normal lung is consider to be safe and effective method. Despite poor anatomical details, lung perfusion scan provide functional information with lower radiation exposure compared to CT angiography. ***Conclusion:*** Lung perfusion scan is a safe, relatively non-invasive, and advantageous procedure to evaluate lung function in pediatric patient prior to surgery. ***References:*** Ciofetta G, Piepsz A, Roca I, Fisher S, Hahn K, Sixt R, Biassoni L, De Palma D, Zucchetta P; Paediatric Committee of the European Association of Nuclear Medicine. EP-1172

Diagnostic Value of F^{18}-FDG PET/CT in Malignances Associated with Neurofibromatosis Type 1- a Case Report

T. Suta[1], *A. Barabas[1], A. Constantin[1], M. Gherghe[1,2]; [1]Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Neurofibromatosis (NF) is a neurocutaneous syndrome characterized by the development of tumors of the central or peripheral nervous system, with Type I (NF1) being accounted for 96% of all cases. Mutations in the neurofibromin 1 tumor suppressor gene were identified in different soft-tissue sarcomas, such as undifferentiated pleomorphic sarcoma (UPS) and malignant peripheral nerve sheath tumors (MPNST). The aim of the paper is to highlight the potential use of F^{18}-FDG PET/CT scan in differentiating malignant lesions associated with NF1. ***Materials and Methods:*** We present the case of a 33-years-old male patient diagnosed with NF1 in September 2021 through resection of neurofibromas on the scalp and right thigh.In February 2023, IRM imaging revealed multiple subcutaneous neurofibromas in the abdominal and pelvic area, as well as a large retroperitoneal tumor mass infiltrating the left hemiabdomen. This condition resulted in significant pain and functional impairment of the left limb.The tumor was excised along with the resection of the femoral nerve, which was considered the origin of the tumor, left nephrectomy and left hemicolectomy; the immunohistochemical assay established the diagnose of undifferentiated pleomorphic sarcoma. Excision of multiple infradiaphragmatic plexiform neurofibromas was performed. ***Results:*** Postoperative evaluation using F^{18}-FDG PET/CT detected a low metabolically active residual tumor at the level of the left iliac fossa, invading the iliac crest, small intestine, abdominal wall and ipsilateral iliopsoas muscle, multiple pulmonary, hepatic and bone lesions with increased values of radiopharmaceutical uptake, as well as paravertebral, mediastinal, mesenteric, prostatic, muscular and soft tissue neurofibromas. The patient undergoes ten cycles of palliative chemotherapy with Epirubicin and Ifosfamide. In march 2024, a follow-up F^{18}-FDG PET/CT scan revealed complete remission of the hepatic lesions, a residual pulmonary nodule in the left upper lobe showing metabolic inactivity, as well as inactive residual lesions in bones. Multiple neurofibromas were detected, some of which were newly appearing, with varying degrees of radiotracer uptake. The expansive tumor found in the left iliac fossa shows minimal uptake of the radiotracer and remains stable in terms of size and metabolism. ***Conclusion:*** Studies have shown that F^{18}-FDG PET/CT scan provides increased accuracy in differentiating MPNSTs from benign neurofibromas. This case outlines the importance of molecular imaging studies in the management of NF1 patients, raising suspicion of malignant lesion polymorphism, both MPNST and UPS, through correlating the differences in radiotracer uptake with the partial response to chemotherapy.

EP-1173

Pericardial Cystic Parathyroid Adenoma: an Uncommon Feature in Primary Hyperparathyroidism

I. Taciuc[1,2], *M. Mutuleanu[1,2], C. Tupea[1], M. Gherghe[1,2]; [1]Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.*

Aim/Introduction: Parathyroid adenomas are the main cause of primary hyperparathyroidism (PHP). Since the only curative treatment is surgical resection, the preoperative localization is essential. The available localization studies comprise cervical ultrasound, computed tomography (CT), magnetic resonance imaging (MRI), parathyroid scintigraphy, and hybrid imaging, the latter providing a more precise and specific characterization of parathyroid lesions. While the prevalence of ectopic parathyroid glands can extend to 20% within the general population, only a few number of cystic adenomas have been documented (ranging between 1-5%) with an even lower reported incidence of intrapericardial parathyroid adenoma (1%). ***Materials and Methods:*** Case presentation: A 79 year old female, diagnosed with PHP in 2019, with abnormal total calcium and parathyroid hormone (PTH) levels. The patient's medical history revealed a well-differentiated follicular adenoma situated in the left thyroid lobe, confirmed through fine needle aspiration biopsy in 2012. The patient's follow-up included regular cervical ultrasound examinations, with negative results for parathyroid nodule. Since 2019, there has been a progressive increase in both calcium and PTH levels, with the highest values of 14 mg/dL and 781 pg/mL, respectively. The patient was referred to our facility for 99mTc-MIBI-SPECT/CT imaging. ***Results:*** The dual phase scintigraphy

with 99mTc-Sestamibi showed no pathological uptake suggestive for a parathyroid adenoma on either early or late acquisition. The SPECT-CT examination, however, revealed the presence of a mixed (fluid and calcified structure), having no radiotracer uptake, located within the pericardium. Usually, the radiotracer uptake in the pericardium is challenging to detect due to the high concentration of 99mTc-Sestamibi in the myocardium. Furthermore, considering the patient's medical history and recognizing that cystic adenomas typically do not exhibit radiotracer uptake, even on F^{18}-choline PET-CT, the diagnosis of pericardial parathyroid adenoma was established. Following SPECT-CT imaging, the patient underwent contrast-enhanced CT, which confirmed the lesion's characteristics. ***Conclusion:*** This case demonstrates the high degree of clinical polymorphism of PHP and its functional-imaging aspects. While various imaging modalities are available for localization, hybrid imaging emerges as a valuable tool for precise localization and metabolic characterization of parathyroid lesions. Thus, the patient's medical background, the extent of biochemical alterations, and the results of other localization studies are crucial for an accurate interpretation.

EP-1174

Endoscopic administration of iodine capsule(I-131) for the treatment of Differentiate thyroid cancer in a child with swallowing difficulty.

I. Sevaslidou[1], *E. Zoros[2], X. Tsantilas[3], A. Velidaki[1], M. Nicolaou[4], M. Dolianiti[4], I. Vasilakis[4], M. Rogalidou[5], E. Garini[6], N. Kokkinaki[7], C. Kanaka-Gantenbein[4];*
[1]Nuclear Medicine Department , General Hospital of ATHENS " LAIKO", Athens, GREECE, [2]Medical Physics Laboratory, Medical School ,National and Kapodistrian University of Athens, Athens, GREECE, [3]Medical Physics Department, Agia Sophia Children's Hospital, Athens, GREECE, [4]First Department of Pediatrics, " Agia Sophia" Children's Hospital, Division of Endocrinology, Diabetes and Metabolism, Athens, GREECE, [5]First Department of Pediatrics, " Agia Sophia" Children's Hospital, Division of Gastroenterology&Hepatology, Athens, GREECE, [6]First Department of Pediatrics, " Agia Sophia" Children's Hospital, Department of Anesthesiology, Athens, GREECE, [7]Nuclear Medicine Department , Children's Hospital " Agia Sophia", Athens, GREECE.

Aim/Introduction: Endoscopic administration of I131 capsule for the treatment of Differentiate thyroid cancer (DTC) following thyroidectomy in a child with swallowing difficulty. ***Materials and Methods:*** We present an 11-year-old girl with history of intellectual disability, behavioral difficulties , and denial swallowing solid food, diagnosed with papillary thyroid carcinoma. She underwent total thyroidectomy and central bilateral lymph node dissection. The histological examination showed to well with metastatic involvement in 20 out of 54 dissected lymph nodes. In accordance with the histological type and staging of the disease, the child is referred to the Department of Nuclear Medicine of the hospital for radioactive iodine (RAI) therapy . The coexistence of swallowing difficulties and the inability to cooperate with the child pose challenges in administering the iodine 131 considering that in our country, the therapeutic radioactive iodine is only available in capsule for oral use.The case was discussed at the Oncology Board of the Hospital, it was decided that the necessity of RAI treatment . At the medical meetings conducted with the participation of endocrinologists, nuclear medicine physicians, radiophysicists, gastroenterologists, surgeons, and anesthesiologists were determined that the safest, and most effective method of administering the I131capsule is directly into the stomach via endoscope. Being incapable of cooperating with the patient, the histological type of the cancer, and her anthropometric characteristics, it was decided to administer 45 mCiI131. For the same reason, a 24h iodine uptake test and a diagnostic I123whole-body scan were not performed. ***Results:*** The administration procedure took place in the radioisotope therapy room. Specialized endoscopic and anesthetic equipment was utilized. All necessary measures were taken to prevent potential radiation exposure. The radioactive capsule (Thyrocap) was administered into the child's stomach with the assistance of an endoscopic guide. After the procedure, visual confirmation was obtained via endoscopy that the capsule was in the stomach and with measurement of the radiation dosage rate in the child's body. She remained in the room for 2d. She was discharged in good general condition. The post treatment whole-body scan revealed intense I131 uptake in the thyroid bed, indicating the presence of thyroid remnants and physiological distribution of the radiopharmaceutical in the body. The endoscopic administration was successfully completed without any reported incidents of radioactive contamination or unnecessary radiation exposure to personnel and caregivers. ***Conclusion:*** Successful treatment of DTC in a child with developmental, psychomotor issues, and swallowing difficulties through endoscopic administration of radioactive iodine capsule

EP-1175

The Value Of Molecular Imaging Techniques In Recurrent Multiple Paragangliomas Management

J. Rabah[1], *R. Drobota[1], T. Suta[1], M. Mutuleanu[1,2], M. Gherghe[1,2];*
[1]Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.

Aim/Introduction: Paragangliomas (PGLs) are tumors originating from extra-adrenal chromaffin cells and are rarely found in the retroperitoneum. A positive diagnosis relies on serum hormone testing, radiological and molecular imaging evaluations, which are essential prior to surgical intervention. Surgical excision remains the only curative therapeutic method, therefore there is an important need for accurate staging and precise evaluation of the disease. ***Materials and Methods:*** We present the case of a 44-year-old patient, diagnosed in 2006 with retroperitoneal PGL with locoregional invasion, who subsequently underwent surgical intervention. For 10 years, the patient did not present for regular follow-up investigations. In 2016 the patient manifested abdominal pain, and the imaging studies showed retroperitoneal recurrences with bladder invasion, bone and lymph node metastases. Total cystectomy was performed en bloc with right prostatovesiculectomy. In 2017, a [123I]-MIBG scintigraphy revealed vertebral metastases with reduced radiopharmaceutical uptake. Chemotherapy and osteoclast inhibitors treatment were initiated. The patient was referred to our clinic and several imaging investigations were performed for treatment response evaluation, two PET-CT scans in 2017 and 2019, completed by somatostatin receptors scintigraphy in 2020. ***Results:*** In 2017, the $^{[18F]}$-FDG PET-CT examination showed metabolically active metastatic lymph nodes localized in specific regions, including the left para-aortic (corresponding to the L3-L4 vertebral region), right external iliac and left internal iliac. The patient continued the treatment with cyclophosphamide, vincristine, dacarbazine (CVD), and zoledronic acid with partial response on the CT scan performed in 2018. The follow-up PET-CT in 2019 confirmed the reduced dimensions of the metastatic lymph nodes but revealed increased metabolic activity in the para-aortic nodes and progression in both metabolic

activity and size of the right external iliac node. In 2020, the follow-up scintigraphy with radiolabeled somatostatin analog [99mTc]-EDDA/HYNIC-TOC, revealed high radiotracer uptake with minimal metabolic and dimensional progression of the lymph nodes involvement, while metastatic bone lesions remained stable. The increased uptake of [18F]-FDG in the metastatic lesion compared to the uptake of the radiolabeled somatostatin analog suggests a more aggressive nature of the tumor. ***Conclusion:*** Molecular imaging plays a critical role in the management of patients diagnosed with PGL, providing vital information to accurately assess the disease extent and characterize the expression patterns of key molecular targets such as SSTR and norepinephrine transporters. This imaging approach is instrumental in guiding the selection and optimization of targeted therapies, including PRRT or [131I]-MIBG, thus improving the precision and effectiveness of treatment in patients with PGL.

EP-1176

[18F]-FDG Avid Pulmonary Nodules in the Follow-Up of a Patient with Colon Cancer: Think About Amyloidosis

***L. Micu*[1]**, *M. Mutuleanu*[1,2], *M. Gherghe*[1,2];
[1]Institute of Oncology „Prof. Dr. Alexandru Trestioreanu", Bucharest, ROMANIA, [2]Univesity of Medicine and Pharmacy " Carol Davila", Bucharest, ROMANIA.

Aim/Introduction: [18F]-FDG PET/CT examination performed for the follow-up of patients with oncological pathology may give false positive results in patients with associated chronic lung diseases.Pulmonary amyloidosis is not rare, but a less diagnosed clinical variant. Three forms of pulmonary amyloidosis are known: nodular, diffuse alveolo-septal or tracheobronchial.Nodular pulmonary amyloidosis has a benign evolution but is difficult to differentiate from a malignant lung tumor or metastasis. In this situation, the [18F]-FDG PET/CT can provide valuable information and guide the therapeutic plan. ***Materials and Methods:*** We present the case of 83 y.o. caucasian female with chronic obstructive pulmonary disease (COPD), multiple comorbidities, and history of colonic adenocarcinoma, followed periodically by CT scan for a right pulmonary nodule of uncertain etiology (bronchoscopy and cytological examination negative). Because the suspicion of lung metastasis was high, PET/CT [18F]-FDG was perform. The result showed two metabolically active lung pulmonary nodules present bilaterally with a subpleural disposition in the upper lung lobes (the left nodule being newly appeared). Atypical lobectomy was performed for the right pulmonary nodule, which had higher metabolic activity. Immunohistochemical examination showed pulmonary amyloidosis. A multidisciplinary team dedicated to amyloidosis performed multiple clinical examinations, echocardiography (equivocal for cardiac amyloidosis), biochemical profile (negative), pyrophosphate scintigraphy (Perugini score of 1) and concluded that amyloidosis is an isolated pulmonary nodular form, not requiring specific treatment. In December 2023, a control PET/CT was performed. ***Results:*** The PET/CT scan showed a left upper lobe pulmonary a nodule with dimensional progression and markedly increased metabolic activity. The patient was reoperated, the histopathological result identified lung adenocarcinoma with rare amyloid deposits. Despite the similar appearance of the remaining nodule to the amyloidotic one, its evolution was unexpected. [18F]-FDG PET/CT studies in patients with nodular pulmonary amyloidosis indicated a heterogeneous metabolic activity, and conclude that lesions with increased metabolic activity suggest neoplasia (MALT, plasmacytoma, or adenocarcinoma). Nodular amyloidosis can reach dimensions of up to 15 cm with a subpleural disposition, similar to our case. This makes it more difficult to follow-up patients with oncological pathology and PET/CT with specific tracers could help discriminate neoplastic lesions from amyloidosis. ***Conclusion:*** [18F]-FDG PET/CT in pulmonary amyloidosis is insufficiently studied. Often this method gives false-positive results for neoplasia, but remains a key investigation, providing information related to the potential hematologic disease, synchronous neoplasia and associated inflammatory-infectious complications.

EP-1177

Tumor thrombus in the internal jugular vein due to metastatic poorly differentiated thyroid carcinoma

B. Stoilovska Rizova, *T. Makazlieva, A. Jankulovska, S. Stojanoski, N. Bozinovska, N. Manevska;
MKD02 - Institute of Pathophysiology and Nuclear Medicine, Macedonia, Skopje, NORTH MACEDONIA.*

Aim/Introduction: Poorly differentiated thyroid carcinoma (PDTC) is a clinical entity that has a morphology and biologic behavior between well-differentiated and undifferentiated carcinomas. The initial presentation of PDTCs usually involves a large local invasion and extrathyroidal expansion. PDTCs typically spread to the brain, bones, and lungs. Cases with a gross thrombus of the internal jugular vein (IJV) are incredibly uncommon. We report a case of PDTC patients with IJV tumor extension found by multimodality imaging. ***Materials and Methods:*** A 56-year-old woman underwent surgery due to an ultrasound confirmed multinodular goiter that presented as benign on a fine needle aspiration biopsy and cytology. A near-total thyroidectomy was performed because of the invasive spread to the surrounding structures. ***Results:*** Histopathology revealed PDTC G3/NG3 (pathological stage pT3B, pNX, pMX); Stage II. Following surgery, a sonographic assessment and a computed tomography (CT) scan, despite the remnant thyroid tissue, revealed an extensive thrombus in the left IJV measuring 8.5 cm. Anticoagulant therapy was given to the patient two weeks prior to the administration of radioiodine. One week after the ablation with 100 mCi of 131-I, WBS was performed, where we detected remnant thyroid tissue, iodine avid tumor thrombus in the left IJV, as well as lung metastasis. ***Conclusion:*** IJV tumor thrombus is a rare metastasis of PDTC; thus, patients with thyroid cancer should be assessed for tumor thrombosis, particularly with multimodality imaging, as it has prognostic implications.

EP-1178

The Diagnostic Role of 2-[18F]FDG-PET/CT in Chronic Recurrent Multifocal Osteomyelitis (CRMO): a Case Report

O. Silva, *I. C. Ferreira, A. Prata, M. R. Victor, A. I. Santos;
Hospital Garcia de Orta, Almada, PORTUGAL.*

Aim/Introduction: Chronic recurrent multifocal osteomyelitis (CRMO) is a rare nonbacterial inflammatory disorder that can affect any bone, potentially leading to bone destruction if untreated. The diagnosis requires excluding other causes, particularly infectious and malignant aetiologies. Given the limited awareness of CRMO, the diagnosis can be challenging. We aim to raise awareness of this condition and emphasize the importance of 2-[18F]FDG-PET/CT (FDG-PET/CT) in the diagnosis. ***Materials and Methods:*** We report the case of a 9-year-old female patient with a history of action tremors and developmental coordination and speech disorders since the age of 5. At 7-years-old she was admitted into the Paediatric ward due to left-sided torticollis, neck and lower limb

pain and slowing gait speed over the preceding weeks. Laboratory findings revealed anaemia and elevated ferritin and erythrocyte sedimentation rate. Serological tests and autoantibodies were negative. A cervical CT scan showed heterogenous density of the posterior arch of the C1 vertebra, with cortical bone discontinuity. Further characterization by cervical MRI showed T2 hyperintensity in the left lateral aspect of the C1 vertebra's arches and an adjacent poorly defined collection, raising suspicion of juvenile idiopathic arthritis or infectious arthritis. ***Results:*** A FDG-PET/CT scan was requested and demonstrated hypermetabolism in the C1 vertebra, left iliac bone, lower right and upper and lower left tibial epiphyses and 2nd left metatarsal, with associated bone density changes in the CT component of the study. These findings were suggestive of active inflammatory/infectious processes. Since inflammatory/infectious lesions in multiple bone locations were found, a bone biopsy was performed on the distal left tibial lesion, which showed no evidence of neoplastic infiltration or identifiable infectious agents, thus excluding malignancy and infectious aetiologies, respectively. As a result, a diagnosis of CRMO was established by exclusion. The patient underwent four months of non-steroidal anti-inflammatory treatment (naproxen), which provided pain relief. She is currently under follow-up care in the Paediatric Rheumatology unit. ***Conclusion:*** CRMO is a diagnosis of exclusion, relying on a combination of clinical, imaging and histopathological criteria for accurate identification. This clinical case exemplifies the typical CRMO patient, diagnosed in paediatric age and with multifocal bone involvement. FDG-PET/CT scan played an important role in identifying all bone lesions, not only raising suspicion for this pathology but also enabling a baseline assessment of the patient.

EP-1179

Splenic surprises: Unusual Breast Carcinoma Metastasis on ^{18}F-FDG PET/CT

Y. Khandelwal, *P. Singh;*
AIIMS, New Delhi, INDIA.

Aim/Introduction: Breast cancer is the most common malignant neoplasm in women resulting in high mortality and morbidity. FDG PET/CT imaging has emerged as a powerful tool in the staging and restaging of breast cancer, allowing for the detection of distant metastases. While lymph nodes, bones, lungs, and liver are the typical sites of spread for breast carcinoma, unusual metastases can also occur. The use of FDG PET/CT can help in identifying and characterizing these uncommon sites of metastasis thus accurately guiding the staging. Here we report a case of Carcinoma breast with spleen metastasis. ***Materials and Methods:*** A 54-year-old post-menopausal female presented with c/o lump in right breast since 5-6 months. O:E lump was 3 x 4 cm in right breast. Trucut biopsy was performed which was suggestive of invasive ductal carcinoma. No axillary lymph node was palpable. The clinical stage of the patient was IIA (cT2N0Mx). ***Results:*** Baseline FDG PET CT was done for staging. FDG PET/CT revealed a large well defined lobulated soft tissue density mass lesion with central area of necrosis within upper outer quadrant of right breast (measuring ~5.3 x 4.4 cm). It is involving underlying muscles and overlying skin. FDG avid perilesional satellite nodule is noted in upper outer quadrant of right breast (measuring ~2.0 x 1.7 cm), which was involving overlying skin causing its retraction. Also noted were, other FDG avid ill-defined enhancing soft tissue density lesion with central areas of necrosis is noted in upper central quadrant of right breast (measuring ~3.5 x 3.3 x 4.2 cm). It was closely abutting underlying pectoralis muscles and also involving nipple-areola-complex and overlying skin. Few satellite nodules were noted in lower quadrant of right breast. Thus, a multicenteric primary was present in right breast. FDG avid subcentimetric right cervical level IV, V, supraclavicular, infraclavicular, right-sided axillary lymph nodes with interpectoral and internal mammary lymph node were noted. FDG avid enlarged gastro-hepatic, coeliac, right retrocrural, paraaortic and aortocaval lymph nodes are noted. Also noted was FDG avid ill-defined hypodense lesion is noted in the superior pole of spleen (measuring ~2.0 x 2.1 cm). ***Conclusion:*** The role of FDG PET/CT in uncovering unexpected metastatic sites, such as the spleen in this case, highlights its importance as an indispensable tool in the comprehensive assessment of breast carcinoma, ultimately influencing patient management and outcomes.

EP-1180

$^{[18F]}$-FDG PET-CT Value in a Challenging Case of Pseudomyxoma Peritonei

M. Mutuleanu[1,2], *I. Ioana[1], R. Lita[1], M. Gherghe[1,2];*
[1]Institute of Oncology "Prof. Dr. Alexandru Trestioreanu", Bucharest, Romania, Bucharest, ROMANIA, [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, ROMANIA.

Aim/Introduction: Pseudomyxoma peritonei (PMP) is a rare, slowly growing neoplasm, characterized by the production of diffuse gelatinous ascites with mucinous implants on peritoneal surfaces. Typically, the development of PMP is associated with the rupture and intraperitoneal dissemination of various mucus producing neoplasms from the appendix, small and large bowel, stomach or ovary. Imaging studies includes contrast computed tomography (CT) scan, gadolinium enhanced magnetic resonance imaging (MRI) and fluorine 18- fluorodeoxyglucose ($^{[18F]}$-FDG) positron emission tomography (PET-CT). ***Materials and Methods:*** We present the case of a 73-year-old woman who underwent appendectomy, partial omentectomy and complete hysterectomy with bilateral adnexectomy for low grade metastatic appendiceal mucinous carcinoma in 2017. Chemotherapy was initiated postoperatively with good response. For almost three years the patient's evolution was stable with no signs of disease. Follow up imaging performed in 2020 included both CT and PET-CT scans. ***Results:*** In 05.2020 the CT scan revealed moderate ascites with median eventration and nonspecific hyperdensities within the peritoneum. The PET-CT exam was performed shortly after in 07.2020 and showed multiple confluent lesions with mixed densities located on both diaphragmatic domes, on the peritoneal surface of the liver, stomach, colon, intestinal loops and in the paracolic gutters and pelvis, presenting mostly peripheral minimal/moderate uptake of $^{[18F]}$-FDG. The voluminous median eventration contains the same type of lesions with moderate radiotracer uptake, SUVlbm up to 2.37, and massive peripheral calcifications. ***Conclusion:*** Diagnosing PMP early and accurately is challenging because of its rarity and characteristics. Even if PET-CT exam is not indicated for routine evaluation of this disease, by including it in the work-up of these patients, especially in subtypes with aggressive behaviour, it can help increase the precision of the diagnosis, staging and has the potential to be used in treatment response evaluation.

EP-1181

Keep in mind: ^{18}F-FDG PET CT in the Detection of Metachronous cancer, a case report.

O. Bourogianni, *N. Kapsoritakis, A. Tsaroucha, M. Stathaki, E. Papadaki, G. Lamprakopoulos, S. Koukouraki;*
University Hospital of Crete, Heraklion, GREECE.

Aim/Introduction: Gastric cancer is the fifth most common and third leading cause of cancer death worldwide. Though survival from gastric cancer remains poor, an increase has been observed due to gradual improvements in diagnosis and treatment. The early diagnosis of gastric cancer has increased and the survival has been prolonged with gastrectomy and extended lymph node dissections. Gastric cancer patients are at risk for secondary primary malignancies. This long-term complication was first described by Warren and Gates in 1932. Synchronous malignancies are defined as occurring with 6 months of the primary diagnosis, whereas metachronous tumors occur more than 6 months after the initial event. The risk of secondary primary malignancies is dependent on factors including patient age, cancer stage at diagnosis, and treatment modality. Second primary cancers occurred in 5 per cent of patients with early gastric cancer, mostly within 10 years of the original surgical treatment. ***Materials and Methods:*** We present the case of an 59 year-old female patient with gastric adenocarcinoma. The patient underwent surgery and adjuvant chemotherapy. The patient was investigated through thoraco-abdominal imaging (CT and ultrasonography) following the routine examination. No evidence of metastatic disease was showed. A follow-up programme involving combinations of blood analysis, abdominal computed tomography, chest radiography, ultrasonography and endoscopy of the gastrointestinal tract was carried out every 3 months for the first year. ***Results:*** 18 months later the patient underwent follow up ^{18}F-FDG PET/CT, which revealed a solitary pulmonary nodule 15mm in diameter in the right upper lobe with increased of ^{18}F-FDG (SUVmax 15.57). A CT -guided biopsy of the pulmonary nodule was performed and histopathologic examination revealed a non small lung cancer adenocarcinoma and the patient underwent surgery. ***Conclusion:*** Colorectal cancer and lung cancer show the highest incidences of occurrence as second primary cancers. Therefore, careful preoperative and postoperative examinations for second primary cancer as well as for the extent of primary gastric cancer or the recurrence site are needed. ^{18}F-FDG PET/CT demonstrates high diagnostic accuracy for detecting synchronous and metachronous tumors. Postoperative follow-up with ^{18}F-FDG and close surveillance of patients with gastric cancer should focus on the early detection of recurrence and a second primary cancer.

EP-1182

Metastatic Parathyreoid Carcinoma And Evaluation By PET-CT $^{[18F]}$-FDG And SPECT-CT 99mTC-Sestamibi: A Case Report

K. M. Zuna Vasquez, *G. B. Coura-Filho, L. N. Santos, R. Ferrari, F. C. Prola, G. Carvalho, P. S. Duarte, M. T. Sapienza, C. A. Buchpiguel; Hospital das Clínicas of the Faculty of Medicine of the University of São Paulo (HCFMUSP), São Paulo, BRAZIL.*

Aim/Introduction: Parathyroid carcinoma (PC) is a rare malignant neoplasm of the endocrine system, representing only 0.005% of all cancers. Predominantly, PC secretes parathyroid hormone, being the cause of approximately 1% of cases of primary hyperparathyroidism and may progress with lymphatic, hematogenous, or contiguous metastases to various organs. The present case report seeks to demonstrate the sensitivity of PET-CT $^{[18F]}$-FDG in the identification of active disease, as well as its extension, helping in the indication of a biopsy site and in the planning for therapeutic control of this condition. ***Materials and Methods:*** CASE REPORT: A 33-year-old female patient with a history of shoulder fracture due to falling from her own height, renal lithiasis, difficulty in locomotion and weight loss, diagnosed with primary hyperparathyroidism, underwent left lower parathyroidectomy with ipsilateral hemithyroidectomy and cervical lymphadenectomy in July/2022, obtaining as a result anatomopathological and immunohistochemical parathyroid carcinoma. In December/2022, the patient suffered fractures due to falling from her own height, progressing in June/2023 with dysphagia for solids and weight loss. The biochemical tests performed in March/2024 showed parathyroid hormone of 2753 pg/mL and serum calcium of 15.5 mg/dL. The PET-CT carried out in April/2024 showed two hypoattenuating solid nodules, one adjacent to the anterior face of the right lobe of the thyroid measuring 1.7 cm (SUVmax: 1.9) and another located in the left cervical paratracheal space without a plane of cleavage with the esophagus, measuring about 3.0 cm (SUVmax: 3.1), suspected of active neoplasm, in addition to diffuse bone textural alteration with areas of hyperuptake, probably related to hyperparathyroidism. ***Results:*** The parathyroid scintigraphy examination with 99mTC-SESTAMIBI performed in February/2024 showed a consistent pattern with hyperfunctioning parathyroids congruent with the nodules previously described in the PET-CT. A biopsy of an ulcerated lesion was performed in the proximal esophagus with an immunohistochemical profile being positive for CK AE1/AE3, pancitoq, Chromogranin A, Ki-67 and parathyroid hormone, in adition to negative for Caldesmon, CDX-2, Synaptophysin and S100, consistent with infiltrative carcinoma favoring the parathyroid gland as a probable primary site. The patient is scheduled for surgical resection of metastasis. ***Conclusion:*** Nuclear medicine contributed significantly to the diagnosis of metastasis and therapeutic planning of parathyroid carcinoma, which is a rare cancer with high morbidity. PET-CT, in addition to corroborating the findings of scintigraphy, showed an increase in glycolytic metabolism in the bone framework of this patient who has high serum levels of calcium and PTH.

EP-1183

Non Hodgkin lymphoma on ^{18}F-FDG-PET/CT in breast cancer follow up: an interesting finding

O. Bourogianni, *N. Kapsoritakis, A. Tsaroucha, G. Lamprakopoulos, M. Stathaki, E. Papadaki, S. Koukouraki; University Hospital of Crete, Heraklion, GREECE.*

Aim/Introduction: Site-specific second cancers have been extensively studied in breast cancer survivors over the past four decades. There is an elevated risk for malignancies of the contralateral breast, colon, pancreas, lung, oral cavity and pharynx, uterine corpus, soft tissue, melanoma, leukemia and non-Hodgkin lymphoma. Following chemotherapy or radiotherapy, patients with breast cancer are at greater risk of developing non Hodgkin lymphoma. Non-Hodgkin lymphoma is the most common hematologic malignancy worldwide. There is no established etiology for NHL as this disease does not constitute a single disorder but rather a group of disorders involving heterogeneous subtypes with variable clinical behaviors and treatment outcomes. ***Materials and Methods:*** We present a case of a 68-year-old patient with a right breast mastectomy in 2017. Pathology revealed infiltrating ductal carcinoma. She was treated with chemotherapy and radiotherapy. In 2023 on physical examination she presented palpable axillary and inguinal lymphnodes. She underwent a CT scan that identified multiple enlarged lymphnodes in the mediastinum, enlarged paraaortic lymhnodes in the abdomen, enlarged axillary, iliac and inguinal nodes. The clinical dilemma: metastatic disease or second malignancy. CT guided lymphnode biopsy from an inguinal lymphnode was performed but it revealed no diagnosis. ***Results:*** ^{18}F FDG PET/CT was performed in order to characterize the metabolic aspect of the lesions, to exclude

another primary tumor, and choose a proper biopsy place. ^{18}F-FDG PET/CT showed FDG avid lymphnodes in the mediastinum, in the abdomen, in the axillary and inguinal regions. CT guided biopsy of the most metabolic area according to the PET/CT findings was performed. Pathology findings revealed characteristic histological features of non Hodgkin follicular lymphoma and the patients started treatment. ***Conclusion:*** It is important for breast cancer survivors who have undergone chemotherapy and radiotherapy to be aware of the risk of second malignancy, like non Hodgkin lymphoma. ^{18}F-FDG PET can reveal the right area for biopsy. This case illustrates the superiority of FDG PET/CT over CT not only in the detection of a second malignancy but also in guiding the biopsy and leading to the correct diagnosis.

EP-1184

Graves' Disease with Negative TSH Receptor Antibodies and Positive Thyroid Peroxidase Antibodies: The Role of Thyroid Scintigraphy

D. Nakro, *M. Bel Lakhdar, M. Zekri, C. Bensaid, M. Aboussabr, D. Alami, I. Zahfir, A. Mouaden, I. Ghfir, H. Guerrouj;*
Department of Nuclear Medicine, Ibn Sina Teaching Hospital, Faculty of Medecine and Pharmacy, Mohammed V University, Rabat, MOROCCO.

Aim/Introduction: Hyperthyroidism in Graves' disease is primarily driven by the generation of TSH-receptor stimulating autoantibodies. The thyroid receptor antibodies (TRAbs) are the pathological hallmark of GD and are present in nearly all patients with the disease. However, in some patients the measurement of TRAB titers may be in normal level therefore posing a problem of differential diagnosis with Hashimoto's thyroiditis. We report a case of Grave disease with positive anti-TPO antibodies, and negative TRAbs, where scintigraphy helped its discriminating from other autoimmune thyroiditis. ***Materials and Methods:*** A 31-year-old woman who presented clinical symptoms of hyperthyroidism. She had no personal or family history of thyroid disease. Clinically, she exhibited a palpable goiter. The biochemical assessment typically revealed low TSH levels and elevated thyroid hormones level. Additionally, anti-TPO antibodies and anti-thyroglobulin antibodies were high, but the measurement of TRAbs was negative.Thyroid ultrasound demonstrates an enlarged gland with heterogenous echogenicity without nodules. Color Doppler ultrasonography reveals heightened vascularization within the parenchyma. Thyroid scintigraphy was performed and the images were obtained after 20 minutes of intravenous injection of 185 MBq of 99mTc-pertechnetate. ***Results:*** The thyroid scintigraphy revealed an enlarged thyroid gland with regular contours and an intense homogeneous uptake. The diffuse increase in uptake was compatible with Grave's disease and has enabled us to exclude the diagnosis of Hashimoto thyroiditis, characterized by a decrease or absence of uptake of the radiotracer.Our findings align with the Doppler ultrasound results, indicating a peak systolic velocity in the inferior thyroid artery exceeding 60 cm/sec, whereas in Hashimoto thyroiditis, it typically falls below 40-50 cm/sec. Subsequently, the patient was referred to her endocrinologist for appropriate therapeutic management. ***Conclusion:*** The thyroid scintigraphy plays a critical role in confirming the diagnosis of GD , particularly in cases presenting with hyperthyroidism, positive anti-TPO antibodies, and negative TRAbs. Additionally, it serves as a valuable tool in distinguishing Graves' disease from Hashimoto's disease, facilitating accurate diagnosis and appropriate management strategies for patients with thyroid disorders.

EP-1185

68Ga-DOTATATE uptake in leiomyoma

M. Dobrenic[1,2];
[1]University Hospital Centre Zagreb, Zagreb, CROATIA, [2]School of Medicine, University of Zagreb, Zagreb, CROATIA.

Aim/Introduction: This is a case report of a 54-year-old woman with a history of metastatic neuroendocrine tumor and long-acting octreotide therapy who underwent 68Ga-DOTATATE PET/CT scan for revaluation. ***Materials and Methods:*** 60 minutes after injecting 149 MBq of 68Ga-DOTATATE, PET/low dose CT scan from the top of the head to mid-thigh was performed. ***Results:*** The PET/CT scan showed multiple foci of radiopharmaceutical uptake in liver parenchyma and moderate DOTATATE uptake in a solid soft tissue mass with a diameter of 19.8 cm in uterus. DOTATATE uptake in liver was consistent with known metastases of neuroendocrine tumor. Due to the size of the soft tissue mass in uterus, surgery was scheduled and hysterectomy and bilateral adnexectomy were performed. The patohistological finding of uterine lesion was consistent with leiomyoma. ***Conclusion:*** 68Ga-DOTA-conjugated peptides has been used for staging and revaluation of neuroendocrine tumors via binding to somatostatin receptors that are overexpressed in this tumor type. Although 68Ga-DOTATATE PET/CT scans are highly accurate for neuroendocrine tumors imaging, DOTATATE uptake could also be seen in various non-neuroendocrine conditions, including thymoma, prostatitis, and vertebral haemangioma. And in case of DOTATATE uptake in uterus, diagnosis of leiomyoma should also be considered. ***References:*** Liu H, Zhang W, Chen Y. Incidental 68Ga-DOTATATE uptake in uterine leiomyoma. Endocrine. 2020;68(1):233-234. Hofman MS, Eddie Lau WF, Hicks RJ. Somatostatin receptor imaging with 68Ga DOTATATE PET/CT: clinical utility, normal patterns, pearls, and pitfalls in interpretation. Radiographics. 2015;35:500-16. Malan N, Vangu MDT. Normal variants, Pitfalls and Artifacts in Ga-68 DOTATATE PET/CT imaging.

EP-1186

Investigating the Timeline: Breast Implant-Associated Anaplastic Large Cell Lymphoma and Systemic Lupus - A Case Report

D. Craciun[1], *C. Mazilu[1], C. Tutui[1], S. Solomon[1], L. Pauna-Cristian[2], A. Eddan[2], R. Mititelu[1,3];*
[1]Clinic of Nuclear Medicine, Central Universitary Emergency Military Hospital Bucharest, Bucharest, ROMANIA, [2]Department of Radiology Medima Health, Bucharest, ROMANIA, [3]Department of Nuclear medicine, University of Medicine and Pharmacy Dr Carol Davila, Bucharest, ROMANIA.

Aim/Introduction: PET-CT with ^{18}F-fluorodeoxyglucose ($^{[18F]}$FDG) is a well-established method for staging and assessing therapy response in haemato-oncological diseases. This case report presents a distinctive type of non-Hodgkin's lymphoma known as breast implant associated with anaplastic large cell lymphoma (BIA-ALCL), in a patient with systemic lupus erythematosus (SLE). ***Materials and Methods:*** A 45-year-old woman has an established diagnosis of BIA-ALCL and SLE, presenting with inflammation, redness and purulent discharge at the incision scar. The diagnosis was immunohistochemically confirmed, showing negative anaplastic lymphoma kinase (ALK) and positive CD30 expression. The patient exhibited clinical and biological manifestations characteristic of SLE, including cutaneous eruptions and elevated biomarkers. Previous ultrasound and MRI imaging concluded with a BIRADS score of 4c. She underwent $^{[18F]}$FDG PET-CT for staging. ***Results:*** The PET-CT scan revealed high

[18F]FDG avid diffuse lesion in the right breast, particularly in the prepectoral area, with evidence of invasion into the thoracic wall and accumulation of periprosthetic fluid. A small glucose avid lesion was also noted on the outer edge of the left side of the breast. There were glucose avid lymph nodes in the retropectoral, axillary and internal mammary areas, bilaterally. Following bilateral breast capsulectomy and three cycles of chemotherapy with immunotherapy using brentuximab vedotin, the patient exhibited no abnormal metabolic activity in the breast or lymph nodes upon subsequent PET-CT imaging during follow-up. Biopsy findings after surgery indicated only inflammatory activity, with no evidence of disease extension from the primary site of origin. At follow up, the patient demonstrated negative SLE markers, with mild distal peripheral neuropathy emerging as the sole adverse effect attributed to immunotherapy. Some authors suggest that textured implants have a higher risk of developing BIA-ALCL with estimated incidence of 1 in 4000 cases. Immune involvement such as SLE can also occur as an independent factor that can manifest after breast augmentation, according to literature. In this patient, immune-related complications appear to have developed concurrently with BIA-ALCL. ***Conclusion:*** The use of [18F]FDG PET-CT in the staging of this rare disease is of great importance. In our patient, a multidisciplinary approach allowed a thorough assessment of disease progression and showed successful post-therapeutic outcome.

EP-1187

Hypermetabolic cranial button sequestra and peripheral cortical osteolytic lesions as pivotal FDG PET-CT super pattern to decipher skeletal syphilis

I. Pirsan[1], *P. A. Vion[1], D. Elessa[2], F. N. El-Sissy[3], V. Meignin[4], S. Mouly[2], F. Paycha[5];*
[1]Nuclear Medicine department, Pitié-Salpêtrière Universitary Hospital, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE, [2]Internal Medicine department, Lariboisière Universitary Hospital, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE, [3]Pathology department, Lariboisière Universitary Hospital, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE, [4]Pathology department, Saint-Louis Universitary Hospital, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE, [5]Nuclear Medicine department, Lariboisière Universitary Hospital, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE.

Aim/Introduction: Syphilis is a sexually transmitted bacterial chronic infection caused by Treponema pallidum (TP). Syphilis has been described as the great imitator because of its protean clinical manifestations. Skeletal involvement is an unusual manifestation of late syphilis, heralded by bone pain. ***Materials and Methods:*** A 32-year-old man was hospitalized for a work-up of subacute multiple bone pain and headache. Livedoid erythema spreading over both arms was observed. Physical examination proved otherwise unremarkable. Cranio-encephalic MRI elicited multiple lesions located on skull outer table, left zygomatic and fronto-orbital bones, harbouring bone sequestra. Meningeal layers and brain were normal. Biological tests disclosed an elevated CRP (25 mg/L). Blood creatinine level, PTH, calcium, alkaline phosphatase were normal. SPEP depicted polyclonal gammopathy, immunofixation negative for monoclonal protein and no serum light chain excess identified. Battery of auto-immunity disorders and specific histiocytoses mutations revealed negative. ***Results:*** A diagnostic procedure launched FDG PET-CT and bone SPECT-CT imaging. Hybrid imaging evidenced multiple osteolytic lesions scattered over skull and 4 limbs. Skull exhibited several hypermetabolic button sequestra. Limbs lesions were small-sized, Lodwick II phenotype, involved cortical bone, and distributed bilaterally. Spino-pelvic bone and bone marrow were spared. Osteolytic lesions displayed moderately increased SUV (range: 3-6) contrasting with sharp increased bone turn over. PET delineated numerous intensively hypermetabolic (SUV range: 6-14) infra-centimetric lymph-nodes (neck, axillary, inguinal areas), and hypertrophied oropharyngeal lymphoid organs, satellites of bone lesions. No visceral target could be disclosed. A primary diagnostic filtering was operated from bone SPECT-CT and FDG PET-CT imaging patterns, yielding the diagnostic triad: Langerhans cell histiocytosis, lymphoma, syphilis. A further diagnostic filtering was provided by skin changes: livedoid erythema was reclassified syphilitic roseola. A Venereal Disease Research Laboratory test and TP hemagglutination assay were positive, substantiating diagnosis of syphilis. PET-targeted biopsies were undertaken, zeroing on left tonsil and a skull vertex lesion. Pathological examinations showed no morphological or immunohistochemical arguments for histiocytosis, lymphoma or solid tumour but staining confirmed the presence of spirochetes and PCR test for TP DNA was positive. The patient received 2 weeks of daily intramuscular benzathine penicillin, resulting in bone pain improvement and disappearance of skin stigmata. ***Conclusion:*** Multifocal skin and bone (SKIBO) disorders encompass a bewildering spectrum of differential diagnoses. However, FDG PET-CT and bone SPECT-CT, as panoramic hybrid imaging modalities, may prove a powerful tool to narrow the differential diagnosis gamut, providing that a multi-scale, integrative (PET + CT) anatomo-metabolic pattern is systematically searched for.

EP-1188

Cardio-renal syndrome in one image: a clinical case

I. Grierosu[1,2], *A. Petris[1,3], C. Stefanescu[1,2];*
[1]UMF 'Grigore T. Popa', Iasi, ROMANIA, [2]Nuclear Medicine Laboratory, County Emergency Clinical Hospital 'Sfantul Spiridon', Iasi, ROMANIA, [3]Medical Cardiology Clinic, County Emergency Clinical Hospital 'Sfantul Spiridon', Iasi, ROMANIA.

Aim/Introduction: Chronic kidney disease (CKD) represents a major risk factor for cardiovascular disease (CVD), increasing global morbidity and mortality. Patients with CKD, in relation to chronic uremic condition, exhibit an elevated cardiovascular risk displaying high blood pressure, heart failure, and even sudden cardiac death. The entity called cardio-renal syndrome (CRS) defines different clinical conditions in which heart and kidney dysfunctions bind. There are five stages of CRS: acute cardiorenal, chronic cardiorenal, acute nephrocardiac, chronic nephrocardiac and secondary to another predominant disease [1]. ***Materials and Methods:*** A patient from the Cardiology Department was refer to our laboratory to perform a 99mTc-DTPA radioisotope nephrography. After the 30 minutes dynamic acquisition, for the static images the gamma camera (dual headed Siemens) was center to view the kidney and the heart in the same image. Considering the high cardiac radiotracer fixation, a ratio between heart fixation and a mirrored reference region was perform. ***Results:*** We report the clinical case of a 73-year-old woman, with medical personal history of oscillating arterial hypertension grade III, insulin-requiring type 2 diabetes, grade III obesity and chronic kidney disease-G4. Renal parameters were abnormal: urea of 96 mg/dL, and serum creatinine 2.15 mg/dL. The dynamic nephrogram highlighted a small left kidney, with an altered curve, and decreased differential function (23.4%). The total glomerular filtration rate scintigraphically estimated was 15 mL/minute. We noticed that the ratio for the heart fixation / mirrored reference fixation of the radiotracer was 2.84. ***Conclusion:*** In literature it is

already stated that endothelial dysfunction in uremia can result in cell-to-cell junction loss and increased permeability, contributing to cardiovascular disease (CVD) development [2]. In our case, the uremic toxins correlated with chronic inflammation status induced and aggravated the cardiac pathology. Henceforth, we showed in one image the link between CKD and CVD. ***References:*** [1] Di Lullo L, Bellasi A, Barbera V, Russo D, Russo L, Di Iorio B, Cozzolino M, Ronco C. Uremia Impacts VE-Cadherin and ZO-1 Expression in Human Endothelial Cell-to-Cell Junctions. Toxins (Basel).2018, 10(10), 404.

EP-1189

Polyostotic fibrous dysplasia: the role of bone scintigraphy in changing the diagnosis

S. E. Prisco[1], *A. Romeo[2], M. Santoro[2], A. Golemi[2], S. Zoboli[2], P. E. Orlandi[3], S. Fanti[1,2];*
[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [3]Radiology Unit, Maggiore Hospital "Carlo Alberto Pizzardi", Bologna, ITALY.

Aim/Introduction: Fibrous dysplasia (FD) is a rare benign, non-hereditary skeletal disorder, affecting children and young adults, due to a mosaic post-zygotic mutation of the GNAS gene, responsible for the proliferation of undifferentiated skeletal progenitor cells. It consists of replacing native tissue with a poorly mineralised fibro-osseous matrix, which tends to fracture and deform. The incidence is probably underestimated as it can present with a wide spectrum of clinical manifestations, ranging from asymptomatic monostotic to polyostotic forms and/or associated with extraosseous manifestations (café-au-lait skin macules and endocrinopathies constituting McCune-Albright syndrome). Although progression to osteosarcoma is extremely rare, it is more common in the polyostotic form. Diagnosis is radiological, but monostotic forms may require hystology. Treatment is surgical and involves excision of the lesions and correction of the deformities. However, it is often burdened by complications such as worsening of the pain syndrome, excessive resections, and unsuccessful reconstruction using bone grafts and implants. Therefore, systemic therapies are being investigated and tested such as small molecules, antibodies, and CRISPR-based gene editing technologies. ***Materials and Methods:*** We present the case of a 27-year-old female patient with a left radius fracture over an area of known FD. She had a history of only one other fracture, at the same site, at the age of 5 years, which allowed the diagnosis of monostotic FD. Radiographs showed the known area of FD and another similar area in the distal humerus. She also presented with hyperpigmented patches extending from the abdomen to the shoulder and the left side of the back, and café-au-lait spots in the gluteal region. Blood tests showed no evidence of altered phosphor-calcium metabolism or signs of endocrinopathies. She was referred to our nuclear medicine department for a bone scan to complete the diagnosis. ***Results:*** 99mTc-HDP whole-body bone scintigraphy showed multiple bone foci involving the mandible, scapula, left humerus and radius, left first metacarpal, all vertebral segments, multiple costal arches and the right femur. The SPECT/CT scan showed osteo-structural changes compatible with FD. The patient's diagnosis was changed to polyostotic FD and she was referred for follow-up due to an increased risk of malignant progression. ***Conclusion:*** Whole-body bone scintigraphy helped to refine the patient's diagnosis and corrected the relative risk of malignant progression. With new systemic therapies already being studied and tested, bone scintigraphy could be a valid tool for correctly diagnosing patients, given its wide availability and its relatively low cost.

EP-1190

Non-ossifying Fibroma Of Proximal Humerus, Case Report

M. Mehesen, *M. Ashraf;*
National Cancer Institute, Cairo university, Egypt., Cairo, EGYPT.

Aim/Introduction: Non-Ossifying Fibroma is a benign fibrogenic lesion that results from dysfunctional ossification. It commonly affects the metaphysis of long bones. Its incidence is about 30-40% in children. It is most frequently located in the distal femur and tibia and less commonly affects the upper extremities. ***Materials and Methods:*** A 18-year-old male patient complained of left arm pain and swelling following trauma. Plain radiographs showed a left proximal humeral shaft intra-medullary lytic lesion, lateral side cortical destruction, and a small extra-osseous component. There was no pathological fracture. This lesion had low signal intensity at T1WI, heterogeneous high signal intensity at T2WI, and STIR with heterogeneous post-contrast enhancement on MRI examination. ***Results:*** The patient was referred to our nuclear medicine unit and requested an F^{18}-FDG PET/CT examination to survey the whole body for any additional lesions.FDG PET/CT imaging revealed a proximal left humeral, well-defined intra-medullary bony lesion associated with an extra-osseous soft tissue sheet as well as a small area of cortical discontinuity at its anterolateral aspect. It displayed low-grade metabolic activity of SUV max 1.9 and measured about 3.5x2 cm. There were no other FDG-avid lesions at the rest of the entire body. The biopsy was taken and the diagnosis of non-ossifying fibroma was established. ***Conclusion:*** Non-ossifying fibromas usually appear in childhood and late adolescence. Histopathology is necessary to obtain an accurate diagnosis because, in certain cases, there may be differential diagnoses.

EP-1192

The first case of 99m Tc-FAPI Uptake in Optic Nerve sheath Meningioma

P. Sahafi, *F. Jafari Zarrin Ghabaei, K. Aryana, S. Aledavood, A. Aghaee;*
Ghaem Hospital, Mashhad university of medical science, mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: This case study presents the first demonstration of FAPI-ligand uptake in a patient with optic nerve sheath meningioma . The patient, a 23-year-old woman who had previously undergone surgery for refractory optic meningioma, was referred to our department for 177Lu-Dotatate therapy. After three cycles of 177Lu-Dotatate administration, her proptosis significantly decreased. Two months after her last therapeutic cycle, a 99mTc-FAPI scan was performed. Thescan revealed a mass with moderately increased uptake in the left retro-orbital region. This study is believed to be the first to demonstrate FAPI-ligand uptake in a patient with optic nerve sheath meningioma. ***Materials and Methods:*** The patient, a 23-year-old woman who had previously undergone surgery forrefractory optic meningioma, was referred to our department for 177Lu-Dotatate therapy. After three cycles of 177Lu-Dotatate administration, her proptosis significantly decreased. A recent MRI revealed a hypo signal mass in the retro orbital region with pressure effect on

the optic nerve. The third cycle of 177Lu-Dotatate scan showed intense increased uptake in the orbital region with a good target to background ratio. For more evaluation as an approved clinical trial study, a 99mTc-FAPI scan was performed after being consulted in a multidisciplinary team. ***Results:*** The 99mTc-FAPI revealed a large mass with moderately increased uptake in the left retro-orbital region. However, the target to background and intensity of the FAPI scan was lower than that of 177Lu-Dotatate. ***Conclusion:*** Nonetheless, FAPI avidity may offer hope for future treatment planning with 177Lu-FAPI in patients who are refractory to 177Lu-Dotatate treatment. Overall, this study highlights the potential use of FAPI-ligand uptake as a diagnostic and therapeutic tool for optic nerve sheath meningioma patients who have not responded well to traditional treatments. Further research is needed to explore this potential further and optimize treatment strategies using FAPI-ligands. This study is the first to demonstrate FAPI-ligand uptake in optic nervesheath meningioma. The uptake observed in the 99mTc-FAPI scan suggests that 177Lu-FAPI treatment may be beneficial for patients who do not respond well to 177Lu-DOTATATE treatment, but further studies are needed to confirm this potential benefit

EP-1193

Importance of dynamic myocardial perfusion SPECT in the assessment of patients with MINOCA

R. M. Angulo Amorese[1], *M. Aguirre[2], A. Palomar Muñoz[2], A. Cardozo Saavedra[2], M. Díez Castro[2], M. Pizzi[3], A. Roque Pérez[4], C. Gámez Cenzano[2];*
[1]Nuclear Medicine Department, University General Hospital of Ciudad Real, Ciudad Real, SPAIN, [2]Nuclear Medicine Department, Hospital Universitario Vall d'Hebron, Barcelona, SPAIN, [3]Cardiology Department, Hospital Universitario Vall d'Hebron, Barcelona, SPAIN, [4]Radiology Department, Hospital Universitario Vall d'Hebron, Barcelona, SPAIN.

Aim/Introduction: Currently a high percentage of patients with chest pain and detectable myocardial ischemia do not have obvious lesions in invasive coronary angiography, giving rise to two concepts regarding this pathology. MINOCA is a syndrome characterized by myocardial injury and normal coronary arteries or those with stenosis ≤50%, and INOCA is the presence of ischemia without non-obstructive coronary artery disease. An important cause in the development of this condition is microvascular involvement defined as microvascular dysfunction, that could be structural and/or functional, leading to decreased coronary flow reserve (CFR). Patients with this condition have a higher risk of developing major cardiac events and a higher mortality compared to normal population without ischemic heart disease. In recent years nuclear medicine techniques have been developed for the assessment of myocardial blood flow (MBF) and CFR, using PET and, more recently, dynamic SPECT techniques, using cardiodedicated CZT (cadmium-zinc-telluride) gammacameras, when PET is not available. ***Materials and Methods:*** We report the case of a 58-year-old woman (body mass index, 31 kg/m2) with hypertension, hyperlipidemia, and smoking. She developed symptoms of chest tightness and exertional dyspnea. The electrocardiogram (ECG) did not show changes, and normal echocardiogram and a coronary CT angiography without lesions were also performed. After 10 months the patient has recurrence of chest pain and dyspnea, this time with pathological ECG and elevated markers of myocardial damage, but without significant stenosis on invasive coronary angiography. Acetylcholine provocation test during procedure coronary angiography was also performed to rule-out epicardial vasospasm, with normal findings. Medical treatment was indicated, but the symptoms persisted, so molecular imaging tests were recommended to evaluate coronary microcirculation. ***Results:*** The findings of this study using stress/rest SPECT myocardial perfusion imaging (MPI) showed normal myocardial relative uptake in the left ventricle. The dynamic analysis found global deterioration in CFR and MBF (0.64 and 0.93 ml/g/min, respectively). These findings were below the cut-off value, and it allows the diagnosis of microvascular disease. Thus suggests a higher mortality compared to the rest of the population. ***Conclusion:*** The CZT gammacamera enables list-mode dynamic image acquisition for the assessment of MBF and CFR. Pathological values obtained through CZT SPECT, as in our patient, allow identification of patients with increased risk for developing major cardiovascular events. Correct diagnosis and early treatment of these patients reduces symptoms and prevents future cardiovascular events.

EP-1194

A case of leukocytoclastic vasculitis showing PSMA uptake mimicking metastasis in a prostate cancer patient with a history of brain metastasis

K. Toplutas, *M. Sağer, H. Sayman, K. Sönmezoğlu;*
Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: We will discuss the new lesion showing PSMA uptake , which mimics brain metastasis in the imaging performed after Lu-177 PSMA treatment, and which was diagnosed with leukocytoclastic vasculitis as a result of histopathological examination, in a prostate cancer patient who had a previous history of cranial radiotherapy due to multiple brain metastases. ***Materials and Methods:*** A 63-year-old patient diagnosed with prostate cancer (Gleason Score 4+5), having multiple brain, bone and lung metastases at the time of diagnosis, had underwent radiation therapy for these metastases two years ago. As disease progressed under Abiteron after androgen deprivation treatments and chemotherapy, he was referred for Lu-177 PSMA treatment. Then, Lu-177 PSMA post-treatment scans was evaluated together with other imaging and histopathological findings. ***Results:*** This patient, admitted to the hospital with complaints of disorientation and confusion, underwent a cranial MRI which showed a 33x22x16mm lesion in the corpus callosum centrally necrotic with peripheral contrast enhancement that was incompatible with previous metastatic regions, not showing diffusion restriction, and indistinguishable from metastasis. Stereotactic cranial biopsy findings were consistent with leukocytoclastic vasculitis, thought to be secondary to radiotherapy. The patient treated with steroids. After the fourth course of Lu-177 PSMA treatment, suspicious uptake was detected in the brain on the post-treatment whole-body scan. In the SPECT/CT, cranial slices showed PSMA uptake in the area corresponding to the lesion identified in the brain MRI images. Follow-up MRI and Ga-68 PSMA PET scans, performed to assess treatment response, showed regression of this lesion. ***Conclusion:*** Late complications of radiation therapy to the brain include vasculopathy in small and/or large arteries. Leukocytoclastic vasculitis in the central nervous system (CNS) is a very rare condition and has been described in systemic diseases such as hypersensitivity vasculitis, Behçet's disease, SLE and Mycoplasma pneumonia infection, which usually occurs with the accumulation of immune material deposits in small vessels. Cases with CNS involvement have been described together with systemic involvement, but isolated leukocytoclastic vasculitis, especially in the CNS, is published in only 2 cases. Without having

any additional findings suggesting systemic disease, this is the first case that has PSMA uptake small vessel inflammation, namely leukocytoclastic vasculitis. ***References:*** 1-Panchal NJ,Niku S,Imbesi SG. Lymphocytic vasculitis mimicking aggressive multifocal cerebral neoplasm:MR imaging and MR spectroscopic appearance. AJNR .2005Mar1;26(3):642-5.2-Bhesania S, Raol K, Medina C, Ilyas S, Bhesania J, Barmanwalla A. Leukocytoclastic vasculitis: depiction of the diagnostic dilemma. Cureus. 2021 Aug 26;13(8).

EP-1195

A Case of Metastatic Pulmonary Calcification detected on both ^{99m}Tc-FAPI SCAN and ^{99m}Tc-MDP Bone Scan

P. Sahafi, *A. Saber Tanha, S. Ataei Azim, K. Aryana, A. Aghaee;*
Ghaem hospital, Mashhad university of medical science, mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: A 59-year-old woman with recent history of weakness, loss of appetite, and significant weight loss was referred for malignancy workup. On the first day, the patient underwent a 99mTc-MDP scan which revealed diffuse pulmonary uptake in both lungs. Two days later, 99mTc-FAPI scan was performed and showed diffuse pulmonary uptake in the planar and SPECT/CT images. The study present an interesting case demonstrating FAPI-ligand uptake in metastatic pulmonary calcification. ***Materials and Methods:*** A 59-year-old woman was admitted to the hospital due to poor oral intake, weakness, and significant weight loss. Laboratory studies at that time revealed the following (reference ranges provided parenthetically): calcium 17.1 mg/dL (8.6-10.3 mg/dL); phosphorus 4.4 mg/dL (2.6-4.5 mg/dL); creatinine 3.67 mg/dL (0.6-1.3 mg/dL); total 25-hydroxyvitamin D level 37.5 ng/mL (approx. 30 ng/mL); and parathyroid hormone 26 pg/mL (15-65 pg/mL). Upon arrival at the emergency department, the patient was quickly admitted to the intensive care unit for immediate and aggressive medical intervention due to the life- threatening hypercalcemia. The initial workup showed a speculated pulmonary nodule in the apex of right lung which was suspicious for primary lung cancer, which was subsequently confirmed by biopsy results. 99mTc-MDP bone scintigraphy was performed for metastasis work up. For more evaluation as an approved clinical trial study, a 99mTc-FAPI scan was performed after being consulted in a multidisciplinary team. ***Results:*** The whole body bone scan and SPECT/CT images demonstrated diffuse uptake in both lungs, with no significant lesion in underlying CT slices. The scan findings in the lungs were compatible with metastatic calcification. Also the 99mTc-FAPI whole body scan revealed increased radiotracer uptake in the same areas identified by the bone scan. Also the SPECT/CT images revealed a pulmonary nodule in the right lung with slightly higher uptake compared to the adjacent lung. ***Conclusion:*** This study demonstrated that 99mTc_FAPI scan, like 99mTc-MDP scan, have the potential to diagnose metastatic pulmonary calcification.

EP-1196

^{99m}Tc-FAPI uptake in a rare case of Metastatic urachal Carcinoma

P. Sahafi, *S. Soltani, K. Aryana, A. Aghaee;*
Ghaem hospital, Mashhad university of medical science, mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: A 37-year-old man presented with a mass in the right lower quadrant of the abdomen. Upon examination, it was determined that he had urachal cancer. Further evaluation using 99mTc-FAPI scan revealed activity in the malignant part of the urachal mass and in the metastases. Due to the presence of multiple metastases, the patient's surgery was cancelled. This case emphasizes the importance of utilizing 99mTc-FAPI for initial staging in patients diagnosed with urachal cancer. To our knowledge, this study represents the first investigation into the potential use of FAPI-ligands in treating urachal cancer. Additionally, incidental normal 68Ga-FAPI-46 uptake was observed in the urachal remnant.1 ***Materials and Methods:*** Here, we present the case of a 54-year-old man who was found to have an incidental mass in the right lower quadrant of the abdomen during a recent ultrasonography. Further examination through cystoscopy and biopsy confirmed the presence of well-differentiated, enteric type urachal adenocarcinoma . To assess the extent of the disease, an abdominal CT scan was performed. The spiral CT scan revealed a multi-locular cystic mass measuring 102*99*81 mm, located in the midline of the abdomen near the bladder, with no evidence of distant metastases. Based on these CT scan findings, the patient was admitted for partial cystectomy. Prior to surgery, for further assess the malignancy in a clinical trial study, after obtaining informed constent, 99mTc-FAPI scan was performed under the guidance of a multidisciplinary research center. ***Results:*** The 99mTc-FAPI scan revealed multiple areas of distant metastases in the skull, thoraco-lumbar spine, right scapula, ribs, and pelvic bone. Additionally, the whole body scan showed a photopenic region with a foci of intense uptake adjacent to the right side of the bladder, which were consistent with urachal cyst and a component of malignancy in the right posterior side of the bladder. In the SPECT/CT images, destruction of the left frontal bone and adjacent soft tissue component were observed. ***Conclusion:*** This case emphasizes the importance of utilizing FAPI ligand imaging for initial staging in patients diagnosed with urachal cancer and To our knowledge, this study represents the first investigation in evaluation this potentiality. ***References:*** 1. Maliha PG, Jafarvard M, Czernin J, et al. Incidental Focal 68Ga-FAPI-46 Uptake in a Urachal Remnant: A Potential Pitfall Mimicking a Malignant Peritoneal Lesion. Journal of Nuclear Medicine. 2023;64:992-992.

EP-1197

Unusual Location and Orientation of crossed fused Kidneys in a Patient with History of Repaired Congenital Diaphragmatic Hernia and Hypoplastic Lung: Importance of Tc-99m DMSA SPECT/CT and Correlation with Diuretic Renal Scan and VCUG

P. Sahafi, *A. Saber Tanha, R. Sadeghi;*
Ghaem hospital, Mashhad university of medical science, mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: We presented a 2.5-year-old boy with medical history of the left pulmonary hypoplasia, repaired congenital diaphragmatic hernia and multiple episodes of pyelonephritis who was referred to our department for 99mTc-DMSA and 99mTc-EC renal scintigraphy. The scans revealed an unusual pattern of renal uptake with horizontally aligned kidneys located high on left lower thoracic region extended to the mid abdomen. SPECT/CT of the DMSA scan clearly showed the nature of the patient's unusual location of the kidneys which was due to crossed fused renal ectopia and elevated diaphragm. Diuretic renal scans showed no evidence of renal obstruction. Additionally, the VCUG scan indicated vesicoureteral reflux in both ureters. ***Materials and Methods:*** A 2.5-year-old boy with history of the left pulmonary hypoplasia, repaired congenital diaphragmatic hernia and multiple pyelonephritis episodes was referred to our nuclear medicine center due to fever and acute pyelonephritis for 99mTc-DMSA renal scintigraphy. also the patient underwent

99mTc-EC scan to asses the possibility of obstruction. ***Results:*** The planar 99mTc-DMSA images showed unusual shape and location of fused kidneys with horizontal orientation on the left side of the body. Two areas of decreased uptake was suspicious of being cortical defects. The patient underwent SPECT/CT imaging which revealed a single kidney with homogenous 99mTc-DMSA uptake on the left lower thoracic region extending to the mid abdomen. Areas of decreased activity were proven to be dilated pyelocalyceal systems. The kidney was abutting the left diaphragm which was elevated due to left lung hypoplasia. The 99mTc-EC scan was performed in posterior and anterior views, revealing the presence of fused kidneys with two ureters on the left side of the body and good response to lasix injection. Dynamic images showed two pyelocaliceal systems, and the time-activity curve (of the posterior view) indicating normal initial uptake without evidence of obstruction. Additionally, the VCUG scan showed vesicoureteral reflux in both ureters. ***Conclusion:*** Diuretic renal scan would also be useful in identifying renal outflow obstruction and estimating its impact on renal function. Our study showed the importance of SPECT/CT images in the correct diagnosis of renal anomalies and normal variations in atypical cases.

EP-1198

A Rare Case of Osteoid Osteoma of the Medial Cuneiform bone at tibialis anterior insertion confirmed by bone scan SPECT/CT

P. Sahafi, *R. Sadeghi, A. Mousavian;*
Ghaem hospital, Mashhad university of medical science, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: A 34-year-old man presented with progressive foot pain that was initially on the medial soft tissue but eventually localized to the medial side of midfoot. Despite undergoing various imaging tests and conservative treatments over two years, the patient remained undiagnosed. After six months, soft tissue and bone involvement were observed on the medial cuneiform. A needle biopsy was inconclusive. Since bone tumor is rare in the medial cuneiform the patient was referred to our department for 99mTc-MDP bone scan. The imaging and clinical findings suggested osteoid osteoma as the likely diagnosis, which was confirmed after surgical resection and pathological examination. ***Materials and Methods:*** A 34-year-old man presented with severe foot pain in the medial aspect of his foot for over 30 months, disrupting his sleep. Pain has been intermittent and in medial soft tissue for the first 6 month. Initial imaging studies were inconclusive, and needle biopsy after 24 months did not provide a specific diagnosis. Further evaluation (30 months later) revealed a calcified focus in the articular surface and tibialis anterior attachment site of medial cuneiform on the radiography and CT imaging and significant edema in the medial cuneiform on MRI images. However, these findings were not specific enough for a definitive diagnosis. Due to the persistent severe foot pain, the patient was referred to our department for a 99mTc-MDP scan. ***Results:*** The scan showed increased blood pool and tracer accumulation in the medial part of the mid foot, corresponding to the calcified focus in the medial cuneiform on the SPECT/CT images . Although osteoid osteoma is rare in the medial cuneiform, after evaluating all findings and the patient's symptoms, the first differential diagnosis to consider was osteoid osteoma. One centimeter nidus unattached to surrounding osteoporotic fragile cancellous bone was removed from attachment site of tibialis anterior tendon. Pathological evaluation confirmed the diagnosis of osteoid osteoma. Following surgery, the patient experienced resolution of pain and improved sleep quality. ***Conclusion:*** Our case shows the importance of bone scan and SPECT/CT in diagnosis of osteoid osteoma in unusual locations.

EP-1199

Congenital Hypothyroidism, Risk Factor For Autism Spectrum Disorder

P. Spiridon, *D. Neagu, R. Maaz, G. Voicu, A. Goldstein;*
National Institute of Endocrinology "C.I. Parhon" Bucharest, Romania, Bucharest, ROMANIA.

Aim/Introduction: Congenital hypothyroidism (CH) is characterized by hormone deficiency present at birth due to a defect in thyroid gland development.Ectopic thyroid tissue is an uncommon entity that may be found anywhere along the line of the obliterated thyroglossal duct, resulting from failure of the embryonic development and migration of the thyroid gland to its normal pre-laryngeal site. In most cases, patients develop subclinical hypothyroidism due to inadequate hormone production. Untreated, this condition puts them at risk of developing irreversible neurological deficits.A typical neuropathological finding caused by thyroid hormone insufficiency is a decrease in the parvalbumin of GABAergic neurons, condition that has been observed also in post-mortem brains of patients with autism spectrum disorder. Autism spectrum disorder (ASD) is a complex neurodevelopmental condition with both genetic and environmental influences. Thyroid hormones including T3 (triiodothyronine), thyroxine (T4), and thyroid stimulating hormone (TSH, produced in response to low T3 and T4), have been hypothesized to play an important role in ASD etiology given their critical role in brain development. ***Materials and Methods:*** We present a case of a 6-year-old male patient who was referred to our clinic after incidental finding of a mass located in the tongue root. ***Results:*** The patient did not describe any pressure symptoms. The physical examination revealed a swelling at the base of the tongue and did not identify any palpable thyroid gland in the pre-tracheal region. The cervical CT and US examinations showed the absence of the thyroid tissue in its normal location and found a mass in sublingual region. The thyroid scan with Tc-99m pertechnetate confirmed the presence of sublingual thyroid tissue. Hormonal profile diagnosed primary hypothyroidism and substitution treatment with levothyroxine was initiated and adjusted based on TSH levels. After a 6-year follow-up, the patient reported symptoms of insomnia, shyness, and introversion and after a psychiatric evaluation was diagnosed with autism spectrum disorder. ***Conclusion:*** The aim of this presentation is to present the case of a 6-year-old male patient and highlight the importance of thyroid dysfunction caused by ectopic thyroid gland in psychiatric disorders and the correlation between congenital hypothyroidism resulting from thyroid dysgenesis and autism spectrum disorder, both conditions being characterized by a decrease in parvalbumin expression.

EP-1200

Cancer Integrin Imaging with [^{68}Ga]Ga-Trivehexin PET/CT for a Patient with Breast Cancer and Neuroendocrine Neoplasm: A case both [^{18F}]FDG and [^{68}Ga]Ga-DOTATATE positive but [68Ga]Ga-Trivehexin PET for Integrin αvβ6 negative lesion

G. Beydagi[1], *N. Alan-Selcuk[1], K. Akcay[1], B. Caner[1], O. Yaprak[2], M. Kalayci[3], L. Kabasakal[4];*
[1]Yeditepe University, Department of Nuclear Medicine, Istanbul, TÜRKIYE, [2]Medipol University Hospital, Department of General Surgery, Istanbul, TÜRKIYE, [3]Yeditepe University, Depertman

of General Surgery, Istanbul, TÜRKIYE, [4]Istanbul Unıversity-Cerrahpasa, Department of Nuclear Medicine, Istanbul, TÜRKIYE.

Aim/Introduction: This study evaluates the diagnostic performance of [18F]FDG PET/CT and [68Ga]Ga-Trivehexin PET/CT in detecting and characterizing primary and secondary malignancies. We highlight the case of a 71-year-old woman with a diagnosis of right breast lobular carcinoma and a suspicious pancreatic lesion. ***Materials and Methods:*** The patient underwent an initial [18F]FDG PET/CT that identified a hypermetabolic mass in the retroareolar region of the right breast and a nodular lesion in the head-body of the pancreas. Given the potential for [18F]FDG PET/CT false positivity in pancreatic masses, a [68Ga]Ga-Trivehexin PET/CT was performed. Subsequently, the patient received a biopsy of the pancreatic mass, and further imaging with [68Ga]Ga DOTATATE PET/CT was conducted to assess somatostatin receptor expression. ***Results:*** The [18F]FDG PET/CT scan revealed a 3x2 cm hypermetabolic breast mass and a 23x22 mm pancreatic lesion. The latter did not show uptake in the [68Ga]Ga-Trivehexin PET/CT, suggesting a low likelihood of malignancy. However, the biopsy confirmed a Grade 2 neuroendocrine tumor (NET). The [68Ga]Ga DOTATATE PET/CT exhibited intense somatostatin receptor expression in both lesions, indicating a neuroendocrine characteristic. Also, a mild hypermetabolic lymphadenopathy was noted in the mediastinum, which was negative on both [68Ga]Ga-Trivehexin and [68Ga]Ga DOTATATE PET/CT scans. ***Conclusion:*** This case underscores the importance of utilizing multiple imaging modalities to improve diagnostic accuracy in oncology. The [68Ga]Ga-Trivehexin PET/CT showed potential in distinguishing false positives in pancreatic lesions seen on [18F] FDG PET/CT, though its role in neuroendocrine tumors remains unclear. Further studies are warranted to establish the definitive diagnostic value of [68Ga]Ga-Trivehexin PET/CT in various malignancies. This case also highlights the complex nature of integrin involvement in tumor angiogenesis and the potential of targeted PET radiopharmaceuticals in clinical applications.

EP-1201

Unexpected behaviour in 131-I retention rate in a patient with diffuse bone involvement from Differentiated Thyroid Cancer

G. Follacchio[1], *G. Rossi[2], B. Criscuoli[1], C. Manni[1], S. Fattori[2], F. Capoccetti[1];*
[1]Nuclear Medicine Unit, Macerata Hospital, Italy, Macerata, ITALY, [2]Medical Physics Unit, Macerata Hospital, Italy, Macerata, ITALY.

Aim/Introduction: Patients with bone metastases from Differentiated Thyroid Cancer (DTC) at diagnosis represent a therapeutic challenge. After thyroidectomy, radioiodine (RAI) is the treatment of choice. We report a case of diffuse "bulky" bone involvement from DTC showing a peculiar 131-I whole-body (WB) time/activity curve (TaC) at post-RAI dosimetry. ***Materials and Methods:*** A 82-years-old female with history of thyroid goitre with 4cm left nodule underwent lumbar and pelvic MRI due to acute hip pain, showing a large mass involving left pelvic bone and soft tissues and multiple spine metastases. Bone biopsy was consistent with metastasis from follicular thyroid carcinoma. ^{18}F-FDG PET/CT showed two hypermetabolic areas in left thyroid lobe and multiple hypermetabolic bone metastases. Total thyroidectomy with central lymphadenectomy was performed. Final histology demonstrated a follicular carcinoma of the left lobe with vascular invasion (pT2). One month later, RAI treatment was performed under levothyroxine withdrawal [TSH 2,93mUI/ml, fT4 4,4pg/ml, Thyroglobulin 61208,38ng/ml]. Pre-treatment dosimetry was performed with serial blood and external WB counts, assessing Maximum Tolerated Dose (MTD) to bone marrow and theoretical 131-I dismissal rate. Post-treatment dosimetry was performed by the same method. ***Results:*** On the basis of theoretical 131-I dismissal rate, the patient received 1850MBq of 131-I; post-RAI WB scan showed multiple 131-I-avid areas in the thyroid bed, in right laterocervical region and in multiple bone metastases, including left sphenoid and left pelvic bone. Post-RAI dosimetry showed a peculiar 131-I whole-body TaC characterized by an upward trend followed by a stable plateau, with a consequent stable 131-I retention rate. Six months later, II RAI treatment was performed under levothyroxine withdrawal [TSH 3,17mUI/ml, fT4 6,6pg/ml, Thyroglobulin 12050ng/ml]. Considering pre-RAI dosimetry, the patient received 2220MBq of 131-I. Post-RAI dosimetry confirmed the peculiar trend in 131-I whole-body TaC. At last follow-up in April 2024, the patient showed partial disease response in both functional [TSH 2,23 mUI/ml, Thyroglobulin 7196 ng/ml] and instrumental evaluation (^{18}F-FDG PET/CT). ***Conclusion:*** This case, showing an unexpected 131I TaC after 131-I treatment, emphasizes the role of dosimetry in patients with diffuse "bulky" bone metastases from DTC. Pre-RAI dosimetry is helpful to choose the most appropriate 131-I activity to be administered on the basis of bone marrow limit and theoretical 131-I dismissal rate. Post-TRM dosimetry is fundamental to assess 131-I TaC. On the hypothetical bases, the peculiar trend of 131-I TaC in this metastatic patient could be associated to an incremental 131-I efficacy even for administered activities below 3700MBq.

EP-1202

Lung ventilation and perfusion scintigraphy pattern in Swyer-James-MacLeod syndrome

J. Carvalho, *J. Duarte, A. Marques, F. Abreu, S. Pintão;*
Unidade Local de Saúde de Lisboa Ocidental, E.P.E., Carnaxide, PORTUGAL.

Aim/Introduction: Swyer-James-MacLeod syndrome (SJMS) is a rare lung disorder which occurs as a result of childhood bronchiolitis obliterans, with an estimated prevalence of 0.01%. It is characterized by unilateral hyperlucency of a part of or the entire lung, with diminished arterial blood flow. Although most cases are diagnosed during childhood in the context of frequent respiratory infections, some patients remain asymptomatic until adulthood. Occasionally it is an incidental imaging finding. We report a case of a young adult patient who underwent lung ventilation and perfusion scintigraphy for suspected SJMS. ***Materials and Methods:*** We report a case of a 26-year-old woman who presented to our outpatient clinic with a suspected mixed connective tissue disease. In this context, a thoracic CT scan was performed, which revealed decreased size of the middle and lower lobes of the right lung, as well as lobar hyperlucency, air trapping, hypoplasia of the pulmonary vascular bed and bronchiectatic changes in this region. Therefore, SJMS was suspected and the patient underwent lung ventilation and perfusion SPECT/CT. ***Results:*** Lung ventilation and perfusion SPECT/CT showed markedly decreased perfusion in the middle and lower lobes of the right lung, with a matched heterogeneous ventilation defect. The low-dose CT scan demonstrated similar findings as the previous thoracic CT, namely increased lucency of the affected lobes. These findings were consistent with SJMS. ***Conclusion:*** Lung ventilation and perfusion scintigraphy is a useful noninvasive procedure for the differential diagnosis of hyperlucent lung on conventional imaging, while being also helpful in assessing the extent of the disease. SPECT/CT provides

both anatomic and functional information, improving diagnostic precision. Despite being a rare condition, it is essential for nuclear medicine physicians to be familiar with its scintigraphic pattern, as it may be an incidental finding in the investigation of other diseases, namely pulmonary thromboembolism. ***References:*** Mehra S, Basnayake T, Falhammar H, Heraganahally S, Tripathi S. Swyer-James-MacLeod Syndrome-A Rare Diagnosis Presented Through Two Adult Patients. Respirol Case Rep. 2017;5(5):e00245.

EP-1203

Free $TcO4^-$ in ^{99m}Tc-PSMA Scan A Case Report and Review of an Old Pitfall in the New Era of Modern Imaging

P. Sahafi, *K. Aryana, S. Zarehparvar Moghadam, K. Sadri, E. Askari;*
Ghaem Hospital, Mashhad university of medical science, mashhad, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: In a recent 99mTc-HYNIC-PSMA study conducted at our department, we examined 2 patients with prostate cancer referred for initial staging on the same day. The whole-body scans revealed radiotracer uptake in the gastric mucosa and thyroid glands, alluding to high levels of free TcO4– in the injected vial. The scans were repeated after confirming acceptable radiopharmaceutical purity of 97% (normal range, 95%-100%). Interestingly, 1 patient had liver metastases at presentation, which remained non-PSMA-avid after repeating the scan. We have reviewed this pitfall, which has been reported with many radiotracers, yet not reported with PSMA tracers. ***Materials and Methods:*** On the same day, 2 patients with a previous history of prostate cancer underwent 99mTc-HYNIC-PSMA imaging for staging purposes in our department ***Results:*** Both scans showed foci of uptake in the gastric mucosa and thyroid glands compatible with the presence of free TcO4– in the kit. In 1 patient, some of the metastatic lesions were also visualized. The scans were repeated after checking the quality control of the kits. One patient had a non-PSMA-avid liver lesion as well as widespread PSMA-avid bone and a few PSMA-avid pelvic lymph node metastases. Comparing the baseline scan with the repeated scan revealed additional lesions in the ribs, humerus, and thoracic spine. The other patient had no extraprostatic PSMA-avid abnormality. ***Conclusion:*** To the best of our knowledge, no study has reported such a pitfall. The presence of free TcO4– in 99mTc-PSMA imaging may lead to false-negative results, which might be of clinical importance to candidate patients for radioligand therapy.1 ***References:*** 1. Sartor O, De Bono J, Chi KN, et al. Lutetium-177-PSMA-617 for metastatic castration-resistant prostate cancer. N Engl J Med. 2021;385:1091-1103.

EP-1204

Redistribution of Brain Metabolism from the Neocortex to Evolutionary Ancient Brain Structures in a Patient with Hodgkin's Lymphoma

C. Ramos, *K. Amaral, E. Souza, A. Santos, M. Takahashi, B. Amorim, G. Duffles, C. Souza;*
University of Campinas, Campinas, BRAZIL.

Aim/Introduction: In a recent study, we highlighted a distinctive pattern of brain metabolic redistribution from the neocortex to evolutionarily ancient brain structures during the acute phase of COVID-19 respiratory syndrome (1). Here, we present a case of a patient with extensive lesions caused by Hodgkin's lymphoma, whose PET/CT revealed alterations in FDG distribution in the brain, characterized by decreased uptake in the neocortex and a relative increase in the basal ganglia, resembling findings observed in acute COVID-19 (1). ***Materials and Methods:*** A 57-year-old female patient with a medical history of hypertension and hypothyroidism presented with weight loss and generalized lymphadenopathy. Biopsy confirmed nodular sclerosis classical Hodgkin's lymphoma. A $^{[18F]}$FDG PET/CT was requested for disease staging. ***Results:*** $^{[18F]}$FDG PET/CT revealed significant hypermetabolism in lymphadenopathy below and above the diaphragm, spleen, and bone marrow, consistent with lymphoma infiltration. Additionally, reduced radiotracer uptake was noted in the cerebral neocortex, with relatively increased uptake in the basal ganglia. Semiquantitative analysis using dedicated software showed marked uptake reduction in the frontal, parietal, and temporal lobes (-9.4 SD to -14.3 SD) and preserved uptake in the striatum (1.1 SD). Before chemotherapy initiation, the patient experienced weakness, multiple episodes of diarrhea, and decreased level of consciousness, ultimately developing hemophagocytic syndrome, septic shock, and succumbing 19 days post-PET/CT. ***Conclusion:*** Aggressive lymphomas often exhibit intense FDG uptake and high tumor burden, which can elevate blood lactate levels, potentially serving as an alternative energy substrate for the brain and reducing FDG uptake (2). This phenomenon is akin to observations in individuals engaged in intense exercise, where decreased FDG uptake may result from potential lactate utilization by the brain (3). The relatively preserved FDG uptake in the basal ganglia could be interpreted as a physiological protective response to reduced glucose availability for the brain. Given the brain's inability to store metabolic products for later use, metabolic redistribution during competition with neoplastic cells for available energy substrates may serve to preserve essential brain functions.We conclude that patients with Hodgkin's lymphoma and high tumor burden may exhibit not only a global reduction in cerebral glucose uptake but also a redistribution of glucose consumption from the neocortex to older brain structures essential for survival. ***References:*** (1) Souza, SPM et al. EJNMMI Res 2024.12;14(1):28.(2) Yi HK, Yoo J, et al. Sci Rep 2022. 25;12(1):12639.(3) Hanaoka K, et al. Ann Nucl Med 2010. 24(10):707-11.

EP-1205

Improvement in microvascularisation evaluated with 99mTc-MIBI Tissue Perfusion scan in Diabetic Patient after Tarsal Tunnel Decompression surgery

N. Manevska[1], *S. Pejkova[2], G. Georgieva[2], A. Jankulovska[1], S. Paljoskoska Jordanova[3], B. Srbov[2], S. Stojanoski[1], I. Sazdova Danova[1], S. Tusheva[2], T. Makazlieva[1];*
[1]Institute of Pathophysiology and Nuclear medicine, Faculty of Medicine, University of Ss Cyril and Methodius, Skopje, NORTH MACEDONIA, [2]University Clinic for Plastic and Reconstructive Surgery, Faculty of Medicine, University of Ss Cyril and Methodius, Skopje, NORTH MACEDONIA, [3]University Clinic for Cardiology, Faculty of Medicine, University of Ss Cyril and Methodius, Skopje, NORTH MACEDONIA.

Aim/Introduction: Tissue perfusion is a diagnostic functional nuclear medicine method that can evaluate the foot perfusion in diabetic patients, delineating foot angiosomes of increase and decreased perfusion. Diabetic neuropathy leads to microvascular complication that presents with loss of foot sensation further complicated by the development of diabetic ulcer that affects the quality of life. We hypothesized that decompressing the tibial nerve for diabetic neuropathy patients would increase blood flow, decrease time for ulcer healing and increase sensibility to plantar area. ***Materials and Methods:*** We present a case of a 62-year-

old woman who had a non-healing diabetic neuropathic ulcer on her right foot for an average of 12 months. She had diabetes diagnosed 36 months ago, with good glycemic control and positive Tinel sign at the tarsal tunnel. We assessed blood flow by Doppler ultrasonography of posterior tibial artery at ankle. "DellonTarsal Tunel Decompression" was performed in four medial ankle tunnels. Three months post - operation, tissue perfusion was compared between operated foot and non-operated foot,using dual phase (rest and stress) 99mTc-MIBI scintigraphicmethod. Stress method was performed after 60 flexion/extension of the feet. ***Results:*** Three-month post operation tissue perfusion analysis revealed lower vascularization in the left foot in both studies, as well as lower perfusion on the late static images with total counts of the feet: L(rest) - 14169, R (rest) - 17237, L(stress) -45858, R (stress) - 55314. The perfusion reserve was preserved and symmetrical in both feet L - 223%, R - 220%. Doppler ultrasonography demonstrated enhanced blood flow within posterior tibial artery where flow rate increased from 1.60 cm^3/sec to 2.15 cm^3/sec after six months follow up visit period. No wound infections or new ulcers were noted post-operatively. ***Conclusion:*** Dellon decompression of tarsal tunnel improves sensibility and blood flow as well as enhances tissue perfusion, which plays a vital role in promoting wound healing in the plantar area of diabetic foot patients. This case underscores the significant impact of optimized tissue perfusion on enhancing sensibility and accelerating ulcer healing in diabetic neuropathy.

EP-1206

Cardiac aspergillosis: a case report.

B. Hervás-Sanz[1], *P. C. Notta[1], I. E. Sánchez-Rodríguez[1], E. Claver-Garrido[2], J. L. Díaz-Moreno[1], M. Cortés-Romera[1]; [1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [2]Cardiology Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

Aim/Introduction: Aspergillosis is a fungal infection caused by the fungus Aspergillus. In immunosuppressed individuals can cause severe infection, usually affecting the lungs, although it can also spread to other parts of the body. Confirmatory diagnosis requires histological study. The diagnosis of suspicion and follow-up of patients is performed by imaging tests. ***Materials and Methods:*** 46-year-old male from Pakistan, monitored at our centre for diagnosis of pulmonary aspergillosis, who was lost to follow-up due to change of address. He reconsulted two years later due to a worsening of his general condition, for which reason an [18F] FDG-PET/CT was requested to assess his current condition. The examination revealed several pulmonary, cutaneous and bone hypermetabolic lesions, compatible with invasive aspergillosis. It is worth mentioning an area with high hypermetabolism at the level of the interventricular septum that seems to infiltrate the posteroinferior wall of the right atrium and could be attributed to vasculitis vs. primary tumour or, with lower degree of suspicion due to its low prevalence, to cardiac involvement by aspergillosis. For a better characterization of the cardiac lesion, an [18F]FDG-PET/MRI was requested, which confirmed presence of edema in the mid-basal interventricular septum with a notable hypermetabolism extending towards the right atrium. ***Results:*** Figure 1: MIP shows several focal deposits of the radiopharmaceutical, of remarkable intensity, located at the cranial calotte, lung parenchyma and right femur.PET, CT and fusion images, in axial plane, showing cutaneous lesions.PET, CT and fusion images, in axial plane, showing the pulmonary lesions.PET, CT and fusion images, in axial plane, at the right femoral head, showing the hypermetabolic lesion. Figure 2: PET, CT and fusion images showing hypermetabolism in the interventricular septum, which appears to extend into the right atrium. Figure 3: PET/MRI images (PSIR, CINE, STIR) showing hypermetabolism at the interventricular septum, which behaves like the rest of the lesions, leading to a diagnosis of cardiac aspergillosis. The patient was treated with oral posaconazole and anidulafungin. A control [18F]FDG-PET/CT study was performed 3 months later with improvement of the lesions. Figure 4: PET, CT and fusion images showing a morphometabolic decrease in lung lesions and also an the cardiac level, which supports the diagnosis of underlying aspergillosis. ***Conclusion:*** [18F]FDG-PET/CT is a good tool for diagnosis, response assessment and follow-up for patients with invasive aspergillosis. [18F]FDG-PET/MRI allows better tissue characterization of the disease at the cardiac level, with a higher sensitivity and specificity compared to PET/CT.

EP-1207

Infectious thrombosis in femoropopliteal bypass: a case report.

B. Hervás-Sanz[1], *P. C. Notta[1], L. M. Gràcia-Sánchez[1], S. A. Bolívar-Cuevas[2], J. L. Díaz-Moreno[1], M. Cortés-Romera[1]; [1]Nuclear Medicine-PET (IDI) Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN, [2]Radiodiagnosis Department, Bellvitge University Hospital-IDIBELL, L'Hospitalet de Llobregat, SPAIN.*

Aim/Introduction: Lower limb occlusive disease can be asymptomatic or manifest in three ways depending on the severity: intermittent claudication, pain at rest or tissue necrosis. The latter two evolve into major amputation if measures are not taken in time, so these patients may benefit from surgical treatment by performing a bypass. The femoropopliteal bypass is performed in those patients with involvement of this territory in order to alleviate the symptoms and improve their quality of life. The main complications are thrombosis, infection or formation of a prosthetic pseudoaneurysm due to degeneration. The aim of this work is to recognize the features visualized on [18F]FDG-PET/CT, in a patient with bypass infection. ***Materials and Methods:*** 85-year-old woman with a history of peripheral vasculopathy and infragenicular amputation of the left lower extremity more than 15 years ago. In January 2024 she was admitted for severe ischemia of the right lower limb requiring femoropopliteal bypass with saphenous vein. Subsequent admission in March 2024 for thrombosis of the bypass. An unsuccessful mechanical thrombectomy was attempted, so a PTFE (poly-tetra-harin-ethylene) vascular prosthesis was placed. In April 2024 she consulted our center for symptoms of less than 24 hours of evolution in the form of disorientation, drowsiness and fever up to 38.5º. Physical examination revealed a 2cm dehiscence at the right supragenicular level with slight exudate discharge, with no signs of acute infection (cellulitis, erythema). Several complementary tests were performed, showing elevated acute phase reactants and growth of methicillin-sensitive S. aureus in blood cultures. Given the findings, she was admitted to the Infectious Diseases Department and [18F]FDG-PET/CT was requested to confirm the infectious focus and assess the extent of it. ***Results:*** Figure 1: MIP shows a remarkable homogeneous hyperenhancement in the proximal third of the right lower extremity. PET, CT and fusion images, in axial plane, showing contiguity solution with fistulous tract and air bubbles at the inner distal third of the right thigh, extending towards the bypass, which shows an increase of the glycemic metabolism along its entire femoral tract, in relation to an associated thrombosis. PET, CT and fusion images, in the coronal plane. Likewise, several fractures are also observed in the

right costal grid related to traumatic antecedent. ***Conclusion:*** [18F]FDG-PET/CT allows us to obtain a global vision, being able to locate the infectious focus, assess its local extension as well as the presence of septic emboli in the rest of the organism.

EP-1208

^{18}F-FDG-PET/CT in the end-stage of ADPKD and MCTD

C. Olianti[1], *M. Dona[2];*
[1]University Hospital of Florence, Florence, ITALY,
[2]New Hospital of Prato, Prato, ITALY.

Aim/Introduction: 18F-FDG-PET/CT is a diagnostic tool for infection localization and clinical management in fever of unknown origin FUO [1] with limitation to kidney/urinary-tract infections. It's also useful for metabolic assessment of muscle connective tissue disease MCTD [2]. A case which summarizes all these pathologic conditions. ***Materials and Methods:*** We present the comparison between the images of a 55y female patient affected by autosomal dominant polycystic kidney disease ADPKD in 4years dialysis, hepatic-renal involvement and MCTD with sick-syndrome, photosensitivity, Raynaud-phenomenon. In June2012 she underwent ^{18}F-FDG PET/CT for MCTD, in April2024 for persistent FUO. ***Results:*** Peritoneal infection due to peritoneal dialysis lead to chronic entericCD+colitis E.Coli-VanA-related, and chronic diarrhea. Also gastric uremic disease with multiple erosions was seen during endoscopy. Other complications were systemic hypertension, iatrogenic osteoporosis (L1-L2, left ischial bone, costs fractures). ^{18}F-FDG findings were: respect the WB-PET-CT of 2012, the WB-PET/CT of 2024 showed: 1)severe numeric increment and enlargement of cysts in the liver, currently disseminated and associated to a mean reduction of metabolic activity (hepatic mean SUV 1,57 vs 2,34) in all segments, 2)severe numeric increment and enlargement of cysts into the kidneys with current huge extension to the pelvis 3)in the right kidney presence of inhomogeneous intense glucose hypermetabolism (max SUV 16.3) in the anterior kidney profile around cysts, and probable compressive phenomenon of renal pelvis, deformed and dislocated. 4)not significant intestinal FDG-hypermetabolism, moderate gastric activity 5)appearance of evident ascitic effusion, in pelvis and flanks 6)appearance of evident bilateral pleural effusion 7)appearance of upper paratracheal cystic alterations into the thyroid parenchima 8)diffuse reduction of metabolic activity of left ventricular myocardium 9)diffuse metabolic and volumetric reduction of all muscles mostly for lower limbs 10) focal intense bone hyperactivity in the 6th-right cost and in the left ischial insertion 11)diffuse calcific depots on the principal vessels 12)high normal brain activity. ***Conclusion:*** We consider ^{18}F-FDG-PET/CT of paramount importance in the assessment of organs involvement, functional evaluation and space-consuming impact in this life-threatening inherited human systemic disorder. In the most common hereditary kidney disease, ^{18}F-FDG PET/CT allows a correct localization of the infection-site being the renal kidneys not-functioning in dialytic phase. FDG-PET/CT demonstrated useful for the management of very complex cases, with unexpected rapid evolution and timing of possible surgical solutions in infected kidney cysts. ***References:*** [1]Kouijzer IJE et al. Semin Nucl Med. 2018 Mar;48(2):100-107. doi: 10.1053/j.semnuclmed.2017.11.004. Epub 2017 Dec 8. PMID: 29452615.[2] Okabe Tet al. Clin Nucl Med. 2011 May;36(5):350-4. doi: 10.1097/RLU.0b013e318212c858. PMID: 21467850.

EP-1209

PET-CT ^{18}F FDG in the Management of Splenic Red Pulp Small B-Cell Lymphoma: A Clinical Case Report

M. Sanchez Torrente, *S. Martin Aguilar, P. Guardia Jimena, L. Mena Bares, M. Ureña Lara;*
Hospital Universitario de Jaen, Jaen, SPAIN.

Aim/Introduction: Splenic diffuse red pulp small B-cell lymphoma (SDRPL) is a rare disease, representing <1% of all non-Hodgkin lymphomas. The most common clinical manifestations include splenomegaly, lymphocytosis, and hemocytopenia. A diagnosis of SDRPL can be challenging, as it shares multiple clinical and laboratory features with splenic marginal zone lymphoma, hair cell leukemia, and HCL variant. Obtaining splenic tissue remains the gold standard for diagnosis. In the cases where splenic tissue is not available, diagnosis can be established by a review of peripheral blood and bone marrow studies. SDRPL is characterized by a diffuse involvement of the splenic red pulp by monomorphous small-to-medium sized mature B lymphocytes effacing the white pulp. ^{18}F FDG PET-CT characteristically shows splenomegaly with a mild and diffuse increase in metabolic activity and mild hypermetabolism in the bone marrow, according to what has been described in the literature so far. ***Materials and Methods:*** A 64-year-old male patient was referred for a hematology study due to moderate leukothrombopenia that had been going on for years, with no other clinical or analytical findings. During the physical examination, splenomegaly was detected and the patient was referred for an ultrasound and CT study that confirmed splenomegaly of 21cm, with no other findings.Immunophenotype in peripheral blood, bone marrow biopsy and ^{18}F-FDG PET-CT are requested. ***Results:*** The immunophenotype in peripheral blood shows a result compatible with type B non-Hodgkin lymphoma suggestive of SDRPL. The bone marrow biopsy shows a result of interstitial lymphocytosis of small lymphocytes of phenotype B that suggests infiltration by a lymphoproliferative process of small lymphocytes.The ^{18}F-FDG PET-CT shows splenomegaly of 21.5cm with metabolic activity slightly higher than that of the liver (SUVmax=5.22), without evidence of focal lesions, diffuse hypermetabolism of the bone marrow, and multiple supradiaphragmatic and infradiaphragmatic nodes, all of them with an SUVmax lower than the hepatic one and less than 1cm in diameter. ***Conclusion:*** Splenic small cell lymphoma B of the red pulp is a rare type of primary splenic lymphoma, and although the diagnosis is based on splenic and bone marrow biopsies and immunophenotype. Recognizing the characteristic involvement of this pathology in ^{18}F-FDG PET-CT is important to assess the extension and support the diagnosis in cases of doubt.

EP-1210

PET-CT ^{18}F FDG evaluation of Paraneoplastic Skin Manifestations in Hodgkin Lymphoma: A Case Report and Review

M. Sanchez Torrente, *S. Martin Aguilar, A. Santos Bueno, L. Mena Bares, M. Ureña Lara;*
Hospital Universitario de Jaen, Jaen, SPAIN.

Aim/Introduction: Hodgkin's lymphoma is a monoclonal lymphoid neoplasm that is mainly characterized by multinucleated Reed-Sternberg cells on a background of non-neoplastic inflammatory cells. The incidence rate of Hodgkin's lymphoma is 2.5 new cases per 100,000 people per year. Paraneoplastic syndromes are conditions that are related to malignancy; however, they are not a result of tumor invasion. These paraneoplastic syndromes can occur virtually at any point

in the disease course, and their various forms are not well studied. Paraneoplastic skin conditions like diffuse hyperpigmentation, erythema nodosum, and acquired ichthyosis have been described in the literature. The main pathophysiology is hypothesized to be T cell dysregulation and increased Th2 cytokine profiles conducive to atopy.In this case, we analyze a case of Hodgkin lymphoma with paraneoplastic skin involvement. ***Materials and Methods:*** A 61-year-old woman presented with generalized pruritus, skin lesions and lymphadenopathy, and after a lymphadenopathy biopsy, she was referred to hematology with initial suspicion of peripheral T lymphoma NOS, which was later confirmed as Hodgkin Lymphoma upon completion of the immunophenotype analysis. ***Results:*** The ^{18}F-FDG PET-CT at diagnosis showed hypermetabolic supra- and infradiaphragmatic lymphadenopathy and multiple suspicious hypermetabolic skin lesions on the limbs and trunk.Given the suspicion of skin involvement, a biopsy of one of the skin lesions was performed, which showed a result of superficial perivascular lymphocytic dermatitis. Suggesting probable paraneoplastic etiology of the lesions. The patient was treated with an ABVD (adriamycin, bleomycin, vinblastine, dacarbazine) regimen. The interim ^{18}F-FDG PET-CT 3 months after starting treatment showed complete response to treatment and resolution of the skin lesions, which were metabolically undetectable.In line with what was published in the literature, the skin lesions resolved after a favorable response to treatment. ***Conclusion:*** The presence of hypermetabolic skin lesions in a ^{18}F-FDG PET-CT atf Hodgkin lymphoma should initially make us think, due to its greater frequency, of paraneoplastic etiology. However, a biopsy must be obtained to confirm the diagnosis, and rule out malignant skin infiltration, which, although less common, is also possible.

EP-1211

Disseminated localizations of plasmoblastic lymphoma in an AIDS presenter patient

S. Pacella[1], *G. Bellettati[2], F. Rossi[1], L. Airò Farulla[2], N. Rampi[1], A. Castello[1], F. Passamonti[3], A. Bandera[3], M. Castellani[1];*
[1]IRCCS Fondazione Cà Granda Ospedale Maggiore Policlinico, Milano, ITALY, [2]Università degli Studi di Milano, Milano, ITALY, [3]IRCCS Fondazione Cà Granda Ospedale Maggiore Policlinico; Università degli Studi di Milano, Milano, ITALY.

Aim/Introduction: HIV-associated lymphoma was first classified as an AIDS-defining disease by the American Center for Disease Control and Prevention (CDC) in 1985. Non-Hodgkin's lymphomas (NHLs) are the most frequent malignancies in AIDS patients; ^{18F}-FDG PET/CT could help to reveal their localizations. ***Materials and Methods:*** We present a case report of an AIDS patient with a voluminous vulvar lesion that underwent PET/CT examination with an evidence of diffuse metastatic localizations of disease. A biopsy of the vulvar lesion revealed a rare form of NHL, the plasmoblastic lymphoma (PBL). ***Results:*** A patient with deteriorating clinical conditions presented to the Emergency Department of our hospital. Blood tests revealed increased values of LDH, ferritin and beta2-microglobulin with initial pancytopenia and positivity of anti-HIV1-2 antibodies at HIV test; in this setting, a high quantitative HIV RNA and a low CD4+ lymphocyte count were highlighted. A mass in the vaginal canal with extension to the uterine cervix and pathological lymph nodes in the left inguinal area were found at CT images. Additional ^{18F}-FDG PET/CT findings were a diffuse bone marrow uptake, further lymphadenopathies in left laterocervical area and in the mediastinum, as well as nodulations/inhomogeneities of the subcutaneous adipose tissue in the right gluteal region. Two tracer uptake foci were also observed in the head and body of the pancreas. Consistent with the presence of carcinomatous lymphangitis were the multiple areas of uptake on parenchymal bilateral pulmonary lesions. Bone marrow and pelvic lesion biopsies were suggestive of plasmoblastic lymphoma (PBL). ***Conclusion:*** ^{18F}-FDG PET/CT proved to be an important diagnostic tool in localizing nodal and extranodal sites of AIDS-related disease. This could impact on management of AIDS presenter patients with poor-prognosis lymphoma. ***References:*** -Liu Q, Yang T, Chen X, Liu Y. Clinical value of 18F-FDG PET/CT in the management of HIV-associated lymphoma. Front Oncol. 2023 Jan 26;13:1117064. doi: 10.3389/fonc.2023.1117064. PMID: 36776334; PMCID: PMC9909962.

EP-1212

Pulmonary Necrotic Inflammation Mimics Lung Cancer on [68Ga]Ga-FAPI-46 PET/CT and ^{18F}F-FDG PET/CT

E. Fortunati[1], *L. Zanoni[1], G. Cuzzani[2], C. Nanni[1], I. Brusa[1], G. Bandelli[3], F. Giunchi[4], F. Antonacci[5], P. Solli[5], P. Candoli[3], S. Fanti[1,2];*
[1]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [2]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [3]Interventional Pulmonology Unit, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [4]Pathology, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [5]Division of Thoracic Surgery, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: A 73y.o. male patient underwent a thoracic diagnostic-CT to investigate the presence of a lung lesion after the onset of haemoptysis. CT-scan detected a voluminous, solid and inhomogeneous lung lesion in the left superior lobe near to pleura, with hypodense and colliquative areas, irregular and spiculated margins. Some enlarged mediastinal lymph nodes were described. ***Materials and Methods:*** The patient was referred to our Centre for a standard ^{18F}F-FDG PET/CT to evaluate the lung lesion in the left superior lobe and, in the suspect of lung cancer, enrolled to perform an additional [68Ga]Ga-FAPI-46 PET/CT(2days later) within an ongoing prospective monocentric investigational trial(EudraCT number:2021-006570-23). PET scans were acquired 60 minutes after the radiopharmaceutical injection, with a field-of-view from the vertex to the proximal thighs. ***Results:*** ^{18F}F-FDG PET/CT detected intense and inhomogeneous uptake(SUVmax=14.8) in the known lung lesion in the left superior lobe, with some central areas of absent uptake due to possible necrotic phenomena; a moderate uptake was detected in subaortic (#5, SUVmax=4.3), left hilar (#10; SUVmax=7.8) and left interlobar peribronchial (#11, SUVmax=7.8) lymph-nodes(T2N2M0). [68Ga]Ga-FAPI-46 PET/CT detected an intense and inhomogeneous uptake in the lung lesion (SUVmax=21.3) and focal uptake only in left interlobar peribronchial lymphnodal region (#11, SUVmax=9.3) (T2N1M0). Endobronchial ultrasound-guided biopsies resulted inconclusive in lung and exlcluded malignancy in #4L (TXN0M0). Subsequent surgery (left superior lobectomy) demonstrated necrotic inflammation with hilar abscess and contiguous areas of pneumonia. Inflamed lymph nodes were detected in #5, #7, #9, #10, #11. Immunochemistry was also performed with FAPI staining: immunoreactivity in fibroblasts and plasma cells was detected. ***Conclusion:*** As previously reported, the novel promising tracer FAPI can show diffuse/multifocal uptake in pneumonia and chronic inflammations[1-3], thus mimicking lung cancer, similarly to the false positives often observed with standard ^{18F}F-FDG PET/CT. Interestingly, in this case [68Ga]Ga-FAPI-46 PET/CT detected less lymph nodal involvement than

[18F]F-FDG PET/CT, raising some concern whether it was a tumour downstaging compared to FDG or an impressive pitfall to be encountered within the non-oncological FAPI uptake. A deeper analysis of the [68Ga]Ga-FAPI-46 PET/CT uptake(also collecting and comparing semiquantitative parameters) with respect to the definitive histological diagnosis is awaited in the ongoing trials, in order to better understand the tracer behaviour. ***References:*** [1]Tang W,Wu J,Yang S,Wang Q,Chen Y.Organizing Pneumonia With Intense 68Ga-FAPI Uptake Mimicking Lung Cancer on 68Ga-FAPI PET/CT.ClinNuclMed. 2022;47(3):223-225.doi:10.1097/RLU.0000000000003855[2]Hotta M, Rieger AC, Jafarvand MG,et al.Non-oncologic incidental uptake on FAPI PET/CTimaging. EP-1213

A case of occult invasive urothelial carcinoma with bone metastasis on ^{18}F-FDG PET/CT

B. Ince, *A. Namazova, N. Urgancı, S. Asa, S. Sager, K. Sönmezoğlu, N. Çomunoğlu, H. B. Sayman;*
Istanbul University-Cerrahpasa, Istanbul, TÜRKIYE.

Aim/Introduction: We present ^{18}F-FDG-PET/CT images of a case with occult metastatic invasive urothelial carcinoma diagnosed by bone biopsy. ***Materials and Methods:*** The patient was administered 0.15 mCi/kg FDG intravenously. PET/CT imaging was obtained from whole body at 60th minute after the injection. ***Results:*** A 67-year-old man with no known chronic disease presented with a 3-month history of left hip pain. Lumbar MRI revealed osteolytic lesions with periosteal reaction and heterogeneous contrast enhancement in lumbar vertebrae, sacrum, and left pelvic bone, accompanied by edema in surrounding soft tissues. It has been stated that it may be compatible with metastasis, osteomyelitis, fibrous dysplasia or metabolic bone diseases. Subsequent FDG-PET/CT imaging revealed extensive hypermetabolic sclerotic bone lesions in sacrum, left pelvic bones, and proximal left femur. Additionally, multiple hypermetabolic bone lesions were detected in parietal bone, sternum, L3-L4-L5 vertebrae, right iliac and right femur accompanied by sclerosis in some of them. A focal FDG uptake was detected in prostate gland. Prostate needle biopsy revealed high-grade prostatic intraepithelial neoplasia and chronic prostatitis, but no invasive tumour was detected. A subsequent sacral osteocut biopsy revealed invasive urothelial carcinoma metastasis, with positive immunohistochemical staining for PanCK, CK7, GATA3, and Uroplakin-3. PET images were re-evaluated retrospectively after the pathology report, no pathological involvement was detected in the urinary system that could be distinguished from urinary FDG activity. MRI urography study also didn't reveal any finding in the urogenital system that could indicate a primary tumour. Follow-up bladder washing cytology was also negative for malignancy. Cisplatin, gemcitabine and zoledronic acid treatment was started by medical oncology with the diagnosis of metastatic urothelial carcinoma. ***Conclusion:*** Urothelial carcinomas are malignant tumors arising from transitional cells throughout the urinary system, most commonly in bladder. Distant metastasis is rare at the time of diagnosis (approximately 5%). Distant metastases are frequently to the liver, lung and bones. Occult metastatic urothelial carcinoma is very rare, with only a few case reports in the literature. In our case, only multiple bone metastases were present at the time of diagnosis, mainly in pelvis, left femur and lumbar vertebrae. It is known that the most common bone metastasis localizations of urothelial carcinomas are pelvic and vertebral bones. Therefore, the possibility of urothelial carcinoma metastasis should be considered in cases of unknown primary bone metastases, particularly in these locations. ***References:*** 1.Bu K,et al. An occult urothelial carcinoma with wide multiorgan metastases and its genetic alteration profiling. Medicine. 2019;98.

EP-1214

FDG PET/ CT in the evaluation of therapy response assessment of hepatic alveolar hydatid disease (Echinococcus multilocularis) in non- endemic areas- case report of two treated patient

A. Peter[1,2], *M. Ružić[3,2], S. Lučić[1,2], D. Stojanović[1], V. Cimbaljević[1];*
[1]Insitute of Oncology Vojvodina, Sremska Kamenica, SERBIA, [2]University of Novi Sad, Faculty of Medicine, Novi Sad, SERBIA, [3]Clinical Center of Vojvodina, Novi Sad, SERBIA.

Aim/Introduction: Alveolar or multilocular echinococcosis is an infection with the larval form of the tapeworm Echinococcus multilocularis. In comparison to cystic echinococcosis (CE) this form of infection is rarebit more severe and both infections most commonly affect the liver. Recent epidemiological studies show that it is becoming a growing public health issue, and it has a progressive spread to other non- endemic regions. AE if left untreated can be fatal, once diagnosed the treatment is difficult and therapy response assessment is also not easy. It also gas a long asymptomatic incubation period, approximately from 5 to 15 years and the development and progression of a primary liver AE is very slow. Because of its non- specific clinical symptoms and imaging characteristics the diagnosis and the evaluation of response to treatment can be sometimes challenging. In the follow- up and therapy response assessment PET/ CT has been suggested as a very useful imaging modality. ***Materials and Methods:*** The FDG PET/ CT was done by using standard protocols, with normal glycaemia and after 4- 6 hours of fasting. In these patients delayed images of the abdomen were also obtained 3 hours after injection. Two patients were classified according to the PNM system (P- parasitic mass; N- neighbouring organ involvement; M- metastatic disease) and FDG PET/ CT was performed after therapy with radical surgery and after adjuvant therapy with albendazole. ***Results:*** PET/ CT in one patient did not show increased liver uptake in the region of treatment and in the other patient it showed only discreet rim uptake in the region of the liver lesion. On delayed images both patients did not have an increase of FDG uptake. These findings were interpreted as good response to therapy with stable disease or even resolution. ***Conclusion:*** Therapy response assessment is very challenging for morphological imaging modalities like computed tomography (CT) and magnetic resonance imaging (MRI) and therefore FDG PET/ CT has been proposed as a tool for follow- up of treated patients. Reduced or negative perilesional FDG uptake following treatment can be taken as a marker of stable disease with good response to therapy or resolution even in the presence of morphological lesions.

EP-1215

Case Report: ^{18}F-FDG PET/CT For Fuo Contributes To Uncover Atypical Presentations Of Rare Whipple Disease Infection

L. Carrara[1], *S. Proto[1], L. Zanoni[2], C. Nanni[2], L. Attard[3], S. Fanti[1,2];*
[1]Nuclear Medicine - Alma Mater Studiorum of Bologna, Bologna, ITALY, [2]Nuclear Medicine - IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [3]Infectious Diseases Unit, Department for Integrated Infectious Risk Management, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY.

Aim/Introduction: We present the case of a 60-year-old man admitted to the hospital presenting with high fever of unknown origin (FUO), strong headache, face erythematous-desquamative cutaneous lesions, long history of abdominal pain and diffuse myalgia. He was also previously treated with immunosuppressants and currently managed with corticosteroids for a seronegative rheumatic disease. Given the immunocompromised state, an infective aetiology was suspected. ***Materials and Methods:*** The patient was referred, as part of standard clinical practice, to perform a routine 18F-FDG-PET/CT, to identify potential causes of FUO. The patient signed written informed consents for data treatment and images' use for scientific purpose and publication. ***Results:*** The FDG-PET/CT scan revealed diffuse bone marrow uptake, without focal areas, involving the whole axial skeleton and the proximal part of humeri and femora bilaterally (SUVmax in the femur=5.6) which could indicate functional bone marrow activation in response to ongoing infection. Interestingly, multifocal uptake was observed in all muscular soft tissue (SUVmax=5) included in the standard field-of-view. Considering PET resolution limitations and physiological unspecific-functional bowel uptake, no significant focal uptake was depicted at the gastrointestinal level. Whipple disease (WD) is a very rare, systemic disease, caused by a gram-positive bacillus bacterium Tropheryma whipplei that primarily targets the intestinal epithelium but can affect various organs, generally presenting at the onset with polyarthritis (approximately 60% of cases), often misdiagnosed as rheumatic disease. Exceptionally it can cause inflammation of muscles and soft tissues: cases of bilateral extraocular myositis, of WD mimicking an autoinflammatory disease with myositis and soft tissue inflammation, of dermato-polymyositis-like presentation have been reported.To the best of our knowledge, this is the first instance where FDG-PET/CT has revealed multifocal muscular uptake in WD. At first non -pathological muscles' hyper-contraction due to elevated fever with shaking chills during 18F-FDG uptake time (also requiring paracetamol administration) was an option, but still in differential diagnosis with haematological, rheumatological and infectious aetiologies. Finally, when a small bowel (duodenum) biopsy pathologically confirmed the clinical suspect of WD, infectious muscular involvement remained the only most reliable hypothesis, prompting the initiation of specific antibiotic therapy (ceftriaxone, trimetroprim + sulfametoxazole). ***Conclusion:*** These unusual imaging findings highlight the crucial application of FDG-PET/CT in the flow-chart of FUO, being able to uncover also atypical manifestations and to expand our understanding of rare diseases. However, WD diagnosis remains challenging due to its rarity, clinical manifestations heterogeneity and slow progressive course mimicking autoinflammatory/autoimmune/malignant diseases, thus requiring multidisciplinary approach.

EP-1216

Bone scan in Camurati-Engelman disease: a case report

G. Frusciante[1], *S. E. Prisco[1], A. Romeo[2], S. Zoboli[2], M. Santoro[2], A. Golemi[2], P. E. Orlandi[3];*
[1]Nuclear Medicine-Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine Unit, IRCCS Azienda Ospedaliero, Università di Bologna, Bologna, ITALY, [3]Radiology Unit, Major Hospital, Bologna, ITALY.

Aim/Introduction: Camurati-Engelmann disease (CED) is a rare disorder characterized by progressive cranial hyperostosis and diaphyseal sclerosis of the long bones. Chronic intracranial hypertension gradually occurs due to progressive cranial vault hyperostosis. (1) ***Materials and Methods:*** A 35-year-old patient complained about pain in right leg since August '22 so he performed some exams, in which, a rx which described a thickening in right shinbone and in the radius and ulna. The orthopaedic surgeon suspected a CED and suggested to perform a bone scan to analyse the metabolic state of the bone. ***Results:*** The bone scan described uptake of radiotracer in left shinbone, at the ulna, at the femur and at the bone skull. Genetic analysis is in progress. ***Conclusion:*** Bone scintigraphy can be an useful tool in the diagnosis and assessing the severity of suspected Camurati-Engelmann disease. ***References:*** (1) 10.1007/s00223-019-00532-1

EP-1217

An Alternative Therapeutic Approach to Neuroendocrine Prostate Cancer

J. Rebelo[1], *A. Morão[1,2], R. Silva[1,2], G. Costa[1,3];*
[1]ULS Coimbra - Centro Hospitalar Universitário de Coimbra, Coimbra, PORTUGAL, [2]ICNAS - Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL, [3]Universidade de Coimbra - Faculdade de Medicina, Coimbra, PORTUGAL.

Aim/Introduction: Androgen deprivation therapy (ADT) has become the standard treatment for patients with prostate cancer, owing to the unique role of the androgen in the growth and progression in prostate cancer (PC). Tumors receiving ADT eventually progress to an androgen-resistant state, known as CRPC (castration resistant PC) or more lethal NEPC (neuroendocrine PC). So, NEPC is an aggressive variant of prostate cancer, usually diagnosed at an advanced stage and shows great increase in incidence due to the rapid development of drug resistance, making the discovery of new therapeutic approaches of paramount importance. Here, we discuss a case of utilization of 177Lu-DOTATATE in the treatment of a patient with NEPC. ***Materials and Methods:*** A 71-year-old male, with a previous diagnosis of prostate cancer in another institution, started follow-up in our center, where a prostate biopsy was performed, that led to the diagnosis of prostate adenocarcinoma, Gleason 9 (5+4), with neuroendocrine diferentiation (small cell neuroendocrine carcinoma). ***Results:*** After undergoing an initial course of two months of chemotherapy (cisplatin + etoposide), a PET/CT 68Ga-DOTANOC was requested, showing bone lesions with mild radiopharmaceutical uptake. The cromogranin A level was 1238 ng/mL and the PSA level 10.67 ng/mL. With these results, the patient was proposed to be treated with 177Lu-DOTATATE, undergoing a total of three cycles (from october/2018 to february/2019), showing a good biochemical (the cromogranin A levels dropped from 1238ng/mL pre-treatment to 205.8 ng/mL after the third cycle) and clinical response (no new lesions detected during the treatment). The patient continued then follow-up, with hormonotherapy and chemotherapy until he passed away, in september/2023. ***Conclusion:*** Neuroendocrine prostate cancer (NEPC) is a highly aggressive subtype of prostate cancer (PC) that commonly emerges through a transdifferentiation process from prostate adenocarcinoma and evades conventional therapies. This case shows that 177Lu-DOTATATE may be an important alternative for the treatment of NEPC.

EP-1218

Very rare case of solitary fibrous tumour of the pleura with intermediate/hight risk of malignancy discovered incidentally on bone scintigraphy

S. E. Prisco[1], *M. Rapa[1], A. Romeo[2], G. Frusciante[1], A. Golemi[2], M. Santoro[2], S. Zoboli[2], A. Musto[2], P. E. Orlandi[3], S. Fanti[1,2];*
[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine, IRCCS, Azienda Ospedaliero-

Universitaria di Bologna, Bologna, ITALY, [3]Radiology Unit, Maggiore Hospital "Carlo Alberto Pizzardi", Bologna, ITALY.

Aim/Introduction: Solitary fibrous tumour of the pleura (SFTP) is a rare neoplasm originated from the mesenchymal layer of the pleura, but occasionally found in other sites. Historically considered benign with slow tumour growth, recent literature has shown that such tumours often exhibit unpreadictable histologic behaviours, make it a challenge for pathologists to differentiate between benign and malignant form. Patients are usually asymptomatic, manifesting atypical symptoms upt to 40%, and only at advanced stage presenting with mechanical chest compression. In rare cases, non-diabetic patients may develop hypoglycaemia due to SFTP secreting insulin-like growth factor 2 (IGF-2). Treatment is surgical, but because of the late diagnosis, it is hampered by the effects of large pleuropulmonary resections in often elderly patients with comorbidities. We present the case of a patient with chronic left lower limb pain, who was diagnosed and treated for SFTP based on bone scan results, before compression symptoms developed. ***Materials and Methods:*** A 78-year-old female patient presented with severe left low-back pain unresponsive to conventional antalgic therapies. To rule out metastases and lytic bone lesions, she was referred for further evaluation with a CT scan of the pelvis and left femur, which showed only calcific enthesopathy of the great trochanter, followed by bone scintigraphy. ***Results:*** A 99mTc-HDP bone scintigraphy was performed and showed, in addition to signs of polydistrict arthrosis, a large oval area of relative tracer uptake in the right mid-thoracic region of probable lung relevance. Consequently, the patient underwent a CT scan of the thorax, which showed a large solid neoformation, starting from the visceral pleura, at the middle lobe. Subsequent ^{18}F-FDG PET/CT scan revealed low uptake of the lesion (SUVmax=2). A transtoracic biopsy revealed spindle-cell mesenchymal tissue with morphological and immunophenotypic features consistent with SFTP, areas of ischaemic necrosis and uncertain biological malignancy potential (intermediate/high risk). Therefore, the patient underwent surgical excision of the tumour with atypical resection of middle lobe lung parenchyma by thoracotomy without post-operative sequelae. Few other cases of SFTP uptake on bone scintigraphy have been reported. ***Conclusion:*** In this case, bone scintigraphy allowed the early diagnosis of a potentially malignant SFTP in an asymptomatic patient, providing us with another example of non-bone disease detectable with 99mTc-HDP.

EP-1219

Rebound Thymic Hyperplasia Following Corticotherapy: A Case Report Demonstrated on 2-[18F] FDG-PET/CT

I. Ferreira, *O. L. Silva, R. T. Ferreira, D. Barbosa, C. Luz, M. R. Victor, J. A. Sequeira, A. I. Santos;*
Unidade Local de Saúde Almada-Seixal - Hospital Garcia de Orta, Almada, PORTUGAL.

Aim/Introduction: Thymic Rebound Hyperplasia (TRH) is a recognised phenomenon characterised by the proliferation of thymic tissue following periods of stress, such as thermal burns or cardiac surgery, post-chemotherapy or, less frequently, after discontinuation of oral corticosteroid treatment (CST). These latter cases have been particularly described in children who received CST for lymphoma. Currently, PET/CT with 2-[18F]FDG (2-[18F]FDG PET/CT) plays an important role in staging malignancies as well as in detecting tumour recurrence. However, interpreting lesions encountered in the anterior mediastinum during malignancy follow-up can be challenging. We aimed to review the role 2-[18F]FDG PET/CT had in identifying a case of RTH following the resolution of hypercortisolism after adrenalectomy for an adrenocortical tumour. ***Materials and Methods:*** We report the case of a 39-year-old man with a history of nephrolithiasis and recently diagnosed arterial hypertension, who presented to the emergency department of our institution with symptoms consistent with renal colic. Initial evaluation with abdominal computed tomography excluded ureteral obstruction but revealed a suspicious 5 cm nodule in the left adrenal gland. He was referred to an Endocrinology evaluation. Blood work revealed ACTH-independent hypercortisolism and abdominal magnetic resonance imaging suggested diagnosis of an atypical adenoma versus a collision tumour. Given the suspicion of malignancy, 2-[18F] FDG PET/CT was requested and demonstrated moderate focal hypermetabolism in the adrenal lesion with no other suspicious foci. The patient underwent laparoscopic left adrenalectomy without complications. Postoperatively, CST was started, initially administered as hydrocortisone via intravenous infusion, and changed after 2 days to an oral physiologic replacement dose, with sequential slow tapering. ***Results:*** The histopathological analysis identified an adrenal cortex neoplasm of uncertain malignant potential. Blood pressure and cortisol values normalised post-operatively and antihypertensive medication was suspended. Six months post-surgery, re-evaluation with 2-[18F]FDG PET/CT revealed resolution of adrenal hypermetabolism and the appearance of diffuse and intense radiopharmaceutical uptake in an enlarged thymus, which was previously absent. This pattern was consistent with reactivity to CST, namely TRH. Currently, the patient remains asymptomatic on clinical and imaging follow-up. ***Conclusion:*** Our case highlights the importance of including TRH in the differential diagnosis of mediastinal lesions following corticotherapy. The interpretation of 2-[18F]FDG PET/CT findings in this context needs careful consideration of clinical history and imaging characteristics to avoid misdiagnosis. 2-[18F]FDG PET/CT is, therefore, a valuable emerging tool in these situations, facilitating optimal patient care by avoiding futile aggressive management strategies and allowing conservative approaches for follow-up.

EP-1220

Radioguided Occult Lesion Localization (ROLL) to perform pre-surgery marking of non-palpable thigh melanoma metastasis of multi-recurrent scalp melanoma: a case report

F. Monastero[1], *S. Prisco[2], G. Frusciante[3], R. Bonfiglioli[4], S. Fanti[5]; [1]Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, Bologna, ITALY, [3]Nuclear medicine, Alma Mater Studiorum Universityof Bologna, Bologna, ITALY, [4]Nuclear medicine, IRCSS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, Bologna, ITALY, [5]Nuclear Medicine, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, Bologna, ITALY.*

Aim/Introduction: Our aim is to describe our pilot experience of ROLL (Radioguided Occult Lesion Localization) technique with 99mTC-MAA to perform pre-surgical precision marking of non-palpable retro popliteal melanoma metastasis, already described by ^{18}F-FDG PET/CT, in 80 year-old male patient ***Materials and Methods:*** The ROLL is performed under local and intramuscolar anesthesia. Once the lesion is located by ultrasound-guided technique, it is accessed with a needle 18G, it is estimated that the administered dose is 25 MBq. Once the radiopharmaceutical is administered, it is confrmed by local deposit with a posterior static

acquisition and SPECT/CT view performed by GE 670 gamma-camera ***Results:*** The methodical shows a focal and limited localization of the radiopharmaceutical, without local spilling, above the right retro popliteal fossa to omolateral distal femoral diaphysis between the short and long heads of the biceps femoris muscle, in correspondence to the already know finding described by ^{18}F-FDG PET/CT. The metastasis was subsequently localized by the surgeons deep in the posterior muscle planes adherent to nerve structures and was removed without complications ***Conclusion:*** the methodical, in particulare the SPECT/CT view, obtained a pre-surgical high marking accuracy with an improvement in space localization, and it seems to be a simple, safe and reproducible technique.

EP-1221

Wash-out index used in 99mTc-MIBI scintigraphy in differentiating benign from malignant thyroid nodules

N. Manevska, *B. Stoilovska Rizova, I. Sazdova Danova, A. Jankulovska, N. Bozinovska, T. Makazlieva, S. Stojanoski;*
Institute of Pathophysiology and Nuclear medicine, Faculty of Medicine, University of Ss Cyril and Methodius, Skopje, NORTH MACEDONIA.

Aim/Introduction: Nuclear medicine scintigraphic methods are useful diagnostic tools in evaluating thyroid nodules. In ultrasonographically suspected thyroid nodules as well as indeterminate fine needle aspiration biopsy findings, thyroid scintigraphy with 99mTc-MIBI has been used in nuclear medicine centers to differentiate benign from malignant thyroid nodules. ***Materials and Methods:*** We evaluated 32 nodules, from 30 euthyroid patients, both gender. All patients presented with suspected thyroid nodules upon ultrasound examination, primarily categorized as indeterminate nodules (Bethesda III and Bethesda IV) on fine needle aspiration biopsy, with only five falling under the Bethesda II classification. A thyroid scan lasting 10 minutes was conducted using a dual phase approach, with images at 10 minutes and 1 hour after iv administration of 370 MBq 99mTc-MIBI. Total and average counts were obtained from mirrored regions of interest (ROIs), accounting for background levels. The washout index (WOI) for each nodule was calculated using the formula (LR/ER*100-100). ***Results:*** Thyroid nodules were described mostly as hypoechoic-non-chomogenous by structure, mainly cold on pertechnetate scan, while five were isoechoic and three were hyperechoic. Their size varied from 9mm to 40mm. 16 thyroid nodules were located in the right thyroid lobe, while the rest were in the left thyroid lobe. In the benign group we revealed 9-Follicular adenoma, 2 - Tumor of unknown malignant potential and 3 - Struma nodosa, 2 - Thyroiditis Hashimoto. In the malignant group we post surgically received 10-Papillary thyroid carcinoma (3 being Microcarcinoma papillare), 3 - Papillary thyroid carcinoma with follicular variant, 2 - Follicular carcinoma, 1 - Hurthle carcinoma.The WOI values displayed distinct ranges specific for malignant and benign nodules respectively, with the following specifications: (54.6±10.9) and (43.5±7.1), accompanied by standard deviations of 12.9 for malignant and 8.6 for benign samples. Analysis using the Mann- Whitney U test two-tailed comparisons has revealed a statistically significant difference between the observed samples at a significant value $p<0.05$. ***Conclusion:*** The computation of WOI derived from 99mTc-MIBI thyroid scintigraphy proves to be a valuable diagnostic tool, in delineating benign from malignant thyroid nodules for proper future thyroid patient managment.

EP-1222

Not Everything Is As It Seems - a Case Report of a Rare Thyroid Cancer

D. Filipan[1], *R. Granić[1], H. Čupić[2,3], L. Pažanin[2], A. Frobe[1], T. Jukić[1,3];*
[1]University Department of Oncology and Nuclear Medicine, Sestre Milosrdnice University Hospital Centre, Zagreb, CROATIA,
[2]Clinical Department of Pathology and Cytology "Ljudevit Jurak", Sestre Milosrdnice University Hospital Centre, Zagreb, CROATIA,
[3]University of Zagreb School of Medicine, Zagreb, CROATIA.

Aim/Introduction: Papillary thyroid cancer (PTC) and medullary thyroid cancer (MTC) originate from different cells and show no shared genetic origin. There are only several cases describing a tumor containing both MTC and PTC features - condition known as mixed medullary and follicular cell-derived thyroid carcinoma (MMFTC), which occurs in <1% of all malignant thyroid tumors. ***Materials and Methods:*** A 54-year-old female patient with Graves' disease and bilateral thyroid-associated ophthalmopathy was treated by thiamazole for 7 years before undergoing definitive treatment by total thyroidectomy. The histopathology report showed PTC of the left thyroid lobe, 9 mm in diameter, with metastases to the central lymph nodes of the neck. The patient was referred to our clinic for adjuvant radioactive iodine therapy. ***Results:*** On neck ultrasound exam, a nodule was found in the thyroid gland bed, as well as suspicious metastatic lymph nodes in the central and lateral neck regions. Fine-needle aspiration of the suspicious lymph nodes uncovered metastases of the medullary and papillary carcinoma, with high levels of calcitonin (5000 ng/L) and thyroglobulin (Tg) (>3550 ug/L) in the aspirate. Serum thyroid-stimulating-hormone (TSH) levels were normal, while serum Tg level was mildly increased (2,35 ug/L) and declining since surgery date (14 days post-operatively Tg was 71,75 ug/L; 5 weeks post-operatively Tg was 3,01 ug/L), with undetectable anti-thyroglobulin antibodies. Serum calcitonin levels were checked and were very elevated (801 ng/L), as well as carcinoembryonic antigen levels (31 ug/L). Histopathological revision of the original material was indicated. Immunohistochemical analysis showed a part of tumoral cells in the thyroid gland, as well as the majority of tumoral cells in the extirpated central neck area lymph nodes were positive for calcitonin stains and negative for thyroglobulin. Therefore, the tumor was re-characterized as MMFTC. The patient underwent dissection of the central and lateral neck regions. Histopathological analysis revealed metastatic lymph nodes occupied by tumoral cells of MMFTC. The patient is expected to receive ablative radioiodine treatment with pretreatment by recombinant human-TSH, and pulse corticosteroid therapy. ***Conclusion:*** Patterns of MMFTC should be recognized because of their significance in the correct diagnosis, due to significantly worse prognostic and treatment implications in such patients. ***References:*** Wang Y, Yin D, Ren G, Wang Z, Kong F. Mixed medullaryfollicular thyroid carcinoma: A case report and literature review. Oncol Lett. 2023 Aug 18;26(4):429. doi: 10.3892/ol.2023.14015.

EP-1223

PET/CT findings of primary cutaneous malignant rhabdoid melanoma of the shoulder: a case report

J. Charfi, *H. Boudriga, K. Ayed, T. Dardouri, A. Ezzine, M. Nouira, K. Chatti;*
Sahloul Hospital, Sousse, TUNISIA.

Aim/Introduction: Cutaneous melanoma is a tumor that develops from melanocytes in the skin. It is a rare neoplasia accounting for less than 5% of all skin cancers, but has the poorest prognosis. The four most frequently encountered histological

subtypes are superficial, nodular, malignant lentiginous and acrolentiginous malignant melanoma. Rhabdoid melanoma is an extremely rare subtype of cutaneous melanoma. In this poster, we embark on an exploration of the role of ^{18}F-FDG PET in the evaluation of this tumor. ***Materials and Methods:*** We report the case of a 35-year-old patient who presented in January 2023 with an abscessed cutaneous mass of the right scapular region. This mass was laid flat and then reappeared twice after 3 and 6 months in the same region as a hemorrhagic pigmented budding lesion excised each time.Pathological examination concluded that the lesion was a melanoma with rhabdoid differentiation.The rest of the clinical examination revealed no palpable axillary or cervical adenopathy, particularly on the right.Imaging examinations, notably cervical ultrasound and cervico-thoraco-abdomino-pelvic CT scan, were without abnormalities.He was referred for an ^{18}FDG PET-CT scan to complete the extension work-up.The patient underwent whole-body acquisitions after injection of 230MBq of ^{18}FDG. ***Results:*** The ^{18}FDG PET scan showed : A hypermetabolic centromedullary lesion of the right lower femur suggestive of secondary lesion.Hypermetabolic submandibular and upper left jugulocarotid lymph nodes associated with homolateral dental focus suggesting an inflammatory originHomogeneous osteomedullary hypermetabolism.The centromedullary lesion of Diffuse, globally homogeneous hypermetabolism of the right scapular region probably due to a reactive origin(recent surgery). The right femur was checked by MRI, which showed clear signs of malignancy and the patient underwent local radiotherapy at a dose of 45Gywith good evolution. ***Conclusion:*** Rhabdoid melanoma is a very rare histological subtype of cutaneous melanoma, with a very poor prognosis. With its high sensitivity for melanoma metastases, particularly bone metastases, ^{18}FDG PET is proving to be a powerful imaging tool for the extension assessment of these aggressive tumors ***References:*** Till Heusner a , Philipp Gölitz a , Monia Hamami b , Wilfried Eberhardt c , Stefan Esser d , Michael Forstinga et al."One-stop-shop" staging: Should we prefer FDG-PET/CT or MRI for the detection of bone metastases?.European Journal of Radiology 78 (2011) 430-435

EP-1224

Multiple enchondromatosis in Ollier's disease. Can bone scintigraphy be useful in detection of malignant progression?

S. E. Prisco[1], *M. Rapa[1], A. Romeo[1], A. Golemi[2], M. Santoro[2], S. Zoboli[2], P. E. Orlandi[3], S. Fanti[1,2];*
[1]Nuclear Medicine, Alma Mater Studiorum University of Bologna, Bologna, ITALY, [2]Nuclear Medicine, IRCCS, Azienda Ospedaliero-Universitaria di Bologna, Bologna, ITALY, [3]Radiology Unit, Maggiore Hospital, Bologna, ITALY.

Aim/Introduction: Ollier syndrome is a rare genetic condition characterized by numerous enchondromas within the long bones, especially at the epiphyses and metaphyses. The enchondromas can vary in size and cause bone deformities, growth retardation and limitations in joint mobility. Up to 50% of patients with Ollier syndrome develop a malignancy over time. In this context, active surveillance is useful for early diagnosis. ***Materials and Methods:*** A 47-year-old woman with congenital hypoplasia of the left appendicular skeleton and diagnosis of Ollier disease has been complaining for months of knee pain that worsenes at rest and flexion and decreases during deambulation. An initial X-ray of the left knee showed osteolytic area predominantly in the proximal epiphyseal region of the tibia. Subsequent TC and MRI demonstrated polylobular neoformative process in the region previously described on RX deserving of bioptic investigation. The diagnosis at biopsy was atypical cartilage tumour. Bone scintigraphy was performed to studied other bone district. ***Results:*** A two phase SPECT-TC bone scintigraphy with 99mTc-HDP was performed. It showed an intense uptake in the early blood pool phase and a very intense focal uptake at the left tibial lesion with central reduction of uptake in relation to the presence of the malignant lesion described at previous imaging studies. The degree of uptake was visually different from that showed in other multiple bone segments, particularly at the level of the left iliac wing, right head and proximal third of femur, scapula, proximal left humerus, left second and third ribs, proximal third of right fibula and distal third of right tibia consistent with cartilage malformations at increased phospho-calcium turnover. The patient underwent surgical excision of the lesion. Eight months after surgery, a subsequent MRI showed local recurrence so a resection of the proximal tibia with bone graft and joint arthroplasty was performed. ***Conclusion:*** Bone scintigraphy proves useful in detecting multiple bone localisation in genetic syndromes such as Ollier syndrome. Moreover, in this case, the simultaneous presence of the benign lesion and the malignant one allows a direct visual comparison between the degree of uptake of the two types of lesions. Bone scintigraphy is useful in determining the true extent of bone changes in patients with predisposing genetic conditions. Additionally it may allow suspicion of malignant progression based on uptake intensity, but more studied are needed.

EP-1225

Unexpected focuses of metastasis in a patient with thyroid and breast cancer: what is the source of the metastasis?

A. Özdal[1], *T. Seber[2], S. Karaçavuş[1];*
[1]University of Health Sciences Turkey, Kayseri City Training and Research Hospital, Department of Nuclear Medicine, Kayseri, TÜRKIYE, [2]University of Health Sciences Turkey, Kayseri City Training and Research Hospital, Department of Radiology, Kayseri, TÜRKIYE.

Aim/Introduction: Thyroid cancer is an endocrine malignancy whose incidence has been increasing in recent years. It is often associated with breast cancer. Although it's a cancer with a good prognosis, the stage of diagnosis is important in determining the survival. The aim of this case report is to emphasize rare metastatic sites in a patient with thyroid cancer and concomitant breast cancer who was not staged at the time of diagnosis and was not followed up subsequently. ***Materials and Methods:*** case datas were evaluated ***Results:*** A 65-year-old female patient diagnosed with thyroid follicular carcinoma underwent right thyroid lobectomy in 2004, but was not followed up postoperatively. The patient received chemoradiotherapy after breast mastectomy in 2020. In 2021, F^{18} FDG PET/CT study showed diffuse metastatic nodular lesions in both lungs and metastatic lytic expansive lesions in the skeletal system. The pathological results of tru-cut biopsy obtained from lung and bone tissue was found to be compatible with thyroid carcinoma metastasis. The patient underwent a complementary left lobectomy operation. The patient, who had not received radioactive iodine therapy (RAI) before, received 200 mCi and 230 mCi RAI in 2022 and 2023 due to elevated Tg during follow-up. Control PET/CT study revealed multiple nodular lesions in both lungs, lytic sclerotic lesions in the bones, hypermetabolic nodules on the anterior abdominal wall at the level of the suprapubic region and under the skin at the level of the posterior right scapula. Incisional biopsy was performed on the lesion defined at the suprapubic region. The biopsy result

was reported as compatible with thyroid carcinoma metastasis. Simultaneous contrast-enhanced abdominal MRI study showed prominent contrast enhancing mass lesions in both kidneys after IV contrast and was accepted as thyroid carcinoma metastasis with the decision of the radiology council. ***Conclusion:*** In recent years, many studies have suggested possible bidirectional relationship between breast cancer and thyroid cancer. In the literature, renal and skin metastases are reported to be very rare in follicular thyroid cancer. In our patient, who was also diagnosed with breast cancer, metastatic lesions observed in the lung, kidney, bone and skin were found to be of thyroid origin by biopsy. In the postablative scanning study, the lesions detected on PET-CT and MRI images were found to be densely iodinated. Correctly identifying the source of metastases in patients with both types of cancer is crucial for treatment and prognosis.

EP-1226

Old but still gold: Nuclear Medicine technique still the best way to non-invasively detect thoracic splenosis.

***F. Serani*[1],** *A. Cinquino*[1]*, M. Mattoli*[1]*, R. Vezzaro*[2]*, F. Marino*[3]*, A. Spacone*[4]*, A. Di Nicola*[1]*;*
[1]"Spirito Santo" Hospital, Nuclear Medicine, Pescara, ITALY,
[2]"Spirito Santo" Hospital, Radiology Unit, Pescara, ITALY,
[3]"Spirito Santo" Hospital, Thoracic Surgery Unit, Pescara, ITALY,
[4]"Spirito Santo" Hospital, Pneumology Unit, Pescara, ITALY.

Aim/Introduction: Thoracic splenosis (TS) is a rare condition characterized by the autotransplantation of splenic tissue into the chest cavity, typically following splenic trauma or surgery.A 39-year-old Caucasian man presented to the emergency department of our center for an acute exacerbation of its known chronic neck pain and an outpatient standard chest X-ray showing a suspicious left upper mediastinal enlargement with dimensions 27x18mm. ***Materials and Methods:*** Patient's medical history included smoke (10 cigarettes per day) and a past splenectomy and left nephrectomy consecutive to a severe gun accident. The patient still had retained bullets and could not have taken a magnetic resonance (MR) for his neck pain.In the ER a chest contrast enhanced CT confirmed the presence of a solid, expansive mass in the left hemithorax, located in the costovertebral angle of the second rib, pertaining to the pleura, with regular outlines and axial diameters of approximately 32x6mm, which infiltrates the extra-pleural adipose tissue, located in the upper posterior left mediastinum. The mass, probably of pleural or ganglionic origin, which showed contrast enhancement, could not be better classified. An inhomogeneous neoformation of the left adrenal gland was reported. In the suspect of neoplasia, either originating from pleura or from the nervous ganglia a 2-fluorine-18-deoxyglucose positron emission tomography/computed tomography (FDG PET) was required, which showed no pathologic uptake.In the context of a multidisciplinary board, the medical history and all the available imaging were reviewed, and a suspect of splenic residue was detected. After case revision and according to patient's medical history, a diagnosis of thoracic splenosis (TS) was suspected. The planning for a biopsy of the left mediastinal mass was, therefore, suspended. A spleen scintigraphy with [99mTc]Tc-nanocolloid was proposed to confirm the suspected diagnosis of TS. Scintigraphy was performed with antero-posterior planar images acquisition of the thorax and upper abdominal region after around 30 minutes from the injection of 170 MBq of [99mTc]Tc-nanocolloid in the right arm. ***Results:*** The images demonstrated uptake corresponding to the known thoracic mass,confirming the diagnosis of TS. Based on the scintigraphy results, a biopsy of the mass was avoided. This approach prevented unnecessary aggressive procedures and allowed the patient to focus on managing his neck pain. ***Conclusion:*** This case highlights the importance of considering "old" techniques in the constantly evolving field of Nuclear Medicine, reminding us that spleen scintigraphy with [99mTc]Tc-nanocolloid offers a valuable tool for confirming the diagnosis of TS and avoiding unnecessary biopsies.

EP-1227

Histopathological proven papillary thyroid cancer in Marine-Lenhart syndrome, A therapeutic dilemma.

P. Nemutaduni, *N. Zondi, N. Nyakale;*
Sefako Makgatho health sciences university, Pretoria, SOUTH AFRICA.

Aim/Introduction: A variant of Graves' disease where there are coexistent autonomous thyroid nodules is referred to as Marine-Lenhart syndrome. The most definitive management is radionuclide therapy and thyroidectomy ***Materials and Methods:*** This study involved a 23-year-old female with a slow growing anterior neck mass for 4 years. The diagnosis was made on the basis of thyrotoxicosis, elevated thyroid stimulating hormone receptor antibody I, scintigraphy and ultrasound (U/S). ***Results:*** On U/S, both lobes appeared enlarged L>R. The left lobe had heterogeneous echotexture with increased flow and a solid heterogeneous mass. On scintigraphy the left lobe appeared heterogeneous with an area of photopenia seen in the inferior pole. Technitium 99m Methylene di iso betyl iso nitrile (MIBI) did not show any avidity in the left lobe. Fine needle aspiration biopsy confirmed papillary thyroid cancer (PTC) and a total thyroidectomy was done. Iodien123 scan diagnostic scan done under TSH of >100 after 6 weeks revealed residual tissue in the neck, lytic skull lesion and cervical lymph node. Iodine 131 therapy was given. The patient was lost to follow up and treatment response scan was not done. The patient had stopped Eltroxin and was admitted in a psychiatric hospital for psychosis . On recovery TG was 0,3 and T4 of 18.6 . A year later, the patient fell pregnant, and treatment had to be halted until 5/12 post-partum. Breast feeding was stopped prior iodine 123 scan. The maximally TSH stimulated scan showed intense uptake in the breast bilaterally and a new iodine 123 avid lesion in the right distal femur. All other previous lesions were not visualized. A multi-disciplinary team comprising of orthopedic and NM team reached a consensus to perform a magnetic resonance study (MRI) which confirmed a small eccentric sub periosteal lesion in the right femoral medial metaphysis. The orthopedic team was reluctant to operate on the basis of possible complications including future revision and infection. Two more doses of iodine 131 therapy were given with an accumulative dose of 346 mCi. The scan done 6 months after the last dose showed no residual disease. ***Conclusion:*** The co-existence of Graves' disease with a cold nodule warrants further investigation that will help to exclude malignancy. In a patient with marine Lenhardt syndrome and proven PTC, Iodine 131 is a reliable therapeutic option even in complicated cases aiding in rendering the patient disease free and likely improve the quality of life.

EP-1228

A patient with heart transplantation and Quilty lesion at endomyocardial biopsy: ^{18}F-FDG PET/CT findings

A. Franchini, *A. Scarale, A. Spataro, G. Cabrini, E. Gay, C. Rossetti, S. Capitanio;*
Nuclear Medicine Unit, Dipartimento Ematologia, Oncologia e Medicina Molecolare, ASST Niguarda Hospital, Milan, ITALY, Milan, ITALY.

Aim/Introduction: Heart transplantation represents the best therapeutic opportunity in terms of survival benefit for patients with end-stage heart failure. Acute rejection represents the main complication to this procedure. Early diagnosis and grading of acute rejection are of pivotal importance in the clinical management of heart recipients. In this setting, percutaneous endomyocardial biopsy (EMBs) remains the standard method for surveillance of allograft rejection after heart transplant.Beyond acute rejection, the presence of nodular endocardial inflammatory infiltrates represents another possible histologic finding observed in EMBs. This finding, known as Quilty lesion, seems to be an indicator of previous acute cellular rejection probably correlated with cardiac allograft vasculopathy. In this case report we show a Quilty lesion detected by ^{18}F-FDG PET/CT. ***Materials and Methods:*** CASE REPORT: a 48-year-old man underwent orthotopic cardiac transplantation for obstructive hypertrophic cardiomyopathy. This patient developed two episodes of acute rejection respectively after 54 and 82 days from transplantation and was admitted to our hospital for follow up investigations.A new endomyocardial biopsy was performed one year after transplantation and showed a lymphocytic infiltrate suggestive for Quilty lesion although a low-grade lymphoproliferative disorder could not be ruled out with certainty. For this reason, it was decided to submit the patient to a 18F-FDG PET/CT scan after 12 hour fasting and under high-fat, low-carbohydrate diet for at least 24 hours before the scan, in order to assess the possible presence of cardiac myocardial inflammatory infiltrate even excluding a lymphoproliferative disorder. ***Results:*** 18F-FDG PET/CT showed an intense focal myocardial uptake of the tracer at the left ventricular walls, particularly at the apex with extension to the distal portion of the septal, anterior and inferior walls and at the basal portion of the lateral wall. No other pathological extra-myocardial site of significant uptake were found. ***Conclusion:*** This case report underlines the utility of ^{18}F-FDG-PET in the identification of myocardial inflammatory burden in cardiac transplanted patients. The presence of an intense cardiac uptake was consistent with the presence of inflammatory infiltrate demonstrated by the biopsy support the hypothesis of Quilty lesion.The non-invasive nature of ^{18}F-FDG-PET together with its capability to detect inflammatory infiltrate, could be potentially helpful in clinical management of cardiac transplant patients. ***References:*** Cho, Haeyon et al. "Quilty Lesions in the Endomyocardial Biopsies after Heart Transplantation." Journal of Pathology and Translational Medicine Awad, Morcos A et al. "Current status and outcomes in heart transplantation: a narrative review."

EP-1229

Safety of elevated pulmonary doses from [^{177}Lu]Lu-PSMA-617 and ^{90}Y-radioembolization therapies

S. Jain, *S. A. Graves;*
University of Iowa Hospitals and Clinics, Iowa City, IA, UNITED STATES OF AMERICA.

Aim/Introduction: Treatment with [177Lu]Lu-PSMA-617 is generally considered safe from the point of view of lung radiation exposure, however elevated lung absorbed dose may result from some benign but chronic lung diseases. Although external beam radiotherapy-derived lung dose limits are available, the extrapolation to multi-cycle therapy with 177Lu-based agents may not accurately predict dose-effects. Similarly, lung shunting and dosimetry is crucial in the planning of liver-directed transarterial radioembolization (TARE) using Yttrium-90 labeled microspheres. Here we present a case with concern of higher lung exposure who underwent [177Lu]Lu-PSMA-617 therapy with dosimetry. Additionally, we report a case of a patient who underwent sequential TARE procedures resulting in cumulative lung dose in excess of the commonly accepted 50 Gy limit. ***Materials and Methods:*** Two cases were retrospectively reviewed, one patient undergoing therapy with [177Lu]Lu-PSMA-617 and one patient undergoing therapy with TARE - in both cases the patients received much greater than typical cumulative lung doses for their respective therapeutic agents. ***Results:*** Case 1: A 65-year-old male with metastatic castration resistant prostate cancer underwent [68Ga]Ga-PSMA-11 PET/CT scan prior to [177Lu]Lu-PSMA-617 therapy. He had a history of occupational lung disease and the imaging revealed diffusely increased PSMA uptake in both the lungs. He underwent 4 cycles of [177Lu]Lu-PSMA-617 therapy (7.4 GBq) with post-therapy dosimetry for cycles 1 - 3. Dosimetry following cycles 1, 2, and 3 revealed lung doses of 7.45 Gy, 4.18 Gy, and 3.4 Gy, respectively, for an estimated cumulative lung dose of ~18 Gy. No adverse pulmonary effects were observed. Case 2: A 71-year-old male with renal cell carcinoma metastatic to the liver underwent seven sequential liver directed therapies. The estimated lung doses (and lung shunt fractions) of 6.93 Gy (13%), 7.95 Gy (10.6%), 9.33 Gy (10.8%), 3.73 Gy (2.3%), 2.75 Gy (3.5%), 30.1 Gy (21%), and 13.8 Gy (18%) for the treatments 1,2,3,4,5,6 and 7, respectively, administered over 4 years. The estimated cumulative lung dose of ~75 Gy. No significant pulmonary adverse effects were observed. ***Conclusion:*** These cases demonstrate the value of routine dosimetry in optimizing systemic and liver directed radionuclide therapies. Although lung exposure from systemic 177Lu-based radiopharmaceutical therapies is typically quite low, benign lung conditions can result in significantly elevated pulmonary absorbed dose. For TARE, although some limits are used, additional data and reports are needed to confirm and refine our understanding of lung dose-effect relationships following radionuclide-based therapies. Additional cases of elevated lung exposure will be presented.

EP-1230

Radioguided Surgery in the Treatment of Lymphedema Secondary to Oncologic Lymphadenectomy.

D. Rodriguez Oviedo, *L. Castillejos Rodriguez, M. Alvarez Moreno, C. Galindo Fernandez, K. Guichay Duran, M. Tagliatori Nogueira, M. De La Rubia Marcos, C. Paniagua Correa, A. Herrero Muñoz, M. Garcia Alonso;*
Hospital Universitario de Getafe, Madrid, SPAIN.

Aim/Introduction: Radioguided surgery is a set of techniques developed between nuclear medicine and surgical services. Our work involves the use of lymphoscintigraphy (LG) to evaluate and locate the lymphatic drainage systems of the limbs. ***Materials and Methods:*** Vascularized lymph node transplantation (VLNT) is a promising technique for treating lymphedema. However, one of the main challenges of this procedure is selecting the right donor site for transplantation. The inguinal region is the most used location because it contains lymph nodes that drain from the lower limb and superficial abdominal region, which are optimal for the procedure. However, there is a risk of accidentally removing lymph nodes belonging to the lower limb, which can lead to iatrogenic lymphedema. To prevent this complication, nuclear medicine techniques such as standard lower limb LG are used. During surgery, an intraoperative gamma-detecting probe is used to locate the lymph nodes originating from the superficial abdominal system, while avoiding those originating from the limb. This allows the surgeon to selectively choose only those

lymph nodes that are ideal for the procedure when creating the flap. ***Results:*** Fig1. 47-year-old woman with invasive ductal breast carcinoma, treated with mastectomy, axillary lymphadenectomy, and adjuvant chemo-radiotherapy, developed secondary lymphedema. LG is performed according to standard protocol. Intraoperatively, lymph nodes draining the lower limb in the inguinal region (green arrow) are identified using a gamma-detecting probe (white arrow), to avoid their inclusion in the flap for VLNT, aiming to reduce iatrogenic lymphedema. Fig2. 45-year-old woman with invasive ductal breast carcinoma received the same treatment and developed secondary lymphedema. LG is performed according to standard protocol. In the operating room, after identifying the lymph nodes draining the lower limb in the inguinal region (green arrow), verification is conducted to ensure they are not present in the flap chosen for VLNT (blue arrow) using the gamma-detecting probe (white arrow), aiming to reduce the risk of iatrogenic lymphedema in the donor limb. After 16 weeks of follow-up, the patients have not exhibited any symptoms in the donor limbs, fulfilling the purpose of the procedure, making this technique safer, and reducing adverse effects. ***Conclusion:*** The use of nuclear medicine techniques in innovative surgical procedures and the treatment of highly morbid and difficult-to-control pathologies has the potential to make techniques safer and more efficient. Although more cases are needed to fully incorporate nuclear medicine into the VLNT protocol, the initial cases have shown promising results.

EP-1231

SUVmax in ^{18}F FDG-PET/CT in managment of the relapsed vasculitis : an example of tailored therapy.

C. Olianti, *D. Malandrino;*
University Hospital of Florence, Florence, ITALY.

Aim/Introduction: We tested the semiquantitative Standartized Uptake Value as index of disease metabolic hyperactivity during the pathway of a large vessel vasculitis to check if the variations of this index would be useful to asses therapy response, follow up, suspicion of relapse, confirmation of relapse and after fist line response to therapy. ***Materials and Methods:*** We compared the values of SUVmax in most relevant vessel districts in the acute phase, after therapy, first and second follow up and after first line CCS therapy in subsequent ^{18}F FDG-PET/CT whole body scan. An expert nuclear medicine on reumatologic/inflammatory disease revised all the wb-scans for a final opinion. ***Results:*** See Table 1.After high doses of corticosteroid we documented a reduction in SUVmax values measured at staging with normalization of flogosis indexes; an initial increment one year later and the confirmed suspicion or relapse some months later. The first line CCS therapy was attemped as first choice avoiding cyclophosphamide, more toxic and difficult to manage.The SUVmax vlues measured in all district allow to consider not so severe the pathologic hypermetabolism, and a few month later the final FDG-PET/CT confirmed a stability/reduction of SUVmax value after the first choice therapy. ***Conclusion:*** SUVmax is a useful tool to manage the disease trough the metabolic activity and help the immunologist to choice the first line more tolerable therapy and avoid toxicity of cyclosfamide. ***References:*** [1] Slart RHJA; Writing group; Reviewer group; Members of EANM Cardiovascular; Members of EANM Infection & Inflammation; Members of Committees, SNMMI Cardiovascular; Members of Council, PET Interest Group; Members of ASNC; EANM Committee Coordinator. EP-1232

Redistribution of Brain Metabolism during Autoimmune Encephalitis: Hypermetabolic Thalami: an amazing finding.

O. Bourogianni, *N. Kapsoritakis, G. Lamprakopoulos, A. Tsaroucha, M. Stathaki, E. Papadaki, S. Koukouraki;*
University Hospital of Crete, Heraklion, GREECE.

Aim/Introduction: Immunotherapy with chimeric antigen receptor T-cell (CAR-T) therapy is one of the most important advances in the treatment of cancer and, particularly, hematologic malignancies. In lymphoma, CAR-T cells targeting CD19 have been widely developed. CAR-T cell therapy is associated with high rates of unique toxicities, namely cytokine release syndrome and neurotoxicity. Neurotoxicity is recognized as a frequent and major complication in patients receiving CAR T cell therapy. There is a rather narrow time window associated with the occurrence of CAR T cell-related neurotoxicity, starting around day 3 after T cell infusion and lasting until about 2 weeks later but a delayed onset of neurological complications is also possible. ***Materials and Methods:*** We present a case of a 68-year-old male patient with Diffuse Large B cell Lymphoma who received CAR T cell therapy. 6 months later the patient presented with impaired consciousness, confusion and delirium. As with complications due to other immunotherapeutic approaches, other causes that could explain the neurological condition should be ruled out with an appropriate diagnostic work-up. MRI of the brain showed unspecific T2/FLAIR hyperintensities in various regions but no generalized edema. CSF cultures and polymerase chain reaction assays for the detection of neurotrophic viruses (herpes simplex virus 1 and 2, human herpes virus 6 and 7, Epstein Barr virus, cytomegalovirus, enterovirus, parvovirus B19, adenovirus, and severe acute respiratory syndrome coronavirus-2) were negative. The patient underwent an ^{18}F-FDG PET/CT to exclude replase of lymphoma and involvement of central nervous system and treatment with steroids started. ***Results:*** ^{18}F-FDG PET/CT scan revealed an impressive predominance of thalamic hypermetabolism and hypometabolism in the other regions of the brain. During autoimmune insults to the brain, the metabolic redistribution suggested by our finding may contribute to preserving essential brain functions. None pathological finding was revealed from the whole body scanning and no evidence of lymphoma replapse was observed. ***Conclusion:*** ^{18}F-FDG PET/CT could be useful in the detection of neoplasia as the cause of encephalitis but surprisingly could be useful for detecting initial brain metabolic alterations in encephalitis in comparison to normal MRI, with brain region hypo/hypermetabolism.

EP-1233

Undifferentiated Pleomorphic Sarcoma : Does ^{18}FDG PET-CT scan surpass MRI ?

J. Charfi, *T. Dardouri, M. Bettaieb, H. Boudriga, S. Mensi, A. Ezzine, M. Nouira, K. Chatti;*
Sahloul Hospital, Sousse, TUNISIA.

Aim/Introduction: Undifferentiated Pleomorphic Sarcoma (UPS), formerly known as malignant fibrous histiocytoma (MFH), represents an heterogenous and challenging entity within the soft tissue sarcomas. Its aggressive behavior and variable clinical

presentation, poses significant diagnostic and therapeutic dilemmas for clinician.In recent years, positron emission tomography with ^{18}F-fluorodeoxyglucose (^{18}F-FDG PET) has emerged as a valuable tool in the evaluation of UPS, offering insights into its metabolic activity and aiding in disease staging, response assessment, and treatment planning. In this poster, we aim to discuss the role of ^{18}F-FDG PET in UPS, shedding light on its contributions to staging, therapeutic decision-making and its constraints. ***Materials and Methods:*** We report the case of a 57-year-old patient who presented with muscle pain and swelling of the right thigh. After radiological exploration, the mass was biopsied. The histopathological examination favored an undifferentiated pleomorphic inflammatory sarcoma. The patient then underwent resection of the right anterior quadriceps muscle. The patient received four cycles of chemotherapy. A follow-up MRI showed the persistence of a tissue nodule in the resection compartment. The patient was then referred to our department for an ^{18}FDG PET-CT scan examination for evaluation and consideration of radiotherapy. Then after six months, he was referred to us again for evaluation. ***Results:*** The initial examination showed two intensely hypermetabolic tissue lesions on the anterior aspect of the right thigh. The first lesion, located near the femoral neck, exhibited heterogeneous solid-cystic characteristics (SUVmax=10.8). The second, a nodular lesion adjacent to the lateral vastus muscle, correlated with the MRI findings (SUVmax=7.5). Biopsy results from both nodules confirmed metastasis from the pleomorphic sarcoma, prompting local radiotherapy treatment. The patient returned for a post-therapeutic evaluation, revealing complete morpho-metabolic regression of the previously observed tissue lesions. However, a new hypermetabolic focus (SUVmax=6.9) emerged adjacent to the lateral vastus muscle at the mid-third of the right femoral diaphysis.Additionally, a deep mixed lesion within the right femoral muscle exhibited weakly hypermetabolic activity (SUVmax=3). Due to the intra- and interlesional heterogeneity typical of soft tissue sarcomas, a definitive malignant origin could not be conclusively determined. An MRI of the thigh performed favored a malignant origin instead. ***Conclusion:*** ^{18}F-FDG PET represents a powerful tool in the armamentarium against UPS, offering clinicians valuable insights into tumor biology and aiding in personalized treatment approaches on the condition that variations in the metabolism of soft tissue tumors, which may elude diagnosis, are taken into account.

EP-1234

Myelodysplastic syndrome presenting with bone marrow uptake on 68Ga-PSMA PET/CT

D. Barbosa, *H. Duarte, I. Próspero, D. Silva, N. Vasconcelos, J. Ferro, J. Teixeira, I. Sampaio;*
Portuguese Institute of Oncology, Oporto, PORTUGAL.

Aim/Introduction: Prostate-specific membrane antigen (PSMA) ligand uptake on positron emission tomography/computed tomography (PET/CT) can be found in non-prostate diseases, which is challenging and must be recognized to avoid misdiagnosis. As PSMA-avid hematological disorders are scarcely mentioned in the literature, we present the case of a patient with prostate cancer with 68Ga-PSMA bone marrow uptake attributable to a myelodysplastic syndrome. ***Materials and Methods:*** A 68-year-old man with prostate cancer, Gleason score 6 (3+3), initial prostate-specific antigen (PSA) 10ng/ml, cT1cN0M0, was referred to our institute for brachytherapy treatment. His previous medical history was irrelevant, normal preoperative blood count and no hematological/urological complaints. He remained under surveillance for 3 years, at which time biochemical recurrence was assumed (PSA: 6,750ng/ml) and 68Ga-PSMA-PET/CT was requested. ***Results:*** 68Ga-PSMA-PET/CT showed intense radiotracer uptake in the left seminal vesicle (SUVmax = 16,52) and in a right external iliac lymph node (SUVmax = 8,85), suggesting locoregional recurrence. Furthermore, diffuse and heterogeneous radiotracer bone uptake, with focal uptake in some costal arches and sternum (SUVmax = 4,31), were reported as undetermined etiology findings, but raising the hypothesis of some underlying hematological disorder. Most of the bone marrow uptake seen on 68Ga-PSMA-PET did not show corresponding lytic or sclerotic lesions on contrast-enhanced CT performed two months later. Further analytical investigation revealed anemia, leukopenia and thrombocytopenia and the patient reported asthenia. Hormonal therapy with goserelin was started. The patient underwent additional investigation, including myelogram and bone marrow biopsy from the iliac crest that revealed hypercellular bone marrow, with signs of trilinear dysplasia, compatible with involvement by myelodysplastic syndrome. The patient started erythropoietin and at this time (after starting goserelin and before starting erythropoietin), PSA value was 1,390ng/ml. During the 6 months of treatment with erythropoietin, the patient received 6 red blood cell transfusions with worsening fatigue. Erythropoietin was discontinued due to lack of response and chemotherapy with azacitidine was started. No new red blood cell transfusions had been needed since. Currently, 1 year after 68Ga-PSMA-PET/CT hypothesized a hematological disorder, and 9 months after the confirmed diagnosis of myelodysplastic syndrome, the patient remains on treatment with azacitidine (3rd cycle) and reported a clear improvement in his quality of life. ***Conclusion:*** The present case highlights that alternative diagnoses other than prostate cancer, including hematological diseases, should be considered in the presence of diffuse bone/bone marrow 68Ga-PSMA uptake.

EP-1235

Abnormal 99mTc-DMSA uptake in the lung, the spleen and the liver:report of four cases

H. Trabelsi, *M. Somai, H. Rokbani, I. Yeddes, S. Cherif, I. Slim, I. Meddeb, A. Mhiri;*
Salah Azaiez Institute, Tunis, TUNISIA.

Aim/Introduction: One of the most common problems associated with radiopharmaceuticals is abnormal unexpected biodistribution, which can have a significant clinical impact when interpreting scintigraphic images. We present four cases of extra-renal uptake of 99mTc-DSMA in the spleen, lung and liver, focusing on the possible molecular mechanisms involved. ***Materials and Methods:*** Case report: 99mTc-DMSA renal scintigraphy was performed on 30/01/2024 in six patients with recurrent urinary tract infections and/or vesico-ureteral reflux. The scintigraphic examinations of four of the six patients were found to be uninterpretable due to abnormal extra-renal radiotracer fixation. All patients received the same preparation, and were injected at the same time. ***Results:*** In the first two patients, normal fixation was found, exclusively renal with kidneys in place, evenly contoured, with no detectable cortical defects. In the third patient, five hours after injection of 2mCi of 99mTc-DMSA, scintigraphy showed homogeneous renal fixation with distribution in both lung fields. The fourth patient was a 7-month-old child who received 1.4mCi of 99mTc-DMSA. Scintigraphic images obtained after 5h post-injection showed abnormal radiotracer uptake in the spleen, liver and lung, with more intense uptake in the spleen. The last two

patients received 1.5mCi and 1.6mCi of 99mTc-DMSA respectively, and presented a similar appearance, with intense uptake in the lungs and to a lesser degree in the kidneys and liver. ***Conclusion:*** Despite our well-established knowledge of the biodistribution of the various radiopharmaceuticals, we are sometimes confronted with unsuitable and unforeseen fixations that can compromise the interpretation of the examination, hence the importance of checking the chain of preparation and injection of the radiopharmaceutical to identify its origin in time. ***References:*** Abnormal focal 99mTc-DMSA uptake in the lung — report of two casesElahe Pirayesh1, Mahasti Amoui1, Ali Asghar Halimi Asl2, Majid Assadi3Altered Biodistribution of Radiopharmaceuticals: Role of Radiochemical/Pharmaceutical Purity, Physiological, and Pharmacologic FactorsShankar Vallabhajosula, PhD, Ronan P. EP-1236

Impact of delaying radioiodine in high-risk thyroid cancer patients: a retrospective analysis in Mexican population after COVID-19 due to hospital saturation

S. Medina-Ornelas;
Ángeles Lindavista, Mexico City, MEXICO.

Aim/Introduction: The optimal time for initiating radioactive iodine (RAI) therapy for differentiated thyroid cancer (DTC) patients is controversial. we investigate the relationship between the timing of initiating RAI and the clinical response based on dynamic stratification risk in high-risk DTC patients in the Mexican population after COVID-19 due to hospital saturation. ***Materials and Methods:*** We evaluated 71 patients with high-risk DTC who received a dose of RAI to 150 - 200 mCi and were retrospectively reviewed. the patients were divided into 2 groups agreeable initial therapy (between total thyroidectomy and initial RAI), called time interval therapy (TIT): Group A: TIT < 3 months (n=34), and Group B: TI ≥ 3 months (n=37). Six and twelve months after RAI, we followed up on these patients and evaluated the therapy response with neck ultrasound, whole-body scan SPECT/CT, and measures of thyroglobulin and antibodies anti-thyroglobulin. According to the therapy stratification system, the therapy responses to RAI were assessed as either excellent response (ER), biochemical incomplete response (BIR), indeterminate response (IR), or structural incomplete response (SIR) at every follow-up. We conducted a univariate and multivariate analysis to determine different factors associated with different responses. A $p < 0.05$ was considered to be statistically significant. ***Results:*** the overall response to RAI was statistically significantly different between 2 groups during dynamic follow-up, Group A had significantly lower SIR rates (33.4 vs 65.8 and 48.7 vs 70.2, all P<0.05, respectively) and higher ER rates (35.7 vs 16.9 and 40.6 vs 19.6, all P<0.05, respectively) than group B during dynamic follow-ups. By univariate and multivariate analyses, prolonged TIT (HR: 7.44, 95%CI: 2.891-17.621, P=0.001), soft tissue invasion (HR: 6.88, 95%CI: 1.902-29.454, P=0.004), metastatic disease (HR: 7.79, 95%CI: 2.805-24.886, P=0.002) were manifested to be independent risk factors for IR, SIR and BIR. The highest levels of thyroglobulin before starting treatment were also an independent risk factor for BIR (p=0.045). Doses of 200 mCi were not significant in both groups (p=0.28) but had an increase more adverse events. Only patients with micronodular lung metastatic disease had a decreased number of lung lesions with higher doses ***Conclusion:*** Starting treatment with RAI early is associated with greater biochemical response, except in patients with the initial highest levels of thyroglobulin. ER is higher in patients who start treatment early. Delayed initial RAI (≥3 months after thyroidectomy) is associated with poor response.

EP-1237

Brain Glucose Metabolism is altered in COVID-19 disease: An activation likelihood estimation Meta-analysis

K. Pak[1,2], *D. Kang[2], H. Jung[2];*
[1]Pusan National University Hospital, Busan, KOREA, REPUBLIC OF, [2]Pusan National University, Busan, KOREA, REPUBLIC OF.

Aim/Introduction: COVID-19 disease, which is caused by infection of the SARS-CoV-2 virus has brought massive changes to modern society and lifestyle. Thus, by comparing brain glucose metabolism of patients with COVID-19 disease with healthy controls, we can identify the brain regions affected by COVID-19 disease. ***Materials and Methods:*** We performed a systematic search of MEDLINE/EMBASE for English-language publications using the keywords of "positron emission tomography", "single-photon emission computed tomography", and "COVID-19". The inclusion criteria were original research articles that reported the changes in brain glucose metabolism after COVID-19 disease. For each experiment, the modeled activation map is calculated by finding the maximum across each focus's Gaussian. For each voxel, the ALE value is calculated from the union of the modeled activation map. ALE values were combined across studies and tested against a null hypothesis of random distribution of ALE values, which are higher than could be expected by chance. A threshold of FWE 0.05 for both cluster-level forming thresholds and 0.05 for cluster-level inference was applied to the resulting ALE map. ***Results:*** Eight papers were deemed suitable for inclusion in the study. Two studies reported increased brain glucose metabolism from 19 COVID-19 disease patients after comparison with 58 controls. A significant increase in brain glucose metabolism was observed in the left anterior cingulate gyrus, right thalamus, brainstem. Studies of hypometabolism in COVID-19 disease were categorized into subgroups according to 1) the patient's age, and 2) the time interval between COVID-19 disease and PET scanning. In children with COVID-19 disease, we observed the decreased glucose metabolism in 5 regions including cerebellum, left amygdala/hippocampus, left anterior cingulate gyrus, right amygdala. In adult with COVID-19 disease, we found one hypometabolic cluster: right temporal lobe. We divided the studies into 2 groups according to the time interval between COVID-19 disease and PET scanning. In acute phase of COVID-19 disease, hypometabolism was observed in right temporal lobe and brainstem. In chronic phase, hypometabolism was observed in 7 clusters: left posterior cingulate gyrus, left precuneus, right cerebellum, right insula, right anterior cingulate gyrus, left occipital lobe, left globus pallidus. ***Conclusion:*** COVID-19 disease alters brain glucose metabolism. COVID-19 disease generally manifests on 18F-FDG PET as areas of decreased brain glucose metabolism, however, there can be areas of increased brain glucose metabolism. This decrease of brain glucose metabolism was dependent on the patients' age, and the time interval between COVID-19 disease and PET scanning.

EP-1238

Characterization of a Group of COVID-19 Patients Who Underwent V/Q Scintigraphy.

P. Parra, *F. Pardo, B. Bardessi, I. Diaz, C. Waeger, P. Canales, F. Aguila, N. Covarrubias;*
Pontificia Universidad Católica de Chile, Santiago, CHILE.

Aim/Introduction: The study focuses on assessing COVID-19 patients to detect pulmonary thromboembolism (PE) using ventilation/perfusion (V/Q) scintigraphy. Given the potential for severe pulmonary complications like PE, precise diagnostic tools are essential. While pulmonary angiography via computed tomography (CT angiography) is common, it has limitations. Thus, V/Q scintigraphy is proposed as a non-invasive and safe alternative. ***Materials and Methods:*** Retrospective study analysed 25 confirmed COVID-19 patients who underwent V/Q scintigraphy between March 2020 and May 2023 at a centre in Santiago, Chile. Demographic and clinical data, including age, gender, comorbidities, and additional test results, were collected. ***Results:*** Results indicated that most patients were elderly with comorbidities like hypertension and type 2 diabetes. The majority had received at least one dose of the COVID-19 vaccine. Analysis of V/Q scintigraphy revealed PE in 48% of patients, with most showing a single defect in the study. ***Conclusion:*** In conclusion, V/Q scintigraphy appears valuable in detecting PE in COVID-19 patients, especially those with comorbidities. However, larger prospective studies are necessary to confirm these findings and better understand its role in various disease stages. ***References:*** Konstantinides SV, Meyer G, Becattini C, et al. Spontaneous Remission of Advanced Follicular Lymphoma Following SARSCOV-2 Infection: A Case Report

M. Sanchez Torrente, *S. Martin Aguilar, A. Santos Bueno, H. Palacios Gerona, M. Ureña Lara;*
Hospital Universitario de Jaen, Jaen, SPAIN.

Aim/Introduction: Follicular lymphoma is the second most common subtype of lymphoma worldwide and the most common of the indolent lymphomas. Patients usually present with asymptomatic lymphadenopathy and advanced disease. Patients with asymptomatic and low burden disease are managed in a watch and wait approach and patients with high tumor and/or symptomatic disease are treated with immuno-chemotherapy. There are few case reports about lymphoma remissions after bacterial or virus infections, including recently the SARSCOV-2 infection, suggesting that the infection can trigger the immune system against the tumor cell.Here, we show the case of a patient with advanced follicular lymphoma that presented spontaneously remission after a SARSCOV-2 infection. ***Materials and Methods:*** We present a 53 year old male patient diagnosed with follicular lymphoma, E-IV FLIPI-2 (intermediate risk), in 2019. He achieved a complete response after treatment with R-CHOP + Rituximab maintenance regimen. Subsequently, ^{18}F-FDG PET-CT showed a relapse in September 2023.He was admitted to the hospital with severe bilateral pneumonia due to SARSCOV-2 in December 2023, and was only treated with antibiotic and corticosteroid treatment. Since the SARSCOV-2 infection prevented from considering the possibility of starting lymphoma treatment. ***Results:*** Once the patient is discharged after partially recovering from his pneumonia. ^{18}F-FDG PET-CT was performed in March 2024, to reevaluate the lymphoma due to suspected evolution in the absence of treatment, showing a marked decrease in metabolic activity and size of all lesions. Since the patient did not receive treatment, the study suggests partial response due to immune response induced by SARCOVS-2 infection. ***Conclusion:*** The response/remission of lymphomas induced by SARSCOV-2 infection, although it is rare, some cases have been described. We consider it important to exhaustively assess the patient's clinical history and be aware of this possibility, in order to carry out a correct evaluation of the patient.

EP-1240

Estimation of the carbon footprint of a french nuclear medicine department

C. Drouet[1], *J. Oosthoek[2], P. Léo[1], E. Fontaine[1], M. Dahmani[1], L. Houot[1], M. Quermonne[1], A. Cochet[1], F. Godard[1];*
[1]CGFL, DIJON, FRANCE, [2]Aktio, PARIS, FRANCE.

Aim/Introduction: In France, the Health sector accounts for about 8% of the national greenhouse gas (GHG) emissions. We estimated the carbon footprint of our nuclear medicine department with the help of Aktio, a specialized consulting firm. ***Materials and Methods:*** The estimate of GHG emissions comprises direct and indirect emissions. Direct emissions are due to fuels consumption (by the hospital and by hospital's vehicles), refrigerant leaks and impact of buildings on biomass (land use change). Indirect emissions include upstream and downstream emissions. Upstream emissions are linked to electricity and heating consumption, transport of merchandises, transport of patients and employees, business travels, purchases, and fixed assets. Downstream emissions are due to usage and disposal of manufactured products created by the hospital. Different GHGs (CO2, CH4, N2O, fluorinated gases...) each have a different global warming potential. To aggregate all GHG emissions, the results were expressed in carbon dioxide equivalent (CO2e). For this purpose, we used Aktio tools, and emissions factors from the french database Base Empreinte. We also used a few emission factors from the US Environmental Protection Agency. ***Results:*** in 2022, 13 303 diagnostic and therapeutic procedures were performed in our department, for an estimated carbon footprint reaching 772 tons of CO2 equivalent. This value corresponds to the mean annual carbon footprint of 78 french citizens, or to 27 kgCO2eq per patient visit in our department. Transport of people accounts for 66.4% of total emissions: 60.3% due to patients

travelling to and from the hospital, 4.6% to professionals travelling from home to work and 1.5% to medical missions outside the hospital or attendance to scientific conferences. Of note, 96% and 99% of patients and employees transport relies on combustion-powered vehicles, respectively. Transport of merchandises only accounts for 0.4% of total emissions. Purchases are responsible for 13.6% of total emissions: 11.8% due to radiotracers supply and the rest due to ink, paper, disposable examination sheets and small office supplies. Imaging devices (2 PET/CT, 2 SPECT/CT and 1 cardiac imaging dedicated CZT camera) account for 5.5% of emissions. Real estate, IT infrastructure and furniture account for 2.1%, 1.5% and 0.1%, respectively. Energy consumption accounts for 6.9% of total emissions: 4% for electricity and 2.7% for heating by heat network. ***Conclusion:*** Our emissions are mainly due to indirect emissions, which is a common result in tertiary sector. This estimate is the first step to understanding and controlling our emissions as much as possible.

EP-1241

The use and effect of listening to music to reduce anxiety in patients during PET/CT imaging protocol

O. Ekmekcioglu[1], *M. Calis[2], A. I. Yasin[3], E. Pirdogan Aydin[4];*
[1]University of Health Sciences, Nuclear Medicine Department, Sisli Etfal Education and Research Hospital, Istanbul, TÜRKIYE,
[2]University of Health Sciences, Radiation Oncology Department, Sisli Etfal Education and Research Hospital, Istanbul, TÜRKIYE,
[3]University of Health Sciences, Medical Oncology Department, Sisli Etfal Education and Research Hospital, Istanbul, TÜRKIYE,
[4]University of Health Sciences, Department of Psychiatry, Sisli Etfal Education and Research Hospital, Istanbul, TÜRKIYE.

Aim/Introduction: Most of the patients who come for PET/CT scans are oncology patients and feel a certain level of anxiety. However, it is observed that the anxiety level of patients additionally increases during the PET/CT preparation phase. This study aimed to observe the anxiety levels of patients during the technical preparation phase during the PET-CT scan and to investigate whether listening to meditative music, which is officially reported to be calm and relaxing, affects reducing the patient's anxiety. ***Materials and Methods:*** To perform $^{[18F]}$FDG-PET/CT scanning, 28 patients (14 experimental and 14 control groups) aged 30-81 years (mean 60 ±15 SDTS), who were referred for scanning from the oncology clinic, were included in the study. The number of men and women in each group was selected equally. The study, which was conducted with informed consent, was conducted using the short version of the Spielberger State and Trait Anxiety Inventory (STAI-S). The pre-procedure survey focused on demographic information, oncological status, and pre- and post-procedure subjective perception of anxiety and STAI testing. During the PET-CT technical preparation phase, the experimental group was given headphones and information to listen to quiet music during the post-injection waiting period of approximately 45-60 minutes, and they were asked to fill out the questions in the survey form before and after the music. ***Results:*** Significant differences were found between the intervention group and controls in terms of the effect of music listening on the anxiety score on the short version of the Spielberger State-Trait Anxiety Inventory (STAI-S) in patients. The patient group listening to music presented lower mean scores on the STAI state anxiety scale post-intervention and showed statistically significant differences with the control group ($P<0.005$). ***Conclusion:*** Our study shows statistically that relaxing meditative music can be used as a complementary method for psychological relaxation and anxiolytic mechanisms in patients during the technical preparation phase before PET-CT studies. In this context and in light of our results, the details of the patient preparation phase, which is one of the issues where quality standards in nuclear medicine units can be increased, and the importance of the support of the technical team with whom we work one-on-one on technical details in the field, were also emphasized.

EP-1242

Adverse Drug Reactions in Radiopharmaceutical Therapy for Bone Metastases: A Comprehensive Review of ^{89}Sr, ^{153}Sm, and ^{186}Re Safety Reports from 1991 to 2022

Â. Jesus[1], *C. Pinho[1,2], S. Martins[3,1,2], A. Martín-Suaréz[3];*
[1]LAQV/REQUIMTE, Escola Superior de Saúde, Instituto Politécnico do Porto, Porto, PORTUGAL, [2]Instituto Português de Oncologia do Porto FG, EPE, Porto, PORTUGAL,
[3]Universidad de Salamanca, Institute of Biomedical Research of Salamanca, Salamanca, SPAIN.

Aim/Introduction: Bone metastases are one of the most frequent complications of advanced cancers and a therapeutic option is the use of radiopharmaceuticals, which can cause adverse drug reactions (ADRs). Despite its use on a smaller scale, compared to other drugs, radiopharmaceuticals can cause ADRs and it is extremely important to update knowledge about these, in order to allow their detection, understanding, evaluation and prevention. This study aimed to analyse the individual case safety reports (ICSRs) of suspected ADRs related to the active substances 89Sr, 153Sm and 186Re (all with β– decay), obtained through spontaneous reporting, and recorded in the EudraVigilance, VigiAccess, Spanish Pharmacovigilance System (FEDRA) and Portuguese National Pharmacovigilance System databases between 1991 and 2022. ***Materials and Methods:*** This observational and cross-sectional study analysed the ICSRs of suspected ADRs to the radiopharmaceuticals 89Sr, 153Sm and 186Re . Data collected was analysed according study variable: number of cases reported per year; identification of the medicine associated with ADRs; identification of the origin of the notification; demographic characterization of the population affected by ADRs and characterization of the type of ADRs reported. ADRs were manually coded by System Organ Classes (SOC) according to the MedDRA 25.1 dictionary. ***Results:*** Most reports pertained to male individuals (66,5% in EudraVigilance, 73,5% in VigiAccess and 77,8% in FEDRA) between 18 and 85 years of age. Health professionals were the primary source of these reports (88.6% in EudraVigilance and 100.0% in FEDRA). The largest number of ADRs reported belong to the SOC "diseases of the blood and lymphatic system" (26.1% of ADRs in EudraVigilance; 20% of ADRs in VigiAccess and 28.6% of ADRs in FEDRA). EudraVigilance is the database that provides more information, with 94,5% of ADRs being considered serious and 26,1% of cases declared fatal. ***Conclusion:*** The fact that only 975 ADRs were reported over 31 years in the analysed databases may be due to underreporting and as such, it is extremely important that healthcare professionals and patients themselves are more alert and more involved in pharmacovigilance of radiopharmaceuticals. The limited data of adverse events makes it challenging to detect rare or unexpected reactions, as large datasets are often needed to identify signals for uncommon ADRs.

EP-1243

Remote reporting in Nuclear Medicine: no more a vision of the future

A. Miceli, *R. Piva, E. Pomposelli, L. Tommasi, H. Rouhanifar, M. Deserventi, D. Ricci, A. Muni;*
AOU SS Antonio e Biagio e C. Arrigo, Alessandria, ITALY.

Aim/Introduction: With the great digital development in Nuclear Medicine during the last decades and worldwide internet connections, remote reporting is not a mirage and is more and more feasible. Many organizational, technical, and legal issues have limited, up to now, the spread of the application of remote reporting systems. The COVID-19 pandemic, however, has pushed the broader introduction of telemedicine and "remote/flexible working" maintaining the health care assistance levels as before, firstly accelerating the spread of remote work technology. Secure access to workstations from home and optimal portable devices dedicated to remote reporting can now assure the quality of the process and potentially lead to an increase in productivity and efficiency (e.g. opportunity to report in a controlled environment with no distractions), with more flexibility and autonomy for the workers (e.g. reduced travel time and costs). In this prospective study we aim to promote remote reporting as a stable and effective organizational work model in Nuclear Medicine. ***Materials and Methods:*** Since November 2023, one day a week has been allocated for each doctor to work from home. The hospital, through the data center, has provided a laptop with secure access to its network and reporting systems. Data were obtained from the radiological information system (RIS) database at our institution, which recorded the reporting activities. The number of personal daily PET scans reported has been counted and compared to the previous 6 months as a reference. The Psychological General Well-Being Index has been recorded at the beginning, at 3 months and it will be verified at 6 months to assess the impact of this new working model on workers life. ***Results:*** Each doctor has reported more than the previous reference period, with a mean increase of 43% on the number of reports (10,3 [9-15] vs 7,2 [6-12]; p< 0.05). Moreover, the time between the PET scan and delivery of the report to the patient was shortened by at least one day, with a notable impact on clinical management of patients. The first psychological assessment has demonstrated a clear benefit in term of quality of life, above all for what concerns the commute to work. ***Conclusion:*** These preliminary results demonstrated that remote reporting in Nuclear Medicine can be adopted as a organizational model that is possible, effective and beneficial to the worker's well-being. In future, this efficient model can potentially solves the expected problem of Nuclear doctors shortages, too.

Application of Audience Response System in Radiology Residents' Lecture Sessions with the Examination Score Outcome in Nuclear Medicine Theory

S. Vachatimanont[1,2], *S. Leksuwankun[3], C. Sukprakun[1];*
[1]Nuclear Medicine Unit, King Chulalongkorn Memorial Hospital Thai Red Cross Society, and Faculty of Medicine, Chulalongkorn University, Bangkok, THAILAND, [2]Chulalongkorn University International Doctor Of Medicine Programme (CU-MEDi), Faculty of Medicine, Chulalongkorn University, Bangkok, THAILAND, [3]Department of Medicine, King Chulalongkorn Memorial Hospital Thai Red Cross Society, and Faculty of Medicine, Chulalongkorn University, Bangkok, THAILAND.

Aim/Introduction: Audience response systems are technologies promised to enhance learner engagement and knowledge retention. Although audience response systems are extensively studied in undergraduate medical education, their utility in postgraduate residency training remains relatively unexplored. Therefore, we introduced Kahoot, an audience response system, in nuclear medicine theory lecture sessions for radiology residents before assessing their perceptions and exam performance. ***Materials and Methods:*** This retrospective study involved two classes of first-year radiology residents in a teaching hospital. There were 26 residents who participated in the audience response system class. We collected anonymous questionnaires from those residents to evaluate their perceptions, and we compared their examination scores to the other class, which consisted of 24 residents, without audience response system. ***Results:*** Twenty-four residents from the audience response system classes (92.3%) responded to the questionnaires. The percentages of respondents who preferred lectures with audience response systems, lectures with minimal in-class interactions, and lectures with direct face-to-face questioning were 75.0%, 29.4%, and 11.1% respectively. The level of mental stress caused by audience response system was significantly less than that caused by direct questioning (36.4% vs 6.67%, $p < 0.001$). All residents in the audience response system class and the class without it took the examinations that had the total score of 60. The scores of the audience response system class (Median = 44, IQR = 5.75) and the class without audience response system (Median = 40, IQR = 6) were not significantly different ($p = 0.880$). ***Conclusion:*** The majority of radiology residents prefer audience response systems due to their significantly lower stress levels compared to direct questioning during lecture sessions. Although audience response system might not lead to significantly higher scores in examination, the use of audience response system may be encouraged in place of direct questioning to promote in-class participation without exacerbating stress levels among the residents.

Facile radiolabeling optimization of a new piroxicam analogue using Design Expert® Software

H. Feli[1], *M. Mosayebnia[1], Z. Sheikholislam[2,3], M. Azami Movahed[1], M. Mahjoub[4], M. Rezaeianpour[1];*
[1]Department of Pharmaceutical Chemistry and Radiopharmacy, School of Pharmacy, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Medicinal chemistry, School of Pharmacy, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Biophysics, Faculty of Biological Sciences, Tarbiat Modares University, Tehran, IRAN, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Pharmaceutics, School of Pharmacy, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: cyclooxygenase (COX) is a key enzyme in the process of prostaglandins (PGs) synthesis. The products of this enzyme could play a major role as the mediators of the inflammatory response, cancer and some neurodegenerative diseases. The pharmacologic effects of nonsteroidal anti-inflammatory drugs (NSAIDs) are attributed to inhibition of COX-1 and COX-2 enzymes. COX-2 is one the most important targets overexpressed in the inflammation and tumor sites (1-2).

So, efficiently radiolabeled COX-2 inhibitors can precisely detect these lesions. Providing high quality radiopharmaceuticals with fewer experiments can be achieved by optimized radiolabeling process. The present study aimed to utilize the polynomial analysis for optimization of radiolabeling process of piroxicam analogue with 99mTc as a new tracer targeting COX-2. ***Materials and Methods:*** Such various parameters affecting the radiolabeling reaction as the amount of ligand -piroxicam analogue- (100-1000 µg), SnCl2 (10-100 µg), co-ligands (50-300 µg), vitamin C (50-600 µg), radioactivity (370-1850 MBq), pH (7-11) and incubation time (15-45 min) were studied. According to the proposed design, 46 experimental runs of radiolabeling reaction were performed. The mathematical model was statistically analyzed for providing tracer with radiochemical purity (RCP) > 95%. ***Results:*** Our results revealed that quadratic model was the best fit to explain the influence of variables (p-value = 0.0011; F-value = 5.13; R2 = 0.9191; non-significant Lack of Fit). The maximum RCP (95.5%) was found in kit formulation containing 100 µg ligand, 36.82 µg SnCl2, 54 µg co-ligand, 480 µg vitamin C which was labeled using 1850 MBq of radioactivity after 40 min of incubation at pH 11. ***Conclusion:*** 99mTc-piroxicam analogue as a promising agent for detection of inflammation and tumor sites was successfully developed by response surface methodology. Using this method, personnel radiation exposure during radiopharmaceutical preparation can be reduced. ***References:*** 1. In Vivo Behavior Study of Chemical in Household Products in Rats using Preclinical Techniques in Nuclear Medicine: $^{[Cu-64]}$Cu-DOTA-Branched polyethylenimine ($^{[Cu-64]}$Cu-DOTA-BPEI)

S. Choi[1], *J. Park[2], J. Jeong[1], J. Jang[1], M. Kwon[1], J. Park[1], S. Oh[1], C. Park[1], J. Jeon[2], I. Lee[1];*
[1]Korea Institute of Radiological and Medical Sciences (KIRAMS), Seoul, KOREA, REPUBLIC OF, [2]Department of Applied Chemistry, Kyungpook National University, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: Polyethyleneimine (PEI) is widely used as an ingredient in household chemical products, such as laundry detergents, pet deodorizers, dishwasher detergents, and fabric refreshers, because it can be deodorized by absorbing anionic odorants. These products are mainly sold in pump sprays that can potentially enter the body through the air when used. In this study, we radiolabeled the main ingredients, BPEI, with Cu-64 in household products, and investigated in vivo behavior of $^{[Cu-64]}$Cu-DOTA-BPEI via intratracheal (i.t.) instillation in rodents. ***Materials and Methods:*** The precursor (DOTA-BPEI) and $^{[Cu-64]}$Cu-DOTA-BPEI were synthesized using a previously reported method. [1] To evaluate in vivo biodistribution, $^{[Cu-64]}$Cu-DOTA-BPEI was instilled into rats via i.t.. Rats were sacrificed at 5 min and 3, 6, 24, 48, and 72 h post-instillation, the organs were removed, weighed, and counted the radioactivity. In the microPET/CT study, [Cu-64]Cu-DOTA-BPEI was instilled using the same administration method, and PET/CT images were acquired at 5 min and 24, 48, 72, and 96 h post-instillation of $^{[Cu-64]}$Cu-DOTA-BPEI. The acquired PET images were reconstructed using a 3D-OSEM algorithm. In the excretion study, urine and feces were collected from 1 to 7 d in metabolic cages after instillation of $^{[Cu-64]}$Cu-DOTA-BPEI to rats via i.t., and radioactivity was counted. ***Results:*** The in vivo biodistribution of [Cu-64]Cu-DOTA-BPEI via i.t. instillation showed dominant uptake in the lung after 5 min (45.65%ID/g) and retained a high uptake of $^{[Cu-64]}$Cu-DOTA-BPEI in rats at 72 h (38.69%ID/g) post-instillation. Uptake of $^{[Cu-64]}$Cu-DOTA-BPEI in other organs was not observed except in the trachea, which is the instillation route, and all were less than 1% ID/g up to 72 h. Consistent with the in vivo biodistribution results, PET/CT images showed no uptake of $^{[Cu-64]}$Cu-DOTA-BPEI in other organs, and a high uptake of $^{[Cu-64]}$Cu-DOTA-BPEI was observed in the lungs from the initial time point to 96 h post-instillation. In the excretion study, the cumulative excretion rate of the instilled $^{[Cu-64]}$Cu-DOTA-BPEI dose in rats was 2.37% in urine and 13.07% in feces up to 144 h, with a total excretion of 15.44%. ***Conclusion:*** These results elucidated the in vivo fate of $^{[Cu-64]}$Cu-DOTA-BPEI in rats via respiratory administration. This study can be useful in preparing basic information for investigating the risks of chemicals in household products in various living subjects using radioisotopes and nuclear medicine techniques. ***References:*** 1. Poster-275, 25th International Symposium on Radiopharmaceutical Sciences, Honolulu, Hawaii, USA, May 22-26, 2023.

EP-1247

In Vivo Biodistribution and Mass Balance Studies of [C-14]C12-Benzylalkyldimethylammonium chloride ([C-14]C12-BKC) in rats via intranasal administration

D. Kim[1], *J. Jeong[1], S. Choi[1], J. Jang[1], M. Kwon[1], J. Jeon[2], I. Lee[1];*
[1]Korea Radioisotope Center for Pharmaceuticals (KRICP), Korea Institute of Radiological and Medical Sciences (KIRAMS), Seoul, KOREA, REPUBLIC OF, [2]Department of Applied Chemistry, Kyungpook National University, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: Benzylalkyldimethylammonium chloride (BKC) is a cationic surfactant widely used as a disinfectant because of its microbial effect. [1] It is important to evaluate their distribution and elimination in the body via respiratory exposure because most household chemical products that contain BKCs are sold in spray pumps. In this study, we radiolabeled BKC with C-14, and conducted an in vivo biodistribution and excretion study to evaluate the behavior of BKC following intranasal (i.n.) administration in rats. ***Materials and Methods:*** [C-14] C12-BKC was synthesized using a previously reported method. [1] To evaluate the in vivo biodistribution, [C-14]C12-BKC was administered to rats i.n.. Rats were sacrificed at 5 min and 3, 6, 24, 48, 72, and 144 h post-instillation, the organs of interest were collected, weighed, and radioactivity was measured by LSC. In the excretion study, urine and feces were collected from days 1 to 7 in metabolic cages after i.n. administration of [C-14] C12-BKC to rats, and radioactivity was measured. ***Results:*** In vivo biodistribution data showed high uptake (3.63-9.53%ID/g) of [C-14]C12-BKC in the trachea, stomach, small intestine, and large intestine at the initial time points, 5 min and 3 h, with the highest uptake (4.66%ID) in the large intestine at 48 h post-administration. In contrast, other organs showed [C-14]C12-BKC uptake of 2%ID/g at all time points, but the heart, pancreas, and adrenal gland showed uptake accumulation up to 48 h post-administration. In the excretion study, the cumulative excretion rate of the administered [C-14]C12-BKC dose in rats was 13.6% in urine and 86.5% in feces for up to 168 h, with a total excretion and recovery rate of 100.1%. ***Conclusion:*** This study provided a basis for toxicity assessment by determining BKC accumulation in rats. These results elucidated the in vivo fate of [C-14]C12-BKC in rats via respiratory administration and were consistent with previously reported QWBA analysis results [2], confirming the need for toxicity assessment, particularly for the heart, paracentesis, and adrenal

gland. ***References:*** 1. Nadagouda et al., Med. Chem. Res. 31 (10), 1663-1678 2. Park et al., Chemosphere 338 (2023) 139460.

EP-1248

Novel Radiolabeling Strategy for Al[F18]FAPI-74 complex using Water-in-oil Microemulsions

S. Choi, *Y. Lee, D. Kim;*
Korea Institute of Radiological and Medical Sciences (KIRAMS), Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Al[F18]F radiolabeling method is a metal-based radiochemistry that has recently been widely used in radiopharmaceutical development [1]. However, Al[F18]F required high temperatures (100-120 °C) and appropriate pH for chelation. Additionally, most biologically active vectors pose challenges for labeling due to their complex structures, low solubility in water, and sensitivity to temperature and pH. To overcome these challenges, radiometal chelate labeling using microemulsions has been reported [2]. In this study, the synthesis of Al[F18]FAPI-74 required high temperatures, so we investigated the possibility of synthesizing it under mild conditions using microemulsion. ***Materials and Methods:*** Automated radiosynthesis of Al[F18]FAPI-74 was performed using a TRACERlab FXFN module and purified by C18 Seppak cartridge. [F18]F- was eluted from QMA with 0.5 M NaOAc was converted to Al[F18]F by reaction with 10 µL of 10 mM AlCl3 at r.t. for 5 min. Al[F18]F was coordinated to NOTA-FAPI-74 precursor in the 0.5 M NaOAc buffer (pH 4.0) and DMSO (100 oC, 20 min), The crude mixture was purified using C18 Seppak cartridge. Final Al[F-18]FAPI-74 was eluted with EtOH and diluted with 0.1 M NaCl solution. For the Al[F18]FAPI-74 synthesis using microemulsion method, Al[F18]F was synthesized by the same method as above, and the coordination reaction was followed by water-in-oil microemulsion method to synthesize Al[F18]FAPI-74. Microemulsion was generated with isooctane containing 1 wt% Span 80. Al[F18]F was coordinated with NOTA-FAPI-74 precursor in a microemulsion with sonication for 30 min at r.t. and vortexing every 10 min. At the end of reaction, TFA was added to break microemulsion and the mixture was centrifuged at 3000 rpm for 1 min. The aqueous layer was extracted and the radiolabeling yield was confirmed using HPLC. ***Results:*** Radiochemical synthesis of Al[F18]FAPI-74 using an automated production module was obtained in 15-22% radiochemical yield, while the synthesis using microemulsion method was confirmed in 20-35% radiochemical yield. Total synthesis time was 50 and 60 min, respectively, with the microemulsion method taking longer. HPLC analysis confirmed that the retention time of Al[F18]FAPI-74 by both methods was the same (10-11 min). ***Conclusion:*** [F18]FAPI-74 was synthesized using a water-in-oil microemulsion in high radiochemical yield. This result demonstrated that using microemulsion has potential to be used as reaction media for the synthesis of radioligand. ***References:*** 1. McBride et al., J. Nucl. Med. 2009 (6), 991-999 2. EP-1249

First experiences with scanning patients with a long axial field of view PET/CT scanner

B. Ferreira, *A. Pritchard, H. Shirsavar, A. Leite, T. Wilson, D. McCool, T. Wagner, B. Holman;*
Royal Free London, NHS Foundation Trust, London, UNITED KINGDOM.

Aim/Introduction: The Royal Free Hospital, London, had the first long axial field of view (LAFOV) PET/CT in the UK. This acquisition system allowed shorter acquisition times, lower administered activities and, at the same time, allowed an increased scanning capacity. Patient workflow previously set-up for conventional PET/CT scanners had to be reviewed to take advantage of this new acquisition system. The goal of this project is to evaluate the impact of this acquisition system on staff satisfaction, patient experience and scan workflow effectiveness. Also, since scanning capacity has increased, staff radiation exposure was also assessed prior and post the use of this new acquisition system. ***Materials and Methods:*** The LAFOV PET/CT scanner had implications at different levels within our department: at booking level, patient preparation, space available, shift patterns, reconstruction times and also how training is provided. To assess staff satisfaction, an anonymous questionnaire was handed to technologist to assess this. Patients were asked about their experience through their scan. Workflow effectiveness was assessed by comparing the time different scan stages took place by analysing respective time stamps (recorded by radiology information system), before and after the use of the LAFOV PET/CT. Radiation exposure of staff members, recorded by electronic personal dosimeters, was also compared. ***Results:*** After two months of utilising a LAFOV PET/CT scanner, the feedback obtained from PET technologists has been quite positive. However, there were some concerns with the increased turnover of scans. Feedback from patients was also quite positive, mainly because of reduced acquisition time. With regards to workflow, time between patient attendance to injection time hasn't shown any significant difference, nor the difference between planned and actual scan acquisition start. Staff radiation exposure has been greatly reduced even considering there had been a significant number of manual radiotracer administration. Another comment made by technologist is regarding the availability of radiotracer to inject, especially when dealing with limited amounts such as 68Ga-DOTATATE and 68Ga-PSMA due to production limitations. ***Conclusion:*** The use of a LAFOV PET/CT scanner has been quite positive experience in our department, not only from staff perspective, but also form patients' one. Thus, it had a significant impact in our current scanning capacity. ***References:*** Long-axial field-of-view PET/CT: perspectives and review of a revolutionary development in nuclear medicine based on clinical experience in over 7000 patients; I Alberts et all; Cancer Imaging, 23 Article number:28 (2023).

Study protocol: A randomized phase 2 trial of FLEXible and extended dosing of ^{177}Lu-PSMA-617 Molecular Radioligand Therapy in mCRPC (FLEX-MRT)

A. Holzgreve[1,2], *A. Delker[2], Z. Ells[1,2], J. Brosch-Lenz[3], S. Zhu[1], S. Lira[1], J. Nikitas[1], T. Grogan[4], D. Elashoff[4], L. M. Unterrainer[1,2], M. Dahlbom[1], M. Allen-Auerbach[1], J. Czernin[1], J. Calais[1];*
[1]Ahmanson Translational Theranostics Division, Department of Molecular and Medical Pharmacology, David Geffen School of Medicine, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA, [2]Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY, [3]Department of Nuclear Medicine, School of Medicine, and Klinikum Rechts der Isar, Technical University of Munich, Munich, GERMANY, [4]Department of Medicine Statistics Core (DOMStat), Department of Medicine's Division of General Internal Medicine and Health Services Research, David Geffen School of Medicine, UCLA, Los Angeles, CA, UNITED STATES OF AMERICA.

Aim/Introduction: The European Medicines Agency (EMA) approved 177Lu-PSMA-617 radioligand therapy (RLT) for patients with metastatic castration-resistant prostate cancer (mCRPC) with a fixed dosing schedule of 7.4 GBq administered once every

6 weeks for up to a total of 6 doses. However, a patient-tailored more flexible and extended dosing schedule may increase treatment efficacy of 177Lu-PSMA RLT. ***Materials and Methods:*** We here present the study protocol of the randomized FLEX-MRT trial. ***Results:*** In this investigator-initiated prospective phase 2, open-label, randomized, controlled, parallel group, single-center trial, we aim to assess the efficacy of a response-based flexible dosing schedule of 177Lu-PSMA-617 RLT administered up to 12 treatment cycles in men with mCRPC. Progressive mCRPC patients post-ARSI, post taxane-based chemotherapy are eligible by PSMA PET VISION trial criteria. Exclusion criteria include prior RLT and less than 6 weeks since the last myelosuppressive therapy. We hypothesized 2-year survival rates of 55% in the investigational group and 30% in the control group. A two-sided log rank test with an overall sample size of 90 subjects (45 per group) achieves 80.3% power at a 0.050 significance level to detect a hazard ratio of 0.4966. Randomization will allocate patients in a 1:1 ratio: The investigational arm is treated with up to 12 cycles including potential "treatment holidays" depending on the treatment response; the control arm receives 6 cycles administered in six-week intervals. Imaging response to RLT is assessed using 177Lu-PSMA-617 SPECT/CT 24h after each cycle and PSMA PET/CT every 3 months during treatment holidays, respectively. RLT will be re-started after a treatment holiday in the investigational arm, if the patient experiences ≥25% PSA progression and an imaging progression according to the RECIP criteria. The primary endpoint is the 2-year survival rate calculated from the date of the first treatment cycle. Secondary endpoints include safety by CTCAE and dosimetry, and determination of overall and progression-free survival (evidence of progression as defined by either radiographic, PSA, or clinical progression, or death from any cause). The FLEX-MRT trial has been approved by the FDA (IND #168362) and the UCLA IRB (#23-000931) and it is registered on ClinicalTrials.gov (NCT06216249). Start of enrollment is in May 2024. The study will last for 48 months of which subject accrual (entry) occurs in the first 12 months. ***Conclusion:*** The randomized FLEX-MRT trial aims to generate evidence for the efficacy of a response-based extended dosing schedule of 177Lu-PSMA RLT in patients with advanced mCRPC.

EP-1251

Customer satisfaction surveys for Nuclear Medicine department, measured through patients and referring clinicians' surveys

M. Boya Román[1,2], *M. Gabari[1,3], N. Moreno[1], M. J. Ribelles[1,2], M. I. Blanco[1,2], F. Lozada[1,2], N. Rudic[1,2], L. Paruta[1,2], E. Goñi[1,2];*
[1]Hospital Universitario de Navarra, Pamplona, SPAIN,
[2]Nuclear Medicine Department, Pamplona, SPAIN, [3]Clinical Support Service and Management, Pamplona, SPAIN.

Aim/Introduction: The purpose of this survey is to identify improvement areas within the care process in line with ISO 9001:2015 standard. ***Materials and Methods:*** Patients have been approached by the technical team who requested their collaboration and provided a free of charge telephone number for further questions or concerns. Interviews were carried out by telephone questionnaire handled by the CATI program (Computer Assisted Telephone Interview). Average interview time was 454 seconds. 89 patients were contacted, 50 sample holders and 39 substitute. 50 patients responded, 28 sample holder an 22 substitutes. Physicians survey was conducted through a cover letter and a Google Form questionnaire, sent by corporate mail to head of department and clinical director who distributed the questionnaire to the physicians. The survey was sent in March 2023, containing 7 questions (score 1 to 5 and NR/DK). 31 responded, we do not know the number of surveys sent. ***Results:*** Average score of Patients was 8.74 and the majority of the patients replied that they would recommend the department 9.00 (1 to 10 scale). Highest value indicator was "Active listening and empathy" (9.59), "technical proficiency of staff" (9.43), "quality of care" (9.28), "cleanliness" (9.04) and "privacy during examination" (9.04). Lowest value indicators were "waiting list" (7.40) and "confidentiality" (6.90). Results of Referring Clinicians were substantially high, with only one indicator being below reference, namely "participation in hospital committees" (41.9%). All other indicators with a high satisfaction value: "reporting time" (80.6%), "report & study quality" (93.5%), "waiting time scheduling" (80.6%), "reports of unexpected finding" (74.2), "clear communication / courtesy" (90.3%) and "global satisfaction" (96.8%). As improvement measurement, we incorporated automated appointment scheduling and registration processes (SIGUE program) and increased the participation in hospital committees from 5 to 11. ***Conclusion:*** The data from this study highlights areas for improvement such as patients' privacy and additional participation in hospital committees. Deployment of additional surveys in nuclear medicine departments could serve to establish best practice and improve the overall service level to patients and professionals

EP-1252

Cost-Effectiveness of PET/CT in Head-Neck Cancer & comparisons with CT-MRI

N. Papathanasiou[1], *J. Yfantopoulos[2], M. Spiliotopoulou[1], E. Karagkouni[1], P. Katsakiori[1], D. Apostolopoulos[1], N. Kotsopoulos[2];*
[1]University Hospital of Patras, Patras, GREECE,
[2]University of Athens, Athens, GREECE.

Aim/Introduction: To evaluate the cost-effectiveness of Positron Emission Tomography/Computed Tomography (PET/CT) in the initial N-staging of Head-Neck Cancer (H-NCa) and compare it with CT and Magnetic Resonance Imaging (MRI) within the Greek National Healthcare System. ***Materials and Methods:*** A cohort of 100 clinically N0 H-NCa patients was evaluated for a 10 years' time horizon. Initially, a decision tree model was constructed including 3 different imaging strategies for H-NCa staging, namely a) Whole-Body Fluoro-deoxy-Glucose (FDG)-PET/CT, b) CT of the neck, chest, and abdomen ("CT") and c) MRI of the neck plus CT of the chest-abdomen ("MRI"). Afterwards, a Markov Model was applied simulating transition in different disease states such as recurrence and death. Input parameters (disease prevalence, diagnostic accuracy estimates and transition probabilities) were based on recent literature and costs were adjusted to the Greek Healthcare System. Total Life-Years (LYs) were defined as Health Outcome. ***Results:*** Total costs per patient were 144.822€ for PET/CT yielding 4,095 LYs. For MRI the costs were 144.904€ with yield of 4,094 LYs and for CT 144.586€ with 4,094 LYs respectively. PET/CT marginally dominated MRI while the Incremental Cost Effectiveness Ratio (ICER) of PET/CT vs. CT was estimated at 179.562€ for 1 LY gained. ***Conclusion:*** All 3 imaging strategies had comparable health outcomes and costs. PET/CT is an appropriate and preferred imaging modality as it has high diagnostic accuracy in initial N-staging of H-NCa.

EP-1253

Harnessing Accelerator Mass Spectrometer (AMS) and C-14 micro-tracing for the long-term in vivo behavior evaluation of polystyrene (PS) microplastics via inhalation exposure

M. Kwon[1], *S. Choi[1], J. Jang[1,2], J. Seo[1], K. Kim[1], J. Song[1], I. Lee[1];*

[1]Korea Institute of Radiological and Medical Sciences (KIRAMS), Seoul, KOREA, REPUBLIC OF, [2]Department of Applied Chemistry, Kyungpook National University, Daegu, KOREA, REPUBLIC OF.

Aim/Introduction: Recently, it has been reported that microplastics are not only the cause of environmental pollution, but also enter the human body through various pathways, affecting human health, and microplastics are most frequently introduced through the respiratory tract [1]. In this study, to evaluate the long-term in vivo behavior of microplastics, PS was radiolabeled with C-14 (half life: 5730 y), and in vivo biodistribution and excretion studies were conducted in rats after inhalation exposure of [C-14]PS-Bn using an accelerator mass spectrometer (AMS) capable of measuring trace amounts of radiocarbon. ***Materials and Methods:*** [C-14]PS-Bn was synthesized from PS and [C-14]benzyl bromide in the presence of K2CO3 in DMF/H2O. SD rats were exposed to [C-14]PS-NH-Bn for 4 h using nose-only inhalation exposure equipment. The organs were collected at 5 min, 3, 24, 48, and 72 h, and 1, 2, 3, and 4 weeks after exposure to [C-14]PS-NH-Bn, carbonized, and the fraction of modern carbon (fMC) was measured using AMS. In the mass balance study, after inhalation exposure of rats to [C-14] PS-NH-Bn, urine and feces were collected for 4 weeks in metabolic cages and carbonized, and fMC was measured by AMS as described above. ***Results:*** [C-14]PS-NH-Bn (average size: 254 nm) was successfully radiolabeled with C-14 in 12% radiochemical yield. The calculated inhalation exposure doses were 7.94-11.05 mBq/rat, considering the respiratory rate and weight of the rats. In vivo behavioral results showed a decreasing pattern over time, with less than 5% ID/g in the blood, kidney, large intestine, small intestine, liver, stomach, and trachea up to 1 w post-exposure, after which it was not detected. In contrast, the lungs showed high uptake, ranging from 21.70 - 9.32%ID/g from the initial time to 4 w. An excretion study showed that 50% of [C-14]PS-NH-Bn was excreted in urine within 1 d and in small amounts in feces up to 11 d after exposure. ***Conclusion:*** This study overcame by AMS and C-14 microtracing techniques the limitations of the in vivo behavior evaluation of microplastics using short half-life radiotracer. These methods are applicable to various environmental toxicants and are expected to be useful tools to provide basic data for toxicity assessments of accumulation organs in the human body. ***References:*** [1] Environmental Science & Technology 53, 12(2019): 7071

EP-1254

Assessment of Economic Implications of CXCR4-Directed Molecular Imaging in Marginal Zone Lymphomas: A Cost-Consequence Analysis

L. Camacho[1], *M. Kurte[2,3], C. Rupprecht[2], R. Dengler[4], W. Schlötelburg[5], J. Duell[6], A. Buck[5], F. Kron[2,7,8];*
[1]VITIS GmbH, 50823 Köln, GERMANY, [2]VITIS GmbH, Köln, GERMANY, [3]Faculty of Medicine, University Duisburg-Essen, Essen, GERMANY, [4]Oncologic Healthcare Consulting, München, GERMANY, [5]Department of Nuclear Medicine, University Hospital of Würzburg, Würzburg, GERMANY, [6]Department of Haematology / Oncology, University Hospital of Würzburg, Würzburg, GERMANY, [7]Department I of Internal Medicine, Center for Integrated Oncology, Köln, GERMANY, [8]Faculty of Medicine, University Hospital Cologne, Köln, GERMANY.

Aim/Introduction: Marginal Zone Lymphomas (MZLs) represent approximately 7% of all non-Hodgkin lymphomas and are, therefore, the second most common form of indolent lymphoma. Current diagnostic guidelines recommend a thorough diagnostic assessment. Recent studies have highlighted the overexpression of C-X-C motif chemokine receptor 4 (CXCR4) in MZL, making it a potential target for imaging and therapy. The novel positron emission tomography (PET) tracer [68Ga]Ga-Pentixafor has shown promising diagnostic performance in initial staging and therapeutic monitoring in MZL. This health economic analysis evaluates the cost-of-illness and cost-consequence of [68Ga]Ga-Pentixafor PET/ computed tomography (CT) scans in managing hospitalized patients diagnosed with MZL ***Materials and Methods:*** Patients diagnosed with MZL from 2016 to 2024 at University Hospital of Würzburg were divided into two groups. From 2016 to 2020, one group was diagnosed and staged according to the applicable guideline procedures, while the other group, from 2020 to 2024, received additional [68Ga]Ga-Pentixafor PET/CT. A cost-consequence analysis assesses the impact of this intervention on subsequent therapies and associated costs, with reference to the up- and downstaging distribution and management changes observed by Duell et al. (2023). ***Results:*** We anticipate examining a cohort of 400 patients diagnosed with MZL over the study period. Drawing from the evidence of Duell et al. (2023), we expect to observe distinct distributions of up- and downstaging among the patient cohort, indicating potential variations in treatment responses and subsequent therapies. As a result, we expect a difference in patient-related and health economic parameters between these two groups. ***Conclusion:*** By comparing patient cohorts and evaluating treatment responses, as well as subsequent costs, we seek to provide insights into the value proposition of adopting innovative imaging techniques into the diagnostic and therapeutic algorithms for MZL. The potential resource-savings and improvements in patient outcomes associated with [68Ga]Ga-Pentixafor PET/CT imaging could have significant implications for healthcare resource allocation decisions and patient care delivery. ***References:*** Duell, J., Buck, A. K., Hartrampf, P. E., Schlötelburg, W., Schneid, S., Weich, A., ... & Werner, R. A. (2023). Chemokine Receptor PET/CT Provides Relevant Staging and Management Changes in Marginal Zone Lymphoma. Journal of Nuclear Medicine, 64(12), 1889-1894.

EP-1255

Improving reporting quality in PET/CT Imaging of Lymphomas: the influence of Lugano classification

A. Kukashvili[1], *S. Kukava[2], M. Baramia[2];*
[1]Tbilisi State Medical University, Tbilisi, GEORGIA,
[2]Todua Clinic, Tbilisi, GEORGIA.

Aim/Introduction: Fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT) has become vital in oncologic imaging, aiding in disease detection, staging, and treatment response assessment [1]. However, subjective interpretation can lead to variability in reporting and clinical decisions. Deauville scoring system was introduced in 2009 to standardize the interpretation of FDG PET/CT scans, providing a quantitative measure of tracer uptake in lesions relative to background activity. In 2014, the Lugano classification criteria [2] further enhanced reporting. This abstract explores the significance of Lugano classification reporting compared to traditional reporting in FDG PET/CT imaging. ***Materials and Methods:*** We conducted a retrospective overview in our hospital of FDG PET/CT reports in lymphoma patients who underwent treatment, including interim and end-of-treatment scans, in the years 2020 and 2023. Traditional reporting involved subjective visual assessment, while Lugano classification provided standardized numerical scoring. ***Results:*** Deauville scoring has transformed interpretation, minimizing interobserver variability and enhancing reproducibility. Studies demonstrate its superiority

over traditional assessment, with higher scores correlating with poorer outcomes [3]. However, retrospective analysis of PET/CT reports in lymphoma patients in year 2020 and 2023 showed that the percentage of Deauville reporting did not increase, remaining stable at 61% in 2020 (total 146 reports) and 59% in 2023 (total 149 reports). A significant portion of reports still lacked Deauville scores, indicating the need for further dissemination and education among clinicians. ***Conclusion:*** The implementation of Lugano classification has significantly improved the utility of FDG PET/CT in lymphomas. Standardized, quantitative assessment enhances interobserver agreement and offers valuable prognostic insights. Despite advancements, the retrospective comparison highlights the ongoing need to popularize Deauville scoring across specialties. Embracing standardized reporting practices holds promise for advancing precision oncology and personalized medicine. Continued efforts in education and practice integration are essential to maximize the benefits of Lugano classification. ***References:*** 1) D'souza MM, Jaimini A, Bansal A, Tripathi M, Sharma R, Mondal A, Tripathi RP. EP-1256

Long-Term Follow-Up Results and Factors Affecting Survival In Oncocytic Thyroid Cancer

G. Yilmaztekin, *B. Yılmaztekin, B. B. Demirel, G. Uçmak; Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Ankara, TÜRKIYE.*

Aim/Introduction: Oncocytic (Hurthle cell) carcinoma of thyroid, constitutes 3-4% of all thyroid cancers and it was classified as oncocytic thyroid carcinoma (OTC) in the 2017 WHO classification, separated from the thyroid follicular cancer subtype. Our study aimed to classify the pathological and clinical features of patients diagnosed with OTC and to determine long-term follow-up results and prognostic factors affecting survival. ***Materials and Methods:*** 56 patients with a diagnosis of OTC were included in the study. Demographic data, pathological features, biochemical data, radioactive iodine (RAI) doses, disease status during follow-up and follow-up periods of the patients were recorded. ***Results:*** 56 patients with OTC pathology were included in our study. Bilateral total thyroidectomy (BTT) was performed in all patients. All patients received RAI treatment at least once. At diagnosis, local lymph node metastasis was detected in 4 (7.1%) patients and distant metastasis was detected in 2 patients. Recurrence was observed in 11 of the patients with excellent response or indeterminate response. The mean time to recurrence was 5.3 ± 3.39 years and the median follow-up time after recurrence was 8.4 years (95% CI 7.27-9.63). Distant metastases were observed in a total of 10 patients during diagnosis and follow-up, and their localizations were lung, bone and liver, in order of frequency. In the latest status in follow-up; mortality was observed in 5 patients (9%), all of whom were distant metastatic. The median follow-up period in the entire patient group was 14.4 years (95% CI 12.9-15.9); RFS (recurrence-free survival) was found to be 86% at 5 years, 78% at 10 years and 75% at 20 years. Tumor size >4cm (p=0.006) and ETE+ (p<0.01) were found to be statistically significant in affecting RFS (Figure 1). According to the treatment response after BTT + RAI; The 5-year RFS of those with a excellent response was 90%, and the RFS of those with an indeterminate response was 66%. In the entire patient group, OS (overall survival) was found to be 98% at 5 years, 94% at 10 years and 89% at 20 years. Age at diagnosis >45 (p=0.005), tumor size >4cm (p=0.006), and ETE+ (p=0.005) were found to be statistically significant in affecting OS. ***Conclusion:*** Although oncocytic thyroid cancer is known to have a poor prognosis among differentiated thyroid cancers; In the light of our clinic's data, it has been concluded that long survival times can be achieved with the correct treatment and personalized dynamic approach.

EP-1257

Environmental sustainability in Radionuclide Therapy

L. Perry[1], *M. Deng[1], G. Lowe[2], N. Dickinson[3]; [1]Imperial College Healthcare NHS Trust, London, UNITED KINGDOM, [2]East and North Hertfordshire NHS Trust, Northwood, UNITED KINGDOM, [3]University Hospitals of Leicester NHS Trust, Leicester, UNITED KINGDOM.*

Aim/Introduction: The World Health Organisation has stated that climate change is the single biggest health threat facing humanity[1].The UK National Health Service (NHS) has committed to reaching net zero by 2045[2] requiring input and adaptation of all healthcare services.There is limited data regarding the environmental footprint of radionuclide therapies.This work aims to estimate the environmental impact of common starting points for sustainability projects including patient transport,paper usage and consumable disposal in radionuclide therapies. ***Materials and Methods:*** The environmental impact of patient transport was estimated from the average patient travel distance to a large London NHS Trust and published conversion factors for different modes of transport[3].An estimate of the environmental impact of paper used for patient communications and record keeping was calculated from the average A4 sides produced for as range of first cycle treatments across three nuclear medicine institutions and published conversion factors[3].The environmental impact of consumable disposal was estimated from the consumable weight,packaging weight and observed disposal route for a range of therapies together with disposal emissions factors[4]. ***Results:*** The emissions equivalent for 30.3km average travel distance depended on mode of transport and were 0.8kgCO2e by underground train, 1.1kgCO2e by train, 2.4kgCO2e by bus and 5.1kgCO2e by car. The average sides of A4 produced for a first cycle treatment was 19-29 across the therapies in this study. The emissions equivalent were 0.10kgCO2e for I-131 sodium iodide, 0.10kgCO2e for Lu-177 oxodotredotide, 0.12kgCO2e for Ra-223 dichloride and 0.13kgCO2e for Lu-177 PSMA therapies. The weight of consumables varied from 0.04-1.3kg per therapy cycle (excluding the radiopharmaceutical and associated packaging).The emissions from consumable disposal were estimated as 0.01kgCO2e for I-131 sodium iodide, 0.62kgCO2e for Ra-223 dichloride, 0.79kgCO2e for Lu-177 oxodotredotide and 0.81kgCO2e for Lu-177 PSMA therapies. ***Conclusion:*** This early work estimates the environmental impact of patient transport, paper usage and consumable waste in radionuclide therapies. Patient transport had the highest estimated emissions equivalent followed by consumable disposal and paper usage.This initial work is limited in the radionuclide therapies included and number of centres together with their geographical distribution but may help priortise sustainability projects.Further work to estimate whole life-cycle environmental impact of radionuclide

therapies across the full range of practices will be required as we work towards net-zero. ***References:*** [1]"Climate Change" Fact sheet, World Health Organisation, October 2023; [2]Delivering a 'Net Zero' National Health Service, NHS England, October 2020 [3] UK Government GHG Conversion Factors for Company Reporting v1.1 2023[4]NHS England. EP-1258

A promising new era for diagnosis and therapy of Spinocerebellar Ataxia

M. Wang[1], *C. Chan[1], H. Yu[1], C. Ho[1], H. Hsieh[2];*
[1]National Atomic Research Institute, Taoyuan, Taiwan, TAIWAN,
[2]National Taiwan Normal University, Taipei, TAIWAN.

Aim/Introduction: Currently, polyglutamine (polyQ) disorders, such as spinocerebellar ataxia (SCA), are lethal and lack of effective treatment. Diagnosis largely relies on post-mortem examinations, and tools like the Scale for the Assessment and Rating of Ataxia (SARA) and coordination tests suffer from a lack of objectivity. Consequently, there is a critical need for the development of effective diagnostic and therapeutic approaches for SCA. In this study, we aim to explore the use of exosomes derived from adipocyte mesenchymal stem cells (ADSC) as a therapeutic agent and assess their efficacy in treating SCA through the Rotarod performance test and F18 Florbetaben (F^{18} FBB) PET imaging. ***Materials and Methods:*** The identification of spinocerebellar ataxia in transgenic mice is conducted using polymerase chain reaction (PCR) techniques and genetic mapping when the mice reach one month of age. Behavior assessments were evaluated using a multi-channel Rotarod for measuring the time until they fall. F^{18} FBB, known for its beta-amyloid imaging capabilities, was utilized in SCA transgenic mice studies. A therapeutic dosage of 2x10^5 exosomes from ADSCs was injected into the SCA transgenic mice through the tail vein weekly for a duration of four weeks. Post-treatment, the Rotarod test assessed the mice's motor skills, and F^{18} FBB imaging was used to detect accumulation in the cerebellum. Additionally, the exosomes were tagged with Ga-68 to study their distribution within the body. ***Results:*** The Rotarod performance on SCA transgenic mice treated with ADSC-derived exosomes indicated that some of the transgenic mice exhibited improved excercise capability, and there was a decrease in cerebellar uptake of F^{18} FBB among these SCA transgenic mice. Furthermore, imaging revealed that the exosomes displayed significantly higher accumulation in the cerebellar region of SCA mice compared to normal mice. ***Conclusion:*** Our finding suggest that F^{18} FBB, widely recognized as a beta-amyloid imaging agent, holds potential for imaging protein agglomerates, and exosomes derived from ADSCs has promising as a therapeutic agent for SCA.

EP-1259

Investigating therapeutic and imaging applications of exosomes in leukemia

S. Liu, C. Ho, K. Cheng, ***M. Wang;***
National Atomic Research Institute, Taoyuan, TAIWAN.

Aim/Introduction: Childhood acute lymphoblastic leukemia represents 26% of all pediatric cancer cases, poses significant challenges with traditional treatments due to associated toxicities. This study explores the role of exosomes in the growth of leukemia cells and combines the use of radiolabeled exosomes to detect infiltration outside the bone marrow. ***Materials and Methods:*** Exosomes from Wharton's jelly mesenchymal stem cells (WJMSC) and leukemia cells were isolated through tangential flow filtration and ultracentrifugation techniques. The effect of WJMSC exosomes on the proliferation of human acute lymphoblastic leukemia cells (Reh cells) and acute myeloid leukemia cells (HL60 cells) was evaluated using cell proliferation assays. Additionally, a 67Ga-oxine-labeled Reh exosome was created to explore its ability to return to the original cells in a human leukemia xenograft model. ***Results:*** The findings indicated that WJMSC exosomes reduced the growth of Reh cells but did not affect HL60 cell proliferation, and they extended the lifespan of leukemia xenograft mice. The 67Ga-oxine-Reh exosome showed promise in detecting extra-medullary lesions, demonstrating its bio-distribution and selective localization within the lymphatic system of a mouse leukemia model via whole-body SPECT/CT imaging. ***Conclusion:*** The preliminary results suggest that WJMSC exosomes could serve as a potential drug delivery mechanism for treating leukemia. Furthermore, the 67Ga-oxine-Reh exosome could enhance diagnostic precision and contribute to improved management of leukemia cases involving extra-medullary spread. ***References:*** Cancer Epidemiol Biomarkers Prev 2023 Aug 1; 32(8):1030-1037.

EP-1260

New Theranostic Approach in the Treatment of Bone Metastases: 161Terbium-DOTAZOL

C. Sezgin[1], *E. Uygur[1], Y. Parlak[1], K. Karatay[2], U. Avcibasi[1], Z. Biber Muftuler[2], G. Gumuser[1];*
[1]Celal Bayar University, Manisa, TÜRKIYE,
[2]Ege University, İzmir, TÜRKIYE.

Aim/Introduction: Prostate cancer is one of the most common types of cancer among men, and the progression of the disease often leads to the development of bone metastases, significantly impacting patients' quality of life. Prostate cancer-associated bone metastases are typically osteoblastic lesions that involve increased bone formation and cause bone pain, and also lead to complications such as pathological fractures, spinal compression, and hypercalcemia, thereby increasing morbidity and mortality. The conjugation of bisphosphonates with macrocyclic chelators holds great potential in bone-targeted radionuclide therapy and imaging. Currently, DOTAZOL based on zoledronic acid, the most potent bisphosphonate, has shown high potential in initial patient studies, especially when treated with the low-energy β-emitter 177Lu. Recently, 166Terbium (161Tb) has been considered as an effective alternative to 177Lu. The superior therapeutic effects of 161Tb demonstrated in vitro and in vivo studies present a new approach in the treatment of prostate cancer bone metastases. This study examines the radiolabeling and biodistribution of 161Tb labeled DOTAZOL in vivo for the treatment of bone metastases. ***Materials and Methods:*** DOTAZOL was radiolabeled with Tb-161, and conditions such as pH, temperature, and TLC solvent systems were optimized by researchers. The radiochemical yield of Tb-161-DOTAZOL was determined using High-Performance Liquid Radiochromatography (HPLRC) and Thin Layer Radiochromatography (TLRC). In vivo studies were conducted on Albino Wistar rats, involving scintigraphic imaging and biodistribution studies ***Results:*** The radiochemical yield of Tb-161-DOTAZOL was found to be 99.98 ± 0.02% (n=3). The binding efficiency of 161Tb-DOTAZOL was observed to be an

average of 98.37 ± 2.78% over 24 hours. The log P value of 161Tb-DOTAZOL was determined to be 0.61 ± 0.19. Biodistribution and scintigraphy studies of 161Tb-DOTAZOL showed low soft tissue uptake and high bone accumulation. High retention was observed in the epiphyses, where bone growth is actively occurring and osteoblastic activity is high, suggesting DOTAZOL's accumulation in osteoblastic bone lesions. All scintigraphic images showed similar levels of low renal retention. ***Conclusion:*** The findings of this study evaluating the radiochemical yield of 161Tb labeled DOTAZOL in the treatment of osteoblastic bone metastases indicate that 161Tb-DOTAZOL has high radiochemical efficiency and stability. Scintigraphic imaging and biodistribution studies show significant retention of 161Tb-DOTAZOL in bone tissue. Consequently, more detailed preclinical studies are planned for the therapeutic use of 161Tb-DOTAZOL in bone metastases.

EP-1261

Assessing the therapeutic potential of exosomes derived from Wharton's jelly mesenchymal stem cells in the 5xFAD mouse of Alzheimer's disease

S. Liu[1], C. Ho[1], K. Cheng[1], C. Chan[1], H. Hsieh[2], T. Lin[3], ***M. Wang[1];***
[1]National Atomic Research Institute, Taoyuan, TAIWAN,
[2]National Taiwan Normal University, Taipei, TAIWAN,
[3]Chang Gung Medical Foundation, Taoyuan, TAIWAN.

Aim/Introduction: Alzheimer's disease is the leading cause of dementia, severely affecting patients' memory and cognitive functions. In this study, we explored the potential therapeutic benefits of exosomes derived from Wharton's jelly mesenchymal stem cells (WJMSC exosomes) on β-amyloid accumulation and spatial learning and memory capabilities in the 5xFAD mouse model of Alzheimer's disease ***Materials and Methods:*** WJMSC exosomes were administered intravenously to 5xFAD mice at a dosage of 2 ×109 particles weekly for a duration of four weeks. Neurogenic function was evaluated by conducting amyloid imaging of the 5xFAD mice's brains using positron emission tomography-computed tomography (PET-CT) with ^{18}F-Florbetaben. Additionally, spatial learning and memory abilities were assessed using the Barnes maze test to determine the therapeutic effectiveness of WJMSC exosomes in the mouse model of Alzheimer's disease. ***Results:*** WJMSC exosomes provided dual advantages, notably improving spatial memory in 5xFAD mice ($p = 0.003177$, n=6) and diminishing the buildup of β-amyloid peptides in the brains of the 5xFAD mouse model of Alzheimer's disease ($p = 0.005356$, n=6). ***Conclusion:*** The outcomes suggest that exosomes from Wharton's jelly mesenchymal stem cells offer considerable promise as a non-cellular therapeutic approach for combating Alzheimer's disease.

EP-1262

Optimizing Image Quality in Meningioma Diagnosis: Retrospective Analysis of Reduced Scan Time Utilizing $^{[18F]}$SiFAlin-TATE PET Imaging

K. Kyrou[1], *G. Adamou[1], P. Hadjitheodorou[1,2], I. Tsechelidis[1], A. Vrachimis[1,2];*
[1]Department of Nuclear Medicine, German Oncology Center, Limassol, CYPRUS, [2]School of Medicine, European University Cyprus, Nicosia, CYPRUS.

Aim/Introduction: Meningiomas are the most common benign tumors of the adult brain. Meningiomas typically overexpress somatostatin receptors (SSTR). $^{[18F]}$SiFAlin-TATE is a novel diagnostic agent for Positron Emission Tomography (PET) to assess expression of SSTR. This study aimed assess image quality by reducing scan time while maintaining the radiopharmaceutical activities. ***Materials and Methods:*** Fifteen patients with 22 World Health Organization (WHO) grade I and II meningiomas undergone list-mode $^{[18F]}$SiFAlin-TATE PET/CT, were retrospectively assessed. Images were acquired 30-60 minutes, after administration of average of 146 MBq, for 10-minutes (PET10min). Subsequently, images were reconstructed for each patient using the first 5 (i.e. 50% time reduction; PET5min) and 3 (i.e. ~67% time reduction; PET3min) minutes of acquisition. Besides a visual interpretation from two experienced readers, a quantitative image quality assessment was conducted by measuring the mean, max, and peak, SUV values and comparing them with those obtained from PET10min. Tumour to Background Ratio (TBR) were calculated for each lesion, along with descriptive statistics. Statistical analysis employed a single-factor ANOVA with a significance level set at $P < 0.05$ and an Fcrit value of 3.14. ***Results:*** In the qualitative evaluation, no significant differences were observed between PET10min, PET5min and PET3min across the 22 lesions. For the PET10min the TBRmean (using SUVmean) was 53.19 and the TBRmax (using SUVmax) was 50.20. In the case of PET5min, TBRmean and TBRmax increased by 44% and 38%, respectively. Similarly, PET3min led to an increase in TBRmean and TBRmax by 31% and 32%, respectively. ANOVA analysis did not show any significant difference in TBRmean ($P = 0.34$, Fcrit=1.10) or TBRmax ($P = 0.37$, Fcrit=1.02). ***Conclusion:*** Reconstructed images using reduced scan times of 5 and 3 minutes maintained qualitative and quantitative diagnostic quality. The reduction in acquisition time could increase patient throughput and minimize patient discomfort (thus reducing the possibility of motion artifacts).

EP-1263

Elevated Serum Osteocalcin Levels Correlate Positively with Abnormal Nuclear Scintigrams in Lame Thoroughbred Racehorses.

P. Tually[1], *S. Tagore[1], G. Currie[2], J. Meadows[1];*
[1]TeleMedVET, Perth, AUSTRALIA, [2]Charles Sturt University, Wagga Wagga, AUSTRALIA.

Aim/Introduction: The purpose of this study was to determine if serum biomarkers can be used to accurately predict musculoskeletal injury based on positive nuclear scintigraphic studies of the distal limbs of racehorses in training. ***Materials and Methods:*** This was a prospective observational case control study that concurrently measured serum Osteocalcin (OC) and C-terminal telopeptides of type I collagen (CTX) as well as radiomic markers of radionuclide uptake in bone and joints of racehorses in training. The source population comprised racehorses referred for nuclear scintigraphy as part of lameness investigations. Blood samples taken from study subjects at the time of imaging were analysed for levels of serum biomarkers for OC and CTX using commercial equine-specific ELISA kits. Comparison between serum biomarker levels for horses with normal and abnormal scintigraphic findings was determined using the Wilcoxon signed-rank test and paired t test. ***Results:*** A total of 68 racehorses were included in the study. Fifteen percent of horses (10/68) had normal qualitative bone scans and 85% of horses had increased radiotracer uptake as determined by qualitative assessment. In the latter group, 31/68 (46%) has moderate radiotracer uptake and 27/68 (40%) had strong uptake in at least one skeletal region, which was supported by the radiomic analysis of the scans. Mean serum OC levels were normal for the normal bone scan group of horses. Moderate and strongly positive scans had significantly elevated OC levels compared to those from the normal group (Figure 1). Mean CTX

levels were not significantly elevated for any group of horses. ***Conclusion:*** The results of our study support the hypothesis that a positive correlation exists between elevated serum osteocalcin levels and abnormal scintigrams in lame racehorses. Therefore, significant serum elevations of OC in racehorses with clinical or subclinical lameness could forewarn of significant, even catastrophic, musculoskeletal injury. However the results did not support the same correlation for CTX. It is apparent that continued investigation of musculoskeletal biomarkers as a screening tool for injury in athletic horses is warranted. ***References:*** Currie, G., et al., 2019. EP-1264

A technical improvement about ct-SPET in sentinel lymph node study

M. Schiavini[1], *M. Bardo[1], F. Buffoni[1], S. Attanasio[1], D. Capolongo[1], L. D'Antonio[1], B. Raise[1], M. Rognoni[1], L. Sembele[2], M. Castellani[1];*
[1]IRCCS Fondazione "Cà Granda" Osp. Maggiore Policlinico di MILANO, Milan, ITALY, [2]Latvian Maritime Medical Center, Riga, LATVIA.

Aim/Introduction: Lymphoscintigraphy(LS) is the gold standard practice for pre-operative staging of cutaneous cancers such as melanomas. Nevertheless the localization of sentinel lymph node(SLN) with a standard acquisition protocol may not be sufficient for a precise surgical access when cancer is located in complex anatomical region such as in head-neck district. The role of ct-SPET images in the detection of SLN of melanoma located in eyelid region is shown our clinicar routine. ***Materials and Methods:*** 37 Mbq-[Tc99m]nanocolloidal radiotracer in a small volume of max 0.3 ml, splitted into to three tuberculin syringes, was injected using a 30 G needle in the eyelid region of a 67-year-old patient with melanoma of the right lower eyelid. Three subcutaneous injections were performed by nuclear physician, in the medial canthus of the right eye, in the medial portion of the upper eyelid, and in the middle area of the lower eyelid. Dynamic planar anterior images were immediately acquired using a dual-head gamma-camera; patient's head was rotated in left lateral position to better visualize any lymph node of contralateral-cervical basins. Three min. anterior and lateral static planar images were acquired after positioning one Cobalt-57 sheet source under patient's head for attenuation correction of tissue. Additional ct-SPET was performed with a low-dose co-registrated ct raw data. ***Results:*** On early dynamic images, SLN was grossly identified and marked with dermographic pen in right latero-cervical region. At images acquired using the Cobalt-57 sheet source, SLN was better depicted in the upper latero-cervical area, even though the anatomic cervical level remained unclear. Finally, SLN was identified in the right latero-cervical IB level at ct-SPET images and the patient underwent radical surgery about 5/6 hours after LS. Hybrid image-guided surgery allowed an easy and precise identification of SLN with intraoperative gamma probe. ***Conclusion:*** In recent years the use of image-guided surgery is being increasing, allowing safer, less invasive and time-consuming surgical procedures. The case here presented is paradigmatic of how the evolution of LS acquisition techniques has improved the accuracy of localization of SLN especially in complex anatomical districts such as latero-cervical lymphatic chain. However, besides the use of coupled ct-SPET images, also the oldest image techniques may still have a role in anatomic localization of SLN, especially if "tricks" such as the Cobalt-57 sheet source are used.

EP-1265

Impact of music intervention on psychological and physiological parameters of patients undergoing myocardial perfusion scintigraphy

L. Vieira[1], *A. Rotaru[2], I. Rodrigues[3], A. Martins[4], C. Carvalho[2], A. Alvernaz[5], L. Oliveira[3], A. Grilo[2], M. Carapinha[6];*
[1]Health & Technology Research Center, ESTeSL - Escola Superior de Tecnologia da Saúde de Lisboa, Fernão Ferro, PORTUGAL, [2]Health & Technology Research Center, ESTeSL - Escola Superior de Tecnologia da Saúde de Lisboa, Lisbon, PORTUGAL, [3]Clínica Joaquim Chaves Saúde, Miraflores, PORTUGAL, [4]Clinica Joaquim Chaves Saúde, Fernão Ferro, PORTUGAL, [5]Clínica Joaquim Chaves Saúde, Mirafloes, PORTUGAL, [6]Escola Superior de Tecnologia da Saúde de Lisboa, Lisbon, PORTUGAL.

Aim/Introduction: Myocardial Perfusion Scintigraphy (MPS), a well-established imaging procedure for diagnosing ischemic heart disease, has multiple phases that can induce patients' anxiety, discomfort, and dissatisfaction. Several non-pharmacological strategies have been used to alleviate anxiety and improve patient comfort and satisfaction, such as music-intervention. The aim of this study was to evaluate the efficacy of musical-intervention in the outcomes of patients undergoing MPS. ***Materials and Methods:*** A randomized clinical trial was conducted on patients undergoing a MPS one-day protocol stress-rest, in a Nuclear Medicine Department between January 15, and March 18, 2024. Patients were divided into a control group (CG) and the experimental group (EG). In the EG, a musical-intervention was performed during the rest image acquisition, allowing patients to choose from a selection of musical tracks curated by a music lecturer. Anxiety levels were assessed at four different moments in both groups: before and after the stress image acquisition (T1 and T2), and before and after the rest image acquisition (T3 and T4), using physiological parameters at all times and psychological parameters for CG at T1 and T4 and for EG at T1, T3 and T4. Image quality analysis was performed using measures of contrast, noise, number and amplitude of patients movements. All studies were reviewed by two researchers and evaluated by three nuclear medicine technologists. ***Results:*** The sample comprised 30 participants with an average age of 71±11.02yrs [45-87yrs] with 15 participants enrolled in each group. Patients in EG reduced their anxiety scores from 36±9.44 at T1 to 33±7.07 at T3 and 28±9.11 at T4, while patients in CG reduced their anxiety scores from 39±10.62 at T1 to 33±9.66 at T4. Regarding patient motion, there was a reduction from the CG to EG in movements between 1-2 pixels (CG = 21, EG= 19) and movements higher than 2 pixels (CG =19, EG=6). In some myocardial walls on the three tomographic slices, the correlation between psychological parameters and image noise were lower in T4 for the EG. No significant results were found to image contrast. ***Conclusion:*** For the EG, the image noise was ~3% lower than in CG. Anxiety decreased throughout the MPS procedure with lower values at T4 for the EG. Additionally, the musical intervention seems to be effective as the EG showed lower values of patients movement. Acknowledgements: The authors would like to thank the support from the funding from IDI&CA - IPL, to the IDI&CA2023/I2P2_MPS project.

EP-1266

PET-MRI Quantification of ^{18}F-Florbetaben Uptake in the Brains of Asymptomatic Middle-aged and Elderly Chinese Subjects

S. Sun, *J. Liu, Y. Chang, R. Wang, S. Yao, Y. Sun, S. Wu, J. Song, D. Zhao;*
Department of Nuclear Medicine, Chinese PLA General Hospital, Beijing, CHINA.

Aim/Introduction: Alzheimer's disease (AD) is a progressive neurological disorder characterized by the accumulation of senile plaques primarily composed of β-amyloid, leading to neurodegeneration, cognitive decline, and ultimately, death. 18F-Florbetaben (FBB) has emerged as a highly promising tracer due to its strong affinity for β-amyloid deposits and its favorable radiochemical attributes that render it suitable for positron emission tomography (PET). With 18F-FBB PET, the diagnostic approach has evolved from simple visual categorization to a more nuanced, quantitative assessment of amyloid deposition. This study aims to determine the metabolic characteristics and standardized uptake values (SUV) of various brain regions in middle-aged and elderly cognitively normal Chinese individuals through 18F-FBB imaging, thereby establishing a normative database. ***Materials and Methods:*** A retrospective analysis was conducted on 45 cognitively healthy adults (mean age 65.0±6.69 years), consisting of 20 males (mean age, 64.4±8.51 years) and 25 females (mean age 65.4±5.56 years). All participants underwent magnetic resonance imaging (MRI) and 18F-florbetaben PET scans. Utilizing the uAI Research Portal, we employed super-resolution reconstruction algorithms and brain analysis methods based on T1-weighted images to divide the patients' brains into 109 regions of interest (ROI). Rigid registration was applied to align T1 images with PET images, allowing for the mapping of 109 ROIs onto the PET images, thereby calculating the SUV. The mean SUV for each brain region was computed for every subject, and independent sample T-tests were utilized to investigate potential sex-based differences in SUV across brain regions, with statistical significance set at $P<0.05$. ***Results:*** The SUV showed a high uptake in white matter (1.61±0.47), intermediate uptake in gray matter (1.02±0.26), and low uptake in cerebrospinal fluid (0.75±0.22). Statistically significant sex-related differences were observed in several brain regions, including the left globus pallidus (1.56±0.26 vs. 1.39±0.24, P=0.03), left cerebellar white matter (1.88±0.33 vs. 1.69±0.26, P=0.03), right cerebellar white matter (1.85±0.31 vs. 1.67±0.27, P=0.04), and the medulla oblongata (1.70±0.29 vs. 1.50±0.27, P=0.02), where SUVs were higher in males compared to females. ***Conclusion:*** Through the performance of 18F-FBB PET-MRI imaging on a cohort of cognitively normal middle-aged and elderly subjects, we have successfully established a standard database for β-amyloid deposition in their brains. Our findings revealed that β-amyloid deposits in the left globus pallidus, bilateral cerebellar white matter, and medulla oblongata were significantly higher in males, suggesting potential gender-specific physiological variations or incipient β-amyloid deposition in these brain areas among middle-aged and elderly individuals with normal cognition.

Medication Interaction In [18F]FE-PE2I PET - Evaluation Of A New Questionnaire In Daily Practice

L. Langhoff Lund[1,2], *B. Hjulskov Christensen[1,2], L. Marner[1,2];*
[1]Klinisk Fysiologisk og Nuklearmedicinsk afdeling, Copenhagen, DENMARK, [2]Bispebjerg og Frederiksberg Hospital, Copenhagen, DENMARK.

Aim/Introduction: Switching from [123I]FP-CIT SPECT to [18F] FE-PE2I PET has increased patient flow due to shorter injection-to-scan and acquisition time. Patient preparation now includes peripheral vein catheterization, tracer administration and no prearrival precautions is needed from the patients. As several medications can interfere with tracer binding to dopamine transporters, our department implemented a questionnaire to the daily patient preparation about medication that could interfere with [18F]FE-PE2I binding, such as methylphenidate, modafinil and the antidepressant sertraline*. The aim was to evaluate the implementation of additional patient preparation. ***Materials and Methods:*** In a quality assurance study approved by the local authorities, we included 145 patients who underwent [18F]FE-PE2I PET from Jan-24 to ultimo Feb-24 (Group A) after implementing the new patient preparation. For comparison, we used a control group (Group B) of 145 patients without the questionnaire from Nov-23 to ultimo Dec-24. Examination comments and final interpretations were reviewed for comments about medication. Technologist experienced in patient preparation with [18F]FE-PE2I PET, were asked to fill out a questionnaire regarding minutes spent on asking for relevant medication and how the workload was experienced. Reading physicians were also asked to fill out another questionnaire. ***Results:*** In patient group A, 16% (23/145) had an examination comment regarding relevant medicine. Of these, 43% (10/23) of the comments were used in the final interpretation conclusion. Thus, 7% (10/145) of patients in group A had an examination comment that was included in the final interpretation. In patient group B 1,4 % (2/145) of the patients had included comments about relevant medicine that could influence the interpretation in the conclusion. 80% (4/5) of the reading physicians thought it was helpful when comments of relevant medicine were added to the examination description. 15% (2/13) of the technologists found the questionnaire difficult. 38 % (5/13) spend < 1 min, 38% (5/13) spend 1-2 min, 15 % (2/13) spend 2-5 min and 8 % (1/13) spend > 5 min. ***Conclusion:*** The new questionnaire is helpful with acceptable consumption of time. The number of final interpretations taking medication into account increased from 1.4% to 7% after implementation of a new questionnaire for medication during patient preparation. Further, 80% of reading physicians found the questionnaire helpful. The median technologist time spend on the questionnaire was 1-2 min, although 15% found the questionnaire difficult and spend >2 min. ***References:*** *Justesen et al. (2023) EJNMMIres 13:46.

EP-1268

Comparison of quantification methods in dopamine transporter SPECT

T. C. Herrygers, *K. Haring, R. J. J. Knol, S. V. Lazarenko, F. M. van der Zant;*
Northwest Clinics, Alkmaar, NETHERLANDS.

Aim/Introduction: Dopamine transporter (DAT) single-photon emission computed tomography (SPECT) is an important tool in the early diagnosis of Parkinson's disease (PD). Normal DAT SPECT results rule out presynaptic striatal dopaminergic insufficiency. Inter-software and interoperator variability in measurements may impede accurate diagnosis, especially when the measured values are close to the cut-off point. The objective of the present study was to compare the quantification methods of two different software packages that are clinically used in DAT SPECT quantification. ***Materials and Methods:*** DAT SPECT datasets of patients referred from November 2023 until March 2024 were semi-quantitively analyzed using the Neurology module of Symbia.

NET and the newer MI Neurology application in Syngo.via. Left and right striatal-to-occipital ratios of all patients were measured by two experienced nuclear medicine technologists (HTC and KH), expressed as mean ± standard deviation, and evaluated by paired-tests. Interoperator variability between both technicians was assessed for both quantification methods using the Pearson correlation test. P-values ≤0.05 were considered significant. ***Results:*** DAT SPECT datasets of 50 patients (female n=31(62%) and male n=19(38%); mean age 70±8 years) were included in this study. The mean±SD of the striatal/occipital ratios were 2.6±0.55 for ratios obtained from the Symbia.NET software but 2.8±0.54 for the ratio's produced by syngo.via (p <0.001). Correlation between both reading technologists was r =0.945 for the Symbia.NET module, and r =0.990 for the Syngo.via application (p <0.001). ***Conclusion:*** Syngo.via's MI Neurology application produces slightly, but significantly higher striatal-to-occipital ratios in DAT SPECT datasets, compared to the older Neurology module of Symbia.NET. Interoperator variability proved to be low for both software packages, given the very high correlation between measurements of both reading technologists. ***References:*** Akdemir ÜÖ, Bora Tokçaer A, Atay LÖ. Dopamine transporter SPECT imaging in Parkinson's disease and parkinsonian disorders. Turk J Med Sci. 2021 Apr 30;51(2):400-410. doi: 10.3906/sag-2008-253. PMID: 33237660; PMCID: PMC8203173.

EP-1269

Evaluating Diagnostic and Quantitative Outcomes of Thyroid Scintigraphy With a Reduced Post-Injection Time

M. Rode, *Z. Khaled Safi, J. Damgaard Mortensen, A. Dahl Johannsen, N. Lynge Kofod Topp, P. Abadi;*
Lillebaelt Hospital, University Hospital of Southern Denmark, Vejle, DENMARK.

Aim/Introduction: The EANM Guidelines for thyroid scintigraphy recommends acquisitions 15-20 min post [99mTc]-pertechnetate injection due to optimal activity uptake and the reported wash-out effect that occurs 20 min post-injection. As the mean time from injection to acquisition at the current department is 30 min, the aim of this study was to evaluate an early acquisition compared to the standard, both in regards to diagnostic and quantitative outcomes. ***Materials and Methods:*** A patient dose of 170 MBq ± 10% [99mTc)-pertechnetate was injected and static acquisitions were acquired on a gamma camera with pinhole collimator. Identical acquisitions consisting of an overview image of 5 minutes and a zoom image of 10 minutes/200 kilo-counts, were performed 5 and 25 minutes post-injection. Three nuclear physicians examined all images in regards to diagnostic value, to determine whether the same conclusion could be obtained from both images. To eliminate interpretation bias, images were blinded in regards to time from injection to acquisition, prior to evaluation by the observers. To obtain qualitative measurements, images were analyzed by inserting ROI's in the thyroid gland and the background, after which the contrast-to-noise ratios (CNR) were calculated. To determine potential significant differences between the early and late acquisitions, a Student's t-test was applied. ***Results:*** Forty-five patients were included in the study, and the observers were able to conclude identical diagnostic outcome regardless of time from injection in 40 patients (88.9%). The diagnostic outcome was uncertain/different for five patients, however there was not consensus among the three observers. It is noticeable that the observer, who categorized all patients with the same diagnosis, was the most experienced. The mean activity uptake in the images was slightly higher 25 minutes post-injection (31.4) compared to the uptake 5 minutes post-injection (30.0), however this difference was statistically significant (p=0.00024). The CNR might be more valuable for the diagnostic outcome than activity uptake, and no significant differences were determined between the images 5 and 25 minutes post-injection, with CNR's of 12.6 and 13.7, respectively. ***Conclusion:*** The vast majority of patients received the same diagnostic outcome regardless of time from injection to acquisition. No patients were categorized with different diagnostic outcome by all nuclear physicians, suggesting interpreter variability. While performing early thyroid scintigraphy results in a significant reduced activity uptake in the thyroid gland, it does not lead to a significant lower CNR when compared to later acquisitions, which is more valuable for accurate diagnosis.

EP-1270

Assessment of correlation between 2-hour radioactive iodine uptake and ^{99m}Tc-pertechnetate uptake on thyroid scintigraphy in patients with thyrotoxicosis

A. Ahad, *N. A. Damle, P. kumar, C. Bal, M. Tripathi, S. Ballal, A. Goyal, R. Gupta, P. GB;*
All India Institute of Medical Sciences, New delhi, INDIA.

Aim/Introduction: The thyroid uptake is an important factor in the diagnosis of thyrotoxicosis. The thyroid uptake is determined by using 123Iodine and 99mTechnetium radioisotopes, with 131Iodine being used where 123Iodine is not available. Studies assessing correlation between 99mTc -Pertechnetate and 2hr 131Iodine RAIU values are scarce. Since many centers in our country do only 99mTc -Pertechnetate uptake due to its easy availability, cost effectiveness and no requirement of thyroid uptake probe, it would be useful to establish this relation. ***Materials and Methods:*** Thirty adult patients (mean age = 40.5 ± 14 years) with diffuse toxic goiter were intravenously administered 3-5 mCi 99mTc pertechnetate through cannula. The static images (anterior view) of the loaded syringe, empty syringe, thyroid gland and cannula was taken under a Gamma camera (GE Healthcare, Brivo NM 615). The 99mTc pertechnetate thyroid uptake was calculated by drawing a region of interest around the loaded syringe, empty syringe, cannula and thyroid image of the patient to know the counts in them. The percentage uptake was obtained by dividing the thyroid counts by syringe counts with background counts correction. The same patients were administered 10 to 20 µCi 131I orally. The radioactive iodine uptake was determined by using a thyroid uptake probe and was calculated by taking background corrected neck counts divided by reference dose counts in thyroid neck phantom. The percentage thyroid uptake by both the radioisotopes (99mTc-pertechnetate and 131I) was correlated. ***Results:*** The median (IQR) 99mTc-pertechnetate uptake and 2hr radioactive iodine uptake was found to be 10.4 (6 - 24) % and 25.6 (13.6- 57.9) %, respectively. The median uptake percentage of RAIU was approximately 2.4 times of 99mTc-pertechnetate uptake. The result indicated a positive coefficient of correlation (0.917) between 2hr RAIU and 99mTc-pertechnetate uptake (p value <0.001). A positive correlation between 99mTc-pertechnetate uptake % and RAIU % with T3 and T4 was also observed. Moreover, the results also indicated a possible association of goiter grades with the uptake percentage of RAIU and 99mTc-pertechnetate. ***Conclusion:*** The simplicity and reproducibility of 99mTc-pertechnetate % uptake with no requirement of Uptake probe make 99mTc-pertechnetate uptake a viable option in patients with Diffuse Toxic Goiter.

EP-1272

Evaluation of ^{99m}Tc-DMSA administered activities in paediatric patients

R. Chagas, *G. Pitts;*
Derriford Hospital, Plymouth, UNITED KINGDOM.

Aim/Introduction: Balancing image quality with radiation dose is a goal with every diagnostic procedure requiring radiation, especially in paediatric population. Children have a greater risk to experiencing undesirable health effects from exposure to radiation than adults. Our institution evaluated the dosing of 99mTc-DMSA (dimercaptosuccinic acid) for paediatric patients, comparing prescribed activities with administered activities to evaluate compliance with our local Diagnostic Reference Levels (DRLs) based on the figures given in the ARSAC Guidance Notes 2022. ***Materials and Methods:*** Data was collected for all patients younger than 17 years receiving a Renal Nuclear Medicine procedure with 99mTc-DMSA between February 2024 and September 2024. Data collected included age, weight, prescribed activity, assayed activity, and residual syringe activity. For paediatric patients, prescribed activity is calculated based on weight. 99mTc-DMSA syringe was assayed before and after administration, and the residual was recorded to calculate syringe adsorption and administered activity. Administered activity should be +/- 10% of the prescribed activity. ***Results:*** The mean activity remaining in the syringe after administration was 24%, with a range of 11%-50%. No correlation was found between time in syringe and residue. 99mTc-DMSA is more adsorbed in 3ml syringes than in 1ml syringes, with an average of 43% and 20% of activity adsorbed respectively. On average 73% of prescribed activity was administered with only one patient received less than 50% of prescribed activity. No patient was overdosed. (Study still on-going. Further results will be added at later date). ***Conclusion:*** All administered activities failed to comply with our local DRLs (+/- 10% of the prescribed activity). The activity administered was significantly affected by the amount of residue left in the syringe. This data can provide clinicians with greater guidance in dosing 99mTc-DMSA in paediatric patients. Syringe residue needs to be considered when standardizing protocols and calculating patient dose. The inclusion of residual activity during patient dose calculations or the use of a system that eliminates the activity lost needs further investigation.

Analysis of outcomes of peptide receptor radionuclide therapy as a third line therapy in patients with advanced neuroendocrine tumors

F. Velickovic[1], *M. Vlajkovic[1], M. Stevic[1], T. Andjelkovic[1], N. Topic[1], D. Macut[2];*
[1]Clinical Center of Nis, Nis, SERBIA, [2]Clinical Center of Belgrade, Belgrade, SERBIA.

Aim/Introduction: Surgical treatment of neuroendocrine neoplasms (NEN) is primary whenever possible, followed by the use of somatostatin analogs, chemotherapy, immunotherapy, mTOR inhibitors, and radiation therapy in treatment. Peptide receptor radionuclide therapy (PRRT) represents one of the modalities in the treatment of these tumors, especially for well-differentiated neuroendocrine tumors. The aim of this study is to present the outcome of advanced NEN treatment as well as to demonstrate the response to treatment and survival of patients with G2 NEN treated with peptide receptor radionuclide therapy. ***Materials and Methods:*** The study included 34 patients who were treated with PRRT in accordance with a standard procedure involving the administration of labeled Y90 and/or Lu177 peptides, as the third line of treatment after surgery and other therapeutic modalities. PRRT was the first treatment option for only one patient due to an inoperable tumor of large dimensions. There were a total of 15 women with an average age of 64.8 ± 10 years and 19 men with an average age of 63.1 ± 11.4 years. Regarding localization, there were 25 patients with gastroenteropancreatic tumor (GEP-NET), among which 20 patients were of G2 grade, one of G3 grade, and 4 of G1 grade. Among 3 patients with pulmonary NET, two were of G2 grade and one of G1 grade. Among 5 patients with tumors of unknown primary localization, 4 were of G2 grade and 1 of G1 grade, while the patient with paraganglioma had a G2 grade tumor. Twenty-six patients received one cycle of PRRT, while 8 received repeated cycles of PRRT. ***Results:*** Twenty-six patients received only 1 cycle of PRRT, while 8 received repeated cycles of PRRT. Patients were followed up for 48 months after the last PRRT, and longer in patients who received repeated cycles of PRRT. The time to disease progression was 26.0 ± 15.6 months, while overall survival was 44.6 ± 21.2 months. In patients who received repeated cycles of PRRT, survival was significantly longer (57.8 ± 33.1 months) compared to those who received only one cycle, with 40.6 ± 14.6 months ($p < 0.05$). Leukopenia occurred in two subjects during and after therapy, and renal function impairment occurred in one subject. ***Conclusion:*** Peptide receptor radionuclide therapy is a powerful therapeutic tool in the complex treatment of patients with NET, showing significant slowing of disease progression and contributing to longer patient survival. Repeated cycles further extend patient life.

EP-1274

Evaluation of voxel-based absorbed doses calculated using SPECT imaging in iodine-131 therapy for hyperthyroidism

H. Iwanaga[1], *N. Fujita[2], S. Abe[2], K. Kato[1];*
[1]Nagoya University, Nagoya, JAPAN, [2]Nagoya University Hospital, Nagoya, JAPAN.

Aim/Introduction: In Iodine-131 therapy for hyperthyroidism, pretreatment evaluations of the thyroid mass, radioiodine uptake (RIU), and effective half-life (EHL) are used to estimate the absorbed doses and determine the required radioactivity for administration. These estimates assume a homogeneous distribution of I-131 within the thyroid gland; however, its accumulation is often heterogeneous. This is particularly evident in Plummer's disease, in which I-131 uptake is intensive only in autonomous nodules, leading to heterogeneous I-131 distribution within the thyroid. Such heterogeneity in absorbed doses can result in either excessive or insufficient radiation in parts of the thyroid gland, potentially affecting treatment outcomes. In this study, we aimed to assess the heterogeneous distribution of absorbed doses within the thyroid during I-131 therapy and compared the dose distributions in Plummer's disease and Graves' disease. ***Materials and Methods:*** We included 15 patients with Plummer's disease

and 35 with Graves' disease. Single-photon emission computed tomography (SPECT) images were captured on days one and seven after I-131 administration to calculate the 24-h RIU and EHL for each voxel. Prior to the dose calculations, a phantom filled with iodine-131 (78 MBq) was used to compute the cross-calibration factor (CCF). The RIU (24 h) was calculated by converting voxel counts into radioactivity based on SPECT images captured 24 h after administration using CCF and dividing by the administered radioactivity. The EHL per voxel was derived by approximating the voxel-based RIU from the SPECT images on days one and seven through exponential fitting. Based on this data, voxel-based absorbed doses were calculated using the Medical Internal Radiation Dose (MIRD) method. Average absorbed doses, standard deviations, and coefficients of variation were calculated for each patient. ***Results:*** In patients with Graves' disease, the EHL per voxel was almost uniform. Similarly, the absorbed doses were visually uniform with a coefficient of variation within 40%. Conversely, in patients with Plummer's disease, the EHL was shorter in the autonomous nodular areas and exhibited an overall heterogeneous distribution. The absorbed dose variability was more pronounced, with some cases showing a coefficient of variation over 50%. ***Conclusion:*** The method of calculating voxel-based absorbed doses from SPECT images post-I-131 administration was proven effective for evaluating thyroid dose distributions in both Plummer's and Graves' disease. Particularly in Plummer's disease, the significant variability in thyroid-absorbed doses underscores the importance of considering the heterogeneous uptake of I-131 when assessing dosimetry.

EP-1275

Management of Pregnancy in Metastatic Differentiated Thyroid Cancer

A. Khelifa, *A. Talbi;*
Bab El Oued Hospital, Alger, ALGERIA.

Aim/Introduction: Differentiated Thyroid Cancer (DTC) is more common in young women during their reproductive period. Management of DTC during pregnancy is the same as non-pregnancy except for the use of radioactive iodine which is an absolute contraindication, and this can be extremely difficult when we are facing pregnant metastatic patient with active DTC. The aim of this study is to manage and support women with metastatic DTC and to see the impact of pregnancy on the disease. ***Materials and Methods:*** This study was conducted at the Nuclear Medicine department of Bab El Oued University Hospital, Algiers. Pregnant metastatic DTC women were managed and seen at least 4 times. All the data were reported including biological profile under Levothyroxine (LT4) treatment, TSH, FT4 and Thyroglobulin (Tg), and neck ultrasonography, also the morphogram of the fetus on obstetric ultrasound. After delivery, the same biological profile under LT4, neck ultrasound and more radiological exams are performed, we also looked at the childbirth. ***Results:*** 10 pregnant women with metastatic Papillary Thyroid Cancer (mean age 32 years). 9 lung and node metastases and for one patient an association of bone and lung metastasis. We kept a low TSH level inferior to 0,1 µUI/ml for all patients. All the birth went well except for one death in utero, due to toxemia gravidarum. We reported no progression of the disease during pregnancy and after delivery. And we continue to treat with iodine 131 after birth. ***Conclusion:*** Management and monitoring metastatic Differentiated Thyroid Cancer during pregnancy is a difficult situation that must be based on a suppressive treatment with Levothyroxine until using radio iodine 131 after delivery. We noticed no impact of pregnancy on the progression of the disease.

EP-1276

Enhancing the accuracy of vertebral bone metastasis detection in non-small cell lung cancer with high-resolution xSPECT/CT imaging

S. Zhang, *Y. Dong, X. Du, H. Feng;*
The First Affiliated Hospital of Dalian Medical University, Dalian, CHINA.

Aim/Introduction: Traditional bone scintigraphy, while widely used, lacks specificity and could result in false-positive results, particularly in the context of benign spinal lesions such as osteoarthritis [1]. The high resolution xSPECT/CT bone imaging can enhance image quality and without any additional increase in radiation dose [2]. However, xSPECT/CT bone imaging for vertebral bone metastasis of non-small cell lung cancer(NSCLC) have not been well studied. This study was conducted to evaluate the effectiveness of xSPECT/CT in the prompt and precise identification of vertebral bone metastases in patients diagnosed with NSCLC. ***Materials and Methods:*** A prospective trial enrolled 22 patients with NSCLC and concurrent vertebral bone metastases, as well as 20 patients with non-neoplastic spinal osteoarthritis as a control group. The study was approved by the local IRB, and written informed consent was obtained from all subjects. Quantitative analysis was performed to calculate the SUVmax, SUVavg, and SUVmin in all cases of vertebral bone metastases in the NSCLC group and for the control group's spinal osteoarthritic changes. Receiver Operating Characteristic (ROC) curves were utilized to determine the optimal SUV cutoff values for distinguishing between vertebral bone metastases and benign spinal lesions. ***Results:*** The analysis included 33 NSCLC vertebral bone metastases, which exhibited a mean SUVmax, SUVavg, and SUVmin of 30.85±13.64, 10.37±5.96, and 5.44±4.36, respectively. For the control group 58 spinal osteoarthritic lesions, the mean SUVmax, SUVavg, and SUVmean were 14.34±5.96, 5.91±2.12, and 3.20±1.8, respectively. Significant differences were observed in SUVmax, SUVavg, and SUVmin between the metastatic and osteoarthritic groups ($p \leq 0.001$). With a SUVmax cutoff of 18.23 for NSCLC vertebral bone metastases, sensitivity and specificity predictive values were 94% and 81%, respectively. ***Conclusion:*** The results of this study demonstrate that xSPECT/CT scans can aid in distinguishing malignant from benign spinal lesions more reliably, enhancing the diagnostic performance of bone scintigraphy. This approach shows promise in improving the accuracy of detecting vertebral bone metastases in NSCLC patients, potentially leading to better clinical management and improved patient outcomes. ***References:*** 1. EP-1277

The Step-and-Shoot Continuous Mode Improves SPECT Scanning Efficiency:A Preliminary Phantom and Clinical Test

L. Jicheng, *Z. Kai, L. Jiangyan;*
Lanzhou University, Lanzhou, CHINA.

Aim/Introduction: The aim of the study was to investigate the value of Step-and-Shoot Continuous (SSC) scanning mode in enhancing image quality, and to explore the appropriate scanning parameters in reducing the scan time. ***Materials and Methods:***

This study was composed of a phantom study and two clinical tests. The differences in the visual score of image quality, in the Coefficient of Variance (COV) of the background, in the image Signal-to-Noise Ratio (SNR) and Contrast-to-Noise Ratio (CNR), and in the Recovery Coefficient (RC) of the sphere in different "shoot" acquisition times (5s/10s/15s) and "step" (3-degree/6-degree/9-degree) were compared between SSC mode and conventional SS (Step-and-Shoot) mode in the phantom study. The differences in the visual score of image quality, in the COV of the background, in the image SNR and CNR, and in the Standard Uptake Value (SUV) of lesions were compared correspondingly in a bone scan test and a parathyroid scan test, with 15 patients enrolled in each of them. ***Results:*** In the phantom study, the visual score of SSC mode was higher than that of SS mode; the COV of the background of SSC mode reduced significantly ($P<0.05$); the SNR and CNR of SSC mode increased significantly ($P<0.05$); while no significant alteration of RC was found ($P>0.05$). In the clinical tests, there were not significant differences between the optimal SSC scan combination (10-second "shoot" and 6-degree "step") and the traditional SS scan combination (15-second "shoot" and 6-degree "step") in the visual score of image quality, in the COV of the background, in image SNR and CNR, and in the SUV of bone and parathyroid high uptake lesions ($P > 0.05$). ***Conclusion:*** The acquisition time of SSC mode can be of 33% reduced, while keeping the similar image quality and quantification accuracy compared to those of the SS mode. An SSC scanning with 10-second "shoot" acquisition and 6-degree "step" of a 360-degree rotation is suggested clinically.

EP-1278

Low energy all-purpose collimator provides superior image quality to low energy high-resolution, for imaging cold defects of sizes seen in lung ventilation/perfusion SPECT

***R. Kappel*[1]**, *L. G. Kristensen*[1], *P. C. Holdgaard*[1], *N. A. Bebbington*[2];
[1]Department of Nuclear Medicine, Lillebaelt Hospital - University Hospital of Southern Denmark, Vejle, DENMARK,
[2]Siemens Healthcare A/S, Runevej 2, Aarhus, DENMARK.

Aim/Introduction: Diagnosis of pulmonary emboli with lung ventilation/perfusion SPECT involves fast acquisitions for identification of defects typically ≥20mm diameter. Low energy high resolution (LEHR) and low energy all purpose (LEAP) collimators allow scans to be optimised for high resolution or high sensitivity (low noise). The aim was to determine which collimator provides the best image quality for detecting cold defects, corresponding to optimal detection of pulmonary emboli in clinical practice. ***Materials and Methods:*** The NEMA-IEC PET Body-Phantom background was filled with 111MBq Tc-99m-pertechnetate and water solution. The spheres were filled with inactive water providing cold volumes, representing lung perfusion defects. Six consecutive step-and-shoot SPECT-CT acquisitions were made with both LEAP and LEHR collimators, with a dual-headed SPECT-CT system at 5, 10 and 20 minutes sampling time. Acquisition times were decay-corrected for comparable acquisition time for LEAP and LEHR scans. Reconstructions were made with ordered subset expectation maximisation and resolution recovery, with CT-based attenuation correction. Volumes of interest were assigned to the 4 largest spheres (17-37mm) on the CT images (corresponding to real physical sphere size) and copied to the SPECT reconstructions. The 10-13mm spheres being smaller than defect sizes of clinical interest were omitted from analysis. Contrast-to-noise-ratio (CNR) was calculated for each sphere: [(mean background counts/mean sphere counts)/(standard deviation of background/mean background counts)]. CNR was compared between LEAP and LEHR collimators for each sphere at each scan time. ***Results:*** For both collimators, CNR increased with increasing scan time and increasing sphere size, due to reduction in noise and partial volume effect, respectively. When comparing collimator for a given sphere size and scan time, CNR was consistently higher for the LEAP as compared with LEHR, with CNR values at: 14.4-17.1, 17.2-20.7 and 24.0-31.5 for the LEAP collimator for 5, 10 and 20 min scans respectively; and 10.7-12.7, 12.4-15.6 and 16.6-22.9 for the LEHR collimator. These data demonstrate 33-45% increase in CNR depending on sphere size and scan time for the LEAP as compared with LEHR collimator. ***Conclusion:*** These findings indicate that the LEAP collimator is more suitable than the LEHR, for SPECT imaging of relatively large, cold defects. Hence, we can infer that general purpose (LEAP) collimators are more appropriate than high resolution (LEHR) for lung ventilation/perfusion imaging, allowing improved image quality for the same scan time, or reduced scan time for comparable image quality. These data also demonstrate the importance of optimising collimator choice according to scan type.

EP-1279

Towards Whole Body imaging-Institutional experience

***N. Salkica*[1]**, *A. Begić*[1], *A. Beganović*[2], *H. Ćorović*[1], *S. Hadžimusić*[1], *Š. Cerić*[1], *A. Skopljak-Beganović*[2];
[1]Clinic for nuclear medicine, Sarajevo, BOSNIA AND HERZEGOVINA, [2]Department for medical physics and radiation protection, Sarajevo, BOSNIA AND HERZEGOVINA.

Aim/Introduction: Conventional nuclear medicine has been upgraded with the introduction of the hybrid Single Photon Emission Tomography (SPECT) with Computed Tomography (CT). This new modality significantly increased sensitivity and specificity of the scintigraphy procedures. After new detector systems have been created, focus of the clinical research is on advanced software solutions. All major nuclear medicine equipment producers offer new acquisition and reconstruction modalities such as resolution recovery (RR) algorithms with focus on dose/time reduction. Since major disadvantage of the conventional SPECT is long acquisition duration these new solutions offer same image quality with reduced scanning time. Fery fast SPECT acquisition can eliminate patient discomfort and incidence of the artifacts created with patient movement during very long scanning procedure. Fast SPECT acquisition offers possibility to create SPECT sequence of more than one anatomical region which then can be implemented in Whole Body (WB) SPECT/CT. WB SPECT/CT potential is well documented for bone, parathyroid, Somatostatin Receptor Scintigraphy (SSRS) and I-131 scintigraphy. ***Materials and Methods:*** We performed prospective study for 100 patients who underwent planar WB bone scintigraphy. After planar imaging, we performed SPECT/CT acquisition with conventional and ultra-fast scan duration. For the process of reconstruction of tomographic images, we used classic and specific (with RR algorithm) program. For the image quality we measured noise index, Signal to Noise Ratio (SNR) and Contrast to Noise Ratio (CNR). Two experienced nuclear medicine specialists evaluated image sharpness, lesion detection and lesion background ratio. ***Results:*** Conventional SPECT acquisition with standard reconstruction protocol offers good image quality while RR reconstruction protocol results in better image quality. Ultra-fast scanning acquisition with standard reconstruction algorithm results in poor image quality, while RR reconstruction protocol offers the same image quality as the one obtained during conventional acquisition. Subjective image quality assessment performed by physicians confirmed these

findings since lesion detection and demarcation can be preserved. Use of RR reconstruction protocol results in high sensitivity and specificity for ultra-fast SPECT acquisition. ***Conclusion:*** Ultra-fast SPECT acquisition can be utilized in the WB SPECT/CT not just for bone scintigraphy. New studies suggest WB SPECT/CT procedure has potential for detection of ectopic parathyroid tissue and thyroid cancer metastases. Furthermore, 2-3 Field of View (FOV) WB SPECT/CT has become a standard imaging technique in SSRS scintigraphy. Our clinical study has been performed for bone scintigraphy only, but new research suggests every other SPECT/CT protocol can be optimised for future WB SPECT/CT purpose.

EP-1280

Optimizing reconstruction updates in SPECT imaging enhances visualization of cold defects relevant for pulmonary emboli detection

R. Kappel*[1]*, *L. G. Kristensen*[1]*, P. C. Holdgaard*[1]*, N. A. Bebbington*[2]*;*
[1]Department of Nuclear Medicine, Lillebaelt Hospital - University Hospital of Southern Denmark, Vejle, DENMARK,
[2]Siemens Healthcare A/S, Runevej 2, Aarhus, DENMARK.

Aim/Introduction: To diagnose pulmonary emboli with lung ventilation/perfusion SPECT, the detection of cold defects is crucial. Iterative reconstruction methods enhance image quality to improve the detection of cold defects, compared with filtered back projection. In the 2009 EANM-guideline, 16 updates were recommended, and in the 2019-version, 32 updates were recommended, without a clear justification. The aim was to determine the optimal number of updates for reconstructing lung SPECT, according to qualitative and quantitative measures. ***Materials and Methods:*** Cold defects were provided using the NEMA body phantom, with a background of 111 MBq Tc-99m pertechnetate and spheres filled with inactive water. Step-and-shoot SPECT acquisitions were performed using a low-energy all-purpose collimator at 5, 10, and 20 minutes sampling times, all decay-corrected. Images were reconstructed with 16, 30, and 60 updates with CT attenuation correction. The four largest spheres (17, 22, 28, and 37mm) were used for contrast-to-noise ratio (CNR) calculation. A simple Visual Grading Analysis (VGA) was conducted using one physician as observer. Visualization of each sphere size was graded -2 to 2, resembling "Clearly inferior" to "Clearly superior" to the reference, respectively. Grade 0 representing "Equal to the reference". VGA reference was 30 updates. Visual evaluation was done with a white-on-black color scale. ***Results:*** CNR increased notably with a lower number of updates and larger sphere sizes. Comparison of CNR values for 16, 30, and 60 updates at 5, 10, and 20-minute sampling times, with sphere sizes ranging from 17 to 37mm, revealed the highest CNR at 16 updates (28.17-32.6, 41.1-48.4, and 57.7-70.8) compared to 30 (20.3-24.2, 28.5-34.8, and 40.6-52.3) and 60 (13.9-17.9, 20.8-26.7, and 28.3-39.7). VGA showed 60 updates to be comparable or superior to 30 and 16 updates at each scan time. At larger sphere sizes (28 and 37mm) and most relevant for pulmonary emboli detection, 30 and 60 updates were comparable, with 16 updates being inferior. At smaller sphere sizes (17 and 22mm) less relevant for detecting emboli, 60 updates were superior to both 30 and 16 updates. ***Conclusion:*** For optimal CNR, 16 updates are preferable, but 30 and 60 updates are preferred visually, with optimal visualization provided by an even greater number of updates than those recommended in the latest EANM guidelines . This discordance between CNR, visual-evaluation, and guideline, combined with only one observer in this study, suggests a need to further investigate and document the optimal settings for lung ventilation/perfusion SPECT.

EP-1281

A Comparison of Image Quality and Scan Speed between Digital and Non-Digital ^{18}F-FDG PET-CT for a Weight Based Activity

A. McCredie, *A. J. Gemmell, P. Gomes, K. Thomson, S. Small;*
West of Scotland PET Centre, Glasgow, UNITED KINGDOM.

Aim/Introduction: This study used signal to noise ratio (SNR) to evaluate image quality following install of a digital PET scanner. 235 patients received a whole body 18F-FDG PET-CT scan on a digital PET using flow motion (A) (n=136) or pre-existing non-digital PET scanner using "step and shoot" (B) with regularised iterative reconstruction (n=101). Scan time, patient positioning and patient weight were investigated as contributing variables. ***Materials and Methods:*** A target activity of 4 MBq/kg of 18F-FDG (+/- 10%) was set as per local guidelines. Two scan speeds were used on scanner A (1 mm/second and 1.5 mm/second) and a bed duration of 3 minutes per bed on scanner B. Automated placement of a 3cm diameter ROI in the liver helped with standardisation, though region was moved if necessary - patients with extensive liver disease or where large respiratory artefacts were present were excluded. SNR was calculated as mean counts in ROI divided by standard deviation. SNR versus scan time, arm position and weight were compared. ***Results:*** For a bed speed of 1 mm/s, scanner A had similar SNR (p= not significant) to scanner B at 3 minutes per bed: however, scan time is significantly shorter at an average of 15 mins compared to 22 minutes ($p< 0.0001$). For scanner A, the SNR was significantly lower for 1.5 mm/sec compared to 1 mm/sec ($p< 0.0001$) - images were visually assessed by radiologists as maintaining sufficient image quality (this became standard protocol and reduced overall scan time from an average of 15 minutes to 9.8 minutes). Patient positioning (arms up/down) had no significant effect on SNR for either scanner or at different speeds. 95% patients were administered with target activity of 4 MBq/kg (+/- 10%). The 4 MBq/kg weight-based protocol was introduced to help equalise SNR across the patient weight range, however this project shows it working for scanner B, but not scanner A (significant downward trend on SNR with increasing weight). ***Conclusion:*** Scanner A shows similar image quality as scanner B for a reduced average scan time (15 versus 22 minutes). Scan time can be reduced further to 9.8 minutes on scanner A while maintaining clinically suitable image quality. The department prioritised acceptable image quality with reduced scan time for operational reasons. Further research will be conducted on whether an adjustment of weight-based activity or adjusting scan speed for heavier patients on the digital scanner will equalise the SNR.

EP-1282

Can Deep Learning Reconstruction Enable Low-Dose ^{18}F-FDG PET Imaging?: A Validation Using Clinical Data

Y. Shirakawa, *K. Ebine, M. Kawada, J. Suyama;*
Kyorin University Hospital, Mitaka, JAPAN.

Aim/Introduction: The advanced intelligent clear-IQ engine-integrated (AiCE), a deep learning reconstruction (DLR) technology, effectively reduces noise without compromising contrast, thereby improving image quality despite lower fluorine-18 fluorodeoxyglucose (18F-FDG) doses compared with conventional methods. This study aimed to evaluate the association of AiCE with the image quality and quantification of low-dose positron emission tomography (PET) images using clinical data as well as verify the practicality of low-dose PET examinations. ***Materials and Methods:*** Cartesion Prime (Canon

Medical Systems, Otawara, Japan), a SiPM-PET/CT, was used to conduct abdominal imaging, including the liver, with 2-3 min of list-mode acquisition for each case. The participants consisted of 51 cases in the low-dose group (LD, ≤2.5 MBq/kg) and the standard-dose group (SD, 3.7 MBq/kg). Image reconstruction was conducted using 3D-OSEM + TOF + PSF, 4 mm Gaussian filter (GF), and AiCE. The evaluation was conducted based on the liver signal-to-noise ratio (SNR) and liver SUV (max, mean). ***Results:*** The median liver SNR for GF and AiCE was 8.8 and 16.3 in the LD group and 10.1 and 16.3 in the SD group, respectively. Additionally, the median liver SUV (max, mean) was 3.7, 2.6 for GF and 3.2, 2.6 for AiCE in the LD group, whereas 3.5, 2.7 for GF and 3.4, 2.7 or AiCE in the SD group. ***Conclusion:*** Even with low 18F-FDG doses, DLR technology demonstrated equivalent liver SNR to standard-dose PET images compared with conventional image reconstruction methods. Additionally, this technology obtained stable quantitative values compared with conventional reconstruction methods, indicating improved image quality and quantitative accuracy of low-dose PET images, thereby demonstrating the feasibility of low-dose PET examinations. ***References:*** 1) Tsuchiya J, Yokoyama K, Yamagiwa K, et al. Accuracy of hybrid PET-MRI combined with whole body PSMA PET-MRI in diagnosing prostate cancer recurrence: New horizon and future perspectives

***N. Chiodini*[1],** *L. D'Alessio*[2], *G. Bonfitto*[3];
[1]*Università di Pavia, Pavia, ITALY,* [2]*I.R.C.C.S Ospedale San Raffaele, Milano, ITALY,* [3]*I.R.C.C.S. Ospedale San Raffaele, Milano, ITALY.*

Aim/Introduction: Prostate cancer (PCa) shows the second highest incidence of all cancers among the male population worldwide. Despite increasing therapeutic options, early diagnosis is crucial for a favorable prognosis. In the past decade, several tests contributed to the early diagnosis, such as the measurement of Prostate Specific Antigen (PSA). MRI sequences represent the gold standard examinations for the definition of PCa morphology, while PET acquisitions are essential for its staging. This study aims to develop a hybrid PET-MRI protocol in order to obtain the simultaneous morphological and stage imaging of a biochemical recurrence after radical prostatectomy. ***Materials and Methods:*** We conducted a retrospective evaluation of patients with suspected biochemical relapse using a Hybrid 3T PET/MRI system, using homemade Fluorine18 coupled with PSMA as a tracer. Every patient who underwent Total Body PET/MRI acquisition and PET-MRI High Statistic-Fluoro-PSMA couch, combined with prostate-specific MRI sequences such as T1, T2 weighted sequences, DWI with b-value 50/800/1400/1600 and synthetic reconstruction value of 2000 with related ADC map. ***Results:*** ^{18}F-PSMA-1007 PET/MRI imaging appears very promising in staging and restaging patients with PCa, especially when biochemical relapse is under consideration. Currently available ^{18}F-labeled PSMA agents provide a more accurate and earlier detection of prostate disease than conventional imaging. Labeling PSMA agents as ^{18}F has several advantages over 68Ga. Studies has shown an overexpression of PSMA in PCa tissue compared with normal tissue, which increased even further at advanced stage and grade of PCa. PET/MRI acquisition is quite sensitive for detecting bony metastases, but its specificity is lacking as both neoplastic and inflammatory causes of MRI signal abnormality exist. Normal bone marrow signal intensity is homogeneous, whereas early bone metastases disrupt this normal signal, creating heterogeneity within the marrow space. Diffusion-weighted and dynamic contrast- enhanced (DCE) MRI have potential to furnish biological characterization of tumor aggressiveness in PCa patients. ***Conclusion:*** This study demonstrated a potential quality improvement over conventional imaging. The combination of high- resolution prostate PET/MRI associated with PET/MRI Total Body, serving as the reference modality for local tumor assessment and biochemical recurrence, along with ^{18}F-PSMA-1007-PET for staging presents a very promising diagnostic approach. Using both techniques: PET/MRI for Total Body acquisition and PET/MRI for prostate couch significantly reduces the time required for the entire protocol, completing two specific exams in the duration of one, unlike other studies that last more than one.

EP-1284

Ventilation Simulation: An effective technique to assess gas flow

***L. Macdonald*[1,2],** *A. Bolster*[1,2,3], *S. Williams*[1,2,3];
[1]*Department of Clinical Physics and Bioengineering, Glasgow, UNITED KINGDOM,* [2]*Department of Nuclear Medicine, North East Sector, Glasgow, UNITED KINGDOM,* [3]*College of Medical, Veterinary and Life Sciences, University of Glasgow, Glasgow, UNITED KINGDOM.*

Aim/Introduction: Ventilation agents are used for lung VQs and various manufacturers produce these agents using different equipment. Recently, our [99mTc]-ventilation machine failed and an engineer was unable to attend for over a week; limiting our options for lung VQs, a high-priority procedure. Despite the patient breathing well, the ventilation machine did not deliver the radiopharmaceutical. With a second attempt using a new kit and burn, the issue persisted due to a faulty battery. To maintain the clinical service, [81mKr]-ventilation agent was ordered but the quality control failed, leaving us without ventilation agent. To address the issue, the engineer sent a battery with replacement instructions. We enquired about testing the machine following repair but there was no formal test to confirm the ventilation agent was being delivered before use with a patient. ***Materials and Methods:*** To ensure that the ventilation machine was working properly, we had to simulate patient's breathing in a contained manner to avoid unnecessary radiation exposure. We required an instrument that would extract air out of the ventilation - we utilised a balloon pump. A ventilation kit was attached to the ventilation machine and the mouthpiece attached to a balloon pump set to extract air. The balloon pump was placed into a bag and the opening of the bag was zip-tied to ensure a tight seal. The filter on the kit would prevent any ventilation agent from being pushed back out and by confining the balloon pump to an airtight bag, we could ensure no radiopharmaceutical would escape into the background. ***Results:*** We successfully built a breathing simulation instrument and tested it on our gamma camera; we burned the [99mTc]-ventilation agent and placed our instrument on the bed. The balloon pump simulated breathing while the gas was being delivered. We started with one breath to check for leaks, then gradually increased the breaths to check if the counts were increasing. After acquiring a few breaths, we

left the instrument under the camera to investigate any leaks. We found that there were no leaks and that the ventilation agent was contained within the instrument. ***Conclusion:*** This instrument was developed due to issues with availability of ventilation agents for lung VQs while waiting for an engineer visit. The instrument we developed was successful at simulating ventilation before using the [99mTc]-ventilation machine on a patient and was used to confirm the counts increased as expected.

EP-1285

Evaluation of Deviceless AI Gating System in PET-CT

M. De Summa[1], *S. Spinosa[1], A. Capotosti[2], I. Moretti[2], R. Moretti[2], L. Indovina[2], M. De Spirito[2], A. Giordano[2], S. Annunziata[2]; [1]Medipass S.p.A. - Ergèa Group.Integrative Service PET/CT - Radiopharmacy, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, Italy, Roma, ITALY, [2]Department of Diagnostic Imaging, Oncological Radiotherapy and Hematology, Fondazione Policlinico Universitario A. Gemelli IRCCS, Roma, Italy, Roma, ITALY.*

Aim/Introduction: This study evaluates the efficacy of Siemens' deviceless AI respiratory gating system in PET scanners, focusing on its precision in tracking respiratory motion and its potential impact on improving PET image quality ***Materials and Methods:*** A CIRS programmable phantom motor emulating respiratory movements and a phantom plate with NEMA IEC spheres were utilized. The spheres were filled with a ^{18}F-FDG solution at a concentration of approximately 20 kBq/mL, precisely meeting the requirements for the image quality test for EARL accreditation. Imaging was performed while the spheres were affixed to the moving motor, with assessments of the gating system's effectiveness conducted through image reconstruction with and without the AI algorithm provided by a Siemens Biograph Vision Edge 600 PET/CT scanner ***Results:*** The analysis focused on the largest sphere (37 mm)to avoid partial volume effects. The image quality showed a marked improvement when using the AI-based gating algorithm. In the static condition, the RC for this sphere was 0.95. For dynamic imaging, the RC improved from 0.62 in the non-gated reconstruction to 0.85 in the gated reconstruction, showing a significant increase of approximately 37%. This substantial enhancement in RC suggests a significant reduction in motion artifacts and an increase in lesion detectability ***Conclusion:*** The Siemens deviceless AI gating system has proven effective in compensating for respiratory motion in PET imaging, as demonstrated in a controlled phantom study. The increase in RC with the gated reconstruction, especially in the largest sphere, underscores the potential for this technology to enhance diagnostic accuracy in clinical PET imaging, paving the way for more reliable oncological assessments without the need for external devices

EP-1286

Using Recursive Feature Elimination in Random Forest for Progression Prediction of Mild Cognitive Impairment with Tc-99m ECD SPECT Images

S. Tseng[1], *H. Yang[1], Y. Ni[1], C. Lin[1], C. Chang[2]; [1]Department of Radiation Protection, National Atomic Research Institute, Taoyuan, TAIWAN, [2]Department of Neurology, Kaohsiung ChangGung Memorial Hospital, Kaohsiung, TAIWAN.*

Aim/Introduction: Identifying individuals at risk of progressing from Mild Cognitive Impairment (MCI) to Alzheimer's Disease (AD) is crucial for early intervention and appropriate therapy application. Our study aims to utilize Tc-99m ECD SPECT images of MCI patients and the random forest-recursive feature elimination (RF-RFE) algorithm to classify MCI into progressive (pMCI) and stable (sMCI) subtypes. ***Materials and Methods:*** The study included 58 sMCI and 62 pMCI subjects. In this retrospective study, we collected Tc-99m ECD SPECT images from MCI subjects, distinguishing between pMCI (patients progressing to AD) and sMCI (unchanged status after 30 months). Spatial normalization using SPM5 software and intensity normalization with the cerebellum as a reference region standardized the images. After preprocessing, the images were segmented into 91 brain regions, and cerebral blood flow statistics in each region served as features for machine learning. We employed RF-RFE algorithm for pMCI/sMCI classification, comparing RFE-selected features with those from F-score feature selection and regions with significant voxel statistical differences from Statistical Parametric Mapping (SPM) analysis. Training on 80% of the data, with 20% for independent testing, and 5-fold cross-validation mitigated overfitting and selection bias. Model performance metrics included sensitivity, specificity, precision, accuracy, and F1 score. ***Results:*** The classification of pMCI/sMCI using RF-RFE resulted in an accuracy of 75.00%, sensitivity of 83.33%, specificity of 66.67%, an AUC of 0.80, and an F1 score of 76.90% after RFE. Without RFE, the accuracy was 70.83%, sensitivity was 83.33%, specificity was 58.33%, AUC was 0.79, and F1 score was 74.10%. Feature importance analysis revealed key regions including the inferior temporal gyrus, fusiform gyrus, parahippocampal gyrus, and orbital part of superior/inferior frontal gyrus across all three feature selection methods. ***Conclusion:*** Our study demonstrates the efficacy of utilizing Tc-99m ECD SPECT images and a RF-RFE algorithm for progression prediction of MCI. It also identifies the brain regions that are indicated to be meaningful for predicting transitions in MCI patients.

EP-1287

Optimization Of Technical Aspects For Using The Innovative Stepbrain Brain Phantom In Nuclear Medicine Imaging Simulations

D. Ciotola[1], *G. Pecchia[1], B. Alfano[2], C. Del Vasto[1], E. Di Giorgio[1], S. Imbimbo[1], C. Lanotte[1], L. Mansi[3], A. Restaino[1], S. Piccolo[1], M. A. Pirozzi[4], M. Quarantelli[5], C. Silva[1], M. Spadafora[1]; [1]Nuclear Medicine Unit, Ospedale del Mare, Naples, ITALY, [2]Human Shape Technologies S.r.l., Naples, ITALY, [3]CIRPS, Interuniversity Research Center for Sustainability, Rome, Italy- Medicina Futura, Acerra, Naples, ITALY, [4]Department of Advanced Medical and Surgical Sciences, University of Campania "Luigi Vanvitelli", Naples, ITALY, [5]Institute of Biostructure and Bioimaging, National Research Council (CNR), Naples, ITALY.*

Aim/Introduction: The standardization of hybrid diagnostic brain imaging in nuclear medicine is a challenging task to allow evaluation of the sensitivity of different equipment and methods, also through multicenter studies. To this aim, anthropomorphic brain phantoms are developed for the assessment of medical equipment, reconstruction, and partial volume effect correction algorithms, or even to study the impact of different compartmental concentrations of tracers on images. In this study, the technical and procedural aspects of using an innovative anatomical brain phantom, StepBrain (SB), which is the first composed of 3 compartments: dorsal striatum (DS), gray (GM), and white matter (WM), for the simulation of images of normal brains and patients suffering from dementia, were presented. ***Materials and Methods:*** The radiopharmaceutical preparations, the filling and mixing of phantom solutions, as well as the image acquisition parameters on Siemens Biograph PET/CT scanner,

were optimized. In an FDG-PET-like simulation, the phantom was filled with different concentrations of ^{18}F-FDG to simulate the correct concentration ratios GM/WM = 2.80 and a BG/WM = 2.63 of a healthy brain, as reported in other studies, to obtain the counting gradients of real PET/CT. After filling, SB was placed on an automatic rotating system, set up to mix the solutions and avoid air bubbles, as detected on a preliminary CT. Similarly, amyloid-PET acquisitions were simulated, thus also evaluating the different acquisition and processing protocols of both CT and PET images, simulating concentration ratios ranging from 0% GM and 100% WM, up to 120% GM and 100% WM. ***Results:*** The filling procedure favored the absence of significant air bubbles, particularly in the DS, in over 80% of the acquisitions. Furthermore, thanks to the automatic mixing system, the radioactive fluids inside the compartment were homogeneously distributed. The acquisition/reconstruction parameters provided images of comparable quality to real patients. The simulations obtained, both FDG-PET-like and PET-Amyloid, were qualitatively evaluated by three experts in PET/CT studies. ***Conclusion:*** The likelihood of the images obtained has been assessed as optimal, both in reproducing the activity ratios of a healthy brain and in simulating different degrees of disease progression in patients suffering from dementia (i.e., Alzheimer's disease).The technical-procedural methodology developed in our laboratory allowed the use of the SB phantom for technical, qualitative, and quantitative evaluations of the performance of nuclear medicine hybrid imaging scanners, with a degree of accuracy never achieved before with imaging phantoms.

EP-1288

SUV Evaluation of ^{99m}Tc Myocardial Perfusion Scintigraphy in Stand-alone SPECT: Accuracy Evaluation by Cardiac Phantom

Y. Ichikawa[1,2], *H. Daisaki[2];*
[1]Sumitomo Besshi Hospital, Ehime, JAPAN, [2]Gunma Prefectural College of Health Sciences Graduate School, Maebashi, JAPAN.

Aim/Introduction: It is widely known that evaluation of ischemic heart disease by myocardial scintigraphy underestimates multi-vessel disease because of the relative assessment of blood flow. The EANM practice guideline for quantitative SPECT-CT [1] mentions the possibility of quantitative assessment of myocardial perfusion using SPECT-CT. However, about 60% of nuclear medicine facilities in Japan have stand-alone SPECT scanner, and many of these facilities do not perform attenuation correction (AC) and scatter correction (SC), so quantitative SPECT-CT images cannot be obtained. The purpose of this study was to compare the accuracy of SUVs that can be calculated from non-AC/SC SPECT images obtained with a stand-alone SPECT scanner with SUVs obtained from quantitative SPECT-CT images as a reference. ***Materials and Methods:*** RH-2 myocardial phantom (theoretical SUV: 3.82) was acquired by Symbia E (Canon). Acquisition parameters were as follows: LEHR collimator, 64 matrix size, zoom 1.45, scan duration of 1200s/72 views, and scan mode of detector auto-contouring. All projection data were reconstructed using OSEM (subsets of 6, iteration of 8, Butterworth filter of 0.55cycles/cm) without AC/SC. AC/SC SPECT images were also generated as reference data with similar acquisition and reconstruction parameters using CT images acquired by different CT scanners and SC of TEW method. All SPECT images were converted to the SUV scale by normalizing using dose and volume after applying Bq calibration factor. SPECT images were converted to Polar-map and the accuracy of the mean SUV of 17 segments was evaluated with mean recovery coefficient (meanRC). The uniformity of SUV between segments was evaluated by ΔSUVsegment and standard deviation (SD) of ΔSUVsegment (SDΔSUVsegment), where ΔSUVsegment is the deviation between the average SUV of 17 segments and the SUV of the individual segments. The meanRC, ΔSUVsegment, and SDΔSUVsegment were compared for non-AC/SC and AC/SC. ***Results:*** The meanRC in non-AC/SC and AC/SC were 0.35, 0.57, respectively. The maximum ΔSUVsegment in non-AC/SC and AC/SC were +12.6%, +12.7%, respectively. The SDΔSUVsegment in non-AC/SC and AC/SC were 0.069, 0.054, respectively. ***Conclusion:*** The mean RC of the non-AC/SC SPECT images was lower than that of the AC/SC SPECT images, but the ΔSUV segment and SDΔSUV segment were only slightly different, indicating that the uniformity of SUV between segments is comparable. The SUV evaluation of stand-alone SPECT scanner has acceptable accuracy, although the absolute value of SUV may be slightly lower than that of quantitative SPECT-CT. ***References:*** [1] Dickson JC, et al. Eur J Nucl Med Mol Imaging. 2023 Mar;50(4):980-995.

EP-1289

No More Tossing and Turning: The Type of Pillow has a Significant Impact on Patient Head Movement During PET/CT Acquisition

M. Rode, *P. Holdgaard, J. Terzic;*
Lillebaelt Hospital, University Hospital of Southern Denmark, Vejle, DENMARK.

Aim/Introduction: Accurate image-registration between CT and PET signals during a PET/CT-scan, is crucial for image quality and thus diagnostic outcome. Comfortable patient positioning prior to scan is very important to maintain same position throughout the scan duration. Different aids, such as armrests, head- and knee pillows are used, all in an effort to reduce patient movement. There are currently two different head pillows used at our department, one of them has an indent for cranial support. The aim of this study was to examine, if the use of the cranial-support-pillow(CSP) with indent results in fewer artefacts due to patient head movement when compared to the standard arm-rest-pillow(STD). ***Materials and Methods:*** Consecutive patients for PET/CT-scans were included and the use of pillow type alternated on a daily basis on the two used PET/CT-scanners. Patients were excluded if scanned as head-and-neck scanning protocol, a demetia patient or other positioning aids had been used. Information regarding pillow type, scan duration, age and gender were recorded. Patient movement was evaluated both visually and was quantified, as an angle measurement between the CT- and PET signal at the tip-off the nose to evaluate head rotation, and was categorised in groups of 0°, 1-9° or ≥10° difference. The technologists evaluating images for movement were blinded to pillow type. Significant differences between the CSP and STD were evaluated with Chi2 test for categorical data and ANOVA test for quantitative data. ***Results:*** In the study, 141 patients were included; 74 in the ARP-group and 67 in the CSP-group. The two patient groups were identical, with no significant differences between ages, gender and scan duration. A significant reduction in head movement was observed between the two groups, as 42 patients (62.7%) in the CSP-group had no registered movements between CT and PET compared to 22 patients (29.7%) in the STD-group ($p<0.0001$). Angle differences from 1-9° was 15 patients (22.4%) in the CSP-group compared to 35 patients (47.3%) in the STD-group. Measured differences ≥10° was reported in 10 patients (14.9%) in the CSP-group and 7 patients (22.9%) in the STD-group. The angle differences between the two groups were statistically significant ($p<0.001$). The mean scan duration in the degree-groups were 11:37, 13:46 and

12:48 minutes for group 0°, 1-9° and ≥10°, respectively (p>0.05). ***Conclusion:*** Using the CSP pillow results in a significant reduction in registered head movement of patients, which is crucial to ensure satisfactory image quality.

EP-1290

Clinical Study of Amyloid PET Dose and Collection Time

K. Onuki[1], *S. Takemoto[2], K. Tanimoto[2], S. Kimura[3], K. Tsuda[4], K. Murakami[2];*
[1]Juntendo Tokyo Koto Geriatric Medical Center, Tokyo, JAPAN, [2]Juntendo Hospital, Tokyo, JAPAN, [3]Juntendo Hospital, Tokyo, JAPAN, [4]Juntendo University, Tokyo, JAPAN.

Aim/Introduction: The Amyloid PET examination represents a pivotal diagnostic modality that enables visualization of amyloid β protein deposition within cerebral tissue. This imaging technique, utilizing the radiopharmaceutical Flutemetamol (^{18}F), an activity ranging from 185 Mbq to 370 Mbq, as specified in the product infomation. Notably, the commencement of imaging exhibits considerable variability, spanning a window of 60 to 90-minutes post-administration.However, there is a paucity of clinical literature concerning Fultemetamol formulations with respect to dosing and imaging timing, specifically the initiation of imaging at the 60-minute mark. Consequently, we undertook a rigorous investigation employing the following methodology. ***Materials and Methods:*** The investigation encompassed a cohort of 22 patients, whose images were acquired during the period spanning December 2022 to December 2023.The instrumentation employed consisted of the Celesteion Canon. Additionally, the VIZCalc C.I.1 software, developed by Nihon Medi-Physics and facilitated the subsequent analysis.Image acquisitions were conducted at 10-minutes (aligned with an administration of 143 to 185 Mbq) and 20-minutes (standard protocol) relative to the 60-minute imaging initiation timepoint.Subsequently, a visual assessment was performed on each image. Quantitative analysis involved measuring pixel values using the Centiloid VOI method, calculating the standardized uptake value ratio (SUVr), and scrutinizing changes on the Centiloid Scale. ***Results:*** The visual assessment results revealed no discernible disparity between negative and positive evaluations.In the context of physical evaluation, no statistically significant variation in standardized uptake value ratio (SUVr) was observed among negative cases. However, a notable discrepancy emerged in positive cases, contingent upon the reference site. Analogous findings were obtained using the Centiloid Scale.The phenomenon of brain drug accumulation diminishing over time due to washout likely contributes to the observed differences, particularly influenced by the imaging start time. ***Conclusion:*** This study, encompassing 22 cases (comprising 13 negative cases and 9 positive cases), suggests that despite the limited sample size, it remains feasible to generate clinical images under distinct conditions. Encouragingly, each facility should persist in testing consistently within the parameters established by the facility itself.If concordance could be established with the 90-minute post-administration image employed in the preceding study, it would facilitate the harmonization of protocols across different institutions and radiopharmaceuticals.

EP-1291

Enhancing SUV values determination through Lean Body Mass Normalization to Reflect Patient Weight and Body Composition Variations using ^{18}F-FDG and ^{18}F-somatostatine analogue PET-CT imaging.

A. Hurtado de Mendoza[1], *M. Yaryes Bravo[1], C. Pizarro[2], C. Soza Ried[1], H. Amaral Pineda[1];*
[1]Positronmed, Santiago, CHILE, [2]San Sebastian University, Santiago, CHILE.

Aim/Introduction: This study aimed to evaluate the impact of standardizing SUV measurements by weight (SUVbw) in comparison to lean-body-mass (SUL) within both FDG and AlF-NOTA-Octreotide (FAN) PET/CT scans. We focused on SUVmean in the liver comparing outcomes derived from the two normalization methods across different patient cohorts. Moreover, we compared these two methods within a cohort of patients undergoing weight fluctuations between two consecutive visits to our center. ***Materials and Methods:*** SUVmean measured both FDG and FAN PET/CT scans were normalized utilizing the weight (SUVbw) and the lean-body-mass (SUL) parameters. For FDG PET/CT scans, we conducted a retrospective analysis of data encompassing 172 patients stratified into three groups according to their BMI: normal (<25), overweight (25-29.9), and obese (≥30). Additionally, a cohort of 11 patients who lost weight during two consecutive visits, characterized by a decrease within ±10% of initial weight, was followed. For FAN PET/CT scans, we grouped 60 patients into normal and overweight groups. Statistical analyses were conducted to compare the SUV values between weight-based and LBM-based normalization methods within each patient category. ***Results:*** In FDG PET/CT scans, SUVbw mean was significantly higher in obese patients (43 patients) compared to those with a normal BMI (62 patients) (2.23 ± 0.48 and 1.88 ± 0.36 respectively; P ≤0.001), showing significant differences across BMI categories, while SUL mean did not exhibit such differences (P >0.05). In FAN PET/CT scans, SUVbw mean exhibited significant differences between BMI categories (P = 0.038), with higher values observed in obese patients (31 patients) compared to those with normal BMI (29 patients)(3.66 ± 1.35 and 2.72 ±1.19 respectively), whereas SUL measurements failed to show differences between normal BMI and obese groups (P >0.05). Analysis of patients who lost ±10% of their initial weight during consecutive visits to our center, revealed no statistical differences when normalized by the two distinct methods. However, SUVbw measurements showed considered variation between the assessed time-points compared to measurement with SUL. ***Conclusion:*** Our findings showed that LBM normalization provides a more consistent and reliable approach for SUV measurements in both FDG and FAN PET/CT scans. Weight-based normalization resulted in significant differences across BMI categories, a phenomenon not observed with LBM normalization. Likewise, SUL is more consistent in evaluating patients undergoing repetitive PET/CT compared to SUVbw. Thus, our results suggest that using LBM normalization enhances the reliability of quantitative SUV measurements in PET/CT imaging, leading to more accurate clinical interpretation.

EP-1292

Comparison of Image Quality and Quantification Parameters between Q.Clear and OSEM Reconstruction Methods in FDG-PET/CT Imaging

C. Sezgin, *D. Goksoy, G. Gumuser, E. Sayit, Y. Parlak;*
Celal Bayar University, YUNUSEMRE, TÜRKIYE.

Aim/Introduction: With the advancement in hardware features and reconstruction algorithms in PET/CT imaging, image quality has improved significantly. Q.Clear, a block sequential regularized expectation maximization reconstruction algorithm, reduces noise and enhances image contrast. This study compared image quality and quantification parameters between Q.Clear and OSEM algorithms in patients with liver metastases undergoing

F^{18} FDG-PET/CT imaging ***Materials and Methods:*** Twenty patients (8 females, 12 males; average age 62 ± 10.9 years) were included in the study. Prior to PET/CT imaging, patient preparation and acquisition parameters were standardized. To assess image quality, three-dimensional regions of interest (ROIs) were drawn in the right lobe of the liver and the aortic arch as a blood pool. Analyses were performed on ROIs of three different sizes (1.26, 3.51, 6,72 cm^3) using both reconstruction methods. The Q.Clear and OSEM algorithms were compared for maximum standardized uptake value normalized by lean body mass (SULmax in g/mL), SUVmax (g/mL), contrast, signal-to-noise ratio, and background variability. Statistical analysis was conducted on the calculated image quality and quantitative parameters (SULmax and SUVmax). ***Results:*** Q.Clear reconstruction showed higher SUVmax (8.05 ± 3.2 vs. 7.6 ± 3.3) and SULmax (5.5 ± 2.2 vs. 5.4 ± 2.1) values compared to OSEM reconstruction. However, there was no significant difference in the calculated SUVmax and SULmax across all volumes of interest. When comparing image quality-related parameters, Q.Clear significantly outperformed OSEM reconstruction in terms of contrast, signal-to-noise ratio, and background variability. ***Conclusion:*** In conclusion, Q.Clear reconstruction demonstrated better signal-to-noise ratio, contrast, and higher SUVmax and SULmax. No significant differences in terms of artifacts were observed between the two reconstruction methods. These findings highlight the importance of using the same reconstruction method for monitoring patients' treatment response and follow-up.

EP-1293

Exploring the Influence of Time-of-Flight on Lesion Detection and Quantification in Somatostatin Receptor PET Imaging: A Simulation of Patient Study Across Various Acquisition Durations

H. Zhang[1], *M. Liu[1], X. Yan[1], L. Shi[2], Y. Liu[2], Y. Wang[2], J. Luo[2], Y. Zhao[2], L. Huo[1];*
[1]Peking Union Medical College Hospital, Beijing, CHINA,
[2]Shanghai United Imaging Healthcare, Shanghai, CHINA.

Aim/Introduction: Time-of-flight (ToF) PET enhances lesion detection and quantification, especially for small lesions with low counts. This study investigates the impact of varying ToFs and acquisition times on neuroendocrine tumors (NETs) lesion detection and quantification by simulating different ToFs using SSTR imaging patient PET rawdata from uMI Panorama, a 190-ps ToF PET system. ***Materials and Methods:*** We prospectively analyzed 13 patients (6 males, 7 females; mean age 46.3 ± 12.2 years; mean BMI 22.7 ± 3.5 kg/m2) undergoing list-mode SSTR PET/CT scans (n=7, 4, 2 for 18F-ALF-NOTA-LM3, 68Ga-NODAGA-LM3 and 68Ga-DOTATATE, respectively) at 120 s/bed with an average dose of 217 ± 72 MBq. ToF images (190, 350, 500 ps, and non-ToF) were reconstructed using ToF rebin simulation. Each ToF group underwent further OSEM reconstruction (2 iterations, 10 subsets, matrix 192×192) into 120, 90, 60, 45, 30 s/bed by data trimming. Lesion detection rates were calculated for all image groups, with 190-ps-120 s/bed images (G190-120) as the reference. Volumes of interest (VOIs) were delineated for lesions, and SUVmax measured. A 30-mm circular ROI was placed in the right liver lobe for SD and SUVmean. Tumor-to-Background Ratio (TBR) and Signal-to-Noise Ratio (SNR) were calculated. The Cochran's Q test supplemented by the Wilcoxon signed-rank test, and repeated measures ANOVA or the Friedman test (with Bonferroni corrections for multiple comparisons), were used to compare the lesion detection and quantification across groups, respectively. ***Results:*** Out of 250 lesions detected in the reference group, no significant differences were observed between this group and G190-90, G190-60, G190-45, G350-120 and G350-90 groups ($P > 0.05$). Among 126 lesions consistently detected across all groups (SUVmax 13.5 ± 12.4; diameter 12.7 ± 9.1 mm; TBR 5.6 ± 5.5; all measured in reference group), both SUVmax and TBR of these lesions were significantly lower in non-190-ps groups ($P < 0.001$). For inter-duration subgroup comparison, SNR in each duration subgroup of the 190-ps group was significantly lower than the corresponding subgroup of the non-ToF group ($P < 0.001$), but statistically comparable ($P > 0.05$) to the 300/500-ps subgroups. ***Conclusion:*** Findings suggest that the NET lesion detection rates for the G190-45 and G350-90 groups can be comparable to the reference group. Lesions measured at 190-ps exhibited higher SUVmax and TBR relative to other groups while maintaining an acceptable SNR compared to the 350/500-ps group. A ToF setting of 190-ps allows shorter acquisition times while still providing sufficient compatibility and feasibility for NETs imaging.

EP-1294

Comparison of Zero-Time-Echo and Atlas Attenuation Correction in ^{11}C-β-CFT PET Imaging Using PET/MR

J.Song, J. *Liu, S. Sun, P. Yang, R. Wang, S. Wu;*
Department of Nuclear Medicine ,the First Medical Center of Chinese PLA General, Beijing, CHINA.

Aim/Introduction: This study aimed to evaluate the accuracy of zero-echo-time attenuation correction (ZTEAC) and atlas-based attenuation correction (AtlasAC) compared to Computed Tomography (CT) attenuation correction in 11C-β-CFT PET imaging for patients with Parkinson's disease (PD). ***Materials and Methods:*** A prospective study included 13 PD patients undergoing PET/MR imaging. 11C-β-CFT PET data and MRI sequences such as ZTE and LAVA-Flex were acquired, followed by a 18F-FDG PET/CT examination. Attenuation correction was performed using CTAC, AtlasAC, and ZTEAC maps. Standardized uptake value ratio (SUVR) calculations were done with SPM12 software. Paired t-tests were utilized to analyze SUVR deviations among various attenuation correction methods across the entire brain and specific brain regions, with statistical significance set at $P < 0.001$. ***Results:*** ZTEAC demonstrated lower deviation in whole-brain PET SUVR (1.05% ± 1.29%) compared to AtlasAC (2.44% ± 2.17%). AtlasAC overestimated PET SUVR in the amygdala (3.76% ± 1.24%) and hippocampus (2.99% ± 0.01%). No significant differences were found between ZTEAC and CTAC across all evaluated brain regions ($P > 0.001$). ***Conclusion:*** In the context of 11C-β-CFT PET imaging in PD patients, ZTEAC demonstrates superior accuracy over AtlasAC, presenting a more reliable diagnostic tool in clinical practice.

EP-1295

The DPL algorithm optimizes PET imaging for patients with different BMIs and enhances the diagnostic value of lesions of various sizes

J. Zhang, *S. Chen, S. Song;*
Fudan University Shanghai Cancer Center, Shanghai, CHINA.

Aim/Introduction: This study aims to evaluate the impact of the Deep Progressive Learning (DPL) reconstruction algorithm on the image quality and diagnostic performance for lesions of varying sizes in patients with different Body Mass Index (BMI) undergoing PET/CT imaging. ***Materials and Methods:*** The study included 146 patients who underwent PET/CT imaging with ^{18}F-FDG. According to the Chinese BMI standards, patients were divided into three groups: underweight (BMI<18.5, 42 cases),

normal (BMI 18.5-24, 66 cases), and obese (BMI>24, 38 cases). All PET images were reconstructed using both the Ordered Subset Expectation Maximization (OSEM) and Deep Progressive Learning (DPL) algorithms. Subjective image quality was assessed using the Likert five-point scale, involving overall score, clarity, noise, and diagnostic credibility. Objective evaluation was based on parameters such as the Standard Uptake Value Standard Deviation (SUVSD), Maximum SUV (SUVmax), Mean SUV (SUVmean), Signal-to-Background Ratio (SBR), Signal-to-Noise Ratio (SNR), Contrast-to-Background Ratio (CBR), and Contrast-to-Noise Ratio (CNR), quantifying the image quality of different BMI patients and reconstruction algorithms. Additionally, 277 sub-centimeter lesions and 177 lesions larger than one centimeter from the included patients were selected to compare SUVmax, SBR, SNR, CBR, and CNR, assessing the impact of different reconstruction algorithms and BMI values on the quantitative performance of lesions of different sizes. ***Results:*** In subjective evaluations, the DPL algorithm significantly outperformed the OSEM algorithm across all BMI groups ($p<0.05$). Objective evaluations showed that the DPL algorithm's SBR, CBR, SNR, and CNR values were significantly higher than those of the OSEM algorithm in all groups, with a more notable improvement in the obese patient group. For lesions of different sizes and patients with different BMI, the DPL algorithm's SBR, CBR, SNR, CNR, and SUVmax values were significantly higher than those of the OSEM algorithm ($p<0.001$). Particularly in the obese patient group, the SNR and CNR of sub-centimeter lesions increased significantly after using the DPL algorithm, by 156.59% and 174.29%, respectively. ***Conclusion:*** The DPL reconstruction algorithm provides superior image quality within the same acquisition time compared to the OSEM algorithm, and this advantage is influenced by the patient's BMI. The quantitative performance of lesions of different sizes is also affected by BMI and the reconstruction algorithm.

EP-1296

Evaluation of Radiomics Based Information to Detect Stenosis in Gated Myocardial Perfusion Imaging

S. Entezarmahdi[1], *H. Shariati[2], R. Faghihi[2], F. Dehghan[1], M. Sadeghi[1], M. Haghighatafshar[1], N. Shahamiri[3], P. Izadpanah[1]; [1]Shiraz University of Medical Sciences, Shiraz, IRAN, ISLAMIC REPUBLIC OF, [2]Shiraz University, Shiraz, IRAN, ISLAMIC REPUBLIC OF, [3]Institute for Artificial Intelligence in Medicine, Essen, GERMANY.*

Aim/Introduction: Radiomics, a collection of techniques used to automatically extract large amounts of quantitative features from medical images, holds significant promise for predicting coronary artery disease in Myocardial Perfusion Imaging (MPI) SPECT when combined with machine learning methods. In this study, we assess the utilization of functional radiomics features extracted from gated-single photon emission computed tomography (SPECT) studies to detect coronary artery stenosis diagnosed by coronary angiography (CA). ***Materials and Methods:*** 250 patients who underwent both MPI SPECT and CA are comprised the dataset. The population average age was 58.3, with 40% being male. Patients those with significant stenosis were categorized based on CA reports. LV gated segmentation and quantification were performed using Cedars QPS/QGS package 2015. Subsequently, radiomics features were extracted through the SERA framework from four polar maps generated by QGS (end diastole perfusion amp, end systole perfusion map, wall motion map, wall thickening map). Area Under the Curve (AUC) metric was used for a comprehensive analysis of univariate feature performance. A multivariate analysis was conducted to detect coronary artery stenosis where a subset of extracted features was selected. Features were primarily selected statistically and followed by a recursive feature selection algorithm. A support vector machine was used as the classifier, and its performance was assessed through multiple criteria, including AUC, accuracy, precision, recall, and F1-score. ***Results:*** Some extracted gated-features exhibited high AUC values in effectively distinguishing patients with stenosis from those without (the highest AUC reached 0.75). The most relevant features were extracted from the end diastole perfusion polar map and wall motion polar map. Furthermore, machine learning models demonstrated impressive performance in classification, with the highest AUC and accuracy reaching 0.78 and 0.81 respectively. ***Conclusion:*** Based on the results, it can be concluded that radiomics features extracted from gated-single photon emission computed tomography (SPECT) studies, specifically those contributed to end diastole perfusion and wall motion, can provide useful information for precise quantitative analysis in MPI scans and disease detection when coupled with machine learning methods. This approach has the potential to improve the accuracy of predicting coronary artery disease in MPI-SPECT.

EP-1297

The impact of reconstruction parameters on the discriminatory performance of texture analysis for HER2 status on dbPET

K. Itagaki[1], *K. K. Miyake[2], T. Oishi[3], Y. Nakamoto[3]; [1]Division of Clinical Radiology Service, Kyoto University Hospital, Kyoto, JAPAN, [2]Department of Advanced Medical Imaging Research, Graduate School of Medicine Kyoto University, Kyoto, JAPAN, [3]Department of Diagnostic Imaging and Nuclear Medicine, Graduate School of Medicine Kyoto University, Kyoto, JAPAN.*

Aim/Introduction: In recent years, discriminating HER2-low and -positive (ie, immunohistochemistry (IHC) score of 1+, 2+, or 3+) from HER2-zero (ie, IHC score of 0) has become important in determining treatment strategies for breast cancers (BCs). We aimed to investigate the impact of reconstruction parameters on the discriminatory performance of HER2-zero and HER2-low+positive using texture analysis on dedicated breast PET (dbPET). ***Materials and Methods:*** A total of 31 BCs in 29 patients who underwent dbPET with 18F-fluorodeoxyglucose were retrospectively analyzed. HER2 status assessed by IHC staining: Tumors scored as 1+, 2+, or 3+ were classified as HER2-low+positive, otherwise HER2-zero. dbPET images were reconstructed using the 3D-DRAMA method with different regularization parameters (β) of 10, 20, 50, 70, and 100. BCs were semi-automatically delineated and 93 texture features (TFs) were calculated using PyRadiomics. For each reconstruction protocol, a prediction model for HER2 status classification was built using a random forest method. The discriminatory performance of the HER2 status for each model was assessed using Out-Of-Bag (OOB). In addition, TFs of high importance for discriminating HER2 status were selected by using the mean decrease gini. The selected TFs extracted from dbPET images reconstructed with different β values were compared to that from β of 20 (standard setting in the clinical practice). Furthermore, associations between these TFs and HER2 status were assessed for each β value. ***Results:*** dbPET images reconstructed with high β values showed better ability to discriminate HER2 status, with OOB of 47.1, 41.9, 32.3, 36.1, and 32.9 for β value of 10, 20, 50, 70, and 100, respectively. For HER2 status discrimination, 6 important TFs (Kurtosis, Skewness, Idmn, Large-Area-Emphasis, Zone-Variance, and Dependence-Variance)

were selected. In all reconstruction conditions, Large-Area-Emphasis, Zone-Variance, and Dependence-Variance showed statistically significant differences between β of 20 and the other β values. Kurtosis and Large-Area-Emphasis were significantly lower for HER2-low+positive tumors than for HER2-zero tumors with any β values. For HER2-low+positive tumors, Dependence-Variance and Skewness were significantly lower than for HER2-zero tumors for all β values except for β of 10 and 100, respectively, and Zone-Variance for HER2-low+positive tumors was significantly lower than HER2-zero only at β of 50 and 100. ***Conclusion:*** Some TFs important for HER2 status discrimination were affected by β values. dbPET images reconstructed with high β values may have better ability to discriminate HER2 status than those of standard β value (20).

EP-1298

Treatment response evaluation using texture analysis on F^{18} FDG PET/CT in patients with locally advanced breast cancer

N. Singh[1], *A. K. Pandey[2], G. Arora[2], R. Kumar[2];*
[1]Fortis Memorial Research Institute (FMRI), Gurugram, INDIA,
[2]All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: The objectives of this study were firstly, to utilize the ability of texture analysis to evaluate the treatment response and overall survival (OS) in patients with locally advanced breast cancer (LABC) and secondly to compare the results of texture analysis with PET/CT parameters. ***Materials and Methods:*** 57 patients with histopathologically proven LABC were retrospectively analysed. ^{18}F Fluorodeoxyglucose positronemission tomography/computed tomography (^{18}F FDG PET/CT) scan was performed at the baseline and after 6-12 cycles of chemotherapy. Thirteen haralick texture features were derived from the baseline scan. An independent nuclear medicine physician evaluated the ^{18}F FDG PET/CT parameters in the baseline scan. Mann Whitney U test & independent T-test were performed to determine the significance of the difference in the mean value of texture parameters & PET/CT parameters. Cox-regression & Kaplan- Meier tests were applied for survival analysis. ***Results:*** Mean age of patients was (46.07 ± 1.46 years). Based upon the clinical follow-up, out of 57 patients, 39 patients were categorized as responders & 18 patients as non - responders. Out of the thirteen texture parameters, two of the texture parameters: sum average (V6) with p = 0.071 & sum variance (V7) with p= 0.069 were found to approach a statistically significant level. Responders had higher values of TLG and MTV than non-responders. The trend for OS, according to the Kaplan-Meier test was such that patients with higher values of metabolic tumor volume (MTV) and total lesion glycolysis (TLG) had a lower overall survival (OS) compared to patients who survived. Neither texture parameters nor PET parameters showed statistical significance in distinguishing between responders and non-responders. Additionally, these parameters did not demonstrate significant differences between the two survival groups (those who died and those who survived). ***Conclusion:*** It was concluded that the two texture parameters, specifically sum average (V6) and sum variance (V7), which were approaching significance, could potentially play a role in predicting treatment response if studied in a larger sample size with a more homogenous patient population.

EP-1299

A Multicenter Study on the Application of [18F]FDG PET/CT-Derived Molecular Radiomics in Predicting Lymph Node Metastasis and PD-L1 Expression in Non-Small Cell Lung Cancer

W. Chen[1,2], *Q. Liu[1], J. Zhang[1], S. Song[1];*
[1]Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, Shanghai, CHINA, [2]Academy for Engineering and Technology, Fudan University, Shanghai, CHINA.

Aim/Introduction: To develop and validate the effectiveness of a molecular radiomics model, built upon [18F]FDG PET/CT imaging, for predicting lymph node metastasis and programmed death-ligand (PD-L1) expression in non-small cell lung cancer (NSCLC) patients. ***Materials and Methods:*** We retrospectively analyzed clinical data on NSCLC patients who underwent surgical resection and tumor proportion score (TPS) testing at two hospitals between 2016 and 2024. All patients were examined using preoperative [18F]FDG PET/CT imaging. The study participants were divided into two groups: the lymph node metastasis prediction cohort and the PD-L1 expression prediction cohort. ITK snap 3.8.0 was employed to segment the region of interest and automatically generate the peritumoral region. Radiomics feature extraction was carried out using Python 3.7.0 (extracting 1967 features from both CT and PET signatures). The LASSO algorithm and Spearman correlation analysis were applied to select the most relevant radiomics features. Subsequently, based on these selected features and multiple classifiers, models for tasks A (lymph node metastasis task) and B (PD-L1 expression task) were constructed, including the PET intra-tumoral model, PET peritumoral model, CT intra-tumoral model, CT peritumoral model, PET and peritumoral model, and CT and PET/CT peritumoral fusion models. The predictive performance of each model was analyzed using the receiver operating characteristic (ROC) curve, area under the curve (AUC), sensitivity, specificity, accuracy, positive predictive value, negative predictive value, and F1-score. The clinical utility of each model was also assessed through decision curve analysis (DCA). ***Results:*** For task A, the SVM_IPF_LNM model outperformed both the clinical model and the other six radiomics models, achieving an AUC of 0.845 (95%CI: 0.716-0.973) in the test. In task B, the PET/CT peritumoral fusion model (LR_IPF_PD-L1) established using logistic regression was better than others, with an AUC of 0.776 (95%CI: 0.664-0.942) in the test. DCA demonstrated that the molecular radiomics models hold clinical advantages in predicting lymph node metastasis and PD-L1 expression. ***Conclusion:*** The molecular radiomics model based on PET/ CT can accurately predict lymph node metastasis of NSCLC patients and continuously monitor the PD-L1 status during treatment, which provides a non-invasive tool for clinicians to formulate precise treatment plans.

EP-1300

Personal comparison of Dose Exposure before and during pregnancy in a PET-CT Department

S. Martins Aragao Rodrigues, *S. Pereira, S. Curry;*
King's College London, London, UNITED KINGDOM.

Aim/Introduction: Personal Comparison on the dose exposure and daily practices of 1 technologist before and during pregnancy ***Materials and Methods:*** Using a Tracerco PED Blue (Model: T414-1) data from 1 PET-CT technologist was acquired during October 2021 before declaration of pregnancy and November 2021 While pregnant. The acquisition of the extra data (in addition to Badges Laundauer Luxel+ passive dosimeters) was already a

normal practice of this Technologist ***Results:*** Dose exposure in October 2021, before declaration of pregnancy and in 23 working days, was 97.18 µSv and in November, whilst pregnant and in 17 working days, was 2.94 µSv. Badge readings on the passive dosimeter in October are 0.15mSv for body, 10.31mSv for left finger and 6.38mSv for right finger. In November the readings are below detectable levels. The drastic difference of exposure values is a result of awareness of pregnancy and applying change of practices during working time (non-radioactive tasks only) with collaboration of colleagues ***Conclusion:*** According to the guidelines for expectant mothers working safely with ionising radiation from HSE and over the declared term of pregnancy from Regulation 9(6) of IRR, the maximum dose exposure to the foetus is 1mSV. Extrapolating the results to the remaining months of pregnancy, we can say that in terms of dose exposure, it is safe to continue to work in a PET-CT department with change of practices. During the research about this subject a lack of papers about pregnant workers in PET-CT was noted, probably due to the process being personal and confidential ***References:*** Working safely with ionising radiation, Guidelines for expectant mothers, Health and Safety Executive. The Ionising Radiations Regulations 2017.

EP-1301

Use of conventional hospital rooms for [177Lu]Lu-DOTA-Octreotate treatment, for high risk patients at an established hospital.

L. Neeson, *M. Gilhen, P. Jackson, G. Kong;*
Peter MacCallum Cancer Insitute, Melbourne, AUSTRALIA.

Aim/Introduction: Peptide Receptor Radionuclide Therapy (PRRT) treats somatostatin receptor-expressing neuroendocrine neoplasms. Hospital admission may be necessary for certain patients experiencing acute symptom flares during or after PRRT. Previously, treatments were conducted in shielded rooms, albeit with staffing ratios not optimised for such patients. This study aims to investigate if PRRT could be safely provided from a radiation safety standpoint, in a room with enhanced staffing ratios and resources for handling symptom flares, despite the absence of structural radiation shielding. ***Materials and Methods:*** On average 46% of [177Lu]Lu-DOTA-Octreotate (LuTate) is excreted within 4 hours of administration. In Australia, treatments are commonly performed as an outpatient procedure (in accordance with State Regulations). The Enhanced Care Unit (ECU) provides intensive nursing care for patients requiring specialised care. Two single occupancy ECU rooms were identified as potential LuTate therapy treatment areas for patients at high risk of hormone flare. Before treating the first patient, a comprehensive radiation risk assessment was conducted. Radiation protection measures included staff training, mobile lead shields, patient toilet designation, contingency plans for waste and spill management and radiation signage. The patient received 10 GBq of LuTate. Utilising a handheld survey meter, radiation dose rates were measured at locations in and adjacent to the patient's room before and after LuTate therapy infusion at various time points over 24 hours. The Radiation Safety Officer and a Medical Physicist calculated radiation doses for ECU staff, patients, and visitors based on measurements. An application for continued room use was submitted to local authorities. ***Results:*** The maximum radiation dose rate in adjacent areas to the patient's room was 0.5 µSv/hr above background. For staff standing behind a lead shield next to the patient, the maximum dose rate during infusion was 0.6 µSv/hr, decreasing to 0.4 µSv/hr 18 hours post-infusion. The calculated ECU staff's radiation dose performing hourly observations was about 30 µSv per patient per 12-hour shift, well below the public dose limit of 1 mSv in a 12-month period. Rooms were chosen based on low occupancy in surrounding areas (due to external walls and stairwell behind both rooms). The Victorian Department of Health granted regulatory approval for two treatment rooms for ongoing LuTate use. Five treatments have been performed without ICU escalation, fatalities, or radiation incidents. ***Conclusion:*** In Victoria, Australia, delivery of LuTate in conventional hospital rooms is safe and feasible. Radiation risk to occupationally and publicly exposed persons is very low.

EP-1302

Investigation On Current Situation Of Knowledge And Practice Of Radiation Protection Among Medical Staff In Radiology Department And Analysis Of Influencing Factors

L. Cao;
Mianyang Central Hospital, Minayang, CHINA.

Aim/Introduction: To investigate the current situation of radiation protection knowledge and practice of medical staff in radiology department and analyze the influencing factors, so as to standardize the radiation protection behavior of medical staff and provide basis for enriching the radiation protection training content ***Materials and Methods:*** A self-designed radiation protection knowledge and practice questionnaire was used to investigate conveniently selected radiology medical staff, and the factors affecting radiation protection knowledge and practice were analyzed by multiple linear regression ***Results:*** A total of 351 questionnaires were sent out, and 335 were effectively collected, with an effective recovery rate of 95.4%. The total score of radiology medical staff was 59.0 (10.4) points, 8.65 (4.63) points for knowledge, 21.35 (2.45) points for attitude and 28.99 (5.85) points for behavior. The results of multiple linear regression analysis showed that age, education level, Experience of radiation protection education, Number of children born, Knowledge about radiation protection and Attitude towards radiation protection were the factors affecting the score of radiation protection (Adjusted $R2 = 0.516$, $F = 30.655$, $p < 0.001$). ***Conclusion:*** Medical staff in radiology department have good knowledge and practice of radiation protection, positive attitude and behavior, but lack of knowledge of radiation protection. The relevant organizations and departments of the hospital should take specific measures, such as providing regular training and education on radiation protection, to ensure the safety of medical staff and patients during the examination.

EP-1303

Self-service Station for Patient Dose-rate Measurements

S. Rajala[1], *H. Ryyppö[1], M. Salomaa[1], A. Acheva[1], M. Ladev[1], V. Ahtiainen[1,2], M. Tenhunen[1], K. Nousiainen[1], V. Reijonen[1];*
[1]Comprehensive Cancer Center, Helsinki, FINLAND,
[2]University of Helsinki, Helsinki, FINLAND.

Aim/Introduction: External dose-rate is measured from patients treated with radiopharmaceuticals before their discharge from the hospital. The process of measuring dose-rate is relatively straightforward, and it can be further simplified and made more accessible through the implementation of a self-service station. Here, we report how we constructed such a station and validated the dose-rate measurements. ***Materials and Methods:*** A high-sensitivity gamma detector was mounted to a mobile cart at a

height of one meter. The detector was connected to a monitor displaying dose-rate reading, and a traffic light indicator (red light indicating > 30 µSv/h, the dose-rate limit for discharging outpatients). A tape was fixed on the floor one meter away from the detector, to mark the place where to stand during the measurement. Written operating instructions were also provided. We performed dose-rate measurement comparison between the self-service station and a hand-held survey meter. The dose-rate calibration of both detectors had been checked using a traceable quality assurance source, and the devices were also tested using I-131 and Lu-177 radiopharmaceutical samples. To keep the measuring geometry identical, the survey meter was placed each time in the same location on the cart as the mounted detector. ***Results:*** We measured 30 patients using both the self-service station and the handheld survey meter: ten patients treated with ablative I-131, ten patients treated with Lu-177-DOTATATE (dodecane tetraacetic acid-octreotate), and ten patients treated with Lu-177-PSMA (prostate specific membrane antigen). The treatment activities and time of the dose-rate measurement varied between the patients, but the comparative measurements were always taken at the same time-point. Paired samples t-tests were conducted to see if there was a difference between the dose-rate measurements. The results indicated no significant difference between the hand-held device (mean M=0.77 µSv/h, standard deviation SD=0.64 µSv/h; M=6.7 µSv/h, SD=5.1 µSv/h; M=8.0 µSv/h, SD=6.0 µSv/h) and the self-service station (M=0.74 µSv/h, SD=0.55 µSv/h; M=6.2 µSv/h, SD=4.0 µSv/h; M=8.1 µSv/h, SD=5.8 µSv/h) for I-131 ablation, Lu-177-DOTATATE or Lu-177-PSMA treated patients, respectively. ***Conclusion:*** We built a self-service station for patients to measure dose-rate in a repeatable manner. The dose-rate measurements were validated with 30 molecular radiotherapy patients. The self-service station offers a reliable and patient-inclusive way to ensure compliance with radiation safety regulations and has mostly replaced our department's manual dose-rate measurement procedures.

EP-1304

Contribution of CT scan range to patient's effective dose in parathyroid SPECT/CT scintigraphy

S. Rep, *I. Slodnjak, A. Sočan, P. Tomše, L. Jensterle, K. Zaletel, L. Ležaič;*
Division of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: Dual phase technetium-99mTc-methoxy isobutyl isonitrile (MIBI) SPECT/CT may be the most accurate conventional imaging approach for localization of enlarged parathyroid gland (EPG). The EPG can only be localized from the angle of the lower jaw to the mediastinum, so it makes sense to limit the CT scan to the site of location, because the limitation of the FOV is the basic in the optimization of the diagnostic procedure. This study aimed to estimate and optimize the contribution of computed tomography (CT) scan and scan range to effective dose (ED) in dual-phase MIBI SPECT/CT parathyroid scintigraphy. ***Materials and Methods:*** The study included seventy-four patients; thirty-seven with reduced and thirty-seven with extended CT scan range. The ED caused by the CT scan was calculated using Dose Length Product (DLP) data and estimated using the Imaging Performance Assessment of CT scanners (ImPACT) calculator. ***Results:*** For all patients, the contribution of CT to the ED in a combined SPECT/CT examination was 2.62 ± 0.29 mSv (48%). The contribution of CT to the total ED was 1.8 ± 0.18 mSv (33%) when using reduced and 3.44 ± 0.23 mSv (64%) when using extended scan range. The DLP and ED were statistically significantly different between the reduced and extended CT scan range ($p < 0.001$) in the first and second phases. The individual organ dose was reduced from 8% to 94%. ***Conclusion:*** The hybrid SPECT/CT improves the interpretation of nuclear medicine images and also increases the radiation dose to the patient. An adequately defined CT scan range on SPECT/CT imaging, can significantly reduce a patient's ED. ***References:*** Rep S, Hocevar M, Vaupotic J, Zdesar U, Zaletel K, Lezaic L. ^{18}F-choline PET/CT for parathyroid scintigraphy: significantly lower radiation exposure of patients in comparison to conventional nuclear medicine imaging approaches. EP-1305

Radiation Safety: the Impact of an Automated Preparation and Administration System

S. Pichierri, *A. Roletto, L. D'Alessio, P. Cerè, V. Crippa, G. R. Bonfitto; I.R.C.C.S. Ospedale San Raffaele, Milan, ITALY.*

Aim/Introduction: In Nuclear Medicine, especially during PET/CT procedures, the handling and administration of radiopharmaceuticals significantly influence the radiation exposure of involved personnel. The recent shift in many hospitals towards automated preparation and injection systems aims to minimize staff exposure to radiation, while improving the accuracy and efficiency of the radiopharmaceutical injection process. However, studies on their efficacy and potential benefits are still limited. The aim of this pilot study is: comparing radiation exposure of Nuclear Medicine radiographers using the automatic preparation and administration technique with the manual preparation and administration technique. ***Materials and Methods:*** Radiographers' chest radiation exposure during routine clinical practice with 100 $^{[18F]}$FDG PET/CT examinations was prospectively recorded with thermoluminescent dosimeters from December 2023 to February 2024. In 50 cases the examinations were handled using a commercially available automated preparation and injection system, while in the remaining 50 a manual preparation and administration technique was employed. In both cases, the stages of the operational chain evaluated are: $^{[18F]}$FDG vial insertion, activity preparation, $^{[18F]}$FDG intravenous injection, and patient positioning. ***Results:*** The mean individual chest radiation exposure for each PET/CT examination was 4.03 µSv ± 1.2 using the automatic preparation and administration technique, and 6.93 µSv ± 1.5 employing the manual preparation and administration technique. This resulted in a significant reduction of 41.85 % in chest radiation exposure with the automatic preparation and administration technique ($p < 0.05$). ***Conclusion:*** The use of an automated preparation and injection system holds the potential for a significant reduction of the radiation exposure of Nuclear Medicine radiographers. The results of this study aim to pave the way for an increase in the adoption of such systems in routine clinical practice, to the benefit of the whole Nuclear Medicine staff.

EP-1306

Personal radiation exposure in robotic arm assisted FDG PET/CT guided biopsy

V. Jain, *S. K. Velliangiri, D. Khan, S. Sagar, B. Aarya, G. Arora, B. S. NAYAK, A. Tyagi, A. K. Pandey, N. A. Damle, C. Bal, M. Tripathi;*
All India Institute of Medical Science, Delhi, INDIA.

Aim/Introduction: Positron emission tomography (PET/CT) -guided biopsy plays an important role in tissue diagnosis when the target lesion is unidentifiable through conventional imaging modalities and in the presence of necrosis which may result in inconclusive or false-negative histopathological results. However, PET/CT guided biopsy procedures result in radiation exposure to the physicians and staff performing the procedure which must be kept as low as possible according to ALARA principle. The main aim of our study was to find the personal radiation exposure to physicians and technologists during robotic arm-assisted F^{18} fluoro-deoxy glucose (FDG) PET-CT guided biopsy and to assess its relationship with procedure time. ***Materials and Methods:*** This is a prospective study done at a tertiary care institution. Institutional ethics committee approval was taken. All patients who were referred for ^{18}F FDG PET/CT guided biopsy from January 2024 to May 2024 were included. Informed written consent was taken. All patients were injected ^{18}F FDG followed by an uptake period. Then a limited field of view PET/CT was taken depending on the site of biopsy using a hybrid PET/CT scanner followed by confirmation of FDG uptake in site of biopsy and planning of biopsy path. Under robotic arm guidance, FDG PET/CT guided core biopsy of the target lesion was done. All persons (Physician and technologist) were provided with pocket dosimeters before the start of the procedure and individual radiation exposure was measured at the end of the procedure. ***Results:*** A total of 9 patients were included in our study. The mean age was 48 years and there were 4 males and 5 females. The site of biopsy was thorax in 4 patients and abdomen & pelvis in 5 patients. The median injected activity was 137±66 MBq. The median uptake time post FDG injection was 58 minutes. The median procedure time was 36±14 minutes. The mean radiation dose for physician and technologist were 2.3±1.8 µSv and 1.6±1.1 µSv respectively. There was no significant correlation between uptake time and radiation exposure for physician and technologist. However, we found a significant correlation between procedure time and radiation exposure to physician (p=0.05). ***Conclusion:*** The procedure time must be kept as low as possible to reduce the radiation exposure to the performing physician. However, in view of small sample size studies with larger sample size are needed to support our findings.

EP-1307

Dose rate measurements when working with Gallium 68

A. Sherwani, *M. Rønes, L. Gridset, T. T. Shino, L. G. Mikalsen, M. Stavrinou;*
Oslo university hospital, Oslo, NORWAY.

Aim/Introduction: When using radiotracers labelled with gallium 68 (68Ga) we administer the tracer to the patient with a syringe and not an auto injector. Compared to Fluor 18 (18F) 68Ga results in a higher skin dose to the handler due to higher positron energy (68Ga: E max=1.89 MeV vs. 18F: E max = 0.634 MeV) [1]. Another study [1] has shown that 1 GBq of 68Ga in a 5 ml syringe, will result in a 8,7 mSv dose rate to the skin is enough to exceed the Norwegian 500 mSv skin dose limits for radiation workers in less than a minute. Shielding the user from positron exposure is therefore critical to reduce skin dose. Syringe shields made of tungsten is an efficient way of reducing the dose, but are unpractical due to weight. Shields made of polymethyl methacrylate (plexiglass) are easier to handle and have shown to reduce skin dose by stopping positrons, but do not reduce the dose received from gamma photons. We have investigated whether plexiglass syringe shields are useful in our workflow to reduce skin dose to the user.. ***Materials and Methods:*** A Thermo Radeye B20 was used as doserate meter. Two 1 ml syringes was prepared with 1 MBq of 18F and 68Ga respectively. Dose rates were measured at distances of 5, 15 and 30 cm. The syringes were measured unshielded and with shields of plexiglass, lead and tungsten. We used 1 MBq in the syringes to not exceed the dose rate limit of the dose rate meter at 2 mSv/h. ***Results:*** Our measurements show that the dose rate is 20 times higher for 68Ga than 18F. At 5 cm distance, the plexiglass shield reduces the dose rate by 97 %. In comparison, the tungsten shield reduces the dose rate by 99%. ***Conclusion:*** Plexiglass is adequate for shielding the user from positrons. Even though tungsten has higher efficiency in shielding the user, the weight is a considerable hindrance when preparing and injecting the tracer. ***References:*** [1] Kemerink GJ, Vanhavere F, Barth I, Mottaghy FM. Extremity doses of nuclear medicine personnel: a concern. Eur J Nucl Med Mol Imaging. 2012 Mar;39(3):529-32. doi: 10.1007/s00259-011-1973-z.

EP-1308

Potential utility of SPECT/CT based absolute quantification of ^{177}Lu-DOTATATE uptake and tumor volume in patients with inoperable/ metastatic neuroendocrine tumor for determining therapeutic efficacy.

K. Kaur, *P. Aggarwal, M. Kumar, A. Sood, J. Shukla, B. R. Mittal;*
Post Graduate Institute of Medical Education and Research, Chandigarh, INDIA.

Aim/Introduction: 177Lu-DOTATATE has emerged as a promising theragnostic agent in neuroendocrine tumors (NET) facilitating post-therapy imaging and image-based quantification to measure the response to therapy. For dosimetry, necessary absolute quantification has become possible using quantitative SPECT/CT that can also be calibrated to provide standardized uptake values (SUV). The aim of the study was to quantify uptake and tumor volume in patients with inoperable/ metastatic NET using quantitative SPECT/CT and estimate the absorbed dose delivered in one cycle. ***Materials and Methods:*** The prospective study was performed in Department of Nuclear Medicine, PGIMER, Chandigarh. A total of 10 inoperable/ metastatic NET patients (6 F/4M; mean age 46±5; range 10-61 years) on 177Lu-DOTATATE were included in this study. Post-therapy regional quantitative SPECT/CT were acquired in all the patients and data was reconstructed and analyzed using QMetrix software for absolute uptake, SUVmean and tumor volume and compared for consecutive post-therapy scans for the efficacy of therapy. Wilcoxon signed-rank test (W) was applied to see the difference in value of the quantitative parameters (significance level p=0.05). The mean absorbed dose for tumor was also estimated using MIRD. ***Results:*** The W-test showed statistically significant decrease in absolute uptake and absorbed tumor dose (z= -2.191, p=0.028), and SPECT SUVmean (z= -2.293, p=0.022) in the two consecutive cycles on SPECT/CT, showing the efficacy of therapy with statistically significant decrease in SUVmean b/w baseline and interim PET/CT. However no statistically significant difference was observed in tumor SPECT volumes (z=-.561, p=0.575) in the two consecutive cycles. An average mean dose of 11±7.2Gy was delivered to tumor in a cycle. ***Conclusion:*** Absolute Uptake of 177Lu-DOTATATE and SUV derived from quantitative SPECT/CT using Q.Metrix is reproducible and may be used for dosimetric analysis with higher accuracy with its utility in response evaluation to therapy. However, larger samples are required to confirm the results.

EP-1309

The practicalities and challenges of centre participation in multi-centre dosimetry based clinical studies

H. Sharman, *J. Taprogge, Y. Fox-Miller, S. Yusuf, S. Patel, K. Wong, C. Abreu, K. Newbold, G. Flux;*
The Royal Marsden NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: INSPIRE (ClinicalTrials.gov Identifier: NCT04391244) is an investigator-led prospective observational multi-centre clinical trial to investigate radiation dosimetry in 150 thyroid cancer patients treated with radioiodine. The aim of the current work was to identify considerations and challenges encountered by participating centres in this study, to inform future trials in this field. ***Materials and Methods:*** The present work evaluated the practicalities and challenges in patient recruitment, data collection and data analysis. As part of the INSPIRE study, questionnaires were sent to the 10 participating centres to determine the potential of centres to perform quantitative imaging, to identify variations in clinical practice with imaging timepoints, and to assess readiness to perform clinical dosimetry. ***Results:*** Across all sites, to-date 74 patients have been approached for INSPIRE, with 26% declining due to concerns including radiation exposure and treatment anxiety. Data collection revealed variations in post-therapy imaging protocols, ranging from 24 hours to 7 days, including differences in whole-body, SPECT, and SPECT/CT imaging, potentially leading to inadequate data collection. Additionally, discrepancies were noted in the extent of biochemical data collection before radioiodine therapy. Challenges such as CT artefacts and saliva uptake complicated thyroid and salivary gland data analysis, further affected by variations in patient positioning. The set-up questionnaire indicated that 4 out of 20 SPECT/CT systems were previously calibrated for Iodine-131 quantitative imaging. Survey results showed barriers to local dosimetry calculations, including insufficient staffing (67%), camera availability (67%), clinical demand (56%), and lack of reimbursement (44.4%). Two sites performed dosimetry post-Iodine 131 therapy for research and radiation advice. Centres reported that technologists/radiographers, physicists, clinicians, and nurses were involved with I-131 administrations. ***Conclusion:*** As part of this non-interventional, observation study, challenges in data collection were observed due to local differences in standard of care across the INSPIRE sites, potentially leading to missing or inconsistent data. Communication with sites was found to be essential for the acquisition of consistent data, such as standardisation of patient positioning for accurate dosimetry calculations. The involvement of multiple staff groups in I-131 therapy is encouraging. Acknowledging and addressing these difficulties will help assess readiness for future multi-site dosimetry studies.

EP-1310

Construction and preclinical evaluation of a ^{68}Ga-labeled peptide-based PET probe for imaging TIM-3 expression in preclinical tumor models

M. Zhou, *S. Hu;*
Xiangya Hospital, Central South University, Changsha, CHINA.

Aim/Introduction: T cell immunoglobulin and mucin domain-containing-3 (TIM-3) is an immune checkpoint expressed mainly on CD4+ and CD8+ T cells. In addition to negatively regulating inflammatory T cell function, TIM-3 is a promising immunotherapy target. Herein, it is necessary to develop an immuno-positron emission tomography (immunoPET) probe for noninvasively characterizing TIM-3 expression and our goal is to develop a first-in-class peptide-based positron PET probe for imaging TIM-3 in various animal models. ***Materials and Methods:*** The lead compound NOTA-GK12 was radiolabeled with 68Ga in NaAc-buffer at pH 4 (100°C, 10min). The stability and purity of [68Ga]Ga-GK12 were measured by Radio-HPLC. Cellular uptake assays were performed using the human peripheral blood mononuclear cells (hu-PBMCs), which were activated by IFN-γ. Micro-PET/CT imaging was conducted with [68Ga]Ga-GK12 at 0.5 h p.i in hu-PBL-SCID (PBL) mice and NOD-scid IL2Rgamma null (NSG) mice. Immunohistochemical and HE staining studies were also carried out using the tissue of mice models. ***Results:*** The radiochemical yield of [68Ga]Ga-GK12 was 82.76 ± 6.37% and the radiochemical purity (RCP) of the tracer was more than 99%. For in vitro stability, the tracer incubated in saline and serum maintained relatively high stability (RCP>95%). Cellular uptake experiments confirmed that the uptake of [68Ga]Ga-GK12 in activated PBMCs was significant higher than that in normal PBMCs at each time point. Until 17 days after injection of PBMCs, the prominent [68Ga]Ga-GK12 uptake (1.81 ± 0.17 % ID/g) was observed in the spleen of PBL mice, while hardly any uptake was observed in NSG mice without PBMC injection. IHC staining of spleen in PBL and NSG mice illustrated the TIM-3+ lymphocytes infiltrate, corresponding with the uptake of [68Ga]Ga-GK12 as delineated by PET. ***Conclusion:*** [68Ga]Ga-GK12 enables easy radiosynthesis and shows excellent in vitro and in vivo TIM-3 targeting characteristics.The high spleen uptake of PBL mice at early imaging time points demonstrate the feasibility of [68Ga]Ga-GK12 for imaging of TIM-3 expression in vivo models. These results demonstrate the feasibility of [68Ga]Ga-GK12 immunoPET in tracking TIM-3 and highlight a new opportunity to optimize TIM-3-targeted immunotherapies.

EP-1311

^{68}Ga-labeled peptide-based PET radiotracers for imaging PD-L2 expression in lung cancer

M. Zhou[1], *S. Hu[2];*
[1]Xiangya Hospital, Central South University, Changsha, CHINA,
[2]Xiangya Hospital&, Central South University, 长沙市, CHINA.

Aim/Introduction: Programmed Death Ligand-2 (PD-L2), another crucial immune checkpoint molecule interacting with PD-1, correlates with the efficacy of various tumor immune therapies. What's more, we investigate the expression of PD-L2 in non-small cell lung cancer (NSCLC) patients following anti-PD-1 therapy and its predictive value for clinical survival outcomes. Herein, it is necessary to develop PET radiotracers for noninvasively characterizing PD-L2 expression and our goal is to develop first-in-class peptide-based PET radiotracers for imaging PD-L2 in lung cancer. ***Materials and Methods:*** The lead compounds NOTA-HN11-1 and NOTA-HN11-2 were radiolabeled with 68Ga in NaAc-buffer at pH 4 (100°C, 10min). The stability and purity of [68Ga]Ga-HN11-1 and [68Ga]Ga-HN11-2 were measured by Radio-HPLC. Cellular uptake assays were performed using the transduced PD-L2 expressing lung cancer cell line A549 (A549-PD-L2) and wild-type A549 cells as negative control. Micro-PET/CT imaging was conducted with [68Ga]Ga-HN11-1 and [68Ga]Ga-HN11-2 at 1 h p.i in A549-PD-L2 mice and A519 mice. Immunohistochemical and HE staining studies were also carried out using the tissue of mice models. ***Results:*** The radiochemical yield of [68Ga]Ga-HN11-1 and [68Ga]Ga-HN11-2 were 84.16 ± 6.17% and 82.53 ± 5.95% respectively. The radiochemical purity (RCP) of both tracers were more than 99% and the stability of both tracers were high (RCP>95%) in saline and serum. Cellular uptake experiments confirmed that the uptake of [68Ga]Ga-HN11-1 in A549-PD-L2

cells was 4.51 ± 0.04%, which was 3 times that of [68Ga]Ga-HN11-2 ($P < 0.001$, $n = 5$). Dynamic PET imaging of [68Ga]Ga-HN11-1, [68Ga]Ga-HN11-2 were performed in A459-PD-L2 tumor xenograft models. At 10, 20, 30, 40, 50 and 60 min after injection, the tumor uptake values of [68Ga]Ga-HN11-1 were 2.61 ± 0.16 %, 2.97 ± 0.18 %, 3.36 ± 0.29 %, 3.22 ± 0.23 %, 3.06 ± 0.36 %, and 2.76 ± 0.42 %ID/g in A459-PD-L2 tumor xenograft models. These values notably exceed those observed in the [68Ga]Ga-HN11-2 group, which were 1.71 ± 0.14 %, 2.17 ± 0.12 %, 2.29 ± 0.17 %, 2.10 ± 0.03 %, 1.97 ± 0.07 %, and 1.82 ± 0.06 %ID/g. Immunohistochemistry showed that A549-PDL2 was highly expressed in A549-PDL2 mice. ***Conclusion:*** We successfully synthesized two peptide-based PET radiotracers with high yield and purity. [68Ga]Ga-HN11-1 showed better imaging capability for PD-L2 than [68Ga]Ga-HN11-2 in both cell and animal experiments. Experiments results also demonstrate the feasibility of [68Ga]Ga-HN11-1 immunoPET in tracking PD-L2 and are encouraging for further clinical applications of screening potential beneficiaries of ICI therapy.

EP-1312

A Promising PET Imaging Agent Targeting Asialoglycoprotein Receptors for Assessing Liver Disease Severity

M. Wang[1], *C. Kuo[1], H. Yu[1], K. Lin[1], C. Yang[1], C. Chan[1], W. Li[1], Y. Chen[1], K. Ho[2], W. Lee[2];*
[1]National Atomic Research Institute, Taoyuan, Taiwan, TAIWAN,
[2]Linko Changung Memorial Hospital, Taoyuan, Taiwan, TAIWAN.

Aim/Introduction: The survival of patients with liver diseases heavily relies on the competent residual liver function. Given the significant difference in the number of asialoglycoprotein receptors (ASGPR) present on the parenchymal cell membrane between a normal and a diseased liver, imaging of asialoglycoprotein receptors offers a sensitive method to distinguish between healthy and diseased liver tissues. Ga-68 Hexa-Lactoside, developed at our institute, demonstrates effective targeting of the asialoglycoprotein receptors on the hepatocyte membrane. This study aims to explore its potential in assessing the severity of chronic hepatitis and liver cancer. ***Materials and Methods:*** Thirty subjects scheduled for hepatic carcinoma surgery were selected to measure residual liver function using Ga-68 Hexa-Lactoside and Computer Tomography Volumetry (CTV), respectively. Each subject received a single intravenous injection of approximately 2 mCi of Ga-68 Hexa-Lactoside (40μg). Conventional liver function tests, including Fibroscan, Indocyanine Green Excretion Rate, and Histopathological Examination, were conducted to assist in the evaluation. ***Results:*** Ga-68 Hexa-Lactoside sensitively detects changes in liver disease severity, offering an assessment tool for chronic hepatitis and liver cancer. It provides a more accurate delineation of hepatoma, differentiates benign from malignant lesions, and evaluates liver function. This plays a crucial role in future clinical diagnosis and decision-making. The intravenous administration of Ga-68 Hexa-Lactoside showed no toxicological findings. ***Conclusion:*** The clinical utility of Ga-68 Hexa-Lactoside hinges on its binding to the asialoglycoprotein receptor on the hepatocyte surface. In hepatoma patients, the number of ASGPRs is significantly reduced. The unique information provided by Ga-68 Hexa-Lactoside, which is not readily available through other methods, will enable physicians to clearly visualize the severity of liver disease and the hepatoma region, thereby facilitating accurate planning for hepatectomy.

EP-1313

Optimization study of radiopharmaceutical activity measurements of the automated dose activity dispenser

A. Pipintakou, *A. Vatalis, E. Panagiotidis, A. Paschali, T. Kalathas, L. Zoglopitou, A. Makridou, V. Chatzipavlidou;*
Theagenio Cancer, Thessaloniki, GREECE.

Aim/Introduction: Quantitative imaging in nuclear medicine procedures is becoming increasingly important in the diagnosis and staging of cancer. Radiation measurements should be performed with the highest possible accuracy to avoid systematic errors. The aim of this study was to investigate the most efficient method of deriving activity measurements in a well-type dose calibrator that uses a reentrant ionization chamber ***Materials and Methods:*** An automated dose activity dispenser, a commercial well-type dose calibrator, and 740 MBq of the radiopharmaceutical ^{18}F-FDG were used for the measurements. First, the point of highest activity reading within the dose calibrator well (effective point) was determined. Since the automated dispenser positioned the syringe 8 cm away from this point, a tube extension was added. Activity measurements, ranging from 185 MBq to 444 MBq, which are commonly used in clinical practice, were then performed with and without the extension. Finally, the shielding factor, calculated from the ratio of activity measurements with and without shielding using the three available configurations, was determined ***Results:*** The effective point of the dose calibrator was found at 5 cm from the bottom and 20 cm from the top of its well chamber. The measurements taken with and without the tube extension, showed a difference of 27±5 % of their values and the shielding factor was calculated at the value of 6,1 ***Conclusion:*** Proper calibration of the dose calibrator is essential for obtaining reliable activity measurements. This is a critical step before performing quantitative imaging procedures, such as PET/CT scans, which rely on accurate activity values ***References:*** 1.Zimmerman BE, Cessna JT Experimental determinations of commercial dose calibration settings for nuclides used in nuclear medicine. In-house synthesis of ^{99m}Tc Ethambutol as a tubercular imaging agent: Experience from tertiary centre

A. Tyagi, *N. Damle, G. Arora, V. Tiwari, S. Maurya, S. Katala, A. Roy, D. Khan, S. Sagar, A. Gawande, S. Shreya, A. Ghazal, S. Kumar, P. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: Ethambutol is a popular antitubercular agent used in the treatment of tuberculosis. We aimed to label the drug with 99mTechnetium in house to assess its utility in various clinical settings. Data pertaining to its labelling efficiency and various other parameters from a large number of in house synthesis procedures is presented here. ***Materials and Methods:*** Labelling procedure described in literature was standardized for in house synthesis and carried out under aseptic precautions. To 3.5mg Ethambutol, aqueous solution of 10mg/mL mannitol was added followed by 2mg pyrophosphate, 0.5mg stannous hydrochloride, and 99mTc pertechnetate. Solution was incubated at room temperature and then passed through 0.22um Millipore filter. Standardization was done for amount of ethambutol, mannitol, SnCl2, amount of radioactivity and incubation period to attain the highest labelling yield. 60 in-house synthesis of 99mTc ethambutol were performed over a period of 40 months from November 2019 to April 2024. Visual analysis was done to check for the colour

and clarity of solution, pH was determined using litmus paper and radiochemical purity was tested by paper chromatography. 101 patients were injected, followed by sequential imaging to study bio-distribution and to assess uptake in suspected lesions. ***Results:*** Mean starting activity was 25.80±3.41 mCi averaged over 60 synthesis, out of which 4.88±1.70 mCi was retained in the filter and average of 15.75±3.53 mCi was received after filtration. Average 90.65±12.44% labelling efficiency was obtained with >90% in 47 synthesis showing satisfactory bio-distribution in the form of liver, kidneys, bladder and gall bladder activity, with no evidence of free pertechnetate. Very few scans, in-vivo colloid formation was seen characterised by enhanced liver and bone marrow uptake. Reduced labelling yield and/or increased in vivo colloid formation was observed to be most likely associated with stale elution, increased preparation time or inappropriate mixing order. No patients reported any early or delayed adverse effects. ***Conclusion:*** Inhouse labelling was standardised successfully with reproducible labelling yield. Long duration between elution and synthesis, mixing order of the chemicals was observed to play crucial role in determining efficacy of the labelled product, however 80% of the times the labelling efficiency exceeded 90%. Inhouse labelling has a distinct advantage of ready availability as per patient needs. ***References:*** 1.Kartamihardja, A.H.S., Kurniawati, Y. & Gunawan, R. Diagnostic value of 99mTc-ethambutol scintigraphy in tuberculosis: compared to microbiological and histopathological tests. Ann Nucl Med 2018, 32 60-68.2. Inhouse synthesis of ^{99m}Tc-Ubiquicidin (29-41) as an infection imaging agent: Experience from a tertiary center

A. Tyagi, *N. Damle, G. Arora, V. Tiwari, S. Maurya, S. Katala, S. Garg, D. Khan, A. Gawande, S. Shreya, A. Ghazal, S. Kumar, P. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: 99m Tc- Ubiquicidin is an cationic antimicrobial peptide helpful in diagnosis of infection. In the present study, we present data from inhouse synthesis of 99mTc UBI 29-41 over four years. ***Materials and Methods:*** Briefly, to 50ug Ubiquicidin, buffered 99mTcO4- and stannous hydrochloride was added followed by incubation at room temperature. After passing through millipore filter (0.22um) and saline addition, radiochemical purity was analyzed. One hundred and nine in-house syntheses were performed using the aforementioned method. Standardization was done for amount of Ubiquicidin, SnCl2, amount of radioactivity, pH and incubation period to attain the highest labelling yield. ***Results:*** A total of 109 syntheses were carried over a period of 42 months. A total of 122 patients underwent imaging with 99m Tc- UBI. Out of 109 syntheses, 11 syntheses were cold kit based (procured from a commercial supplier). In the remaining 98 syntheses, mean labelling efficiency was 94.24±10.46%. In the initial 8 syntheses reaction pH was kept 3-4 which showed in-vivo colloid formation with visualization of liver, kidneys, bladder and spleen. In rest of the 90 syntheses when reaction pH was kept at 7-8, tracer uptake was observed in kidneys and bladder with minimal liver and no spleen uptake. Reduction in amount of SnCl2 from 2.5mg to 30ug and its prompt handling during the synthesis, improved the labelling efficiency of the final product. Mean retained radioactivity in the millipore filter was 5.68±4.05mCi and in the filtrate was 11.21±4.23 mCi. ***Conclusion:*** Procedure of In-house radiolabelling of 99mTc UBI was standardized with consistent labelling efficiency and satisfactory biodistribution. It is a simple, cost effective procedure but factors such as reaction pH, SnCl2 amount need stringent control. Inhouse labelling has a distinct advantage of ready availability as per patient needs. ***References:*** 1. Validation of radiosynthesis and first in-human dosimetry of 68Ga-NOTA-UBI-29-41: A Proof of Concept study

N. Singh, *P. Thakral, N. Rana, M. Koley, J. Gupta, D. Thakrani, S. S. Das, D. Mailk, I. Sen;*
Fortis Memorial Research Institute (FMRI), Gurugram, INDIA.

Aim/Introduction: Antimicrobial peptides (AMPs) like UBI-29-41 offer a distinctive approach for precise detection due to their unique interactions with bacteria and makes them promising candidates for specific and selective imaging. The aim of the study was to validate the in-house manual synthesis of 68Ga-NOTA-UBI-29-41, evaluate its uptake in patients with suspected infection and estimation of patient-specific dosimetry to ensure optimal clinical application. ***Materials and Methods:*** 68Ga-NOTA-UBI-29-41 was synthesized by adding the variable amount of UBI-29-41 (60-90µg) to 555MBq of Ga-68 in 0.05M HCl and heating the reaction mixture at 90°C for 12 mins at pH:3.5-4 to obtain the radiotracer with high radiochemical purity (RCP) and high yield. 68Ga- NOTA-UBI-29-41 PET/CT scans at variable timepoints were done to assess its biodistribution and maximum uptake time. Furthermore, patient specific dosimetric estimation were done using the HERMES software. ***Results:*** 5µg /37MBq (5µg/mCi) of NOTA-UBI-29-41 at 90°C for 12 mins were the optimal parameters to obtain 88-90% of yield and 98-99% of radiochemical purity. 68Ga-NOTA-UBI-29-41 showed high renal excretion and rapid blood clearance. PET/CT imaging (n=8) at 60mins post injection was found to be the optimal time for imaging with 68Ga-NOTA-UBI-29-41. The critical organ was the urinary bladder wall with a mean dose of 138.02 ± 58.48µSv/MBq followed by 53.81 ± 31.23µSv/MBq for kidneys with a mean effective dose of 1.52 ± 0.64mSv. ***Conclusion:*** The protocol for in-house manual labelling of 68Ga- NOTA-UBI-29-41 was reproducible providing high yield and radiochemical purity. 68Ga-NOTA-UBI-29-41 administration was found to be safe and non-toxic. The favourable tracer biodistribution and the first-in-human patient-specific dosimetry ensures optimal clinical application.

EP-1317

In-house synthesis of 68Ga NOTA UBI as an infection imaging agent: Experience from tertiary centre

A. Tyagi, *N. Damle, S. Ballal, A. Singhal, V. Tiwari, S. Maurya, A. Gawande, G. Arora, P. Kumar, S. Kumar;*
All India Institute of Medical Sciences, New Delhi, INDIA.

Aim/Introduction: UBI is a synthetic antimicrobial peptide, which

when labelled with 68Ga using NOTA as the bifunctional chelating agent is helpful in better diagnosis of infection. We labelled NOTA-UBI with 68Ga in-house to analyse its utility as an infection imaging agent. ***Materials and Methods:*** Manual synthesis procedure was performed using 12-15 mCi buffered 68GaCl3, to which 150-450ug NOTA UBI was added followed by incubation at 90°C for 15 minutes. It was then passed through the charged C-18 cation exchange cartridge and subsequently flushed using the solution of 50% Ethanol with 50% ultrapure water, 10 ml saline and 10 ml air. Final eluate was received in product vial and filtered using a 0.22um Millipore filter. Radiochemical purity was analysed using ITLC SG and sodium citrate. A total of 35 patients were recruited in the study between December 2022 to August 2024. ***Results:*** A total of 24 synthesis were performed with an average of 322.85±98.54ug of peptide(NOTA UBI). Mean 10.76±3.28 mCi of radioactivity was used, out of which only 0.9±0.3 mCi was retained in the C-18 cation exchange cartridge. 6.59±2.85 mCi of radioactivity on an average was received finally, ensuring the radioactivity yield of 57.57±13.56%. Reproducible labelling efficiency was observed with mean 94.38±4.34%. Tracer showed normal bio-distribution with physiological uptake in liver, kidney, and urinary bladder in all patients with pathological uptake at site of disease in some patients. ***Conclusion:*** In-house labelling of NOTA-UBI with 68 Ga can be performed on a routine basis with acceptable radioactivity yield, consistent labelling efficiency and good in-vivo representation. Clinical indications of 68 Ga NOTA-UBI PET/CT are currently being explored. ***References:*** 1. Ebenhan T, Sathekge MM, Lengana T, Koole M, Gheysens O, Govender T, Zeevaart JR. 68Ga-NOTA-Functionalized Ubiquicidin: Cytotoxicity, biodistribution, radiation dosimetry, and first-in-human PET/CT Imaging of Infections. EP-1318

Production of ^{68}Ga-labeled DOTATOC and PSMA-11 in the same automated module: Our one-year experience

H. Lee[1], *J. Choi[1], B. Lee[1], J. Park[1], H. Kim[1], W. Lee[1], B. Lee[1,2];*
[1]Seoul National University Bundang Hospital, Seongnam, KOREA, REPUBLIC OF, [2]Graduate School of Convergence Science and Technology, Seoul National University, Suwon, KOREA, REPUBLIC OF.

Aim/Introduction: The use of 68Ga on the strength of worldwide growth in positron emission tomography (PET) as well as radionuclide ligand therapy (RLT) has been considerably increased, especially during the last two decades. Due to clinical needs and short half-life of 68Ga, it is important to maintain the consistency of 68Ga radiopharmaceuticals for in-house production. Here, we introduce our one-year experience with a cassette-type automated module (BIKBox®) was used for producing of 68Ga-PSMA-11 and 68Ga-DOTATOC in our hospital. ***Materials and Methods:*** The eluted 68GaCl3 from 68Ge/68Ga generator (iThemba Labs) by the help of 0.6 N HCl (2.5 mL) was transferred to BIKBox® (BIK Therapeutics) contained the precursor (20 µg for 68Ga-PSMA-11 and 50 µg for 68Ga-DOTATOC) and HEPES buffer (600 mg, pH 4). After 68Ga-labeling at 100 oC for 10 minutes, the product was purified on a tC18 cartridge and then passed through a 0.22 µm sterile filter for the final formulation. The quality control of 211 batches of 68Ga-PSMA-11 and 49 batches of 68Ga-DOTATOC were performed under EP guidelines from May 2023 to April 2024. ***Results:*** 68Ga-PSMA-11 and 68Ga-DOTATOC were successfully produced with 72.0 ± 2.5% (n = 211) and 66.3 ± 4.3% (n = 49) radiochemical yields, respectively, at end of synthesis. The total synthesis time was 27 minutes from the elution of 68Ge/68Ga generator to the final formulation. The radiochemical purity of 68Ga-radiopharmaceuticals was continuously reported greater than 99% by the radioTLC scanner. The final products were determined to be sterile, colorless and pH 6-7. ***Conclusion:*** Based on our results, two 68Ga-radiopharmaceuticals were well established in the one automated module was shown the applicable performance for routine clinical use without critical failures.

EP-1319

Successful applicability of 68Ga-UBI for debridement surgery in chronic osteomyelitis patient.

S. Nogueira[1], *F. A. B. Da luz[1], V. Iacone[1], P. L. Caiado[1], M. F. de Barboza[1], A. Osawa[1], D. d. B. Santos[1], L. Y. I. Yamaga[1], A. Dell'Aquila[2,3];*
[1]Hospital Israelita Albert Einstein, São Paulo, BRAZIL, [2]Hospital do Servidor Público Estadual, São Paulo, BRAZIL, [3]Instituto de infectologia "Emilio Ribas", São Paulo, BRAZIL.

Aim/Introduction: Identifying the source of infection during debridement surgery in patients with chronic osteomyelitis is crucial for successful treatment. In this context, antimicrobial peptides, such as the 29-41 fragment of Ubiquicidin (UBI29-41) labeled with PET radionuclides, emerge as a radiopharmaceutical for identifying infectious processes. This study aims to describe the adapted radiolabelling and quality control processes of 68Ga-UBI under GMP conditions at the hospital radiopharmacy. In addition, we report a successful case of a patient referred for a PET/CT with this tracer as a preoperatory planning of a surgical debridement for chronic osteomyelitis. ***Materials and Methods:*** The 68GaCl3 was eluted with 0.1 M HCl through a cationic filter, which was extracted by 5N NaCl/ 5.5N HCL into the reaction vial, reacting with 50µg of DOTA-UBI (29-41) of acetate buffer pH = 4.5. After 15 minutes at 90oC, the product was purified by a SepPak C18-Plus cartridge. The radiochemical yield was determined, as well the radiochemical purity, by Sep-PakC18 and ITLC-SG strip, confirming the stability at room temperature until 120 minutes by uHPLC.The radiochemical purity remained >97% for up to 120 minutes. The radiochemical yields and purity were 78±11% and 97.7±2%, respectively (n=12), resulting in a sterile and endotoxin-free final product. The 68Ga-UBI PET/CT was performed on Biograph mCT 40 PET/CT scanner (Siemens Healthineers); the image began 60 minutes postinjection of the radiotracer. ***Results:*** To demonstrate the successful applicability of this tracer, we report a 39-year-old patient who had several surgical cleanings associated with prolonged antibiotic therapy because of an infected pseudoarthrosis after a comminuted fracture of the right tibia. PET/CT images revealed 68Ga-UBI focal uptake suspicious to bacterial infection in the edges of the pseudoarthrosis cavity, in adjacent deep soft tissue and in a cutaneous fistula in the right leg. Surgery for local cleaning was performed and culture of a specimen collected from the surgical site confirmed the presence of Staphylococcus aureus corresponding to the areas of abnormal 68Ga-UBI uptake. Clinical exam and laboratory tests after surgery demonstrated no signs of infection. ***Conclusion:*** The 68Ga-UBI synthesized in a hospital radiopharmacy included all the characteristics for a radiopharmaceutical to be administered intravenously. In the present case, 68Ga-UBI PET/CT, a non-invasive imaging modality, identified the infectious foci in vivo, indicating its potential clinical use for surgical

EP-1320

^{18}F-FDG PET/CT for detection and follow-up of immune-mediated hepatitis: a case report.

S. Nogueira, *F. A. B. Da luz, A. M. d. Petinati, M. Aleksandravicius, A. C. C. Miranda, J. Mejia, M. F. de Barboza, F. B. F. Carvalhaes, R. C. Q. Fonseca, L. Y. I. Yamaga;*
Hospital Israelita Albert Einstein, São Paulo, BRAZIL.

Aim/Introduction: Immunotherapy has increased the life expectancy of cancer patients but has also resulted in an increase in immune-related adverse events (IRAEs) due to drug toxicity. This report demonstrates the importance of ^{18}F-FDG PET/CT for early detection and monitoring of hepatitis caused by immune-mediated toxicity. ***Materials and Methods:*** A 62-year-old male patient with melanoma showed a focal ^{18}F-FDG uptake in a non-calcified nodule in the basal segment of the left inferior lobe of the lungs. The nodule was 0.8 cm in size (SUV=2.5). A follow-up ^{18}F-FDG PET/CT scan, conducted six months after the initial diagnosis, demonstrated increased size and radiopharmaceutical uptake in the pulmonary nodule. It now measures 1.4 cm (SUV=14.6), which is suspicious of metastasis. The medical recommendation was to start treatment with a combination of ipilimumab/nivolumab (ipi/nivo) and repeat the ^{18}F-FDG PET/CT scan after three treatment cycles. ***Results:*** The new scan carried out in January 2024 showed a reduction of pulmonary nodule dimensions. However, there was also new glycolic hypermetabolism in cervical, axillary, pulmonary hilar, upper abdominal, and retroperitoneal lymph nodes. Furthermore, there was an increase in the dimensions and ^{18}F-FDG uptake in the liver, possibly due to inflammation. After the PET/CT scan, the laboratory tests reported increased serum hepatic enzyme levels. A liver biopsy confirmed acute immune-mediated hepatitis. As a result, the immunotherapy was immediately suspended, and the standard corticoid treatment was initiated. Following a 3-month treatment period, a new ^{18}F-FDG PET/CT scan was carried out. It revealed the total absence of abnormal lymph node uptake, a reduction in the liver's ^{18}F-FDG uptake and dimensions, and a decrease in hepatic enzyme levels, confirming the reversal of immune-mediated toxicity. Despite the excellent response rate, therapies based on the combination of ipi/nivo increase the risk of irAEs, one of which is immune-mediated hepatitis, which can be lethal in critical cases. In such patients, immediate interruption of immunotherapy should be mandatory. Because ^{18}F-FDG PET/CT is essential for monitoring melanoma patients, reports of the detection of irAEs have become increasingly frequent. In this context, it can be inferred that the probability of observing irAEs increases with the widespread use of immunotherapy. ***Conclusion:*** This report provides evidence that, in addition to its usefulness for disease staging,^{18}F-FDG PET/CT is an essential tool for detecting and following up on irAEs in melanoma patients.

EP-1321

The impact of the duration of the hypoglycemic diet for the study of endocarditis by ^{18} F-FDG PET-CT - Case study

C. Pereira, *P. Dias, P. Soeiro;*
Unidade de Saúde Local de São João, Porto, PORTUGAL.

Aim/Introduction: Endocarditis can lead to acute complications and significant costs to hospitals. PET-CT with $^{[18F]}$FDG has demonstrated to play a pivotal role in diagnosing challenging cases of endocarditis and its associated complications. A strict hypoglycemic and hyperproteic diet prior to the exam is essential to minimize the physiological expression of heart GLUT4, thus ensuring accurate results. Clinical assessment is performed prior to the exam, to ensure patients' adherence to the prescribed diet. Nevertheless, communication challenges often arise, and patients frequently struggle to comply with the diet, compromising exam results, resulting in rescheduling, or repeating the exam. Our aim was to outline various hypoglycemic diet protocols lasting for 12, 24, and 72 hours, with the goal of reducing physiological uptake by the heart during endocarditis scans, as demonstrated through a case report. ***Materials and Methods:*** A 73-year-old male, non-diabetic, underwent a 43-day course of targeted antibiotic therapy for infective endocarditis involving a biological valve, caused by E. faecalis. After completing the treatment, a PET-CT with $^{[18F]}$FDG was requested to evaluate any remaining peri-valvular complications. However, due to communication issues, 3 separate separate scans were required to complete the procedure and answer the clinical question. The first scan was conducted after a 12-hour fasting period. For the second and third scans, the patient followed hypoglycemic diets lasting 24 and 72 hours, respectively. All procedures were performed on a PET-CT digital scanner (whole body, 2 minutes per bed with respiratory movement digital correction). Additionally, cardiac assessment was conducted for 10 minutes, synchronized with a 4 lead ECG. The time between scans and the dose of radiopharmaceutical were adjusted in accordance with the recommended guidelines by the specialist physicist, to minimize radiation exposure to the patient. ***Results:*** In the first scan, intense physiological uptake of $^{[18F]}$FDG was observed in the myocardium. In the second scan, there was a reduction in $^{[18F]}$FDG uptake, although some peri-valvular focal uptake was seen, that proved challenging to evaluate. In the final scan, no $^{[18F]}$FDG uptake was observed in the myocardium, and no signs of peri-valvular infection were detected. ***Conclusion:*** This case highlights the challenges in communication and information disclosure with patients. Frequently, patients require guidance from healthcare professionals to comprehend the dietary instructions and adhere to them accurately. Additionally, it emphasized the advantages of a 72-hour hypoglycemic diet compared to a 24-hour regimen, as it yields more precise and sensitive outcomes in the targeted area.

EP-1322

Lutetium-177 therapy and the role of the medical assistant

J. Ritskes, *M. Kieft, M. W. J. Versleijen, E. A. Aalbersberg;*
Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Aim/Introduction: The number of 177Lu-therapies at our hospital has increased almost fivefold over the past eight years. This resulted in an higher workload for the nurses in the clinical/radionuclide therapy ward. Timing is crucial when working with radioactivity and due to the elevated workload it is often challenging to adhere to the Lutetium-177 administration timeframe. To ensure a seamless procedure, decrease the nurses workload and enhance patient service, medical assistants (MA) from the nuclear medicine department are taking over 'extended arm' nurses tasks at our radionuclide therapy ward since 05-2023. The aim of this research is to assess the added value of MA at the radionuclide therapy ward, particularly identifying their specific contributions and how to further enhance collaboration with the nurses. ***Materials and Methods:*** In 01-2024 an online questionnaire was sent to disciplines involved in 177Lu-therapies (nurses, nuclear physicians, technical physicians and nuclear technologists). Questions concerned the added value of MA's by word and rating (-3 till +3) and how the MA can further contribute in the 177Lu-therapy workflow. By gathering these insights, the

role and opportunities for improvement of this new collaboration became more clear. ***Results:*** All 20 responders expressed positive feedback to the added value of the MA at the therapy ward; 12/20 rated score 3, 8/20 rated score 2. Taking over tasks such as admission interviews, preparing materials, placing intravenous drips and answering patient questions lowers the nurses workload. The MA facilitates easy communication between the ward, administering team from the nuclear medicine department and the patient. This enables swift action in case of clinical queries resulting in better patient service and recognition. Task expansion suggestions were also made. Assisting by observing the patients wellbeing during administration may facilitate parallel administration of multiple patients. The MA's knowledge and experience in working with radioactivity could be utilized for correct handling in case of contaminations and releasing the radiation chambers after use. Taking over administrative actions concerning the Electronic Health Records would further enhance efficiency. Currently, the MA is locally not authorized to report anamnesis, perform second verification during 177Lu-therapies and medication administration, or dispense prescribed medication. However authorization for these tasks is being reconsidered. ***Conclusion:*** The MA adds value to the administration of 177Lu-therapies. Both in lowering the nurses workload and enhancing communication. Altogether these tasks are an extension and opportunity for growth in the occupation of the MA in the nuclear medicine department.

EP-1323

Hypnosis in nuclear medicine: Where, when, and how?

S. Erismann, *P. Leite Ferreira, J. O. Prior;*
Nuclear Medicine and Molecular Imaging Department, University Hospital, Lausanne, SWITZERLAND.

Aim/Introduction: Since a year, we have been providing a support with the use of hypnotic techniques administered by a nuclear medicine technologist to our patients needing help to undergo their examination. ***Materials and Methods:*** A nuclear medicine technologist was trained to obtain a certificate of advanced studies in art and hypnotic techniques in the fields of health and social work. Data were acquired by direct observation of the patients by the nuclear medicine technologist team and by collecting the patient feedback at the end of the examination. ***Results:*** During the first year, 41 hypnotic supports have been realized, lasting an average of 38.5 minutes. The median duration was ≤45 minutes for 98% of patients with an excellent success rate of 98% (1 failure). The techniques used were formal hypnosis (66%), conversational hypnosis (19%) and combined formal and conversational hypnosis (15%). Most of the request (54%) came from patients themselves, 39% from referring or nuclear medicine and 7% from the nuclear medicine technologists. Requests mainly came from cardiology (23%), gynecology (23%) and oncology (18%). Most (65%) hypnosis supports have been realized for PET/CT imaging, while 19% for SPECT/CT imaging and 2% for radioactive therapy treatment. Most frequently, hypnosis support was for image acquisition due to claustrophobia (73%) and 20% for pain management during radiopharmaceutical injections or venous line placement. The remainder cases were associated with general anxiety about radioactivity, fear of diagnosis and others. ***Conclusion:*** Our experience shows that the use of hypnosis during the imaging has several advantages: (1) reduced anxiety and stress with improvement patient comfort and increase of a successful examination; (2) reduced pain associated with radiopharmaceutical injections and reduced negative experience of side effects; (3) realization of examinations likely to fail due to claustrophobia; and (4) better relaxation of patients during image acquisition and decrease of spurious motion related to a lack of comfort. Hypnosis in nuclear medicine is promising, as it improves patient experience and quality of examinations for claustrophobic and/or painful patients. Our first-year experience is very positive and patient feedback very encouraging. The use of hypnotic techniques has enabled the imaging of several patients for whom we had expected examination failure. This success and the increase in hypnosis support demand has prompted us to train a second nuclear medicine technologist in 2024.

EP-1324

Optimization of storage and disposal of solid radioactive waste in a nuclear medicine department

D. Maranzana, *H. Belloni, R. Latella, M. Muratori, R. Piva, S. Pivetti, E. Pomposelli, P. Puglisi, L. Tommasi, H. Rouhanifar, R. Russo, D. Valentini, A. Miceli, A. Muni;*
Nuclear Medicine, Alessandria, ITALY.

Aim/Introduction: The generation of radioactive waste in solid, liquid, and gaseous forms that need to be managed safely to ensure that they are not dispersed in the environment is one of the major issues of the use of radioactive sources in Nuclear Medicine activities. Such management includes their collection, sorting, treatment, temporary storage in suitable places, and finally disposal. This process has a great impact on the management of the nuclear medicine department in terms of costs, time, responsibility, and dedicated staff. We aim to compare, in terms of cost-effectiveness, two ways to manage radioactive waste: i) delivery to an authorized private disposer; ii) storage in the hospital until complete decay (< 1KBq/Kg) to proceed later with their disposal as general medical waste. ***Materials and Methods:*** Management Control provided the data regarding the expenses for radioactive waste disposal incurred by our hospital in 2022, by comparing with a possible complete in-house management. We have performed an estimation of solid waste volumes, an assessment of local storage requirements, a cost analysis of the renovation of the storage room, an estimation of staff hours and the purchase of a system for automatic release authorization. ***Results:*** The waste delivered to an authorized disposer, who provides the transport drums and arranges for their collection, has the main advantage of having less legal and administrative responsibilities of the employer, in the face of higher operation costs. However, the savings produced by the in-house management are greater than 80% in the first year, nonetheless a greater amount of workload for the staff (approximately 300 hours/year). The savigings will be greater from the second year as the renovation expenses will be amortized. ***Conclusion:*** In conclusion, it is recommendable to set up an internal pathway within the hospital to store the radioactive waste generated on-site and then dispose it later as treated non-radioactive hospital waste, thus avoiding the need to deliver it to a private carrier with large savings in economic resources.

EP-1325

Undesirable events reporting in Nuclear Medicine: A necessary step towards continuous practice improvement

S. Figueiredo, *M. Nicod-Lalonde, P. Ferreira, J. O. Prior;*
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: The management of undesirable events is a fundamental part of a Quality Assurance System as it helps improving safety of patients and healthcare staff through targeted actions that prevent incidents recurrence. We support

a "No-name, no-blame, no-shame" policy in our department, so that any employee can objectively and fearlessly report an event considered undesirable, via our institutional reporting platform. The aim of our retrospective study was to categorize the different reported undesirable events and identify the most recurrent ones to efficiently improve our overall quality assurance system. ***Materials and Methods:*** Data extracted from our institutional reporting platform are periodically analysed by a multidisciplinary group to identify recurrent issues and possible improvement. Reports received from January 2018 to December 2023 were analysed and divided into 5 categories: inter-departmental collaboration (e.g., miscommunication), patient care (e.g., incorrect patient preparation), scheduling flow (e.g., events impacting examination workflow), radiation protection (e.g., contamination events) or other cases (e.g., instrumentation and/or software failures). ***Results:*** Within the 6-year follow-up period, a total of 347 undesirable events were reported. Among these, 51 were related to inter-departmental collaboration, 82 to patient care, 83 to scheduling flow, 57 to radiation protection, and 74 other types of events. A peak of reporting was recorded in 2023, representing 26.6% of the overall cases. Since 2018, we have observed a constant increase of reporting undesirable events, mainly due to our policy of awareness-raising and non-punitive vigilance, as well as to the increase in the number of examinations carried out. All these reports lead us to reflect on our practices and promote continuous improvements in our department through constructive self-criticism. As part of our improvements, we have introduced targeted continuous training for healthcare staff, revised internal procedures and held discussions with the different departments to improve collaboration within our institution. ***Conclusion:*** These improvements have resulted in a better patient care policy and improved communications between healthcare professionals. The trend observed during this analysis is a direct consequence of the work performed within our department to raise awareness on the importance of adverse event reporting. This behaviour reflects the commitment of our healthcare professionals towards the continuous improvement of quality assurance system playing a crucial role in ensuring the safety of patients and healthcare staff and guarantees high-quality care.

EP-1326

Influence Of Patient's Arms Position On The Occurrence Of Motion Artifacts In Pet/Ct Imaging

J. Peric, *D. Sercic, K. Zevnik;*
Institute of Oncology Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: PET/CT data acquisition is commonly performed with the patient's arms placed above the head during the examination. In cases where the patient is unable to place their arms above their head or when it is necessary due to clinical indication, patients have their arms down, which can lead to many artifacts. Aim of the research was to investigate whether differences exist in the presence of a motion artifact (uncorrected fusion) in the elbow area of PET/CT based on the patient's arms position. Additionally, we checked the impact of the patient's gender, body mass index (BMI) and the PET/CT system used to perform the examinations. ***Materials and Methods:*** The variable that we checked in the research was presence of motion artifacts (uncorrected fusion) on PET/CT images, depending on patient's arms position, gender, BMI and the PET/CT system. We retrospectively took a random sample of 119 patients who underwent a total body 18F-FDG (fluorodeoxyglucose) PET/CT examination. Examinations were performed in 2023 at the Department of Nuclear Medicine of the Institute of Oncology Ljubljana on Siemens Biograph mCT 40 and Biograph Vision PET/CT systems. After accessing the data, we made additional post-processing transverse plane fused PET/CT reconstruction in the elbow area for each case. These reconstructions were anonymously uploaded to the ViewDex 3.0 and evaluated by a nuclear medicine specialist. The collected data were analysed with Chi-squared tests in the SPSS Statistisc 20.0 with a significance level set at 5%. ***Results:*** Data analysis revealed statistically significant influence of patient's arms position on the occurrence of motion artifacts on PET/CT images (p≤0,001). The occurrence of motion artifacts was not statistically significant for the patient's gender (p=0,611), BMI (p=0,093) and the PET/CT system used to perform PET/CT examinations (p=0,742). ***Conclusion:*** 4.14% of patients with motion artifact had their arms positioned on their abdomen. On the other hand, 81.97% of those in whom motion artifacts did not occur had their arms positioned next to their body. ***References:*** 1. Corrigan A J G, Schleyer P J, Cook G J (2015). Pitfalls and artifacts in the use of PET/CT in oncology imaging. Semin Nucl Med 45:481-99. 2. Ledge M, Mhlanga J, Cho S, Wahl R (2011). Effect of patient arm motion in whole-body PET/CT. PET CT: Do we understand our patient's expectations?

S. Sa, *C. Orongan, E. Nowosinska, L. Menezes, B. Ribeiro, N. Fernandes, B. Sanghera;*
Barts Health NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: The PET-CT department at St Barts Hospital provides patient care for the East London Region and beyond. PET imaging procedures particularly with $^{[18F]}$FDG and [82Rb]chloride are in constant high demand resulting in long patient appointment waiting times. Despite our service having implemented previously a robust booking system and recently increased service capacity and workforce, DNAs and cancellations remain to be a challenge. A preliminary audit between September and December 2023 of a total of 91 DNAs and cancellations for Rubidium procedures were carried out. Patient factors such as claustrophobia and non-compliant scan preparation were predominant, most of the time leading to cancellation on the day. As to ensure these could be tackled, we decided to improve the information offered to patients and empowered them to better understand PET-CT imaging. ***Materials and Methods:*** A survey of 500 patients was carried out on arrival to the department to understand how well prepared they were for their appointment. Dedicated staff contacted patients undergoing complex examinations to explain the full procedure and provide a risk assessment. While waiting for their examination, patients were given the opportunity to familiarize themselves with their specific journey in PET-CT scanning through text, media and video formats.Following the procedure, patients were invited to complete a questionnaire on their experience. A comparison of these patients experience with a control group was also performed. ***Results:*** Between September and December 2023, there were a total of 44 DNAs and 47 cancellations. The top three reasons in order were patient illness (12%), non-compliant scan preparation (11%) and claustrophobia/anxiety (8%). We are planning to carry out a further audit on DNAs and cancellations after all patients have completed this study. ***Conclusion:*** We aimed to improve patient experience when undergoing a PET-CT examination through the use of audit data. The outcome of this will increase patient wellbeing and improve service delivery for the NHS.

Adaptation of Nuclear Medicine procedures in the progressively older population (+65 years): studies in nuclear neurology and pneumology

S. Ferreira[1,3], *B. Marques[1], P. Justo[1], J. A. Silva[1,2];*
[1]Higher School of Health Dr. Lopes Dias, Polytechnic Institute of Castelo Branco, Castelo Branco, PORTUGAL, [2]Santo António University Hospital Center, Porto, PORTUGAL, [3]AGE.COMM - Interdisciplinary Research Unit - Functional Ageing Communities, Castelo Branco, PORTUGAL.

Aim/Introduction: The increase in life expectancy has led to a rise in the incidence of neurological and respiratory diseases in the elderly, resulting in a greater demand for Nuclear Medicine exams in these areas. However, it is crucial to adapt these procedures to the specific needs of this population, which faces challenges that may affect the performance of these exams. This study aimed to verify whether Nuclear Neurology and Pneumology procedures are properly adapted to the elderly population (+65 years) through questionnaires directed at Nuclear Medicine Technicians (NMTs), and to identify the most common adaptations. ***Materials and Methods:*** An online questionnaire via Google Forms, plus the informed consent, was sent by email to Nuclear Medicine technicians in clinical practice, excluding those unavailable for participation, working in commercial companies of medical equipment and software, radioisotope production and research. Ensuring anonymity and approved by the Ethics Committee and Data Protection Office of the Polytechnique Institute of Castelo Branco, the questionnaire presents questions about technician's adaptations in patient preparation, positioning, image acquisition, among others. ***Results:*** It was obtained 17 responses to the questionnaire. The results revealed a higher number of exams performed in Nuclear Pneumology to elderly patients, accounting for 41.2% of exams, while Nuclear Neurology represented 23.5%. Parkinson's Disease was the most common indication for Nuclear Neurology exams (94.1%), while in Nuclear Pneumology, Pulmonary Thromboembolism was predominant (100%). Positioning elderly patients was referenced as more challenging in Nuclear Neurology (64.71%) than in Nuclear Pneumology (35.29%), but in both areas, adaptation of communication to calm patients was the most performed (94.1% and 100%, respectively). About 57.14% of respondents reported that positioning adaptation improves image quality due to reduced patient movement during acquisition. The most frequently adjusted acquisition parameters included time/image counts (82.35% in Nuclear Neurology and 76.47% in Nuclear Pneumology). The complexity in administering the radiopharmaceutical in ventilation scintigraphy prompted 77.78% of professionals to consider adaptations, highlighting the need for flexible approaches in these clinical specialties. ***Conclusion:*** Clear communication and the use of immobilization accessories to improve patient comfort are the most adapted fields to ensure the quality of the exam performed in elderly patients. Some limitations were identified in this study, namely a small sample size and the inability to address all proposed hypotheses.

EP-1329

Artificial Intelligence in radiography education: A scoping review

C. Kammies[1,2], *E. Archer[2], P. Engel-Hills[3], M. Volschenk[2];*
[1]University of Johannesburg, Johannesburg, SOUTH AFRICA, [2]Stellenbosch University, Cape Town, SOUTH AFRICA, [3]Cape Peninsula University of Technology, Cape Town, SOUTH AFRICA.

Aim/Introduction: The expansion of Artificial Intelligence (AI) in radiography is predicted to transform future clinical workflows, decision-making, and the role and responsibilities of practitioners. If AI is to be an important aspect of radiography practice, it may be reasonable to expect that future graduates need to be equipped to engage in competent and safe utilisation of these technologies. Little research has explored the current and emerging influences of AI in radiography education. The purpose of the scoping review is to map the existing literature regarding AI applications in radiography education and how these technologies will potentially impact radiography education. ***Materials and Methods:*** Using the Johanna Briggs methodology, an initial search was conducted in EBSCOhost to determine whether the search strategy that was developed with a librarian would capture the relevant literature by screening the title and abstract of the first 50 articles. Any additional search items identified in the articles were then added to the search strategy. Thereafter PubMed, Scopus and Web of Sciences databases were searched. Additionally, grey literature was also sourced from ProQuest and relevant university institutional repositories. Abstract and full-text articles will be reviewed by two reviewers according to the predefined inclusion and exclusion criteria of the study. Thereafter, results will be reported using the Preferred Reporting Items for Systematic Reviews and Meta-Analysis Extension for Scoping Reviews. ***Results:*** The database searches were concluded in April 2024 and yielded 2 827 results. The final scoping review will present the findings in tabular form and through narrative description. ***Conclusion:*** With the continued growth of AI in radiography, this scoping review will provide an understanding of the current applications of AI in radiography education and how this technology will impact radiography education. ***References:*** Hardy M. FOCUSMEETING.EANM.ORG

JANUARY 30 - FEBRUARY 1, 2025

EANM FOCUS 6

SHAPING THE FUTURE OF BREAST CANCER CARE WITH MOLECULAR IMAGING

European Association of Nuclear Medicine | e-Mail: office@eanm.org | www.eanm.org

OCTOBER 22, 2024

From 19:00

EANM CLUBBING

hosted by **EARL**

SPIELBUDENPLATZ 21/22, 20359 HAMBURG

GAGA CLUB

Addendum

S43:
305
Sunday, October 20, 2024, 09:45 - 11:15
Hall Y4-Y9
Cutting Edge Science Track - Featured Session:
Radiation Protection Committee / EARL:
Radiation Protection for Radionuclide Therapy
and Animal Protection

OP-091
The Rhisotope Project
J. Larkin;
University of the Witwatersrand, Johannesburg, SOUTH AFRICA.

OP-092
EARL: Radiation Protection for Radionuclide Therapy
O. Ivashchenko;
University Medical Center Groningen, Groningen, NETHERLANDS.

S235:
OP-492
What are the Steps to Accurately Perform a Semi-Quantitative Analysis?
D. Cecchin;
Nuclear Medicine Unit, Department of Medicine – DIMED, Padua, ITALY.

S268:
1208
Tuesday, October 22, 2024, 08:00 - 09:30
Hall G2
Joint Symposium 6 - Radiation Protection
Committee - Nuclear and Radiological
Emergencies - Preparedness and Response

OP-563

International Radiological Emergency Preparedness and Response - IAEA Response and Assistance Network

Takeo Kurita;

International Atomic Energy Agency (IAEA), Incident and Emergency Centre (IEC), Department of Nuclear Safety and Security, Vienna, AUSTRIA.

OP-564

Biological Dosimetry for Emergency Preparedness

Ursula Oestereicher;

Federal Office for Radiation Protection, Biological Dosimetry, Neuherberg, GERMANY.

OP-565

Medical Management of Persons in a Nuclear or Radiological Emergency

Wolfgang Burchert;

Universitätsklinik der Ruhr-Universität Bochum, Institut für Radiologie, Nuklearmedizin und Molekulare Bildgebung, Bad Oeynhausen, GERMANY.

S344:

OP-723

Imaging Non Oncological Targets

C. Decristoforo;

Medical University Innsbruck, Innsbruck, AUSTRIA.
